friction increase from the rough sides and, if a penstock tunnel, is equipped with a rock trap to catch loose rock pieces before they can enter the turbines. Most of these have been successful, particularly if operations could be scheduled for periodic shutdowns for maintenance repair of rockfalls; the Laramie–Poudre Irrigation Tunnel in northern Colorado experienced only two significant rockfalls in 60 years, each easily repaired during a nonirrigation period. In contrast, a progressive rockfall on the 14-mile (23-kilometre) Kemano penstock tunnel in Canada resulted in shutting down the whole town of Kitimat, British Columbia, and vacationing workers for nine months in 1961 since there were no other electric sources to operate the smelter. Thus, the choice of an unlined tunnel involves a compromise between initial saving and deferred maintenance plus evaluation of the consequences of a tunnel shutdown.

ROCK CHAMBERS

While chambers in 1971 were being excavated in rock to fulfill a wide variety of functions, the main stimulus to their development had come from hydroelectric-power-plant requirements. Though the basic concept originated in the United States, where the world's first underground hydroplants were built in enlarged tunnels at Snoqualme Falls near Seattle, Washington, in 1898 and at Fairfax Falls, Vermont, in 1904, Swedish engineers developed the idea into excavating large chambers to accommodate hydraulic machinery. After an initial trial in 1910–14 at the Porjus Plant north of the Arctic Circle, many underground power plants were subsequently built by the Swedish State Power Board. Swedish success soon popularized the idea through Europe and over the world, particularly to Australia, Scotland, Canada, Mexico, and Japan, where several hundred underground hydroplants have been built since 1950. Sweden, having a long experience with explosives and rock work, with generally favourable strong rock, and with energetic research and development, has even been able to lower the costs for underground work to approximate those for surface construction of such facilities as power plants, warehouses, pumping plants, oil-storage tanks, and water-treatment plants. With costs in the United States being five to ten times greater underground, new construction of underground chambers was not significantly resumed there until 1958, when the Haas underground hydroplant was built in California and the Norad underground air-force command centre in Colorado. By 1970, the United States had begun to adopt the Swedish concept and had completed three more hydroplants with several more under construction or being planned.

Swedish work on rock chambers

Favourably located, an underground hydroplant can have several advantages over a surface plant, including lower costs, because certain plant elements are built more simply underground: less risk from avalanches, earthquakes, and bombing; cheaper year-round construction and operation (in cold climates); and preservation of a scenic environment—a dominant factor in Scotland's tourist area and now receiving recognition worldwide. A typical layout involves a complex assembly of tunnels, chambers, and shafts. Figure 10 shows the world's largest underground powerhouse, Churchill Falls in the Labrador wilderness of Canada, with a capacity of 5,000,000 kilowats, under construction since 1967 at a total project cost of about $1,000,000,000. By building a dam of modest height well above the falls and by locating the powerhouse at 1,000 feet (300 metres) depth with a one-mile (1,600-metre) tunnel (the tailrace tunnel) to discharge water from the turbines below downstream rapids, the designers have been able to develop a head (water height) of 1,060 feet (320 metres) while at the same time preserving the scenic 250-foot- (75-metre-) high waterfall, expected to be a major tourist attraction once several hundred miles of wilderness-road improvement permits public access. Openings here are of impressive size: machine hall (powerhouse proper), 81-foot (25-metre) span by 154 feet (47 metres) high by 972 feet (296 metres) long; surge chamber, 60 feet (18 metres) by 148 feet (45 metres) high by 763 feet (234 metres); and two tailrace tunnels, 45 by 60 feet (14 by 18 metres) high.

Large rock chambers are economical only when the rock can essentially support itself through a durable ground arch with the addition of only a modest amount of artificial support. Otherwise, major structural support for a large opening in weak rock is very costly. The Norad project, for example, included an intersecting grid of chambers in granite 45 by 60 feet (14 by 18 metres) high, supported by rock bolts except in one local area. Here, one of the chamber intersections coincided with the intersection of two curving shear zones of fractured rock—a happening which added $3,500,000 extra cost for a perforated concrete dome 100 feet (30 metres) in diameter to secure this local area. In some Italian and Portuguese underground powerhouses, weak-rock areas have necessitated comparable costly lining. While significant rock defects are more manageable in the usual 10- to 20-foot (three- to six-metre) rock tunnel, the problem so increases with increasing size of opening that the presence of extensive weak rock can easily place a large-chamber project outside the range of economic practicality. Hence, geological conditions are very carefully investigated for rock-chamber projects, using many borings plus exploratory drifts to locate rock defects, with a three-dimensional geological model to aid in visualizing conditions. A chamber location is selected that offers the least risk of support problems. This objective was largely attained in the granite gneiss at Churchill Falls, where the location and chamber configuration were changed several times to avoid rock defects. Rock-chamber projects, furthermore, rely heavily on the relatively new field of rock mechanics to evaluate the engineering properties of the rock mass, in which exploratory drifts are particularly important in affording access for in-place field testing.

Rock-mechanics investigation. The young field of rock mechanics was beginning, early in the 1970s, to develop a rational basis of design for projects in rock; much is already developed for projects in soil by the older field of soil mechanics (see SOIL MECHANICS, APPLICATIONS OF). Initially, the discipline had been stimulated by such complex projects as arch dams and underground chambers and then increasingly with similar problems with tunnels, rock slopes, and building foundations. In treating the rock mass with its defects as an engineering material, rock mechanics utilizes numerous techniques such as theoretical analysis, laboratory testing, field testing on site, and instrumentation to monitor performance during construction and operation. Since rock mechanics is a discipline in itself, only the most common field tests are briefly outlined below to give some concept of its role in design, particularly for a rock-chamber project.

Techniques of rock mechanics

Geostress, which can be a significant factor in choice of chamber orientation, shape, and support design, is usually determined in exploratory drifts. Two methods are

common, although each is still in the development stage. One is an "overcoring" method (developed in Sweden and South Africa) used for ranges up to around 100 feet (30 metres) out from the drift and employing a cylindrical instrument known as a borehole deformeter. A small hole is drilled into the rock and the deformeter inserted. Diameter changes of the borehole are measured and recorded by the deformeter as the geostress is relieved by overcoring (cutting a circular core around the small hole) with a six-inch (15-centimetre) bit. Measurements at several depths in at least three borings at different orientations furnish the data needed for computing the existing geostress. When measurement is desired only at the surface of the drift, the so-called French flat-jack method is preferred. In this, a slot is cut at the surface, and its closure is measured as the geostress is relieved by the slot. Next, a flat hydraulic jack is inserted in the rock. The jack pressure necessary to restore closure of the slot (to the condition before its cutting) is considered to equal the original geostress. As these methods require a long drift or shaft for access to the area of measurement, development is underway (particularly in the United States) to extend the range of depth to a few thousand feet. Such will aid in comparing geostress at alternate sites; and hopefully avoid locations with high geostress which has proven very troublesome in several past chamber projects.

Shear strength of a joint, fault, or other rock defect is a controlling factor in appraising strength of the rock mass in terms of its resistance to sliding along the defect. Although partly determinable in the laboratory, it is best investigated in the field by a direct shear test at the work site. While this test has long been used for soil and soft rock, its adaptation to hard rock is due largely to work performed in Portugal. Shear strength is important in all problems of sliding; at Morrow Point Dam, in Colorado, for example, a large rock wedge between two faults started to move into the underground powerhouse and was stabilized by large tendons anchored back in a drainage tunnel plus strut action provided by the concrete structure that supported the generator machinery.

The modulus of deformation (that is, the stiffness of the rock) is significant in problems involving movement under stress and in sharing of load between rock and structure, as in a tunnel lining, embedded steel penstock, or foundation of a dam or heavy building. The simplest field test is the plate-jacking method, in which the rock in a test drift is loaded by hydraulic jacks acting on a plate two to three feet (60 to 90 centimetres) in diameter. Larger areas can be tested either by radially loading the internal surface of a test tunnel or by pressurizing a membrane lined chamber.

Analysis methods in rock mechanics have helped in appraising stress conditions around openings—as at Churchill Falls—to identify and then correct zones of tension and stress concentration. Related work with rock block models is contributing to understanding the failure mechanism of the rock mass, notable work being underway in Austria, Yugoslavia, and the United States.

Chamber excavation and support. Excavation for rock chambers generally starts with a horizontal tunnel at the top of the area to be excavated and progresses down in steps. Rock is excavated by drilling and blasting, carried on simultaneously in several headings. This procedure may give way, however, as moles gain in their ability to cut hard rock economically and as a rock saw or other device is developed for squaring up the circular surface normally cut by the mole. High geostress can be a real problem (causing inward movement of the chamber walls) unless handled by a careful sequence of partial excavations designed to relieve it gradually.

Excavation methods for rock chambers

Many of the earlier underground hydroplants were roofed with a concrete arch, often designed for a major load, as in some Italian projects in weak rocks or where blast damage was considerable, as at a few projects in Scotland. Since about 1960, however, most have relied solely on rock bolts for support (sometimes supplemented with shotcrete). That such a light support has been widely successful can be attributed to careful investigation resulting in locations with strong rock, employment of techniques to relieve high geostress, and controlled blasting to preserve rock strength.

Sound-wall blasting. Sound-wall blasting is a technique, primarily developed in Sweden, that preserves the finished rock surfaces in sound condition by careful design of the blasting charges to fit the rock conditions. In underground work, Swedish practice has often produced remarkable results almost like rock sculpturing in which the excellent shaping and preservation of the rock surfaces often permits omitting concrete lining at savings greater than the extra cost of the engineered blasting. While Swedish success is due partly to the generally strong rock in that country, it is due even more to energetic research and development programs to develop (1) theoretical methods for blasting design plus field blast tests to determine pertinent rock properties, (2) special explosives for different rock conditions, and (3) institutes for the training of specialized blasting engineers to apply these procedures in the field construction.

Swedish work on sound-wall blasting

In the United States, sound-wall blasting has enjoyed only indifferent success underground. Reluctance of the blasting industry to change from its customary empirical approach and the lack of specialized blasting engineers trained in Swedish practices have led to a return to the more costly technique of mining an initial pilot bore to afford stress relief, followed by blasting successively thinner slabs toward the free face of the pilot bore.

For excavation from the ground surface, the requirements of sound-wall blasting largely have been met by the technique of presplitting, developed in the United States in the late 1950s. Basically, this technique consists of creating a continuous crack (or presplit) at a desired finished excavation line by initially firing a line of closely spaced, lightly loaded holes drilled there. Next, the interior rock mass is drilled and blasted by conventional means. If a high horizontal geostress is present, it is important that it first be relieved (as by an initial cut a modest distance from the presplit line); otherwise, the presplit crack is not likely to occur in the direction desired. Stockton Dam, in Missouri illustrates the benefit of presplitting. Here, vertical faces in dolomite up to 110 feet (34 metres) were successfully presplit and promptly rock bolted; this permitted a major reduction in thickness of the concrete facing, resulting in a net saving of about $2,500,000.

SHAFTS

The mining industry has been the primary constructor of shafts, because at many locations these are essential for access to ore, for ventilation, and for material transport. Depths of several thousand feet are common. In public-works projects, such as sewer tunnels, shafts are usually only a few hundred feet deep and because of their high cost are avoided in the design stage wherever practical. Shallower shafts find many uses, however, for penstocks and access to underground hydroplants, for dropping aqueduct tunnels beneath rivers, for missile silos, and for oil and liquefied-gas storage. Being essentially vertical tunnels, shafts involve the same problems of different types of ground and water conditions but on an aggravated scale, since vertical transport makes the operation slower, more costly, and even more congested than with horizontal tunneling. Except when there is a high horizontal geostress in rock, the loading on a shaft support is generally less than for a tunnel. Inflowing water, however, is far more dangerous during construction and generally intolerable during operation. Hence, most shafts are concrete lined and waterproofed, and the lining installation usually follows only a short distance behind excavation. The shape is usually circular, although, before present mechanized excavation methods, mining shafts were frequently rectangular. Shafts may be sunk from the surface (or drilled in smaller sizes), or, if an existing tunnel provides access, they may be raised from below.

Shaft sinking and drilling. Mining downward, generally from the surface, although occasionally from an underground chamber, is called shaft sinking. In soil, shallow shafts are frequently supported with interlocking

steel sheetpiling held by ring beams (circular rib sets); or a concrete caisson may be built on the surface and sunk by excavating inside as weight is added by extending its walls. More recently, large-diameter shallow shafts have been constructed by the "slurry trench method," in which a circular trench is excavated while filled with a heavy liquid (usually bentonite slurry), which supports its walls until finally displaced by filling the trench with concrete.

Freezing method of shaft sinking

For greater depth in soil, another method involves freezing a ring of soil around the shaft. In this method, a ring of closely spaced freezing holes is drilled outside the shaft. A refrigerated brine is circulated in double-wall pipes in the holes to freeze the soil before starting the shaft excavation. It is then kept frozen until the shaft is completed and lined with concrete. This freezing method was developed in Germany and The Netherlands, where it was used successfully to sink shafts through nearly 2,000 feet (600 metres) of alluvial soil to reach coal beds in the underlying rock. It has also been applied under similar conditions in Britain, Poland, and Belgium. Occasionally, the freezing technique has been used in soft rock to solidify a deep aquifer (layer of water-bearing rock). Due to the long time required for drilling the freezing holes and for freezing the ground (18 to 24 months for some deep shafts), the freezing method has not been popular on public-works projects except as a last resort, although it has been used in New York City for shallow shafts through soil to gain access for deep water tunnels.

More efficient methods for sinking deep shafts in rock were developed in South African gold-mining operations, in which shafts 5,000 to 8,000 feet (1,500 to 2,400 metres) deep are common and generally 20 to 30 feet (six to nine metres) in diameter. South African procedure has produced progress around 30 feet (nine metres) per day by utilizing a sinking stage of multiple platforms, which permits concurrent excavation and concrete lining. Excavation is by drilling and blasting with muck loaded into large buckets, with larger shafts operating four buckets alternately in hoisting wells extending through the platforms. Grouting is carried a few hundred feet ahead to seal out water. Best progress is achieved when the rock is pregrouted from two or three holes drilled from the surface before starting the shaft. Since the shallower shafts on public-works projects cannot justify the investment in the large plant needed to operate a sinking stage, their progress in rock is much slower—in the range of five to ten feet (1.5 to three metres) per day.

Occasionally, shafts have been sunk through soil by drilling methods. The technique was first used in British practice in 1930 and was subsequently further refined in The Netherlands and Germany. The procedure involves first advancing a pilot hole, then reaming in several stages of enlargement to final diameter, while the walls of the hole are supported by a heavy liquid (called drilling mud), with circulation of the mud serving to remove the cuttings. Then a double-wall steel casing is sunk by displacing the drilling mud, followed by injecting concrete outside the casing and within the annular space between its double walls. One use of this technique was in the 25-foot- (eight-metre-) diameter Statemine shaft in The Netherlands, 1,500 feet (460 metres) deep through soil that required about three and one-half years before completion in 1959. For the 1962 construction of some 200 missile shafts in Wyoming in soft rock (clay shale and friable sandstone), a giant auger proved effective for sinking these 65-foot- (20-metre-) deep, 15-foot- (five-metre-) diameter shafts, generally at the rate of two to three days per shaft. Perhaps the largest drilled shaft is one in the Soviet Union: 2,674 feet (815 metres) deep, which was enlarged in four stages of reaming to a final diameter of 28.7 feet (about nine metres), progressing at a reported rate of 15 feet (five metres) per day.

More dramatic has been the adaptation in the United States of oil-well-drilling methods in a technique called big-hole drilling, used for constructing small shafts in the diameter range of three to six feet (90 to 180 centimetres). Big-hole drilling was developed for deep emplacement in underground testing of nuclear devices, with over 150 such big holes drilled in the 1960s up to 5,000 feet (1,500 metres) deep in Nevada in rocks ranging from soft tuff to granite. In big-hole drilling the hole is made in one pass only with an array of roller-bit cutters that are pressed against the rock by the weight of an assembly of lead-filled drill collars, sometimes totalling 300,000 pounds (135,000 kilograms). The drill rig must be huge in size to handle such loads. The greatest impediment controlling progress has been the removal of drill cuttings, where an air lift is showing promise.

Big-hole drilling

Shaft raising. Handling cuttings is simplified when the shaft can be raised from an existing tunnel, since the cuttings then merely fall to the tunnel, where they are easily loaded into mine cars or trucks. This advantage has long been recognized in mining; where once an initial shaft has been sunk to provide access to and an opportunity for horizontal tunnels, most subsequent shafts are then raised from these tunnels, often by upward mining with men working from a cage hung from a cable through a small pilot hole drilled downward from above. In 1957 this procedure was improved by Swedish development of the raise climber whose working cage climbs a rail fastened to the shaft wall and extends backward into the horizontal access tunnel into which the cage is retracted during a blast. Simultaneously in the 1950s Germans began experimenting with several mechanized reamers, including a motor-cutter unit pulled upward by a cable in a previously down-drilled pilot hole. A more significant step toward mechanized shaft raising occurred in 1962 when United States mole manufacturers developed a device called a raise borer, in which the cutting head is rotated and pulled upward by a drill shaft in a down-drilled pilot hole, with the power unit being located at top of the pilot hole. The capacity of this type of borer (or upward reamer) generally ranges from three- to eight-foot- (90- to 240-centimetre-) diameters in lifts up to 1,000 feet (300 metres) with progress ranging up to 300 feet (90 metres) per day. Furthermore, available cutters when operating on raise borers can cut through rock often almost twice as hard as rock moles can deal with. For larger shafts, bigger diameter reamers may be operated in an inverted position to ream downward, with the cuttings sluiced to the access tunnel below. A 12-foot- (four-metre-) diameter, 1,600-foot- (500-metre-) deep vent shaft was completed by this method in 1969 at the White Pine Copper Mine in Michigan. Starting from a ten-inch (25-centimetre) pilot hole, it was enlarged in three downreaming passes.

The introduction of a workable raise borer in the 1960s represented a breakthrough in shaft construction, cutting construction time to one-third and cost to less than one-half that for an upward-mined shaft. At the beginning of the 1970s, the procedure was being widely adopted for shaft raising, and some projects had been specifically designed to take advantage of this more efficient method. At a Northfield Mountain (Massachusetts) underground hydroplant (completed in 1971), the previously common large surge chamber was replaced by a series of horizontal tunnels at three levels, connected by vertical shafts. This layout permitted significant economy by the use of jumbos already available from other tunnels of the project and the use of a raise borer for starting the shafts. If very large shafts are involved, the raise borer is particularly useful in simplifying the so-called glory-hole method, (Figure 11), in which the main shaft is sunk by blasting; the muck is then dumped in the central glory-hole, previously constructed by a raise borer. The example is based on the construction of a 133-foot- (40-metre-) diameter surge shaft above the Angeles penstock tunnel near Los Angeles. The glory-hole technique was also used in 1944 in constructing a series of 20 underground fuel-oil chambers in Hawaii, working from access tunnels driven initially at both top and bottom of the chambers and later used to house oil and vent piping. The advent of the raise borer should now make this and similar construction more economically attractive. Recently, some deep sewer projects have been redesigned to utilize the raise borer for shaft connections.

IMMERSED-TUBE TUNNELS

Development of method. The immersed-tube, or sunken-tube, method, used principally for underwater crossings, involves prefabricating long tube sections, floating them to the site, sinking each in a previously dredged trench, and then covering with backfill (Figure 13). While more correctly classified as a subaqueous adaptation of the dry-land cut-and-cover procedure often used for subways, the immersed-tube method warrants inclusion as a tunneling technique because it is becoming a preferred alternate to the older method of constructing a subaqueous tunnel under compressed air with a Greathead shield. A major advantage is that, once the new section has been connected, interior work is conducted in free air, thus avoiding the high cost and major risk of operating a large shield under high air pressure. Furthermore, the immersed-tube method is usable in water deeper than is possible with the shield method, which essentially is restricted to less than 100 feet (30 metres) of water by the maximum air pressure at which workmen can safely work.

Advantages of immersed-tube method

The procedure was first developed by an American engineer, W.J. Wilgus, for the construction (1906–10) of the Detroit River twin-tube railroad tunnel between Detroit, Michigan, and Windsor, Ontario, where it was successfully used for the 2,665-foot (812-metre) river-crossing portion. A structural assembly of steel tubes was prefabricated in 262-foot- (80-metre-) long sections with both ends temporarily bulkheaded or closed. Each section was then towed out and sunk in 60 to 80 feet (18 to 24 metres) of water, onto a grillage of I-beams in sand at the bottom of a trench previously dredged in the river-bottom clay. After being connected to the previous section by locking pins driven by a diver, the section was weighted down by surrounding it with concrete. Next, after removal of the temporary bulkheads at the just-completed connection, the newly placed section was pumped out, permitting completion of an interior concrete lining in free air. These basic principles proved so practical that with subsequent refinements they still form the basis of the immersed-tube method.

After use on a four-tube New York subway crossing under the Harlem River in 1912–14, the method was tried for a vehicular tunnel in the 1925–28 construction of the 3,545-foot- (1,081-metre-) long, 37-foot- (11-metre-) diameter Posey tunnel at Oakland, California. Because these and other experiences have indicated that the problems encountered in building large vehicular tunnels could be better handled by the immersed-tube method, it has been preferred for subaqueous vehicular tunnels since about 1940. While shield tunnelling continued in a transition period (1940–50), subsequently nearly all of the world's large vehicular tunnels have been constructed by the immersed-tube method, including such notable examples as the Bankhead tunnel at Mobile, Alabama; two Chesapeake Bay tunnels; the Fraser River tunnel at Vancouver, British Columbia; the Maas River tunnel in The Netherlands; Denmark's Limfjord tunnel; Sweden's Tingstad tunnel; and the Hong Kong Cross Harbor tunnel.

Modern practice. The world's longest and deepest application to date is the twin-tube subway crossing of San Francisco Bay, constructed between 1966 and 1971 with a length of 3.6 miles (5.8 kilometres) in a maximum water depth of 135 feet (41 metres) (Figure 12). The 330-foot- (100-metre-) long, 48-foot- (15-metre-) wide sections were constructed of steel plate and launched by shipbuilding procedures. Each section also had temporary end bulkheads and upper pockets for gravel ballast placed during sinking. After placement of the interior concrete lining at a fitting-out dock, each section was towed to the site and sunk in a trench previously dredged in the mud in the bottom of the bay. A tower mast at the forward end of each section was used for survey alignment. Before sinking each section, gravel bedding was placed at the bottom of the trench and carefully levelled. With diver guidance, the initial connection was accomplished by hydraulic-jack-powered couplers, similar to those that automatically join railroad cars. By relieving the water pressure within the short compartment between bulkheads at the new joint, the water pressure acting on the forward end of the new section provided a huge force that pushed it into intimate contact with the previously laid tube, compressing the rubber gaskets to provide a watertight seal. Following this, the temporary bulkheads were removed on each side of the new joint and interior concrete placed across the connection.

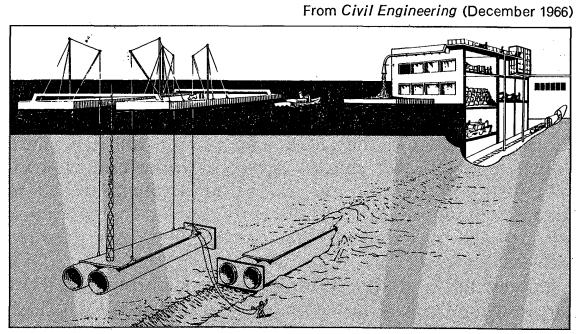

Figure 12: Immersed-tube tunnel building procedure (see text).

Most applications of the immersed-tube procedure outside the United States have been by a Danish engineer–constructor firm, Christiani and Nielsen, starting in 1938 with a three-tube highway crossing of the Maas River in Rotterdam. While following United States technique in essence, European engineers have developed a number of innovations, including prestressed concrete in lieu of a steel structure (often consisting of a number of short sections tied together with prestressed tendons to form a single section 300 feet [90 metres] in length); the use of butyl rubber as the waterproofing membrane; and initial support on temporary piles while a sand fill is jetted beneath. An alternate to the last approach has been used in a Swedish experiment on the Tingstad tunnel, in which the precast sections were supported on water-filled nylon sacks and the water later replaced by grout injected into the sacks to form the permanent support. Also, the cross section has been greatly enlarged—the 1969 Schelde River tunnel in Antwerp, Belgium, used precast sections 328 feet (100 metres) long by 33 feet (10 metres) high by 157 feet (48 metres) wide. This unusually large width accommodates two highway tubes of three lanes each for a total of six lanes, one two-track railroad tube, and one bicycle tube. Particularly unusual was a 1963 use of the immersed-tube technique in subway construction in Rotterdam. Trenches were dug or, in some cases, made out of

European innovations

abandoned canals and filled with water. The tube sections were then floated into position. This technique had been first tried in 1952 for one of the land approaches of the immersed-tube Elizabeth tunnel in Norfolk, Virginia; in low-elevation ground with the water table near the surface, it permits a considerable saving in bracing of the trench because keeping the trench filled eliminates the need for resisting external water pressure.

Thus, the immersed-tube method has become a frequent choice for subaqueous crossings, although some locations pose problems of interference with intensive navigation traffic or the possibility of displacement by severe storms (one tube section of the Chesapeake Bay tunnel was moved out of its trench by a severe storm during construction). The method is being actively considered for many of the world's most difficult underwater crossings, including the long-discussed English Channel Project.

IV. Future trends in underground construction

ENVIRONMENTAL AND ECONOMIC FACTORS

Improvement of surface environment. Unexpectedly rapid increases in urbanization throughout the world, especially since World War II, have brought many problems, including congestion, air pollution, loss of scarce surface area for vehicular ways, and major traffic disruption during their construction. Some cities relying principally on auto transport have even found that nearly two-thirds of their central land area is devoted to vehicular service (freeways, streets, and parking facilities), leaving only one-third of the surface space for productive or recreational use. During the past decade there has been a growing awareness that this situation could be alleviated by underground placement of a large number of facilities that do not need to be on the surface, such as rapid transit, parking, utilities, sewage and water-treatment plants, fluid storage, warehouses, and light manufacturing. The overriding deterrent, however, has been the greater cost underground—except in Sweden where energetic research has reduced underground costs to nearly equal the surface alternates. Hence planners have rarely dared to propose underground construction except where the surface alternate was widely recognized as intolerable. Underground construction in urban areas has, thus, generally been limited to situations without a viable surface alternate; as a result, additional increases in surface construction have further aggravated the problem. At the same time, the low volume of underground construction has provided insufficient incentive for the development of innovative technology.

New approach to underground construction

A different approach for the United States was crystallized from a 1966–68 study by the National Academy of Sciences and the National Academy of Engineering, which proposed cost reduction from government stimulated technologic research plus broader evaluation of social impacts. This would often show the underground alternate as the better investment for society. A reduction of at least one-third in cost and one-half in construction time over the next two decades was foreseen, and it was proposed that social and environmental costs be included in estimates as well as construction costs. In 1970 an international meeting of some 20 countries was held in Washington, D. C., under the Organization for Economic Co-operation and Development (an assembly of NATO countries) to share views and develop recommendations on government policy in this area. The conference recommended that energetic stimulation of underground construction be adopted as national policy in each of the 20 countries represented and in effect visualized the underground as a largely undeveloped natural resource. This resource, it was pointed out, could be used to expand urban areas downward to help preserve the upper environment—for example, by tunnels for transport and interbasin water transfer, for recovery of minerals increasingly needed by the economy, and in developing presently unreachable resources under ocean areas adjoining the continents. Such international consensus suggests that this is indeed a powerful concept ready for acceptance.

Scope of the tunnelling market. While informed people foresee a great increase in underground construction, numerical estimates are crude at best, particularly since statistics have not been accumulated in the past for underground construction as a separate item either in the public-works or the mining sectors. The 1970 conference mentioned above included a survey suggesting an average annual volume in its 20 member countries of about $1,000,000,000 in public works for the 1960–69 decade ($3,000,000,000 including mining) and forecast that this volume should at least double for the 1970–79 decade. Such estimates assumed the continuation of the current rate of technological improvement and recognized that the increase would be far greater if stimulated by government support in an energetic research and development program to reduce cost. All estimates are alike in forecasting a huge increase in underground construction during the next two decades. Key factors affecting the actual increase are technological improvements reducing costs and an increasing awareness on the part of society and public-works planners of the many potential applications for better use of the underground.

POTENTIAL APPLICATIONS

Future applications are expected to range from expansion of existing uses to the introduction of entirely new concepts. Several of these are considered below; many others are likely to emerge as innovative planners turn their attention to utilizing the underground space. For the next decade, at least, the largest increase is likely to be in rock tunnelling: partly from the nature of the projects and partly from the expectation that improved moles will make rock tunnelling more attractive than soil tunnels, with their usual requirement for continuous temporary support plus a permanent concrete lining.

Intercity transit

Deep rock tunnels for rapid transit between cities are beginning to receive very serious consideration. These might include a 425-mile (680-kilometre) system to cover the nearly continuous urban area between Boston and Washington, D. C., probably with an entirely new type of conveyance at speeds of several hundred miles per hour. A forerunner system in Japan, the New Tōkaidō Line, using standard railroad equipment at about 150 miles (about 250 kilometres) per hour, is currently undergoing expansion with many new tunnels. Highway tunnels are beginning to increase in number as well. Urban highway tunnels conceivably may offer a convenient opportunity to reduce pollution by treating the exhaust air that has already been collected by the ventilating system essential for longer vehicular tunnels.

There is increasing recognition that many more interbasin water transfers will be needed, involving systems of tunnels and canals. Notable current projects include the California Aqueduct, which transfers water from the northern mountains some 450 miles (725 kilometres) to the semi-arid Los Angeles area; the Orange–Fish Project in South Africa, which includes a 50-mile (80-kilometre) tunnel; and early studies for possible transfer of surplus Canadian water into the southwestern United States. Drainage can also be a problem, as in the old lakebed area occupied by Mexico City, where current expansion of the drainage system involves some 60 miles (100 kilometres) of tunnel.

Urban tunnels

Shallower tunnels for subways are bound to increase beyond those expansions currently under design or under construction in many cities, including San Francisco, Washington, D. C., Boston, Chicago, New York, London, Paris, Budapest, Munich, and Mexico City. Multiple use is likely to receive further consideration as communication agencies begin to show interest in adding space within the structures for the several types of utilities. Some merchants visualize mechanized movement of pedestrians between stores. One notable example is Montreal's extensive assembly of underground shopping malls, which interconnect most new downtown buildings as well as provide access to the subway and commuter railroads—a project that has relieved the streets from pedestrian traffic, particularly during severe weather. Another example involves utilization of space excavated above subway stations for parking facilities, as on the Toronto subway and more recently on the Paris

Metro, where the space above one of the stations in the Champs-Élysées area provides seven levels of parking.

Subaqueous crossings are becoming more ambitious. The world's longest railroad tunnel, for example, currently underway in Japan, is the 30-mile (50-kilometre) Seikan undersea rock tunnel between the islands of Honshu and Hokkaido, now being explored by a pilot tunnel that is also being utilized as a proving ground for several new types of moles. Of comparable scope is the more publicized projected English Channel tunnel for a rail connection between France and England, using special cars for auto transport. Studies early in the 1970s were concentrating on two alternatives: twin mole-excavated tunnels in chalk plus a service tunnel or an immersed-tube structure providing comparable space. The immersed-tube procedure is also being considered for a number of other difficult crossings; *e.g.*, from Denmark to Sweden and from Sicily to Italy. Immersed tubes are likely to become more attractive with improvement in methods for trench dredging in deeper water and for grading the trench bottom to support the tube structure. The Japanese are experimenting with an underwater bulldozer, robot-manned and television-monitored. One innovative proposal for supplying additional water to Southern California visualizes the immersed-tube method to construct a large pipeline for some 500 miles (800 kilometres) under the shallower ocean along the continental shelf. Subaqueous tunnelling also is likely to be involved as procedures are developed for utilizing the vast continental-shelf areas of the world; concepts are already being studied for tunnels to service oil wells and for extensive undersea mining such as has been pioneered in Britain and eastern Canada.

Fluid storage

Both Norway and Sweden have reduced the direct costs of fluid storage by storing petroleum products in underground chambers, thus eliminating the maintenance cost for frequent repainting of steel tanks in a surface facility. Locating these chambers below the permanent water table (and below any existing wells) ensures that seepage will be toward the chambers rather than outward; thus, the oil is prevented from leaking out of the chamber, and the lining may be omitted. Further economies may result from orienting the chambers vertically to take advantage of the raise borer and glory-hole techniques, previously mentioned. There are a number of underground installations for the storage of highly compressed gas cooled to a liquid state; these may increase once improved types of lining have been developed. Although the method involves only limited tunnelling for access, the United States Atomic Energy Commission has developed an ingenious method for disposal of nuclear waste by injecting it into fissured rock within a cement grout so that hardening of the grout reconverts the nuclear minerals into a stable rocklike state. Other disposal methods involve more tunnelling, such as within salt, which has particularly good ability for shielding against radiation.

A good example of an imaginative concept is Chicago's Underflow Tunnel and Reservoir Plan, which is intended to alleviate both pollution and flooding. Like most older cities, Chicago has a combined sewer system that carries both storm runoff and sanitary sewage during wet weather but only sanitary sewage during dry weather. The city's huge growth has so overtaxed older portions of the system that severe storms cause flooding in low areas. While sewage treatment has essentially eliminated sewage pollution of Lake Michigan, making Chicago virtually the only major city on the Great Lakes continuing wide recreational usage of its lake beaches, the treatment plants generally are sized to handle only the dry-weather flow. Thus, overflow during major storms is discharged into streams draining away from the lake as a mixture of sanitary sewage diluted by storm water. Conventional solutions adopted in the past, such as adding a second pipe system to collect only the storm water, discharging it into the streams, or adding plant capacity to treat all combined flow during severe storms, have proved tremendously expensive. An early version of a proposed solution of this problem is illustrated in Figure 13; a novel aspect of the plan is temporary storage of excess

water in large underground caverns, which after each storm could be pumped out for gradual treatment by the existing sewage plants. Inclusion of the surface reservoir shown in Figure 13 makes practical the use of the diluted sewage in a pumped storage hydroplant; in this type of facility the fluid is pumped up during offpeak-electric-power night periods, when steam power is cheaply available, and then allowed to flow back to generate peak power when demand exceeds economic capacity of the steam plants. A second multiple use is the opportunity to reduce present surface quarrying for crushed stone aggregate by using the dolomitic limestone mined from the deep tunnels and caverns. Extension of the tunnel and reservoir plan to suburban areas was under consideration in the early 1970s; the enlarged project, requiring 120 miles of tunnels, would serve an area of 375 square miles. The concept is being studied by Boston and other cities.

The use of rock chambers for underground hydroplants seems certain to increase in most countries, particularly those in which until recently surface plants have been favoured because of their apparently lower cost. Scotland has been one of the first countries to recognize that extra construction cost can often be warranted to preserve the scenic environment, also recognized by choice of an underground location for recent U.S. pump–storage plants —Northfield Mt. in Massachusetts and Raccoon Mt. in Tennessee, plus others being planned. Sweden's use of the underground for plants treating sewage and water, for warehouses, and for light manufacturing is likely to find further application. The relatively small annual temperature range in the underground has made it a desirable environment for facilities requiring close atmospheric control. In the vicinity of Kansas City, Missouri, mined-out space in underground limestone quarries is being used effectively for laboratory space, for dehumidified storage of corrosion-sensitive equipment, and for refrigerated food storage, an application also favoured in Sweden.

Temperature underground

Similar environment factors plus the probability of less disturbance during earthquakes have made the underground desirable for a number of scientific installations, including atomic accelerators, earthquake research, nuclear research, and space telescopes. Since earthquake risk is a big factor in locating nuclear powerplants, the merits of an underground location are attracting interest in siting studies for future plants.

IMPROVED TECHNOLOGY

Worldwide efforts are under way to accelerate improvements in the technology of underground construction and are likely to be stimulated as a result of the 1970 OECD International Conference recommending improvement as government policy. The endeavour involves specialists such as geologists, soil- and rock-mechanics engineers, public-works designers, mining engineers, contractors,

equipment and materials manufacturers, planners, and also lawyers, who aid in the search for more equitable contractual methods to share the risks of unknown geology and resulting extra costs. Many improvements and their early applications have been previously discussed; others are briefly mentioned here, including several that have not yet moved from the research stage to the pilot, or trial, stage. Projects in rock are emphasized, since the field of rock engineering is less developed than its older counterpart, soils engineering.

Geological prediction and evaluation

Geological prediction and evaluation are universally recognized as deserving a high priority for improvement. Since ground and water conditions are controlling factors in choosing both the design and construction method underground and seem destined to be even more so with greater use of moles, efforts are directed toward improving boring information (as with borehole cameras); faster borings (the Japanese are trying to bore one to three miles [about 1,600 to 4,800 metres] ahead of a tunnelling mole); geophysical methods to estimate rock-mass properties; and techniques to observe pattern of water flows. For evaluation, the new field of rock mechanics is concentrating on measuring geostress and rock-mass properties, failure mechanics of jointed rock, and analytical methods for applying results to design of underground openings.

For rock excavation, improved cutters are generally considered the key for expanding economic ability of moles to include harder rock. Much effort is being devoted to improving current mechanical cutters, including technical advances based upon space metallurgy, geometry of cutter shape and arrangement, mechanics of cutting action, and research in presoftening rock. Concurrently, there is an intensive search for entirely new rock-cutting methods (some nearing a pilot application), including high-pressure water jets, Russian water cannon (operated at high pressures), electron beam, and flame jet (often combined with abrasive powder). Other methods under research involve lasers and ultrasonics. Most of these have high power requirements and might increase ventilating needs from an already overtaxed system. Though some of these novel methods will eventually reach the stage of economic practicality, it is not possible to predict at present which ones will eventually succeed. Also needed is a means for testing rock in terms of mole drillability plus correlation with mole performance in different rocks, where promising work is under way at several locations.

New rock-cutting methods

A decided change in current materials-handling systems seems inevitable to keep up with fast-moving moles by matching the mole's rate of excavation and fragmentation sizing of the muck produced. Schemes now under study include long belt conveyors, high-speed rail with completely new types of equipment, and both hydraulic and pneumatic pipelines. Useful experience is being accumulated with pipeline transport of ore slurries, of coal, and even of such bulky material as canned goods.

For ground support, rock-mechanics engineers are working toward replacing past empirical methods with a more rational basis of design. One key factor is likely to be the tolerable deformation for mobilizing but not destroying the strength of the rock mass. There is wide agreement that progress will best be aided by field-test sections at prototype scale in selected ongoing projects.

Underground support

While several newer types of support have been discussed (rock bolts, shotcrete, and precast-concrete elements), developments are under way toward entirely new types, including lighter material plus yield-controllable types as a corollary to above tolerable deformation concept. For projects using concrete lining, major changes seem inevitable to keep pace with fast-moving moles, probably including some entirely new types of concretes. Current efforts include work with precast elements, plus research into stronger and faster set materials, which use resins and other polymers in lieu of portland cement.

Preservation of ground strength is beginning to win acceptance as vital for the safety of large rock chambers and also often a means of cost saving in tunnels. For preserving strength of the rock mass around tunnels, a mole-cut surface provides a solution. For large chambers, consideration is being given to cutting a peripheral slot with a wire saw of the type used to quarry monument stone. Where chambers are blasted, engineered soundwall blasting has provided a solution in Sweden.

Ground strengthening by precementation with chemical grouts is a technique notably developed in France and Britain through extensive research by specialized grouting firms. Figure 14 shows the world's outstanding appli-

cation at the Auber Station of the Métro Express beneath the Place de L'Opéra traffic centre of Paris—a large chamber 130 feet (40 metres) wide by 60 feet (18 metres) high by 750 feet (230 metres) long in chalky marl below an existing subway, at a depth of 120 feet (40 metres), about 60 feet (18 metres) below water table. This was completed in 1970 without interrupting surface traffic and without underpinning the many old masonry buildings above (including the historic National Opera Building), a truly courageous undertaking made possible by surrounding the chamber with a pregrouted zone to seal out water and to precement the overlying sand and gravel. Different types of chemical grout were successively injected (totalling about 2,000,000,000 cubic feet [57,000,000 cubic metres]), working from crown and side drifts; then the chamber was mined and supported both top and bottom by prestressed arches of concrete elements. Similar procedure was also successful at the Étoile Station adjacent to the Arc de Triomphe. While this technique of ground strengthening by grout solidification requires highly skilled specialists, it is an instructive example of how a new technology is likely to make economically possible future projects previously considered beyond engineering ability.

Turbine

The word turbine (Latin *turbo*, "a whirling object") designates a machine that converts the energy stored in a fluid into mechanical energy. Conversion is accomplished by passing the fluid through a system of fixed passages and moving finlike blades attached to a rotor, causing the latter to rotate. Turbines fall into three general classifications according to the most commonly used fluids—water, steam, and gas. Though water turbines are used principally for the generation of electric power, by far the greatest source of electric energy comes from steam turbines. These are also used for industrial applications and for propulsion of large oceangoing vessels. The principal application of gas turbines is for jet-propulsion aircraft. Aside from a variety of minor uses, they are also widely employed in the electric-utility industry for meeting peak-load demands and in the natural-gas industry for pumping natural gas through long-distance pipelines.

Development of turbines

The history of turbines goes back to ancient times when man first began to use water and wind to perform useful tasks. Because turbines employing each type of fluid have evolved along somewhat independent lines, they are treated separately here.

HISTORY OF WATER TURBINES

The idea of using water to turn a wheel was utilized centuries ago in China and the Middle East to lift water for irrigation. Water mills for grinding grain were introduced in Rome about 70 BC and soon became common throughout the Roman Empire. The earliest waterwheels were simple paddle wheels immersed in a stream; rotation was achieved by the impact of the current on the paddles. Later models confined the water in a channel, to prevent escape from around the edges of the vanes. Such wheels achieved efficiencies approaching 30 percent and were still in wide use until about 1800. A further development was the overshot wheel, in which water was introduced at the top of the wheel and carried down by gravity before being discharged near the bottom. Such wheels were capable of efficiencies between 70 and 90 percent, approaching that of present-day installations. They were used extensively until about 1850, when they began to be replaced by the more compact water turbines then coming into use (see WATERWHEEL).

Fourneyron's reaction turbine

The development of the modern water turbine began with experiments on the mechanics of reaction wheels by the Swiss mathematician Leonhard Euler and his son Albert, in the 1750s. These experiments led to further investigations, and the French engineer Benoît Fourneyron first achieved success in 1827 with a reaction turbine that could develop about six horsepower. This turbine used a radial outward flow, with water being directed through stationary guide vanes at the centre into curved blades of an outer runner (rotor, or rotating portion). The water discharging from the periphery of the runner created a reactive force causing the runner to rotate. By 1832 a turbine capable of developing about 50 horsepower had been perfected.

In 1838 an inward-flow turbine was patented by Samuel B. Howd of Geneva, New York, and about 1849 a fellow American, James B. Francis, designed a much improved version operating on the same general principle, which became universally known as the Francis turbine, one of the principal types in use today.

HISTORY OF STEAM TURBINES

The first device that could be classified as a steam turbine is generally attributed to Hero of Alexandria about the 1st century AD. Operating on the principle of reaction, this device achieved rotation through the action of steam issuing from curved tubes, or nozzles, in a manner similar to that of water issuing from a rotating lawn sprinkler. It consisted of a hollow sphere that was free to turn upon a horizontal axis above a caldron or boiler. Steam issuing from the caldron passed through two fixed tubes extending from the caldron to the sphere and escaped through two bent tubes attached to the sphere, causing rotation.

Another steam-driven machine, described about 1629, used a jet of steam impinging on blades projecting from a wheel, causing it to rotate. This machine, in contrast with that of Hero, operated on the impulse principle.

The first steam turbines having any commercial significance appear to have been those built in the United States by William Avery in 1831. These turbines consisted of two hollow arms, about two and one-half feet (750 millimetres) long, attached at right angles to a hollow shaft through which steam was supplied. At the extremity of each arm was a small opening through which the steam could issue. The openings were at the trailing edge of the arms, so that rotation was achieved by the reactive force of the steam. About 50 of these turbines were built for sawmills and woodworking shops, and at least one was tried on a locomotive. Although an efficiency approximately equal to that of contemporary steam engines was claimed, the turbines were abandoned because of their high noise level, difficult speed regulation, and frequent need of repair.

Not until the latter part of the 19th century were further significant contributions made. Probably the most prominent among a number of early inventors in the steam-turbine field was Sir Charles Parsons of England, who early recognized the advantage of employing a large number of stages in series so that the energy release by the expanding steam could take place in small steps. This principle opened the way for the development of the modern steam turbine. He also developed the reaction-stage principle, in which pressure drop and energy release are equal through both the stationary and moving blades. Turbines employing this principle are frequently called Parsons turbines.

Parsons' original ten-horsepower steam turbine was built in 1884 using a rotor and casing with attached multiple-stage blading (*i.e.*, several sets of blades in series rather than one), characteristic of modern turbines. Steam entered at the centre and flowed toward the ends.

Another prominent pioneer in the development of the steam turbine was Carl G.P. de Laval of Sweden, who built a small 42,000-revolutions-per-minute reaction turbine in the early 1880s. Although several of these were later employed for driving cream separators, he did not consider them practical for commercial application. De Laval turned to the development of reliable single-stage, simple-impulse turbines operating on the principle illustrated in Figure 1. He is credited with being the first

De Laval's simple impulse turbines

to employ a convergent-divergent type of nozzle in a steam turbine in order to realize the full potential energy of the expanding steam in a single-stage machine. During the period from 1889 to 1897 de Laval built a large number of turbines ranging in size from about five horsepower to several hundred. In 1892 he built a 15-horsepower turbine for marine applications with two turbine wheels, one for forward motion and the other for astern operation. An early model similar to this was exhibited at the World's Columbian Exposition in Chicago in 1893.

In addition to Parsons and de Laval, two other pioneers in the field, C.-E.-A. Rateau of France and Charles G. Curtis of the United States, made important contributions during the 1890s. Rateau developed the multistage-impulse principle, now commonly known as pressure staging, in which pressure drop occurs only in the stationary nozzle elements and not in the moving blades. With this design, fewer stages are required than for a corresponding reaction-type turbine operating under the same steam conditions. Curtis is responsible for the development of the velocity-compounded impulse stage in which two rows of moving blades are employed. In his design, an intermediate row of stationary blading was inserted between the two moving rows in order to direct the steam from the first to the second moving row. He also developed the use of several velocity-compounded stages in series.

Shortly after the turn of the century, steam turbines began to replace steam engines as the principal prime mover in central-station power plants. As a result, developments were rapid and became associated chiefly with large companies rather than individuals. Improvements in both size and efficiency of units followed, leading to the commanding position now occupied by the steam turbine in the field of electric-power generation.

HISTORY OF GAS TURBINES

While the oldest type of gas turbine is undoubtedly the windmill, it can hardly be compared to the modern gas turbine, in which heated gas is used as the motivating force for rotating the turbine shaft. One of the earliest devices that might be classified as a gas turbine was the smokejack designed to operate with the aid of hot gases rising from a fireplace. The smokejack is believed to have first been sketched by Leonardo da Vinci but was later more fully described by John Wilkins, an English clergyman, in his *Mathematical Magick* (1648). The device consisted of a number of horizontal sails, similar to those of a modern windmill, attached to a vertical shaft and placed in a chimney. The hot gases rising past the sails caused the device to rotate. With the aid of a simple gearing system it was possible to employ the smokejack for turning a spit or for performing other simple tasks.

The smokejack

A somewhat similar device was later patented by John Dumbell of England. His device employed a large number of sails, one above the other, all attached to a hollow drum. In addition, he supplied his own furnace underneath, with means for supplying air and fuel and for keeping the component parts from melting.

The first patent for a gas turbine operating on a cycle resembling present-day units was issued to John Barber of England in 1791. The principle of operation was as follows: air and fuel from a gas producer, after being compressed in separate cylinders, were directed into a combustion chamber and burned. The products of combustion were released through a small nozzle onto a turbine wheel. The power thus produced was supposed to be sufficient to compress the air and fuel and to leave enough over for external work. From modern knowledge of the cycle and from the sketch supplied by Barber, it is known that his machine could not have operated successfully. It did, however, represent an ingenious invention and included most of the essential elements found in present-day gas turbines.

In the years following the issuance of John Barber's patent, many novel devices were proposed, but it was not until 1872 that a really significant advance was made. This came with the granting of a patent to F. Stolze of Germany for his fire turbine, which consisted of a separately fired combustion chamber, a heat exchanger, and a multistage axial-flow compressor directly coupled to a multistage reaction turbine. It operated as follows: compressed air was directed into the heat exchanger, where it was heated by means of combustion gases from a separately fired furnace. The heated compressed air passed into the turbine, through which it was expanded back to the atmosphere. Even though Stolze's gas turbine embodied almost every feature of a modern open-cycle gas turbine, it was unsuccessful, largely because the compressor and turbine lacked the necessary efficiency to sustain operation with maximum turbine-inlet temperatures permissible at that time.

The first successful gas turbine, built in Paris in 1903, consisted of a three-cylinder multistage compressor followed by a combustion chamber in which liquid fuel was burned with air supplied from the compressor. The hot gases issuing from the combustion chamber, after being cooled to some extent by the injection of water, were expanded through a two-row impulse turbine wheel. The unit was capable of operating with an efficiency of about 3 percent. Although by later standards this was an unimpressive performance, it was a significant achievement at the time. It is believed to have been the first gas turbine capable of delivering work on a scale suitable for commercial purposes.

First successful gas turbine

Two other contributions should also be mentioned. In these, a different principle of operation was employed, that of exploding a mixture of air and fuel in constant-volume combustion chambers and then allowing the products of combustion to flow through nozzles onto a turbine wheel.

The first of these was a two-horsepower, 10,000-revolutions-per-minute unit built in Paris in 1908. It consisted of a simple de Laval impulse-type turbine wheel about six inches (150 millimetres) in diameter with four explosion chambers arranged around the periphery of the wheel, each leading to a nozzle directed against the wheel. The products of combustion from the four explosion chambers were released in sequence against the wheel. An ingenious method of drawing air and fuel into the chambers was provided. After explosion, the inertia of the gases leaving the chambers was employed to create a momentary partial vacuum inside the chambers that was capable of sucking in a new charge. During tests the device was reported to have a fuel consumption of about one pound (450 grams) of gasoline per horsepower-hour, corresponding to a thermal efficiency of about 2.5 percent.

The second and more important of the two contributions, historically, was the explosion-type turbine developed by Hans Holzwarth of Germany, who began a long series of experiments in 1905. His turbine consisted of a constant-volume combustion chamber into which a charge of fuel and air was introduced under pressure. Following ignition, the pressure was increased to approximately four and one-half times the original value, causing a spring-loaded valve to open, admitting the gases into nozzles directed against the blading of the turbine. The mechanism was so arranged that the valves remained open until the combustion chamber was emptied, after which a new charge was introduced. Although an air compressor was employed in the Holzwarth turbine, the efficiency of the compressor was not extremely important because the air could be supplied at a pressure of only about one-fourth that ultimately achieved during explosion and also because only enough air was required to furnish oxygen for combustion.

Over a period of about 30 years Holzwarth and various collaborators continued development of the turbine. Although now superseded, the Holzwarth explosion turbine represented a unique and important contribution.

The modern gas turbine is the result of the work of many individuals. Among the most prominent was Sir Frank Whittle of England, who early recognized its application to jet-propulsion aircraft. His efforts in this regard led to its development and use in military aircraft in the United Kingdom and the United States during World War II.

Basic principles and applications of turbines

Although turbine designs vary widely, depending on operating conditions and the type of working fluid, all operate on the same fundamental principle, namely, the conversion of energy stored in the fluid into mechanical energy. This transfer is accomplished by the conversion of the stored energy into kinetic energy and the release of this energy in a runner, or rotor, in the form of mechanical-power output.

In the case of a water turbine, the stored energy is in the form of potential energy of water stored in a reservoir at an elevation above the turbine outlet. This energy is measured in feet of head, H, and is based on the principle that to raise water through a difference in elevation of H feet would require an expenditure of energy equal to H foot-pounds per pound of water. Water in the reservoir, therefore, has a greater potential energy than at discharge, and the purpose of a water turbine is to make use of this difference in energy to produce mechanical work.

Enthalpy of steam

In the case of a steam turbine, the energy stored in the fluid is in the form of thermal or heat energy, called the enthalpy and designated by the letter h. The value of h depends upon the pressure and temperature of the steam and has been published in tables for ready use. Knowing the temperature and pressure of the steam at the turbine inlet and the pressure of the steam at the turbine exhaust, it is possible to find the energy available for the production of work. This energy, represented by the drop in enthalpy, is measured in British thermal units per pound and represents for a steam turbine essentially what the difference in head represents for a water turbine. A British thermal unit is the quantity of heat required to raise the temperature of one pound (454 grams) of water one degree Fahrenheit (0.555° C) at or near 63° F (17° C).

For a gas turbine, the energy stored in the fluid is also expressed in terms of the enthalpy. The treatment is similar to that of a steam turbine except that the working fluid usually consists of products of combustion, which, for practical purposes, can be treated as air. For a given temperature and pressure at the turbine inlet and a given exhaust pressure, the enthalpy drop available for conversion into work can readily be calculated by multiplying the specific heat at constant pressure of the air by its change in temperature. If greater accuracy is required, appropriate gas tables can be used instead.

Although water, steam, and gas turbines all operate on the same basic principle, they are sufficiently different to preclude a common treatment.

WATER TURBINES

Classification. Water turbines are divided into two classes: impulse turbines, generally used for high heads of water, and reaction turbines, generally used for heads ranging downward from 2,000 feet (600 metres). These two classes include six main types in common use—the Pelton and turgo impulse turbines and the propeller, Kaplan, Francis, and Deriaz reaction turbines—any of which can be arranged with either a horizontal or a vertical shaft. Wide variations are possible within each type to suit particular hydraulic conditions.

Each type of turbine can be further classified according to its specific speed, which is the revolutions per minute at which a scale model of the actual turbine should operate in order to develop one horsepower at one foot of head.

Impulse turbines. The impulse turbine extracts energy from water by first converting the head of water into kinetic energy by passing it through a carefully shaped nozzle that produces a free jet discharging in air. This jet is directed onto buckets that are fixed on the periphery of the runner and formed in such a way as to remove the maximum energy from the water.

Pelton turbine

Early designs of impulse turbines, using blades on the edge of the runner that caused substantial loss of energy because of impact, have been almost entirely supplanted by the Pelton type of turbine, patented in 1889 by the U.S. engineer Lester Allen Pelton. In this type a splitter edge in the centre of each bucket causes the jet of water impinging on it to divide into two divergent paths as it flows outward to fall clear of the runner (see Figure 2).

For maximum efficiency the speed of the runner of an impulse turbine should ideally be such that the buckets are moving with a velocity equal to about 50 percent of that of the impinging jet. The work produced will be equal to the potential energy surrendered by the water flowing through the turbine multiplied by the efficiency of its utilization by the turbine. The maximum efficiency of impulse turbines is about 91 percent when operating at 60–80 percent of full load.

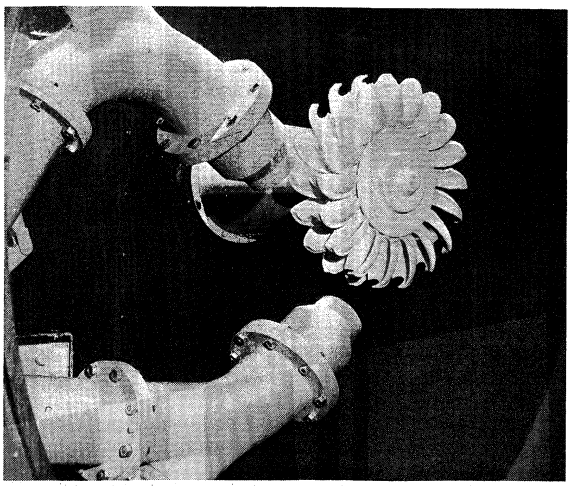

Figure 2: Pelton water turbine with twin jets.
Fox Photos Ltd.

The power of a given impulse wheel may be increased by using more than one jet, the two-jet arrangement being common for a horizontal shaft. With a vertical shaft there are usually four jets on a single runner, though occasionally there may be more. With a horizontal shaft it is also possible to mount two runners on the shaft driving a single electrical generator in order to produce a result equivalent to that of the multijet vertical arrangement.

The quantity of water flowing through each jet is controlled by a spear sliding inside the nozzle. This spear, operated by an automatically controlled oil-pressure motor (servomotor), can partially or completely close the nozzle orifice. The velocity of water leaving the nozzle will remain approximately constant over a wide range of openings; and because the runner will continue to turn at a fixed speed, the efficiency curve of a well-designed impulse turbine can be flat, but not as high as with other types.

It is not possible to reduce the water quantity flowing through the nozzle rapidly when a reduction in load is required, because there would be a large pressure rise in the pipeline. If a full quantity continues to be supplied to the runner after removal of the load, the motor would run too fast. To avoid this and to improve control, a second device in the form of a deflector, or diffuser, is inserted into the jet on load rejection, thus temporarily dissipating the energy of the water until the quantity is reduced by the spear closing off the flow from the nozzle.

Another type of impulse turbine is the turgo type, in which the jet impinges obliquely on the side of the runner and continues in a single path, discharging at the other side. This type of turbine is useful for medium-size units that use medium heads.

Reaction turbines. Reaction turbines achieve rotation mainly through the reactive force created by the acceleration of water in the runner, or rotor, rather than in the supply nozzles, as was the case for the impulse turbine. The basic principle employed is the same as that of a rotating lawn sprinkler, in which water enters the curved arms of the sprinkler at low velocity and leaves at high velocity. The exact manner in which the acceleration is achieved in water turbines, however, differs in accordance with whether the runner is of the propeller, Kaplan, Francis, or Deriaz type.

Runner geometry

Because of the great variety possible in the geometry of the runner, reaction turbines are far more widely used than impulse turbines. In all these types, a fraction of the hydraulic pressure is first converted into velocity in the passage of the water through the inlet structure, which is composed of a spiral casing and a gate apparatus leading to the runner. The power from the water associated with the pressure and velocity at this point is then converted to mechanical power in a single-stage runner that absorbs the full water energy down to a pressure usually below atmospheric pressure.

Of the four main types of reaction turbine, the propeller and the Kaplan turbines have axial-flow runners and are used for lower heads, while the Francis and the Deriaz turbines have mixed-flow runners; *i.e.*, flow is radial at the inlet and axial at the outlet. The runner blades on the propeller and Francis turbines are fixed, while those on the Kaplan and Deriaz turbines are movable.

Axial-flow turbines. A fixed-blade propeller turbine with a vertical shaft is almost invariably used for large units, because its higher specific speed permits a valuable saving in plant cost when compared with the Francis alternative. The running speed can be as much as twice that of the Francis at heads below about 35 feet (11 metres), and 50 percent greater at heads of 60 feet (18 metres). Even so, the running speed of high-output propeller turbines is often below 100 revolutions per minute. Though the components are very large, the form of the runner is such that it is possible to detach the blades for transport and to attach them by bolted flanges at the site so that the limiting item for transport becomes the runner hub.

At low heads (up to about 80 feet, or 24 metres) the turbine has a concrete spiral casing, which, for the larger machines, is provided with two or more rectangular inlets leading to the stay vanes. These vanes may be individually set in concrete, thus reducing one of the bulkier components for transport. The runner envelope, of cylindrical form, leads to the draft-tube cone and bend.

The propeller turbine has been used extensively in North America, where low head and large flow are common, thus requiring the installation of many units in one station. There are 32 propeller turbines in the St. Lawrence Power Station (where the St. Lawrence River forms part of the eastern boundary between Canada and the United States), 16 operated by Canada and 16 by the United States. With such power stations it is possible to run the turbine continually at or near its most efficient output by switching a complete unit in and out as the load fluctuates. If both the water quantity and the power required are such that only a few units are required to deal with a variable load, the efficiency of operation falls off very sharply below a 75 percent load. The same will apply if there is any marked variation in operating head, because an increase in head at a fixed load is equivalent to reduced load at a fixed head.

These limitations of the propeller turbine have been met by making the blade angle of the runner variable in order to match more accurately the correct angle for a given flow of water. This type is called the Kaplan turbine, after the Austrian inventor, Viktor Kaplan, who patented his design in 1920 (see Figure 3). The physical size and operating head for which the turbine can be used have increased markedly, and runner diameters of 30 feet (9 metres) have been employed. British manufacturers have developed designs operating at heads of 190 feet (58 metres), but it is likely that further progress in increased heads will be limited because of the advent of the Deriaz turbine (see *Mixed-flow turbines* below).

Kaplan turbine

The runner-blade angle is varied by an oil-pressure-operated servomotor, which is usually mounted in the runner hub, with the oil being fed down tubes in the bore of the turbine and the alternator shafts. Runners having four to six blades are common, though more blades are used for high heads. The correct relationship of runner-blade angle to the water flow admitted by the turbine gate apparatus is ensured by a cam operated by a pilot servomotor in the governor system. When best performance is required over a wide range of operating heads, several cams may be used and brought into service to match the head at a given time. This flexibility is especially valuable when seasonal variations in head occur.

The Kaplan turbine in its traditional form has a vertical shaft, though one design uses a horizontal shaft and an electrical generator mounted in a nacelle, or metal shell, in the water flow. This design is particularly suitable for lower output machines operating on very low heads, in which case an almost straight water passage is possible. This type of turbine was designed for a French project on the Rance River Estuary, which employs tidal power.

Mixed-flow turbines. The Francis turbine is probably the most extensively used type of turbine because of the very wide head range for which it is suited—from the lowest economically usable (about ten feet, or three metres) to about 2,000 feet (600 metres). The turbines at the top range of heads must be of large output; otherwise the water quantities and the size of the water passages in the runner become too small for reasonable construction. At low heads the propeller turbine is usually more economical unless the output required is small. The Francis turbine, however, reigns supreme in the medium-head range of 400–1,000 feet (120–300 metres) and has a wide range of sizes.

Francis turbines can have either horizontal or vertical shafts, the latter being used for machines having runner diameters of six feet (two metres) or more. Each machine has certain advantages that affect the choice. Vertical-shaft machines usually occupy less space and also permit greater submergence of the runner, with a minimum of deep excavation. On the other hand, horizontal shafts provide a compact unit for small sizes and permit easier access to the turbine, though removal of the alternator rotor becomes difficult as the size increases.

The commonest form of Francis turbine has a fabricated, or cast-steel, spiral casing. This casing distributes water flow equally to the regulating gear, which consists of a number (about 24) of pivoted gates or guide vanes that when closed seal off the throat of the casing and are adjustable to any opening for the required output. The guide vanes are operated simultaneously by a regulating ring and are connected in such a way that if there is blockage no damage occurs. The regulating ring is driven by one or two oil-pressure servomotors controlled by the governor.

The design of the runner, or rotor, must recognize several factors in order to obtain the best efficiency at the required head and output. Its speed involves the correct choice of specific speed determined by experience and consideration of the generator design. The inlet and outlet diameters and the blade height at the inlet are then

determined, after which the blade form is calculated to give smooth entry of water at the inlet and zero rotation at the outlet. The number of blades varies widely, normally from nine to 19. Construction is commonly cast steel or, for high heads, stainless steel. In the former case, stainless-steel protection is added to areas subject to cavitation (formation and collapse of vapour cavities in a turbulent liquid; this phenomenon can damage turbine parts severely). Runners of welded construction permit the formation of more accurate and more highly finished waterways for high-head turbines having long and narrow runner passages and also enable a runner to be made of an appropriate combination of steels.

Cavitation

The extent to which the runner is subject to cavitation depends on the amount of suction produced by the draft tube compared with the setting of the runner centreline relative to the tailwater level. Careful control of the blade form can reduce the tendency for cavitation, particularly on the back of the blades at exit.

Very large and high-output Francis turbines have been installed with outputs exceeding 600,000 horsepower from a single runner, though outputs of 800,000 horsepower were projected in the 1970s.

A form of mixed-flow turbine, named after its inventor (Paul Deriaz, a Swiss engineer), in 1956, has a variable pitch design that improves the efficiency under less than full load for medium-head machines (Figure 4). This

design proved to be very useful for the higher heads and also for pumped-storage applications (see *Pumped storage* below). It also has the advantage of a lower runaway (no-load) speed than the Kaplan turbine, thus giving significant savings in the cost of the generator.

The first nonreversible Deriaz turbine, consisting of a 32,500-horsepower unit in an underground power station, was installed at Culligran in Scotland.

Control of speed and output. The control of the speed and output of water turbines involves the large forces necessary to operate the regulating gear and the high inertia of the water in the pipeline between the reservoir and the turbine inlet.

When a single turbine with governor is supplying an isolated load, any variation in load will initially produce a change in speed that is sensed by the governor. The turbine guide vanes, or the spears in the case of impulse turbines, are then opened or closed by the governor to restore the speed to its original value.

The rate at which the turbine guide vanes, or spears, may be opened or closed is determined by the relative inertia of the water in the supply pipe and the inertia of the rotating parts. If a long pipeline is provided, the closing time must be slow in order to keep the pressure rise within reasonable limits, but, if it is too slow, instability will result. To assist regulation with long pipelines, a surge chamber is often connected to the pipeline as near as possible to the turbine, thus enabling part of the water in the pipeline to pass into the surge chamber as the turbine is closed. This operation also allows a faster opening time to be used. The spiral casings of medium-sized reaction turbines can be provided with pressure-relief valves through which surplus water is passed automatically as the governor closes. For difficult pipelines a combination of the two devices can be used.

Inertia factors in guide vane control

Water turbines supplying large, interconnected power systems are sometimes required to operate on a predetermined load program or to maintain system frequency control according to master clock directions. These requirements can be met by using an electronic governor in which the speed-sensitive pendulum is replaced by an electric actuator operating a hydraulic pilot valve.

Applications. *Generation of electric power.* Water turbines are used almost exclusively for the production of electric power that can be transmitted over high-voltage lines to existing load centres for distribution to surrounding communities. Countries leading in hydroelectric-power production are the United States, the Soviet Union, and Canada, but many other countries have extensive hydroelectric developments. Until the late 1950s the largest units in operation were less than 200,000 horsepower, but since then a number of larger units have been built and many more are projected for completion in the 1970s. Largest of the turbines in operation in the early 1970s were the 12 Francis turbines at Krasnoyarsk on the Yenisey River in Siberia, Soviet Union. These units each have a capacity of 685,000 horsepower, making an aggregate total of 8,220,000 horsepower, or about 6,000,000 kilowatts. Scheduled for completion in the early 1970s was the Sayano-Sushensk plant, also on the Yenisey River, with 12 units, each having a capacity of 740,000 horsepower, aggregating about 6,600,000 kilowatts. At Churchill Falls, Canada, a plant having 11 units, each with a capacity of 648,000 horsepower, was under construction, with completion expected about 1973. This plant employs Francis turbines under a head of 1,025 feet (312 metres). The largest projected plant in the world was at the Grand Coulee Dam on the Columbia River in the United States. There, 12 units, each having a capacity of 600,000 kilowatts, were to be added to the existing plant, which contains 18 units, each capable of 125,000 kilowatts, giving a grand total of about 9,200,000 kilowatts. The new units are Francis turbines operating under a head of 285 feet (87 metres), with a speed of 64.7 revolutions per minute.

Pumped storage. One method of utilizing water turbines for the generation of electricity is a system called pumped storage. With this system, two water reservoirs are used, one at a low level and the other at a higher level. The two reservoirs are connected to each other through a reversible pump-turbine capable of operating as a turbine-generator when rotating in one direction and as a pump when operating in the opposite direction. When the electrical load on the system falls below the desired base load value, the extra power available can be used to pump water from the lower reservoir into the upper reservoir, thus storing it for later use. During peak-load periods, when the power required by the system exceeds the base-load value, the water is allowed to flow back through the reversible-pump turbine unit into the lower reservoir, generating power in the process. Such a system provides a steady load at night and the needed additional power to meet peak demand during the day. Even though pumped storage systems have no inherent source of energy production, they are economical in capital cost compared with thermal plants and have high overall efficiency. The reversible-pump turbine has been developed extensively, and, in the late 1960s, about 60 such units were in operation, varying between 28,000 and 240,000 horsepower in capacity. At the same time, more than 50 additional units were planned or under construction, ranging up to 430,000 horsepower in capacity.

Reversible-pump turbine

The turbine runner for all but the lowest heads is of the

mixed-flow reaction type. Some of the most economical pumped-storage plants have heads exceeding 1,000 feet (300 metres), which in the past were generally considered to be too high for single-stage pumps, and, therefore, multistage nonreversible units were used. Satisfactory reversible-pump turbines have been developed for heads exceding 1,000 feet.

For medium heads, the Deriaz pump turbine is ideal, because of the ease of adjusting the runner-blade angles to suit the differing requirements set by pumping and generating. The pumping load can also be varied, a change that cannot be made satisfactorily with a Francis runner, even when there are guide vanes, because of the hydraulic conditions when they are partly open. A further advantage of the Deriaz pump turbine is that, when starting up as a pump, the runner vanes can be closed to form a smooth cone, and thus it can be started with a minimum of load while submerged in water. Six 52,500 horsepower units of this type were operating at Niagara Falls, Canada, in the early 1970s, and there are reversible units of this type with outputs of more than 100,000 horsepower in Spain (Figure 4).

Future trends. Although hydroelectric sites relatively near to existing load centres are gradually dwindling, there is an increasing demand for pollution-free power generation. Though the hydroelectric plant meets these requirements to a high degree, it is not wholly free from criticism, because the necessity for scarring the landscape and creating a large impoundment of water often meets with resistance from conservationists.

Hydroelectric potential of various rivers

It is believed that hydroelectric turbines of as high as 2,000,000 horsepower are feasible and that such units eventually may be installed in the more remote locations still available. The Fraser River in Canada is estimated to have a potential of 8,700 megawatts (one megawatt equals 1,000 kilowatts). Other rivers having potential hydroelectric sites are the Orinoco in Venezuela, 8,000 megawatts; the Inga in the Congo, 25,000 megawatts; and the Brahmaputra in India, 20,000 megawatts.

In the Soviet Union, the Yenisey–Angara River system is estimated to have a potential capacity of 64,000 megawatts. At the beginning of the 1970s there were three stations completed on this system, with a total capacity of 11,000 megawatts, and three more stations under construction with about the same total capacity. Plans for continued development of the system, running into the 21st century, call for the construction of seven more plants, bringing the ultimate developed capacity to about 52,000 megawatts. The above examples represent only a few of the world's promising hydroelectric resources remaining to be tapped.

STEAM TURBINES

A steam turbine is a machine for converting thermal energy stored as steam into work. It consists of a shaft or rotor resting in bearings and enclosed in a cylindrical casing. The rotor is made to turn smoothly by means of jets of steam issuing from nozzles located around the periphery of the turbine cylinder and impinging upon blades or buckets attached to the rotor. Thus a steam turbine is a prime mover that generates motive power in the same manner as a series of windmills mounted on a single shaft but on a vastly greater scale. Instead of a current of air being used to rotate the shaft, steam is employed as the working agent.

Because of its ability to develop tremendous power within a comparatively small space, the steam turbine has superseded all other prime movers, except hydraulic turbines, for the generation of large quantities of electric energy. The economic importance of the steam turbine has provided an incentive for continued development, resulting in units capable of generating as high as 1,200,000 kilowatts of power on a single shaft and even more in other combinations.

Classification. Steam turbines are complex machines and may be classified in many ways. One method is according to whether rotation is achieved by impulse or reaction forces. In modern turbines this distinction is somewhat blurred because most machines employ a combination of the two methods. Nevertheless, certain manufacturers tend toward machines that are basically of the reaction type while others prefer the impulse type. Another method of classification is according to whether the entire machine is mounted on a single shaft with one electric generator or on two shafts, each with its own generator. The former are called tandem compound turbines and the latter cross-compound turbines.

Condensing and noncondensing steam turbines

Steam turbines may also be classified as condensing or noncondensing, depending upon whether or not the steam is exhausted to a condenser. Noncondensing turbines are those in which steam, after expanding through the turbine, is exhausted to the atmosphere, to a heating system, or to some other type of equipment. Their most frequent application is in industrial plants where steam is needed at low or intermediate pressures and where by-product power can be generated economically by inserting a noncondensing turbine between the steam generator and the equipment requiring steam.

In condensing turbines, condensation of the exhaust steam is effected by the circulation of large quantities of cold water through the tubes of the condenser. The circulating water absorbs the heat given up during condensation and carries it away. The process of continuous condensation maintains a low pressure in the condenser, thus increasing the expansion ratio of the steam (*i.e.*, the ratio of the expanded volume of the steam to its original volume) and the consequent efficiency and work output of the turbine. Because of the necessity of maintaining the highest possible efficiency, all central-station power plants employ condensing turbines, which are connected directly to large electrical generators capable of generating power at high voltage.

An additional classification of turbines may be made on the basis of whether or not a portion of the steam is extracted from the turbine during passage through the machine and in what manner the extraction takes place. On this basis turbines may be classified as follows: (1) straight-through turbines; (2) bleeder turbines; and (3) automatic-extraction turbines.

Straight-through turbines are those in which there are no extraction points, and all steam supplied to the input passes all the way through the turbine and out the exhaust. Bleeder turbines are those in which provisions are made for heating the water that is eventually converted to stream (feedwater). This end is accomplished by extracting steam at various locations along its path of flow through the turbine. In bleeder turbines no attempt is made to control the pressure of the steam extracted. Because of this, extraction pressure automatically varies in almost direct proportion to the load being carried by the turbine. The principal advantage of a bleeder turbine over a straight-through turbine is that steam bled from the turbine does not flow to the condenser; its latent heat (the heat required to vaporize water to steam), therefore, is retained in the cycle. Another advantage is that the exhaust area of the turbine can be smaller because less steam flows to the condenser.

The use of bleed-point steam for feedwater heating is universal in central-station power plants because it increases the thermal efficiency of a plant by 10–15 percent. In most cases, the fraction of steam withdrawn is about 30 percent of the steam initially supplied at the turbine inlet.

Automatic extraction turbines are machines designed for the withdrawal of variable quantities of constant-pressure steam from one or more extraction points along the path of flow, regardless of how much load is being carried by the turbine. Such turbines are widely used in industrial power plants where steam is needed at one or more pressures for process work. Because it is desirable to hold both extraction pressure and speed constant, regardless of power requirements, a complicated system of governing is required. This need makes the turbines more expensive than either bleeder or straight-through turbines. Automatic-extraction turbines may be designed for either condensing or noncondensing operation.

Principal components. The principal components of a steam turbine are: (1) the rotor that carries the blading

employed for converting energy of the steam into rotary motion of the shaft; (2) the casing or cylinder, inside which the rotor turns and that carries fixed nozzle passages through which steam is accelerated before being directed against the rotor blading; (3) the speed-regulating mechanism by which the speed of rotation is governed; (4) the lubrication system for bearings and other apparatus associated with the turbine.

Blading design

Of the various elements of the turbine, perhaps the most difficult to design properly is the blading, because it must have adequate strength and the correct aerodynamic shape to convert the energy of the steam into shaft work efficiently. Various types of blading and blading arrangements have been proposed, but all are designed to take advantage of the principle that when a given mass of substance suddenly changes its velocity, a force is exerted by the mass in direct proportion to the rate of change of velocity.

Two types of blading have been developed to a high degree of perfection: impulse blading and reaction blading. The principle of impulse blading may best be illustrated by referring to Figure 1. This simplified diagram of a turbine rotor wheel shows four fixed nozzles directing high-velocity steam against blades mounted around the periphery of the wheel. If there were no blades in the path of the steam, it would proceed in a straight line. The blades catch the impinging steam, however, and turn it in the opposite direction, thus changing its velocity from a high value at entrance to a low value at exit. This decrease in velocity of the mass of steam produces a force on the rotor blading, causing the shaft, to which the disk and blading are attached, to turn.

Proper operation of an impulse wheel requires that the blading be of approximately symmetrical design and that it move past the nozzles with a speed approximately equal to one-half that of the steam issuing from the nozzles. Figure 5A shows an arrangement of nozzles and blading for a simple impulse-turbine stage.

When reaction blading is employed (Figure 5B), the rotor is designed to turn at a speed approximately equal to that of the steam issuing from the nozzles, instead of half the velocity, as is the case in an impulse stage. The steam thus enters the moving blades with almost zero relative velocity. Also, the blades of the rotor of a reaction turbine are unsymmetrical and have a profile such that the space between blades forms nozzle passages. As the steam flows through these passages, it expands, thereby increasing its velocity relative to the blading. The acceleration of the steam creates a reactive force, turning the rotor in a direction opposite to that of the exit steam.

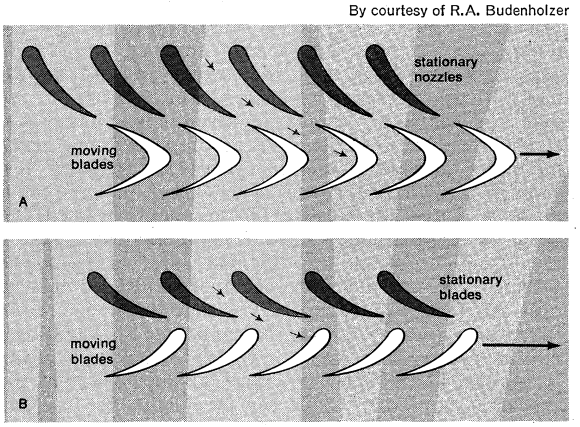

Figure 5: Arrangement of nozzles and blading for (A) a simple impulse-turbine stage and (B) a reaction-turbine stage.

With either impulse blading or reaction blading, the overall principle is the same: the velocity of the steam is first built up in the stationary nozzles, after which it is decreased in the moving blades. Energy stored in the steam is thereby first converted into kinetic energy and then into rotational shaft work.

Turbine staging. In modern turbines a large number of nozzle and moving blade combinations similar to those illustrated in either Figure 5A or 5B are required. Each of these combinations is called a turbine stage. If only one is employed the turbine is a single stage machine whereas if several are employed it is a multistage machine. There are several reasons for staging, the most important of which are the following: (1) steam, in expanding through a modern turbine, often enters under a pressure in excess of 3,000 pounds per square inch (200 kilograms per square centimetre) and exhausts under a pressure below one pound per square inch absolute. (Absolute pressure is the pressure above a vacuum, or zero pressure.) This situation means a several-hundredfold increase in volume of flow between entrance and exit. Such large expansions cannot be accommodated efficiently by a single stage, because the cross-sectional area perpendicular to the flow would have to increase several hundred times through a single row of nozzle passages and one or two rows of moving blades. (2) By breaking the expansion into small steps more efficient nozzle and blade passages can be designed, and thus a velocity relationship that best accommodates the conversion of energy in the steam into work can be realized. (3) Centrifugal and other forces acting on the blading limit its maximum velocity at the tip to values that will not permit the efficient use of only one stage, even when all of the other factors are favourable to such an arrangement.

Reasons for staging

In modern steam turbines, three types of staging are employed, either separately or in combination. These are pressure staging, reaction staging, and velocity compounded staging.

Pressure staging. Pressure staging is simply the use of a number of simple-impulse stages similar to the one illustrated in Figure 5A arranged in sequence. Turbines using this principle employ a large number of stages, each contributing a small fraction to the total power output. Turbines employing pressure staging range in size from a few kilowatts to 1,200,000 kilowatts, or even larger. A turbine with this type of staging is illustrated in Figure 6.

Reaction staging. Reaction staging is similar to pressure staging except that a number of reaction stages are employed in sequence. Turbines using this principle require about twice as many stages as corresponding machines employing pressure staging. The cost, however, is about the same, because blading for pressure staging must withstand greater forces and, therefore, be more rigidly constructed. Reaction turbines are built in the same size range as pressure-stage turbines.

Velocity-compounded staging. This type of staging employs the same type of blading as impulse staging except that two rows of moving blades instead of one are used, and a stationary row is inserted between the rows to redirect the steam from one moving row to another. With this arrangement, four times more power can be obtained from a single velocity compounded stage than from a single pressure stage with the same blade velocity. Velocity-compounded staging is well suited for small turbines in which the steam, after passing through the turbine, exhausts to a heating system or to some other use in which the pressure is atmospheric or higher. A velocity-compounded stage is also frequently employed as the first of a number of stages in large industrial and central-station type turbines. In this application, the velocity-compounded stage serves as a control stage and offers a powerful means of quickly changing the turbine output in response to the slightest change in steam flow as dictated by the governing mechanism. Such a velocity-compounded stage also permits a large drop in pressure and temperature before the steam enters the first moving blades of the turbine. This drop makes possible the use of higher initial temperatures and pressures without the use of special heat-resistant alloys that are expensive and difficult to machine. Also the specific volume of the steam flowing through the blading is greater, allowing the use of longer blades, which results in lower frictional losses.

Power development. The force of the steam acting on the blading of a single-impulse stage and the theoretical

horsepower obtainable can be calculated. These calculations are based on highly idealized conditions that cannot be realized in actual operation, however, and, thus, the true value of power produced will be somewhat less.

For the same blade velocity, pressure staging produces about twice as much power per stage as reaction staging, and velocity compounded staging about eight times as much. Thus, turbines employing reaction staging would require the greatest number of stages to produce a given power output while those employing velocity compounded stages would require the least. Pressure staged turbines would require a number somewhere between the two.

Stage efficiency. The efficiency of a turbine stage may be defined as the power output divided by the enthalpy drop that would occur if expansion of steam took place through the stage without friction, turbulence, or other losses.

Power losses

The maximum ideal efficiency for all three types of turbines is theoretically the same. In actual turbine stages, numerous losses—such as wall friction, turbulence, and leakage losses—serve to reduce the efficiency to well below the theoretical maximum. Efficiency of turbine stages also varies with the ratio of blade velocity to steam-jet velocity. The maximum efficiency of the velocity-compounded stage with two rows of moving blades tends to be less than that of the simple-impulse stage, and both tend to have a lower maximum efficiency than the reaction-type stage. In general, velocity-compounded stages are avoided except for the first control stage of turbines.

Performance characteristics. The performance of a steam turbine is measured in terms of the turbine heat rate, a measure of the heat that must be supplied to the steam in order to produce a specified power output. For central-station applications the turbine is always connected directly to an electric generator, and the combination is called a turbogenerator. The turbine heat rate for this type of machine is defined as the number of British thermal units of heat that must be added to the steam in order to produce one kilowatt-hour of electric-power output. In the case of a turbine not connected to an electric generator, the heat rate is usually expressed in terms of British thermal units per horsepower-hour output.

The turbine heat rate depends upon many factors, the most important being: (1) pressure and temperature of the inlet steam; (2) exhaust pressure; (3) internal efficiency of the turbine, a measure of effectiveness with which the energy in the steam is converted into work; (4) exhaust loss, the kinetic energy loss associated with the high velocity of exhaust; (5) mechanical losses; (6) generator losses. With the exception of the first two factors, the above all depend to some extent upon the fraction of rated load being carried by the turbine.

In general, the turbine heat rate increases with decrease in load. This inverse relation means that more steam is required to generate a unit of output at low load than at high load. Because of various losses, the generator output is usually about 80 percent of the energy in the steam available for producing power.

Taking into account the efficiency of the turbine itself as well as the heat which must be discarded in the condenser, the overall thermal efficiency of the best steam power plants is about 40 percent for fossil fuel plants and about 30 percent for nuclear plants.

Future trends. Until the 1970s most electric energy was generated in fossil-fuel power plants. The soaring cost of such fuel stimulated the building of increasingly larger turbines with higher and higher efficiencies. To secure these efficiencies, it was necessary to raise the pressure and temperature of the turbine-inlet steam to very high values. These reached their peak in the decade 1950–60, which witnessed the introduction of supercritical pressure plants operating with initial pressures as high as 5,000 pounds per square inch (350 kilograms per square centimetre) and temperatures as high as 1,100° F (600° C). In the 1965–75 period, the ever-increasing demand for electric power and the necessity of generating this power with minimal air pollution caused a gradual movement toward the installation of nuclear plants. This trend is expected to continue in succeeding decades and to require even larger steam turbines, since nuclear plants are only economic in very large sizes. In the early 1970s nuclear plants had not reached the stage in development where they could provide the very high temperatures and pressures employed in fossil-fuel plants; consequently nuclear turbines had to be designed for operation at comparatively low pressures—approximately 1,000 pounds per square inch. To secure efficient operation under these conditions and to prevent blade erosion from moisture particles in the steam, provision for separating liquid moisture from the steam as it flows through the turbine must be made. Turbines for nuclear plants were expected to range up to 1,500,000 kilowatts in the 1970s and even larger thereafter. Figure 6 is a cutaway view of a 1,000,000-kilowatt turbine designed for a nuclear-power installation in the early 1970s.

GAS TURBINES

A gas turbine is a form of heat engine for producing work with the aid of heated gases. It differs from the conventional internal-combustion engine in the manner in which the heated gases are employed.

The gas turbine achieves some of the advantages of internal-combustion engines without the complications associated with reciprocating, or up-and-down, motion of conventional piston engines. Its principle of operation is to direct a continuous stream of hot gases against the blading of a turbine rotor. In modern units, the air is first compressed in either an axial-flow or centrifugal compressor before being directed into combustion chambers. In these, fuel is mixed with a portion of the air and burned. Some of the air is bypassed around the burner and subsequently mixed again with the products of combustion to prevent excessive temperature of the gases leaving the combustion chambers. The emerging gases are directed through nozzles and against the blading of the turbine rotor, furnishing sufficient power to drive the compressor with enough left over for other useful purposes. The result is a relatively vibration free, smooth-running machine.

Idealized simple open-cycle gas turbine. Most gas turbines operate on the constant-pressure combustion cycle. Figure 7 is a sketch of a simple open-cycle unit with

accompanying pressure-volume diagram indicating the sequence of processes to which the working substance is subjected as it flows through the various items of equipment. In the idealized cycle shown, air enters the axial-flow compressor at section 1 under atmospheric pressure and temperature. It is then compressed at constant entropy (no heat added or subtracted and without friction or other losses) to section 2. From section 2 the air flows into the combustion chamber, where fuel is added and burned at constant pressure, raising the temperature to its maximum value for the cycle. From the combustion chamber the heated gases enter the turbine, where expansion occurs to atmospheric pressure. The amount of work obtainable from the unit is the difference between that required to compress the gas and that obtained from the turbine. This difference may be represented by areas on the pressure-volume diagram in the insert. In the simple ideal cycle, the efficiency depends on the pressure ratio employed and increases rapidly with pressure ratio, at first, and then begins to level off slowly. Theoretically, if the pressure ratio were to approach infinity, the thermal efficiency would approach 100 percent.

Ideal and actual cycles

Actual simple open-cycle gas turbine. The principal difference between the ideal cycle described above and the actual cycle obtainable in practice is that the compression and expansion processes cannot actually be carried out without friction or other losses as assumed. Instead, the work of compression is increased, and the work of expansion is decreased. The net result is a drastic reduction in the net-work output and thermal efficiency of the cycle. In typical actual cycles, the efficiency of the compressor is about 85 percent and that of the turbine about 87 percent. Maximum cycle temperatures ranging from 1,000° to 1,750° F, (540° to 950° C) are employed, the latter being about the maximum feasible temperature permissible with modern alloys without special arrangements for cooling the blades of the turbine.

Unlike the ideal cycle, where the efficiency depends only on the pressure ratio, the thermal efficiency of an actual cycle increases with maximum temperature of the cycle T_3, and there is an optimum value of pressure ratio for each value of T_3. The maximum temperature must be high if a satisfactory efficiency is to be obtained. The lower the efficiencies of the compressor and turbine, the lower will be the net work output of the cycle. These facts explain the failure of Stolze's turbine and of all similar early models in which high-compressor and turbine efficiencies were unattainable. They also explain the reason for Holzwarth's efforts to perfect the explosion-type turbine, in which the efficiency of compression is less important.

Reheating, intercooling, and regeneration. There are three basic ways in which the efficiency of the simple gas-turbine cycle can be increased. These are: (1) to increase the work output of the turbine; (2) to decrease work input to the compressor; (3) to decrease the amount of heat added by the fuel.

The first of the above objectives can be realized by dividing the expansion process into two or more steps. This division can be accomplished by employing a high-pressure and low-pressure turbine with a combustion chamber in between for reheating the air and combustion products. The effect is to increase the volume of the gas undergoing expansion, thus increasing the work of the turbine.

The second objective may be accomplished by compressing the air in a manner as near isothermal (constant temperature) as possible. The closest practical approach to this objective is to employ intercooling, a process in which the air is compressed in two or more steps and cooled back to inlet temperature between steps. The purpose of such a practice is to maintain the volume of air as low as possible in order to reduce the power required for compression.

To accomplish the third objective, it should be possible by means of a heat exchanger to warm the air on its way to the combustion chamber by transferring some of the heat from the turbine exhaust gases to the air. In practice this warming is accomplished by means of a regenerative heat exchanger in which the hot exhaust gases are passed in such a manner that the heat surrendered by these gases is absorbed by the compressed air before it enters the combustion chamber. This absorption reduces the amount of heat added by the fuel.

This particular type of cycle is advantageous insofar as thermal efficiency is concerned, but the disadvantages of added complexity and first cost often outweigh the advantages.

Design features. Although a detailed discussion of the many design features of gas turbines cannot be undertaken here, enough can be included to give the reader an idea of the arrangement of essential components. Figure 8 is a cross-section drawing of a 3,600-revolutions-per-minute, single-shaft gas turbine designed primarily for electric-power generation. It is rated at about 54,000 kilowatts for base-load service and 60,000 kilowatts for peak-load service when operating with air intake at sea level and 59° F (15° C). It incorporates a 19-stage axial-flow compressor in which air is compressed to several times atmospheric pressure before being discharged into a cavity at the compressor outlet. The air is next turned toward the left and flows through the annular (ring-shaped) space surrounding each of the ten combustion chambers before being fed through liner holes and louvers into the interior-combustion zones. The combustion products are discharged at about 1,600° F (900° C) into individual transition ducts that convey the gas to the three-stage, axial-flow turbine. From the turbine exhaust, the gas is directed through the annular diffuser and turn-

ing-vanes into the stack. During expansion of the gas through the turbine, sufficient work is performed to drive an electric generator (not shown) capable of generating about 60,000 kilowatts. More complicated arrangements are available, including those with provisions for the intercooling, reheating, and regeneration processes mentioned previously.

Applications. The gas turbine is a versatile prime mover and has many applications, notably in aircraft, electric-power generation, industrial, locomotive, marine, and automotive uses.

Aircraft. By far the most important present-day application is in aviation, in which the gas turbine provides the motive power for jet propulsion (see JET ENGINE).

Jet-propulsion engines are most efficient at high altitudes and high airspeeds and are particularly suited for high-performance military aircraft. Modern military jet-propulsion engines are capable of producing tremendous power. In emergencies this can be augmented still further with the aid of an afterburner, which adds heat to the gases just before they enter the exhaust nozzle. This afterburning increases their velocity and adds to the forward thrust of the engine.

Turboprop application

Another gas-turbine application for aircraft is the turboprop. In this application the gas turbine has two purposes: it drives a conventional propeller, and it produces additional thrust by means of the reactive force of the jet leaving the exhaust nozzle of the engine. The advantage of short takeoff inherent in propeller-driven aircraft is thus combined with the faster and higher flying capabilities of the conventional jet-propulsion engine.

Intermediate between the conventional jet-propulsion engine and the turboprop is a later development called the turbofan engine. It differs from the ordinary jet-propulsion engine in that a fan is located at the inlet that takes in a great deal more air than actually passes through the core of the engine. The fan compresses this air slightly and then delivers most of it through a bypass duct around the engine, where it is accelerated and released with a higher velocity than it had at intake, thus adding to the thrust of the engine. The remainder of the air flows through the core of the engine, where it is compressed, heated, and expanded through the turbine and exhaust nozzle as in a conventional jet.

The ratio of air bypassed through the duct surrounding the core of the engine to that passing through the core is called the bypass ratio. This varies widely according to application. Bypass ratios as high as 8 to 1 are common in large turbofan engines. In general, high bypass ratios and high compression ratios result in improved fuel economy.

The turbofan engine has a number of advantages. The added thrust of the engine eliminates the need for carrying heavy additional loads of water sometimes employed for injection to increase the thrust of conventional engines during takeoff on warm days. When operating within the proper speed and altitude range, fuel savings of the order of 20 percent can be realized. These advantages have made this type of engine the favourite for commercial use on very large jet aircraft.

Limitations of the gas turbine for electric-power generation

Electric-power generation. In the field of electric-power generation, the gas turbine must compete with the diesel engine and steam turbine. Gas turbines are limited in capacity by the fact that the pressure involved is low, making it necessary to employ large turbines and compressors in order to handle the huge volumes of air required. For this reason no serious attempt has been made to design a gas-turbine power plant capable of competing with the modern central-station, steam power plant in which single units as large as 1,200,000 kilowatts have been built.

Three applications deserve special mention: (1) operation in combination with steam power plants as a means of increasing the overall efficiency; (2) for standby and peak-load service; and (3) for portable power plants. A promising combined steam-turbine–gas-turbine power plant is one in which high-temperature exhaust gases from a conventional gas turbine are employed to supply oxygen to the furnace of a steam boiler in place of preheated combustion air. This combination is feasible because the gases exhausted from a gas turbine still contain about 80 percent of the oxygen in the air supplied to the compressor inlet. Such an arrangement is capable of increasing substantially the overall efficiency of the plant. It also offers savings in size and weight of the boilers required, less building volume, quicker starting of the boiler, and elimination of the forced and induced draft fans normally required by the boiler.

Other ways in which the gas turbine can be employed to improve the efficiency of a steam power plant are to use the exhaust gases for feedwater heating or for the generation of steam in an exhaust-heat boiler.

The gas turbine offers an attractive means for providing additional peak-load and standby power. It can often be installed for this purpose at lower cost than additional steam or hydroelectric capacity. Furthermore, it offers the advantages of virtually automatic operation, simplicity, small space requirements, and minimum maintenance. Another similar application is for end-of-the-line voltage-booster service on long-distance transmission lines. A third application is for portable power plants. Here the gas turbine can be mounted on railroad cars or barges for emergency use.

Houdry process

Industry. An early and still important application of the gas turbine in industry is in connection with the Houdry process of refining oil. In this application, air under pressure must periodically be passed over a catalyst for the purpose of burning off carbon accumulated during the refining process. The air employed thus becomes heated in the same manner as it would in a combustion chamber and can, therefore, be passed through a turbine

to perform useful work, including that of driving the compressor employed for supplying the air to the catalyst. The result is a gas turbine with the carbon burn-off operation substituted for a combustion chamber. A large number of these units have been manufactured in the United States and are rendering satisfactory service.

Another industrial application is for natural-gas pipeline compressor stations. For this purpose the gas turbine is ideally suited, because natural gas is an excellent fuel and is available at low cost, making fuel economy of secondary importance. By using a regenerator, satisfactory efficiencies can easily be obtained, and stations can be located anywhere along the line because no water supply is needed. Furthermore, fully automatic stations can be built that require practically no supervision and only a minimum of maintenance.

Locomotive. A field of application that received considerable attention in the 1950s was the railroad locomotive. Advantages of the gas turbine for this service are its smoothness of operation, simplicity, and lack of need for water. A number of oil-burning, gas-turbine locomotives built in the United States and Switzerland have provided satisfactory service. They have been unable to replace the diesel locomotive, however, because of lower thermal efficiency. Attempts were made to overcome this economic disadvantage by developing a coal-burning, gas-turbine locomotive, but the engineering difficulties were too great. Much work remains to be accomplished before a successful unit can be built.

Marine. In the field of ship propulsion, the gas turbine offers advantages of light weight and lower space requirements than a corresponding boiler and steam-turbine plant. In the early 1970s an all-gas, turbine-powered ship in the 20,000-horsepower class demonstrated its capability at sea with more than 5,000 engine hours of service. As a result, marine gas turbines were selected to power 30 new United States Navy destroyers, the Navy's first gas turbine-powered combat ships.

There is some indication that, with further development, a gas-turbine outboard motor may become competitive with conventional reciprocating motors. During the early 1960s, at least one model was successfully built and tested.

Automotive. There is much speculation as to the future of the gas turbine for automotive applications. Its principal advantages are its smooth, vibrationless operation, high power at low speeds, light weight, small space requirement, lack of need for a cooling system, and the possibility of burning a cheaper grade of fuel than gasoline. Its disadvantages are high cost of manufacture and materials, high fuel consumption, especially at part load, high noise level, and poor acceleration characteristics.

During the 1960s, work on small gas-turbine engines by automobile manufacturers offered hope that many of these disadvantages could be overcome. The development of new casting techniques made it possible to make satisfactory compressor and turbine wheels, thus eliminating the high cost of individually machining these components. Also, the improvement of rotary regenerators and the use of other schemes—such as adjustable turbine nozzles and two-shaft designs—greatly improved the fuel-consumption outlook for both full- and part-load operation. In addition, they have given the engines much better acceleration characteristics. Several test vehicles were built and operated on a variety of fuels and showed performance approaching that of conventional automobile engines.

The gas turbine also may provide an automotive power plant with cleaner exhaust, because it does not produce as much unburned hydrocarbons and carbon monoxide as reciprocating engines. The combustion process in the gas turbine also minimizes the formation of nitrogen oxides in the exhaust. These considerations became increasingly important with the imposition of higher standards of environmental quality.

Future trends. The many applications for which the gas turbine is especially well suited seem to assure an attractive future. In military and commercial aviation, its status as the leading contender among all types of power plants is unchallenged. In the industrial field, an increasing number of applications can be predicted in marine, locomotive, and even automotive transportation.

In the utility field, it is unlikely that the gas turbine will supersede the large central-station steam turbine, because the gas-turbine cycle requires that all air passing through the turbine must first be compressed. This requirement means that a large portion of the work output of the turbine must be employed to drive the compressor, leaving only a fraction for driving the electric generator.

Still another factor favouring the steam turbine is its ability to expand steam through pressure ratios as high as 10,000 to 1 or more, an ability that permits the use of very high initial pressures, resulting in relatively small turbine components. With the gas turbine, pressures are always low, making large components essential for high power output.

One method of partially overcoming this difficulty is to employ a pressurized cycle in which the unit is first charged with air or other gases and then operated under a pressure level of several atmospheres. Although this method has the advantage of reducing the size of the rotating machinery, it requires a cooling medium capable of lowering the temperature of the turbine exhaust gases back to compressor-inlet temperature before they can be reintroduced into the compressor. It is also necessary to add heat to the compressed gases in a separately fired furnace, or to continuously add sufficient new air and fuel to the cycle, under pressure, to maintain combustion.

A possible future application of the pressurized cycle is in conjunction with a steam cycle in nuclear power plants employing helium-cooled reactors. In such a system, a pressurized helium-gas turbine would be used with the reactor supplying heat in place of the combustion chamber used in conventional units. The helium exhausted from the turbine would first transfer some of its heat to a regenerator, after which it would be cooled back to the compressor-inlet temperature by transferring its remaining heat to the feedwater in the steam cycle. Heat in the gas-turbine portion of the cycle that is normally rejected to the atmosphere would be transferred to the feedwater, increasing the efficiency of the overall cycle.

Turenne, Henri de

The victories of France's marshal-general Henri de la Tour d'Auvergne, vicomte de Turenne in the last years of the Thirty Years' War and his role in suppressing the rebellion known as the Fronde on behalf of the crown have earned him a foremost place in French military annals of the 17th century.

He was born on September 11, 1611, at Sedan, a son of the Protestant Henri, duc de Bouillon, by his second wife, Elizabeth of Nassau, daughter of William the Silent, the stadtholder of the Netherlands.

Victories in the Thirty Years' War. When his father died in 1623, Turenne was sent to learn soldiering with his mother's brothers, Maurice and Frederick Henry, the princes of Orange who were leading the Dutch against the Spaniards in the Netherlands. Though he was given command of an infantry regiment in the French service for the campaign of 1630, he was back with Frederick Henry in 1632. In 1635, however, when Louis XIII's minister Cardinal de Richelieu brought France into open war against the Habsburgs (see THIRTY YEARS' WAR), Turenne, with the rank of *maréchal de camp*, or brigadier, went to serve under Cardinal de La Valette (Louis de Nogaret) on the Rhine. He was a hero of a retreat from Mainz to Metz and was wounded in the assault on Saverne in July 1636. After a mission to Liège to hire troops for the French, he was sent to the Rhine again in 1638 to reinforce Bernhard of Saxe-Weimar at the siege of Breisach; he conducted the assault and won the respect of Bernhard's German troops. Two campaigns fought in Italy, culminating in the capture of Turin on September 17, 1640, confirmed his reputation.

In 1642, when the French army was besieging Spanish-held Perpignan, Turenne was second in command. The conspiracy of the King's favourite, the Marquis de Cinq-Mars, against Richelieu was then brought to light, and the Duc de Bouillon was arrested. Turenne remained loyal to Louis XIII and to Richelieu; but Bouillon had to surrender Sedan in order to obtain his freedom. When Louis XIII died in 1643, the queen, Anne of Austria, became regent for her infant son Louis XIV. She gave Turenne a command in Italy in the same year, but his brother's conduct made him suspect to Richelieu's successor, Cardinal Mazarin; and as no fresh troops were sent to him, Turenne could do nothing. Anne made Turenne a marshal of France, however, on May 16, 1643.

Command of the French forces in Germany

On December 3, 1643, news reached Paris that France's Army of Germany had been scattered in the Black Forest, and its commander was dead. The command was given to Turenne, who made an effective army from this broken force—mainly Germans who had followed Bernhard of Saxe-Weimar. But he had barely 10,000 men and remained weaker than his Bavarian opponents, a fact that dictated his conduct from 1644 to 1648. The Rhineland was devastated, and Turenne could act only by marching far into Germany to seize control of new forage lands. Unless he could join forces with another army, therefore, he could do nothing.

In 1644 Turenne watched the Bavarians take Freiburg in Breisgau, appealed for help, and was joined by the small army of the duc d'Enghien, Louis II de Bourbon, prince de Condé. The latter was younger by ten years than Turenne but took command of both armies because a French prince was senior to a French marshal; even so, they were good colleagues. Three fierce actions near Freiburg induced the Bavarians to leave the Rhine Valley; and Enghien and Turenne took Philippsburg in September and gained control of the Rhine towns as far north as Bingen.

In 1645 Turenne, intending to effect a junction with France's Swedish allies in Germany, marched through Württemberg. But in May the Bavarians made a surprise attack, and half of Turenne's army was lost in the Battle of Marienthal (Mergentheim). Turenne fell back, and Mazarin sent Enghien to rescue him. Their united forces met the Bavarians in the Battle of Nördlingen and reached the Danube, but with such heavy loss in infantry that they soon had to return to the Rhine.

In 1646 Turenne achieved his plan of joining the much stronger Swedish army, though Mazarin feared the Protestant supremacy in Germany that might be the result. Turenne crossed the Rhine at Wesel and met the Swedes under Field Marshal Carl Gustav Wrangel. The two commanders evaded the Austro-Bavarians on the Main, marched straight for the Danube, and threatened Augsburg and Munich. The elector Maximilian I of Bavaria then began negotiations with the French, and, by the Treaty of Ulm (March 14, 1647), abandoned his alliance with the Holy Roman emperor Ferdinand III. But Turenne was thwarted and Ferdinand's Austrians were saved when Mazarin ordered the Army of Germany to operate in Luxembourg. Then, when the army reached the Vosges, the German cavalry mutinied and turned back across the Rhine. For three months Turenne marched with them far into Germany. In the end his powerful personality brought most of them back to the French service.

When Bavaria returned to the Emperor's side in 1648, Turenne rejoined Wrangel and they reached the Danube, the Lech, and—after the Battle of Zusmarshausen—the Inn River, the nearest point to Austria yet attained by the French. Maximilian fled from Bavaria, and the Emperor agreed to the Peace of Westphalia, ending the Thirty Years' War.

Participation in the Fronde. The same year marked the beginning of the so-called Fronde, an aristocratic rebellion against Mazarin. Turenne's family's interests and the friendship of Condé's sister, the Duchesse de Longueville, led him to intervene on the side of the rebellion in the first war of the Fronde, precipitated by the unpopularity of Mazarin's fiscal measures. The Cardinal at once sent a new general and arrears of pay to the Army of Germany, and Turenne fled to Holland just when the compromise peace was being negotiated at Rueil. He returned to Paris in May 1649.

When Mazarin arrested the overbearing Condé on January 18, 1650, Turenne again fled, joining the Duchesse de Longueville at Stenay on the eastern border of Champagne. They tied themselves by treaty to the Spaniards, then at war with France, and waged war in Champagne until Turenne was completely defeated in the Battle of Rethel (December 15, 1650) by superior forces under Marshal du Plessis-Praslin (César, later Duc de Choiseul) and narrowly escaped capture.

Mazarin's voluntary exile from Paris and Condé's release brought Turenne back to Paris in May 1651, with his credit at a low point. In August 1651 he married the firmly Protestant Charlotte de Caumont. He stood aloof from politics without committing himself to Condé's faction. It was his brother, the duc de Bouillon, who came to terms with the Queen-Regent in March 1652, with the result that Turenne was promptly put in command of one of the two divisions of the royal army, each 4,000 strong, which had been assembled on the Loire to oppose Condé and his allies. A few days later his courageous and clear-sighted action in blocking the bridge at Jargeau saved the young King from capture by the rebels; and in April, at Bléneau, he checked Condé and rescued his defeated colleague, Marshal d'Hocquincourt (Charles de Monchy). His campaign of 1652–53, first on the Loire, then before Paris, and in Champagne, was Turenne's greatest service to the monarchy: his resources were small, and but for his great skill he might have been overwhelmed; yet he staunchly kept the Queen-Regent's court from taking refuge far from Paris and thus enabled the young Louis XIV at last to re-enter his capital.

Suppression of the Fronde

Successes in the Franco-Spanish War. With the defeat of the rebellion, good troops from other parts of France could be brought to reinforce those in the northeast and to prosecute the struggle there against the Spaniards, with whom Condé was now serving. The turning point came in 1654, when Turenne and his colleagues stormed three lines of trenches and expelled the army that was besieging Arras. In 1658 Turenne surmounted the physical obstacles to investing Dunkirk and, when the Spaniards advanced, defeated them in the Battle of the Dunes (June 14), skillfully using the difficult ground into which his enemy had unwisely moved. His victory enabled him to hand Dunkirk over to France's English allies and allowed him to move freely in Flanders, taking Ypres and threatening Ghent and Brussels. The Franco-Spanish Peace of the Pyrenees followed in 1659. For the second time Turenne's operations had won an advantageous peace.

Last campaigns. On April 5, 1660, Turenne was appointed "marshal-general of the camps and armies of the King," an extraordinary honour that implied that he might have been constable of France if he abjured his Protestant faith. When he abjured in 1668, after his wife's death (1666), however, he was not made constable (ex officio commander in chief in war). The development of the Ministry of War by the Marquis de Louvois enabled Louis XIV to command in person, and in the War of Devolution (1667–68) and in the invasion of Holland (1672) Turenne marched at his side. Then, when the German allies of the Dutch menaced the lower Rhineland, Turenne was once more sent east of the Rhine, but with only 16,000 men, a secondary command.

Role in the Dutch wars

Yet these campaigns of 1672–75 brought him enduring fame. He resented the detailed control of military affairs by the arrogant Marquis de Louvois, but the minister's supplies enabled him to maintain active operations into the winter. He had long been a master of "strategic chess moves," but he was bolder now; he offered battle more often and looked for opportunities when his more powerful adversaries were weakened by detachments. By January 1673 he had broken the German coalition for a time and by invading the County of Mark had forced the elector Frederick William of Brandenburg to negotiate; he had also prevented the enemy from crossing the Rhine. Later in the year his wider manoeuvring against the emperor Leopold I's army had such success that he could have reached Bohemia; but Louvois refused him reinforcement for a decisive operation, and when Turenne was called back to cover Alsace, the Emperor's forces struck at Bonn and so broke the French control of the lower Rhine.

Greatly superior German forces moved toward the Rhine in 1674. Turenne defeated a detached corps at Sinzheim, near Heidelberg, on June 16, and ravaged the Palatinate. But by September he was again west of the Rhine, with little hope of barring the advance of the main enemy forces. At Enzheim, near Strassburg, he attacked them on October 4, but he drew back before a decisive point was reached; and as the Brandenburgers also joined the Emperor's forces, their 57,000 men seemed in secure possession of Alsace. Turenne replied in December with the most famous of his marches. He turned south on the French side of the Vosges, reappeared at Belfort, and, at Turckheim on January 5, 1675, delivered so heavy a blow on the flank of the main army that the Germans decided to recross the Rhine. Alsace was saved.

In June 1675 Turenne was on the right bank of the Rhine manoeuvring against the Italian field marshal in imperial service Raimondo Montecuccoli for the control of the crossing near Strassburg. The armies were in contact at Sasbach, and Turenne was examining a position when he was killed by a cannon shot on July 27, 1675. He was buried with the kings of France at Saint-Denis. Later the emperor Napoleon had his remains transferred to the Invalides in Paris.

Turgenev, Ivan

The first Russian writer of the 19th century to acquire an international reputation, Ivan Turgenev was a novelist, poet, and playwright whose works offer realistic, affectionate portrayals of the Russian peasantry and penetrating studies of the Russian intelligentsia who were attempting to move the country into a new age. The many years he lived in western Europe as virtually an unofficial cultural ambassador were due in part to his personal and artistic stand as a liberal between the reactionary tsarist rule and the spirit of revolutionary radicalism that held so great a sway in the contemporary artistic and intellectual circles in Russia. He poured into his writings not only a deep concern for the future of his native land but also an integrity of craft that has ensured his place in Russian literature.

Parental influences

Ivan Sergeyevich Turgenev was born on November 9 (October 28, old style), 1818, in Orel, central Russia. He was the second son of a retired cavalry officer, Sergey Turgenev, and a wealthy mother, Varvara Petrovna, *née* Lutovinova, who owned the extensive estate of Spasskoye-Lutovinovo. Turgenev's father, who died in 1834, was a lesser influence in his life than his mother. His memory was to fascinate the author in later years, however, finding its most powerful embodiment in the portrait of the father in Turgenev's famous short story *First Love* (1860). The dominant figure of his mother throughout his boyhood and early manhood probably provided the example, if not the model, for the dominance exercised by the heroines in his major fiction. Her despotic temperament ruled over her son's life and the estate of Spasskoye with equal arbitrariness. Spasskoye itself came to have a twofold meaning for the young Turgenev, as an island of gentry civilization in rural Russia and as a symbol of the injustice he saw inherent in the servile state of the peasantry. On the other hand, Spasskoye, as the source of an idyll, was to be the context not only of many of his later works, particularly his novels, but also of his view of civilization as something that, like the human spirit, was essentially isolated and forever menaced by an outer darkness. Against the social system Turgenev was to take an oath of perpetual animosity, which was to be the source of his liberalism and the inspiration for his vision of the intelligentsia as people dedicated to their country's social and political betterment.

First visit to Europe

Turgenev's earliest memory was of nearly falling into the bear pit in Bern, Switzerland, during his family's grand tour of Europe in 1822. He was rescued by his father, but he was not saved from Europe. Turgenev was to

be the only Russian writer with an avowedly European outlook and sympathies. Though he was given an education of sorts at home, in Moscow schools, at the universities of both Moscow and St. Petersburg, Turgenev tended to regard his education as having taken place chiefly during his plunge "into the German sea" when he spent the years 1838 to 1841 at the University of Berlin. Here he became friendly with leading figures of his own generation such as the anti-Marxist revolutionary Mikhail Bakunin. Through them his interest was aroused in the philosophy of G.W.F. Hegel, which underlay much revolutionary thought, and he was also inspired with the ideal of dedicating his life and talent to the future of Russia. He returned home as a confirmed believer in the superiority of the West and of the need for Russia to follow a course of Westernization.

Early works. Earlier, Turgenev had composed derivative verse and a poetic drama, *Steno* (1834), in the style of the English poet Lord Byron. The first of his works to attract attention was the long poem *Parasha,* published in 1843. The potential of the author was quickly appreciated by the critic Vissarion Belinsky, who soon became Turgenev's close friend and mentor. Belinsky's conviction that literature's primary aim was to reflect the truth of life and to adopt a critical attitude toward its observable injustices became an article of faith for Turgenev. He never believed, however, that social concerns should take precedence over art. Despite the influence of Belinsky, he remained a writer of remarkable detachment, of a cool and sometimes ironic objectivity that his enemies unfairly labelled disdain.

He was not a man of grand passions, although the love story was to provide the most common formula for his fiction, and a love for the renowned singer Pauline Viardot, whom he first met in 1843, was to dominate his entire life from that moment. His relation with Mme Viardot, like his love for Europe, usually has been considered platonic, yet some of his letters to her, often as brilliant in their observation and as felicitous in their manner as anything he wrote, suggest the existence of a greater intimacy. Generally, though, they reveal him as the fond and devoted admirer, in which role he was for the most part content. He never married, though in 1842 he had an illegitimate daughter by a peasant woman at Spasskoye; he later entrusted the upbringing of the child to Mme Viardot.

Love for Pauline Viardot

During the 1840s, Turgenev wrote more long poems, including *A Conversation* and *Andrey Kolosov, The Landowner,* and several pieces of criticism. Having failed in his attempt to obtain a professorship at St. Petersburg university and having abandoned work in the government service, he began to publish short works in prose. These were studies in the "intellectual-without-a-will" so typical of his generation. The most famous was "The Dairy of a Superfluous Man" (1850), which supplied the epithet "superfluous man" for so many similar weak-willed intellectual protagonists in Turgenev's work as well as in Russian literature generally.

Dramatic works

Simultaneously, he tried his hand at writing plays, some, like *A Poor Gentleman* (1848), rather obviously imitative of the older Russian master Nikolay Gogol (1809–52). Of these, *The Bachelor* (1849) was the only one staged at this time, the others falling afoul of the official censors. Others of a more intimately penetrating character, such as *One May Spin a Thread Too Finely* (1848), led to the detailed psychological studies in his dramatic masterpiece, *A Month in the Country* (1855). This was not staged professionally until 1872. Without precedent in the Russian theatre, it required for its appreciation by critics and audiences the prior success after 1898 of the plays of Anton Chekhov at the Moscow Art Theatre. It was there in 1909, under the great director Konstantin Stanislavsky, that it was revealed as one of the major works of the Russian theatre.

Sketches of rural life. Before going abroad in 1847, Turgenev left in the editorial offices of the literary journal *Sovremennik* ("The Contemporary") a short study, "Khor and Kalinych," of two peasants whom he had met on a hunting trip in the Orel region. It was published with the subtitle "From a hunter's sketches," and it had an instantaneous success. From it was to grow the cycle *Sportsman's Sketches,* first published in 1852, that brought him lasting fame. In all he wrote 25 such sketches. Many of them portrayed various types of landowners or episodes, drawn from his experience, of the life of the manorial, serf-owning Russian gentry. Of these, the most important are "Two Landowners," a study of two types of despotic serf-owners, and "Hamlet of Shchigrovsky Province," which contains one of the most profound and poignant analyses of the problem of the "superfluous man." Far more significant are the sketches that tell of Turgenev's encounters with peasants during his hunting trips. Amid evocative descriptions of the countryside, Turgenev's portraits suggest that, though the peasants may be "children of nature" who seek the freedom offered by the beauty of their surroundings, they are always circumscribed by the fact of serfdom.

He could never pretend to be much more than an understanding stranger toward the peasants about whom he wrote, yet through his compassionate, lucid observation, he created portraits of enormous vitality and wide impact. Not only did they make the predominantly upper class reading public aware of the human qualities of the peasantry but also they may have been influential in provoking the sentiment for reform that led eventually to the emancipation of the serfs in 1861. He added to the *Sketches* during the 1870s, including the moving study of the paralyzed Lukeriya in "A Living Relic" (1874).

When the first collected edition appeared, after appearing separately in various issues of the *Sovremennik,* Turgenev was arrested, detained for a month in St. Petersburg, then given 18 months of enforced residence at Spasskoye. The ostensible pretext for such official harrassment was an obituary of Gogol, which he had published against censorship regulations. But his criticism of serfdom in the *Sketches,* certainly muted in tone by any standards and explicit only in his references to the landowners' brutality toward their peasants, was sufficient to cause this temporary martyrdom for his art.

First novels. Although Turgenev wrote "Mumu," a remarkable exposure of the cruelties of serfdom, while detained in St. Petersburg, his work was evolving toward such extended character studies as *Yakov Pasynkov* (1855) and the subtle if pessimistic examinations of the contrariness of love found in "Faust" and "A Correspondence" (1856). Time and national events, moreover, were impinging upon him. With the defeat of Russia in the Crimean War (1854–56), Turgenev's own generation, "the men of the forties," began to belong to the past. The two novels that he published during the 1850s are permeated by a spirit of ironic nostalgia for the weaknesses and futilities so manifest in this generation of a decade earlier.

Themes in the novels

Turgenev's novels are "months in the country," which contain balanced contrasts such as those between youth and age, between the tragic ephemerality of love and the comic transcience of ideas, between Hamlet's concern with self and the ineptitudes of the quixotic pursuit of altruism. The last of these contrasts he amplified into a major essay, "Hamlet and Don Quixote" (1860). If he differed from his great contemporaries Fyodor Dostoyevsky and Leo Tolstoy in the scale of his work, he also differed from them in believing that literature should not provide answers to life's question marks. He constructed his novels according to a simple formula that had the sole purpose of illuminating the character and predicament of a single figure, whether hero or heroine. They are important chiefly as detailed and deft sociopsychological portraitures.

A major device of the novels is to examine the effect of a newcomer's arrival upon a small social circle. The circle, in its turn, subjects the newcomer to scrutiny through the relation that develops between the heroine, who always belongs to the "place" of the fiction, and the newcomer-hero. Promise of happiness is offered, but the ending of the relation is invariably calamitous.

The first of Turgenev's novels, *Rudin* (1856), tells of an eloquent intellectual, Dmitry Rudin, a character modelled partly on Bakunin, whose power of oratory and passionately held belief in the need for progress so affect the younger members of a provincial salon that the heroine,

Natalya, falls in love with him. When she challenges him to live up to his words he fails her. The evocation of the world of the Russian country house and of the summer atmosphere that form the backdrop to the tragicomedy of this relationship is evidence of Turgenev's power of perceiving and recording the constancies of the natural scene. The vaster implications about Russian society as a whole and about the role of the Russian intelligentsia are present as shading at the edges of the picture rather than as colours or details in the foreground. Such suggestibility, so basic to Turgenev's mastery of his art, was fully present in this first long work of prose.

Turgenev's second novel, *Home of the Gentry* (1859), is an elegiac study of unrequited love in which the hero, Lavretsky, is not so much weak as the victim of his unbalanced upbringing. The work is notable for the delicacy of the love story, though it is a shade mawkish on occasion. More important in terms of the author's thought is the elaborate biography of the hero. In it is the suggestion that the influence of the West has inhibited Turgenev's generation from taking action, forcing them to acknowledge finally that they must leave the future of Russia to those younger and more radical than themselves.

The objectivity of Turgenev as a chronicler of the Russian intelligentsia now begins to become apparent. Unsympathetic though he may have been to some of the trends in the thinking of the younger, radical generation that emerged after the Crimean War, he endeavoured to portray the positive aspirations of these young men and women with scrupulous candour. Their attitude to him, particularly that of such leading figures as the radical critics Nikolay Chernyshevsky and Nikolay Dobrolyubov, was generally cold when it was not actively hostile. His own rather self-indulgent nature was challenged by the forcefulness of these younger contemporaries. He moved away from an emphasis on the fallibility of his heroes, who had been attacked as a type by Chernyshevsky, using the short story "Asya" (1858) as his point of departure. Instead, Turgenev focussed on their youthful ardour and their sense of moral purpose. These attributes had obvious revolutionary implications that were not shared by Turgenev, whose liberalism could accept gradual change but opposed anything more radical, especially the idea of an insurgent peasantry.

The novel *On the Eve* (1860) deals with the problem facing the younger intelligentsia on the eve of the Crimean War and refers also to the changes awaiting Russia on the eve of the emancipation of the serfs in 1861. It is an episodic work, further weakened by the shallow portrayal of its Bulgarian hero. Although it has several successful minor characters and some powerful scenes, its treatment of personal relations, particularly of love, demonstrates Turgenev's profound pessimism toward such matters. Such pessimism became increasingly marked in Turgenev's view of life. It may have sprung in part from his unusual relation with Mme Viardot and her husband, but it was undoubtedly aggravated by his own lack of self-confidence. When, in 1859, Chernyshevsky travelled to London to see Aleksandr Herzen, the liberal leader and Turgenev's friend, the confrontation between the older and younger generations of the Russian intelligentsia became an open split. It seems that there could be no real reconciliation between the liberalism of Turgenev's generation and the revolutionary aspirations of the younger intelligentsia. Turgenev himself could hardly fail to feel a sense of personal involvement in this rupture.

Fathers and Sons

Turgenev's greatest novel, *Fathers and Sons* (1862), grew from this sense of involvement and yet succeeded in illustrating, with remarkable balance and profundity, the issues that divided the generations. The hero, Bazarov, is the most powerful of Turgenev's creations. A nihilist, denying all laws save those of the natural sciences, uncouth and forthright in his opinions, he is nonetheless susceptible to love and by that token doomed to unhappiness. In sociopolitical terms he represents the victory of the nongentry revolutionary intelligentsia over the gentry intelligentsia to which Turgenev belonged. In artistic terms he is a triumphant example of objective portraiture, and in the poignancy of his death he approaches tragic stature. The miracle of the novel as a whole is Turgenev's superb mastery of his theme, despite his personal hostility toward Bazarov's anti-aestheticism, and his success in endowing all the characters with a quality of spontaneous life. Yet at its first appearance the radical younger generation attacked it bitterly as a slander, and the conservatives condemned it as too lenient in its exposure of nihilism.

Self-exile and fame. Always touchy about his literary reputation, Turgenev reacted to the almost unanimously hostile reception by leaving Russia. He took up residence in Baden-Baden in southern Germany, to which resort Mme Viardot had retired. Quarrels with Tolstoy and Dostoyevsky and his general estrangement from the Russian literary scene made him an exile in a very real sense. Bitterness at the Russia that had seemed to reject him is discernible in the short pieces "Phantoms" (1864) and "Enough" (1865). His only novel of this period, *Smoke* (1867), set in Baden-Baden, is infused with a satirically embittered tone that makes caricatures of both the left and the right wings of the intelligentsia. The love story is deeply moving, but both this emotion and the political sentiments are made to seem ultimately no more lasting and real than the smoke of the title.

The Franco-Prussian War of 1870 to 1871 forced the Viardots to leave Baden-Baden, and Turgenev followed them, first to London and then to Paris. A similar reorientation occurred in Turgenev's views. The once ardent Germanophile became more sober and sadder. He now became an honoured ambassador of Russian culture in the Paris of the 1870s. The writers George Sand, Gustave Flaubert, the Goncourt brothers, the young Émile Zola, and Henry James were only a few of the many illustrious contemporaries with whom he corresponded and who sought his company. He was elected vice president of the Paris international literary congress in 1878, and in 1879 he was awarded an honorary degree by Oxford University. In Russia he was feted on his annual visits.

Last works

The literary work of this final period combined nostalgia for the past—eloquently displayed in such beautiful pieces as "A Lear of the Steppes" (1870), "Torrents of Spring" (1872), and "Punin and Baburin" (1874)—with stories of a quasi-fantastic character—"The Song of Triumphant Love" (1881) and "Klara Milich" (1883). Turgenev's final novel, *Virgin Soil* (1877), was designed to recoup his literary reputation in the eyes of the younger generation. Its aim was to portray the dedication and self-sacrifice of young populists who hoped to sow the seeds of revolution in the virgin soil of the Russian peasantry. Despite its realism and his efforts to give the work topicality, it is the least successful of his novels. His last major work, *Poems in Prose*, is remarkable chiefly for its wistfulness and for its famous eulogy to the Russian language. The first edition, in 1878, contained 50 poems; the entire collection of 83 was not published until 1930. He died at Bougival, near Paris, on September 3, (August 22, O.S.), 1883, and he was buried in St. Petersburg.

Evaluation. Turgenev's work is distinguished from that of his most famous contemporaries by its sophisticated lack of hyperbole, its balance, and its concern for artistic values. His greatest work was always topical, committed literature, having universal appeal in the elegance of the love story and the psychological acuity of the portraiture. He was similarly a letter writer of great charm, wit, and probity. His reputation may have become overshadowed by those of Dostoyevsky and Tolstoy, but his own qualities of lucidity and urbanity and, above all, his sense of the extreme preciousness of the beautiful in life endow his work with a magic that has lasting appeal. For Henry James he was reputedly "the only real beautiful genius." This estimate, for all its extravagance, has been largely endorsed by a century of readers.

STORIES OR SHORTER NOVELS: (*razskazy* or *povesti*)—Twenty-two stories, dealing mainly with aspects of rural life, most of them published separately in periodicals from 1847 onward, were collected under the title *Zapiski okhotnika* (1852); and later editions included three more such stories, originally published 1872–74 (*Russian Life in the Interior*, 1855; *A Sportsman's Sketches*, 1932; *A Sportsman's Notebook*, 1950). Collected under the title *Povesti i razskazy*, 3 vol. (1856), were the following "tales" or "stories," which date from 1844 onward (undated English titles are those of the Hapgood translation, 1903–04): "Andrey Kolosov" ("Andrei Kolosoff"); "Bretyor" ("The Bully"); "Tri portreta" ("Three Portraits"); "Zhid" ("The Jew"); "Petushkov" ("Pyetushkoff"); "Dnevnik lishnyago cheloveka" ("The Diary of a Superfluous Man," with "Mumu," 1884); "Tri vstrechi" ("Three Meetings"); "Mumu" ("The Dumb Door Porter," 1862; "Mumu," 1884); "Postoyaly dvor" ("The Inn"); "Dva priyatelya" ("The Two Friends"); "Zatishe" ("The Region of Dead Calm"); "Perepiska" ("A Correspondence"); "Yakov Pasynkov" ("Yákoff Pásynkoff"); "Faust." Later short novels and tales (with Hapgood titles as above unless otherwise indicated) include: *Asya* (1858; *Annouchka*, 1884); *Pervaya lyubov* (1860; *First Love*, 1884, 1950); "Prizraki" (1864; "Phantoms"); "Dovolno" (1865; "It Is Enough"); "Istoriya leytenanta Ergunova" (1868; "The Story of Lieutenant Ergúnoff"; *Neschastnaya* (1869; *An Unfortunate Woman*, 1886; *The Unfortunate One*, 1888); *Stepnoy korol Lir* (1870; *A Lear of the Steppe*, 1874); *Veshniye vody* (1872; *Spring Floods*, 1874, 1895); "Punin i Baburin" (1874; "Púnin and Babúrin," 1884); "Son" (1877; "The Dream"); "Pesn torzhestvuyushchey lyubvi" (1881; "The Song of Love Triumphant"); *Klara Milich* (1883).

MISCELLANEOUS WRITINGS OF SPECIAL INTEREST: Obituary article on "Gogol" in *Sovremennik* (1852); essay "Gamlet i Don Kikhot" (1860; *Hamlet and Don Quixote*, 1930); *Literaturnya i zhiteyskiya vospominaniya* (1880; *Literary Reminiscences and Autobiographical Fragments*, 1958); *Stikhotvoreniya v proze*, originally entitled *Senilia* (1878, enlarged edition 1930; *Poems in Prose*, 1883, 1945, 1951).

The earlier Russian collections of Turgenev's works (10 vol., 1880; 12 vol., 1898; 12 vol., 1928–34; 11 vol., 1949; and 12 vol., 1954–58) are superseded by the edition of his complete works and correspondence in 28 volumes (1960–68, supplemented by collections of additional materials). English collections include: *The Novels of Ivan Turgenev*, trans. by Constance Garnett, 15 vol. (1894–99 and 17 vol. 1919–23, with new ed. 1951 ff.); *The Novels and Stories of Iván Turgénieff*, trans. by Isabel F. Hapgood, with introduction by Henry James, 13 vol. (1903–04); *The Plays of Ivan S. Turgenev*, trans. by M.S. Mandell (1924).

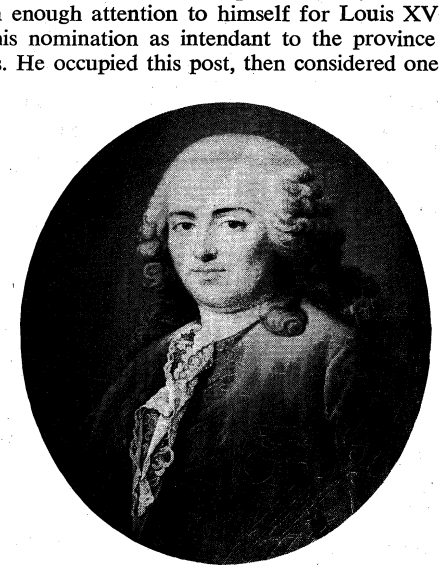
Turgot, Anne-Robert-Jacques



A high functionary during the reign of Louis XV and, briefly, minister of finance under Louis XVI, Turgot attempted those fiscal, administrative, and political reforms by which the French monarchy might have been preserved. As a result of conflicts with certain of the privileged classes he lost his position and his career was ended. His reforms were subsequently abandoned.

He was born in Paris on May 10, 1727, into an old Norman family whose members had already held some important administrative posts. (His father, Michel-Étienne [1690–1751], was to be *prévôt des marchands*, the head of the Paris municipality, from 1729 to 1740.) Destined for the church, he entered the Seminaire de Saint-Sulpice (1743) and the Sorbonne (1749), exhibiting both as a schoolboy and as an advanced student a precocious but sound maturity of intellect. He was influenced from his adolescence by all the fashionable ideas of his day: scientific curiosity, liberalism, tolerance, and an interest in social evolution. In 1751, on the threshold of ordination, he drew back, explaining to his relatives that it would have been impossible for him always to have lived under false pretenses, being, in fact, a deist. His rare attendance at mass was necessitated by his rank.

From that time on, Turgot's friends comprised such Philosophes as the Marquis de Condorcet and Pierre-Samuel du Pont de Nemours, who were both attached to the famous Physiocratic school of thought, which generally has been regarded as the first scientific school of economics. Late in 1751 he announced his intention of seeking a career in the royal administration and entered the law, becoming a *substitut du procureur général* (deputy solicitor general) in January 1752 and later a *conseiller* (counsellor magistrate) to the Parlement (supreme court of law) in Paris (December 1752).

The influence of the Physiocratic school

Early career. In 1753 he bought, as was the custom, the office of *maître des requêtes* (examiner of petitions), thus entering the branch of the magistracy that provided officials for the bureaucracy and that upheld the royal authority. With 39 other *maîtres des requêtes* he was called upon to serve in the Chambre Royale (Royal Chamber), which acted as a supreme court in 1753–54, when the Parlement was exiled for defying the crown. He combined his duties with other forms of intellectual activity. In 1753 he translated into French Josiah Tucker's *Reflections on the Expediency of a Law for the Naturalization of Foreign Protestants* (1752) and the following year published *Lettres sur la tolérance*. Between 1753 and 1756 Turgot accompanied J.-C.-M. Vincent de Gournay, the mentor of the Physiocratic school and an intendant of commerce, on his tours of inspection to various French provinces. By 1761 he had drawn enough attention to himself for Louis XV to accept his nomination as intendant to the province of Limoges. He occupied this post, then considered one of the

least desirable available, for 13 years and there displayed his extraordinary capacities as an administrator, reformer, and economist. In 1766 he published his best known work, *Réflexions sur la formation et la distribution des richesses,* to which he was to add—among other famous works—*Lettres sur la liberté du commerce des grains* (1770; "Letters on the Freedom of the Grain Trade"). He introduced new methods to the peasant region he administered, substituting a small tax in money for the *corvée* (unpaid work required of peasants for the upkeep of roads); compiling a land register (*cadastre*) for tax purposes; and combatting the famine of 1770–71, during which—despite opposition—he maintained the free commerce in grain. He was appointed comptroller general by Louis XVI on August 24, 1774.

Ministry. Turgot was all that a successful courtier should not be. Large and fat, with regular and quite distinguished features, he was nevertheless a shy and awkward bachelor who blushed easily, spoke with hesitation, and was rarely convivially gay. Though his customary serious manner was tinged with humour, he was not persuasive and could irritate a questioner with the brusqueness of his statements, his theoretical cast of thought, and the suppressed irony of his half smile.

Realizing that the young king was inexperienced and wishing to avoid political storms, Turgot temporized during the first days of his ministry, but later, feeling himself threatened by his adversaries, a frenzy for public service drove him to accumulate reforms. He introduced his Six Edicts in 1776. Four of them (suppressing certain dues and offices) were of no great importance, and the fifth (suppressing the guilds of Paris) encountered no serious opposition. It was against the sixth edict, that abolishing the *corvée*, that his enemies, who defended privilege, concentrated their attack. Appealing in vain to the good sense and courage of the young king from whom he had been alienated by a coalition of financiers, place-holders, privileged classes, and the religious party at court, he saw his reforms abandoned and, after his dismissal on May 12, 1776, forgotten. Five years later, on March 18, 1781, having published nothing since his public disgrace, he died in Paris attended by a few friends.

Turkey

Turkey (Türkiye) is a country of the Middle East lying partly in Asia and partly in Europe. Its location in two continents has been a central factor in its history, culture, and politics; Turkey has often been called a bridge between East and West. The country's area of 301,380 square miles (780,576 square kilometres) includes 9,158 square miles in European Turkey, known as Eastern Thrace (Turkish Trakya), and a larger area of 292,222 square miles in Asia, called Anatolia (Turkish Anadolu, derived from the Greek word *anatolē*, "sunrise"—*i.e.*, eastern land). İmroz (Imbros) and Bozca Ada (Tenedos) islands in the Aegean Sea also belong to Turkey.

Turkey is bounded on the east by Iran and the Soviet Union, on the south by Iraq and Syria, and on the west by Greece and Bulgaria. Turkey in Europe is separated from Anatolia by the Bosporus, the Sea of Marmara, and the Dardanelles Strait (anciently called the Hellespont), which form the only sea passage between the Black Sea and the Mediterranean. During the 17th century, when Turkish expansion was at its peak, the Ottoman Empire reached into central Europe to include what is now Romania, Hungary, and most of present-day Yugoslavia. It also included what is now Syria, Iraq, Israel, Egypt, and North Africa as far west as Algeria.

THE LANDSCAPE

The natural environment. *Relief.* Turkey forms part of the belt of young mountain ranges that run from the Balkan Peninsula to Iran. The mean altitude of the country is over 3,600 feet, and it increases eastward to above 6,560 feet. Lofty mountains are interspersed with depressions surrounded by steep slopes and high plateaus. Less than 9 percent of Turkey's area consists of level or gently sloping lands. Lowlands are mainly in the coastal areas. Turkey acquired its rugged relief in relatively recent geological times, and it is still a very active region of the Earth's crust, as is shown by frequent tremors in some areas and occasional destructive earthquakes.

The mountainous relief is dominated in the north and south by ranges of over 10,000 feet that encircle the Central Anatolian Plateau and separate it from the narrow coastal lowlands. North of the central plateau the Pontic Mountains follow the contour of the southern shore of the Black Sea, their altitude increasing eastward to the highest peak in Kaçkar Dağı (12,917 feet [3,937 metres]), where traces of Quaternary glaciation (occurring during the last 2,500,000 years) are extensive and where even today small glaciers are found. South of the central plateau are the Taurus Mountains, composed of several ranges that extend in broad arches along the Mediterranean coast and north of Syria. Their highest points are Mt. Aladag (12,250 feet [3,734 metres]), in the middle Taurus, and the intensely glaciated Cilo Dağı (13,675 feet [4,168 metres]), in the southeastern Taurus. The Taurus system is composed mainly of limestone and therefore is full of caves, potholes, and underground streams, all characteristic of limestone formations.

Central Anatolia is a semi-arid plateau with a core of older rocks overlain by horizontal or slightly tilted Tertiary deposits (from 65,000,000 to 2,500,000 years ago). It is divided into several basins, some of which were prehistoric lakes. Today the greater part of the region is an interior basin with a number of shallow salt lakes (*e.g.*, Tuz Gölü, covering 635 square miles with a depth of only one or two feet) and extensive eroded areas—as around Ürgüp, near the middle course of the Kızıl Irmak River, where there are cave dwellings, underground churches, and subterranean villages. The region is rich in young volcanic features, like the glacier-crowned Erciyes Dağı (12,848 feet [3,916 metres]), the highest point of central Anatolia; many volcanic cones, crater lakes, and explosion pits lie between Konya and Kayseri.

Central Anatolia

Eastern Anatolia is composed of lofty ranges and recent volcanic cones, such as Ağrı Dağı (Mt. Ararat, the highest peak in Turkey with an altitude of 16,945 feet [5,165 metres]—the legendary site where Noah's ark came to rest) and Süphan Dağı (14,547 feet [4,434 metres]). These rise above high plateaus often covered by extensive lava flows. The plateaus are interrupted by basins, one of which is occupied by Lake Van, a salt lake formed by the action of the now-extinct volcano of Nemrut Dağı, which last erupted in 1441.

Western Anatolia, known as the Aegean region, has elongated mountain ridges separated by depressed floors: a system of young, roughly parallel fault lines running east and west. It includes, from north to south, the valleys of Bakır Çayı (ancient Caicus); Gediz (Hermus); Küçükmenderes (Cayster), with the ruins of Ephesus; and Büyükmenderes Nehri (Maeander), where there are the remains of several ancient towns, including Miletus. These valleys form corridors leading from the Aegean up to the plateau.

The landforms of northwestern Turkey around the Sea of Marmara are simple. Thrace is a large basin bounded by mountains of moderate height on the north (Istranca Dağları) and south (Ganos Dağı) and by low plateaus 300 to 500 feet in altitude around the Bosporus on the east. The semi-arid central part of Thrace, filled by recent deposits, forms a rolling plain. The plateaus around Istanbul are deeply dissected by valleys. One of these, the

Bosporus, a former river valley drowned by the rising sea level after the last glaciers melted, is now the channel between the Sea of Marmara and the Black Sea. The Dardanelles, linking the Sea of Marmara at its other end to the Aegean, originated in the same way.

The rivers of Turkey

Drainage and soils. The water divide between the drainage basins of the Atlantic and Indian oceans runs obliquely through eastern Anatolia. The land east of the divide drains to the Caspian through the Kuruçay and Aras rivers and to the Persian Gulf through the Euphrates and Tigris rivers. The country west and north of the main divide drains to the Black Sea through the Kızıl Irmak (Halys) and Sakarya rivers. The Yeşil Irmak (Iris) also empties into the Black Sea. The western regions of the country drain to the Sea of Marmara through the Susurluk (Macestus) river and to the Aegean through the Gediz (Hermus) and the Büyükmenderes (Maeander) rivers. The principal rivers of the Mediterranean basin are the Göksu (Calycadnus), Seyhan (Sarus), Ceyhan (Pyramus), and the lower course of the Orontes (Asi). Approximately one-seventh of Turkey has no exterior drainage. Turkish rivers have generally irregular and shallow beds, and their seasonal changes in depth make them unsuitable for navigation.

The principal lakes of the country are Lake Van, 1,443 square miles, over 330 feet deep, and highly saline, in eastern Anatolia; Tuz Gölü (Salt Lake), 635 square miles and only one or two feet deep, in central Anatolia; and the freshwater lakes Beyşehir, Eğridir, and Burdur, northeast of the Gulf of Antalya.

Turkey has a variety of soil types, reflecting great differences in climate, geology, and vegetation. An outer belt of red and reddish-brown podzolic soils extends over the humid northern and southern marginal regions. The extremely humid eastern Black Sea coasts have strongly acid red soils, whereas the drier northwestern part of the country is covered by slightly acid brown and yellowish-brown podzolic soils. In the Mediterranean area, red and podzolic soil alternates frequently with patches of red clayey soil and in the northwest with rich limy soil. Most of the interior is covered by alkaline, brown and reddish-brown steppe soils. In the driest core of central Anatolia even patches of desertic gray soils occur, and saline soils cover considerable areas. The transitional regions between the dry interior and the humid margins are generally occupied by a belt of brown forest soils. Turkey faces a serious problem in soil erosion, resulting from extensive deforestation that began in the Hellenistic and Roman periods and continued in later times.

Climate. The climate is varied, depending largely on geographic factors. The coastal areas are generally humid, while the interior is semi-arid because it is cut off from the rain-bearing winds by mountain ranges. The northern slopes of the Black Sea mountains receive heavy rain even during summer. Annual rainfall in the coastal areas is more than 27 inches and as much as 96 inches in the eastern Black Sea region. In most of central Anatolia average annual precipitation varies between 10 and 14 inches. Areas of moderate rainfall (15 to 24 inches) include the Marmara and Aegean regions and southeastern and eastern Anatolia.

The low coastal areas have relatively high annual temperatures and warm winters. Along the Mediterranean coast frosts are rare, and snowfall is almost unknown. In the interior, on the other hand, winter temperatures are often below freezing, and in the northeastern plateaus the winters are very cold. Snow cover lasts 20 to 40 days in central Anatolia and more than 120 days in the northeast. The regional differences are much less marked in summer. Four climatic regions can be distinguished. The south and west coasts have a Mediterranean climate with hot, dry summers and mild, rainy winters; the mean annual temperature is about 68° F (20° C) and ranges from 53° F (11° C) in the coldest month to 84° F (29° C) in the warmest month. The Black Sea coast enjoys warm summers, mild winters, and a fair amount of rainfall throughout the year; the mean annual temperature is about 58° F (14° C), ranging from 44° F (7° C) in the coldest month to 73° F (23° C) in the warmest month.

Four climatic regions

The high northeastern plateaus have fairly warm summers but very severe winters, with maximum precipitation in the summer; the mean annual temperature is about 39° F (4° C), ranging from 10° F (−12° C) in the coldest month to 64° F (18° C) in the hottest. The semi-arid interior and southeast have cold, moist winters and hot, dry summers; the mean annual temperature is about 53° F (12° C), ranging from 32° F (0° C) in the coldest month to 74° F (23° C) in the warmest.

Plant and animal life. Large areas in the south, west, and northwest are covered by a Mediterranean vegetation, consisting mainly of thick, scrubby underbrush in the lowlands and deciduous or coniferous forests at higher altitudes up to the timberline (6,000 or 7,000 feet). The humid northern margins of the country are the most densely wooded region of Turkey. On the eastern Black Sea there are subtropical forests. The Anatolian interior is a region of steppes. Forests, mostly oak and coniferous trees, occur only on the elevated parts.

Turkey is fairly rich in wild animals and game birds. The wolf, fox, boar, wildcat, beaver, marten, jackal, hyena, bear, deer, gazelle, and mountain goat are among the animals still found in secluded and wooded regions. Domestic animals include the buffalo, Angora goat (on the Central Plateau), and camel. Major game birds are partridge, wild goose, quail, and bustard.

Geographic regions. *The Black Sea Coast.* Extending along the northern margins of the country from the Soviet frontier in the east to the lower course of the Sakarya River in the west is a mountainous area with abundant precipitation at all seasons. It is densely wooded, comprising more than one-fourth of Turkey's forested areas. It also has the highest rural population density, in some local areas exceeding 500 inhabitants per square mile. The region is mainly agricultural, corn (maize) being the dominant field crop and staple food. Tea is grown in the most eastern coastal strip, hazelnuts around Giresun and Ordu, and tobacco in Samsun and Trabzon. West of Sinop and south of the mountains, the transition toward the Marmara region and the Anatolian interior is marked by increasing acreage in wheat and fallow land. The principal mineral resources of the region are copper in the east (at Murgul) and coal in the west (the Ereğli-Zonguldak Basin). Samsun, Zonguldak, and Trabzon (site of a university) are the leading towns and ports.

The Marmara region. The areas adjacent to the Sea of Marmara, including Thrace, are the most heavily urbanized of the country. The principal cities are, in decreasing order of size, Istanbul (formerly Constantinople), Bursa, İzmit, Adapazarı, and Edirne. Istanbul, situated at the Bosporus, is Turkey's leading industrial, commercial, and cultural centre. The Marmara region is economically the most developed area of Turkey. Its agriculture is variegated, including tobacco, wheat, rice, sunflower, corn, olives, grapes, and natural silk. On the straits and coasts of the Sea of Marmara fishing is well developed. The leading manufacturing districts are around Istanbul and in a narrow coastal strip between Istanbul and İzmit.

The Aegean region. The coastal area from the Dardanelles on the north to the vicinity of Rhodes on the south is densely populated and economically one of the most advanced regions of the country. Its wealth rests on the production of several export crops, including tobacco (more than 50 percent of Turkey's total production), cotton (30 percent of the total), high-quality grapes suitable for drying, olives (more than 50 percent of the Turkish output), and figs. The main cities are İzmir (the leading export outlet of Turkey and site of a university), Manisa, and Aydın. The area draws many tourists with its beaches and historical sites (Pergamum, Ephesus, Miletus). Between the Aegean region and central Anatolia there is a high, thinly populated area specializing in grain and livestock production; in the 1960s it also produced much of the Western world's supply of opium.

Mediterranean region. Turkey's Mediterranean region extends from Rhodes to the Syrian frontier, and is occupied largely by the Taurus Mountains. Principal passes in the Taurus Mountains connecting the interior plateaus with the narrow coastal strip are the Külek Boğazı, lead-

ing to Tarsus and Adana; the Sertavul Pass, between Karaman and Silifke; and the Çubukboğazı pass, between the lake district and Antalya in the west. The Amanus Dağları (mountains) bordering the Gulf of Iskenderun are crossed by the Belen Pass. The region has several subregions: the sparsely populated limestone plateaus of Taşeli in the middle; the lake district in the west with its continental climate, where grain is grown; and the intensively cultivated, densely populated coastal plains. Principal cities of the region include Adana, an important commercial and industrial centre; Mersin; İskenderun (Alexandretta); Antalya; and Gaziantep. The coastal areas produce crops such as cotton (60 percent of Turkey's output), sesame, citrus fruits (more than 90 percent of the country's production), early vegetables, and bananas. The higher parts of the region have relatively little arable land and much soil erosion; grain and livestock are produced, and there is pastoral nomadism among the Yürüks.

Central Anatolia. The middle of the Anatolian plain has a continental steppe climate and scanty rainfall. Grain occupies over 90 percent of the arable land (40 percent of the country's wheat production). More than one-third of Turkey's sheep and nearly all of its Angora goats are raised there. The chief commercial and industrial centres are Ankara (capital of Turkey), Eskişehir, Konya, Kayseri, and Sivas.

Eastern Anatolia. The eastern part of the interior is a high and extremely rugged region with coniferous forests and mountain pastures in the northeast and wooded steppes in the south. Eastern Anatolia is the most thinly populated region of the country, with population densities as low as 13 people per square mile in some areas. Farming is difficult because of the long, severe winters, steep slopes, and eroded soil. Grain, chiefly summer wheat and barley, is the dominant crop. In the humid northeast, beef and dairy cattle are raised; in the south there are pastoral nomads who raise sheep and goats. Eastern Anatolia is rich in mineral resources (iron ore at Divriği, copper at Ergani, chrome at Guleman). The principal cities are Erzurum, Malatya, Elâziğ, and Van.

Southeastern Anatolia. At the foot of the Taurus mountains is a barren plateau drained by the Tigris and Euphrates rivers. Agriculture is confined mainly to irrigated valleys and basins (wheat, rice, vegetables, grapes). Much of the population is nomadic or seminomadic. Turkey's only oil fields are at Raman and Garzan, linked by pipeline to the port of İskenderun. The principal urban centres are Gaziantep, Urfa, and Diyarbakır.

Cultural landscape. *Rural settlements.* Turkey is essentially an agricultural country, and more than 60 percent of its population live in rural areas. There are around 35,000 rural settlements. In physical form these differ from region to region: wooden houses are typical in the Black Sea area; sun-dried bricks and flat roofs prevail in the semi-arid interior, and stone is the dominant building material in the Taurus Mountains, the Aegean region, and parts of eastern Anatolia.

Types of rural settlements

Rural settlement types range from single-residence units and several types of temporarily occupied settlements to agglomerated villages. The types correspond to different natural and economic conditions and to different stages in the evolution of land occupancy. Single rural settlement units and dispersed settlements occur in the eastern and western Black Sea regions, in eastern Anatolia, and in the Taurus Mountains. In eastern Anatolia they are associated with stock raising, while in the eastern Black Sea region they are small farmsteads, based on a subsistence agriculture. In the karst (limestone sink) regions of the Taurus area, the scattered distribution of soil in small depressions accounts for the occurrence of dispersed settlements and single-residence units. In the Mediterranean coastal strip, single rural settlement units usually consist of a two-story dwelling surrounded by a large field in which cash crops such as bananas, citrus fruits, and early vegetables are cultivated; the lower story of the house is used for storage.

Between the single rural settlement units and the more prevalent agglomerated villages, there are many transitional types. A *mahalle* consists of a group of single rural settlement units. *Divans*, occurring mainly in northern Anatolia, comprise a number of *mahalles* organized into a single administrative unit. *Mezraas* are settlements founded on agricultural lands that were originally inhabited only temporarily during plowing and harvesting but later became permanently settled villages or towns. Among temporary settlements, *koms* are usually smaller than *mezraas*. *Yaylas* are temporary summer rural settlements, associated with nomadism. Every nomadic group in southeastern Anatolia or in the Taurus Mountains has its own *yayla*, used solely for pasture. The practice of migrating between summer-dry lowlands and humid mountain pastures has resulted in most permanently inhabited villages in many regions of Turkey possessing one or more *yaylas*. *Kişlas* (literally, "winter quarters") are the sheltered winter quarters of nomads or former nomads. A considerable number of *yaylas* and *kişlas* have in time been transformed into permanent settlements.

The growing towns

Urban settlements. Approximately 40 percent of Turkey's population is located in municipalities of more than 10,000 inhabitants. The percentage of urban population is relatively high in the northwestern and western parts of the country, in northwestern central Anatolia, and around the Gulf of İskenderun. Most towns have fewer than 25,000 inhabitants. Only 20 had more than 100,000 inhabitants in 1970.

*Capital city.

More than half of the towns with more than 25,000 inhabitants are concentrated around the Sea of Marmara, in the western coastal region, and in the Adana subregion. Most are so old that they may be traced back to pre-Roman or Roman times. The great majority are commercial centres benefiting from a favourable location. Others are administrative, manufacturing, mining, or port centres, or a combination of these.

Istanbul, Ankara, and İzmir all had more than 500,000 inhabitants in the early 1970s, and the biggest city, Istanbul, had a population exceeding 2,200,000. The last was a conurbation extending 30 miles from the former village of Küçükçekmece on the west to Pendik on the east and 12 miles north along the Bosporus. Surrounding it is an industrial area that produces nearly one-third of the country's manufacturing output. Ankara, the capital of Turkey, was a flourishing trading centre and military base under Roman rule. Since World War I the city had grown very rapidly, and in 1970 it had more than 1,200,000 inhabitants. İzmir, a busy commercial city, had more than 520,000 inhabitants.

PEOPLE AND POPULATION

Languages, races, and religions. *Linguistic groups.* Turkish is the mother tongue of over 90 percent of the country's population. Modern Turkish, one of the southwestern groups of the Turkic family of languages, has been derived from Ottoman Turkish through a long nationalistic effort to purify it of the Arabic and Persian words and idioms that invaded the literary language during the Ottoman Empire. Turkish is written in Latin script.

The principal linguistic minority groups are Kurds and Arabs. Kurdish (including the Zaza dialect), the mother tongue of about 7 percent of the country's population, is widely spoken by a predominantly rural popula-

tion in the eastern and southeastern regions. Arabic is spoken by 1.2 percent of the population, principally in parts of southeastern Anatolia. Greek, Armenian, and Yiddish are spoken by small groups in the larger cities, mainly in Istanbul. Most Turkish Jews are descendants of Jews expelled from Spain and speak a kind of Spanish mingled with some Turkish words; others speak Yiddish.

Ethnic groups. Turkey has been a melting pot of racially and culturally distinct groups since early prehistoric times. It was penetrated, settled, or ruled by Hittites, Phrygians, and Gauls from the north and northwest; by Greeks and Macedonians from the west; and by Parthians and Mongols from the east. The most decisive influence was the incursion of Turks from the east, who introduced a new element of mixed Mediterranean-Mongoloid origin into the country's ethnic composition. The rise and decline of the Ottoman Empire contributed to the racial mixture, particularly during the empire's decline, when many Muslim groups living in former Turkish territories in southeastern Europe and in countries around the Black Sea migrated to the home country. It is at present almost impossible to define an average Turk ethnically. He may be blond and blue-eyed or even red haired; he may be of roundheaded alpine stock with dark hair and eyes; he may be of longheaded Mediterranean stock; or he may be Mongoloid with high cheekbones. The dominant stock seems to be Mediterranean-Turkic, giving way to Mediterranean in western and southern coastal areas and mixed with Alpine stock in the interior and the east.

Population density of Turkey.

Religious groups. Over 99 percent of the country's

population are Muslims. The Sunnī rite is predominant, followed closely by the Shīʿite. Christians are few: in 1965 there were about 74,000 Orthodox Christians (mostly Greeks), 70,000 Gregorians (mostly Armenians), and 26,000 Roman Catholics. There were 18,000 Jews. The Christian and Jewish minorities live mainly in Istanbul, Ankara, and İzmir. In the *il* of Mardin in southeastern Anatolia a community of 22,000 Nestorians has survived. Religion and the state were strictly separated in Turkey after the foundation of the republic in 1923.

Demographic trends. Turkey has had one of the highest rates of population increase in the world. Total population, only 13,648,000 in 1927, almost tripled in the following 43 years to exceed 35,000,000 in 1970. Between 1950 and 1970 the annual average rate of population growth was approximately 27 per 1,000.

Population growth

The rapid increase in Turkey's population is largely the consequence of a high birth rate, estimated at about 40 per 1,000 in recent decades. The average death rate, on the other hand, was believed to be around 15 per 1,000 in the same period and as low as 11 per 1,000 for the urban population. No detailed statistical data have been published for rural birth and death rates and their geographical distribution. It is known, however, that in rural regions of Turkey both the birth and death rates are considerably higher than in urban areas. The highest birth rates occur in underdeveloped eastern and southeastern Anatolia, where the average time interval between two successive births in the same family is only 22.7 months. The metropolitan areas of Istanbul, Ankara, and İzmir have the lowest birth rates in the country and the largest average time interval (33.2 months) between successive births in the same family.

As in other countries with high rates of natural increase, Turkey's population is young. About 66 percent of the population were under 30 years of age in 1970, and only 7.2 percent were 60 and over. Males outnumbered females by 455,000, but females predominated in rural areas because of migration of males to the cities.

In the 1960s and 1970s large numbers of Turks emigrated to western Europe as workers. In 1970, 300,000 were living in West Germany, and 100,000 in Switzerland, Belgium, and The Netherlands. Emigration is regulated by mutual agreement among the countries concerned.

Although the population density rose from 45 per square mile in 1927 to 118 in 1970, Turkey was not heavily populated in comparison with other countries. There were striking differences between the sparsely populated areas of Anatolia and the dense agglomerations in the northern and western parts of the country, in which over 40 percent of the population lived. The most densely inhabited area was the eastern Black Sea coastal strip, averaging over 260 people per square mile. Relatively high population densities also occurred around the Sea of Marmara, in the agriculturally developed plains of the Aegean region and around the Gulf of İskenderun.

Migration from rural areas to the cities was another important demographic trend of the second half of the 20th century, associated with the increasing industrialization of the country. The general pattern of migration was from the rural eastern *iller* (provinces) of the country toward the cities, including Istanbul, Zonguldak in the coal and metallurgical district in the northwest, Ankara in the interior, Adana and Mersin in the south, and İzmir in the west. Urban population grew from 24 percent of the total in 1927 to 38.7 percent in 1970. (S.Er.)

THE NATIONAL ECONOMY

Although mostly in Asia, the country's economy is oriented to Europe and the Western world. This orientation has provided the impetus for rapid industrialization since 1950. At the same time, Turkey has close economic links with Iran and Pakistan within the framework of Regional Cooperation for Development (RCD), with other countries in the Middle East, and with eastern Europe.

Gross national product (GNP) rose by an average of about 6.5 percent per annum in real terms in the 1960s. Because the population continued to increase by 2.5 percent per annum, the net improvement in GNP per capita was just under 4 percent per annum. Turkey's exports, which increased in value by 139 percent (to 6,909,000,000 lire) between 1960 and 1970, are represented chiefly by agricultural produce, mainly cotton, fruit, nuts, and tobacco. Imports increased in the same period by 117 percent (to 9,161,000,000 lire), and the cost of importing development capital brought about a chronic payments deficit. The lire was devalued by two-thirds in August 1970.

Unexploited mineral wealth

National resources. *Mineral resources.* Turkey is believed to be rich in a wide variety of mineral deposits, but relatively few of these have been exploited on a large scale because of a lack of domestic capital for exploration and exploitation, political pressures that have discouraged wide-scale investment from abroad, a preponderance of large but inefficient state mining concerns, and inadequate processing facilities.

State enterprises dominate the production of hard coal, lignite, copper, sulfur, mercury, iron ore, lead, salt, and chrome; while private producers are the principal exploiters of asbestos, antimony, barites, boron minerals, zinc, meerschaum, manganese, emery, magnesite, marble, sodium sulfate, dolomite, and other minerals. Bauxite deposits were being tapped on a big scale in the early 1970s by an aluminum-manufacturing centre near Konya. Crude oil production began on a regular basis in 1961.

Turkey's hard coal is of poor quality, and only negligible quantities are exported. The marketable annual output late in the 1960s was 4,700,000 tons. Lignite was becoming an increasingly important fuel, its annual output increasing from 4,000,000 tons early in the 1960s to 9,000,000 tons in the early 1970s. Iron-ore production, formerly exported, was barely keeping pace with the rising home demand in the early 1970s; annual production in the early 1970s was 3,000,000 tons. Chrome ore reserves are widespread; annual output approached 750,000 tons in the early 1970s. The output of blister copper averaged around 24,000 tons per annum but was expected to rise to over 60,000 tons per annum with the completion of a new plant on the Black Sea coast. Crude oil output quintupled after 1962, reaching 3,600,000 tons annually early in the 1970s. Exploration for oil was continuing over a wide area in the 1970s.

Biological resources. Turkey has a wide diversity of climate and ecology. The total area used for field crops increased by nearly 60 percent in the 1950s, reaching what appears to be its maximum feasible extent. Further increases will require greater use of fertilizers and irrigation and more efforts to combat soil erosion.

Vineyards, gardens, and orchards cover 9,000 square miles. A gradual extension of this area in the 1970s, especially in the Çukurova and Aegean regions, was probable in the light of the government's plans to develop fruit and vegetable production. About one-fourth of Turkey is covered with forests, which are predominantly coniferous but also include deciduous beech, poplar, oak, and walnut. Virtually all forest land is state owned, but only a fraction has been made productive, and much is completely virgin; untold damage has been done by the large peasant population in the forest areas. In the 1970s serious steps were being taken to implement a long-term forestry development plan; lumber and timber production were expected to reach 240,000,000 cubic feet in 1972, compared with 95,000,000 in 1962.

Hydroelectric power. Turkey has many rivers and mountain watercourses, but much remains to be done in harnessing these resources. Hydroelectric power rose from only 3.8 percent of the electricity output of 790,000,000 kilowatt-hours in 1950 to 27 percent of the 9,624,000,000 kilowatt-hours produced in 1971. The percentage was to rise sharply in 1973 with the coming into production of the 620-megawatt Keban (Euphrates) and the 300-megawatt Gökçekaya power stations (a megawatt equalling 1,000,000 watts). At least two more Euphrates hydroelectric schemes were planned for the 1970s. Although, like Keban, these were to be linked into the national grid, they would help to open up the sparsely populated eastern regions of the country.

Sources of national income. *Agriculture, forestry, and fishing.* The livelihood of 70 percent of the population and

31 percent of the national income came from agriculture, forestry, and fishing in the late 1960s. The 1963 census of agriculture showed that of 3,500,000 agricultural holdings only 491 were of more than 1,200 acres, while 1,600,000 were of seven acres or less and a further 1,100,000 of between 7.7 and 25 acres. The situation in the early 1970s was basically the same, although the government intended to introduce legislation to prevent or at least to inhibit the further fractionalization of land used for farming.

Major crops

Cereals—predominantly wheat and barley—are the largest crop, covering 32,000,000 acres in 1970; industrial crops—principally cotton, tobacco, sugar beets, and oilseeds—were sown over 4,200,000 acres. Other major agricultural products included pulses, potatoes, grapes, citrus and soft fruits, olives, hazelnuts, and tea. In the 1970s the government was attempting to guarantee minimum prices for the main crops without inducing the large surpluses of low-grade tobacco and tea and sugar beet that accumulated during the 1960s. It was also encouraging farmers to adopt improved methods by subsidizing credit, fertilizers, and improved seeds.

Livestock holdings totalled 84,000,000 head early in the 1970s, including 14,000,000 cattle, 36,000,000 sheep, and 6,000,000 Angora goats. The fishing industry contributes only 0.3 percent of the national income. Better organization, modern equipment, and an appreciation of the potential of deep-sea fishing are all urgently needed.

Forestry development was given a high priority in the early 1970s, at which time it provided less than 0.5 percent of the national income.

Very substantial sums of foreign aid capital have been invested in coal, lignite, copper, and bauxite mining and processing, along with government funds. State and foreign investment in the oil industry has been high. Mining and quarrying nevertheless accounted for only about 1.7 percent of the national income in the late 1960s.

Manufacturing. The manufacturing industries provided approximately 18.5 percent of the national income annually late in the 1960s, compared with 13 percent early in the decade. Manufacturing attracted about 20 percent of all investment in the late 1960s. The textile industry was the most important and had been considerably modernized in preceding years. Motor-vehicle production (assembly and parts manufacturing) had grown in importance, along with chemicals, petroleum products, rubber and plastics, and iron and steel products. Other dynamic manufacturing industries included processed foodstuffs, paper, nonferrous metals, domestic appliances, beverages, and cement and building materials. State-run firms accounted for about one-third of the overall output of manufacturing. The state had a monopoly only in cigarettes, tea, spirits, and newsprint; in other fields it competed with private industry.

Turkey's balance-of-payments problems in the early 1950s caused the government to favour industries that would reduce the need for imports. After 1968, however, when the State Planning Organization was made responsible for approving many investment projects, greater attention was paid to the earning rather than the saving of currency. Industrial growth in the 1970s was expected to be dictated largely by the needs of export markets.

Output in manufacturing was still generally well below capacity; and the labour force, especially in the state sector, was above the optimum level for economic production. By international standards, therefore, productivity was rather low.

Energy consumption

Between 1962 and 1967 Turkey's energy consumption increased by almost 50 percent, to the equivalent of 30,600,000 tons of coal. Consumption in 1972 was expected to be 42,600,000 tons, double the 1962 total. But consumption per capita remained extremely low. In the mid-1960s about 29 percent of the energy consumed was provided by petroleum products (approximately half of which were imported), 22 percent by wood, 18 percent by dried dung, 28 percent by hard coal and lignite, and only 3 percent by hydroelectric power.

Financial services. The Central Bank of the Republic of Turkey, set up in 1931, effectively controls the banking system. It is the only note-issuing bank, is the sole channel for the issue of import licenses (on behalf of the Ministry of Commerce), provides access to foreign currency, and plays a key role in the administration of the government's credit policies. There are 33 commercial banks, a state-run Agriculture Bank, and a number of special-purpose, state-owned institutions, such as the Sümerbank (concerned with industrial enterprises), the Etibank (mining and electric power), and the Turkish Maritime Bank (Denizçilik Bankası).

The main source of new finance for the numerous state enterprises is the State Investments Bank. The private sector was depending increasingly in the 1970s for its development funds upon the Industrial Development Bank of Turkey (established with World Bank assistance in 1950) and to a lesser extent upon the Industrial Investment and Credit Bank. Turkey in the 1970s did not yet have an organized capital market. The true public company that raises capital by selling its securities to the public was still practically unknown, and the vast majority of the many joint-stock companies were family-owned or family-controlled enterprises. The stock exchange at Istanbul dealt mainly in government securities.

Foreign trade. Between 1960 and 1970 export earnings increased by 139 percent to 6,909,000,000 lire, or at a slightly lower average annual rate of growth than that of the economy as a whole. During this period cotton displaced tobacco as the largest single currency earner. By 1971 agricultural products still accounted for 73 percent, minerals for 6 percent, and industrial and processed goods for only 21 percent of total earnings. The limitations of world demand for such traditional exports as cotton, tobacco, dried fruit, and nuts made imperative the development of exports of manufactures and other items, such as fresh fruit and vegetables.

The countries of the European Economic Community (EEC), or Common Market, accounted for more than 40 percent of all exports. The countries of the European Free Trade Association (EFTA) took 18 percent of all exports in 1970. The U.S., Japan, and Canada took 18 percent. Exports to eastern Europe, Yugoslavia, and Egypt averaged 18 percent of the total.

Imports rose by an average of 12 percent annually in the 1960s, an increase not enough to meet industrial requirements; in the late 1960s there were serious shortages of raw materials, capital equipment, and spare parts. In the early 1970s, however, the balance of payments account showed much improvement; all shortages of essential imported goods were eradicated. The chief suppliers of Turkey's imports in 1970 were West Germany, the United States, the United Kingdom, Italy, Switzerland, the Soviet Union, and France.

Management of the economy. *The role of government.* Turkey's first ventures into industry were made in the 1930s, in the early years of the republic, when the state was of necessity the principal investor. Although the state still owned nearly half of the country's economic resources in 1970, increasing importance was being given to private industry, which provided almost 50 percent of the new fixed capital investment. The state sector was concerned mainly with investment in fields in which the capital requirement was too large or the expected returns too low to attract private enterprise.

The State Planning Organization

The State Planning Organization, set up in 1960, became the arbiter of all foreign investment, as well as of all major Turkish private and state investment. Its five-year plans and annual programs set the guidelines for economic development. Through the Central Bank, the Agriculture Bank, and other state banking institutions, the government maintained a firm hold on all financial and investment operations. The railways, post office, airways, and internal sea passenger services were operated as government enterprises.

Taxation. Annual treasury revenue in the late 1960s totalled 24,028,000,000 lire. Direct taxation accounted for 6,798,000,000 lire, indirect taxation for 12,343,000,000 lire, foreign aid counterpart funds for 1,019,000,000 lire, and nontaxation revenues for 1,560,000,000 lire. The net revenues from state monopolies, the universities,

and the State Farms Administration amounted to 836,000,000 lire; treasury bonds raised 600,000,000 lire, and savings bonds, which are compulsorily purchasable at the rate of 3 percent of taxable income, raised 727,000,000 lire. Direct taxation consisted mainly of an income tax on private individuals and companies and a corporation tax. There was widespread tax evasion, largely resulting from a shortage of qualified inspectors and also from the absence of a recognized body of professional accountants. The government continued to rely heavily on indirect taxation, such as sales and excise taxes. Banking, insurance, and other transactions were also subject to indirect taxation.

Trade unions. The trade union movement was relatively unimportant until the 1960s. Before July 1963, when the Strikes, Lockouts and Collective Agreements Law came into force, strikes and lockouts had been illegal. In the early 1970s there were about 1,000 unions, the majority affiliated to the moderate Turkish Trade Union Confederation and a few to the left-wing Confederation of Reformist Workers' Unions. Union membership totalled about 4,000,000.

The government fixes minimum wages by geographical areas, but these bear little relationship to actual rates, which in most establishments are determined by collective agreements. The agreements also cover a wide variety of such fringe benefits as holiday pay, performance bonuses, and food allowances. Social insurance and fringe benefits are equal to more than 60 percent of basic wages. The Confederation of Employers' Associations of Turkey grew rapidly in the 1960s.

Balance of payments. Since the inception of the First Five-Year Plan in 1962–63, the government has tried to achieve a 7 percent annual increase in national output. The deterioration of the balance of payments in the later 1960s led to a two-thirds devaluation of the lira and to the adoption of austerity measures in August 1970. Short- and medium-term policies called for greater emphasis on investment in currency-earning enterprises, for the curbing of internal demand and of price increases, and for an overall improvement in productivity. (E.I.U.)

Transportation. The Turkish Republic began very early to improve the transportation system as a means of integrating isolated regions and of developing the national economy. The length of railway tracks increased from about 2,500 miles in 1924 to around 6,000 in 1970. After World War II more emphasis was placed on road and harbour construction. The result was to give Turkey the best developed road and rail network in the Middle East. In 1970 the highways carried 43 percent of the freight traffic and 70 percent of the passenger traffic; the railroads carried 55 percent of the freight traffic and only 28 percent of the passenger traffic.

Passenger and freight traffic

The heaviest traffic is between Istanbul and Ankara, followed by that of the Aegean region, with İzmir as its centre, the area around the Gulf of Iskenderun, with Adana as its centre, and the Ankara–Zonguldak route. Istanbul is the chief harbour; there are heavy flows of passengers and freight by sea between İzmir and Istanbul through the Aegean, between the southern coasts of the Sea of Marmara and Istanbul, and between Istanbul and the Black Sea ports of Zonguldak, Samsun, and Trabzon.

Roads. All-weather highways totalled 37,000 miles in 1971, of which over 13,000 miles were paved, the rest consisting of stabilized gravel or macadam. The main highways radiate from Ankara, in central Anatolia, from Istanbul and İzmir, in the west, from Adana, in the south, and from Erzurum and Diyarbakır, in the east.

Railways. The railroad pattern consists of a ring around the central Anatolian Plateau, from which branches radiate to the peripheral regions: two to Zonguldak and Samsun, on the Black Sea; three to the western ports of Istanbul, İzmir, and Bandırma; three to the east; and one to the south (via Adana to Syria and Iraq).

Port facilities. Turkey's merchant shipping fleet is relatively small, consisting in 1971 of 714,000 gross tons, of which 80 percent were oil tankers or cargo carriers. The port of Istanbul handles more than 50 percent of the country's imports and 11 percent of its exports. İzmir ranks second, handling 35 percent of the exports. Other principal ports, in decreasing order, are Mersin and İskenderun in the south and Zonguldak, Samsun, and Trabzon, in the north; all of these ports are located at the end of rail or land routes serving large hinterlands. Inland water transportation does not exist in Turkey except on Lake Van.

Air transport. The state-owned Turkish Airlines (Türk Hava Yolları) flies from Ankara to Istanbul, İzmir, Adana, Erzurum, Van, Samsun, and Trabzon. While Ankara is the major junction of the domestic air routes, Istanbul is the busiest airport and the principal terminus of international lines. İzmir ranks third in traffic volume. (S.Er.)

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Turkey is a republic, with its capital at Ankara. Under the constitution of 1961, political authority is centred in the Grand National Assembly, which has a lower chamber, the National Assembly, composed of 450 elected members, and a Senate made up of 165 members, 150 elected and 15 nominated by the president of the republic. There are also a few senators for life: army officers who carried out the 1960 revolution.

The head of state is the president of the republic, elected by the Grand National Assembly for a term of seven years. He is not eligible for a second consecutive term. The president selects a prime minister, who forms a government subject to approval by the National Assembly.

The provinces and districts

The country is divided into 67 provinces. Each province (*il* or *vilâyet*) is subdivided into districts and each district (*ilçe* or *kaza*) into communes. The highest administrative official in each is, respectively, the *vali* (governor), the *kaymakam* (prefect), and the *nahiye müdürü* (district official). The *vali*, who is appointed by the president on the recommendation of the minister of the interior, is the chief administrative officer of the province, representing all the national departments (except those of war and justice) and coordinating their work in his province. He corresponds directly with each ministry and has a staff of advisers, who also form an administrative council under his chairmanship. The organization of the district under the *kaymakam* and of the commune under the *nahiye müdürü* follows the same pattern. The commune comprises a number of villages, each of which has a headman (*muhtar*) and a council of elders (*ihtiyarlar meclisi*) numbering from 5 to 12 according to the size of the village. A provincial council, elected for four years, debates questions of local administration, and its resolutions have legal effect; the *vali*, who is president of the council, may, however, refer proposals to the Council of State. In every headquarters town of a province or district and in all other towns of 2,000 inhabitants or more, there is a municipality (*belediye*). At its head is the mayor (*belediye reisi*), assisted by an elected council and a committee composed of officials and of persons chosen by the council for a year's term.

All citizens over 21 are entitled to vote unless they have been legally deprived of their rights. Deputies to the National Assembly are elected every four years, and a third of the senators are elected every two years. The constitution prescribes a secret ballot. Actual voting procedures are determined by legislation. Before 1961 a party securing a majority in a province was given all the deputies from that province. The electoral law of 1961 introduced a form of proportional representation by which the deputies of a province were apportioned among the parties according to the size of each party's vote.

Turkey was a one-party state until 1946. Since then a number of parties have contested elections, and in October 1971 eight had deputies in the National Assembly.

The judicial system is entirely independent of the assembly and the government. The old Muslim legal and judicial system was swept away in the early years of the republic, and a new Western system was adopted that was based on the Swiss civil code, the Italian penal code, and German commercial law. The highest court, the Constitutional Court, was created in 1961 to review the legislation of the Grand National Assembly; it has 15 regular

and 5 alternate members. The highest administrative court is the Council of State, with 31 judges, which serves as the final court of appeals for the decisions of lower administrative courts. There is a Court of Cassation that serves as a court of last resort for reviewing the decisions of other courts. A system of courts run by the Ministry of Justice handles ordinary civil and criminal cases.

The military

The military forces had a total strength of about 508,500 men in 1971, of which 420,000 were in the army, 50,000 in the air force, and 38,500 in the navy. Young men are subject to two years of compulsory service at the age of 20. Turkey is a member of the North Atlantic Treaty Organization (NATO) and of the Central Treaty Organization (Cento). United States influence has been strong, exercised by a military mission in Ankara that directs the delivery of arms from the U.S. and supervises training programs in the three services. In 1971 land forces included 12 infantry divisions, one armoured division, four armoured brigades, and two parachute battalions. The navy had 12 submarines and ten destroyers. There were three tactical air forces. Headquarters of the Southeastern Command of NATO is at İzmir.

Education, health, and welfare. At the time the Turkish Republic was formed, the population was estimated to be only 10 percent literate. By the start of the 1970s, primary education was compulsory for all children from seven to 12, but a considerable number of children, particularly in the provinces, did not attend school. Although the educational system underwent great expansion after World War II, many peasants were reluctant to send their children to school or could not afford to keep them there during planting and harvesting seasons. The literacy rate in 1970 was estimated at 55 percent of the population of six years and over. Over 5,000,000 children attended primary school early in the 1970s, while the number in secondary schools and lycées was a little over 1,100,000. There were 245,000 in technical and vocational schools and colleges and 155,000 in various institutes of higher education. Religious instruction, forbidden in the early years of the republic, was permitted in primary schools and in the schools training religious personnel.

The Ministry of Health and Social Welfare carried out public health programs and operated a large number of hospitals and dispensaries. Others were run by the Ministry of Labour. State medical services are provided free to the poor. There are also private medical institutions run by philanthropic organizations and large business enterprises. In 1969 there was one hospital bed for every 495 persons and one doctor for every 2,267 persons.

Successful public health campaigns have been conducted against tuberculosis, trachoma, malaria, and syphillis, but in the late 1960s trachoma and tuberculosis were still endemic. Infant mortality, which stood at 160 per 1,000 live births in 1960, was 153 per 1,000 in 1970.

A basic law concerning labour and social insurance and regulating conditions of employment, passed in 1936, established the 48-hour week with paid holidays of 12 to 24 working days, depending upon length of service. Later legislation provided health and accident insurance and old-age pensions. In the late 1960s approximately 1,000,000 workers were covered by social insurance.

Housing conditions

Housing standards in general have been low, and overcrowded conditions in the cities have given rise to shantytowns (*gecekondu*) on the outskirts, put up by peasants migrating from the countryside. The Ministry of Reconstruction and Resettlement was established in 1958 to organize and direct this migration. In the mid-1960s it was estimated that persons living in shantytowns comprised 45 percent of the population of Ankara, 21 percent of that of Istanbul, and 18 percent of that of İzmir. On the other hand, all of the larger cities contain modern, middle-class residential areas that have expanded at a rapid rate and in which people live by Western standards.

The maintenance of internal security is the responsibility of the police, the gendarmerie, and the army. The police are organized on a national basis under the Ministry of the Interior but carry out their duties at the command of local civil authorities. In each province there is a directorate of security, divided into administrative, judicial, and political sections. The gendarmerie is a paramilitary force drawn from military conscripts and assigned to sectors not under police jurisdiction, notably rural frontier areas. It is attached to the Ministry of the Interior and subject to the same local authorities as the police.

CULTURAL LIFE AND INSTITUTIONS

Turkey has a long and various cultural heritage. When the Turks arrived in Anatolia in the 11th century they had already adopted Islām, and they soon fell under the influence of the highly developed Iranian and Arab civilizations. Another part of the Turkish inheritance came from the Byzantine civilization that had developed in the Eastern Roman Empire. As the Ottoman Empire expanded into Europe, it received cultural influences from the West, and, when the empire entered on its downward course in the 19th century, the cultural pressure of Europe became stronger. At the same time, European interest in Turkish language, history, and art inspired many educated persons in Turkey with a desire to strengthen and preserve the national culture. Among the most important of the reforms carried out after the national revolution were those aimed at reviving the Turkish language and breaking the hold of Islām upon the nation.

Modern Turkish culture has been dominated by nationalism. Writers, artists, and musicians have abandoned the long tradition of Islām and returned to the vernacular in literature, village scenes in painting, and folk ballads in music. The theatre has become popular, and innumerable Turkish or foreign plays are performed. The Ankara State Opera was founded in 1940 and the Istanbul Opera in 1950; both perform classical Western works.

The popular arts flourish and are encouraged. Popular literature takes the form of narrative (*hikâye*) and poetry (*siir*), recited by minstrels known as *âşiks*. There are many popular dances and games, varying according to region. Folk instruments include drums, trumpets, flutes, pipes, tambourines, viols, and cymbals, along with some modern instruments. Popular drama includes shadow plays, performed by dolls reflected on a linen screen, and the *orta oyunu*, a type of improvized comedy.

Formal cultural institutions begin with the Ministry of Culture, set up in 1971. Various organizations are devoted to the sciences and arts, including three music conservatories, in Ankara, İzmir, and Istanbul; the Academy of Fine Arts, in Istanbul; the National Folklore Institute, in Ankara; the Turkish Folklore Society, in Istanbul; and a number of scientific and professional societies. Every province has its museums. There are archaeological museums in Ankara, Istanbul, and İzmir and a Museum of Turkish and Islāmic Art in Istanbul. The National Library (Milli Kütüphane) in Ankara had over 500,000 volumes at the beginning of the 1970s.

Ankara early in the 1970s had 18 daily newspapers and ten weeklies; Istanbul had 24 dailies and 24 weeklies. There were six dailies in İzmir, three each in Adana and Bursa, and two in Eskişehir. Radio and television broadcasting are carried on by the government. In the early 1970s Radio Ankara had three domestic services and three to foreign listeners. Radio Istanbul had two domestic services. Television broadcasting began in Ankara in 1965 and by 1971 was carried on four days a week. A station in Istanbul began operating in 1971. (A.Te.)

Turkistan, History of

Turkistan, an area of Central Asia, lies partly in the Soviet Union and partly in the People's Republic of China. Historically, it can be divided into three broad geographic zones, each possessing quite distinct features. The first of these, known in Islāmic times as Mā Warā' an-Nahr, is the area lying between the Rivers Amu Darya (called Oxus by the Greeks and Jayḥūn by the Arabs) and Syr Darya (the Jaxartes to the Greeks and the Sayḥūn to the Arabs). This is an arid, semidesert region where, prior to the recent development of irrigation projects, the sedentary population maintained itself by intensive cultivation of the oases or of the riparian tracts bordering the Amu Darya, the Syr Darya, and the Zarafshan—the river of Samarkand.

The second zone is the steppe region, extending northeast of the Syr Darya and north of the Tien Shan as far as the foothills of the Altai—an expanse of fertile grazing lands ideally suited for pastoral nomadism. On the south this region is bounded by the Tien Shan and on the north by the Siberian forest zone; on the west it passes unbroken into the great Eurasian steppe zone, stretching as far as the Ukraine; while on the east it is confined by the foothills of the ranges lying between the Altai and the Tien Shan. To the Turks the area to the south and east of Lake Balkhash was known as the Yeti Su (Land of the Seven Rivers), and from this is derived the Russian name of Semirechiye.

The third zone, Kashgaria, possesses characteristics different from both Mā Warā' an-Nahr and Semirechiye. This region is dominated by the Takla Makan desert, one of the most forbidding tracts on the face of the earth, bounded on the north by the Tien Shan, on the west by the Pamirs, and on the south by the Kunlun Range. There human settlement is restricted to the higher land ringing the desert or to oasis settlements watered by the streams that lose themselves in the Takla Makan—the Tarim and its main tributaries, the Khotan and Yarkand rivers.

Neither the Pamirs nor the Tien Shan, although both climb to impressive altitudes, have ever restricted movement into or out of Kashgaria, either in the direction of Mā Warā' an-Nahr or of Semirechiye. Indeed, one striking characteristic of the Turkistan region—notwithstanding the prevailing aridity, the expanse of desert, and the barriers presented by lofty ranges—has been the comparative ease with which it has been traversed at all times, especially by nomadic tribes acting as a catalyst upon the sedentary civilizations—Iranian, Indian, and Chinese—on its peripheries. Paradoxically, although the inhospitality of so much of the terrain has served as a check to extensive contacts between the Far East, India, the Middle East, and the Mediterranean world, the caravan routes that straddled it have provided the means for varied cultural and commercial interchange.

WEST TURKISTAN

Inclusion in the Achaemenid Empire

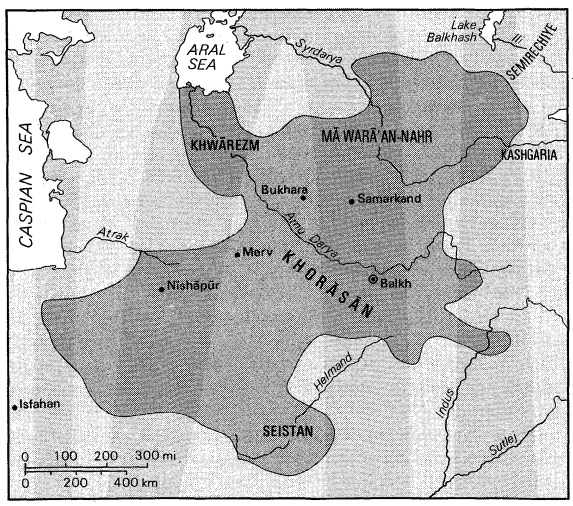
The early empires. The recorded history of West Turkistan begins with its inclusion in the Achaemenid Empire of Cyrus the Great in the 6th century BC. The rock inscription of Darius I (Achaemenid king, 522–486 BC) at Bīsitūn (Behistun) lists three Persian satrapies beyond the Amu Darya, the historic frontier of Iran—Suguda, the Sogdiana of the Greeks, between the Amu Darya and the Syr Darya; Uvarazmish, the Chorasmia of the Greeks, on the lower Amu Darya southeast of the Aral Sea; and Saka, the steppes beyond the Syr Darya. The Sogdians and the Chorasmians were mainly sedentary cultivators, while the Sakas were nomadic pastoralists related to the Scythians of the steppes north of the Black Sea; but all were of Iranian stock and spoke Iranian languages. The Sogdians, assisted by Saka auxiliaries, proved resourceful foes of Alexander the Great during his extended campaign in the eastern satrapies of the defunct Achaemenid Empire (4th century BC). Only with great difficulty did Alexander succeed in overcoming them, and at the close of the campaign he made an overt gesture of conciliation: he himself married Roxana, daughter of the Bactrian Oxyartes, defender of the unidentified stronghold known as the Rock of Sogdiana, while his general Seleucus married Apama, daughter of the Sogdian Spitamenes and his most intrepid opponent.

From the second half of the 3rd century BC both the newly founded Parthian Empire of the Arsacids and the Greco-Bactrian kingdom of Diodotus I and his successors faced ever increasing pressure from Saka nomads who had penetrated Sogdiana and were pressing southward along the line of the Amu Darya. By the second half of the 2nd century BC they had crossed the river and established a foothold in Bactria. The southward movement of the Sakas was part of a chain reaction resulting, in the first instance, from the expanding power of a tribal confederacy—known as the Hsiung-nu and identified with the ancestors of the later Huns—poised upon the Mongolian frontiers of China. The Hsiung-nu attacked and dispersed another tribal confederacy centred in Kansu, the Yüeh-chih, who fled westward down the valley of the Ili and onto the steppes north of the Syr Darya, where they met with the Saka tribes, who, threatened now from the east, began to press southward with renewed vigour, first into Sogdiana and then across the Amu Darya into Bactria. By the close of the 1st century BC the Yüeh-chih had driven the Sakas deep into what is now Afghanistan and even across the Indus into the Punjab.

The Yüeh-chih are probably to be identified with the Tochari of Western documents, among whom the dominant clan or clans consisted of the group later known as Kushans. Under Kujūla Kadphises, early in the 1st century AD, the Kushans controlled a vast area that included Sogdiana between the Amu Darya and the Syr Darya, as well as Bactria and Gandhāra on the upper Indus, stepping-stone to future conquests in India. This area remained under Kushan rule for about two centuries, and during that time Sogdiana participated fully in the syncretistic culture of the Kushan Empire, exposed both to Mahāyāna ("Greater Vehicle") Buddhism and to the Buddhist art of Gandhāra. It was finally lost to the Kushans as a result of the eastward drive of Ardashīr I, founder of the Sāsānid Empire in Iran, perhaps in AD 227, the last known regnal year of the Kushan emperor Vasudeva I.

Under the Sāsānids

Under the Sāsānids, Sogdiana was administered, together with Bactria and Gandhāra, by governors of the Sāsānid royal house. Holding the title of *kushanshāh*, these continued down to the middle decades of the 4th century, when the region was invaded by the Huns, probably the northern wing of the former Hsiung-nu confederacy. Advancing from the steppes beyond the Syr Darya, the Huns penetrated Sogdiana in successive waves, which have been tentatively classified as three distinct groups —Chionites, Kidarites, and Hephthalites, of whom the last became a great scourge in northern India during the 5th and 6th centuries. For nearly 200 years the Huns were to threaten the frontiers of the Sāsānid Empire, but in about AD 559 they were crushed by the Sāsānid ruler Khosrow Anūshīrvān (reigned 531–579), in alliance with new invaders from beyond the Syr Darya—the Western Turks under a khan known as Sinjibu or Silzibul. For the next 100 years Sogdiana continued under the rule of the Western Turks, although it is unlikely that their overlordship greatly reduced the influence of the indigenous Sogdian chieftains or disturbed the basic social and economic organization of the sedentary population. The life-style of the Sogdian ruling elite was an impressive one, if judged by the striking series of wall paintings discovered by Soviet archaeologists at Pyanjikent, on the upper Zarafshan. The culture of the region, in any case, had long been highly syncretistic, influenced by Zoroastrianism, Nestorian Christianity, Judaism, Manichaeism, and Buddhism; and to this welter of faiths the Turks added the characteristic shamanism of the Central Asian steppe zone.



Muslim rule. The decline of the Western Turks in the second half of the 7th century tempted the Muslim Arabs, advancing from the southwest, to embark upon the conquest of Sogdiana, to which they gave the name Mā Warā' an-Nahr, meaning "that which lies beyond the river" (equivalent to the Latin name of Transoxania). The annexation of Sogdiana to the Umayyad caliphate

proved a difficult task; and although it began shortly after the appointment of 'Ubayd Allāh ibn Ziyād to the governorship of Khorāsān in 674, it was not until the governorship of the famous Qutaybah ibn Muslim (who was killed in Farghana, the valley of the upper Syr Darya, in 715) that any substantial progress was made in the task of pacification. Even so, the death of Qutaybah produced an immediate reaction. While the Arab tribes in Khorāsān, which provided the troops for the garrisons in Sogdiana, indulged themselves in reckless tribal feuds, the Sogdian chieftains revolted against the Arab yoke and sought the assistance of the Türgesh Turks, whose entry into Sogdiana temporarily ended Arab rule. Shortly afterward, however, the Türgesh were defeated in battle by the governor of Khorāsān, Asad ibn 'Abd Allāh al-Qaṣrī, whose successor, Naṣr ibn Sayyār—a dexterous and conciliatory administrator appointed in 737—was able to place the Arab administration upon a sound and stable footing. Even then, however, the new province of the caliphate was still exposed to danger. Within a year of the revolution that substituted the rule of the 'Abbāsids for that of the Umayyads, a Chinese army invaded the valley of the upper Syr Darya (751), where it was defeated by the troops of Ziyād ibn Ṣāliḥ, a general of Abū Muslim.

Under the 'Abbāsids, Sogdiana (or Mā Warā' an-Nahr, as it will henceforth be called) was gradually drawn into the Islāmic culture zone, to be celebrated in later centuries for the scholars and saints it gave to the Muslim world, especially from Bukhara, the *quṭb al-Islām* ("Pillar of Islām"). The late 9th century, which saw 'Abbāsid control in the eastern provinces disintegrating with the de facto independence of the Ṭāhirids in Khorāsān and of the Ṣaffārids in Seistan, witnessed the rise in Mā Warā' an-Nahr of the Sāmānid dynasty, under whose comparatively mild rule the region enjoyed a substantial degree of peace and prosperity. The Sāmānids (ruled *c.* 874–*c.* 999), natives of Balkh in Khorāsān who claimed a probably spurious descent from the famous Sāsānid general Bahrām Chūbīn, were of Iranian stock and stood out as generous patrons of the so-called New Persian Renaissance of the 10th century. Under their rule Bukhara became a brilliant centre of Irano-Islāmic culture, while the stability of the regime rested on the support of an extensive class of small landholders (*dehqāns*) and a professional army of pagan Turkish slaves (*mamlūks*), recruited from beyond the Syr Darya.

Rise of the Sāmānid dynasty

Territories controlled by the Sāmānid dynasty in the 10th century.

For all their wealth, their extensive military power, and their identification with traditional Iranian culture values, the Sāmānids remained unswervingly loyal to the Sunnī 'Abbāsid caliph in Baghdad. By the close of the 10th century, however, their possessions south of the Amu Darya had passed into the hands of the Turkish Ghaznavids, while Mā Warā' an-Nahr itself was occupied by the Turkish Qarakhanids (Karakhanids), who finally took Bukhara in 999. Although the origin of the Qarakhanids is uncertain, they were probably a branch of the Qarluq tribe, which by the mid-10th century occupied an extensive territory to the north and south of the Tien Shan, with the centres of their power at Balāsāghūn on the River Chu, Talas (now Dzhambul) to the west, and Kashgar across the mountains.

The Qarakhanids exercised a loose control over the whole of Mā Warā' an-Nahr, though they were prevented from advancing south of the Amu Darya by the Ghaznavids, who also seized Khwārezm south of the Aral Sea (the ancient Chorasmia). Nor did Qarakhanid rule endure for long, though its end is confused and uncertain since, by the middle of the 11th century, both Mā Warā' an-Nahr and Khorāsān, as well as an extensive area to the west, had passed into the hands of the Seljuqs, a branch of the Oğuz Turks that appeared in Mā Warā' an-Nahr at the close of the Sāmānid period as auxiliaries of the ruling house in its struggle with the Qarakhanids. For a century Mā Warā' an-Nahr was part of the far-flung Seljuq Empire, but even before the death, in 1157, of Sanjar, the last effective sultan, Seljuq rule had ceased to be anything but a name in the lands beyond the Amu Darya. Meanwhile, Khwārezm had become the seat of an independent Turkish dynasty, that of the Khwārezm-Shāhs, descended from a *mamlūk* officer in the service of the Seljuq sultans. Takash, the ablest of the line, ruled one of the most extensive Muslim states of the 12th century, adding Khorāsān and much of the Iranian plateau to his possessions on the Amu Darya; yet he remained a tribute-paying vassal of the Qarakhitans (Karakhitans), remnants of the Khitan or Liao dynasty of China (947–1125) who, driven out of China by the Juchen or Chin dynasty (1122–1234), had moved westward to occupy the former territories of the Qarakhanids. Takash died in 1200, and his successor, Muḥammad ibn Takash, galled by his dependence upon the Qarakhitans, whose power he rightly judged to be in decline, threw off his allegiance and made himself master of Mā Warā' an-Nahr and of virtually the entire Muslim East.

The Chagatai khans and the Timurids. In striking at the power of the Qarakhitans, the Khwārezm-Shāh had unwittingly weakened the only buffer protecting his frontiers from perhaps the greatest scourge Islām was ever to experience, the Mongols of Genghis Khan, who in the spring of 1220 crossed the Syr Darya and overran Mā Warā' an-Nahr, leaving a trail of devastation—cities sacked, populations massacred, and irrigation works destroyed or abandoned. The view is widely held that the region did not recover its former prosperity until the Russian occupation in the second half of the 19th century.

Mongol invasions

Before his death in 1227, Genghis Khan divided his vast empire among his sons. Turkistan (consisting of Mā Warā' an-Nahr, the steppes northeast of the Syr Darya, and Kashgaria, which had escaped the initial Mongol visitation) passed to his second son, Chagatai, whose descendants ruled this extensive *ulus* (appanage) down to the early 14th century, when the khanate divided into two successor states: an eastern khanate beyond the Syr Darya and the Pamirs, where the Chagatai khans continued to exercise a nominal suzerainty down to the 17th century, and a western khanate, consisting of Mā Warā' an-Nahr, which eventually passed into the hands of the celebrated conqueror Timur. His descendants ruled there until the close of the 15th century, when they were dispossessed by the invading Uzbeks.

The Chagatai khanate. The history of the Chagatai khanate is both confused and obscure, the only relatively detailed chronicle relating to this area being the *Tārīkh-e Rashīdī*, written in Persian by Mīrzā Muḥammad Ḥaydar Dūghlāt, cousin of the Mughal emperor Bābur and ruler of Kashmir between 1541 and 1551; it has been translated into English by N. Elias and E. Denison Ross (London, 1895).

As rulers whose power rested solely upon the support of their tribal followers, the Chagatai khans at first located their headquarters on the steppes close to Lake Balkhash, where there was rich grazing for the flocks and herds of

the nomads. Chagatai himself made his capital at Bishbaliq, an old Uighur centre. It was later transferred to Almaliq between Lake Balkhash and the Tien Shan—whereas his main *orda* (encampment) was generally sited close to the Ili River. The administration of Mā Warā' an-Nahr and its predominantly Muslim population he left to a series of Muslim governors: the first was Maḥmūd Yalavach, a merchant from Khwārezm, who was succeeded by his son Mas'ūd Beg. The Mongols required collaborators of this kind—men of business accustomed to Irano-Islāmic bureaucratic methods and capable of squeezing the maximum revenue out of the khan's subjects. Even under these comparatively enlightened governors the Muslim population of Mā Warā' an-Nahr only slowly recovered from the destruction wrought by the initial Mongol conquest. Urban life in particular was slow to revive, and it received little assistance from such rulers as Barak Khan (reigned 1264–70), who, en route to invade Khorāsān, allowed his troops to plunder his own cities of Bukhara and Samarkand. When the Moroccan traveller Ibn Baṭṭūṭah visited Mā Warā' an-Nahr during the second quarter of the 14th century, he was appalled by the decay of urban life: much of Samarkand was still in ruins, Tirmiz had been rebuilt on a new site, and across the Amu Darya in Khorāsān both Merv and Balkh were utterly desolate.

Like the Mongol elite in the contemporary khanates of Kipchak and Iran, the Chagatai khans and their followers found themselves drawn inexorably toward an Irano-Islāmic life-style such as was still to be found in the cities of Mā Warā' an-Nahr and, to a lesser degree, in those of Kashgaria. This, in turn, involved the adoption of Islām in place of Mongolian shamanism and of the Sharī'ah, the law of Islām, in place of the Yāsā of Genghis Khan and tended to alienate their pagan nomad followers, concentrated mainly on the steppes beyond the Syr Darya. As early as 1264 an imprudent great-grandson of Chagatai became a Muslim, calling himself Mubārak Shāh, but he rapidly disappeared from the scene. More significant of changing times, Kebek Khan (reigned *c.* 1318–26) a half century later transferred the seat of government from Almaliq to Qarshi in Mā Warā' an-Nahr. One of Kebek's younger brothers, Tarmashirin, openly proclaimed himself a Muslim and was driven from his throne (*c.* 1334), but by then the conflict of interests was too deep to be healed. Shortly afterward the unified khanate disintegrated: in Mā Warā' an-Nahr a line of Chagatai khans openly espoused Islām and the Muslim way of life, as did perhaps the majority of their followers, while across the Syr Darya a rival line endeavoured to maintain the traditions of their Genghiskhanid ancestors, though with steadily diminishing success. This latter eastern khanate was known in Mā Warā' an-Nahr and Iran as Mughalistān and its inhabitants as Jāṭs (literally, "robbers").

Adoption of Islām by the Chagatai khans

The Timurids. During the second half of the 14th century, Mā Warā' an-Nahr was the scene of the spectacular rise of Timur Lenk (Tamerlane), a Barlas Turk from Shahr-e Sabz, who first united under his command the dominant Turko-Mongol tribes of Mā Warā' an-Nahr, Khwārezm, and Mughalistān, as well as Khorāsān and Seistan in eastern Iran. Between 1384 and 1395 Timur added to his conquests a vast area consisting of what are now Iran and Iraq, eastern Turkey, and the Caucasus region. In addition, he launched two successful attacks upon the Mongol khanate of Kipchak on the Volga. Moreover, he also invaded northern India (1398–99) and sacked Delhi before turning westward again, between 1399 and 1402, to harry the Egyptian Mamlūks in Syria and the Ottoman sultan, whom he captured in battle at Ankara. At the time of his death at Otrar on the Syr Darya, in 1405, Timur was already bound for the invasion of China.

The extent to which Mā Warā' an-Nahr benefitted from Timur's conquests is open to debate, but much of the plunder acquired on his campaigns was expended upon his capital, Samarkand. On capturing enemy cities he followed the Genghiskhanid precedent of sparing the lives of artisans and craftsmen, who were transferred to Mā Warā' an-Nahr; and it is recorded that after the sack of Delhi, in particular, large numbers of Indian workmen were taken to Samarkand. The city was visited by Ruy González de Clavijo, ambassador of Henry III of Castile, who left an impressive description of the metropolis in the last years of Timur's life. Timur never assumed the full attributes of sovereignty, contenting himself with the title of emir while upholding the fictional authority of a series of puppet khans of the line of Chagatai, to whom he claimed kinship by marriage, in consequence of which he was styled *gurkhan* ("son-in-law").

Timur appears to have lacked the administrative capacity or the foresight of Genghis Khan; and following his death his empire became a bone of contention among a numerous progeny of sons, grandsons, and great-grandsons because there existed among the Timurids no fixed law of primogeniture and because, as with other Turko-Mongol dynasties, it was held that sovereignty was invested in the entire ruling house rather than in a single individual. In the ensuing struggle Timur's youngest son, Shāh Rokh, emerged victorious; but he withdrew to Herāt in Khorāsān, which he made his capital, leaving his eldest son, Ulugh Beg, as his deputy in Mā Warā' an-Nahr. Ulugh Beg's rule in Samarkand, from 1409 to 1446, probably brought a considerable measure of tranquillity to the region. An enthusiastic amateur astronomer and the builder of a celebrated observatory, he ensured that during his lifetime Samarkand would be a major centre of scientific learning, especially in astronomy and mathematics.

Throughout the second half of the 15th century, Mā Warā' an-Nahr was divided into a number of separate principalities, ruled by various descendants of Timur, of which Bukhara and Samarkand were the most important. Together with other Timurid principalities in the Farghana valley and at Balkh and Herāt in Khorāsān, these petty courts patronized Persian literature and also writing in Chagatai, an eastern Turkish language derived partly from the Khaqani spoken at the Qarakhanid court, which now emerged as a flexible vehicle for sophisticated literary expression. These Timurid princelings, however, were locked in unceasing rivalry with each other, and their inability to combine, even temporarily, against intruders from beyond their frontiers was to prove their undoing. By the close of the century the whole of Mā Warā' an-Nahr had passed into the hands of the Uzbeks.

The Uzbek khanates. The early history of the Uzbek people is wrapped in obscurity; but at the time of the establishment of the khanate of Kipchak (the Golden Horde), Genghis Khan's grandson Shibaqan (Arabic: Shaybān) was given as his *ulus* the area stretching east of the Urals toward the upper waters of the Irtysh. His tribes were at that time pagan shamanists; but early in the 14th century, presumably during the reign of the greatest of the rulers of Kipchak, 'Abd Allah Özbeg (Uzbek; reigned 1313–40), they were converted to Islām and perhaps assumed the name of Uzbeks in honour of their distant sovereign (by the late 14th century these tribes were already known by that name). They began to move southeastward during the first half of the 15th century; and under their ruler Abū al-Khayr Khan they reached the north bank of the Syr Darya, whence they threatened the Timurid possessions across the river in Mā Warā' an-Nahr but whence they were also threatened, in turn, by the depredations of the Buddhist Oirats, now advancing steadily westward out of Jungaria (western Mongolia).

Assumption of the name Uzbeks

Before Abū al-Khayr Khan could undertake a full-scale invasion of Mā Warā' an-Nahr, however, he was defeated in battle and killed in 1468 by two kinsmen—Karay and Jani Beg—who, refusing to recognize Abū al-Khayr's paramount position, had defected, together with their tribal followers, and had placed themselves under the nominal suzerainty of the Chagatai khan of Mughalistān. Their descendants were to become the Kazakh hordes of later centuries.

With the death of Abū al-Khayr Khan, the fortunes of the Uzbeks declined, only to revive under the leadership of his grandson Muḥammad Shaybānī, who was an empire builder cast in the ancestral Genghiskhanid mold.

By 1500 he had seized the whole of Mā Warā' an-Nahr, including the metropolis of Samarkand, and was threatening the remaining Timurid rulers in Khorāsān. Although he himself was killed at Merv (1510), fighting Shāh Esmā'īl I the Ṣafavid, he had changed the course of Central Asian history. By the time of his death all the lands between the Syr Darya and the Amu Darya were in Uzbek hands, and so they were to remain.

The Shaybānid dynasty (it should perhaps more correctly be styled the Abū al-Khayrid, since none of the later Shaybānids were lineal descendants of Muḥammad Shaybānī) ruled Mā Warā' an-Nahr down to 1598, with a separate line reigning in Khwārezm. Like the Timurids, the Shaybānids followed Turko-Mongol tradition in selecting as their paramount chieftain the senior member of the ruling family and in dividing their territory into separate appanages for the brothers, sons, and nephews of the khan—a practice tending toward instability. Mā Warā' an-Nahr under the Shaybānids appears to have declined in prosperity by comparison with the preceding century of Timurid rule, due partly to a falling off in the importance of the transcontinental caravan trade. In other respects the Shaybānids followed the precedents set by the Timurids, especially in regard to their patronage of literature and the arts, although neither in architecture nor in miniature painting did the output of the Shaybānid period compare favourably with the best Timurid work. Unlike the Timurids, however, the Shaybānids strove to establish a reputation for impeccable orthodoxy. This was especially the case with the greatest of Shaybānid rulers, 'Abd Allāh Khan II (reigned 1583–98).

On the extinction of the Shaybānid line, Mā Warā' an-Nahr passed into the hands of a family related by marriage to the preceding dynasty, the Janids or Astrakhanids (descended from the former khans of Astrakhan on the Volga). Under the Janids there was a marked decline in material prosperity and in the general level of cultural life; and such pretensions to sovereignty as the dynasty still possessed by the early 18th century vanished with the invasion of Mā Warā' an-Nahr by the Iranian warlord Nāder Shāh, who, in 1740, entered Bukhara as a conqueror before passing on to attack the khanate of Khiva, the name used hereafter for Khwārezm. During the second half of the 18th century the last Janid ruler, Abū al-Ghāzī Khan (reigned 1758–85), lost much of his power to chieftains of the Mangit tribe, who, in the person of Shāh Mūrad (reigned 1785–1800), eventually usurped the throne.

Dominance of the Bukhara, Khiva, and Kokand khanates

At the beginning of the 19th century the area between the Amu Darya and the Syr Darya was dominated by three khanates—Bukhara, Khiva, and Kokand. Not one of these states had defined frontiers with its neighbours; not one was able to keep recalcitrant chieftains permanently in check; and not one could trust its neighbour not to intervene in times of difficulty or crisis. In addition, the emir of Bukhara and the khan of Khiva exercised a nominal suzerainty over the Turkmen tribes of the Karakum Desert, whose slave-raiding proclivities in the direction of Iran they encouraged—to provide labour in the oases of Khiva and Bukhara—but over whose movements they exercised not the slightest control. Paradoxically, however, all three khanates were probably better administered in the first half of the 19th century than at any time during the preceding century: in Kokand both Muḥammad 'Umar Shaykh (died 1822) and his son Muḥammad 'Ali (died 1842) were talented rulers, while in Bukhara the ferocious Naṣr Allāh (Nasrullah; reigned 1827–60) aspired to the role of a second Timur.

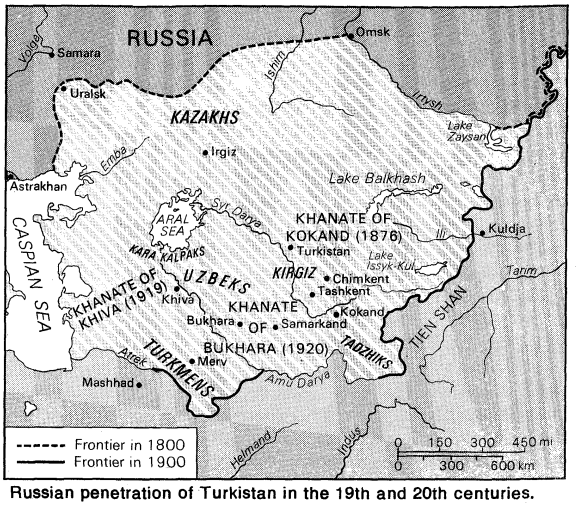
Yet nowhere in the Muslim world during the 19th century were there regimes less prepared to face the challenge of European expansion than the khanates of Central Asia; and it was their geographical isolation alone that impeded the otherwise inexorable advance of Russia, especially in the case of Khiva, ringed by desert, against which Russia mounted unsuccessful expeditions in 1717 and 1839. The Russian conquest began in earnest, however, with the acquisition from Kokand in 1855 of the fort of Ak-Mechet on the Syr Darya. Kokand was attacked in 1864–65, Chimkent and Tashkent taken, and a treaty extracted from Khudāyār Khan in 1866. In 1868 Bukhara was invaded, and the emir was compelled to accept the status of a Russian vassal. The same happened with Khiva in 1873. In 1875 there was an uprising in Kokand, which was swiftly suppressed, and the khanate was formally annexed in 1876. Meanwhile, the occupation of the Turkmen country had begun in 1873. The Turkmens, however, put up a more strenuous resistance than did any of the khanates, and it was not until after the massacre at Geok-Tepe in 1881 and the occupation of the Merv Oasis in 1884 that all opposition was overcome.

The Kazakh khanate. The pattern of Uzbek history in Mā Warā' an-Nahr down to the Russian conquest of the late 19th century was shaped largely by the fact that these former nomadic pastoralists had established themselves in a region where favourable conditions for a pastoral economy were limited and where much of the country's wealth consisted of the revenue derived from taxing the sedentary agriculturist and the urban artisan and merchant. In these circumstances, the Uzbeks gradually adapted themselves to the role of landowners in the oases or became, in some cases, wholly urbanized. Very different was the case of their Kazakh kinsmen, who remained on the steppes north of the Syr Darya after the Uzbeks had crossed into Mā Warā' an-Nahr. In this vast area, perfectly suited to a nomadic pastoral economy and devoid of sedentary agriculture or urban life except along the northern bank of the Syr Darya, the Kazakhs were able to preserve intact all the nomadic traditions of their forebears. Unlike the Uzbeks, whose rulers, in taking possession of such ancient centres of Islāmic culture as Bukhara, had assumed the role of orthodox Muslim potentates, the Kazakhs—and to an even greater extent the Kirgiz of the Tien Shan—remained indifferent Muslims, possessing a rich oral literature but no written language before the coming of the Russians and being altogether without the traditional Irano-Islāmic apparatus of administration, which the Uzbeks had inherited in Mā Warā' an-Nahr.

Kazakh consolidation

During the late 15th century and throughout the 16th century the Kazakhs were able to consolidate a nomadic empire stretching across the steppes east of the Caspian and north of the Aral Sea as far as the upper Irtysh and the western approaches to the Altai. The time was peculiarly favourable: the Oyrat (Oirat) Empire, formidable during the 14th and early 15th centuries, had passed into temporary eclipse; the Chagatai khanate bestriding the Tien Shan was moribund; the Noghay Horde between the mouths of the Volga and the Ural rivers was in a similar condition; and the Uzbeks were preoccupied with the conquest of Mā Warā' an-Nahr and with raiding Khorāsān. Under Burunduk Khan (reigned 1488–1509) and Kasym Khan (reigned 1509–18) the Kazakhs were the masters of virtually the entire steppe region, reputedly able to bring 200,000 horsemen into the field and feared by all of their neighbours. Under Kasym Khan's sons—Mamash (reigned 1518–23), Tagir (reigned 1523–33), and Buydash (reigned 1533–38)—there was, however, a partial weakening of the khan's authority, accompanied by a trend, later to become more pronounced, for the khanate to disintegrate into three separate "hordes." These were, from east to west: the Great Horde, in the Semirechiye north of the Tien Shan; the Middle Horde, in the central steppe region east of the Aral Sea; and the Little Horde, between the Aral Sea and the Ural River. In each horde the authority of the khan, invariably a Genghiskhanid, tended to be curtailed by the de facto power exercised by tribal chieftains known as sultans and perhaps even more by the beys and batyrs (the heads of the clans that were the components of each tribe). Nominally, the khans commanded a formidable force of mounted warriors, but, in reality, they depended upon the loyalty of the sultans, who, in turn, were dependent upon the loyalty of the beys and batyrs. The last son of Kasym Khan to rule the Kazakh steppes, Ḥaqq Naẓar (reigned 1538–80), overcame these obstacles and, having succeeded in reuniting the three hordes, embarked upon systematic raiding into Mā Warā' an-Nahr, a trend that continued under his immediate successors down to the reign of

Tevkkel Khan (1586–98), who even temporarily occupied Samarkand.



During the 17th century the Kazakhs lost ground, although even in the last quarter of the century Tauke Khan (reigned 1680–1718) was still able to hold the tribes together in a single confederacy. By then, however, the Kazakhs were already in decline, having suffered from the ceaseless depredations of the revived Oyrat Empire in Jungaria. These Oyrat raids began as early as 1643 but reached their peak during the reign of the Oyrat ruler Cevang Rabtan (1697–1727), when the Kazakh steppes were ravaged again and again without the Kazakhs being able to offer any effective resistance. Not until the Oyrats were finally overthrown by the Manchu rulers of China in 1757 were the Kazakhs released from this scourge, which had for so long decimated their manpower and appropriated their livestock.

Russian advance onto the Kazakh steppe

The reverses experienced by the Kazakhs at the hands of the Oyrats undoubtedly retarded the emergence of a unified Kazakh state and further depressed the prevailing level of Kazakh cultural life. It also rendered the Kazakhs even less able to resist the encroachments of Russia from the north. The Russian advance onto the Kazakh steppe began with the construction of a line of forts—Omsk in 1716, Semipalatinsk in 1718, Ust-Kamenogorsk in 1719, and Orsk in 1735—which was then steadily advanced southward. Some Kazakhs believed that the Russian presence might at least provide some security against Oyrat raids, and in 1731 the Little Horde accepted Russian protection, followed by the Middle Horde in 1740 and by part of the Great Horde in 1742, although its effect upon the Oyrats was to prove minimal. During the second half of the 18th century the Kazakhs found themselves threatened not only by Russian encroachments from the north but also by the Manchus from the east, who considered themselves the heirs of the Oyrats in Jungaria and who, in 1771, demanded the submission of the khan of the Great Horde. But, in reality, the Manchu Empire was too remote to intervene effectively; it was the Russians alone who were in a position to exert severe pressure on the Kazakhs. Finally, after a series of ineffectual uprisings, of which the most extensive was that of Batyr Srym in 1792–97, Russia resolved to suppress such autonomy as the Kazakh khans still possessed. In 1822 the khanate of the Middle Horde was abolished; in 1824, the Little Horde; and in 1848, the Great Horde.

Under Russian rule. The Russian conquests in Central Asia had given the tsars control of a vast area of striking geographical and human diversity, acquired at relatively little effort in terms of men and money. The motives for the conquest had not been primarily economic; peasant colonization of the virgin steppes and the systematic cultivation of cotton were later developments. The factors that determined the Russian advance into the area were both complex and interrelated. They included the historic pull of the frontier, the thirst for military glory on the part of the officer corps, and the fear of further British penetration into Central Asia from across the Indus, as well as the infectious rhetoric of imperialism common to the age. From the outset, Russia's objectives as a colonial power were strictly limited: to maintain "law and order" at minimum cost and to disturb as little as possible the traditional way of life of its new subjects. Such an approach was favoured by the remoteness of the area and its isolation even from the rest of the Muslim world. It was improbable that an almost wholly illiterate population, its prejudices formed by a venal and obscurantist *'ulamā'* (class of Muslim theologians and scholars), could offer any concerted resistance to the Russian presence; and such, indeed, proved to be the case. The Russians, like other colonial powers, did experience an occasional uprising, generally of a very localized character, but the overwhelming military superiority displayed by the Russians at the time of the initial conquest, the inability of the inhabitants of the khanates to offer effective resistance, and the heavy-handedness with which subsequent insurrection or insubordination was dealt with ensured minimal opposition. Finally, by preserving the titular sovereignty of the emir of Bukhara and the khan of Khiva, they left a substantial part of the population, especially the urban classes, most deeply devoted to the Islāmic way of life, under traditionally minded Muslim rulers.

Russian penetration of Turkistan in the 19th and 20th centuries.

West Turkistan under tsarist rule. Yet the Russians, whether intentionally or not, became agents of change throughout the area in much the same way as any other colonial power. The economy was gradually realigned to meet the Russian need for raw materials and new markets. This required the construction of railroads: by 1888 the Trans-Caspian Railroad had reached Samarkand; between 1899 and 1905 the Orenburg-Tashkent Railroad was completed; the Turkistan-Siberian Railroad came later, begun just before World War I and not completed until 1930. In Tashkent and Samarkand new European suburbs were laid out at a distance from the walled native cities, but as in the case of the newly established garrison towns, such islands of European life required local services and supplies. Nor did the Russians wholly ignore the welfare of their new subjects. An effort was made, halfheartedly at first, to put down the indigenous slave trade; irrigation projects were initiated; and bilingual elementary education was cautiously introduced. As elsewhere in colonial Asia, the work of Russian scholars studying the literature, history, and antiquities of the Central Asian peoples aroused upon the part of a numerically small but influential Russian-educated elite, especially among the Kazakhs, nostalgic awareness of a colourful past and a sense of national, or cultural, identity.

Kazakh response to Russian rule

Of the major racial groups in Central Asia—Uzbeks, Kazakhs, Turkmens, Tadzhiks, and Kirgiz—the Kazakhs were the first to respond to the impact of Russian culture. Their early contacts with their new masters had in the main been carried out through intermediaries—Kazan Tatars, who, paradoxically, had contributed to strengthening the Kazakhs' awareness of being part of a greater Muslim world community and their sense of being a "nation" rather than a welter of tribes and clans. Moreover, through the Tatars they were exposed to current Pan-Turkish and Pan-Islāmic propaganda. In the 1870s the Russians countered Tatar influence by establishing bilingual Russian-Kazakh schools, from which emerged a westernized elite of considerable distinction. The time seemed ripe for a meaningful process of cultural interchange, made more credible by the fact that, despite the growing sense of Kazakh national identity, the Kazakhs were too much on the peripheries of the Islāmic world to feel strongly the pull of Pan-Islāmic or even Pan-Turkish sentiment.

This Russo-Kazakh "dialogue" was, however, doomed to founder on the rock of the government's policy of settling peasants from European Russia and the Ukraine on the Kazakh steppe, where agricultural settlement on an extensive scale could be undertaken only by curtailing the area available for grazing by the nomads' livestock

and by restricting their seasonal migrations. As early as 1867–68 the northwestern fringes of the Kazakh steppe had been the scene of violent protests at the presence of colonists; but it was not until the last decade of the century that the movement got fully under way with the arrival of upward of 1,000,000 peasants, resulting in the inevitable expropriation of Kazakh grazing grounds and in savage conflict between the Kazakhs and the intruders. Finally, in 1916, during World War I, the Kazakhs, driven to desperation by the loss of their lands and by the ruthlessness of the wartime administration, rose up in protest against a decree conscripting the non-Russian subjects of the empire for forced labour. The rebellion assumed the character of a popular uprising, in which many colonists and many more Kazakhs and Kirgiz were massacred. The revolt was put down with the utmost savagery, and more than 300,000 Kazakhs are said to have sought refuge across the Chinese frontier.

With the collapse of tsarist rule, the westernized Kazakh elite formed a party, the Alash-Orda, as a vehicle through which to express their aspirations for regional autonomy. Having found during the Russian civil war that the anti-Communist "Whites" were implacably opposed to their aspirations, the Kazakhs cast in their lot with the "Reds." After the war the Kazakhs were granted their own republic, in which, for the first few years, the leaders of the Alash-Orda maintained a fairly dominant position and were active in protecting Kazakh interests; after 1924, however, direct confrontation with the Communist Party became more intense, and in 1927–28 they were liquidated as "bourgeois nationalists."

The Kazakh republic

The history of the Kazakhs in the first half of the 20th century has been bleak indeed—expropriation of their grazing lands under the tsars, the bloody uprising and reprisals of 1916, the losses in the civil war and in the famine in 1921, purges of the intelligentsia in 1927–28, collectivization during the 1930s, and further peasant colonization after World War II.

In Mā Warā' an-Nahr, divided between the administration of the Russian governor general of Turkistan, based on Tashkent, and that of the emir of Bukhara and the khan of Khiva, opposition to colonial domination was centred in the most conservative elements of a profoundly Islāmic society—the *'ulamā'* and the inhabitants of the bazaar. Nonetheless, the Russian favoured, for reasons of expediency, the preservation of the traditional social framework and endeavoured, with only partial success, to insulate the inhabitants of the region from contact with the more "advanced" Muslims of the empire—the Volga and Crimean Tatars. In this they were aided by the fact that the virtual absence of European colonization provided no fuel for popular resentment comparable to that felt by the Kazakhs; and, in consequence, the westernized products of the bilingual Russian–Uzbek educational system, primarily concerned with reform of the Islāmic way of life, regarded the Muslim "ultras" as their most dangerous opponents.

If the main influence in shaping the outlook of the Kazakh intelligentsia was the educational system imported from European Russia, the catalyst in the case of the Uzbeks was knowledge of the educational reforms and the Pan-Turkish ideology of the Crimean Tatar renaissance of the late 19th century. The Uzbek reformers, known as Jadidists, advocated the introduction of a modern educational system as a prerequisite for social change and cultural revitalization; and despite intense opposition from the clerical classes, they opened their first school in Tashkent in 1901 and by 1914 had established more than 100. After 1908, influenced by the Young Turks of the Ottoman Empire, the Young Bukharans and the Young Khivans worked for a program of radical institutional change in the ramshackle governments of the khanates. By 1917, however, it may be doubted whether the Uzbek intelligentsia had made any substantial impact outside a fairly narrow circle of like-minded persons.

West Turkistan under Soviet rule. Neither before nor after the Russian Revolution were the nationalist aspirations of the Muslims of Central Asia compatible with the interests of the Russian state or those of the European population of the region. This was demonstrated once and for all when the troops of the Tashkent Soviet crushed a short-lived Muslim government established in Kokand in January 1918. Indeed, the Soviet authorities in Central Asia regarded the native intelligentsia, even the most "progressive" of them, with lively and (from their point of view) justifiable apprehension. At the same time there was the problem of an active resistance on the part of conservative elements, which was anti-Russian as much as anti-Communist. Having extinguished the khanate of Khiva in 1919 and that of Bukhara in 1920, local Red Army units found themselves engaged in a protracted struggle with the Basmachis—guerrillas operating in the mountains in the eastern part of the former khanate of Bukhara. Not until 1925 did the Red Army gain the upper hand.

In time, however, the Soviet Union came to realize that armed insurrection was far less dangerous to the new regime than the adherence to local Communist parties of members of the Muslim intelligentsia—former Nationalists turned Marxists but suspected of harbouring separatist and Pan-Turkish designs. This indigenous leadership was therefore systematically liquidated during the 1930s. Thereafter, the Soviets continued to reinforce the administrative and cultural autonomy of Kazakhstan, Uzbekistan, Turkmenistan, Tadzhikistan, and Kirgizia with a view to eliminating Pan-Turkish or Pan-Islāmic sentiment through a policy of "divide and rule." It would be unwise, however, not to recognize the positive advantages accruing to the inhabitants of Russian Central Asia as a result of the Soviet Union's federal structure or to underestimate the scope that it has allowed for the cultural development of each individual republic.

Elimination of local leaders

EAST TURKISTAN

Kashgaria, unlike Mā Warā' an-Nahr and Semirechiye, did not offer favourable conditions for pastoral nomadism except on the slopes of the Tien Shan, where the Kirgiz pasture their flocks, and, in consequence, the area remained somewhat outside the main course of the invasions and migrations that dominated so much of the early history of Central Asia. The importance of Kashgaria was due primarily to the caravan routes that traversed it, coming down to Kashgar and Yarkand from the passes over the Pamirs, either from the watershed of the Amu Darya and Badakhshan or from the watershed of the Syr Darya and Farghana. From Kashgar and Yarkand two ancient roads led toward the Kansu Corridor, a southern road, via Khotan, and a northern one, via Kucha, Turfan, and Hami; part of the famous "Silk Road," it was along this route that Buddhism made its way from India to China, its stages marked by sites—excavated (1900–30) by the Hungarian-British archaeologist Sir Aurel Stein and others—revealing the syncretistic art that flourished in the oases from Kushan times.

The early history of Kashgaria was the scene of recurring conflicts between successive Chinese rulers, claiming suzerainty over the region, and the nomad tribal confederacies to the north, ever seeking to throw off a distant and largely nominal Chinese yoke. With the fall of the khanate of the Uighur Turks of the Orkhon in the 9th century, a number of Uighur tribes moved southwestward, first into the Tien Shan and then into the oases of the Tarim Basin. There they remained the dominant racial component. The Uighurs were in the main Manichaeans, followers of a religion founded by the 3rd-century Persian prophet Mani, but they tolerated both Buddhist and Nestorian Christian communities in their midst. Under the Qarakhanids in the 10th century the process of Islāmization began, though even at the time when the area was incorporated into the Mongol Empire in the early 13th century, the cultural pattern was still extremely diverse. Kashgaria, together with Mā Warā' an-Nahr and Semirechiye, was part of the *ulus* of Chagatai; and, following the breakup of the khanate in the middle decades of the 14th century, the Muslim cities south of the Tien Shan—Kashgar, Uch Turfan, Aksu, Kucha, Yangi Hissar, and Yarkand—acted as a magnet to the infidel khans of the East and their retainers in the same way that the

cities of Mā Warā' an-Nahr had already lured the khans of the West.

By the second half of the 15th century the rulers of the eastern Chagatai khanate were wholly Islāmicized; but already their power was waning, assaulted by the Oyrats in Jungaria, the Kazakhs in Semirechiye, and the Kirgiz in the Tien Shan. Throughout the 16th century this decline continued, although it was temporarily halted during the reign of Sa'id Khan (reigned 1514–*c.* 1533). By the beginning of the 17th century, however, the khan had become a mere figurehead, the cities having passed into the hands of a quasi-theocratic dynasty of Khwājahs from Bukhara while the countryside was dominated by rival Kirgiz confederacies. In the late 17th century the whole Tarim Basin became part of the Oyrat Empire of the khan Galdan, who, nevertheless, left the Khwājahs as de facto rulers in Kashgar and Yarkand. In 1758–59 the area was occupied by the Manchus, following their defeat of the Oyrats, and it was finally incorporated into the Chinese Empire under the Manchu (Ch'ing) dynasty.

Manchu rule

The new administration, supervised by Manchus, left the inhabitants of the area very much to themselves, disturbing neither their religion nor their traditional way of life. Manchu rule was bitterly unpopular, however, and the exiled Khwājahs frequently attempted to foment insurrection from Kokand, across the mountains. In 1867 Kashgaria passed into the hands of a Kokandī adventurer, Ya'qūb Beg, who proclaimed his independence and established diplomatic contacts with British India and the Ottoman Empire. Not until 1878 were the Manchus able to reassert control. From that time the administration of the region, now known as Sinkiang (New Dominion), was somewhat more closely regulated from Peking, especially because the period witnessed a dangerous growth of Russian influence in the area. Following the 1911 Revolution in China, Sinkiang became the "fief" of a Yunnanese (Chinese) warlord, Yang Tseng-hsin, who ruled with an iron hand until 1928, at a time when the disturbances across the Russian frontier made the region peculiarly vulnerable. After 1933 Sinkiang was ruled by another formidable warlord, Shang Shih-ts'ai, who was nonetheless compelled to surrender it to the Kuomintang (Chinese Nationalists) in 1941. In 1949 it passed into Communist hands, and in 1955 the Sinkiang Uighur (*q.v.*) Autonomous Region was set up. In none of these events, at least after 1878, had the indigenous Turkish inhabitants of the region played any active part.

Turkmen Soviet Socialist Republic

A sun-beaten land of deserts and oases, the Turkmen Soviet Socialist Republic (also known as Turkmeniya, or Turkmenistan) is situated on the same latitude as the Mediterranean but deep in the heart of the Asian continent, the southernmost Soviet territory. With 188,500 square miles (488,100 square kilometres), it was the home of 2,495,000 persons by the mid-1970s. It was formed on October 27, 1924, and on May 13, 1925, formally became one of the constituent republics of the Soviet Union; its capital is at Ashkhabad. Its Central Asian neighbours are the Kazakh S.S.R. to the north, the Uzbek S.S.R. to the east, and Iran and Afghanistan to the south, while the Caspian Sea forms its western boundary.

For related information, see SOVIET UNION; AMU DARYA (RIVER); KARA-KUM DESERT; CENTRAL ASIAN PEOPLES, ARTS OF; ALTAIC LANGUAGES; INNER ASIA, HISTORY OF; TURKISTAN, HISTORY OF.

THE LANDSCAPE

Deserts occupy 90 percent of Turkmenistan's territory. The Kara-Kum (Black Sand) is one of the world's largest sand deserts, taking up the entire central part of Turkmenistan and extending into Kazakhstan. Topographically, four-fifths of Turkmenistan is plains—the southern part of the Turan Plain. Mountains and foothills rise mainly in the southern part of the republic, the Kugitangtau and Kopet-Dag ranges being spurs of the Pamir-Alay mountain ranges. The Kopet-Dag is geologically young, its instability indicated—as in 1929 and 1948—by intermittent earthquakes of great destructive force.

Climate. Turkmenistan's position deep inside Asia, the resultant unique air-mass circulation, and the character of the relief are responsible for a strongly continental climate, which exhibits great fluctuations in temperatures during the day and the year. The average annual temperature is 57°–61° F (14°–16° C), but this figure masks an extremely wide range. The temperature is seldom lower than 95° F (35° C) during summer days, and the absolute maximum high temperature in the southeast Kara-Kum reaches 122° F (50° C) in the shade. By contrast, in winter, the temperature in Kushka drops to −27° F (−33° C). Humidity is very low and rainfall meagre. Precipitation occurs mainly in the spring and ranges from about 3 inches (80 millimetres) per year in the northwest desert to as much as 12 inches (300 millimetres) in the mountains.

Water resources and irrigation. Turkmenistan's main rivers are the Amu Darya (the Oxus of classical times), flowing along its northeastern border toward the Aral Sea, and the Tedzhen, Murgab, and Atrek; there are also numerous small mountain rivers. The annual total of water transported by the republic's rivers reaches 2,100,000,000–2,300,000,000 cubic feet (60,000,000–65,000,000 cubic metres). Unfortunately, however, the geographical position of the rivers and the direction of their flow do not coincide with the location of cultivable lands; the most fertile—and still insufficiently used—lands lie chiefly in the south, northeast, and west, whereas the principal rivers run mostly in the east. A great number of canals and reservoirs has been built. The construction, across the Kara-Kum, of the world's largest irrigation and shipping canal, the Karakumsky Kanal (Kara-Kum Canal), began in the mid-1950s; when completed it will be 870 miles (1,400 kilometres) long. By the mid-1970s the canal was irrigating about 300,000 hectares, and construction was proceeding in the direction of Krasnovodsk, on the shores of the Caspian.

The Karakumsky Kanal

Soils and plant and animal life. Turkmenistan's soils are varied. A unique feature is that there is no definitely formed soil layer in most of the desert region. In

the northern and western Kara-Kum, on raised areas, the sand gives way to sandy loam and sandy and clay soils, sometimes mixed with broken rock. In the oases, a layer suitable for irrigated cultivation has formed.

The biological resources are varied but not abundant. Except in the oases and mountain valleys and plateaus, vegetation is of a pronounced desert character. In the mountain valleys of the Kopet-Dag, wild grape, almond, fig, and walnut are found, while juniper and pistachio trees grow on the open slopes. On the riverbanks and islands, chiefly in and along the Amu Darya, stand *tugai* forests of black poplar, willow, reed, and cane.

The animal world is represented mainly by desert creatures: steppe and Persian fox, wildcat, Kara-Kum gazelle, and tortoise. The wildlife of the mountains includes mountain rams and goats; such wild cats as the cheetah, lynx, and snow leopard; and the porcupine. Jackals, wild boars, and birds frequent the *tugai*. Rare pink deer are also found along the Amu Darya, and wild donkeys roam the Badkhyz and Karabil plateaus in the southwest. The eastern coast of the Caspian Sea is the winter home of vast flocks of ducks, geese, and swans.

In the waters of the eastern Caspian, various kinds of herring, sprat, roach, and sturgeon (including the beluga, prized for caviar) are widespread; the Amu Darya and its lakes, and other rivers, contain carp, barbel, and pike.

The human imprint. There is much variety in the different regions of Turkmenistan, but two broad divisions may be seen: an oasis region—characterized by adequate water supply, cultivated lands, and developed industry—composed of the Kopet-Dag, Tedzhen, Murgab, Middle Amu Darya, and Lower Amu Darya oases; and a desert region, subdivided into Western Turkmenistan, with a well-developed industry, and the Kara-Kum, with cattle raising and resources of natural gas and petroleum under the sands.

The Kopet-Dag Oasis

The oases. The Kopet-Dag Oasis stretches along the northern foothills of the Kopet-Dag Range, the slopes of which offer large areas for nonirrigated farming; both the mountains and foothills are also rich in mineral resources. The economic and cultural centre of the oasis is Ashkhabad, the republic's capital, with about 290,000 inhabitants. The development of the capital has stimulated industry, turning an agrarian oasis into the industrial-agrarian core of the republic. The Central Asian Railway, linking Tashkent, in the Uzbek S.S.R., with Krasnovodsk, via Ashkhabad and other cities of Turkmenistan, runs between the foothills and the Kara-Kum. The Firyuza and Chuli mountain valleys, rich in water and with a mild climate, have become known as health resorts.

The Murgab Oasis is famous for its fine-staple cotton, silk, handmade carpets and rugs, and Karakul sheep. The Murgab River, now that its lower reaches are crossed by the Karakumsky Kanal, can supply more water for irrigation. Mary (formerly Merv), with some 70,000 inhabitants, is the centre of the oasis and the surrounding region, and one of the most attractive towns in the republic.

Separated from the Murgab by a stretch of the Kara-Kum, the Tedzhen Oasis formed along the Tedzhen River. Because of the scarcity of water, only small areas of wheat, barley, and melons could be cultivated. After the oasis was crossed by the Karakumsky Kanal, however, and the Khauz-Khan Reservoir was built, large areas were irrigated, thus making possible the cultivation of long-staple cotton and the construction of cotton-processing plants. The economic and cultural centre is the town of Tedzhen, with 25,000 inhabitants. South of the oasis lies the Badkhyz National Reserve, with unique pistachio tree woodlands strongly resembling African savanna.

The Middle Amu Darya Oasis, in contrast to other oases, stretches almost without interruption for hundreds of miles and is almost entirely cultivated. The Amu Darya waters are very rich in silt, an excellent natural fertilizer. Raising of cotton and silkworms has long been widespread in that area. It is an important producer of kenaf and other fibre crops and the only supplier of wild licorice in the Soviet Union. The adjoining deserts provide fodder for Karakul sheep. Industries processing agricultural products and mineral raw materials have been developed in the oasis and the adjoining Gaurdak-Kugitang district. The Soviet Union's largest deposits of sulfur as well as deposits of potassium and other salts are found here, together with building materials. The economic and administrative centre of the oasis and the region is Chardzhou (with about 104,000 inhabitants), the second largest city and industrial centre in Turkmenistan.

The Lower Amu Darya Oasis lies in the ancient delta of the Amu Darya; Turkmenistan's northernmost oasis, it is one of the most important agricultural regions of the republic. The oasis is cut by a dense network of old riverbeds as well as by irrigation channels and ditches beginning in the neighbouring Uzbek S.S.R. The climate is more continental than that of other oases, but it is warm enough to grow medium-staple cotton and alfalfa. Rice, sweet sorghum, beans, kenaf, sesame, grapes, vegetables, and melons are also grown, and cattle and silkworms are raised. Most industrial enterprises are concentrated in the regional centre, the town of Tashauz (population about 75,000).

The deserts. The desert of Western Turkmenistan is an enormous and almost waterless expanse, with only a small oasis irrigated by the Atrek River in the extreme southwest. The mountainous part of Western Turkmenistan, a continuation of the Caucasus Mountains, has mineral and fuel resources. The unique deposits of mirabilite in the Kara-Bogaz-Gol Gulf of the Caspian Sea, petroleum (with natural gas and iodine- and bromine-containing waters), and rock salt and common lake salt are of great importance.

Western Turkmenistan

Western Turkmenistan is one of the most developed regions of the republic industrially, emphasizing oil extraction and refining, chemical and mining industries, and fisheries and fish processing. The rural population in Western Turkmenistan is less dense than that in the east. People are mostly engaged in raising sheep, goats, and camels and, to a lesser extent, grains and melons.

In the southern part of the Krasnovodsk Plateau, overlooking a bay of the Caspian Sea, stands the city of Krasnovodsk (53,000 inhabitants). Nebit-Dag (62,000) lies inland, east of Krasnovodsk.

The three parts of the Kara-Kum and the other featureless deserts—occupying the greater portion of the republic—enter, in part, all of the above-mentioned areas. They are distinguished by the same desert landscape, lack of surface water, exceptionally meagre precipitation, and high summer temperatures. At the same time, the desert is a zone of fuel and mineral resources, and its richest pastures can be used all the year round for sheep, goats, and camels.

THE PEOPLE

Demographic trends. The population of Turkmenistan had reached 2,495,000 by January 1975. The republic has a high natural population increase because of a high birth rate (34 per 1,000 population) and low mortality rate (seven per 1,000).

It is a multinational republic with Turkmens (66 percent of the total in 1970, compared with 61 percent in 1959) the predominant nationality, followed by Russians (14.5 percent), Uzbeks (8.3 percent), Kazakhs (3.2 percent), and small numbers of Tatars, Ukrainians, Armenians, Azerbaijanis, and Kara-Kalpaks. The 1,417,000 Turkmens living in the republic at the census of 1970 made up almost 93 percent of all Turkmens in the Soviet Union; the remaining 7 percent live mainly in Uzbekistan, Tadzhikistan, and the Northern Caucasus and the Astrakhan *oblast* of the Russian S.F.S.R.

Population distribution

The population is distributed unevenly, the average density in 1970 being about 11.4 persons per square mile (4.4 per square kilometre), only 40 percent of the overall Soviet average; in the Kara-Kum and mountain regions, there are fewer than three persons per square mile, but in the oases the figure reaches 780 per square mile (300 per square kilometre). With the development

of the Turkmenistan economy, numbers of non-Turkmen skilled workers and scientific and technical intelligentsia —with a large proportion of youth and women—immigrated to the republic.

There is a large urban population (48 percent of the total) inhabiting 15 major and more than 70 minor settlements. The rest of the people live in rural settlements and villages. Since the 1950s, the number of towns has been growing, while that of the traditional rural settlements has been diminishing, although the size of individual settlements is on the increase. Turkmens made up only 31.7 percent of the republic's town and city dwellers in 1970. The urban population consisted mainly of outsiders, those from the Soviet west and the Russian S.F.S.R. being concentrated in the principal centres: 95.7 percent of the republic's 313,079 Russians lived in towns, as did 83.3 percent of Ukrainians, 91.8 percent of Tatars, 97.4 percent of Armenians, and 96.8 percent of Azerbaijanis. In the capital city, Ashkhabad, those same five ethnic groups accounted for 56.1 percent of the residents, while Turkmens constituted 38.2 percent.

Ethnic characteristics. For centuries the Turkmens were divided into numerous tribes and clans, the largest being the Tekke, Ersari, and Yomut, whose total number exceeded 500,000. The number of people in other tribes (the Salor, Sarïq, Goklan, and Chaudar) fluctuated between 20,000 and 40,000.

Up to the time of the Russian Revolution (they had come under Russian domination in the 19th century) most of the Turkmens were pastoral nomads, though during the 18th and 19th centuries many had settled in the oases and become agriculturalists. Their tribal organizations and loyalties were strong. They had always been warlike and had commonly hired themselves out as mercenaries to various rulers in Central Asia. The establishment of the Turkmen S.S.R.—which was not done without a struggle, in which Turkmens joined with Bukharan Uzbeks and others in a protracted battle to throw off Russian domination—had the effect of bringing greater unity to the Turkmen tribes and of giving them the beginning of a sense of nationhood.

THE ECONOMY

By 1970, 450,000 factory and office workers and 230,000 collective farmers were employed in the Turkmenistan economy. The republic now specializes in cotton growing and in oil and gas extraction. Although it occupies a relatively small place in overall Soviet industrial and agricultural output, the republic turns out considerable quantities of certain products: 24–28 percent of iodine and bromine, and about 40 percent of the Soviet Union's sodium sulfate total.

Resources. Turkmenistan is rich in various minerals and in petroleum and natural gas. The potential reserves of the latter, occupying second place (in the Soviet Union) after the Russian S.F.S.R., are estimated at 210,000,000,000,000 cubic feet (6,000,000,000,000 cubic metres). Chemical resources are also extensive, especially those of mirabilite and other similar salts in the Kara-Bogaz-Gol area of the Caspian. Deposits of sulfur, potassium, and sodium chloride and oil-field waters containing iodine and bromine are also considerable. Dolomites, limestone, and marl are found in the mountains and foothills, and the Kara-Kum supplies sands used in making glass and bricks.

Reserves of natural gas

Industrial development. The radical reconstruction of the economy was finished by 1930. Old branches (cotton ginning, oil pressing, and carpet making) were retained, and new ones (heavy and light industry, and food processing) made their appearance. The net result has been a 40-fold increase in gross industrial output during the Soviet period.

Petroleum deposits and the associated oil industry are centred in the Caspian plain in Western Turkmenistan and in the offshore oil fields to the west of the Cheleken Peninsula in the Caspian Sea. In oil extraction Turkmenistan holds third place among the Soviet republics, after the Russian S.F.S.R. and Azerbaijan. Turkmenistan oil is of a very high grade, both as a fuel and as a chemical raw material, and its production reached nearly 16,000,000 tons annually by the mid-1970s. The prospects for the gas industry are good, 22 deposits having been discovered between 1950 and 1975. These include the Shakhetli deposit, with estimated reserves of 35,000,000,000,000 cubic feet (1,000,000,000,000 cubic metres). A network of gas pipelines links gas deposits in Western Turkmenistan with Ashkhabad, Krasnovodsk, Cheleken, and the central regions of the republic.

Significant in the chemical industry are the Chardzhou superphosphate plant, mirabilite from the vicinity of the Kara-Bogaz-Gol, sulfur from Gaurdak, iodine and bromine factories on the Cheleken Peninsula, and sulfanole production at the Krasnovodsk oil refinery.

Turkmenistan has a number of thermal power stations, using liquid fuel, at Nebit-Dag, Ashkhabad, Bezmein, Krasnovodsk, and elsewhere; a station near the town of Mary uses natural gas. Hydropower stations include the Hindu Kush plant, as well as plants at Kaushtubent and at the Tashkeprin Reservoir on the Murgab River.

Electrical power

Engineering and metal-processing enterprises include repair shops for diesel locomotives, railway cars, and agricultural machinery. In Ashkhabad and in Mary there are plants producing, among other products, equipment for extracting and refining oil. Textile and cotton-ginning industries are also important; there are silk-winding and silk-weaving mills, as well as cotton, cotton-wool, and worsted mills. Textile production amounted to more than 26,700,000 linear metres (87,700,000 linear feet) in 1974. Artificial furs, leather footwear, and sewn goods are also produced.

The most important branches of the food industry are vegetable oil, fish, meat, and flour production and wine making. The republic exports oil, butter, wine, fish, and salt to other parts of the Soviet Union.

Domestic industries, especially carpet and rug making, occupy an important place in the republic's economy. Turkmen carpets and rugs, long renowned for their durability and unique designs, are exported to more than 50 countries. Among Turkmen carpets well known in the West are those made by the Tekke, Yomut, Salor, and Ersari Turkmens and called by those names.

Agriculture. The growing of cotton and the raising of Karakul sheep, horses, and camels (see Table) are the most important branches of agriculture. Turkmenistan is the largest producer of fine-staple cotton in the Soviet Union.

Agricultural enterprises are large; there were in 1975 about 330 large collective farms (*kolkhozy*) and 55 state farms (*sovkhozy*). The average collective farm has 458 households, 3,535 acres of sown land, and about 8,000 sheep and goats.

Kenaf is a new industrial crop, and sesame is important among oil-bearing plants. Wheat and barley account for much of the area sown in grain crops; areas under millet and rice are as yet insignificant. Fodder crops (maize, alfalfa, and others) occupy one-sixth of the sown area. Turkmenistan melons have long been famous, and the republic's grapes are also well known.

The republic produces Karakul pelts, including black *arabi*, golden *sur*, and silver-gray *shirazi*, all very beautiful, durable, and in great demand in the world market; indeed, Karakul sheep account for more than 70 percent of all sheep in the republic.

Horse-breeding traditions

Over the centuries, Turkmens have also evolved the horses of the Akhal Tekke and Yomut breeds, valued for their physical endurance, speed, and beauty. Camels—mainly Arabian, and indispensable in the desert as a means of transport for sheep herders, for getting water from desert wells, and as a source of meat, wool, and milk—are also traditional Turkmen livestock. Turkmenistan leads the Soviet Union in the production of silkworm cocoons.

Transportation. The basic means of transport is the railways, though the density of the rail network (1,310 miles, or 2,110 kilometres, of track in 1970) is much below the Soviet average. The main trunk line is between Krasnovodsk and Tashkent (in the Uzbek S.S.R.), with branch lines from Mary to Kushka and from Nebit-Dag to Vyshka. In the 1950s a line was built to link Chardzhou, and areas as far northwest along the Amu Darya as Kungrad, to the central regions.

Motor transport is developing more rapidly than rail, and trucks handle most freight traffic within the republic (1,289,000,000 ton-miles, or 1,882,000,000 ton-kilometres in 1970). The main highways pass near railway lines and supplement them, especially in short-distance deliveries, but roads are also being constructed in more remote regions.

There is a merchant fleet, and the Krasnovodsk–Baku ferry provides a 210-mile link across the Caspian Sea; the electrically powered ferries are each capable of handling a freight train and making two trips daily. River transport, in seasonal operation on the Amu Darya and the Karakumsky Kanal, is of local importance.

Passenger planes and helicopters connect Ashkhabad, the capital, with many towns in the republic and elsewhere in the Soviet Union, as well as with remote geological prospectors' camps.

A network of pipelines connects the oil fields and gas deposits with transportation or consumption points. Natural gas is taken to central regions of the Russian S.F.S.R. and to the Urals through a two-pipe line, each pipe being up to five feet in diameter.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional framework. The republic has its own flag, emblem, and anthem; its official languages are Turkmen and Russian. According to the 1937 constitution, all power in Turkmenistan derives from the workers; however, there are no democratic elections, hence no effective channels for exercising the will of an electorate.

The Supreme Soviet

The highest body of republic government is the one-chamber Supreme Soviet of the Turkmen S.S.R., which is elected for a four-year term. The great majority of its 300 deputies are Turkmens, and about a third are women. All citizens of the republic reaching the age of 18 are eligible to vote, and those over 23 years of age can be elected deputies. The Supreme Soviet of the Turkmen S.S.R., however, exercises no real power. It meets for only a short time at six-month intervals, and deputies are selected from a single list of persons provided by the authorities without primary contests. The ethnic makeup of the Supreme Soviet is mixed, though there are no specifically stated protections for the various nationalities, nor are selections for the single list of candidates organized ethnically. Rather, candidates appear as designees from precincts, though often they are neither residents of the given precinct nor even permanent residents of the Turkmen S.S.R. (high-ranking Russian generals of the Soviet Army, for example, often emerge from the list as deputies to both the republic and union-wide supreme soviets). The Turkmen S.S.R., along with all other constituent republics, is represented in the national Supreme Soviet, the country's highest organ of state power. The Presidium of the Supreme Soviet consists of a chairman, two vice chairmen, a secretary, and 11 members.

The highest executive and administrative body in the republic is the Council of Ministers, formed by the republican Supreme Soviet; it organizes and supervises the activity of all ministries and other accountable departments. The chairman of the Council of Ministers of the republic is ex officio a member of the Council of Ministers of the Soviet Union.

Local government is carried out through district, town, rural settlement, and village soviets, elected for terms of two years.

The highest judicial body is the Supreme Court of the republic; in districts and in cities there are people's courts, with judges and people's assessors elected from one list of candidates provided by the authorities.

Communist Party

The Communist Party in Turkmenistan (there is no Turkmen Communist Party or party division) is a branch of the Communist Party of the Soviet Union (CPSU) and the real centre of organized power in the republic. In 1967 Turkmens were vastly under-represented in the party, with only 53 percent of the 62,679 members within Turkmenistan.

Though Russians made up less than 15 percent (1970) of the republic's population, they supplied nearly 25 percent of this privileged organization's membership (1967). These proportions represented a gain for Turkmens from 50 percent, and a comparable decline for Russians from 27 percent, in 1959. However, between 1969 and 1972, union-wide Turkmen membership, despite an advance from 38,963 card carriers to 43,111, failed to move relatively from 0.3 percent of the overall CPSU total, and Turkmens generally lacked a powerful voice in higher party councils.

Public health. The public health system has undergone radical changes. In pre-Revolutionary Turkmenistan there were fewer than one doctor and three hospital beds for every 10,000 of the population; present-day figures are more than 23 and about 100, respectively. Medical service is free.

Education. Until the collapse of the Khanate of Bukhara in 1920, Turkmens not attending schools in the Khanate of Khiva (also terminated the same year) largely received their education from the *mektebs* (primary schools) and *medreses* (seminaries) of Bukhara, that ancient, multi-ethnic Muslim centre, as well as in a scattering of New Method (Jadid) schools established by Muslim reformers in the early 20th century in towns such as Kerki and Chardzhou. A great extension of Turkmenistan's educational facilities has occurred since 1924, though the beginnings were relatively ineffective, compared with the best years of the late 19th-century revival in the Muslim educational system.

There were in the mid-1970s about 1,800 general primary and secondary schools serving more than 600,000 pupils of all ethnic groups. The six institutions of higher learning—the Turkmen State University (located in Ashkhabad), a teachers' training college, and medical, agricultural, and polytechnical institutes—together with 30 specialized secondary schools enroll an additional 58,000 students.

Education is supported from turnover taxes affecting most employees and from levies upon factories and other firms. It is provided tuition-free to students, and those selected for higher education receive stipends from the republic budget.

In the scientific field, the major institution is the Academy of Sciences of the Turkmen S.S.R., set up in 1951. It incorporates 16 research institutes of various kinds employing highly qualified staffs.

Cultural life. The intellectual and cultural life of Soviet Turkmenistan, led initially by the outstanding graduates of Bukharan seminaries such as Abdulhekim Qulmuhammed-oghli (died about 1937)—once active in the resistance movement, later a Communist, and influential as writer, editor, researcher, and cultural organizer—passed into the hands of Soviet-educated persons after the Stalinist purges of the 1930s "liquidated" men such as Qulmuhammed-oghli.

The widespread Turkmen traditional practice of composing poetry orally gave way, after printing became

well established in Turkmen centres in the 1920s, to writing and to the dissemination of verse and prose in book form. Though written Turkmen literature dates back at least to the 18th-century poet Mahtum Quli (Magtim Guli), it underwent a burst of growth when the literary publications of the new republic began to appear in the late 1920s and '30s.

Publishing

In 1973, volumes of literature in all languages published in Turkmenistan numbered 545, with 5,300,000 copies. In general, publishing of books in the Turkmen language declined sharply between 1958–61 and 1968–71 (from 423 titles annually, on the average, to 266), and though the number of copies was increased substantially, books available to readers dropped from 2.7 per person per year to 2.3, in the same period.

There are about 1,200 libraries in the republic (containing some 7,100,000 volumes), about 800 trade-union and collective-farm clubs, eight museums, and six theatres, with 700,000 visits annually. A film studio in the capital produces features and documentaries, and Ashkhabad and Krasnovodsk have television stations. Films, television, radio, and theatre, however, are largely carried on in the Russian language and for Russian constituents rather than in Turkmen for the eponymous nationality. In 1970, for example, Ashkhabad television devoted less than 18 percent of its time to offerings in Turkmen; 82.3 percent of the transmissions, in terms of time, were in Russian; further, Turkmen-language programs included many devoted to translations from Russian or about Russian subjects and themes.

PROSPECTS FOR THE FUTURE

The Turkmen S.S.R. has great prospects for development as more natural wealth is utilized and, in particular, as more thermal power stations are built and connected to the Central Asian power grid. A unique feature is the republic's potential resources of solar (it has nearly 300 days of sunshine per year) and wind energy, which can be transformed into electrical energy. Thermoelectric, photoelectric, and other generators may well produce cheap electricity that can be used for desalinization of water and also for consumer use in sparsely populated areas where it is unprofitable to build electric-power transmission lines.

The chemical, mining, oil, and consumer-goods industries are likely to witness development in coming decades, whereas desert territories in the outlying and central regions of the Kara-Kum will be used more productively. A vital role will be played by the completed Karakumsky Kanal and by irrigation projects using the waters of the Amu Darya.

Possessing considerable natural wealth in petroleum and mineral resources as well as large land areas available for development, the Turkmens nevertheless do not seem to be benefitting as much, proportionately, as do the large numbers of immigrant workers and specialists who have populated the urban and industrial centres in the republic.

Overwhelming predominance of Russians and Russian-language use in the educational, journalistic, and cultural establishment and networks, concentrated in the towns, has relegated most Turkmens, in their own republic, to a secondary position in high-level employment and thus in economic achievement. The coming years will be crucial for the maintenance and growth of a genuine Turkmen-oriented society.

Turner, J.M.W.

The English Romantic painter J.M.W. Turner was perhaps the greatest landscapist of the 19th century. Although brought up in the academic traditions of the 18th century, he became a pioneer in the study of light, colour, and atmosphere that, despite his lack of any real formal education, was based on considerable scientific inquiry. He anticipated the French Impressionists in breaking down conventional formulas of representation; but, unlike them, he believed that his works must always express significant themes. A line of development can be traced from his early ambitious "historical landscapes" in the manner of the French painters Nicolas Poussin and Claude Lorrain—landscapes given significance as the setting for important human subjects, such as the plagues of Egypt or the story of Dido and Aeneas—to his later studies of sea and sky. Even without figures, these late works were expressions of important subjects: the relationship of man to his environment, to the power of nature as manifested in the terror of the storm or the beneficence of the sun. Unmatched in his time and beyond in the range of his development, he was also unrivalled in the breadth of his subject matter and stylistic treatment.

Early life and works. Joseph Mallord William Turner was born on April 23, 1775, in London, the son of a barber. Nothing is known about Turner's mother except that she died insane in 1804. At the age of ten Turner was sent to live with an uncle at Brentford, Middlesex, where he attended school. Several drawings (British Museum) are dated as early as 1787. These are sufficiently professional to corroborate the tradition that his father used to sell the boy's work to his customers. After some instruction under Thomas Malton, a topographical watercolorist, Turner entered the Royal Academy schools in 1789 and exhibited a watercolour the following year, when he was only 15. He used to spend the summer holidays touring the country in search of subjects and visited Oxford in 1789, Bristol in 1791, and Wales in 1792. His sketchbooks, filled with drawings to be worked up later into finished watercolours for commissions or for exhibition, are preserved in the British Museum. His early work is topographical (concerned with accurate depiction of places) in character, imitating the best masters of the day —Thomas Malton, Edward Dayes, and Paul Sandby. In 1794 he began working for engravers, supplying designs for the *Copper Plate Magazine* and the *Pocket Magazine*. Engraved views of picturesque ruins of castles and abbeys were much in demand at the time. In the winters he attended the evening sessions at the house of Thomas Monro, the doctor and connoisseur who had treated John Robert Cozens, an English landscape painter in watercolours, during his last illness and who owned a number of his drawings. Turner, Thomas Girtin, and other young artists were employed at making copies or elaborations of his unfinished drawings. The influence of Cozens and of the Welsh landscape painter Richard Wilson helped broaden Turner's outlook and revealed to him a more poetic

and imaginative approach to landscape, which he pursued to the end of his career with ever increasing brilliance.

From 1796 Turner began to exhibit oil paintings as well as watercolours at the Royal Academy. The first one, "Fishermen at Sea," is a moonlight scene and was acclaimed by a contemporary critic as the work "of an original mind."

Professional success

In 1799, at the youngest permitted age (24), Turner was elected an associate of the Royal Academy, and in 1802 he became a full Academician, a dignity he marked by a series of large pictures in which he emulated the achievements of the old masters, especially the 17th-century painters Poussin, Claude, Aelbert Cuyp, and the Van de Veldes. He took his duties seriously, attending academic functions regularly, filling various offices, and bequeathing £20,000 to the Academy. He was helpful and encouraging to other artists insofar as his shyness and brusque manner allowed. In 1807 he was appointed professor of perspective. His infrequent lectures were said to have been difficult to follow but worth it for his diagrams (now in the British Museum). In about 1800 Turner took a studio at 64 Harley Street, London, and in 1804 opened a private gallery, where he continued to show his latest work for many seasons. He was by this time overwhelmed with commissions, and the success of his career was assured.

In the midst of professional success came personal grief. In 1800 Turner's mother became hopelessly ill and was committed to a mental hospital. His father came to live with him and devoted the rest of his life to serving as a studio assistant and general agent. Turner's private life, such as it was, was secretive, unsociable, and somewhat eccentric. In 1798 he entered into an affair, which was to last about ten years, with Sarah Danby, a widow who bore him two children. As he never married, was very close with money, and devoted his time almost entirely to his art, he was able to amass a considerable fortune.

He continued to travel in search of inspiration. His travels in 1797 took him to Yorkshire and the Lake District, in 1798 to Wales again, in 1801 to Scotland, and in 1802 to the Continent for the first time. The crossing to Calais was rough, and in his picture "Calais Pier" he has left a vivid record of his experience on arrival. From Paris he proceeded to Lyons, Grenoble, Geneva, around Mont Blanc to Courmayeur and Aosta, over the St. Bernard Pass to Vevey, then to Interlaken, the St. Gotthard Pass, Zürich, Schaffhausen, and back to Paris through Strasbourg and Nancy. He made more than 400 drawings during the tour and continued for many years after to paint pictures of scenes that had impressed him on the tour, the most important being three pictures of Bonneville, Savoy (1803 and 1812); "The Festival upon the Opening of the Vintage at Macon" (1803; Graves Art Gallery, Sheffield); the watercolours "Devil's Bridge" and "The Great Falls of the Reichenbach" (1804; Cecil Higgins Museum, Bedford); "Falls of the Rhine at Schaffhausen" (1806; Museum of Fine Arts, Boston); and "Snowstorm: Hannibal and His Army Crossing the Alps" (1812; Tate Gallery, London). In Paris he made detailed notes in the Louvre, where all the paintings brought from Italy by Napoleon were then displayed. He filled a sketchbook with copies and criticism of the paintings, showing that his taste was for the great Venetians of the 16th century and for Poussin but not for Rubens, whose landscapes struck him as "one continual glare of colour." Turner's figure compositions "Venus and Adonis" and "Holy Family" (1803; Tate Gallery) show that he tried his hand in the Venetian manner. These pictures and the many early seapieces, in which he surpasses the Dutch 17th-century marine painters, reveal his methodic attempt to master every style he admired and the ease with which he accomplished this. The rivalry he felt with painters who had influenced his style—Poussin, Wilson, and Claude, for example—is suggested by his bequest to the National Gallery of his "Dido Building Carthage, or the Rise of the Carthaginian Empire" (1815) and "Sun Rising Through Vapour: Fishermen Cleaning and Selling Fish" (1807) on condition that they be hung beside his two favourite Claudes.

In 1807 Turner began his great enterprise of publishing a series of 100 plates known as the *Liber Studiorum*. His aim was to perpetuate the great variety and range of his work; some of the subjects were taken from existing paintings and watercolours; others were specially designed for the *Liber*. He employed several engravers, although he supervised the work at every stage, etched some of the plates himself, and made innumerable preparatory drawings. The publication was issued in parts consisting of five plates each, covering all the styles of landscape composition, such as historical, architectural, mountainous, pastoral, and marine. The first part appeared in June 1807 and the last in 1819, when Turner evidently lost interest in the project and abandoned it after the publication of 71 plates.

Development of an original style

The treatment of landscape in the oil Thames sketches of about 1807 and "The Shipwreck" (1805; Tate Gallery) suggests that at this time Turner was also developing an original approach to landscape—emphasizing luminosity, atmosphere, and romantic, dramatic subjects. "The Shipwreck" was the first of many works to be engraved. A list of subscribers to the engraving of "The Shipwreck" shows that by this time Turner had a wide public among the nobility and collectors as well as among fellow artists.

Middle years. During the second decade of the 1800s, Turner's painting became increasingly luminous and atmospheric in quality. Even in paintings of actual places, as "St. Mawes at the Pilchard Season" (1812; Tate Gallery) and the two pictures of Oxford painted between 1809 and 1812 (exhibited in 1812), the hard facts of topography are diffused behind pearly films of colour; other pictures, such as "Frosty Morning," are based entirely on effects of light.

Turner was much in demand as a painter of castles and countryseats for their owners. Two examples of such paintings are "Somer Hill, Tunbridge" and "Linlithgow Palace" (1810; Walker Art Gallery, Liverpool). He continued to excel in marine painting, one of the most ambitious works being "Wreck of a Transport Ship" (1810; Gulbenkian Foundation, Lisbon).

The Earl of Egremont, who had bought a seapiece in 1802, became a regular patron and close friend. Turner probably paid his first visit to his other great friend and patron, Walter Fawkes, at Farnley Hall, Yorkshire, in 1810 and subsequently spent some weeks there nearly every summer until the death of Fawkes in 1825.

Turner continued to make extensive tours, between 1811 and 1813 of Devonshire, Cornwall, and Somerset, and in 1815 and 1816 of Yorkshire for the purpose of supplying 20 watercolours to illustrate T.D. Whitaker's *History of Richmondshire*. The following year he went to the Continent, primarily to visit the battlefield of Waterloo, of which he afterward painted a dark and romantic picture, "The Field of Waterloo" (1818; Tate Gallery).

With "Dido and Aeneas, Leaving Carthage on the Morning of the Chase" (1814; Tate Gallery), Turner began a series of Carthaginian subjects, in which he presaged the decline of Britain as a great power. The last exhibits of his life, at the Academy in 1850, included four works on the same theme. By appending long poetic quotations either from James Thomson's *Seasons*, Byron, Milton, Shakespeare, Pope, or from his own composition, *Fallacies of Hope*, he showed that he regarded the poetic interpretation as of paramount importance. Among the most ethereal dreams of this period are "Lake of Geneva" (1810; Los Angeles County Museum), "Crossing the Brook," and "England; Richmond Hill, on the Prince Regent's Birthday," one of his largest and most ambitious pictures.

Advance of style in Italy

As if he felt that he had done all he could with the beauty of his native country, he set out in the summer of 1819 on his first visit to Italy. He spent three months in Rome, visited Naples, Florence, and Venice, and returned home in midwinter. During his journey he made about 1,500 drawings, and in the next few years he painted a series of pictures inspired by what he had seen. They show a great advance in Turner's style, particularly in the matter of colour, which becomes purer, more prismatic, with general heightening of key. A comparison of "The Bay of Baiae, with Apollo and the Sibyl" with any of the

earlier pictures reveals a far more iridescent treatment resembling the transparency of a watercolour. The shadows are as colourful as the lights, and he achieves contrasts by setting off cold and warm colours instead of dark and light tones.

During the 1820s, tours of the Continent alternated with visits to various parts of England and Scotland. In 1821 Turner painted a series of delicate watercolours of the Seine on blue paper; in 1825 he revisited The Netherlands and Belgium and the following year the Meuse, Moselle, and the Loire. Notable among the pictures of this period are such views as "The Harbor of Dieppe," "Cologne: The Arrival of a Packet Boat: Evening," and "Mortlake Terrace: Early Summer Morning" (Frick Collection, New York). In 1827 he stayed with John Nash, the architect, at Cowes and painted the brilliant sketches of the regatta now at the Tate Gallery. In 1828 he went to Italy again and held an exhibition of some of his pictures in Rome. After his father's death in 1829, Turner often visited the Earl of Egremont at Petworth, Sussex. The splendid sketches of Petworth probably belong to the early 1830s.

Later life and works. In the last years of his life, Turner was more famous, richer, and more secretive than ever. After several years of inactivity as professor of perspective at the Royal Academy, he resigned in 1838. In 1839 he bought a cottage in Chelsea, where he lived incognito under the assumed name of Booth. He was looked after by his old housekeeper, who guarded his privacy so zealously that she made it difficult for people to gain admission to his gallery.

Turner continued to travel, however. In the last 15 years of his life, he revisited Italy, Switzerland, Germany, and France. Observers have recorded the untiring energy with which he sketched while abroad, and the drawings, numbering about 19,000 in the Turner Bequest, bear witness to this labour.

Characteristics of later works

While his earlier paintings and drawings show the most accurate observation of architectural and natural detail, in his later work this is sacrificed to general effects of colour and light with the barest indication of mass. His composition tends to become more fluid, suggesting movement and space; some of his paintings are mere colour notations, barely tinted on a white ground, such as "Norham Castle, Sunrise" and "Sunrise, with a Boat Between Headlands" (1835–45; Tate Gallery). Contemporary accounts describe how Turner used to send canvases in this state to the Academy and add the detail, and perhaps the specific subjects that Turner felt to be necessary before his art was worthy to be shown to the public, on the three or more varnishing days allowed to academicians before the exhibition was formally opened, so that they could make last-minute adjustments to allow for the particular circumstances of the placing and lighting of the work. Turner's extreme exploitation of this opportunity served as a demonstration of his extraordinary virtuosity and, on occasion, of his consideration—or lack of it—for the paintings of his neighbours; Constable, for example, was the victim of an enlarged red buoy in Turner's seapiece "Helvoetsluys," which completely eclipsed the reds in his own "Opening of Waterloo Bridge" at the Royal Academy in 1832. This practice may account for the large number of slightly brushed-in canvases found in Turner's studio at the time of his death. These colourful abstractions are far more appreciated now than the romantic subjects he exhibited.

Apart from fanciful reconstructions of ancient Rome and the scintillating Venetian subjects, which found ready purchasers in his day, the outstanding examples of his late work are "The Parting of Hero and Leander" (1837; National Gallery, London), a daring composition of sunset and moonlight with visions of spirits rising from the waters; "The 'Fighting Téméraire' Tugged to Her Last Berth to be Broken Up, 1838," a tribute to the passing age of sail; and "Rain, Steam, and Speed—the Great Western Railway." Actually, the first picture to be hung in the National Gallery was the opalescent "Venice from the Steps of the Europa" (1842), presented in 1847, while Turner was still alive. Turner's preoccupation with the elements of fire and water appears in the two pictures "Burning of the Houses of Parliament," in the large sketch "A Fire at Sea" (Tate Gallery), and in "Rockets and Blue Lights" (1840; Sterling and Francine Clark Art Institute, Williamstown, Massachusetts). The "Snow Storm" was painted from observations made when Turner crossed from Harwich in such a wild storm that he had to be lashed to the mast for four hours and did not expect to survive. The last pictures he exhibited in 1850 show some falling off of his artistic powers, though the colour is still radiant.

The Turner Bequest

Turner died in London on December 19, 1851, and was buried in St. Paul's Cathedral. By his will he intended to leave his fortune of £140,000 to found a charity for "decayed artists" and his pictures to the nation, on condition that a gallery be built to exhibit them. As a result of protracted litigation with his rather distant relatives, the money reverted to them, while the pictures and drawings of the Turner Bequest became national property. It was not until 1908 that a special gallery was built by Sir Joseph Duveen to house them at the Tate Gallery. All the drawings and watercolours were transferred to the British Museum for safety after the Thames flood of 1928, when the storerooms at the Tate Gallery were inundated. At the time of his death, Turner's own gallery was in such a state of neglect that many of his paintings were said to be mere shadows of what they had been originally. The sketches, not then considered worthy of exhibition, escaped the hands of unskilled restorers and have retained their original freshness and spontaneity.

Reputation. Even in the early years of the 19th century, Turner was strongly criticized by the more conservative critics and connoisseurs, such as Sir George Beaumont, for his forcefulness and high-keyed colour. By the end of his life, although his Venetian subjects and more finished watercolours still appealed to some purchasers, mainly from the newly rich merchant or manufacturing classes, and imitations of his works were beginning to be made, his style was developing along lines totally different from the contemporary taste for realism and high finish typified by such artists as William Powell Frith and the Pre-Raphaelite movement, founded in 1848. Turner's immense reputation in the second half of the 19th century was due largely to the enthusiastic if sometimes misguided championship of the most influential English art critic of the time, John Ruskin, who published the first part of *Modern Painters* in 1843 to prove Turner's superiority to all previous landscape painters and to extol his accurate rendering of natural appearance.

In his pursuit of light and pure colour Turner had anticipated the achievements of the French Impressionists; and when Monet and Pissarro saw his work in London in 1870, they were greatly interested, although few of his truly impressionist sketches were shown at that time. In the 1920s, when the Postimpressionist cult was at its height through the writings of the English art critic Roger Fry, Turner's reputation suffered a temporary eclipse. In 1948 a representative collection of his work was shown at the Venice Biennale and afterward in the principal capitals of Europe, and abstract painters began to find a common purpose with their own work in some of Turner's late colour compositions. Subsequent major exhibitions have further strengthened his status.

MAJOR WORKS

"Fishermen at Sea" (1796; F.W.A. Fairfax-Cholmeley Collection, on loan to Tate Gallery, London); "Buttermere Lake, with Part of Cromack Water, Cumberland, a Shower" (1798; Tate Gallery, London); "Self-Portrait" (*c.* 1798; Tate Gallery, London); "The Fifth Plague of Egypt" (1800; Indianapolis Museum of Art, Indianapolis, Indiana); "Calais Pier: An English Packet Arriving" (1802–03; National Gallery, London); "Venus and Adonis" (1803–05; Huntington Hartford Collection, New York); "Sun Rising Through Vapour: Fishermen Cleaning and Selling Fish" (1807; National Gallery, London); Thames sketches (*c.* 1807; Tate Gallery, London); "Somer Hill, Tunbridge" (1811; National Gallery of Scotland, Edinburgh); "Snowstorm: Hannibal and His Army Crossing the Alps" (1812; Tate Gallery, London); "Frosty Morning" (1813; Tate Gallery, London); "Crossing the Brook" (1815; Tate Gallery, London); "Dort or Dordrecht" (1818; Mr. and Mrs. Paul Mellon Collection); "England; Richmond Hill, on the Prince Regent's Birthday" (1819; Tate Gallery, London); "Rome, from the Vatican" (1820; Tate Gallery, London);

"The Bay of Baiae, with Apollo and the Sibyl" (1823; Tate Gallery, London); "The Regatta at Cowes" (1828; Victoria and Albert Museum, London); "Ulysses Deriding Polyphemus" (1829; National Gallery, London); Petworth landscapes (*c.* 1830; Tate Gallery and Petworth House, Suffolk, London); "The Evening Star" (*c.* 1830; National Gallery, London); "Childe Harold's Pilgrimage: Italy" (1832; Tate Gallery, London); "Burning of the Houses of Parliament" (1835; Philadelphia Museum of Art and Cleveland Museum of Art); "Keelmen Heaving in Coals by Moonlight" (1835; National Gallery of Art, Washington, D.C.); "Norham Castle, Sunrise" (*c.* 1835–45; Tate Gallery, London); "Juliet and Her Nurse" (1836; the late Mrs. G. Macculloch Miller Collection, New York); "Interior at Petworth" (*c.* 1837; Tate Gallery, London); "The 'Fighting Téméraire' Tugged to Her Last Berth to be Broken Up, 1838" (1839; National Gallery, London); "The Slave Ship" (1840; Museum of Fine Arts, Boston); "Peace: Burial at Sea" (1841–42; Tate Gallery, London); "Snow Storm—Steam-Boat Off a Harbour's Mouth Making Signals in Shallow Water, and Going by the Lead" (1842; Tate Gallery, London); "Shade and Darkness: The Evening of the Deluge" (1843; Tate Gallery, London); "Light and Colour" (1843; Tate Gallery, London); "Rain, Steam, and Speed—the Great Western Railway" (1844; National Gallery, London).

Turner also produced thousands of watercolour sketches and drawings, the majority of which are in the British Museum, London.

Twain, Mark

Writing under the pseudonym Mark Twain, Samuel Langhorne Clemens, still the United States' most famous humorist, won a worldwide audience for stories of boy adventure and brusque observations on the fallibility and mendacity of the "damn'd human race."

Youth in Hannibal. Clemens was born on November 30, 1835, in Florida, Monroe County, Missouri, the sixth child of John Marshall and Jane Lampton Clemens. He was four when the family moved to Hannibal, in nearby Marion County, on the west bank of the Mississippi, where his father kept a dry-goods and grocery store, practiced law, and entered local politics. There Samuel spent his boyhood, enchanted by the romance and awed by the violence of river life—the steamboats, keelboats, and giant lumber rafts and also the human flotsam washed up by the river, professional gamblers and confidence men, itinerate stevedores and indigent raftsmen,

quick with fist, knife, or derringer. Away from its boisterous waterfront, Hannibal was an ideal place for a boy to grow up. Nearby Holliday's Hill was just right for picnics or playing pirate or Robin Hood, and the cave near its summit tempted exploration. Glasscock's Island, just a long swim away, invited truant days of fishing or simply watching the river, perhaps with Tom Blankenship, the village drunkard's son, who was to be immortalized years later as Huckleberry Finn. To a boy, the village graveyard was ominous and foreboding, for death was no stranger to a frontier village. Young Samuel saw death on the wharves and in his own home. One of his sisters died when he was four, his ten-year-old brother died when he was seven, and his father died in 1847 when he was 11. From that time on, it became necessary for Samuel to contribute to the family's support. He became —"fretfully," he later remembered, "lazily, repiningly, complainingly"—a delivery boy, grocery clerk, and blacksmith's helper during summers or after school. At the age of 13, with school finally behind him, he became a full-time apprentice to a local printer. When his brother Orion, ten years older than he, established the *Hannibal Journal*, Samuel became a compositor for that paper and soon a contributor who signed himself "Rambler." At 17, a humorous sketch, "The Dandy Frightening the Squatter," appeared over his initials in the *Carpet-Bag*, published in Boston.

First published work

Early travels. At 18 he became in truth a rambler. He left Hannibal for St. Louis, becoming a journeyman printer for a short time, but set out for New York, where he found brief employment printing and then went on to Philadelphia and Washington, then westward again to Muscatine, Iowa, to set type again for his almost equally peripatetic older brother. Soon he was back in St. Louis, until he left again to join his brother, now in Keokuk, Iowa, where Samuel remained uneasily for almost two years.

But the rambler seemed unhappy when too long in one place. At 22 he set out again, this time to discover whether a young man might find his fortune in South America along the lush banks of the Amazon. Clemens achieved some measure of stability when he agreed to furnish the Keokuk *Daily Post* with letters describing his travels. Only five letters, signed "Thomas Jefferson Snodgrass," appeared, for on the way down the Mississippi toward New Orleans, Clemens met a steamboat pilot named Horace Bixby who agreed to take him on as an apprentice and teach him the perils and possibilities for profit provided by the great and treacherous river. For almost four years, Clemens plied the Mississippi; he later remembered these years as the most carefree of his life. He never met a man later anywhere whose kind he had not known on the river. After 1859 he was a licensed pilot in his own right, but two years later the Civil War cut across the river, bringing an end to traffic from north to south. Clemens probably remained briefly in New Orleans, where evidence supplied in a series of letters in the *Cres-*

Experiences on the Mississippi River

cent signed "Quintius Curtius Snodgrass" suggests that he may have had connections with the local militia there; but in general, Clemens' attitude toward and participation in the war is clouded. Years later as Mark Twain, he delighted readers of the *Century* magazine with a "Private History of a Campaign That Failed" (1885), which told of forming a company in Hannibal that tried to attach itself to the Confederate army but disbanded after two weeks when it could not find the main army. Mark Twain's testimony about Samuel Clemens, however, is not always reliable.

Journey west. Meanwhile, Orion Clemens, as a reward for his activities in Abraham Lincoln's presidential campaign, had been appointed secretary to the Nevada Territory. In the summer of 1861, Samuel accompanied his brother on a 21-day journey by stagecoach to the west. In Nevada, after unsuccessful stock speculation in mining and timberlands, and equally unsuccessful prospecting for gold and silver, he became a writer for the Virginia City *Territorial Enterprise*. He signed his contributions "Josh" and delighted in perpetrating such journalistic hoaxes as an account of "The Petrified Man" and "The Empire City Massacre," preposterous tall tales told so plausibly that other newspapers reprinted them as true.

Birth of "Mark Twain"

It was in Virginia City on February 3, 1863, that "Mark Twain" was born when Clemens, then 27, signed a humorous travel account with that pseudonym. The new name was appropriate, for it was a riverman's term for water that was just barely safe for navigation, and, as Huck Finn would later testify, "Mr. Mark Twain . . . he told the truth, mainly." In the spring of 1864, Clemens' redheaded temper and biting pen involved him in a quarrel with a rival editor, which made it advisable for him to leave Nevada for California. In San Francisco he met and was encouraged by the author Bret Harte and spent convivial evenings with Charles Farrar Browne, who, under the pseudonym Artemus Ward, was then one of the most popular American humorists and platform lecturers and who encouraged him to contribute to a collection of western sketches that he planned to publish. Clemens, however, had run afoul of the police because of articles he had written about political corruption in San Francisco, and he retreated once again to the Tuolumne Hills, where he did pocket mining at Angels Camp. With friends at nearby Jackass Hill, he heard the story that Mark Twain would make famous as "The Celebrated Jumping Frog of Calaveras County." He wrote it down as he had heard it and sent it to Artemus Ward for his collection, but it arrived too late and was printed instead in the New York *Evening Press*. Mark Twain, known in California as the "Washoe Giant, the Wild Humorist of the Sage Brush Hills," had now reached the East, and his fame soon spread.

Trips abroad. When, in 1866, the Pacific Steamboat Company inaugurated passenger service between San Francisco and Honolulu, Mark Twain took the trip as a correspondent for the *Sacramento Union*. His letters and the lectures that he later gave in California and Nevada about the trip were immediately popular. Since he enjoyed going places and talking about them, he set out again as "travelling correspondent" for California's largest paper, the *Alta California*; it was advertised that he would "circle the globe and write letters" as he went. The first leg of the journey was to New York by way of the Isthmus of Panama, and in June 1867 he took the excursion steamship "Quaker City" for a voyage to Europe and the Holy Land. The letters that he wrote during the next five months, for the *Alta California* and Horace Greeley's *New York Tribune*, caught the public fancy and, when revised for publication in 1869 as *The Innocents Abroad; or, The New Pilgrim's Progress*, established Mark Twain as a popular favourite. His seemed to be a new voice, authentically American in attitude and tone.

Career as a journalist

Family life and mature writing. But Clemens was restless still. He served briefly as secretary to a senator in Washington and then resumed his career as a public lecturer who charmed audiences with laconic recitations of incredible comic incidents. Meanwhile, he had met Olivia Langdon, the daughter of an established family in Elmira, New York. On February 2, 1870, they were married, and with money advanced by his father-in-law, Clemens purchased a partnership in the *Buffalo Express*. But sedentary work seemed confining and dull, so in September 1871 Clemens moved to Hartford, Connecticut, where he built a large and elaborate house in which he and his family would live for the next 20 years—the happiest and most productive period of his life.

Three daughters were born to the Clemenses. Hartford neighbours, at first aloof, proved finally charming. Authoress Harriet Beecher Stowe was among them, and Joseph Twichell, a clergyman for whom Clemens was to write a few years later the mildly scatological *Conversation, As It Was by the Social Fireside, in the Time of the Tudors* (*c.* 1880). The distinguished novelist and critic William Dean Howells was a frequent visitor from Boston and became a lifelong friend. In 1872 *Roughing It* appeared, a chronicle of Clemens' overland stagecoach journey more than ten years before and of his adventures among the Pacific islands. Meanwhile, he collaborated with his neighbour Charles Dudley Warner on *The Gilded Age*, a satire on financial and political malfeasance that, when published in 1873, gave name to the expansive post-Civil War era.

Using the pseudonym Mark Twain, he continued to lecture with great success in this country and, in 1872 and 1873, in England, holding audiences spellbound with his comic-coated satire, drawling cadences, and outlandish exaggerations. As a writer, however, his imagination temporarily flagged. At Twichell's suggestion, he recorded his experiences as a pilot in "Old Times on the Mississippi" for the *Atlantic Monthly* (1875), expanded eight years later to *Life on the Mississippi*, an authentic and compelling description of a way of life that was, even then, long past. After having written boyhood friends, asking them to send their recollections of old days in Hannibal, he published *The Adventures of Tom Sawyer* in 1876, a narrative of youthful escapades that became an immediate and continuing favourite. In 1878 and 1879 the Clemens family again travelled abroad. A walking tour through the Black Forest with Twichell provided much of the material for *A Tramp Abroad* (1880). A year later, in *The Prince and the Pauper* (1881), Mark Twain again captured popular fancy as he spoke once more of boyhood adventures, this time in old England, but with an undertone of social criticism that ridiculed the pretensions and achievements of monarchy.

Immediate success of *The Adventures of Tom Sawyer*

Mark Twain's books were handsomely made, profusely illustrated subscription books, sold by agents who circulated all through the country. They helped sell Mark Twain's lectures, and his lectures helped sell the books, earning for Clemens more money than any previous American author. Clemens, however, did not trust publishers. They were, he complained, scoundrels, intent on defrauding him, so in 1884, he established his own publishing firm, Charles L. Webster and Company, with a nephew titularly in charge. Webster's published the *Memoirs* of Ulysses S. Grant with great success in 1885 and in the same year published the American edition of Mark Twain's *Adventures of Huckleberry Finn*, the book on which his fame largely rests, although at the time it was considered by many to be vulgar and unfit for young readers. He followed *Huckleberry Finn* in 1889 with *A Connecticut Yankee in King Arthur's Court*, which celebrated American homespun ingenuity in contrast to the superstitious ineptitude of even a chivalric monarchy.

The popular image of Mark Twain was by now well established. He was a gruff, but a knowledgeable, unaffected man who had been places and seen things and was not fooled by pretense. He talked and wrote with contagious human charm, in the language of ordinary people. His prejudices, even his publicly exploited minor shortcomings—like smoking or swearing too much or staying too long in bed—were theirs. At the same time, he scornfully berated man as a poor creature who "begins as dirt and departs as stench," created for no purpose except the entertainment of microbes. Evolution failed, he said, when man appeared, for he has the only evil heart in the entire animal kingdom. Yet Mark Twain was one with

those he scorned: what any man sees in the human race, he admitted, "is merely himself in the deep and private honesty of his own heart." Perceptive, comic, but also bitter, Mark Twain seemed to be the mirror of all men. Samuel Clemens had made him well.

Financial difficulties. Clemens, who had speculated unsuccessfully in Nevada and California, began speculating again. In the late 1880s he had become an enthusiastic supporter of an inventor in Hartford named James W. Paige, who was developing a typesetting machine. For several years he gave large sums, sometimes as much as $3,000 a month, for its construction and improvement. By 1891 he began to feel the effects of his long-term investments and, in order to economize, closed the large Hartford house and moved with his family to Europe. In 1892 the Webster company published *The American Claimant* and in 1894 *Tom Sawyer Abroad*, neither of which was spectacularly successful. The company became more embroiled in financial difficulties. Leaving his family in Italy, Clemens made several trips to America in attempts to rectify his affairs and stave off what now seemed the inevitable failure of the Paige typesetting machines. In 1894 the Webster company filed assignment papers, and the typesetter, though ingeniously devised, failed to stand up in competition against another machine. Clemens was bankrupt and deeply in debt.

Friendship with Henry H. Rogers

Meanwhile, Samuel had met Henry Huttleston Rogers, a major executive of the Standard Oil Company, and an immediate friendship had sprung up between them. Though reputedly harsh in business dealing, in private Rogers was a kindly man, fond of horseplay, billiards, and yachting. He took over the management of Clemens' affairs, stood as a buffer between him and his creditors, and encouraged him to announce that Mark Twain would embark on a worldwide lecture tour, the receipts of which would be used to pay all his debts. He arranged to have Mark Twain's writings assigned to Mrs. Clemens so that income from them could not be attached. He managed Clemens' financial affairs, dissuading him from speculative investments, and put whatever money was available into solid stocks. He saw to the publication of *The Tragedy of Pudd'nhead Wilson* (1894), which is sometimes remembered as Mark Twain's second best novel, and *Personal Recollections of Joan of Arc* (1895), a book that Clemens thought so serious a revelation of what idealistic rectitude might accomplish that he refused to allow the name Mark Twain to appear on the title page, lest readers think it another comic narrative.

In the summer of 1895, Mark Twain set out on the lecture tour that took him as far as Australia and then back to London, where he received news of the death of his oldest daughter, Susy, the only member of the family who had not accompanied him. Grief stricken, the Clemenses remained abroad for five more years. Jean, the youngest daughter, was discovered to be incurably ill; Mrs. Clemens, never robust, was failing. Clemens himself became increasingly bitter. He described his lecture tour in *Following the Equator* (1897), dedicated to Rogers' son. Finally, in 1898, the investments made by Rogers and his management of Mark Twain's publications made Clemens financially solvent again. *The Man That Corrupted Hadleyburg and Other Stories and Sketches* was issued in 1900 by Harper & Brothers, soon to become the exclusive publishers of Mark Twain.

Last years. Late in that year, Clemens and his family returned to the United States. He was widely acclaimed as a man who had refused to bow to bankruptcy but had laboured diligently to pay every creditor every dollar he was owed. The Clemenses lived then in New York, where Mark Twain was greatly in demand as a speaker and where he associated on an intimate basis with Rogers and other wealthy magnates such as Andrew Carnegie, Henry M. Flagler, and William Rockefeller. Yale University conferred an honorary degree on him in 1901, the University of Missouri did the same in 1902, and Oxford University in 1907. In his mid-60s, he was a public hero, lauded and applauded. He spoke out frankly and bitterly on public issues. *To the Person Sitting in Darkness* in 1901 was a scathing indictment of imperialism. *King Leopold's Soliloquy*, published four years later, denounced the baseness of the white man's conduct in subduing the Congo.

In the fall of 1903, the Clemenses again left the United States and, because of Mrs. Clemens' health, settled near Florence, Italy. When she died six months later, Clemens was stricken with grief. *Extracts from Adam's Diary* (1904) and *Eve's Diary* (1906) are whimsical accounts of man's dependency on woman's superior management, and the books speak feelingly of the loneliness of life when a man must lead it alone. In *What Is Man?* in 1906, he fulminated desperately on what fate did to bungling man. Many of his later thoughts on human cupidity were, he thought, so severe that he speculated they could not be published until 100 years after his death. When most of them appeared in 1962 as *Letters from the Earth*, they did not seem as caustic or reprehensible as Clemens seems to have thought them to be.

Last works

In 1906 Clemens began to dictate his autobiography. Portions of it were selected for periodical publication, for enough money to allow Clemens in 1908 to build a new house in Redding, Connecticut, which he called Stormfield. This autobiographical material has been compiled by different editors and published in various volumes over the years to the present time. *Extract from Captain Stormfield's Visit to Heaven* in 1909 was a book over which Clemens had puttered for many years. Its rollicking burlesque humour barely disguised the author's tired despair of the "damn'd human race" of which he was an irrevocable part. He worked over drafts of *The Mysterious Stranger*, which was published in a somewhat garbled form six years after Clemens' death. Increasingly bitter, tired, a pampered public favourite, but in private a wounded lion whose growl grew fainter though not less menacing, he made several trips to Bermuda to bolster his waning health. He died at Stormfield on April 21, 1910.

Tylor, Sir Edward Burnett

Edward Burnett Tylor, one of the first and most eminent British anthropologists, is regarded as the founder of cultural anthropology. He was the first anthropologist to study man's cultural growth rather than merely his physical evolution, and the influence of his method is, in one form or another, felt to this day.

Tylor was born at Camberwell, London, on October 2, 1832, the son of a prosperous Quaker brass founder. He attended a Quaker school until he was 16, when, barred by his faith from entering a university, he became a clerk in the family business. In 1855, at the age of 23, symptoms of tuberculosis led him to travel to America in search of health. He made his way to Cuba in 1856, where, on a bus in Havana, by one of those chance occurrences that can determine the course of a man's life, he entered into conversation with a fellow Quaker, who turned out to be the archaeologist and ethnologist Henry Christy. Christy was on his way to Mexico to study remnants of the ancient Toltec culture in the Valley of Mexico. The two became friends, and Christy persuaded Tylor to accompany him on his expedition.

Travelling in arduous and sometimes dangerous circumstances, they searched for the Toltec remains, Tylor under Christy's experienced direction gaining practical knowledge of archaeological and anthropological fieldwork. The expedition lasted for six months, and after its conclusion Tylor, now firmly set on the course of his life's work, returned to England. In 1858 he married and spent some time travelling in Europe before publishing the experiences of his Mexican expedition in his first book, *Anahuac: or Mexico and the Mexicans Ancient and Modern* (1861). Although mainly a well-conceived travelogue, *Anahuac* contains elements that characterize Tylor's later work when he had become a full-fledged anthropologist: a firm grasp on factual data, a sense of cultural differences, and a curious combination of empirical methods with occasional hints of the superiority of a 19th-century Englishman in judging other cultures.

After *Anahuac*, Tylor published three major works. *Researches into the Early History of Mankind and the Development of Civilization* (1865), which immediately established his reputation as a leading anthropologist, elaborated the thesis that cultures past and present, civilized and primitive, must be studied as parts of a single history of human thought. "The past," he wrote, " is continually needed to explain the present, and the whole to explain the part." Tylor's fame, however, is based chiefly upon the publication of *Primitive Culture* (1871). In it he again traced a progressive development from a savage to a civilized state and pictured primitive man as an early philosopher applying his reason to explain events in the human and natural world that were beyond his control, even though his scientific ignorance produced erroneous explanations. Tylor identified, for example, the earliest form of religious belief as "animism," a belief in spiritual beings, arrived at, he assumed, by primitive attempts to explain the difference between the living body and the corpse and the separation of soul and body in dreams.

Publication of *Primitive Culture*

Primitive Culture also elaborates upon a theme that became a central concept in his work: the relation of the life of primitive to that of modern populations.

> By long experience of the course of human society, the principle of development in culture has become so ingrained in our philosophy that ethnologists, of whatever school, hardly doubt but that, whether by progress or degradation, savagery and civilization are connected as lower and higher stages of one formation.

Thus, "culture" should be studied not only in the artistic and spiritual achievements of civilizations but in man's technological and moral accomplishments made at all stages of his development. Tylor noted how customs and beliefs from a distant, primitive past seemed to have lived on into the modern world, and he became well known for his examination of such "survivals," a concept that he introduced. His evolutionary view of human development was endorsed by most of his colleagues and, of course, by Charles Darwin, who had established biological evolution as the key to human development. "It is wonderful," he wrote to Tylor,

> how you trace animism from the lower races up to the religious beliefs of the highest races. . . . How curious, also, are the survivals or rudiments of old customs.

Assessment

In the late-19th-century political and theological controversy over the question whether mankind belonged physically and mentally to a single species, Tylor was a powerful advocate of the physical and psychological unity of all mankind. "There seems to be no human thought so primitive as to have lost its bearing on our own thought," he wrote in *Primitive Culture*, "nor so ancient as to have broken its connection with our own life." But in this question, as in all anthropological disputes, he based his position on respect for empirical evidence, which he hoped would bring the standards and procedures of the natural sciences, including elementary statistical investigations, to the study of humanity.

His last book, *Anthropology, an Introduction to the Study of Man and Civilization* (1881), is an excellent summary of what was then known and thought in that field and, like all Tylor's work, conveys a vast quantity of information in a lucid and energetic style.

Tylor was made a fellow of the Royal Society in 1871 and given a doctorate of civil law at Oxford in 1875. Eight years later he returned to Oxford to give lectures and stayed there as keeper of the university's museum, becoming reader in anthropology in 1884 and the first professor of anthropology in 1896. He was also elected the first Gifford lecturer, a position created by the endowments of the Scottish judge Adam Gifford, at Aberdeen University in 1888. He retired from active life in 1909 and was knighted in 1912. He died at Wellington, Somerset, on January 2, 1917.

Typewriter

A typewriter is a machine for writing characters like those made by printer's type; when no more than a few copies are needed, it has the advantages of economy over typeset printing and of clarity and speed over handwriting. The typewriter consists of a keyboard that controls impressions made in any sequence from type arranged on separate rods or on the periphery of a disc, cylinder, or sphere. In the machine's early days the term typewriter was also applied to the operator; later the operator became known as a typist.

The typewriter was one of the great transforming factors of modern business. It also has had impact on education, communication, and even the arts, and it first opened to women the doors of business life.

History. The first recorded attempt to invent a typewriter may have been covered by a 1714 British patent for "an Artificial Machine or Method for the Impressing or Transcribing of Letters Singly or Progressively one after another, as in Writing, whereby all Writing whatever may be Engrossed in Paper or Parchment so Neat and Exact as not to be distinguished from Print." No drawings of this machine exist, and its construction is not known. The only other attempt recorded in the 18th century was a machine invented in France in 1784 for embossing characters for the blind. In 1829 a machine called a typographer was patented in the United States; it consisted of type mounted on a semicircular frame that was turned to bring the desired letter to the printing point and was then depressed against the paper by means of a lever.

The first practical typewriter. Several typewriter models followed, but, despite some improvements, such as the introduction of the cylinder, or platen, for holding the paper, none achieved practical success. Most were large and cumbersome, some resembling pianos in size and shape. All were much slower than handwriting in operation. Finally in 1867 the American inventor Christopher Latham Sholes read an article in the journal *Scientific American* describing a new British-invented machine and was inspired to construct what became the first practical typewriter. His second model, patented in 1868, wrote at a speed far exceeding that of a pen. It was a crude machine, but Sholes added many improvements in the next few years, and in 1873 he signed a contract with E. Remington and Sons, gunsmiths, of Ilion, New York, for manufacture. The first typewriters were placed on the market in 1874, and the machine was soon renamed the Remington. Among its original features that were still standard in machines built a century later were the cylinder, with its line-spacing and carriage-return mechanism; the escapement, which causes the letter spacing by carriage movement; the arrangement of the typebars so as to strike the paper at a common centre; the actuation of the typebars by means of key levers and connecting wires; printing through an inked ribbon; and the positions of the different characters on the keyboard, which conform almost exactly to the arrangement that is now universal. Mark Twain purchased a Remington and became the first author to submit a typewritten book manuscript.

Early typewriter, the Sholes and Glidden model of 1873.

The first typewriter had no shift-key mechanism—it wrote capital letters only. The problem of printing both capitals and small letters without increasing the number of keys was solved by placing two types, a capital and lowercase of the same letter, on each bar, in combination with a cylinder-shifting mechanism. The first shift-key typewriter—the Remington Model 2—appeared on the market in 1878. Soon after appeared the so-called double-keyboard machines, which contained twice the number of keys—one for every character, whether capital or small letter. For many years the double keyboard and the shift-key machines competed for popular favour, but the development of the so-called touch method of typing, for which the compact keyboard of the shift-key machines was far better suited, decided the contest.

Another early issue concerned the relative merits of the typebar and the type wheel, first used on the typographer of 1829 and applied in cylinder models brought out in the 1880s and later.

In modern machines of this variety the type faces are mounted on a circle or segment, the operation of the keys brings each type to correct printing position, and the imprint of type on paper is produced by a trigger action. The type-wheel machines offer an advantage in the ease with which the type segments may be changed, thus extending the range and versatility of the machine.

Following the first shift-key typewriter of 1878, the next great advance was visible writing. On all the early typebar machines the bars were arranged in a circular basket, located underneath the carriage, and the type printed at a common point on the underside of the cylinder. This construction compelled the operator to raise the carriage in order to see the writing line.

Introduction of visible writing

The first visible-writing machine appeared in 1883. The early machines employed the downstroke principle, the type striking on top of the cylinder. Later, the front-stroke machines took the lead in the general-business field; the first machine of this kind to attain prominence resulted from the work of John N. Williams, an American, in 1890. In front-stroke machines the typebars are placed in a segment in front of the carriage, and the type prints on the front of the cylinder. This solved the problem of visible writing, and all writing machines of the leading standard makes are of this type.

On nearly all typewriters the printing is done through an inked ribbon, which is fitted on spools, travels with the operation of the machine, and reverses automatically when one spool becomes completely unwound. On other machines an inking pad is used, the type contacting the pad prior to printing.

Noiseless typewriters. The noiseless linkage is a variation of the conventional typebar linkage causing the typebar to strike the platen at a lower velocity but with the same momentum. Although it produces less noise than the conventional typewriter, the noiseless typewriter cannot produce as fine an impression or as many carbon copies.

Electric typewriters. A significant advance in the typewriter field was the development of the electric typewriter, basically a mechanical typewriter with the typing stroke powered by an electric-motor drive. The typist

initiates the key stroke, the carriage motion, and other controls by touching the proper key. The actuation is performed by the proper linkage clutching to a constantly rotating drive shaft. Advantages of this system include lighter touch, faster and more uniform typing, more legible and numerous carbon copies, and less operator fatigue. Especially valuable as an office machine capable of a high volume of output, electric typewriters are produced by all major typewriter manufacturers.

The first electrically operated typewriter, consisting of a printing wheel, was invented by Thomas A. Edison in 1872 and later developed into the ticker-tape printer. The electric typewriter as an office writing machine was pioneered by James Smathers in 1920.

Spherical type carriers

In 1961 the first commercially successful typewriter based on a spherical type-carrier design was introduced by the International Business Machines Corporation. The sphere-shaped typing element moves across the paper, tilting and rotating as the desired character or symbol is selected. The motion of the element from left to right eliminates the need for a movable paper carriage.

Portable typewriters. The early portables of the late 19th century were slow, awkward, type-wheel machines. In 1909 the first successful portables appeared on the market. By the 1950s practically every typewriter manufacturer produced a portable typewriter; all of them were typebar machines similar in operation to the office machines. Designed with lighter parts than those of standard models, portables are more compact but less sturdy. Electrical operation of portable typewriters was introduced in 1956.

Modern developments. The inherent versatility of the typewriter, particularly the electric typewriter, has led to its application to many tasks once considered beyond its scope. One example is the accounting machine, which evolved from the typewriter; another is the adding machine. This office machine is capable of tabulating in vertical columns, performing arithmetic functions concurrently, as well as typing horizontal rows, thus performing complete bookkeeping functions. Its development served as a natural bridge for the entry of the typewriter industry into the data-processing, or computer, field. A typical device illustrating this outgrowth from typewriters to data processing is the paper-tape punch and reader. This machine is connected to a specially modified typewriter so that it may control the printing of the typewriter or may produce punched tape under control of the typewriter.

Typewriter composing machines. Special-purpose typewriting machines have been developed for use as composing machines; that is, to prepare originals that look as if they had been set in printer's type (or at least more so than ordinary typewriting does), from which additional copies can be printed. Ordinary typewriting cannot compare in quality, style, and versatility with printing from type produced directly on metal slugs by standard composing machines, but the high cost of skilled typesetting labour prompted the development of composing typewriters that require far less operator training. Since the fundamental requirement of a composing typewriter is the ability to supply different styles and sizes of type, the type-wheel machine is far more suitable than the typebar. Other major requirements of a typing machine whose output must resemble print are the proportional spacing of characters in a word (rather than centring every character within the same width, as in ordinary typewriting) and justification, or alignment of the right-hand margin. An electric typebar machine was developed that provided proportional spacing—assigning space for each character in proportion to its width. The other requirement, margin justification, proved more difficult to attain. Most of these machines provided for preliminary typing of a line, determining the necessary compensation for the line length, and retyping to the exact length. A more complicated machine was introduced that would automatically justify a line of type with one keyboarding. This was accomplished by a system in which the operator typed manually into a storage unit, from which a computer first automatically compensated for line length and then operated a second typing mechanism. By mid-20th century the typewriter had begun to be used as a composing machine in spite of its limitations, and it became more popular as improvements were developed.

Proportional spacing

Automatically controlled machines. One of the most important advances in the field of typewriters and office machines was the development of automatic controls that allow typing from remote electrical signals rather than from manual control. This technique enabled office-machine manufacturers to develop an integrated system of business communication utilizing remote-control typewriters and computer techniques. With such a system, machines handling all the different office-machine functions, such as the typewriter, calculating machine, and printing telegraph, together with mass data-processing computers and electronic storage systems, are tied together by the use of a "common language" in the form of coded electrical signals. This coded information, coming into an office via appropriate communication channels, can be automatically recorded and printed. Component machines produced by any manufacturer can be connected to any other without the use of special code converters. Other automatic typewriter devices also have become available. A vacuum-operated system, for example, controls and operates any number of standard typewriters from a perforated roll of paper tape, much like the player piano, making possible rapid production of form letters and other papers.

High-speed printers. The need for high-speed printing machines to convert the output of computers to readable form prompted the introduction of a specialized high-speed form of "typewriter" in 1953. In this class of machines, the paper is fed between a continuously rotating type wheel and a bank of electrically actuated printing hammers. At the instant the proper character on the face of the type wheel is opposite the proper hammer, the hammer strikes the paper and prints the character, while the type wheel continues to rotate. By this means, speeds up to 100,000 characters per minute have been attained, as compared with about 1,000 characters per minute attainable with conventional typebar mechanisms. A number of different models operating on this principle were developed; all of them required elaborate electronic controls to solve the complex synchronization problem. Many other high-speed-output devices for computers were developed. Most of them utilize techniques that are remote from the typewriter field, in some cases using printing mediums other than paper. Speeds of up to 10,000 characters per second were attained by certain non-mechanical systems, which, although not actually typewriters, compete with typewriters as computer-output devices (see also COMPUTERS).

Typography

Typography as an art is concerned with the design, or selection, of letter forms to be organized into words and sentences to be disposed in blocks of type as printing upon a page. Typography and the typographer who practices it may also be concerned with other, related matters —the selection of paper, the choice of ink, the method of printing, the design of the binding if the product at hand is a book—but the word without modifier is most usually taken to refer to the activities and concerns of those most involved in and concerned with the determination of the appearance of the printed page.

Thus understood, there was by definition almost—but not quite—no typography before the invention of printing from movable type in the mid-15th century; and, thus understood, it is only by analogical extension that the term can be applied, if ever it can be, to "reading" in which the material at hand is something other than words

that remain stationary on flat firm surfaces. The electronically created letter that lives out its brief life while moving across the face of a signboard or a cathode-ray tube is not a typographic item. Typography, then, exists somewhere between the extreme of manuscript writing, on the one hand, and the transient image on the electronic device, on the other hand. Whether the letter be made by metal type or photographic image is no longer important in defining the subject; whether the finished item is a book or a page influences its inclusion as typographic not one bit.

The nature of typography

TYPOGRAPHY AS A USEFUL ART

An overview of typography suggests that a number of generalized observations may be reasonable:

Relationship between typography and communication

First and most important, typography and printing, the mechanical processes by which the plans of the typographer are realized, are useful arts. Though there is indeed fine typography, typography is not a fine art. Books, the primary source of typographic examples, are written in the main by people with something to say; they are selected for printing in the main by publishers who see merit and hope for profit in disseminating the statements of the writers to an audience; properly they are edited and designed and printed in the main by craftsmen whose boundaries are fixed for them by considerations germane to the needs of the writers to communicate and the needs of the readers to understand and appreciate. The typographer exists not to express his own design preferences, his own aesthetic needs, but to provide a useful (because usable) connection between someone with something to say and someone to say it to.

But to say—as did the late Beatrice Warde, one of England's great typographic authorities—that printing ought to be invisible is not to say that the typographer has no contribution to make; to say that typography is a functional art and as such ought not to get between the writer and the reader is not to say that there is only one solution to every typographical problem, that aesthetics, taste, personal judgments, and imagination cannot find room for expression in the typographic studio.

Nonetheless, there are limitations to what the typographer may and may not do; for, in addition to being a useful art with the generally accepted first use of transmitting information, typography for at least three reasons is a secondary art.

First, it is secondary in that its basic materials, the alphabets or other similar notational systems with which it works, are not of its own invention. The impact of this fact on the art form is obvious. Generally speaking, Western writing, or printing, is accomplished by the use of a relatively small number of individual letters capable of being grouped in almost infinite numbers of meaningful permutations. Even in the face of language differences, there is a wide carry-over of letter shapes and typefaces from one language to another. Because the number of images (letters) to be designed is limited and entirely manageable, the type designer's job is made less difficult. The language carry-over makes possible the establishment of meaningful typologies, the evolution of international styles and conventions, and the development of criteria and traditions of taste by which typographers improve their work. As the result, it is fairly certain that in a little more than 500 years of printing history since Gutenberg, at least 8,000 and very probably 10,000 or 11,000 typefaces have been designed. The practicing typographer has, then, a vast number of types to choose from, and, because the best of those types have evolved within cosmopolitan traditions and have stood the test of judgment by many people in many places over many years, there are, within the several thousands of types available, many that are of unquestioned excellence.

By way of contrast, the Japanese method of writing and printing involves a combination of three systems—some 3,000 kanji (symbols based on Chinese characters) and two groups of phonetic symbols (hiragana and katakana) each of which consists of 48 separate symbols. The problem of individually designing some 3,000 symbols, some of them of incredible complexity, is not one that many designers are able to surmount in a lifetime. As a result, to all intents and purposes, Japanese typographers have had only two typefaces to choose from—*mincho*, roughly equivalent to the West's roman (see below), and Gothic, functionally a Japanese sans serif (see below). In the 1960s a group of Japanese designers produced a third typeface called Typos.

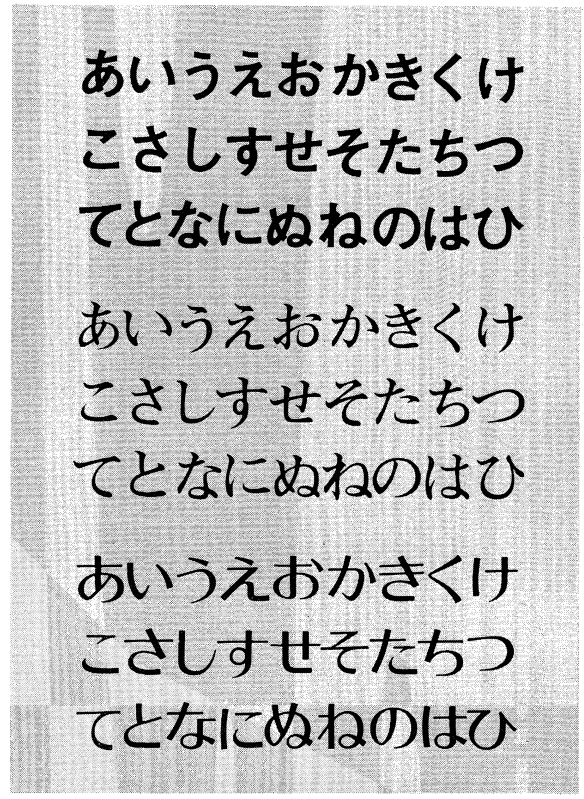

Figure 1: *The three Japanese typefaces.* (Top) Gothic, (centre) *mincho,* and (bottom) the new Typos.

Reading conventions and typography

Second, the typographer is limited by reading conventions over which he has little or no effective control. The appearance of a book page, whether well or badly designed, is governed more by the fact that Western readers begin at the top left of a page and read right, a line at a time until they get to the bottom, than it is by the aesthetic desiderata of the designer. Many typographers have long been attracted to the clean and uncluttered look of so-called sans serif type (the two little bases on which the vertical elements of the lower case "n" rest are serifs, as are the backward pointing slab atop the lower case "i" or "l," and sans serif types are those in which such embellishments are lacking [*T l*]). But the difficulty is that

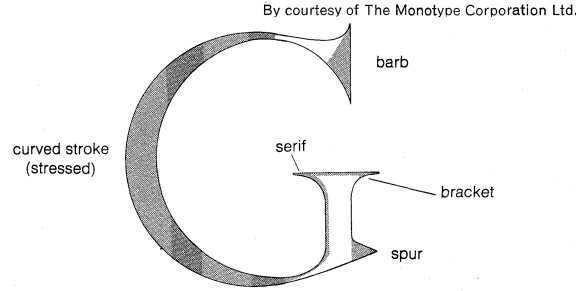

Figure 2: Typeface nomenclature.

almost every study ever completed has indicated that sans serif type is less easy to read in text than is type with the serif. It may well be that if Western texts were printed vertically, from the bottom of a page to the top and read upward so that each letter occupied a separate line with no horizontal connection to those before and after it, the

apparent advantage of serif types in this regard might disappear.

To consider another example of the restrictions put on the typographer by the necessity of working with the reading conventions, it is arguable that the appearance of the printed page would be changed and one of the petty annoyances of reading—"doubling," in which the eyes finish a line and then return to the left margin and begin the same line all over again—could be eliminated if people could be persuaded to accept the following reading pattern:

Typography as an art is concerned with the design,
into organized be to forms letter of ,selection or
words and sentences to be disposed in blocks of type
.page a upon printing as

or

Typography as an art is concerned with the design,
otni dezinagro eb ot smrof rettel fo ,noitceles ro
words and sentences to be disposed in blocks of type
.egap a nopu gnitnirp sa

But the fact, of course, is that the problems involved in winning acceptance of any change as fundamental as this one would appear to be so numerous and so substantial as to preclude its further consideration by any but writers of typographical journal articles or textbooks. Basic changes in the format of written text attributable to the typographer or, his earlier form, the printer-typographer, have been few, though occasionally dramatic, as in, for example, the practice of separating succeeding sentences with periods or of separating paragraphs (which in handwritten manuscripts were separated only by the insertion of the scribe's paragraph mark without the initiation of a new line or indentation).

Third, it would appear to be reasonable to call typography a secondary art because, just as the typographer uses letter forms and reading conventions over which he has had little control, so too what he contributes comes into being only through the intervention of a mechanical process that, as often as not, in the 20th century at least, has become the province of the printer, so that the typographer practices his art at least once removed from its final production. The extreme example of the impact of such a situation may have been seen in the early years of computer-generated typefaces in which, many felt, most faces revealed quite clearly that they had been developed by specialists whose first capabilities were not in the field of typography. And when typographers were later introduced into the process, they found that they had to work through the electronics expert, even as, for many years, those unable to cut their own type had been forced to work through typefoundries.

Dependence upon a mechanical process

It will already have become apparent that there is, at the worst, some confusion and, at the least, some lack of uniformity involved in talking about typographers and typography. The words themselves are of relatively recent origin and have been used self-consciously in their contemporary sense only from about the mid-20th century. The difficulty is, of course, the matter of the process involved. Gutenberg was his own typographer. It may well be, in fact, that his major personal contribution to the invention of printing was the development of a way to cut and cast type so that after the shape of the letter had been fixed and the molds prepared each letter form might be replicated over and over again in one relatively simple process. He was also the publisher, who undertook to risk capital in the selection and preparation of material to be printed for sale; he was presumably the man who designed the layout of each page; he may have done whatever editing was required, and he certainly either printed or supervised an assistant in the printing of the finished product. In the course of years many of the functions at first performed by one man came to be divided among several. Quite early, some printers employed men to cut type to their design; others employed men to design and cut the type; some held their services out for hire to others who became publishers; editors were separated from the process, though not always from decision-making roles in the appearance of the final product. After the introduction of bound volumes, trends were initiated that led eventually to the creation of binding designers as separate artists; it became not uncommon to find persons performing services as book designers and, as such, responsible for coordinating and leading the work of type designers, layout artists, binding designers—all who were in any way responsible for the appearance of the book as a whole. The situation became further clouded by the great variety of practice as to the status of each of the persons who perform one or more or, in some cases, all of these functions. They may be professionals retained by printing concerns for a single project; they may be full-time members of a corporate printing staff; in some very few cases they may be a single artist-craftsman-patron carrying out all of the functions in operations (usually necessarily small) devoted self-consciously to the production of "fine books."

Function of the book designer

Parenthetically, it is significant to note that, in general, the major examples of really fine typography—the significant developments that have raised the possibilities for the improvement of the typographic arts and, in fact, a preponderance of the typographic examples held up as outstanding—have been produced by publisher, printer, and typographer all working within the normal day-to-day requirements of their regular operations. Such a statement must not, however, be taken as dismissing the outstanding services rendered by the best work of the so-called private presses and by the valued demonstration volumes produced in limited numbers by major presses such as the Cambridge University Press in England, in holding up to view the best that the craft is capable of and thus serving as models for the craft itself.

AESTHETIC QUALITIES OF THE TYPOGRAPHIC PAGE

Confusion notwithstanding, the typographer as he is most generally understood is responsible—whether or not he does all of the work himself—for the appearance of the printed page, and his work is best seen in the several examples of the printed page that are used to illustrate the present article.

The typographic page may be considered in terms of two aesthetic qualities. The first of these has been called "atmosphere," "feel," "impress," "sense," and other similar terms. It is easier felt than defined, and it depends in large measure on such things as the size of the block of type, its placement on the page, the kinds of display letters used for titles, running heads, and subheads, and the size of the margins—all elements that in the hands of a competent typographer create an expectation regarding the contents (possibly even the purpose) of the page and lead to a sense of the time of its production, its seriousness, and its function.

The second aesthetic quality is that of colour, the darkness or lightness of the block of type sensed somehow as a whole rather than as a collection of individual letter forms with substantive meanings. Colour is the result of letter shapes, distances between letters and between words, the amount of space left between lines, the inking of the type, the printing process employed in making the impression on paper, and the paper itself.

Design of the letters

Of all elements the design of the letters is, in the dominant view, the most important. It is important that early typography was in fact overtly engaged in the explicit search for typefaces that would mechanically reproduce the written scripts in which, before the invention of printing, books had been prepared. For most of its life since the invention of printing with movable type in the mid-15th century, typography in the West has been dominated by three type families—roman, italic, and black letter (see below). All are easily recognizable as refined and regularized versions of letter styles first developed and standardized by scribes. The debt of sans serif, more a subclass than a family, is apparent but less unequivocal.

To divide the several thousand typefaces that have existed since Gutenberg into three major families is only the grossest type of classification, and historians of typography, like teachers of typography, have found it useful to set up other classifications. Unfortunately, but not unexpectedly, they have not found it possible to agree on a system of classification. The variety of proposals has been

so bewildering as to defeat one of the first purposes of classification. Some have concentrated on the influence of seminal workers in the field and talk of "Caslon's," "Bodoni's," etc. Others have concentrated on the major uses or types of literature from which various dominant types have come and talk, for example, of Humanistic faces. Other systems have employed nomenclatures that emphasize the early manuscript models from which a face evolved or a national influence. In attempts to meet a growing need for standards that can be applied more rigorously in legal and commercial and technical bibliographical uses, some countries and some craft associations have tried to develop classification schemes based on precise, in some cases almost mathematical, descriptions of the various elements of letter shapes. These schemes are not as yet worked out to the satisfaction of all concerned and are matters of some controversy, even among those who applaud the aims.

The system that has enjoyed the longest general favour and seems to be about as useful as any other divides typefaces into four classifications. Unfortunately, though the classifications are based as much on differences in letter styles as on chronology, the names given each suggest a temporal alignment and one that is, at first glance, confusing.

The first of these is called in most places old face—though Americans sometimes call it old style. In general, old faces were largely those types developed from *c.* 1722 to *c.* 1763 (dates of William Caslon and John Baskerville). Their letter forms had marked affinities with the penned letter styles of the scribes: they tended to squareness, there was little contrast between the thick and thin strokes, the stresses (the thickest part of the curves in a letter) were heavy and tilted or slanted, and the serifs tended to be full or thick and had brackets—gracefully rounded curves where they joined the letter body proper.

The second classification is usually described as transitional and, as its name suggests, came more or less between—and had letter styling midway between—old face and modern.

So-called modern types were produced between *c.* 1788 (date of Giambattista Bodoni) and approximately 1820, when type design almost everywhere went into a major decline. Modern faces in general share characteristics resulting from the engraver's tool rather than the pen. There is a marked contrast between the thick and thin strokes of the letter, the thins in particular being almost exaggeratedly thin, and the change from thick to thin is sudden and pronounced; serifs tend to be thinner and somewhat longer, and the stresses are less pronounced and are vertical rather than tilted. The effect is that of a letter less square, more up and down, than old-face letters, with lines more sharply defined.

Old style faces

The classification called old style or, in America, modernized old style is reserved for revivals of old faces undertaken by contemporary type designers, a practice typified by the important work of one of England's truly prestigious type designers, Stanley Morison. It is necessary to establish a special classification for such types because in each case the modern reworking, while it owed much to the original, was in fact sufficiently different to be a new creation in its own right.

It is worth pointing out once more that typefaces are assigned to one or the other classification on the basis of the style in which their letters are drawn and not—despite their time-oriented designations—by the year of their creation.

Finally, and although this is not the place for a detailed history of the evolution of the written letter forms on which printing depends, it is significant that models for all three major type families were in use before the invention of printing by movable type: in England and Germany, a handwriting that was symmetrical, elongated, spiky, magnificently decorative, and difficult to read, not unlike certain parts of letters called today Old English, German script, and Gothic, was to be the origin of black type; in Italy and Spain, a free, open, square, uncluttered writing, not too far from the letter forms regularized by a decree of Charlemagne in the late 8th century, is recognizable today as the seed source of roman type; and a slanted, cursive, more hurried form of the same—from which it evolved by chancery scribes whose work required speed in handwriting—is easily seen to be the origin of italic.

The ready availability of serviceable letter models freed typography from the necessity of creating its own prototypes and left it able to spend its creative impulses in other ways. So well did it succeed that, within the first few decades after Gutenberg, it had brought forth almost every major development that it was to contribute and, in fact, had established itself so well that it may be fair to say that, until the 20th century, the art was a static one for all but the first 50 years of its existence. Further, the fact that the art form could take its basic ingredients from existing sources gave it a stability that it would not otherwise have had. Since it was unnecessary to wait while various producers in various countries came to agreement on which letter shapes to adopt or what reading conventions to employ, the typographer was enabled to get on with the work of overseeing the printing of books for distribution on a scale never before envisioned. The impact on the Renaissance was of incalculable importance if, indeed, it was not one of a cause and effect relationship.

History of typography

TYPE, FROM GUTENBERG TO THE 18TH CENTURY

Whatever else the typographer works with, he works with type, the letter that is the basic element of his trade. It has already been said that there have been but three major type families in the history of Western printing: (1) black letter, commonly and not quite rightly called Gothic by the English; (2) roman, in Germany still called by its historical name of Antiqua; and (3) italic. All had their origin in the scripts of the calligraphers whose work printing came ultimately to replace.

Calligraphy is dealt with at length in other articles (see further CALLIGRAPHY: *Paleography*). It is necessary here only to provide a context for the evolution of the typefaces of the printer's font. The basic letter forms of the Latin alphabet were established by the classical imperial capital letters of 1st-century Rome. Lowercase letters emerged only slowly, with their most vigorous development coming between the 6th and 8th centuries.

Charlemagne, in order to encourage standardization and discourage further experimentation, ordered his educational program for the Holy Roman Empire to be written in a script consisting of roman capitals and a specific form of minuscules (lowercase letters) known as Caroline. The uniformity thus achieved was short-lived. Under the impact of the national and regional styles of the scribes who worked with the alphabet, the letters—clear, simple, and somewhat broad by today's standards—were gradually compressed laterally, until, by the 11th century, the curves had been converted to points and angles, and the body of the letter had been made thinner while the strokes of which it was composed had been made thicker. This was black letter. By the 15th century it had completed its evolution into the formal, square-text Gothic letter.

First model for printer's type

It was this formal black letter that provided the first model for printer's type when printing was invented. It served well in Germany, but when printers in Italy, in part under the influence of the Humanist movement, turned to the printing of Latin texts, they found the pointed elegance of the Gothic letter out of keeping with the spirit of Humanism. For these works, they went back in calligraphic history to a time when the text had been less open than the first Caroline alphabet but more rounded than the narrowed, blackened, and pointed Gothic that it had become. When the printers Konrad Sweynheim and Arnold Pannartz in Subiaco, Italy, brought out an edition of Cicero in 1465, they used a typeface that was explicitly intended to be, but was not, a printed copy of the text of Cicero's own time. To distinguish this type from the Gothic that was more "modern" in the 15th century, the Italians called it Antiqua. Known today as roman, it spread rapidly throughout western Europe except in Germany, where the Humanist movement was blocked by the counter-impulses of the Reformation. There, Gothic type was accepted almost as a national typeface until 1940, when its discontinuance was ordered.

It is notable that most early printers continued for many years to use the Gothic type for non-Humanist texts, ecclesiastical writings, and works on law. In Spain, Jacob Cromberger printed books in which the text was set in roman and commentary on the text in Gothic.

Like the Gothic and roman, the third great family of types had its origins in the writings of the scribes. The italic and the Gothic Schwabacher, which serves as a kind of italic to Fraktur (as black letter is known in Germany), both had their genesis in the fast, informal, cursive, generally ligatured letters developed by chancellery clerks to speed their work.

The early years. *Germany: Gutenberg.* The 11th edition (1910–11) of *Encyclopædia Britannica,* not uniquely in its day, gave the honour of inventing the printing press to Laurens Coster of Haarlem. Later research and more or less common consent today give it to Johannes Gutenberg (*q.v.*), a Mainz goldsmith. Actually, the amount of invention involved in the development is open to argument. Certainly, there was in the air at the time much interest in an artificial method of reproducing calligraphic scripts, and books had already been printed from blocks; the techniques necessary to the punching of type and the making of matrices from which to cast it were known to the metalsmiths; paper was replacing vellum; and wine, oil, and cheese presses were well available as adaptable models. It remained only for someone to combine what was in existence or clearly capable of creation.

Gutenberg began his experiments around 1440 and was ready to put his method to commercial use by 1450. In that year, facing the need (not unknown to later printers) for financing, he borrowed from Johann Fust. About 1452 he borrowed once more from Fust, who at that time became his partner. The only extant printing known for certain to be Gutenberg's is the so-called 42-line (the number of lines in each column) Bible, completed in 1456, the year after Fust had foreclosed on his partner and turned the business over to his own future son-in-law, Peter Schöffer. Experts are generally agreed that the Bible displays a technical efficiency that was not substantially bettered before the 19th century. The Gothic type is majestic in appearance, medieval in feeling, and slightly less compressed and less pointed than other examples to appear shortly.

The Gutenberg Bible

The 42-line Bible, like the other works of its day, had no title page, no page numbers, no innovations to distinguish it from the work of a manuscript copyist—this was presumably the way both Gutenberg and his customers wanted it.

Some five years later, also in Mainz and quite possibly from the re-established printshop of a refinanced Gutenberg, there appeared the *Catholicon,* notable among other reasons for its early use of a colophon, a tailpiece identifying the printer and place of printing, and for the slight condensation of its type—a move toward more economic use of space on the page and greater type variety in printing.

While not all early results of the printer's art were accepted in all quarters (in 1479 the cardinal who later became Pope Julius II ordered scribes to copy by hand a printed edition of Appian's *Civil Wars* as printed in 1472), they were generally well received by a basically conservative literate public that wanted reading matter in clear, legible, compact forms and in quantities greater than, and at prices less than, would have been possible for the copyists of the day. Within 15 years of the 42-line Bible, the printing press had been established in all of western Europe except Scandinavia.

Italy. When printing moved outward from Germany, it established itself first in Italy, where it was nurtured by German and German-trained craftsmen. Sweynheim and Pannartz (mentioned above) were the first printers in Italy. They opened their press in Subiaco in 1465 and almost immediately produced a Cicero (*De oratore*) printed in an early and interesting Antiqua type that would with time become roman. (This, rather than a type cut by another German, Adolf Rusch, in Strassburg in 1464, is generally credited with being the initial roman simply because to most modern eyes its connection with the later face seems more clearly demonstrable, less tenuous. Indeed, more conservative theorists are not entirely convinced that even the Subiaco type was close enough to roman to be so called, except in the light of very informed hindsight.)

First press in Venice

The brothers Johann and Wendelin von Speyer (sometimes called da Spira and sometimes of Spire) opened the first press in Venice in 1469 and, until Johann died in 1470, had a one-year monopoly on all printing in that city. They used a clear and legible typeface that represented another step toward the contemporary roman. Whether or not these earlier types were really roman, there would seem to be no reason for putting the production of the first clearly recognizable roman any later than the work of a Frenchman, Nicolas Jenson, who had learned printing in Germany and set up business in Venice at about the time the von Speyer monopoly ran out. An excellent idealization of the roman typeform, Jenson's type was cut for an edition of Cicero's *Epistolae ad Brutum,* printed in 1470. It has been described by most modern critics as an elegant cutting, and one—Stanley Morison—called it perhaps the most perfect roman face ever cut. The expertness of the work may be attributed to Jenson's training as a medalist before becoming a printer. It is notable that Jenson never used his roman type for the printing of ecclesiastical or legal works—for which various versions of black letter were to remain standard.

By all measurement the commanding figure in late-15th-century typography was Aldus Manutius, also in Venice. Manutius established his business around 1490 and, by 1495, was issuing a series of Greek texts, notable more for their editorial authority than for their typographical excellence. Manutius was his own editor. His type designer and cutter was Francesco Griffo of Bologna, who made two major contributions: he drew on pre-Caroline scripts as the inspiration for a more authentic roman type that soon displaced the Jenson version; and, for what was to become the most important series of books in its time, he cut the first example of the cursive type now known as italic. It was, in the opinion of some critics, not a very good italic face, and it has been described as more a slanted roman than an italic. Nevertheless, it was the first of a new family of typefaces. Interestingly, it was at first a combination of new-face lowercase letters with roman uppercases. Equally interesting, the entire text of the Aldine books for which it was used were set in the new type. Not until 1550 did it become what it is today, a special-function type.

The books for which this new type—based on a chancellery (*cancellaresca*) cursive—was first cut consisted of a spectacularly successful series of Latin texts initiated in 1501, with Virgil's works as the initial release. The series was planned deliberately to interest a market of new readers—Renaissance men who were hardly interested in liturgical writings or Greek classics but who had instead the Humanist's passion for the Latin writers, with whom, somehow, they associated themselves. To fill that market,

Manutius projected a series of books compact enough to be carried easily, set in type that was both economical and highly readable, edited with scrupulous accuracy, and sold as inexpensively as possible. With Griffo's cursive type as the base, the problems of size and readability were both solved; and, by increasing the normal print run to 1,000 copies per edition, the economics were rendered more favourable. They were, indeed, the first pocket-book best sellers, and they were what would today be called an instant success. The volumes were sought after throughout Europe, as much or more for their scholarly authority as for the excellence of their typography. New volumes were issued every two months for the next five years, and Manutius early had the honour, but dubious pleasure, of being pirated.

First pocket-book best sellers

The continuity implicit in the work of Manutius and others during this period destroys the value of that older approach to the history of typography that isolated everything printed from 1455 to 1500 as incunabula. The year 1500 did not provide a genuine dividing point, and later historians have generally marked the end of the first valid "period" in typographic history at around 1540, after which the importance of experiments with typefaces tended to be ignored, if not disapproved of.

France. In Germany and in Italy, the many centres of printing grew up for the most part in the centres of commerce. But in France—where printing was from the first a sponsored activity—there were only two such centres: Lyons, from which significant printing largely disappeared after the Inquisition; and Paris, where it was established *c.* 1470 by the rector and librarian of the Sorbonne, who invited three German printers to occupy university-owned property and who later supervised all of their work. The first book printed in France—a manual of instruction in Latin composition—was printed in an Antiqua type, and, though there is some history of the use of a mixed Gothic until about 1520, France from the start led the way to the victory of roman and italic. Important influences in effecting the almost exclusive use of roman type were the printers Simon de Colines, Henri and Robert Estienne, Geoffroy Tory, and the man who was the world's first commercial typefounder, Claude Garamond.

Perhaps because of the quasi-official nature of printing in France, French publishers early established and long maintained a reputation for careful and elegant work. Their volumes, sumptuous more often than not, were characterized by minute attention to almost extravagant

detailing. Books of the hours, introduced by one Antoine Vérard, whose tastes ran to illustrated and heavily ornamented pages bound in deluxe editions, were important influences in these directions. It is estimated that Vérard published over 200 of these editions in a little more than 25 years, beginning in 1485. They are precise, mannered, delicate, and elegant.

The work of Henri Estienne

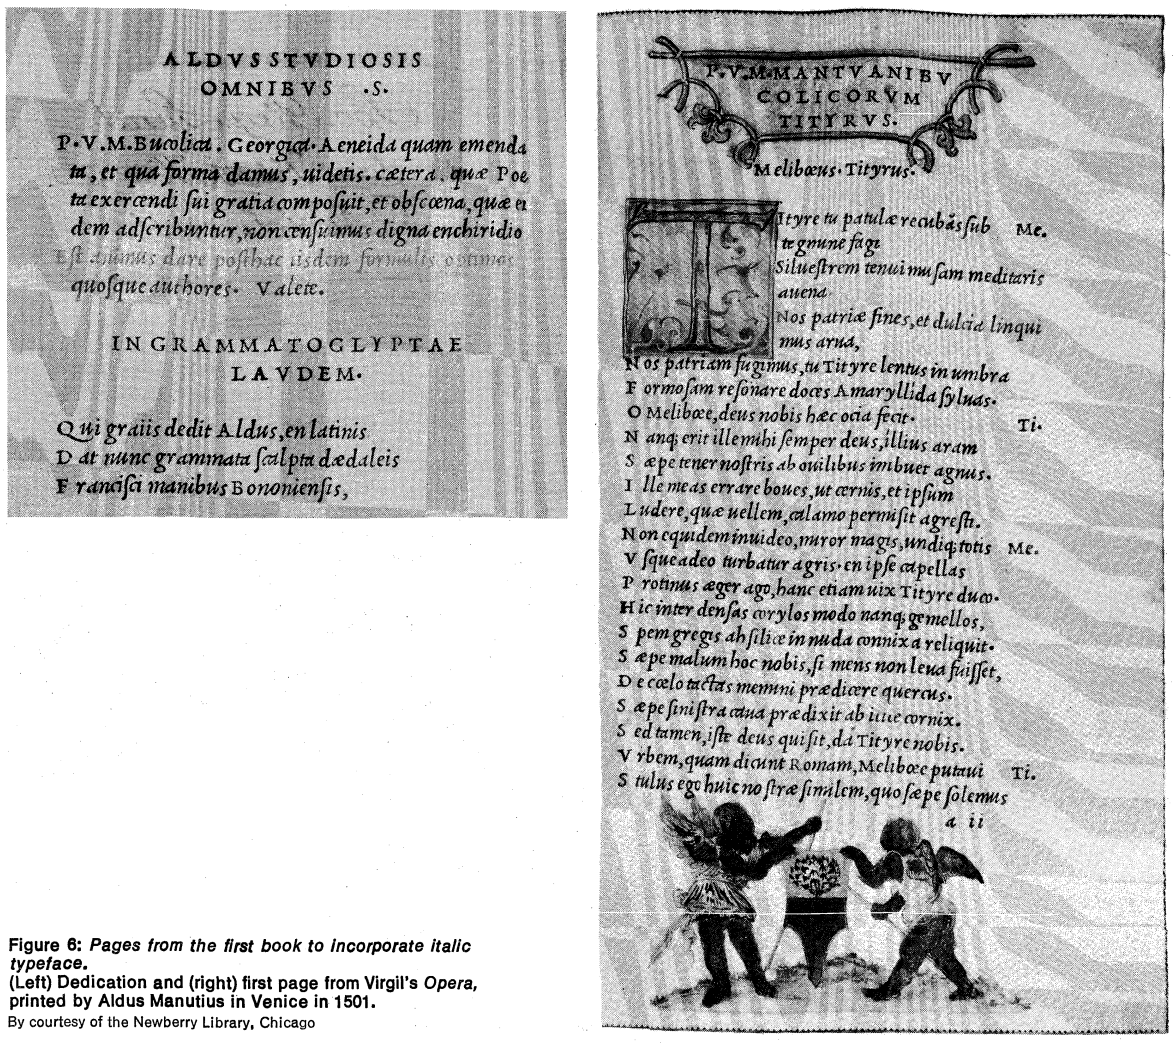
Henri Estienne established himself sometime around the beginning of the 16th century. A scholar, publisher, and printer, he gained his reputation as a publisher of classical literature. His edition of Galen's *De sectis medicorum* is an interesting early scientific work. Estienne, for a time, had as his adviser Geoffroy Tory, a scholar who later became a printer himself. Strongly influenced by Italian typography, Tory experimented with the use of floral ornamentation and ornate initial letters. In 1529 he wrote the first known treatise on the design of type, and in 1530 the title king's printer was created for him.

Tory, Colines, and a few others introduced the Aldine publishing methods into France. Colines designed italic, roman, and Greek type fonts, some of which were cut for him by his punch cutter, Garamond. In 1531 they created, for an edition of St. Augustine's *Sylvius*, the roman typeface to which all later so-called Garamond typefaces are traced.

As the first commercial typefounder, Claude Garamond was a major force in making well-designed and superbly cut types available to printers, including those who could not have afforded the services of capable cutters. Though Garamond's efforts with a Greek font were not notably successful, his French versions of the roman type of Manutius and an italic type of Ludovico degli Arrighi (an official in the apostolic chancellery who soon after 1522 had produced specimen pages of a type based on the cursive letters of the chancellery clerks) were of commanding importance in European typography until the end of the 16th century. In 1540 Garamond perfected a roman type that, though it had affinities with the lettering of scribes, was designed unmistakably for mechanical reproduction. It was sharply drawn, graceful and of good contrast, and it soon displaced most other typefaces then in use. It ushered in the new era in which, for the first time, the typographic book was more common than the manuscript one.

From the middle of the 16th until well into the 18th century, if not later, the most notable type designers in Europe were important more for their refinements on Garamond's modifications of earlier faces than for innovations of their own. One of the very few who attempted new departures was Robert Granjon, who, in addition to some notable versions of Garamond types, also tried—with his type called Civilité—to create a fourth major typeface to be different from and stand alongside roman, italic, and Gothic. He envisioned it as a national type for the use of French printers. Reminiscent of a cursive Gothic, it ultimately found its only acceptance as a display face for nonbook use.

Introduction of printing to England by William Caxton



England. Printing was introduced into England near the beginning of the last quarter of the 15th century by an Englishman who had travelled to Europe to study the art —William Caxton, a gentleman and dilettante. He studied printing, it is said, so that he would be able to print his own translation of a French work—Raoul Le Fèvre's *Recueil des histoires de Troye*—exactly as he wanted it to be printed. Setting up in business in Bruges in 1473, he issued the ***Recuyell***, the first book printed in English, about 1475; in 1476 he returned to England and established a press in Westminster. The first dated book printed in England was the *Dictes and Sayenges of the Phylosophers*, issued from his press in 1477. Printed in black-letter type of an almost startling blackness, its pages command attention by means of a contrast too pronounced to be comfortable to the reader. Caxton printed some 90 books—70 of them in English—before turning his business over to Wynkyn de Worde, his former assistant. De Worde used the first italic type in England in 1524.

Stanley Morison is authority for the statement that English typography in the first 100 years after the invention of printing was of a secondary order except for the work of Richard Pynson, a Norman who operated a press in London from 1490 to about 1530. Pynson, who used the first roman type in England in 1518, issued over 400 works during his approximately 40 years of printing. Of these, a substantial number are legal handbooks and law codes, on the printing of which he enjoyed an effective monopoly.

Maturation of the printed book. Well before the end of the first century of typography, the printer had brought to the book the basic forms of nearly every element that he was to contribute. The styles of the three major typefaces had been formalized to the point at which little other than refinement remained to be added to them; most of the business and craft functions that were to mark the production of books down to the present had been identified and differentiated; the printed book had achieved an acceptance comparable to, and an audience far greater than, that of the manuscript volume; and publishing specialties had already emerged. Fully one-third of all of the books printed during the period of the incunabula—that is from the 1450s to 1500—were illustrated. The printing of music had become practical, and the practice of numbering the pages of a volume in sequence had been adopted.

The printer's mark

The printer's mark, an identifying device, was used—though only briefly at first—in the typographic book from the very beginning. Almost as early, and probably more important, was the typographer's addition of the colophon, in which the printer-publisher recorded the place and date of publication, asserted his claim to credit for his role in the production of the work, advertised the merits of the enterprise, and, on occasion, attempted to protect his property from the depredations of rival printer-publishers. Indeed, Caxton turned the colophon into a short essay in which he included, in addition to the normal elements, an editor's preface and a dedication. Whether or not it is accurate to assert that the title page —the major nonmanuscript feature of the typographic book—emerged from the colophon, it is a fact that the

title page took over some of the content of the colophon, which, however, continued to exist.

The first title page was probably used by Gutenberg's successor, Peter Schöffer, in 1463 on a papal bull. It was Schöffer's only known use of the device, and, like the other early versions that followed, it was really—in today's terms—a half title. The full title page did not appear until 1476, when one Erhard Ratdolt in Venice used it on an astronomical and astrological calendar. The device was well established by the end of the incunabula period. Continuing the tradition of relative anonymity of authorship of the manuscript books, the earliest pages never, and later ones only seldom, revealed the author of the work. The title page, apparently, was meant to provide, first, a protective cover for the text within and, second, an opportunity for advertising for the publisher-printer.

The middle years. The first really notable roman type had been cut by Jenson for a text by Cicero in 1470. It had been replaced in popularity and importance by the romans that Francesco Griffo cut for Manutius in the late 15th century. The first italic had been a Griffo design introduced by Manutius in his pocket editions early in the 16th century. These two faces had, in turn, been displaced in European typography by letters designed in the mid-16th century by Garamond in France: a roman based on Griffo's cutting and an italic based on a form put forth by Ludovico degli Arrighi. The Garamond versions of these faces were to be of prime importance in European typographical work until the end of the 16th century, during which time so many adaptations of them were produced that "Garamond type" came to be used as a generic term.

Romain du Roi. By the end of the 16th century, typography in Europe had, generally speaking, deteriorated in vigour and quality. In France, the first comeback step was taken in 1640 by Louis XIII, who, under the influence of Cardinal de Richelieu, established the Imprimerie Royale at the Louvre. In 1692 Louis XIV ordered the creation of a commission charged with developing the design of a new type to be composed of letters arrived at on "scientific" principles. The commission, whose deliberations were fully recorded, worked mathematically, drawing and redrawing each letter on squares divided into 2,304 equal parts. The approach was far removed from the style of the calligraphers, whose work had provided models for

all of the important alphabets until then. It is probably fortunate that Philippe Grandjean, who was called on to do the punch cutting, did not feel himself to be under constraint to carry out his own work with the mathematical precision of the commission members who had drawn the patterns. Using the basic designs merely as suggestive, he cut a type that almost immediately drove the Garamond style from its favoured position. Known as Romain du Roi, it was used first (1702) in one of the *médaille* books that were then popular as commemorative devices. As might be expected, the type is notable for its regularity and precision; there is a good, though not exaggerated, contrast between the thick and thin strokes, and the addition of flat serifs on the lowercase letters was effective.

Rutger Rescius, imprimeur de Louvain, était savant en grec, et il l'enseignait à Louvain, où il occupait la première chaire des professeurs. Il donna plusieurs éditions d'auteurs grecs; quoiqu'elles ne soient pas fort belles, elles ne laissent pas d'être estimées des savans à cause de leur exactitude : lui-même prenait la peine de corriger ses épreuves. Ses Aphorismes d'Hippocrate passent pour être son chef-d'œuvre.

Jean Belier ou Beller fut imprimeur à Anvers, peu après Plantin. Il était plus instruit dans les langues que ce dernier. Il composa un Dictionnaire latin, tiré de Robert Estienne et de Gesner, et un autre espagnol et latin. Ses éditions sont recommandables par la beauté des caractères et par la bonté du papier. Il y a eu aussi des Beller à Douay; on estime sur-tout les éditions de Balthasar.

Sixte Rusinger, prêtre, natif de Strasbourg, alla s'établir à Naples, et commença d'y travailler en 1471. Il s'y rendit célèbre et même si utile, à ce que rapporte Wimphelinge, que le roi Ferdinand voulut l'honorer de plusieurs charges considérables, lui offrit évêchés et abbayes pour l'obliger à se fixer auprès de lui. Le desir de retourner dans sa patrie l'emporta sur toutes ces offres généreuses.

Jean de Westphalie, célèbre imprimeur de Louvain, avait fait le métier de copiste avant d'exercer l'art typographique. On a de lui un superbe manuscrit des Lettres familières de Cicéron. Il publia, en 1473, le Petri Crescentii Opus ruralium commodorum, in-folio. Cet artiste allait de temps en temps exercer son art hors de Louvain. En 1474, il publia, à Alost, avec Thierry Martens, un Liber prædicabilium, in-8.°, et un autre à Nimègue.

Figure 8: Philippe Grandjean's Romain du Roi type, from the specimen book of the Imprimerie Royale.

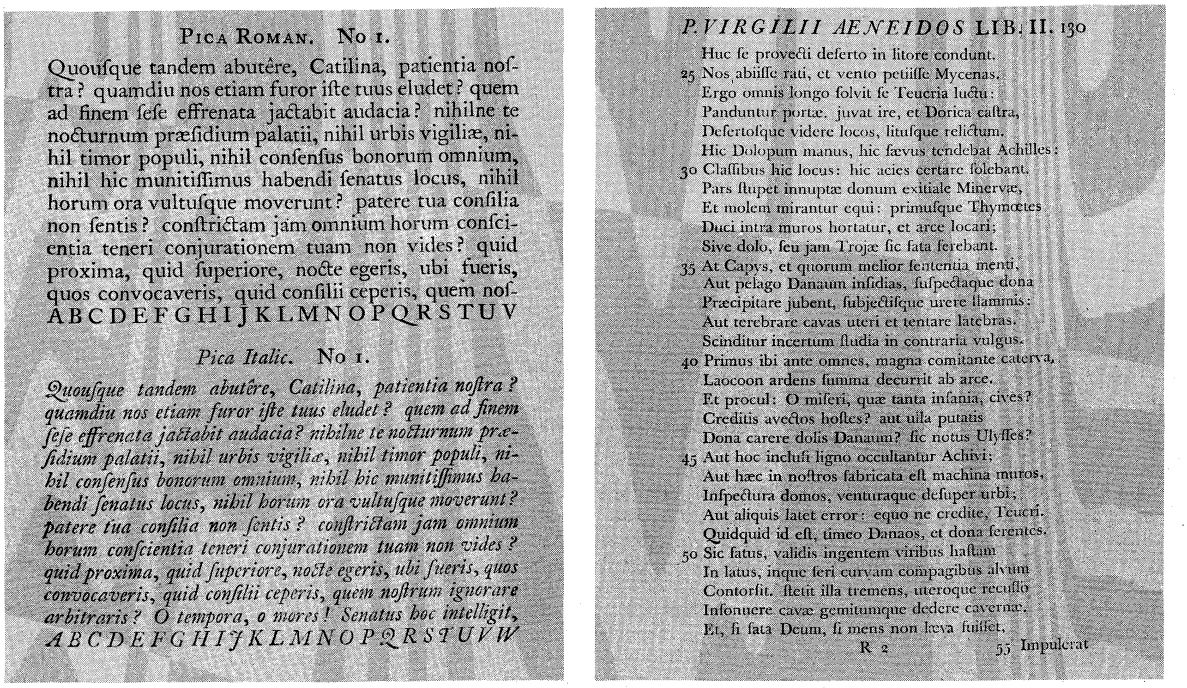
Though intended to be for the exclusive use of the Imprimerie Royale, the new roman was immediately copied by other designers, one of the most active of whom was the founder Pierre-Simon Fournier, who is also remembered for his creation of a wide range of printers' devices that could be combined into festoons, borders, and headpieces and tailpieces for the heavily ornamented *éditions de luxe* that were popular in France then and that were to remain so until the Revolution.

It is reasonable to say—as did designer-theorist William Morris—that the Romain du Roi replaced the calligrapher with the engineer as a typographical influence. In general, the calligrapher was not to be reintroduced until Morris himself performed the operation as an ideological matter in the 19th century. Before that could happen, typography was to undergo further modifications under the influence of three great designers, two in England and one in Italy.

Caslon, Baskerville, and Bodoni. William Caslon, who issued his first type-specimen sheet in 1734, made a number of refinements of the Garamond style and created faces that have become traditional and are still much in use. Caslon's refinement of the Garamond version of the Aldine roman was essentially straightforward and unmannered except for a slightly pronounced contrast between the thin strokes and the thick ones. The letters were graceful and well balanced. Serifs were bracketed (see above). They were well cut, and they made up into type blocks that were comfortable to read.

The type won wide acceptance and became well-known in the American colonies, where it was introduced by Benjamin Franklin. It was the type in which a Baltimore printer issued the official copies of the United States Declaration of Independence.

Even more significant changes in typographical fashions were achieved about a quarter of a century later by John Baskerville in Birmingham. Baskerville, who taught calligraphy, introduced further variations in the spirit of Caslon. His letters suggest a greater concern for aesthetics. Their feeling of gracefulness is more pronounced. They were more original than Caslon's. His roman letters were open and legible; his italics tended to be spidery and quite pinched. Open and quite rounded, they are, perhaps, more self-consciously pleasing to the eye. As a book designer, Baskerville combined his new faces with exaggerated page margins and relatively wide spacings between letters to suggest new directions in style. By the use of special papers, improved press methods, and special inks, he achieved an effect of almost glaring contrast, an effect heightened by his preference for emphasizing the typographer rather than the illustrator or the engraver. Though his acknowledged masterpiece, a Cambridge Bible, was not printed until 1763, he was an important influence on English and European typography almost from the first printing of his Virgil in 1757.



The Bodoni type faces

In Italy, Giambattista Bodoni enthusiastically took up the principle of page design as worked out by Baskerville, though not his typefaces. Further modifying the Aldine roman of Garamond, he mechanically varied the difference between the thick and thin strokes of his letters to achieve the ultimate contrast possible in that direction. His letters are rather narrower than those of either Caslon or Baskerville. He exaggerated his thick lines and reduced the thin ones almost—it seems at times—to the point of disappearance. Like Baskerville, he used opulent papers and inks blended for special brilliance. His pages were not easy to read, but he became, in the words of Stanley Morison, the typographical idol of the man of taste, and his "plain"—though deliberately and artfully contrived—designs were an important factor in the decline in importance of the *édition de luxe* and its replacement by works more austere in feeling, more modern even to today's eyes. He set what was, in general, to be the standard book style of the world until the appearance of William Morris. (W.E.P.)

TYPE AND BOOK DESIGN SINCE THE 19TH CENTURY

Two late-19th-century developments—one technological, the other aesthetic—profoundly changed the course of book typography and design. The advent of mechanical type composition in the 1880s (the so-called Linotype machine was patented by Ottmar Mergenthaler, a German inventor, in 1884; the Monotype, by an American, Tolbert Lanston, in 1887) had much to do with the look of the 20th century book. The Arts and Crafts Movement, whose leader in typography as in other aspects was William Morris, had an equally great influence on the quality of modern book printing.

The private-press movement. The Industrial Revolution changed the course of printing not only by mechanizing a handicraft but also by greatly increasing the market for its wares. Inventors of the 19th century, in order to produce enough reading matter for a constantly growing and ever more literate population, had to solve a series of problems in paper production, composition, printing, and binding. The solution that most affected the appearance of the book was mechanical composition; the new composing machines imposed new limitations not only on type design but also on the number and kinds of faces available, since the money required to buy a new typeface

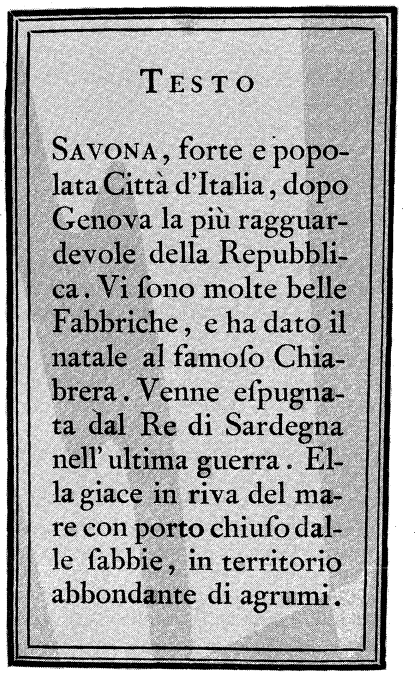
was enough to inhibit printers from stocking faces of slight utility. As a result, Victorian exuberance of design, which might use a dozen or more typefaces within a single book, was effectively curbed.

Influence of the Arts and Crafts Movement



William Morris. It is paradoxical that what became known as the Arts and Crafts Movement, with its roots in the romantic Gothicism propounded by the critic John Ruskin and by Morris, should have had a considerable influence on modern industrial design, including that of the book. An Englishman, William Morris was a fervent Socialist who believed that the Industrial Revolution had killed man's joy in his work and that mechanization, by destroying handicraft, had brought ugliness with it. Morris was above all a decorator; his work in the decorative arts had added great lustre to the fame he had already achieved as a writer when, partly as a result of dissatisfaction with the editions of his own works, he decided to establish a press. In 1888 Morris attended a lecture given by the printer Emery (later Sir Emery) Walker and was entranced by Walker's lantern slides of early types, greatly enlarged. He proposed to Walker that they cut a new font of type that would recapture the strength and beauty of the early letters, based upon medieval calligraphy. The Kelmscott Press, in its brief life (1891–96), printed 52 books that exemplified Morris' standards of perfect workmanship. A firm believer that a return to the past would produce a better society, he commissioned handmade paper like that used in the 15th century, had new, blacker inks made, and used the handpress and hand binding exclusively; a few copies of each title were also printed on vellum. With Walker, he designed three types: a roman, based upon that of Nicolas Jenson, and two Gothics after German models; all were cut and cast by hand. Woodcut initials and borders were engraved to his own design, and wood-block illustrations were cut from drawings by Edward Burne-Jones and other of his friends. The Kelmscott Press's major book was its *Chaucer*, finished in 1896, a sumptuous folio whose rich decorations and strong black pages are reminiscent of the German incunabula Morris admired. A table book, meant to be looked at rather than read, it is one of the most influential books in the history of printing—a revolutionary book, despite its anachronisms, which caused a whole generation of printers and designers to be dissatisfied with the books they saw about them and to attempt to improve the badly made, weakly designed books of the late Victorian age.

Proliferation of private presses

Private presses on the Morris model proliferated in England, on the Continent—especially in Germany and the Scandinavian countries—and in the United States. The best of these, notably the Doves and Ashendene presses in England and the Bremer and Cranach presses in Germany, published books of great style and strength. There were also poorer imitations, as the Roycroft Press in the United States.

Doves Press. The most influential of the private presses was the Doves Press, established in 1900 by T.J. Cob-

den-Sanderson and Emery Walker. Walker, who was one of the prime movers in fine printing for over half a century, also played an important role in creating type for the

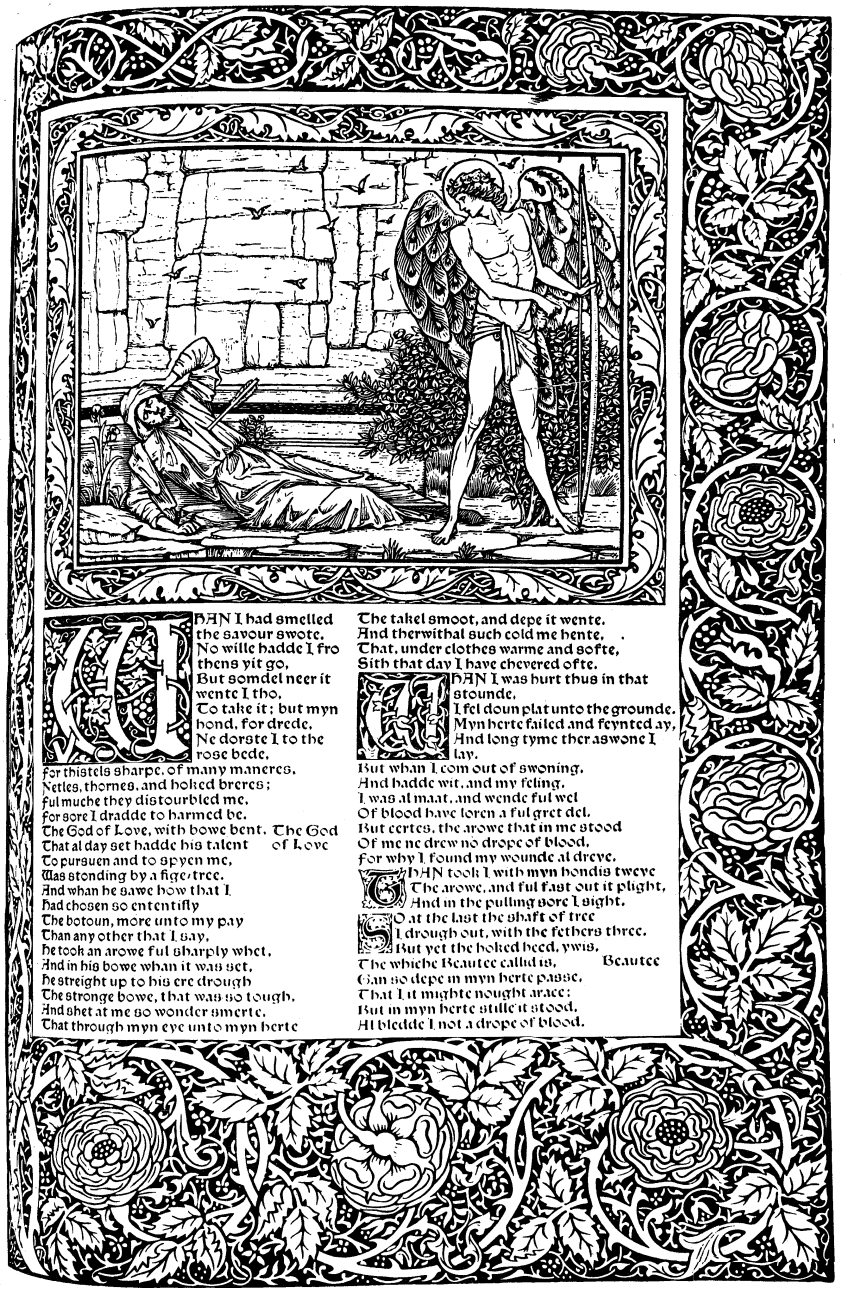
Ashendene and Cranach presses. Cobden-Sanderson was one of Morris' circle at Kelmscott House and had become a bookbinder at the suggestion of Mrs. Morris. The bindings executed at his Doves Bindery are notable for their excellent craftsmanship and their clear, simple design, which often used Art Nouveau motifs (see below). The Doves Press books, printed in a type based on Nicolas Jenson's 15th-century roman, were austere in their typography, eschewing all decoration and illustration and relying for their effect on the beauty of their type, spacing, and presswork. Occasionally a second colour, a splendid red, was used, and superbly drawn initials adorned many of the 50-odd books. A five-volume Doves Bible, issued between 1903 and 1905, is among the monuments of fine bookmaking, as well as one of the most influential modern books, a result of its virility, purity of design, and perfection in craftsmanship.

Ashendene Press. The third great English private press, the Ashendene, was conducted by C.H. St. John Hornby, a partner in the English booksellers W.H. Smith and Son. Hornby in 1900 met Emery Walker and Sydney Cockerell (Morris' secretary at the Kelmscott Press), who encouraged and instructed him and helped in devising two types for his own use: Subiaco, based upon Sweynheim's and Pannartz' semi-roman of the 1460s, and Ptolemy, based upon a late-15th-century German model. The Ashendene Press books, like those of Morris, were often illustrated with wood engravings, and many had coloured initials.

Germany. In Germany Morris' closest counterpart was Rudolf Koch, who gathered around himself at Offenbach, where he taught at the Arts and Crafts School and designed types for the Klingspor foundry, a community of craftsmen who painted, worked in metal, wood, and stone, printed, and wrote. Above all a consummate penman, Koch made the written word the basis of his designs in any medium, whether tapestry or woodcut. A devout Christian, Koch, like the medieval craftsmen he admired, saw the Gothic style as a supreme manifestation of religious spirit; he was no mere imitator but an artist who freely reinterpreted in his types and books the traditional Fraktur type of Germany. Koch also created a number of modern types, among them sans serifs and romans.

Influence of Cobden-Sanderson

Cobden-Sanderson's influence, however, far exceeded that of Morris in Germany. The most important of the German private presses, the Bremer Presse (1911–39), conducted by Willy Wiegand, like the Doves Press, rejected ornament (except for initials) and relied upon carefully chosen types and painstaking presswork to make its effect. The most cosmopolitan of the German presses was the Cranach, conducted at Weimar by Count Harry Kessler. It produced editions of the classics and of German and English literature illustrated by artists such as Aristide Maillol, Eric Gill, and Gordon Craig and printed with types by Emery Walker and Edward Johnston on paper made by hand in France. Kessler's book did not attempt to imitate medieval or Renaissance models; they sought to create—using the same methods as the early printers—books modern—or, rather, timeless, in spirit.



The Netherlands. The most notable figures of the private-press movement in The Netherlands were S.H. de Roos and Jan van Krimpen. De Roos, like Morris a utopian Socialist, was an industrial designer who hoped to create a better society by improving the appearance of ordinary utilitarian objects. His first book, *Kunst en Maatschappij* (1903), was, significantly, a collection of Morris' essays in translation. De Roos's decorative style became simple and less florid under the influence of Cobden-Sanderson, whose work he greatly admired, although his ideals remained those of the Arts and Crafts Movement. Unlike Morris and Cobden-Sanderson, de Roos was a book designer, designing books for others, rather than a printer—one of the earliest of the new school of typographers, who provided layouts for the publisher or printer, specifying type, format, and overall design. Increasingly, as technology became more complex and shops more highly specialized and automated, design became more a profession; the typographer, trained in industrial design or graphic arts, succeeded the printer or the publisher in deciding how a book should look. De Roos, who drew a number of typefaces for the Typefoundry Amsterdam, designed books for the Zilverdistel, the Meidoorn, and other private presses, as well as for trade publishers.

Jan van Krimpen used little decoration in his work, which achieved its effect through a classic clarity of style and impeccable printing. His books, for the Enschedé firm for which he worked, for private presses, or for trade publishers, attempted always to interpret the author's meaning as clearly as possible, to reflect it rather than to enhance it. Krimpen also designed a number of typefaces, all of which show his earlier study of calligraphy. Among them are Lutetia, a modern roman and italic of great distinction; Romulus, a family of text types that includes a sloped roman letter instead of the conventional italic; and Cancellaresca Bastarda, an italic notable for its great number of attractive decorative capitals, ligatures, and other swash (*i.e.*, with strokes ending in flourishes) letters, elegant in appearance.

Krimpen's typefaces

Italy. Another typographer working in the classic mode, Giovanni Mardersteig, spent most of his creative life in Italy, though he was born and trained in Germany. His Officina Bodoni utilized Bodoni's types to print the collected works of D'Annunzio. Mardersteig not only used the handpress for limited editions (usually on handmade Italian papers), which rival 15th-century printing in their beauty of spacing and presswork, but also supervised at the Stamperia Valdònega in Verona long-run editions on high-speed presses, which are likewise remarkable for their craftsmanship. In addition he designed several typefaces, among them Pacioli, Griffo, Zeno, and Dante.

Art Nouveau. The Art Nouveau movement was an international style, expressed in the consciously archaic types of Grasset in France; in posters and magazine covers by artist Will Bradley in the United States; and in initials and decorations by Henry van de Velde in Belgium and Germany. Van de Velde, the leading spokes-

man for the movement as well as one of its most skilled practitioners, in his essay "Déblaiement d'art" (1892) advocated the development of a new art, one that would be both vital and moral, like the great decorative arts of the past, but that would use contemporary modes. For a reprint of the essay, he designed a series of initials and typographic ornaments that express the characteristics of the style: decoration based upon natural forms; pages whose typography and decoration blend to make overall patterns; and a richness of texture reminiscent of illuminated manuscripts. Van de Velde's most important book was an edition of Nietzsche's *Also sprach Zarathustra*, which he designed for the Insel Verlag and had printed by the Drugulin-Presse of Leipzig and for which he created a series of ornaments printed in gold, as well as endpapers, title page, and binding; a small folio, conceived as an architectonic whole rather than a series of unrelated openings, it is a striking, if dated, volume.

Mechanical composition. The private-press movement did much to raise the standards of the ordinary trade book. Small, independent publishers who wished to make a mark not only through the distinction of their titles but also through the distinctiveness of their house styles acted as a bridge between the deluxe bibliophilic editions and ordinary books. Companies such as those of John

Early Linotype and Monotype faces

During the early years of the 20th century, more and more printers installed composing machines (see PRINTING). The early Linotype and Monotype faces, like the foundry faces they imitated, were weak and poor. The first significant face cut especially for mechanical composition appeared in 1912, when a new face based upon the old-style types of Caslon was produced for *The Imprint,* a short-lived periodical for the printing trade published by Gerard Meynell of the Westminster Press in London. Its contributors included Edward Johnston, who not only wrote for the magazine but designed its calligraphic masthead; and Stanley Morison, who began his career as printing historian and typographer on its staff. Other Monotype faces cut at this time included Plantin, based upon the types of the great Antwerp printer, and Caslon; the latter was made at the instigation of George Bernard Shaw's publishers, since Shaw, who had strong views on typography, would not allow any other face for his books. World War I, however, stopped any further development of types for the composing machines.

United States. In America the generation of designers who had begun as disciples of Morris soon began to develop their own styles. Among the most important were D.B. Updike, Bruce Rogers, F.W. Goudy, and W.A. Dwiggins.

Daniel Berkeley Updike opened the Merrymount Press in Boston in 1893. His books, most of which he designed himself, are noteworthy for the clarity of their organization, their easy readability, and their excellent workmanship, based upon the use of a few carefully selected typefaces and immaculate presswork. Updike stocked only types that met the twin criteria of economy in use and beauty of design. His books, whether a complex folio such as the *Book of Common Prayer* (1930), considered by many to be his masterpiece, or the small and amiable *Compleat Angler* (1928), are both functional and pleasing to the eye.

Bruce Rogers was a typographer, trained as an artist, who had the faculty of drawing the best from the printers with whom he worked. His greatest book, a monumental Oxford Lectern Bible of 1935; is the noblest edition of the Bible ever issued in English; his smaller and less ambitious efforts, often decorated with the typographic ornament at which he was a master, possess enormous wit and charm. His one type design, Centaur, based upon Jenson, is among the most successful modern adaptations of an early roman, although too elegant for frequent use.

Goudy's type faces

Frederic William Goudy, the most prolific American type designer, created more than 100 faces during a long career as printer, editor, and typographer. In 1908 he began a long association with the Lanston Monotype Corporation, for which he did much of his best work. Among his types were Forum and Trajan, based upon the roman capital letters inscribed on Trajan's Column; Goudy Modern, his most successful text page; and a number of black-letter and display faces. Goudy edited two journals, *Typographica* and *Ars Typographica,* in which he expounded his theories of design; he also wrote a number of books, among them *Elements of Lettering* and *The Alphabet.*

William Addison Dwiggins, a student of Goudy's, was long associated with the publishing firm of Alfred A. Knopf, whose house style he helped to establish. In hundreds of volumes of trade books he designed, typography was taken seriously (each book carried a brief colophon on the history of the type employed); there was an attempt to use contemporary typographic decoration; and the bindings, using designs made up of repeated decorative units like early printers' fleurons, were extremely successful. Dwiggins designed a number of typefaces for the Linotype, two of which, Electra and Caledonia, have had wide use in American bookmaking. In the U.S., unlike England and the Continent, printers have relied far more upon Linotype than Monotype for book composition.

England. English typography, like that everywhere, marked time during World War I but made remarkable progress soon after. A new generation of typographers, inspired by Morris' ideals of quality but at the same time aware of the need to adapt them to the new mass-production techniques, had begun to make their names. Foremost among these was Stanley Morison, who, after a year's apprenticeship with *The Imprint,* became a typographer on the staff of Burns and Oates, where he worked on a wide variety of books, among them the liturgical texts in which the firm specialized; here he began to develop the rationalistic approach to typographic design that characterizes the English school. Morison demanded that typography be functional: the task of the book and the newspaper designer was to transmit the author's text clearly, and the task of the advertising and display designer was to command attention. In 1922 Morison became typographic adviser to the Monotype Corporation and instituted a program of cutting for the composing machine a repertory of types culled from the best faces of the past, to which were added a number of contemporary faces designed for modern needs. He had prepared himself for the task by a strenuous course of self-education in paleography and calligraphy, in order to understand the written hands that the early types imitated, and in the history of printing design itself. In 1923 he joined Oliver Simon in publishing *The Fleuron,* a journal of printing history and design in which he published a number of important articles on calligraphy and typography.

Morison's work for Cambridge University Press

In 1925 Morison was made typographic adviser to the Cambridge University Press, whose printer, Walter Lewis, had begun a complete reform of its typographic resources. Cambridge stocked most of the types Morison commissioned for Monotype and demonstrated by their intelligent use that mechanical composition could be used to produce books at once handsome and functional. Among these types were Garamond, based upon a 17th-century French letter (see above); Bembo, after an Aldine roman; Centaur, an adaption of Rogers' foundry face; and Baskerville and Bell, based upon English models. Italics included Arrighi, a version of the letter used by the 16th-century papal writing master and printer (see above). Among the modern faces whose design Morison supervised were Eric Gill's Sans Serif, which enjoyed a wide vogue in advertising and avant-garde book typography; Gill's Perpetua, based upon his stonecut letters; and Times New Roman, designed by Morison himself for *The Times* (London), whose staff he joined in 1930. The last has been called the most successful type design of the 20th century, a result of its economy and legibility when used on high-speed presses.

Francis Meynell was another who demonstrated that mechanical composition and printing, properly used, could produce aesthetically satisfying books. The books of Meynell's Nonesuch Press, usually limited editions of the classics reflecting his own catholic and excellent literary taste, are marked by restrained design, fine papers,

and careful presswork. More varied and original than those of the earlier private presses, they were printed not by the proprietor but by large, mechanized shops. Meynell's trade books, published under the same imprint, demonstrated that well-designed and manufactured books need not be costly; the Nonesuch one-volume editions of English classical authors were inexpensive, handsome, and readable.

The most influential modern publisher of English low-priced books, however, was Allen Lane, whose Penguin books, established in 1935 and inspired by such continental publishers as Insel Verlag and Albatross, proved that a well-designed series of inexpensive paperbacks, both worthwhile reprints and new titles, could succeed both commercially and intellectually. They did much to bring about the paperback revolution that swept both the Continent and the United States in the period that followed World War II.

Influence of the Bauhaus

International styles. German typography from World War I until the advent of Hitler was greatly influenced by the Bauhaus, which stressed the graphic arts; its books, heavily illustrated, broke away from traditionally symmetrical layouts, in which pictures were inserted into a rigid framework of text, and strove instead for freer arrangements, usually asymmetrical, in which the type supported the dominant illustrations. The attempt was to create graphic patterns on the page and to enhance the reader's consciousness of the illustrations. Many of the Bauhaus faculty were architects and industrial designers, whose principles demanded that the types they used, like the buildings and machines they designed, be sharp and unornamented, symbolic of a machine-dominated society. Their favourite types were sans serifs, such as Gill's Sans Serif and Paul Renner's Futura. With the Nazi dispersal of the Bauhaus group, its style became truly international. It has since lost favour among book designers, except for art and architectural books, partly because sans serif types and asymmetrical layout proved less legible than traditional modes and partly because typographers grew tired of its rigid limitations.

Other between-war styles, closely linked to literary or artistic movements that affected book design, were Dadaism and Surrealism. The Dadaists' pamphlets, posters, and books employed free, abstract layout, a great mixture of type sizes and faces, and an attempt to create mood through typography. Surrealist writers such as Guillaume Apollinaire and André Breton often collaborated in the design of their own books, attempting to make the typography of their works reflect its mood.

In France, especially, the production of books intended to be works of art in their own right was dominated by painters and sculptors. Publishers such as Ambroise Vollard commissioned members of the School of Paris, among them Braque, Matisse, Bonnard, and Picasso, to illustrate books in which the illustrator worked closely with highly skilled craftsmen to create colourful, original, limited editions, which, while they sometimes may fail as readable books, achieve admirable success as visual decoration.

During the 20th century, styles in book design, as in all the arts, fine or applied, have become increasingly international. Styles born in one country spread throughout the world and die through overuse at a dizzying rate. As a consequence it has become increasingly difficult to distinguish truly individual or national styles—books, magazines, clothes, paintings, music, regardless of country of origin, all resemble one another far more than they differ. BIBLIOGRAPHY. There is a vast literature on typography and printing history. *A Bibliography of Printing*, comp. by EDWARD C. BIGMORE and C.W.H. WYMAN, 2nd ed., 2 vol. (1880–86), was still useful enough to merit reprinting in 1945. Several learned and technical journals print annual bibliographies. See especially *Studies in Bibliography* and *Publications of the Modern Language Association*, which emphasize articles dealing with analytic bibliography and printing history. The best brief history in English is SIGFRID H. STEINBERG, *Five Hundred Years of Printing*, rev. ed. (1962). CURT BUHLER, *The Fifteenth-Century Book* (1960), is an excellent survey of early printing and publishing practice. JOSEPH MOXON, *Mechanick Exercises on the Whole Art of Printing* (1683–84), is the earliest comprehensive manual on printing, typography, and type making. The 1962 edition of HERBERT DAVIS and HARRY CARTER, with an excellent introduction and full annotation, gives considerable insight into the typography and printing of the day; there were no significant changes from the invention, *c.* 1450, until the early-19th century. DANIEL B. UPDIKE, *Printing Types*, 3rd ed., 2 vol. (1962), is a thorough and interesting history of the development of type design from the beginnings to about 1930 —highly personal, highly dogmatic, but the classic work on the subject. Of the many books and articles by STANLEY MORISON, three are especially noteworthy to the non-professional reader: *First Principles of Typography*, 2nd ed., with postscript (1967), is an expanded version of his Britannica article on "Typography," which became the definitive statement of his views on the subject, and has been translated into several languages. *The Typographic Arts* (1950), contains two essays on *inter alia*, the interrelationship between calligraphy, engraving, and type design. *The Typographic Book*, ed. by KENNETH DAY (1962), is an expanded version of an earlier work entitled *Four Centuries of Fine Printing*. It contains good reproductions of specimen titles and text pages spanning 1450–1953. HELLMUT LEHMANN-HAUPT (ed.), *The Book in America*, 2nd ed. (1951), is an historical survey of American printing and publishing from the beginning to the present. KENNETH DAY (ed.), *Book Typography, 1815–1965, in Europe and the United States of America* (1966), contains uneven but generally good articles on its subject. JOHN CARTER and PERCY MUIR (eds.), *Printing and the Mind of Man* (1967), the catalog of two major exhibitions held in London for an International Printing Exhibition, contains much technical information on the technological development of printing and type founding from the invention to today, as well as notes on books important for their intellectual or aesthetic impact. HENRI J. MARTIN and LUCIEN FEBVRE, *L'Apparition du livre* (1958), while heavily French in its emphasis, is a stimulating and original history of the social, economic, cultural, and technical evolution of the book trades from the manuscript period to the 19th century. Of the many modern manuals on typography, mainly reflecting the Bauhaus school, two that are representative and better than average are JAN TSCHICHOLD, *Typographische Gestaltung* (1935; Eng. trans., *Asymmetric Typography*, 1967); and EMIL RUDER, *Typographie* (1967). The latter has text in German, French, and English, and also shows Dadaist and other modern schools. Tschichold became converted to traditional typography, and in *Designing Books* (1951), gives an excellent exposition of his later views. HUGH WILLIAMSON, *Methods of Book Design*, 2nd ed. (1966), is a full and good survey of modern book design and production methods. *The Penrose Annual*, published in London, has technical articles on new developments in design and processes as well as good essays on the history and aesthetics of printing. The *Gutenberg Jahrbuch*, emanating from Mainz, the cradle of printing, emphasizes incunabula but includes articles on later printing, publishing, and binding.

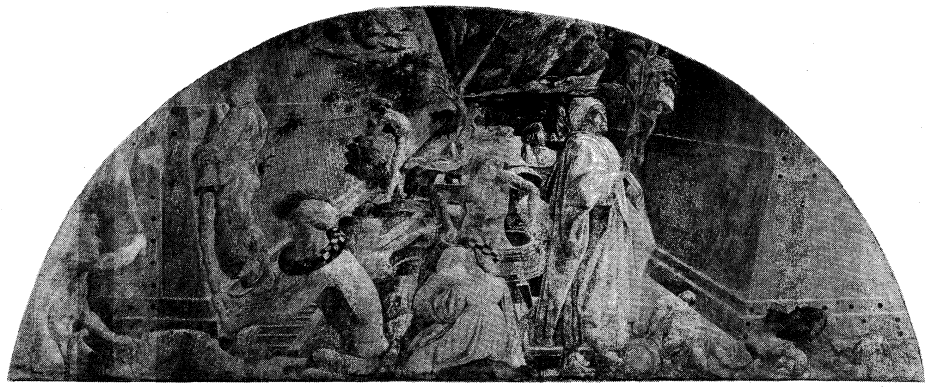
Uccello, Paolo

A painter of early 15th-century Florence whose work represented an original attempt to reconcile two distinct artistic styles—the lingering Gothic tradition, which was essentially decorative, and the new, heroic style of the early Renaissance—Paolo Uccello was long thought to be significant primarily for his role in establishing new means of rendering perspective that became a major component of the Renaissance style. The 16th-century biographer Giorgio Vasari said that Uccello was "intoxicated" by the subject of perspective. Later historians have found the unique charm and the decorative genius evinced by his compositions to be an even more important contribution. Though in ruinous condition, they indicate the immense difficulties faced by artists of his time in taking advantage of new developments without giving up what was best in traditional art.

Apprenticeship with Ghiberti

Paolo di Dono, known as Paolo Uccello, was born in 1397 in Pratovecchio, just outside Florence. By the time he was 10, he was already an apprentice in the workshop of the sculptor Lorenzo Ghiberti, who was then at work on what became one of the supreme masterpieces of the history of art—the bronze doors for the Baptistery of the Florence cathedral, which consisted of 28 panels illustrating New Testament scenes of the life of Christ. In 1414 Uccello joined the confraternity of painters (Compagnia di S. Luca), and in the following year he became a member of the Arte dei Medici e degli Speziale, the official guild to which painters belonged. Though Uccello must by then have been established as an independent painter, nothing of his work from this time remains, and there is no definite indication of his early training as a painter, except that he was a member of the workshop of Ghiberti, where many of the outstanding artists of the time were trained.



Uccello's earliest, and now badly damaged, frescoes are in the Chiostro Verde (the Green Cloister, so called because of the green cast of the frescoes that covered its walls) of Sta. Maria Novella; they represent episodes from the creation. These frescoes, marked with a pervasive concern for elegant linear forms and insistent, stylized patterning of landscape features, are consistent with the late Gothic tradition that was still predominant at the beginning of the 15th century in Florentine studios and have given rise to the hope that Uccello's artistic origins may yet be found in some of these studios.

From 1425 to 1431, Uccello worked in Venice as a master mosaicist. All his work in Venice has been lost, and plans to reconstruct it have been unsuccessful. Uccello may have been induced to return to Florence by the commission for a series of frescoes in the cloister of S. Miniato al Monte depicting scenes from monastic legends. While the figural formulations of these ruinous frescoes still closely approximate the Sta. Maria Novella cycle, there is also a fascination with the novel perspective schemes that had appeared in Florence during Uccello's Venetian sojourn and with a simplified and more monumental treatment of forms deriving from the recent sculpture of Donatello and Nanni di Banco.

Completion of the Hawkwood fresco

In 1436 in the Florence cathedral, Uccello completed a monochrome fresco of an equestrian monument to Sir John Hawkwood, an English mercenary who had commanded Florentine troops at the end of the 14th century. In the Hawkwood fresco, a single-point perspective scheme, a fully sculptural treatment of the horse and rider, and a sense of controlled potential energy within the figure all indicate Uccello's desire to assimilate the new style of the Renaissance that had blossomed in Florence since his birth. Following the Hawkwood monument, in 1443 Uccello completed four heads of prophets around a colossal clock on the interior of the west facade of the cathedral; between 1443 and 1445 he contributed the designs for two stained-glass windows in the cupola.

After a brief trip to Padua in 1447, Uccello returned to the Chiostro Verde of Sta. Maria Novella. In a fresco illustrating the Flood and the recession, Uccello presented two separate scenes united by a rapidly receding perspective scheme that reflected the influence of Donatello's contemporary reliefs in Padua. Human forms in "The Flood," especially the nudes, were reminiscent of figures in Masaccio's frescoes in the Brancacci Chapel (*c.* 1425), perhaps the most influential of all paintings of the early Renaissance, but the explosion of details throughout the narrative again suggests Uccello's Gothic training. More than any other painting by Uccello, "The Flood"

indicates the difficulties that he and his contemporaries faced in attempting to graft the rapidly developing heroic style of the Renaissance onto an older, more decorative mode of painting.

Perhaps Uccello's most famous paintings are three panels representing the rout of San Romano, now in the Louvre, Paris; the National Gallery, London; and the Uffizi, Florence. These panels represent the victory in 1432 of Florentine forces under Niccolò da Tolentino over the troops of their arch rival, Siena. There are Renaissance elements, such as a sculpturesque treatment of forms and fragments of a broken perspective scheme in this work, but the bright handling of colour and the elaborate decorative patterns of the figures and landscape are indebted to the Gothic style, which continued to be used through the 15th century in Florence to enrich the environments of the new princes of the day, such as the Medici, who acquired all three of the panels representing the rout of San Romano.

Most famous paintings and perspective studies

Uccello is justly famous for his careful and sophisticated perspective studies, most clearly visible in "The Flood," in the underdrawing (sinopia) for his last fresco, "The Nativity," formerly in S. Martino della Scala in Florence, and in three drawings universally attributed to him that are now in the Uffizi. These drawings indicate a meticulous, analytic mind, keenly interested in the application of scientific laws to the reconstruction of objects in a three-dimensional space. In these studies he was probably assisted by a noted mathematician, Paolo Toscanelli. Uccello's perspective studies were to influence the Renaissance art treatises of artists such as Piero della Francesca, Leonardo da Vinci, and Albrecht Dürer.

Uccello apparently led an increasingly reclusive existence during his last years. He died in Florence on December 10, 1475.

Uccello's modern reputation as a painter and theoretician has suffered because of the bad state of preservation of his work and, more significantly, because of his naïve attempt to reconcile the two distinct styles of the Gothic and the Renaissance. Although any union of these two styles was destined to be an uneasy one, Uccello's attempt, nevertheless, documents the powerful impact of the new style of the Renaissance on older traditions.

MAJOR WORKS

"The Creation of the Animals"; "The Creation of Adam"; "The Creation of Eve"; "The Fall" (frescoes, early 1430s; Sta. Maria Novella, Florence); "Sir John Hawkwood" (fresco, 1436; cathedral, Florence); "Scenes from Monastic Legends" (frescoes, *c.* 1440; S. Miniato al Monte, Florence); "The Flood," "The Recession of the Flood," "The Sacrifice of Noah," and "The Drunkenness of Noah" (1447–48; Sta. Maria Novella, Florence); "The Rout of San Romano" (mid-1450s; panels in the National Gallery, London; Uffizi, Florence, and the Louvre, Paris); "St. George and the Dragon" (1455–?60; Musée Jacquemart-André, Paris); "St. George and the Dragon" (*c.* 1460; National Gallery, London); "The Profanation of the Host" (*c.* 1466–69; Galleria Nazionale delle Marche, Urbino, Italy); "A Hunt in a Forest" (after 1460; Ashmolean Museum, Oxford, England); "The Founders of Florentine Art" (after 1460?; Louvre).

BIBLIOGRAPHY. The standard and most readable and complete work on Uccello (and his followers) in English is JOHN POPE-HENNESSY, *Paolo Uccello*, 2nd ed. (1969). EVE BORSOOK discusses Uccello's Florentine frescoes in *The Mural Painters of Tuscany, from Cimabue to Andrea del Sarto* (1960). Uccello's role in the investigation of perspective is mentioned by JOHN WHITE in *The Birth and Rebirth of Pictorial Space*, 2nd ed. (1967); and this subject is treated more fully by ALESSANDRO PARRONCHI in *Studi su la dolce Pospettiva* (1964).

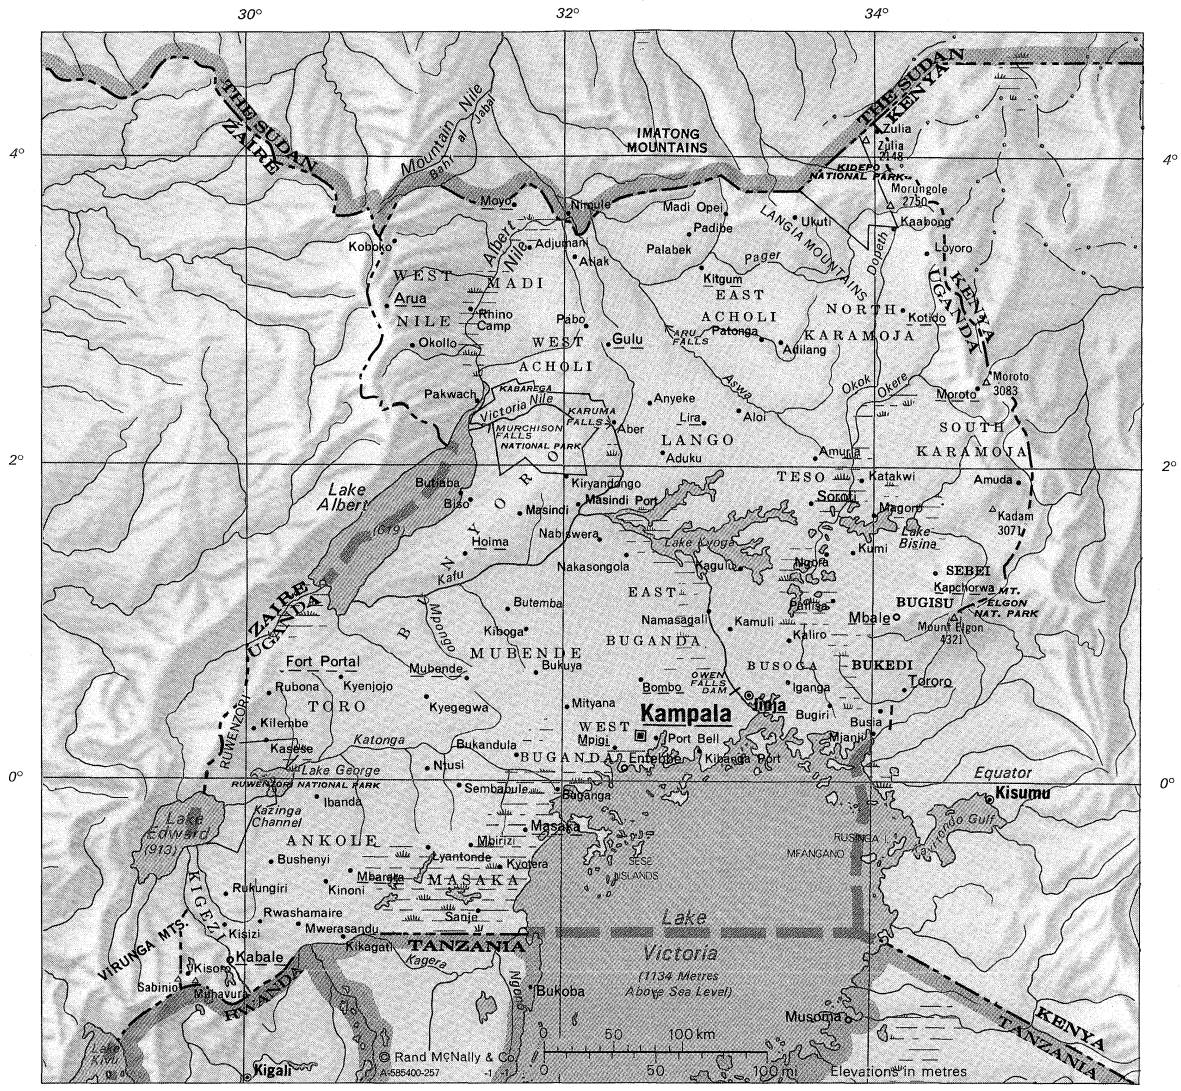
Uganda

Uganda is a landlocked republic of East Africa. At least 500 miles from the Indian Ocean, it is bounded by Kenya to the east. The Sudan to the north, Zaire to the west, Rwanda and Burundi to the southwest, and Tanzania to the south. Not a large country, it covers an area of 91,452 square miles (236,860 square kilometres). By the early 1970s it had a population of over 10,000,000. The national capital is at Kampala.

Uganda is a member of the Commonwealth of Nations, has been in the forefront of the Pan-African movement, was a founder member of the Organization of African Unity, and, together with Kenya and Tanzania, belongs to the East African Community. Since 1962, when Uganda achieved independence, increasing emphasis has been placed on state participation in its economy. Every effort has been made to create an industrial base, but the economy remains basically agricultural and subject to world price fluctuations. Coffee and cotton are the main cash crops. (For history, see EAST AFRICA, HISTORY OF. For physical features, see EAST AFRICAN LAKES; EAST AFRICAN MOUNTAINS; NILE RIVER; and VIRUNGA MOUNTAINS.)



THE LANDSCAPE

The natural environment. *Relief.* Most of the country is situated on part of the Central African Plateau. A great, monotonous expanse, it drops gently from about 5,000 feet in the south to 3,000 feet in the north. The limits of Uganda's plateau region are marked by mountains and valleys.

To the west, this natural boundary is composed of the Virunga (Mufumbiro) Mountains, the Ruwenzori Range, and part of the Great Rift Valley System. The volcanic Virunga Mountains rise to 13,541 feet (4,127 metres) at Mt. Muhavura and include Mt. Sabinio, where the borders of Uganda, Zaire, and Rwanda meet. Further north, the Ruwenzori Range—popularly believed to be Ptolemy's Mountains of the Moon—rise to 16,763 feet (5,109 metres) at Margherita Peak; their heights are often hidden by clouds, and their peaks are capped by snow and glaciers. Between the Virunga and Ruwenzori mountains lie Lakes Edward and George. The rest of the boundary is composed of the western Rift Valley, which contains Lake Albert and the Albert Nile.

The Mountains of the Moon

The northeastern border of the plateau is defined by a string of volcanic mountains, including Mounts Zulia (7,048 feet [2,148 metres]), Morungole (9,022 feet [2,750 metres]), Moroto (10,116 feet [3,083 metres]),

and Kadam (Debasien; 10,074 feet [3,071 metres]). The southernmost mountain—Mt. Elgon—is also the highest of the chain, reaching 14,178 feet (4,321 metres). South and west of these mountains are an eastern extension of the Rift Valley, as well as Lake Victoria. To the north, the plateau is marked on the Sudanese border by the Imatong Mountains, with an altitude of about 6,000 feet.

Drainage. The country's drainage system is dominated by six major lakes—Victoria (26,418 square miles), the world's second largest inland freshwater lake (after Lake Superior in the United States) to the southeast; Edward and George to the southwest; Albert to the west; and Kyoga and Bisina (Salisbury) in the east. Together with the lakes, there are eight major rivers. These are the Victoria Nile in central Uganda; the Aswa, Dopeth-Okok, and Pager in the north; the Albert Nile in the northwest; and the Kafu, Katonga, and Mpongo in the west.

The Victoria Nile

The southern rivers empty into Lake Victoria, the waters of which escape through Owen Falls near Jinja and form the Victoria Nile. The river flows northward through the eastern extension of Lake Kyoga. It then turns west and north to drop over Karuma Falls and Murchison Falls before emptying into Lake Albert.

Lake Albert is drained to the north by the Albert Nile, which is known as the Baḥr al-Jabal, or White Nile, after it enters The Sudan at Nimule. Rivers that rise to the north of Lake Victoria flow into Lake Kyoga, while those that rise north of Kyoga tend to flow into the Albert Nile. The rivers of the southwest flow into Lakes George and Edward.

Except for the Victoria and Albert Niles, the rivers are sluggish and often swampy. Clear streams are found only in the mountains and on the slopes of the Rift Valley. Most of the rivers are seasonal and flow only during the wet season. The few permanent rivers are also subject to seasonal changes in their rates of flow.

Soils and climate. The soils are predominantly ferralites (soils containing iron and aluminum). Interspersed with these are the waterlogged clays characteristic of the northwest and of the western shores of Lake Victoria. In general the soils are fertile, although they are of poorer quality in the north than in the south.

The climate is characteristically tropical—the Equator passing through southern Uganda. Temperatures are modified, however, by altitude and by the presence of the lakes. The major air currents are northeasterly and southwesterly. There is little variation in the height of the sun at midday, and the length of daylight is nearly always 12 hours. All of these factors, combined with an equatorial cloud cover, ensure an equable climate throughout the year.

Most parts of Uganda receive adequate rainfall; amounts range from a low of less than 15 inches a year in the northeast to a high of 80 inches in the Sese Islands of Lake Victoria. In the south there are two wet seasons, that occur in April and May and in October and November and that are separated by dry periods broken by tropical thunderstorms. In the north, the climate is roughly divided into a wet season from the months of April to October and a dry season that lasts from November to March.

Vegetation. Wooded savanna (grassy parkland) is typical of central and northern Uganda. Under less favourable conditions, dry acacia woodland, dotted with the occasional candelabra (tropical African shrubs or trees with huge spreading heads of foliage), euphorbia (plants often resembling cacti and containing a milky juice), and interspersed with grassland, occurs in the south. Similar components are found in the vegetation of the Rift Valley floors. The steppes (treeless plains) and thickets of the northeast represent the driest regions of Uganda. In the Lake Victoria region and the western highlands, the mosaic of elephant grass and forest remnants appears to have resulted from human incursions affecting the former forest covering. The medium-altitude forests contain a rich variety of species, with many representatives of West African vegetation. The high-altitude forests of Mt. Elgon and the Ruwenzori Range occur above 6,000 feet; on their upper margins they give way, through transitional zones of mixed bamboo and tree heath, to high mountain moorland. Uganda's 5,600 square miles of swamp include both papyrus swamp and seasonal, grassy swamp.

Animal life and national parks. Lions and leopards are widely distributed but are seen only infrequently. Hippopotamuses and crocodiles inhabit most lakes and rivers, although the latter are not found in Lakes Edward and George. Mountain gorillas, chimpanzees, and small, forest elephants occur only in the extreme west. Elephants, buffalo, and the Uganda kob (an antelope) are found in the west and north, while the black rhinoceros, white rhinoceros, and giraffe are confined to the north. Zebras, topis, elands, and roan antelopes occur both in the northeastern and southern grasslands, but other kinds of antelopes, such as the oryx, greater and lesser kudu, and Grant's gazelle, live only in the northeastern area. The varied fish life includes ngege (a freshwater, nest-building fish of the tilapia species) and Nile perch. Insects comprise a significant element in the biological environment. The female anopheles mosquito may transmit malaria anywhere below 5,000 feet. Extensive areas of good grazing are closed to cattle because of the presence of deadly tsetse flies.

The three national parks contain an interesting variety of animal life. The Kabarega National Park, with an area of 1,500 square miles, stretches on either side of the Victoria Nile. Paraa and Chobe lodges cater to tourists. The Ruwenzori National Park occupies some 760 square miles in the Lake Edward–Lake George Basin and contains the Mweya Lodge. The Kidepo National Park consists of 500 square miles of magnificent country adjacent to the Sudan frontier.

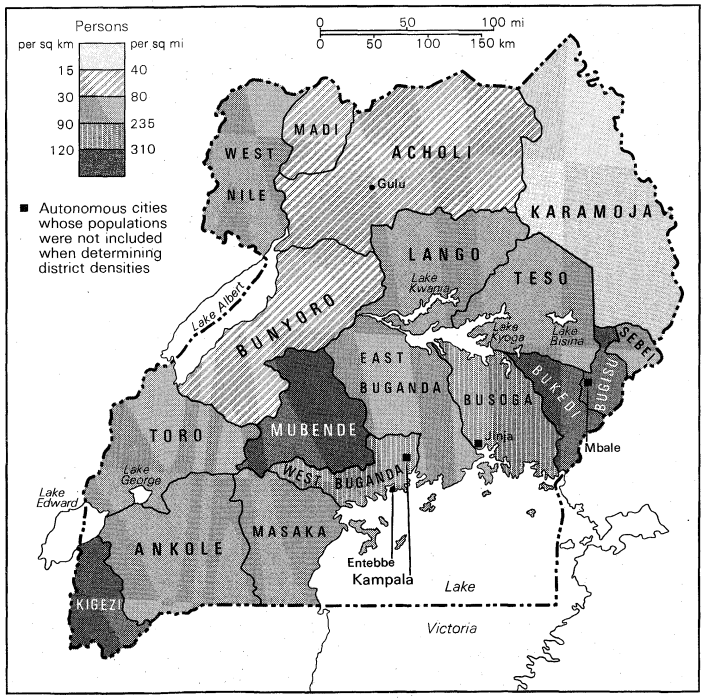
The landscape under human settlement. The traditional regions of Uganda can be divided into two groups on the basis of their past governmental structures. Those areas that had centralized hierarchical governments include the southern regions of the kingdoms of Ankole, Buganda, Bunyoro, Toro, Koki, and the Busoga states. The second group consists of the less centralized state systems of eastern and northern Uganda and of Kigezi district in the extreme southwest. In most of the centralized states government was headed by a king. The king was known as the *kabaka* in Buganda, the *omugabe* in Ankole, and the *omukama* in Toro and Bunyoro.

Uganda's kingdoms

Rural settlement. Rural settlement has been greatly affected by the socio-economic changes that have taken place since 1900. Traditional life in the segmented societies of northern and eastern Uganda revolved around the clan, and people tended to live in clans or communities in particular areas. In the area of the kingdoms, society was more individualistic, although in Ankole society it was—and still is—divided into two groups represented by the ruling pastoralist Hima people and the agricultural Bairu. The Bunyoro and Toro kingdoms were divided along caste lines, while Buganda's society was without caste, if not without class.

The economic differences between the regions of Uganda tend greatly to influence life styles. In Buganda cultivation is left almost entirely to women, while in the north and east both men and women engage in agricultural activities. In the pastoral regions of Ankole, Toro, and Bunyoro, cattle herding is done by men. The introduction of cash crops and modern ranching and the spread of education have greatly affected rural attitudes and expectations.

Urban settlement. One of the major characteristics of the socio-economic change that has occurred has been the growth of towns and cities. As a heritage from the colonial period, every district has at least one township in which government offices and markets are found. Kampala, near Lake Victoria, is the national commercial and administrative capital; before independence, nearby Entebbe was the administrative capital and most of the government offices were located there. Jinja, the industrial capital, was steadily growing in the early 1970s. Mbale is an important centre of the eastern region. Increasing urbanization has led to the depopulation of the villages,



especially in Buganda, because young people are reluctant to adhere to what they often regard as the dull and unexciting life of the countryside. This trend has resulted in an increase in the number of unemployed youths in the towns.

THE PEOPLE

Population groups. *Linguistic groups.* For more than 1,000 years Uganda has been a meeting place of different peoples. The three main linguistic groups are the Bantu, the Nilotics, and the Nilo-Hamitic. As in other parts of East and Central Africa, the Bantu groups are the most numerous, comprising about 70 percent of the population in the south, west, and east. The Nilotics—who are of Sudanic origin—are found in the north, northwest, and north central regions. The Nilo-Hamitic speakers are found in the northeast. English and Swahili serve as common languages. The most widely spoken African language is Luganda.

Ethnic groups. The major Bantu ethnic groups are the Ganda (the largest group), Soga, Nyoro, Nkole (Banyankole), Toro, Chiga (Kiga), Gisu, Gwere, and Nyole (Banyuri). The Acholi, Lango, Karamojong (Bakaramoja), Teso (Iteso), Madi, and Kakwa are the larger Nilotic groups. (To these names the prefix "ba-" is habitually added to denote "people.") Although there has been much admixture of these groups over the centuries, there are still clear linguistic, cultural, and traditional occupational divisions between them. Before the European invasion at the end of the 19th century, the Bantu were largely agricultural, although some districts of the southwest were occupied by a pastoral people called the Hima. The Bunyoro kingdom and northern and northeastern Uganda were partly pastoral and partly agricultural.

About 6 percent of the present African population is composed of recent immigrants from Rwanda, Burundi, Kenya, Zaire, The Sudan, and Tanzania. Since about 1870, foreigners of non-African origin—Arabs, Indians, and Europeans—have settled in the country. Until the 1972 deportation the Indian population, though small, occupied a strategic economic position that has often led to racial tensions in the past.

Population density of Uganda.

English, the official language, is understood by 25 to 30 percent of the population. Luganda, the language of the Ganda people, is understood everywhere but in the non-Bantu areas of the north.

Religious groups. Islām and Christianity were introduced during the 19th century. In 1968 about 60 percent of the population was Christian, 33 percent was animist, and about 5 percent was Muslim. Until the deportation of Asians began in 1972, there were also sizable numbers of Hindus and Sikhs.

Demography. The average population density is about 133 people per square mile, but densities vary from district to district. Areas of heavy concentration are the Bugisu and Bukedi districts in the eastern region and the Kigezi District in the southwest. Density in these areas varies between 350 and 470 persons per square mile of land area. Buganda and Busoga, which stretch along Lake Victoria and contain the principal urban areas, are also densely populated. The lowest density—32 persons per square mile—occurs in North and South Karamoja Districts. The total population numbered 10,127,000 in 1971.

The level of fertility in Uganda is estimated to be 50 per 1,000 females of child-bearing age. The African birth rate is high—between 30 and 40 per 1,000 females. The highest birth rates are recorded among the Chiga (Kiga), Ankole, Karamojong, and Acholi peoples. Low birth rates are recorded among the Teso (Iteso). The Asian population birth rate is also high, being 35 per 1,000. There are signs, however, of a decline in family size among the African and Asian middle-income groups. The adult death rate is about 20 per 1,000, and infant mortality is about 160 per 1,000. The average life expectancy of the inhabitants of these areas is only between 45 and 50 years of age.

The population growth rate of about 3 percent a year is partially due to immigration from Rwanda, Burundi, Kenya, and The Sudan. There is, however, little African emigration. Between the years 1965 and 1972, large numbers of Asians left the country, as did many Africans from Kenya, The Sudan, and Zaire. In the early 1970s the population of Uganda was expected to continue to grow; the birth rate remained high and the death rate decreased.

THE NATIONAL ECONOMY

Uganda is basically an agricultural country. In the past, there was a lack of crop diversification, and the country relied on two major cash crops—coffee and cotton. Fluctuations in the prices of these crops on the world market led to attempts to diversify the cash crops grown. By the late 1960s the economy was fairly healthy, and trade within the East African Community—Uganda, Kenya, and Tanzania—had greatly increased.

The extent and distribution of resources. *Mineral resources.* Uganda is not rich in minerals. Copper and tin ores are the most important minerals, with copper constituting three-quarters of the total minerals produced in 1969. Prospects for finding iron ore are encouraging, but there are no workable coal deposits. Small amounts of tungsten and salt are available. Beryllium ore, used as an alloy and as a source of nuclear energy, is found in large deposits. Small quantities of gold are scattered about, and there are deposits of bismuth, a mineral used in medicines and cosmetics. Industrial and nonmetallic minerals include sand, stone, clay, mica, and phosphate.

Biological resources. Grasslands prevail in dry areas where perennial agriculture is not possible. There are 3,980,000 acres of forest reserves, including stands of mountain bamboo and poor thicket. The government has begun an extensive program of afforestation that includes the introduction of soft woods such as pines.

By 1970 there were 4,400,000 head of cattle, 1,900,000 goats, 900,000 sheep, 10,200,000 poultry, and 74,000 pigs. Cattle, goats, and sheep are concentrated largely in the Districts of North and South Karamoja and Teso in the northeast and of Ankole in the southwest.

Hydroelectric potential

Power resources. There are no known deposits of coal or oil, but many of the rivers are potential sources of hydroelectric power. By 1970 there were three power plants—located on the Victoria Nile, Kagera, and Kiruruma rivers—and plans had been drawn up for additional installations on the Victoria Nile and others.

Sources of national income. *Agriculture, forestry, and fishing.* About two-thirds of the national income is derived from agriculture, and the country is able to meet most of its domestic demand for food. Staple food crops include bananas in the south and west; finger millet (a cereal grass) in the grain belt that stretches across the country from southeast to northwest; sorghum in the extreme northeast and southwest; cassava (manioc) west of the Albert Nile; peanuts (groundnuts) in the southeast; and sesame in the north. Coffee is the most valuable cash crop; the robusta type is grown in the Lake Victoria region and arabica coffee is grown in the east. Most of the cotton crop is grown in the southeast and the northwest. Sugar and tea are grown as cash crops on estates, but tobacco is cultivated by individual farmers. Forestry products include timber, poles, and firewood.

Most fishing on Lakes Victoria, Albert, and George is carried out by canoes on the inshore waters and by motor-powered boats in the deeper waters. Domestic fish ponds are becoming widespread. In 1970 the annual catch was about 130,000 tons, most of which supplied the domestic market. Dried fish is exported to Zaire, and frozen fish fillets are sold to Kenya.

Mining and quarrying. The most important mining operation is the extraction of copper from the Kilembe mine on the eastern flank of the Ruwenzori Range. Other minerals that are mined include tin, tungsten, and beryl. Rock and sand are produced to support the cement industry, while clay is extracted for the production of ceramics.

Manufacturing. Industry has greatly expanded since independence in 1962. Agricultural processing plants—such as cotton gins, coffee works, tea factories, tobacco curing barns, and sugar mills—tend to be situated in their respective crop areas. Jinja has developed as a centre of heavy industry and contains installations for copper smelting, steel rolling, plywood and match manufacture, papermaking, textile production, cigarette manufacture, grain milling, and brewing. Other industries include those producing cement, asbestos, and fertilizer.

Energy. Because of its hydroelectric production, Uganda has not had to rely heavily on imported fuel; gasoline and diesel fuel are, however, imported. The Uganda Electricity Board supplies electricity throughout the country and also exports power to Kenya. More than 90 percent of the country's power in 1970 was produced by the Owen Falls power station. Located near Jinja on the Victoria Nile, its installed capacity is 170,000 megawatts of electricity. There are also two smaller stations—one at Maziba Gorge on the Kagera River, near Kabale, and the other at Kikagati on the Kiruruma River in Ankole District. There are plans to erect another power station at Aru Falls in eastern Acholi District.

Financial services and foreign trade. The Bank of Uganda issues the national currency, acts as banker to the government, and controls the country's commercial banks. In 1970 there were six commercial banks, several of which were branches of banking institutions in the United Kingdom, India, The Netherlands, and Turkey. The Commercial Bank of Africa is represented in Kampala, and the Uganda Commercial Bank has branches throughout the country. Savings may be deposited with cooperative societies, rural thrift and loan societies, and insurance companies.

A distinction may be made between external trade and that within the common market and customs union of the East African Community. The most important external

exports are coffee, cotton, copper, tea, fodder, and hides and skins. The main markets are those of the United States, the United Kingdom, Japan, West Germany, and India. The major imports are machinery, vehicles, and fabrics from the United Kingdom, Japan, West Germany, the United States, and Italy.

Imports from the East African Community include petroleum products, soaps, unmilled wheat, paper and paperboard, and sacks. Exports comprise cotton fabrics, iron and steel bars, and processed foods.

Management of the economy. *The private sector.* The private sector includes all foreign-owned businesses, such as oil companies, banks, insurance companies, and breweries. Since 1970 the government has played a role in this sector and now holds between 40 and 49 percent of these businesses. Many of the originally foreign-owned businesses are now incorporated in Uganda and must retain a specified amount of capital within the country.

The public sector. The government plays an increasingly important economic role in the management of the economy. The government contributes two-thirds of the expenditure in the public sector; the balance is contributed by local authorities, government corporations, and the East African Community. Government corporations include the Uganda Development Corporation, the Uganda Electricity Board, the Coffee Marketing Board, the Lint Marketing Board, the National Trading Corporation, and the Export and Import Corporation.

Taxation. Uganda has one of the highest rates of both direct and indirect taxation in East Africa. Direct taxes include a graduated personal tax, an income tax, and a development tax. Indirect taxes are levied on foodstuffs and contribute to the high cost of living. Customs and excise duties are the responsibility of the East African Community, and their derived revenue is used to run such common services as the railways, postal services, and telecommunications.

Trade unions. Few workers are landless labourers dependent upon wages. Most of them do not identify their long-term interests with wages, and trade unions have consequently been slow to develop. The unions were active in the liberation movement and were closely associated with the urbanization process; they are, therefore, supratribal. An Industrial Relations Charter of 1967—drawn up between the government, the Federation of Uganda Employers, and the Trade Union Congress—established procedures for settling industrial disputes. The government largely established procedures for conciliation and arbitration and has maintained control of the union movement.

Contemporary economic policies. A rapid growth of exports is essential to the attainment of the overall growth-rate target of 6 percent per annum. To help attain this goal, the government has established the Export Promotions Council. The government controls the level of imports by the need to maintain a favourable balance of trade and to keep external reserves at an adequate level. In the industrial sector, steel production using imported iron ore is expected to be greatly expanded by 1974.

Problems and prospects. Contemporary economic policy concentrates on the attraction of foreign capital while encouraging Ugandans to play an increasing role in the management of the economy. The aim is to diversify the range of national resources by such projects as the introduction of a vigorous dairy and ranching industry. Officials hope that by the late 1970s Uganda will not only meet all its beef and dairy needs but will be able to export these products to neighbouring countries. The main economic problems are those of limited capital and the falling or fluctuating of coffee and cotton prices. There is also a relative lack of skilled labour and of highly trained technical personnel.

TRANSPORTATION

Because Uganda is landlocked, the maintenance of an effective line of external communication is essential. An internal transportation system radiates from Kampala, while links with the outside world are maintained by railway, water, and air.

Roads. Uganda's roads are among the best in Africa. Murram, or lateritic (leached, iron-bearing) soil, which is suitable for road construction and hard gravel surfaces, is found everywhere but in the Toro and Kigezi districts. Before World War II such gravel-surfaced roads stood up to the light traffic of that era; the policy in the 1970s is to rebuild old roads while constructing new ones. The road network

There are four main road systems—radial networks around Kampala and Masaka, across the Nile in Busoga District, and in the eastern region in the Teso, Bukedi, and Bugisu districts. There are also mountainous roads in Kigezi District.

Railways. In 1901 the Uganda Railway (later the Kenya–Uganda Railway and now the East African Railway run by the East African Community) was completed. It ran across Kenya from Mombasa on the Indian Ocean to the eastern shores of Lake Victoria, thus linking the country to the sea. In 1912 another line was opened between Jinja and Namasagali on the Victoria Nile, and in 1928 a line joined Jinja to the Uganda Railway at Nakuru, Kenya, creating a direct railway link to the Indian Ocean. In 1931 a further extension connected Jinja to Kampala, another section from Tororo to Soroti was constructed in the late 1940s, and a line from Kampala to Kasese and the Kilembe copper mines was completed in 1957.

Water transport. Lakes Victoria, Albert, and Kyoga and the Albert Nile are navigable. Before the expansion of road and rail transport, steamship services were of vital importance. Since the late 1940s, however, the importance of water transport has declined. A modern passenger vessel maintains a biweekly service round the lake.

Air services. The international airport at Entebbe—capable of handling large jets—lies on one of the main air routes between Europe and South Africa. Several daily flights to Europe are operated by either East African Airways or various European air lines. American and other African air services operate flights between Uganda and West Africa, and there are regular scheduled flights to the Middle East, Pakistan, and India. There are about a dozen domestic airfields, including the field used by the Ugandan air force at Gulu.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *Constitutional framework.* According to the constitution of 1967, Uganda is a sovereign republic within the Commonwealth of Nations. An executive president is the head of state, head of government, and commander in chief of the armed forces. The president is assisted by a cabinet of ministers who are appointed from among the members of the unicameral National Assembly. In theory the National Assembly consists of 82 elected members and such number of specially elected members as may be required to give the party having the greatest numerical strength in the assembly an overall majority of not more than ten. The president takes an active part in the deliberations of the assembly, which sits under the chairmanship of a speaker. The statutory life of the National Assembly was fixed at five years.

Local government. Under the 1962 constitution, the four kingdoms of Ankole, Buganda, Bunyoro, and Toro and the territory of Busoga were in a federal relationship with the central government. The kingdoms were ruled by their traditional hereditary kings, and Busoga was governed by a district council. In 1967 all the kingdoms were abolished and the country was divided into districts. Each district is headed by a commissioner who is officially appointed by the president. The districts are divided into counties, subcounties, and parishes. Kampala, Jinja, Mbale, and Masaka are governed by urban authorities. Responsibility for the whole structure of local government lies with the Ministry of Public Service and Local Administration.

The political process. In 1971 Uganda's one-party government was overthrown by the armed forces. After the coup d'etat, the National Assembly and district and city councils were dissolved and all political activi-

ties were banned. A return to civilian rule was promised as soon as an investigation into the activities of the previous government had been concluded.

Justice. The system of justice was modelled on that of the United Kingdom. The High Court of Uganda, with jurisdiction throughout the republic, consists of a Ugandan chief justice, at least six puisne (associate) judges, and registrars and magistrates. All judges are appointed by the president with the advice of the cabinet. Judges of the High Court can be removed by the president for "bad behaviour or for reasons of infirmity." There is a Judicial Service Commission composed of the chief justice as chairman, the attorney general, and such puisne judges as may be designated with the advice of the chairman. There are also district courts throughout the country. Because of its membership in the East African Community, Uganda is also a member of the Court of Appeal for East Africa, a judicial body which sits in the various national capitals and is presided over by an appeal judge that is appointed by the three presidents of the Community.

The armed forces. The Uganda armed forces evolved out of the colonial King's African Rifles; they are now completely Africanized. The 12,000-man Army consists of battalions, paratrooper units, and an air force. Many of the high-ranking officers have been trained abroad, especially in the United Kingdom and Israel.

Administration. *Education.* Since independence, the role of the missionaries in education has remained prominent, although the government has overall responsibility for educational services at all levels. In 1970 there were about 2,700 public primary schools with about 1,000 private ones. There are relatively few secondary schools. Postprimary-school enrollment is strictly controlled and linked closely to manpower needs. At the beginning of the 1970s, Uganda was spending nearly one-fifth of its revenue budget on education, and there had been rapid expansion of the educational services since independence. In spite of these efforts, less than 45 percent of the children of primary school age attended school. In the early 1970s plans included the expansion of technical and vocational schools.

Primary and secondary schools

Until the early 1960s, Makerere University College in Kampala was the only institution of higher education in East and Central Africa. For a time it became part of the University of East Africa, before becoming an independent university in 1970. It has faculties of arts, social sciences, science, law, engineering, veterinary science, agriculture, and education. Its medical school, founded in 1924, is one of the best in Africa, as is its Institute of Social Research.

Health and welfare services. Health and welfare services are the responsibility of the Ministry of Health and the Ministry of Community Development and Culture. Since 1955 emphasis has been placed on preventive medicine. Health personnel include doctors, nurses, midwives, and health inspectors. There are schools for nursing and midwifery at all major hospitals, the largest of which is in Kampala. Medical facilities include a school of hygiene at Mbale, a department of preventive medicine at Makerere, a vector control unit, and a number of rural health centres. Despite the expansion of health services at all levels, there is still only one doctor for about 8,690 of the population.

Pensions are granted to high civil servants after 25 years of service. Wage earners participate in a contributory social security system, and companies offer contributory pension plans.

Housing. In the early 1970s more than 90 percent of Uganda's population lived in rural areas and provided their own housing. Rural buildings are largely of rectangular design and are constructed of woven branches plastered with mud, roofed with corrugated iron. The urban population was expanding rapidly, especially around Kampala and Jinja, where there was a scarcity of housing for middle-income groups. The National Housing Corporation and private builders had built houses for different income groups, but a tremendous shortage of housing for the low-income group still remained. In urban centres houses are built of concrete blocks or burnt bricks and are roofed with corrugated iron or tiles. Buildings in urban fringe areas are of traditional structure. Various employers, such as the oil companies, the East African Community, and the government, house their employees at nominal or free rents. Outside the urban areas of Uganda, housing is unplanned, and there are no services such as street lighting, waste disposal, or telephones.

Police services. The Ugandan police force numbers between 7,000 and 8,000 men but is understaffed. There are also paramilitary units that assist the armed forces in border patrol and riot control. Police stations are located in all the towns, and there is a police training school in Kampala.

Social conditions. *Wages and the cost of living.* The wages of unskilled workers remain low, a problem that has been aggravated because the growth of employment opportunities has not kept pace with the increase of the labour force. One of the legacies of the colonial period is a salary structure that contains enormous disparities between the highest and the lowest incomes. There is also a difference in wage structure between the urban and the rural areas and between the different urban centres.

Health conditions. The health situation is generally better than that in many other African countries. A number of diseases such as malaria, hookworm, venereal disease, and intestinal disorders are, however, common. Adults do not generally suffer from malnutrition, but the low-protein content of most foodstuffs results in the occurrence of kwashiorkor (a food-deficiency disease) among infants and children.

Social and economic divisions. People in Uganda comprise three groups—the Africans, Asians, and Europeans—among which there is little social contact except at formal gatherings. Most of the Africans comprise the agricultural population; the urban African is a wage earner, salaried civil servant, or university professor. Prior to 1972 the Asians dominated the nation's commerce and provided the largest source of skilled labour. The Europeans are professionals, civil servants, or owners of industry.

CULTURAL LIFE AND INSTITUTIONS

Uganda's varied ethnic groups have each contributed to the general cultural environment. Traditional cultures have generally survived the colonial impact, but not without modifications. Christianity in its various forms, Islām, and other world religions have been influential and seem to be the cultural focus for a fairly large section of the population. Institutions such as the cinema and the theatre are integral components of urban life. In order to promote the performing arts of dance, music, and drama, the government created a Ministry of Community Development and Culture.

The state of the arts. The practice and appreciation of fine arts are limited to a small but expanding section of the population. The Makerere School of Fine Art has trained some of East Africa's leading painters, sculptors, and art teachers; the school also teaches industrial art and design. In order to strengthen the performing arts, the Ministry of Community Development and Culture established the "Heart Beat of Africa," a dancing group consisting of representatives of major ethnic groups. Among the dances traditionally performed only by women are the *bakisimba* and *nankasa* dances of the Ganda, the *bwola* and *jing ding* dances of the Acholi, and the *lunyege* dance of the Anyoro and Toro.

Traditional art forms

On the academic level, historians, musicologists, anthropologists, and theologians delve into oral traditions in order to reconstruct aspects of Ugandan culture. There seems to be an attempt among middle-income groups to reaffirm the cultural heritage; in the dance halls, popular music is frequently interrupted by traditional tunes.

Cultural institutions. Churches, mosques, schools, theatres, and museums are the new repositories of national culture. There is the National Theatre and the Uganda Museum, in Kampala. In Buganda, Bunyoro, and Ankole the royal jawbone (relics of kings) shrines and tombs

recall the historic power of the kingdoms. The Entebbe Botanical Gardens contain local and exotic plants. The Forest Department maintains a library, herbarium, and museum, and there are a game and fisheries museum, zoo, aquarium, and library. There are also museums at the Ruwenzori and Kabarega national parks. Makerere University maintains two libraries.

The press. The press traces its origin to the weekly newspapers published by missionaries. The major Ugandan dailies are *Argus* (published in English) and *Taifa Empya* and *Munno* (both published in Luganda). Kenyan newspapers such as the *Nation* and the *East African Standard* are widely read, as are some British newspapers.

Radio and television. Radio Uganda maintains broadcasting stations in all the major towns and transmits the same program throughout the country. Nearly all of the vernacular languages are used along with Swahili and English. There were plans for an external service in the early 1970s. Television was introduced in 1963. Programs are transmitted as far as Bukoba, Tanzania. Through the services of Radio Uganda and Uganda Television, plays and traditional music are broadcast and drama festivals are organized periodically. A number of educational programs are also broadcast.

PROSPECTS FOR THE FUTURE

The military regime established by the coup d'etat of 1971 may be followed with a return to parliamentary government by 1980. Rural economic development is likely to receive greater attention than it has hitherto. Efforts are being made to increase employment opportunities and to place trained Africans in managerial positions. Uganda has suffered from a long-term drain on capital transfers; there is a need for stricter exchange controls. Despite governmental efforts to diversify the economy, there is still an excessive dependence upon coffee and cotton.

Ugarit

Ugarit was an ancient city lying in a large artificial mound called Ra's Shamrah six miles (ten kilometres) north of al-Lādhiqīyah (Latakia) on the Mediterranean coast of northern Syria. Its ruins, about half a mile from the shore, were first uncovered by the plow of a peasant at Mīnat al-Bayḍā. Excavations were begun in 1929 by a French archaeological mission under the direction of Claude F.A. Schaeffer.

The golden age of Ugarit. The most prosperous and the best documented age in Ugarit's history, dated from *c.* 1450 to *c.* 1200 BC, produced great royal palaces and temples and shrines, with a high priests' library and other libraries on the acropolis. Some of the family vaults built under the stone houses show strong Mycenaean influence. Mycenaean and Cypriot pottery has also been found.

After the discovery of the temple library, which revealed a hitherto unknown cuneiform alphabetic script as well as an entirely new mythological and religious literature, several other palatial as well as private libraries were found, along with archives dealing with all aspects of the city's political, social, economic, and cultural life.

The art of Ugarit in its golden age is best illustrated by a golden cup and patera (bowl) ornamented with incised Ugaritic scenes; by carved stone stele and bronze statuettes and ceremonial axes; by carved ivory panels depicting royal activities; and by other fine-carved ivories. Despite Egyptian influence, Ugaritic art exhibits a Syrian style of its own.

Soon after 1200 BC Ugarit came to an end. Its fall coincided with the invasion of the Northern and Sea Peoples, and probably with earthquakes and famines. In the Iron Age and during the 6th–4th centuries BC there were small settlements on the site.

The excavators of the site were fortunate in the number and variety of finds of ancient records in cuneiform script. The excavations continue and each season throws some new and often unexpected light on the ancient north Canaanite civilization. The texts are written on clay tablets either in the Babylonian cuneiform script or in the special alphabetic cuneiform script invented in Ugarit. Several copies of this alphabet, with its 30 signs, were found in 1949 and later. A shorter alphabet with 25, or even 22, signs seems to have been used by 13th-century traders.

Scribes used four languages: Ugaritic, Akkadian, Sumerian, and Hurrian, and seven different scripts were used in Ugarit in this period: Egyptian and Hittite hieroglyphic and Cypro-Minoan, Sumerian, Akkadian, Hurri-

an, and Ugaritic cuneiform. These show clearly the cosmopolitan character of the city.

The Middle Bronze Age period. A carnelian bead identified with the pharaoh Sesostris I (reigned 1971–1928 BC) and a stela and statuettes, gifts to the kings of Ugarit from other Middle Kingdom pharaohs (*e.g.*, Sesostris II, 1897–1878, and Amenemhet III, 1842–1797), provided the first exact dating in the history of Ugarit. Eggshell ware from Crete (Middle Minoan period) and Babylonian cylinder seals found in the tombs of level II also provided cross datings. During the 18th and 17th centuries BC Ugarit was apparently under the control of new tribes related to the Hyksos, probably mainly Hurrians or Mitannians, who mutilated the Egyptian monuments.

Ras Shamra texts and the Bible. Many texts discovered at Ugarit, including the "Legend of Keret," the "Legend of Aghat" (or "of Danel"), the "Myth of Baal-Aliyan," and the "Death of Baal," reveal an Old Canaanite mythology. A tablet names the Ugaritic pantheon with Babylonian equivalents; El, Asherah of the Sea, and Baal were the main deities. These texts not only constitute a literature of high standing and great originality but also have an important bearing on Old Testament studies. It is now evident that the patriarchal stories in the Old Testament were not merely transmitted orally, but were based on written documents of Canaanite origin, the discovery of which at Ugarit has led to a new appraisal of the Old Testament.

The Ras Shamra mound. Soundings through the Ras Shamra mound revealed a reliable stratigraphic sequence of settlements from the beginning of the Neolithic period. Above the ground level, five main upper levels (levels V to I) were identified. The three lowest levels have been subdivided into smaller layers. The earliest settlement on level V—already a small fortified town in the 7th millennium BC—shows a prepottery stage with flint industries. Also on level V, but in a later layer, light, sun-dried pottery appears. Level IV and part of level III date back to the Chalcolithic, or Copper–Stone, Age, when new ethnic groups arrived from the northeast and the east. This stage shows Mediterranean as well as strong Mesopotamian influence. During the Early Chalcolithic Age, painted pottery of the Hassunan and Halafian cultures of northern Iraq is very common. The Late Chalcolithic shows fresh Mesopotamian influence with its monochromatic, Ubaidian, geometrical painted pottery. The flint industry was then in competition with the first metal tools, made of copper. The Early Bronze Age (3rd millennium) layers, immediately above, in level III, yielded no more painted ware but various monochromatic burnished wares and some red polished ware of Anatolian origin. With Early Bronze Age III, metallurgy quickly developed. In the Middle Bronze Age newcomers, so-called Torque-Bearers, expert in bronze metallurgy, arrived (*c.* 2000–1900 BC). Levels II and I correspond to historical periods within the 2nd millennium BC.

Ukrainian Soviet Socialist Republic

The Ukrainian Soviet Socialist Republic (or Ukrainian S.S.R., also called the Ukraine) lies in the southwest of the European Soviet Union, bordered by the Belorussian S.S.R. on the north; the Russian S.F.S.R. on the east; the Sea of Azov, the Black Sea, the Moldavian S.S.R., and Romania on the south; and Hungary, Czechoslovakia, and Poland on the west. With an area of 233,100 square miles (603,700 square kilometres), it is one of the largest geographical entities in Europe, third in size after the Soviet Union and the Russian S.F.S.R. Nonetheless, it constitutes only 2.7 percent of Soviet territory, though it produces more than 20 percent of the Soviet industrial and agricultural output and one-fourth of its grain. It became a union republic of the Soviet Union in 1924.

In 1975 the population of the Ukraine was estimated at 48,830,000, of whom 74.9 percent were Ukrainians (formerly also called Ruthenians, or Little Russians). The Ukrainian language belongs to the East Slavic group, of which Russian and Belorussian are also members.

The following article describes the land, people, economy, and society of the contemporary Ukraine. For history, see RUSSIA AND THE SOVIET UNION, HISTORY OF; for a description of the capital city, see KIEV; for related physical features, see DNEPR RIVER; DNESTR RIVER; AZOV, SEA OF; BLACK SEA; CARPATHIAN MOUNTAINS; and PRIPET MARSHES; see also SLAVIC LANGUAGES; SOVIET UNION.

THE LAND

Topography. The Ukraine, consisting almost entirely of level plains at an average elevation of 574 feet (175 metres) above sea level, occupies a considerable portion of the East European Plain. Such mountainous areas as the Ukrainian Carpathians and Crimean Mountains occur only on the borders and account for barely 5 percent of the area. The landscape is nevertheless diverse, and the plains are broken by highlands—running in a continuous belt from northwest to southeast—as well as lowlands. The rolling plain of the Dnepr Plateau, which lies between the middle reaches of the Dnepr (Dnipro; alternative spellings given in parentheses are Ukrainian) and Yuzhny (Southern) Bug (Boh, or Buh) rivers, is the largest highland area, broken up by many river valleys, ravines, and gorges, some more than 1,000 feet deep. From the west, the plateau is abutted by the characteristically rugged Volyn–Podolsk (Podilian) Upland, which rises to 1,549 feet (472 metres) at its highest point, Mt. Kamul. On the left bank of the Dnepr the Azov Upland, the highest point of which is Mt. Mogila-Belmak (1,070 feet), stretches gently away from the mountains to the Donets Ridge on its northeastern edge, which is surmounted by Mt. Mogila-Mechetnaya (1,204 feet). The northeastern portion of the Ukraine is a spur of the Central Russian Upland, but it reaches an elevation of only 774 feet (236 metres) at its highest point.

In the northern part of the republic lie the Pripet Marshes, crossed by numerous river valleys. In the central Ukraine is the Dnepr Lowland, flat in the west and gently rolling in the east. The Black Sea Lowland extends along the shores of the Black and Azov seas, its level surface, broken only by low rises and shallow depressions, sloping gradually toward the Black Sea. In the Crimean Peninsula it becomes the North Crimean Lowland. In the Transcarpathian region of the western Ukraine, the Tisa Lowland lies in the valley of the Tisa (Tysa) River and its tributaries. Toward the south it becomes the Pannonian Basin. In the west the parallel ranges of the Carpathian Mountains—one of the most picturesque areas in the Ukraine—extend for more than 150 miles. Easily accessible, the mountains range in height from about 2,000 to 6,500 feet, rising to 6,762 feet (2,061 metres) in Mt. Hoverla, the highest point. A number of passes through the mountains provide routes for both highways and railroads.

The Carpathian Mountains

About 90 miles long and 30 miles wide, the Crimean Mountains lie in three low, parallel ranges, with fertile valleys between them. They form the southern coast of the Crimean Peninsula, the belt of land between the Black Sea and the Sea of Azov; Mt. Roman-Kosh, at 5,069 feet (1,545 metres), is their highest point. The shores of the two seas are low, characterized by narrow, sandy spits of land that jut out into the water.

Climate. The Ukraine lies in a temperate climatic zone, influenced by moderately warm, humid air from the Atlantic Ocean. Winters in the west are considerably

milder than those in the east, which is strongly affected by the northern high-pressure belts, or anticyclones. In summer, on the other hand, the east often experiences higher temperatures than the west. Average annual temperature ranges from 42°–45° F (5.5°–7° C) in the north to 52°–55° F (11°–13° C) in the south. The average temperature in January, the coldest month, is 26° F (–3° C) in the southwest and 18° F (–8° C) in the northeast. The average in July, the hottest month, is 73° F (23° C) in the southwest and 66° F (19° C) in the northeast.

Precipitation

Precipitation is uneven, with two to three times as much rainfall in the warmer seasons as in the cold. Maximum rainfall generally occurs in June and July, minimum in February. Snow falls mainly in late November and early December, varying in depth from a few inches in the Steppe region to several feet in the Carpathians.

The southern shore of the Crimea has a warm, gentle, Mediterranean-type climate. Winters are mild and rainy, with little snow, and the average January temperature is 39° F (4° C). Summers are dry and hot, with an average July temperature of 75° F (24° C). Precipitation totals 16 to 24 inches (400 to 600 millimetres) per year.

River systems and drainage. Inland waters of the Ukraine include rivers, lakes, reservoirs, ponds, and marshes, as well as underground water sources. Almost all of the major rivers flow through the plains toward the Azov–Black Sea Basin; only 3 percent of drainage enters the Baltic Sea Basin. Nearly 23,000 rivers and streams are found within the republic's borders; some 3,000 of these are at least six miles long, and 116 exceed 60 miles in length. Of the total course of the Dnepr, 748 miles (1,204 kilometres) is in the Ukraine, making it by far the longest river in the republic, of which it drains more than half. Like the Dnepr, the Yuzhny Bug, with its major tributary, the Ingul, flows into the Black Sea. To the west and southwest, partly draining Ukrainian territory, the Dnestr (Dnister) also flows into the Black Sea; among its numerous tributaries, the largest in the Ukraine are the Stry and the Zbruch. The Danube River flows along the southwestern frontier of the Ukraine, and one of its tributaries, the Tisa, flows through Transcarpathia. The middle course of the Donets River, a tributary of the Don, flows through the Ukraine and is an important source of water for the Donets Basin. The largest river in the Crimea, the Salgir (Salhyr), flows into the Sea of Azov.

The rivers are most important as a water supply, and for this purpose a series of canals has been built, such as the Donets–Donets Basin, the Dnepr–Krivoy Rog, and the Kakhovka Reservoir–Crimea. Several of the larger rivers are navigable, including the Dnepr, Danube, Dnestr, Pripyat (Prypiat), Donets, and Yuzhny Bug (in its lower course). Mountain rivers are also used for rafting timber, and hydroelectric plants are situated on all of the larger ones.

The Ukraine has a few lakes, all of them small and most of them very old, scattered over the river floodlands. One of the largest is Lake Svityaz (Svytiaz), 11 square miles (28 square kilometres) in area, in the northwest. Small saltwater lakes occur in the Don Basin and the Black Sea Upland. Lakes in the Carpathians are of the small, deep, alpine type. Some artificial lakes have been

Lakes and reservoirs

formed, the largest of which are reservoirs at hydroelectric dams. The Lenin Reservoir of the Lenin hydroelectric station on the Dnepr near Zaporozhye (Zaporizhia) is the best example, but other large reservoirs are found in the Donets and Krivoy Rog (Kryvyi Rih) basins near Zhdanov, Kharkov (Kharkiv), and other industrial centres. Almost 3 percent of the Ukraine is marshland, primarily in the northern river valleys and in the lower reaches of the Dnepr, Danube, and other rivers. Underground water is exceptionally important for agriculture, especially in three large artesian basins: the Volyn–Podolsk (Lvov), the Dnepr–Donets, and the Black Sea.

Soils and vegetation. From northwest to southeast, the soils of the Ukraine may be divided into three major aggregations—a zone of sandy podzolized soils (a podzol is a soil having an acidic surface of forest humus, a light gray zone of leaching beneath it, and a bottom layer of accumulation); a central belt consisting of the famous Ukrainian chernozems (black-earth soils); and in the southeast a zone of chestnut and salinized soils surrounding the Black Sea.

The podzolized soils of the forested steppe, occupying about 21 percent of the republic's area, mostly in the northwest, were formed by the extension of postglacial forests into regions of grassy steppe; most of these soils may be farmed, although they require the addition of nutrients leached by the podzolizing process to obtain good harvests.

The chernozems of the centre are among the most fertile soils in the world, occupying about 65 percent of the republic's area; they may be divided into three broad groups: in the north a belt of the so-called deep, or thick, chernozems (the most fertile; about 5–6½ feet [1.5–2 metres] thick and rich in humus); south and east of the former, a zone of degraded (podzolized) chernozems, lean (eroded) chernozems, and podzolized mountain soils; the southernmost of these southwest–northeast-trending belts consists of ordinary steppe, or prairie, chernozems and the southern chernozems (both of the latter types are thinner than the deep chernozems, about 3 feet [1 metre], and high in humus, the southern less so than the ordinary). About 9 percent of the republic is covered by mixed gray and black-earth soils. Almost all soils in this belt are very fertile when enough water is available.

The remaining 5 percent of the soil cover consists of the chestnut soils of the south and east, similar in chemistry to the chernozems but lower in calcium and higher in sodium; they become increasingly salinized as they approach the Black Sea, where highly saline solonets and solonchak soils are found.

Plant life exists in great variety. In the north the abundant rainfall and moderate temperatures provide favourable conditions for forest vegetation. Woodlands alternate with areas of steppe in the central region. Forest usually covers river valleys and the slopes of ravines and gorges. The total area of forested land, however, is only about 19,800,000 acres (8,000,000 hectares), and nearly one-third of this has been planted by man. Most of the rich forest lands are in the Transcarpathian region, with very little woodland in the south.

Polesye, Lesostep, and Steppe

Three natural zones of vegetation are distinguishable: the Polesye (woodland and marsh), the Lesostep (woodland–steppe), and the Steppe.

The Polesye zone lies in the northwest and north, with an area of about 44,000 square miles (114,000 square kilometres), of which 35 percent is arable land. Nearly one-quarter of this land is covered with mixed woodland, including oak, elm, birch, hornbeam, ash, maple, pine, linden, alder, poplar, willow, and beech. About 5 percent is peat bog, a substantial portion is marshland, and the river valleys are floodplains. Swamp drainage is a primary project in the Ukraine's program of land reclamation; in the 1970s about 7,500 square miles of marshland were being reclaimed annually, most of it in the Polesye.

The 78,000-square-mile (202,000-square-kilometre) Lesostep extends south from the Polesye. Arable land covers about 67 percent of this agricultural region, forests only about 12 percent. Farther south, near the Black and Azov seas and the Crimean Mountains, the Lesostep joins the Steppe zone (92,500 square miles, or 240,000 square kilometres). The natural vegetation of the Steppe is protected in nature reserves, the largest being the Askaniya-Nova reserve in Kherson *oblast*. The lack of moisture makes necessary widespread irrigation, which in the mid-1970s was carried out on about 5,000 square miles of the Ukraine's arid land, mostly in the Steppe zone.

Three other natural regions are found near the borders of the republic: the Carpathians, the Crimean Mountains, and the southern coast of the Crimean Peninsula. In the mountainous areas the lower slopes are covered with mixed forests, the intermediate slopes (4,000–5,000 feet, or 1,200–1,500 metres) with pine forests; these give way to grassland and alpine meadows at higher

altitudes. A narrow strip of land, only six miles wide, along the southern coast of the Crimea constitutes a unique natural region where both deciduous and evergreen grasses and shrubs grow. Near the city of Yalta is located the Nikitsky Botanical Garden, in which plants from almost every country in the world are found. An exceptionally beautiful environment, a warm climate, and the sea make the southern shore of the Crimea one of the finest vacation areas in the world.

Animal life. The animal life of the Ukraine is diverse, with more than 350 species of birds, about 100 of mammals, and more than 200 of fish. The commonest predators are wolf, fox, wildcat, and marten, while hoofed animals include the roe deer, wild pig, and sometimes elk and mouflon (a wild sheep). The wide variety of rodents includes gophers, hamsters, jerboas, and field mice. The major bird species are black and hazel grouse, owl, gull, and partridge, as well as many migrating birds, such as wild goose, duck, and stork. Among the fish are pike, carp, bream, perch, sturgeon, and sterlet. Introduced and well-acclimatized wildlife includes muskrat, raccoon, beaver, nutria, and silver fox. Common insect pests are the meadow butterfly, sugar beet weevil, and cabbage butterfly.

Nature reserves. The conservation of the biological heritage of the republic is given high priority, and considerable manpower is expended on it. The republic established its first nature reserve, Askaniya-Nova, in 1921, three years before it entered the Soviet Union. This reserve, occupying about 25,900 acres (10,500 hectares), preserves a portion of virgin steppe, with characteristic fescue and feather grasses. Some 40 different mammals, including the onager and Przewalski's horse, have been introduced as part of a successful program of breeding endangered species; even ostriches have been successfully introduced.

Among the other important reserves is the Black Sea (established 1927; area 90,400 acres [36,600 hectares]), including protected areas of the sea. It is among the most visited reserves in the Ukraine, the attractions including many species of waterfowl, and is the only breeding ground in the Soviet Union of the gull *Larus melanocephalus*.

The Ukrainian Steppe reserve is discontinuous, comprising four separate sections, each of which preserves a special type of steppe: the Mikhaylovsk (Mykhailiv; virgin meadow steppe), the Strelets (Striletsky; a *stipa*, or grass steppe), the Khomutovsky (chernozem, or black-earth, steppe), and Kammeniye Mogily (Kamiani Mohyly, "Stone Tombs"; a stony steppe). This reserve was established in the period 1925–37. Other major reserves include the Crimean (established 1923, area 65,700 acres), the Azov-Sivash (established 1927, area 21,000 acres), and the Kanev (Kaniv; established 1931, area 2,570 acres).

THE PEOPLE

With 48,830,000 persons in 1975, the Ukraine ranks as the second most populous Soviet republic, after the Russian S.F.S.R., with about 19 percent of the Soviet Union's total population. The annual rate of growth in the mid-1970s was 5.7 per thousand, with a birth rate of 15.1 and a death rate of 9.4. The majority are Ukrainians, who are the second most numerous ethnic group in the Soviet Union, after Russians. Although more than 100 different nationalities live in the Ukraine, 96 percent of the people are linguistically classified as Slavs, including Ukrainians (74.9 percent), Russians (19.4 percent), Poles (0.6 percent), Belorussians (0.8 percent), and Bulgarians (0.5 percent). Jews account for 1.6 percent of the total, and there are small numbers of Greeks, Romanians, Armenians, Gypsies, Hungarians, Tatars, Chuvash, Lithuanians, Bashkirs, and Kazakhs.

Population density

The population density is among the highest in the Soviet Union, with an average of almost 210 persons per square mile (81 per square kilometre) and in some areas, particularly in the highly industrialized Donets Basin and Dnepr Lowland, many more. These two regions also account for 76 to 87 percent of the total urban population. In the Ukraine as a whole, 58 percent of the people live in cities. In 1975 there were 393 cities, 897 towns, and 9,657 rural settlements. At the 1970 census, about 150 cities had populations ranging from 10,000 to 20,000, 130 from 20,000 to 100,000, and 40 or so with more than 100,000 inhabitants. Odessa, Donetsk, Dnepropetrovsk, Zaporozhye, Krivoy Rog, and Lvov (in Ukrainian, Odessa, Donetske, Dnipropetrovske, Zaporizhia, Kryvyi Rih, and Lviv) each had more than 500,000 inhabitants. The only cities with populations of more than 1,000,000 at that time were Kiev and Kharkov (Kharkiv), but in 1974 Odessa also passed the 1,000,000 mark. The rural population is distributed among the villages and the more than 9,600 other settlements, such as *sovkhozy* (state farms), collective farms (*kolkhozy*), and so on. More than 50 percent of the rural population lives in large villages (1,000 to 5,000 inhabitants), most of them located in the Lesostep area.

THE ECONOMY

The complex industrial–agrarian economic structure of the Ukraine is integrally related to that of the entire Soviet Union. In its rate of economic development it ranks second among the Soviet republics (after the Russian S.F.S.R.). The effects of the devastation of the Nazi invasion in World War II have been completely overcome.

Mineral resources. The Ukraine has about 72 kinds of mineral resources. Iron ore reserves, equalling nearly 19,400,000,000 tons, are located in the Krivoy Rog, Kerch, Belozyorka, Kremenchug, and Mariupol regions. The Ukraine is one of the richest areas in the world in manganese-bearing ores. Anthracite and bituminous coal reserves, largely in the Donets Basin (called Donbass), total 39,000,000,000 tons, and reserves of brown coal are estimated at about 6,000,000,000 tons, mostly in the Dnepr Basin.

The three major petroleum-producing areas in the Ukraine are the Ciscarpathian, Dnepr–Donets, and Crimean regions, where nearly 100 separate oil and gas deposits are known. The developed gas reserves at the beginning of 1969 amounted to 24,200,000,000,000 cubic feet (684,000,000,000 cubic metres).

Among the most important deposits of other minerals are the Irsha titanium ores, the Smela and Vysokopolye bauxite deposits, nephelites from the Oktyabrskoye and Yelanchitsa deposits near the Sea of Azov, the Beregovo and Began deposits of alunites, and the Nikitovka mercury (cinnabar, or mercuric sulfide) ores in the Donets Basin. The largest deposit of ozokerite (a natural paraffin wax) in the Soviet Union is near the city of Borislav. Ciscarpathia possesses potassium salt deposits with strata 170–180 feet (50–55 metres) thick. That region and the Donets Basin have very large resources of rock salt. Some phosphorites exist, notably in the Izyum and Krolevets deposits, as well as natural sulfur in the Ciscarpathian and Dnepr regions and in the Crimea. In Transcarpathia and near the cities of Lvov, Kiev, Vinnitsa (Vinnytsia), Poltava, Khmelnitsky (Khmelnytsky), and Kharkov are health spas noted for their mineral springs; spas near the Black Sea and the Sea of Azov specialize in mud baths.

Health spas and mineral springs

Industry. The Ukrainian S.S.R. has a major ferrous-metal industry, producing nearly half of the Soviet Union's cast iron, more than 40 percent of its steel and rolled steel, and about a quarter of its steel pipe. Mining output is also a very high proportion of the Soviet total, the main products being coal, natural gas, and iron ore. Manufactured goods include metallurgical equipment, diesel locomotives, tractors, and television sets. The Ukrainian chemical industry accounts for half of all the coke, 21 percent of the mineral fertilizers, and 18 percent of the sulfuric acid produced in the Soviet Union. The food industry accounts for 60 percent of the national output of granulated sugar, and Ukrainian agriculture produces nearly a quarter of the gross national grain yield, roughly half of the sugar beets and sunflower seeds, and approximately a quarter of all potatoes, vegetables, meat, eggs, and milk. One-tenth of the world's

cast iron, 9 percent of its steel, and 8.5 percent of its coal are produced in the Ukraine. Diversified industry, in more than 150 fields, is the most important sector in the economy in terms of productivity and revenue earned.

Extractive industries. The major product of Ukrainian mining is coal. During the Five-Year Plan covering 1971–75, more than 1,000,000,000 tons of coal were mined, about 90 percent in the Donets Basin. Petroleum is far less significant, only about 14,100,000 tons being extracted in 1975, mainly in the Ciscarpathian region. In this same region, however, the exploitation of natural gas deposits, which began during the postwar period, reached production of almost 2,426,000,000,000 cubic feet (68,700,000,000 cubic metres) in 1975. A new high-capacity field, the Vostochny, is in operation in Kharkov *oblast*.

In 1974, 134,000,000 tons of iron ore were mined. The Ukraine also produces limited amounts of titanium, bauxite, and mercury and ranks first in world production of manganese-bearing ores, which have been mined in the Nikopol area since 1886. Raw materials for the chemical industry are likewise significant, and building materials, ranging from granite to the components of cement (marl and chalk), are extracted from Ukrainian quarries. In the south are found reserves of limestone, graphite, sand, and clay.

Manufacturing industries. The Ukraine is the major Soviet centre for the production of ferrous metals. The Dnepr region accounts for 70 percent of the republic's cast-iron production, much of it coming from mills in Dnepropetrovsk. Railway locomotives and freight cars, seagoing vessels, hydroelectric and thermal steam and gas turbines, electrical generators, and automobiles are also made in Ukrainian factories. Expanded residential and industrial construction demands hoisting and transportation equipment and other machinery for the building trades. The Ukraine is also the principal centre of production of the giant airliner Antey, which can carry up to 720 passengers.

Plants for the production of equipment for food-processing and other light industries are scattered throughout the republic. The Ukraine, one of the great agricultural regions of the world, also has more than 50 factories engaged in the production of a wide range of agricultural equipment, the chief centres of production being Kharkov, Odessa, Lvov, and Kherson. Machine-tool and instrument-manufacturing industries are being developed. The growing importance of consumer goods is reflected in the increasing output of, among other items, cameras, television sets, refrigerators, and washing machines.

The Ukrainian chemical-equipment industry, accounting for one-third of Soviet production, is mainly concentrated in Kiev, Sumy, Fastov (Fastiv), and Korosten. The chemical industry includes coking and the manufacture of coke products, as well as the manufacture of mineral fertilizers, sulfuric acid, synthetic fibres, caustic soda, petrochemicals, photographic chemicals, and pesticides.

Food processing. The larger divisions of the Ukrainian food-processing industry—sugar refining, processing of meat, fruit, and dairy products, wine making, and distilling—are important to the entire Soviet Union. Of the approximately 2,000 products, one of the most important is sugar. Production of vegetable oil, mainly from sunflower seeds, is also significant. Nearly 30 percent of all the wine made in the Soviet Union comes from the Ukraine—in the south, in the Transcarpathian region, and in the Crimea, where the vintners of the Massandra group are established near Yalta. In the coastal cities, such as Odessa, are found local industries processing fish.

Some of the principal products of light industry are textiles, both knitted and woven, ready-to-wear garments, and shoes.

Energy. About 99 percent of the energy for industrial processes in the Ukraine is provided by fossil fuels, hydroelectricity accounting for only 1 percent. Producing 194,400,000,000 kilowatt-hours of electric power in 1975, the Ukraine provided about 19 percent of the Soviet Union's total electricity. Thermal power stations are found in all parts of the republic, though the largest are in the Donets Basin and along the Dnepr. A third electric energy-producing area is in the vicinity of the Lvov–Volyn coal basin, and in the Ciscarpathian region there is a group of six hydropower stations. The major hydroelectric plant, in the Dnepr cascade region near Zaporozhye, the Lenin station, underwent a program of renovation and expansion in the 1970s; the combined capacity of the Lenin station and its sister station, called Dnepr II, nearby, eventually will reach 1,478,000 kilowatts. Two thermal power stations of similar design, one near Zaporozhye and the other at Uglegorsk, in the Donets Basin, were designed for 3,600,000 kilowatts output when completed; by 1975 the installed capacity of both had reached 2,000,000 kilowatts.

The Lenin hydroelectric plant

Agriculture. Although the German occupation in World War II almost completely destroyed Ukrainian agriculture, recovery was achieved by 1955. The Ukraine today accounts for more than 20 percent of the Soviet Union's agricultural produce and, in particular, for more than 23 percent of its grain. Agriculture generates 18 percent of the gross national product of the republic.

Crops. Four-fifths of Ukrainian agricultural production is represented by grain, potatoes, vegetables, fodder crops, fruit, and grapes. Out of a total land area of approximately 150,000,000 acres (60,000,000 hectares), 105,000,000 acres, or 70 percent, are devoted to agriculture. Of these, 84,200,000 acres are under crops, almost half grain. In 1950 the average annual yield of cereals was about 0.38 metric ton per acre; the figure rose to 0.58 in 1960 and to 1.04 during 1971–74, a significant increase.

Cereals

About 10,000,000 acres are allocated to industrial crops. Sugar beets, the most important, occupy 4,200,000 acres, primarily in the Lesostep region. Sunflower seeds, the principal oil crop, are grown on 4,300,000 acres. In the northwest a considerable acreage is allotted to flax. Potatoes occupy about 4,700,000 acres in the northern and central regions. In the southern steppes, especially where irrigation is practiced, vegetables are grown on almost 1,225,000 acres. Truck farming, or market gardening, takes place in the Donets Basin and along the Dnepr River and on the outskirts of the cities of Kiev, Kharkov, and Lvov. Fruit is grown throughout the Ukraine but especially in the Crimea, Transcarpathia and Ciscarpathia, and the Lesostep. About 3,000,000 acres yield almost half of the fruit grown in the Soviet Union. Vineyards in the Crimea and in Transcarpathia cover 659,000 acres.

Stock raising. There are about 23,600,000 head of cattle in the Ukraine, of which 9,000,000 are in dairy herds. Pigs, raised throughout the republic, number at least 20,800,000. Sheep and goats together number 9,500,000 head. Bees are kept chiefly in the Lesostep and the Polesye, and silkworms are raised in Transcarpathia.

Collective farming. Almost 8,000 collective farms (*kolkhozy*) and 1,700 or so state farms (*sovkhozy*) farm 93 percent of the cultivated land and raise 78 percent of the cattle. They also produce 96 percent of the cereal harvest, all of the sugar beets, 65 percent of the meat, and 66 percent of the milk. These highly mechanized enterprises employ about 200,000 agronomists, zoologists, veterinarians, engineers, and other specialists.

Fishing. The Black Sea estuaries are the main fishing grounds, although the Sea of Azov, rivers, lakes, ponds, and reservoirs also contribute to the fish catch. Among the major rivers for fishing are the Dnepr, Danube, Dnestr, Yuzhny Bug, and Donets. There are about 21,000 ponds in the country, covering more than 370,000 acres (148,000 hectares). In the early 1970s Ukrainian fishermen caught about 900,000 tons annually, or 12 percent of the total Soviet catch.

TRANSPORTATION

The flat relief of most of the Ukraine presents few obstacles to transportation, and the republic thus utilizes almost every means of modern transport.

Railroads. The Ukraine's 13,810 miles (22,230 kilometres) of track represents an average of 59 miles of track for every 1,000 square miles (37 kilometres per

1,000 square kilometres) served and 16 percent of the total trackage in the Soviet Union. Freight carried by rail in 1974 amounted to 305,000,000,000 ton-miles (445,000,000,000 ton-kilometres), about 90 percent of total freight carried in the republic. The heaviest concentration of trackage is in the Donets Basin and near the Dnepr River, especially its right bank; the largest railroad centres are Kharkov, Kiev, Dnepropetrovsk, Bakhmach, Yasinovataya, Debaltsevo, Kovel, and Kupyansk.

Waterways. Ukrainian docks on the Black Sea and the Sea of Azov handle more than a fifth of the Soviet Union's ocean freight, mainly at the ports of Odessa, Ilyichevsk (Illichevske), Nikolayev (Mikolayiv), Kherson, Feodosiya (Feodosia), Kerch, and Zhdanov. Ships of the whaling fleet Sovetskaya Ukraina (Soviet Ukraine) sail from Odessa to the Antarctic. River shipping is conducted primarily on the Dnepr and its tributaries (the Pripyat and Desna), on the Yuzhny Bug, and on the Danube, important in trade with other European countries. Ships on the Danube call at the port of Izmail, which is accessible to oceangoing freighters and passenger liners. Through the Dneprovsko–Bugsky (Dnepr–Bug) Kanal, in Belorussia, the inland waterways of the Ukraine are joined to the Vistula Basin of Poland and to the Baltic. Efforts to transform the Dnepr into a continuous, deep waterway have been furthered by the creation of large reservoirs at hydroelectric stations. The largest ports on the Dnepr are Kiev, Dnepropetrovsk, Zaporozhye, and Kherson.

River shipping

Road transportation. The republic has 120,050 miles of roads, of which some 70,090 miles are hard-surfaced. A network of good highways connects all the regions and large industrial centres. The links between Kiev and Moscow, Kiev and Leningrad, Moscow–Kharkov–Simferopol (Symferopol), and Kharkov and Rostov-na-Donu are of importance to the whole Soviet Union. Freight carried by truck within the Ukraine amounts to some 37,800,000,000 ton-miles (55,200,000,000 ton-kilometres) annually, or 17.7 percent of the Soviet total.

Air transportation. Kiev is connected by air with all the regional centres of the republic and with major cities throughout the Soviet Union. Annual air traffic totals some 11,000,000 passengers and 62,000,000 ton-miles of freight. Major airports include Borispol (Boryspil), near Kiev, and those at Kharkov and Odessa.

Pipelines. The exploitation of petroleum and natural gas has brought about the creation of a pipeline transport system, the total length of which is about 6,200 miles (10,000 kilometres). The major natural gas lines connect Mukachevo and Kiev; Shebelinka (Shebelynka) and Kharkov; Shebelinka, Poltava, and Kiev; Shebelinka, Dnepropetrovsk, Krivoy Rog, and Odessa; and Shebelinka and Slavyansk. The chief petroleum pipelines are the Dolina–Drogobych (Dolyna–Drohobych) and Gnedintsy–Priluki lines and a 420-mile segment of the trans-European Druzhba (Friendship) line, which supplies Soviet oil to other eastern European countries.

Distribution patterns. The Ukrainian transportation system makes industrial and agricultural products available to the entire Soviet Union. By this same network, the Ukraine receives petroleum and petroleum products from the Trans-Volga region, nonferrous metals from Kazakhstan and the Urals, and several types of machinery, fabric, footwear, and printed material from the central Soviet regions. By sea, bread, sugar, iron ore, coal, manganese, and machinery are exported to about 70 countries, and coffee, tea, cocoa, fruit, jute, machinery, and equipment are imported from more than 60 countries.

ADMINISTRATION AND SOCIAL CONDITIONS

Government and constitution. The government of the Ukrainian Soviet Socialist Republic is organized according to the 1937 constitution. As amended in 1944, the constitution (like the constitutions of the other union republics, as well as that of the Soviet Union) gives the Ukraine the right to "enter into direct relations with foreign states, to conclude agreements, and to exchange diplomatic and consular representatives with them" and to maintain its own military forces. The only real expression of these constitutional prerogatives in international affairs is the Ukraine's membership in the United Nations (it was one of the founding members), a distinction it shares with Belorussia, the two being the only UN members that are not fully sovereign countries. It is also a member of some 70 other international organizations.

These international contacts are more direct and of longer historical standing than those of most Soviet republics, and, because there are large communities of Ukrainians in Europe and North America, official institutions display considerable nationalism. There is, for example, a society specifically created to maintain cultural relations with foreign organizations and individuals, and two weekly newspapers on events in the Ukraine are published for distribution overseas.

Ukrainians abroad

In the main, however, contacts permitted by the central authorities of the Soviet Union between the Ukraine and foreign countries are not of great importance. While the Ukrainian Ministry of Trade is permitted to establish agreements (especially exchanges) overseas, usually these are limited to the Socialist countries of eastern Europe and are not of great enough value or volume to affect the promulgation of national policy either domestically or internationally.

The highest legislative unit is the unicameral Supreme Soviet of the Ukrainian S.S.R., whose members are elected for four years from a single slate of candidates. The Supreme Soviet meets twice a year for a few days to approve, generally unanimously, budgetary and other proposals made by the central government in Moscow and legislation passed by its Presidium and Council of Ministers. The Presidium of the Supreme Soviet, selected by that body and composed of a chairman, two vice chairmen, a secretary, and 15 members, acts for the Supreme Soviet between sessions, exercising both executive and legislative powers.

The Supreme Soviet

The highest executive and administrative organ is the Council of Ministers, which is equivalent to a cabinet; its chairman is the counterpart of a premier in the West. Most legislation introduced to the Supreme Soviet comes from the Council of Ministers, which is responsible for carrying out policy decisions made in Moscow.

The administrative divisions of the Ukraine include 25 *oblasti* (regions) divided into 477 *rayony* (districts), with 393 cities, 897 towns, and 9,657 rural settlements. In all of these, the unit of government is a Soviet of Workers' Deputies, whose members are nominated by the local Communist Party organization and voted for locally. The soviets elect executive bodies.

Justice. The highest court in the judicial system is the Supreme Court of the Ukrainian S.S.R., consisting of five judges elected for five-year terms by the Supreme Soviet. The court's function is to supervise judicial activities; it does not rule on constitutional questions (a function of the Presidium). On the local level, justice is dispensed by "people's courts."

Political organizations. The only political party is the Communist Party of the Ukraine (CPU), a branch of the Communist Party of the Soviet Union (CPSU) formed in 1918. Most of the major legislation approved by the Supreme Soviet originates in, or is approved by, the CPU. In the mid-1970s it had nearly 2,500,000 members and 80,000 candidates for membership. More than 5,670,000 young persons are members of the Communist Youth League (Komsomol). Under the guidance of the CPSU, the Komsomol administers the Pioneers, of which about 4,000,000 schoolchildren are members.

Sporting organizations. Various sporting clubs are concerned with physical culture, among them the Dinamo (Dynamo), Spartak (Spartacus), and Trudovye Reservy (Labour Reserves), set up by the army, air force, and navy.

Education. In 1917 more than 70 percent of the population was illiterate. Within the next half century, illiteracy was practically wiped out, and 99 percent of the population can now read and write. Universal education is now required for 10 years, and in the 1974–75 school year, 8,300,000 pupils were being taught in 27,000 schools for general education. In more than 80 percent of

the schools, Ukrainian is the main language of instruction, although there are schools in which Russian, Moldavian, Polish, Bulgarian, Hungarian, French, German, Spanish, or English is dominant.

Further education for workers

Great emphasis is placed on general and correspondence schools to allow young industrial and agricultural workers to receive an education without interrupting their work. About 900,000 students are enrolled in these schools. A network of vocational schools trains young persons, about 250,000 annually, for work in industry, transportation, and agriculture. About 730 specialized secondary schools enrolled 780,000 students in the mid-1970s. There were 142 institutions of higher education in the republic, serving 818,000 students, of whom 6,000 came from more than 100 other countries. More than 100,000 students attend the state universities at Kiev, Kharkov, Odessa, Dnepropetrovsk, Lvov, Chernovtsy (Chernivtsi), Uzhgorod (Uzhhorod), and Donetsk (Donetske). The various forms of instruction involve nearly 16,000,000 persons, almost one-third of the population.

Science and research. There are about 162,100 scientific workers in the republic, including some 4,100 doctors of science and 45,000 advanced students and candidates. The largest single scientific organization is the Academy of Sciences of the Ukrainian S.S.R. Founded in 1919, the academy received the Order of Lenin in 1969 for its contributions to science and Soviet life. In the mid-1970s it comprised 76 institutions, staffed by about 11,600 scientific workers, whose work is published in 35 Ukrainian scientific journals and some 440 monographs annually as well as in numerous publications originating elsewhere in the Soviet Union.

After the Academy of Sciences, the largest concentration of scientific and technical workers is in the universities. Among the specialized scientific facilities available in the republic are a half dozen oceanographic research vessels, which are the basis of a substantial concentration of scientific manpower in the areas of mineral resources, biology, and, with the cooperation of schools of chemistry and technology, desalinization of seawater.

Elsewhere in the republic can be found one of the finest experimental nuclear reactors in the world, five computer centres, four astronomical observatories, and seven major botanical gardens. Ukrainian scientists and technicians have made important discoveries and advances in the fields of cybernetics; nuclear and plasma physics; foundry, blast furnace, and powder metallurgy technology; and welding methods. In medicine they have made contributions in the areas of tissue therapy and brain biochemistry.

Social welfare, health, and housing. Some 4,200 hospitals with 565,000 beds, staffed by 151,000 doctors and specialists and more than 470,000 general medical personnel, serve the Ukrainian people. Medical help also is available at about 6,000 medical centres in such places as factories and schools. There are also some 235 sanitation-epidemiological centres, 18,000 institutions staffed by paramedical personnel and midwives, about 4,700 gynecological outpatient clinics, 2,500 children's clinics, and more than 580 sanatoriums and rest homes. More than 2,500,000 workers are sent annually to sanatoriums, rest homes, resorts, camps, and boardinghouses. Many workers get accommodations at one-third of the cost or free of charge. The residue is paid by trade unions from social consumption funds at their disposal. All the funds originally derived from a turnover tax, from various taxes levied on individuals, collective farms, etc., and others.

The death rate has decreased to one-third the level of 1917, and the average life expectancy now stands at 72 years.

Standard of living

The standard of living of the Ukrainian people is rising. More than three-quarters of the republic's income is used for individual workers' funds and collective benefits, such as public health, education, and pension funds. Between 1965 and 1970, the republic's income rose 39 percent and real wages 23 percent. The major supplements to wages from public funds included free medical care and education, pension and stipend payments, vacation benefits, and the maintenance of kindergarten and child-care facilities. The 9,463,000 pensioners in the Ukraine collect between 50 and 100 percent of their former salaries.

During World War II, 714 cities and towns and 26,000 villages were devastated, and reconstruction is still going on. Almost 400,000 apartments are constructed annually, and in 1966–70 new housing was provided for 40 percent of the republic's population.

CULTURAL LIFE AND INSTITUTIONS

Visual arts. Over the centuries Ukrainians have evolved a varied folk art. Embroidery, wood carving, ceramics, and weaving are highly developed, with stylized ornamentation in many regional styles. Intricately designed Easter eggs (*pysanky*) have become popular in many countries that have Ukrainian immigrant populations.

With the introduction of Christianity in the 10th century, the various forms of Byzantine art (architecture, mosaics, frescoes, manuscript illumination, icon painting) spread rapidly and remained the dominant art forms through the 16th century. The mosaics and frescoes of the churches of Kiev, notably the Cathedral of St. Sophia (11th–12th century), and the icons of the more distinctively Ukrainian school in Galicia (15th–16th century) are particularly noteworthy. Western European influences in the 17th and 18th centuries affected iconography and stimulated portrait painting, engraving, and sculpture. From the Ukraine the Western trends penetrated into Russia, where many Ukrainian artists worked, especially after the Ukraine lost its autonomy to Russia in the 18th century. During the late 18th and early 19th centuries the portraitists Dmytro Levytsky and Volodymyr Borovykovsky were among the leading figures of the St. Petersburg Classical school of painting.

The Classicism and the emergent Realism of the 19th century are best exemplified by the poet–painter Taras Shevchenko. New movements—Impressionism, Expressionism, Futurism—affected the work of such 19th-century painters as Ivan Trush and Oleksandr Novakivsky. Modernism and experimentation ended in the Soviet Ukraine in the 1930s, however, when Socialist Realism became the only officially sanctioned method in the arts.

A number of Ukrainian artists have won considerable renown in the West, among them the painter Alexis Gritchenko (Hryshchenko). The sculptor Alexander Archipenko, one of the pioneers of Cubism, who later experimented in Constructivism, Expressionism, and Surrealism, was a major figure of 20th-century European art.

Music. Folk music in the Ukraine retains great vitality to this day. Ritual songs, ballads, and historical songs (*dumy*) were sung *a cappella* or accompanied by folk instruments, of which the multi-stringed *bandura* is the most popular. Church music was patterned on Byzantine and Bulgarian models with local variations evolving in Kiev in the early period. Polyphonic singing developed by the 16th century and was subsequently in the 17th transmitted to Russia, where Ukrainian singers and musical culture soon won a dominant position. Ukrainian choral music reached its peak in the 18th and early 19th centuries in the works of Maksym Berezovsky, Dmytro Bortnyansky, and Artem Vedel.

Choral music

Secular music became ascendant in the 19th century. The opera *Zaporozhets za Dunayem* ("A Cossack Beyond the Danube"; 1863) by Semen Hulak-Artemovsky gained great popularity, as did *Kateryna* by Mykola Arkas and the compositions of Petro Nishchynsky. At the turn of the century, Ukrainian musical life was dominated by Mykola Lysenko, whose output encompassed vocal and choral settings, piano compositions, and operas, including *Natalka Poltavka* (1889), *Utoplena* ("The Drowned Girl"), and *Taras Bulba*. Other major composers of the period were Kyrylo Stetsenko and Mykola Leontovych.

In the early years of the Soviet period several composers produced works of high artistic merit, particularly Lev Revutsky and Borys Lyatoshynsky and their contempo-

rary in Polish-occupied Galicia, Stanyslav Lyudkevych. From the mid-1930s, however, political regimentation dampened individual expression and innovation in musical language. Typical among contemporary composers of the Soviet Ukraine are Kostyantyn Dankevych, Yuliy Meytus, and the brothers Yuriy and Platon Maiboroda.

The Ukraine has six opera theatres, numerous symphony orchestras, academic and folk choirs, and other performing ensembles.

Theatre and motion pictures. The theatre originated in the Ukraine under Western influence in the 17th century. Verse dialogue (*intermedia*) rapidly developed into a specific genre, the school theatre, whose repertory expanded to encompass dramatization of Christian legends, historical drama, and a puppet play (*vertep*) performed on a stage of two levels. The best example of the Cossack Baroque theatre was Feofan Prokopovich's historical play *Vladimir* (1705). After a period of decline, a Ukrainian ethnographic theatre developed in the 19th century. Folk plays and vaudeville were raised to a high level of artistry by such actors as Mykola Sadovsky and Maria Zankovetska in the late 19th and early 20th centuries. The lifting of censorship in 1905 permitted a significant expansion of the repertory to include modern dramas by Lesya Ukrainka, Volodymyr Vynnychenko, and Oleksandr Oles, as well as translated plays.

The real flowering of the Ukrainian theatre occurred between 1917 and 1933. The Berezil Theatre (1922–33) in Kharkov, under the artistic director Les Kurbas, was the most distinguished troupe. Pre-eminent among the playwrights was Mykola Kulish, whose *Patetychna Sonata* ("Sonata Pathétique") combined Expressionist techniques with the forms of the Ukrainian *vertep*. Since the mid-1930s, however, the theatre in the Ukraine has been dominated by Socialist Realism. Oleksandr Korniichuk has been the most favoured of the playwrights writing in the approved manner.

There are about 60 professional theatres in the Ukraine, notably the Ivan Franko Theatre in Kiev and the Maria Zankovetska Theatre in Lvov.

Ukrainian film has achieved some marked successes. The director and scenarist Aleksandr (Ukrainian Oleksandr) Dovzhenko (who died in 1956) was an important innovator in world cinematography. His *Zvenyhora* (1927), *Arsenal* (1929), and especially *Zemlya* (1930; "The Earth") have become classics of the silent film era. More recently *Tini zabutykh predkiv* ("Shadows of Forgotten Ancestors"), directed by Serhii Paradzhanov, won critical acclaim in the West. The motion-picture industry is centred on the O. Dovzhenko Studio in Kiev and on the Odessa studio.

Literature. Oral literature in the Ukraine can be traced back to pre-Christian times. Pagan ritual songs were subsequently much modified by association with various church feasts (*e.g., koliadky* with the Christmas cycle). The heroic epics of the early medieval period (*byliny*) may have survived in the Ukraine until the 16th century, but they were then wholly superseded by historical songs (*dumy*) based on events in the 16th and 17th centuries in the Cossack Ukraine.

Written literature began with Christianization and the introduction of Church Slavonic as a liturgical and literary language, later increasingly influenced by vernacular Ukrainian. Only with the school theatre of the 17th–18th century and with Ivan Kotlyarevsky's *Eneida* (1798) did vernacular Ukrainian begin to develop as an independent literary language.

The earliest works of the Kievan period (10th century and following) were the historical annals: *Povest vremennykh let* ("Tale of Bygone Years"), the Hypatian (Kievan) chronicle, and the Galician–Volhynian chronicle. The 12th-century *Slovo o polku Igoreve* ("Lay of Igor's Campaign") is a unique historical epic, written in the ornamental style. Sermons, tales, and lives of the saints comprised the major genres.

After the Mongol invasions (13th century), literature suffered a period of decline. Revival began in the late 16th century with the introduction of printing, the Reformation ferment, and the advance of the Counter-Reformation into Polish-dominated Ukrainian lands. The Union of Brest-Litovsk (1596), which united several million Ukrainian and Belorussian Orthodox with Rome, stimulated an exceedingly rich polemical literature, with the *Apocrisis* ("Reply"; 1598) of the pseudonymous Khrystofor Filalet and the anonymous *Perestoroha* ("Warning"; 1605) on the Orthodox side and the *Antirizis* ("Refutation"; 1599) of Ipatii Potii in the Uniat camp. The most distinguished and prolific polemicist was the Orthodox Ivan Vyshensky, whose ornate style combines Church Slavonic with vernacular elements.

The major current in Ukrainian literature of the 17th and 18th centuries, as in all of Europe, was the Baroque, with its love of adornment and originality. Among the major figures of this age were Kassian Sakovych and Ivan Velychkovsky in verse, Yoannikiy Galyatovsky in homiletics, and Feofan Prokopovich in the drama. Historical writing is best represented by the Cossack chronicle of Samoil Velychko (*c.* 1720). Of interest for their content and their literary qualities were the 18th-century writings of the philosopher Hryhoriy Skovoroda, styled the "Ukrainian Socrates." (For Ukrainian literature of the 19th and 20th centuries, see LITERATURE, WESTERN.)

Publishing and broadcasting. In the mid-1970s about 2,053 newspapers were being published in the republic (1,600 in the Ukrainian language), totalling about 23,900,000 copies. There were also more than 500 magazines and journals, with total circulations of about 218,200,000 copies. In 1974 about 8,800 book titles were published, a total printing of 153,500,000 copies, of which 104,800,000 were in Ukrainian. Not only the works of Ukrainian and Russian authors are included in this total but a number of foreign writers as well. The works of Ukrainian authors are published in many languages of the Soviet Union and are translated into more than 40 other languages. There are around 30 large publishing houses in the Ukraine, and book dealers in 80 countries buy Ukrainian-produced books.

In the early 1970s there were some 85 radio stations, and about 100 radio relays operating in the republic, as well as 20 television centres and many television relays. Some 8,000,000 radio receivers and 7,000,000 television sets were in use. The Kiev television centre is connected to Moscow, Leningrad, the regional centres of the republic, and television studios in several foreign countries.

Cultural institutions. The Ukraine supports numerous houses and palaces of culture which include libraries, museums, theatres, cinemas, parks, and concert halls. Almost 26,000 such institutions are active in addition to some 27,000 public libraries, 151 museums, 74 theatres, about 28,200 cinemas, and some 500 schools of music, painting, and choreography. The public libraries contain almost 317,000,000 books; the largest single collection is that of the Central Scientific Library of the Academy of Sciences, with more than 7,000,000 volumes.

Creative workers are gathered in unions, including the writers (with about 800 members), the painters (about 1,500), the composers (more than 150), the architects (more than 1,500), and the journalists (about 5,000); there are also organizations of film workers, theatre people, and singers.

THE OUTLOOK

Plans for the future call for expansion in all branches of industry. The major problem for agriculture is to increase the grain yield, and land reclamation has high priority. Great official emphasis will continue to be placed on capital growth and the further improvement of the material and cultural situation of the Ukrainian people.

Ultrasonics and Infrasonics

In physics, ultrasonics is the term applied to periodic stress waves, often loosely referred to as either sound or acoustical waves, that occur at frequencies above the limit of human hearing. Stress waves are called thus because they create a stress or deformation of the medium through which they are passing. Ultrasonic waves exist in frequency ranges over 20,000 hertz (cycles per second), the upper limit of human hearing. At their upper extreme, ultrasonic frequencies are so high that their extremely short wavelengths are comparable to the agitation of molecules caused by heat; these very high waves are called hypersonic waves. Infrasonic waves are those the wavelengths of which are so long and frequency so low that they exist below the level of human hearing; their principal natural source is earthquakes.

Early applications

Until about 1910 ultrasonic waves were little more than a scientific curiosity. Following the successful development of the piezoelectric transducer (described later), they were used in an early form of sonar to detect the presence of submerged submarines. Other attempted early applications were as a means of communication, and as light modulators in early experiments with television. Following the development of radar during World War II, ultrasonic techniques were used in such wide-ranging fields as the study of molecular properties of materials, detection of flaws in metals, ultrasonic cleaning, industrial and dental drills, measuring the thickness of the heart walls in man, and determining the presence of fluid in the sac around the heart.

GENERAL PRINCIPLES

Properties of stress waves. Stress waves exist in three principal forms: longitudinal, transverse, and shear. Longitudinal waves stress the medium through which they travel in the direction in which they propagate. Ordinary sound waves in air are longitudinal; the molecules of air vibrate back and forth in the direction the sound wave is travelling. Transverse waves produce stress at right angles to the direction of propagation, such as occurs with a vibrating string, whereas shear waves are a form of transverse wave travelling through the bulk of a medium. They are accompanied by a time-varying shear of the medium such as may be produced by a torsionally vibrating cylinder immersed in a fluid. Two other types of waves can be generated by special techniques. So-called Rayleigh waves are a special type of shear wave in which the wave is confined to a thin layer at the surface of a solid; earthquakes are an example. Lamb waves are a combination of longitudinal and shear waves travelling inside a very thin medium such as the wall of a thin-walled tube.

Applications of ultrasonics can be divided roughly into two classes: low energy and high energy. In the former, the amplitude (that is, the height of the wave from its highest point to its lowest point) is sufficiently low so that the wave is not distorted in passing through the medium, and the medium is left unchanged except for a slight rise in temperature. High-energy waves, on the other hand, modify the medium in some irreversible manner, either by the generation of large stresses or high temperatures, which induces physical or chemical changes.

When a low-energy ultrasonic wave travels through a medium, its energy decreases rapidly because of a characteristic of the medium known as its absorption coefficient. Absorption is caused by a medium's viscosity and thermal conductivity, though recently it has been found that the absorption coefficient is often much higher than calculations based on viscosity and thermal conductivity alone would indicate. Much information about the molecular properties of materials has been obtained from studies of the variation of this excess absorption with frequency.

Relaxation effect

Another important factor in dealing with the passage of an ultrasonic wave through a material is the relaxation time, or relaxation effect, a measure of how rapidly the material changes its volume as a result of the pressure changes caused by the passage of the ultrasonic wave. If an appreciable lag takes place between the wave's passage and the completion of deformation, a relaxation effect is said to occur. Whenever the relaxation effect exists, the wave velocity through the material depends on the frequency of the wave.

Transducers. An ultrasonic transducer (a device for converting energy from one form to another) generates ultrasonic waves by converting electrical, mechanical, or hydraulic energy into ultrasonic energy. In many cases these devices work both ways, and, for example, by converting ultrasonic energy back into electrical energy, can be used as receivers.

Piezoelectric transducers. A piezoelectric material, such as a quartz crystal, generates an electric voltage in response to mechanical pressure, or oscillates mechanically when an oscillating voltage is applied to it. Transducers made from piezoelectric materials are the commonest form of ultrasonic generator, and, depending upon how they are made, can generate either longitudinal or shear waves. By use of piezoelectric ceramic materials, it is possible to produce transducers that can be molded to any desired shape, such as a section of a sphere, enabling their radiated energy to be focussed into a small volume to give a localized region of very high ultrasonic intensity. For more discussion, see PIEZOELECTRIC DEVICES.

Magnetostrictive transducers. A magnetostrictive material is a material that alters its dimensions parallel to the direction of an applied magnetic field. The variation in the length of a magnetostrictive rod under the influence of an alternating magnetic field is exactly analogous to the thickness variation of a piezoelectric disk under the influence of an alternating voltage. Thus, the rod can be used to generate ultrasonic waves.

The typical magnetostrictive transducer shown in Figure 1 is composed of a laminated core of nickel or nickel–cobalt alloy stampings, with coils wound around the core. A steady current passed through the coils produces an initial elongation of the core. An alternating current of the desired frequency is then superimposed on this steady current. The core is bonded to a tapering cone, the function of which is to force the energy radiated from the core through a smaller area than that of the core, thereby increasing its intensity. The core-plus-cone unit will exhibit a resonance at which frequency the opposing ends of the unit will be moving in opposite directions at any given time. Thus, at some point along the unit there

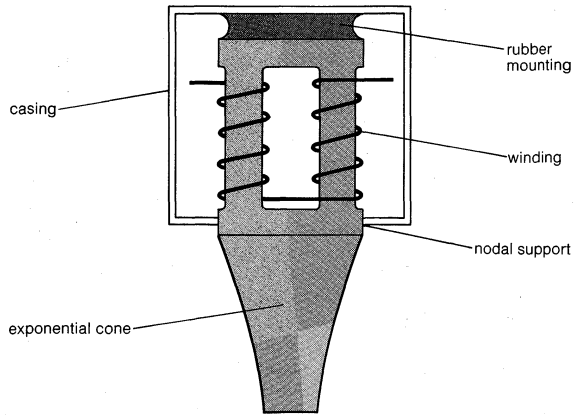

Figure 1: Cross section through typical magnetostrictive transducer.

will be no motion. The unit is mounted at this position, known as a node, since with no motion, no energy will be extracted by the mounting. Magnetostrictive transducers are less efficient than piezoelectric types because of the losses of the core. They are, however, capable of generating intense waves at frequencies up to around 20 kilohertz (20,000 cycles per second).

Mechanical transducers. Mechanical transducers convert mechanical into ultrasonic energy, either by rhythmically interrupting the flow of a gas through a series of holes by means of a toothed disk rotating in front of the holes, as in a siren, or by using the kinetic energy of a stream of gas or liquid to set a cavity or thin wedge into vibration, as in a whistle. Sirens are relatively efficient (70 percent) and can generate several hundred watts of ultrasonic energy at frequencies up to 20 kilohertz. Whistles have much lower efficiencies but can generate a few watts of power at frequencies up to 40 kilohertz.

Sirens and whistles

Electromagnetic and electrostatic transducers. Devices similar to the microphones and loudspeakers of conventional sound systems can also be used to generate and detect ultrasonic waves. These devices are considered in greater detail in the article SOUND RECORDING AND REPRODUCING.

Ultrahigh-frequency transducers. Semiconductor materials (relatively poor conductors of electricity) have been used in recent years in the development of very thin piezoelectric transducers capable of resonating at extremely high frequencies. A very thin insulating layer is formed within the bulk of a semiconducting piezoelectric material, such as cadmium sulfide, by the use of semiconductor device (*q.v.*) techniques. This layer will act as a piezoelectric transducer. A high-frequency transducer can also be made by condensing a thin layer of cadmium sulfide onto a suitable base material.

Ultrasonic detectors. Many transducers not only convert electrical into ultrasonic energy but also work in reverse and can, therefore, be used to detect the presence of ultrasonic waves. Whereas a piezoelectric transducer acting as a receiver will have its maximum response at a resonant frequency (*i.e.*, the frequency at which it vibrates naturally), it nevertheless still gives a useful output at frequencies below resonance. In fact, over a range of frequencies from about 0.1 to 0.6 times the fundamental resonant frequency, the response will be reasonably flat.

The detector being used to probe an ultrasonic field must be physically small so that it will disturb the field as little as possible. For this reason very thin-walled ceramic tubes are used as detectors, with electrodes fired onto the inner and outer walls. A thin wire of nickel with a coil wound on one end will also act as a detector.

Propagation of stress waves. The manner in which ultrasonic waves propagate, or spread, through different media determines their applications. Ultrasonic waves are absorbed in a gas because of its viscosity (resistance to flow) and thermal conductivity (the ability to conduct heat). Relaxation effects, defined above as the measure of how rapidly a material changes its volume as a result of the pressure changes caused by passage of an ultrasonic wave, are also significant. Though liquids absorb for the same reasons as gases, measured values in many cases are greater than would be predicted on the basis of their viscosity and thermal conductivity, indicating that relaxation effects predominate. The thermal conductivity of a solid, like that of liquids and gases, also causes absorption. Thermal conductivity is enhanced in a solid composed of a large number of crystals of microscopic size (microcrystals). In addition, the microcrystals tend to scatter the wave as it passes through. The relation between the fraction of incident energy thus scattered and microcrystal grain sizes is a function of the frequency of the ultrasonic wave, and measurements of scattered energy versus frequency can be employed to determine grain sizes.

An ultrasonic wave produces strains in a medium as it passes through; if the medium is piezoelectric, the strains generate an electrical field. If the piezoelectric medium is also a semiconductor, the current carriers (if negative) are accelerated by a positive electrical field and decelerated by a negative field. In the presence of the ultrasonic wave the current carriers bunch together and drift through the medium with a velocity dependent upon an applied electrostatic field (voltage). If these bunches drift more slowly than the ultrasonic wave, the latter tends to accelerate the bunches. The energy required for this to happen comes from the ultrasonic wave, which is, therefore, absorbed. If the drift velocity of the bunches exceeds the ultrasonic wave velocity, the opposite occurs and energy flows from the current carriers into the ultrasonic wave, which is therefore amplified. Although amplification factors of 30 have been obtained in cadmium sulfide crystals, there have, as yet, been no practical applications of this amplifying technique.

Amplification of an ultrasonic wave

LOWER POWER APPLICATIONS

Flaw detection and thickness gauging. Ultrasonic waves are scattered when they meet an acoustical impedance mismatch—*i.e.*, a point at which the resistance to the passage of ultrasonic waves changes abruptly. This mismatch can occur at a flaw, such as a hole or a crack in a metal casting. The detection of such flaws, vital in metallurgy, can therefore be performed by using an ultrasonic version of radar. In this application, the pulses of the ultrasonic waves are scattered when they strike a flaw in, for example, a metal casting, with some energy returning either to the same or another transducer. By measuring the time required for the ultrasonic wave to pass through the material, be deflected, and return, it is possible to determine the location of the flaw; thickness can be gauged by similar techniques.

Ultrasonic delay line. In certain electronic systems, such as that in the colour separation section of a colour television receiver, it is necessary to delay the passage of an electrical signal from one point to another. This time delay must be precisely controllable, appreciable (that is, greater than a few millionths of a second, or microseconds), and reproducible. One form of delay unit employs two quartz transducers cemented to the sides of a glass polyhedron. Ultrasonic waves emitted by one transducer bounce from side to side of the polyhedron until they reach the other transducer where they are converted back into electrical signals.

Measurement of mechanical stresses. The presence of a stress in a body rotates the plane of polarization of polarized shear waves (a situation in which the particles that propagate the wave are all vibrating in the same direction or plane), and some correlation has been found between the amount of rotation and the magnitude, or physical size, of the stress. In the early 1970s work in this field was still in its early stages.

When a material is stressed it emits bursts of ultrasonic waves at frequencies up to about 40 kilohertz (40,000 cycles per second) for ductile materials and up to 400 kilohertz for brittle materials. Materials undergoing plastic deformation emit signals of a lower amplitude than when the deformation is such as to produce cracks. The repetition rate of the bursts increases with increasing

Ultrasonic bursts

rates of stain. It is anticipated that the detection of these bursts of ultrasonic waves can provide an early-warning system for incipient mechanical failure.

Ultrasonic image converters. The data presented by the type of flaw detector considered above is essentially one-dimensional; interpretation is difficult and somewhat subjective. For this reason much effort has been devoted to developing an ultrasonic camera equivalent to the X-ray machine.

In the ultrasonic camera a transducer generates an ultrasonic wave in a liquid. This wave passes through the object to be investigated and then strikes the metallized surface of a quartz disk that forms the front plate of a cathode-ray tube. The variation in ultrasonic intensity across the surface of the disk produces a corresponding variation in the alternating charge pattern appearing at the rear surface of the disk. This rear surface is scanned by an electronic beam that converts the charge pattern into a visible image on the face of a television picture tube. The picture on the television tube will then be an ultrasonic "X-ray" of the object.

A hologram is a three-dimensional picture made (without a camera) on photographic film by the pattern of interference formed by laser light reflected from the object; the picture is viewed by passing laser light through the film (see also LASER AND MASER). In recent years optical holography (see HOLOGRAPHY) has appeared as a powerful tool for optical imaging. Some work is being carried out to develop an ultrasonic hologram. In one

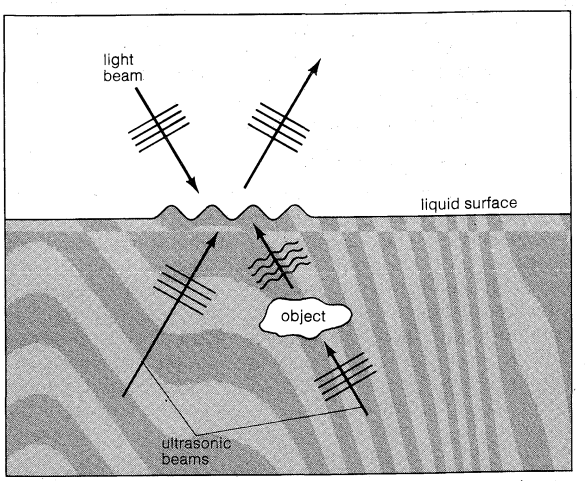

Figure 2: System for production of ultrasonic hologram (see text).

system, illustrated in Figure 2, two beams of ultrasonic waves at identical frequencies are directed at an angle to the underside of a liquid surface. One of these beams passes through the object to be investigated. At the surface, the two beams interfere to produce an ultrasonic wave pattern containing, effectively, an ultrasonic hologram of the object. This wave pattern is visualized by shining monochromatic (single-frequency) light at an oblique angle onto the liquid surface. The liquid wave pattern behaves like a diffraction grating and the first order diffraction image contains a picture of the ultrasonic cross section. In fact, the light beam is behaving in the same way as the beam used to reconstruct a picture from an optical hologram.

Ultrasonic holography, as so far developed, has a much higher resolving power than the ultrasonic camera.

Underwater applications. Underwater applications of ultrasonic waves are basically flaw-detection systems, in which an object such as a submarine, shoal of fish, or the seabed acts as the flaw. Such systems are treated in the article SONAR. Ultrasonic waves have been used for short-range underwater communication but most transducers are so highly directive that their use is of limited value.

Applications in air. The applications of ultrasonic waves in air are similar to those in liquids and solids and are essentially forms of flaw detection. Ultrasonic waves have been used to count objects travelling along a belt, each object breaking the sound beam as if it were an optical beam. In the early 1970s a hand-held sonar blind-guidance device showed promise. In this device an ultrasonic beam is radiated; the presence of an obstacle causes this beam to be reflected, and the reflected beam is indicated by a tone in a headset worn by the operator. The pitch of the tone indicates the distance to the obstacle. Another interesting application is as an intrusion detector, in which a transducer sets up a pattern of ultrasonic waves in a room, producing a specific amplitude at a detector. An intruder alters the ultrasonic wave pattern and therefore alters the ultrasonic amplitude at the detector, setting off an alarm.

Measuring fluid flow rates

Ultrasonic viscometer. The acoustic impedance (resistance to the passage of acoustic waves) of a liquid for transverse or shear waves involves the liquid's viscosity. If the electrical impedance of a shear wave transducer is measured in air (which presents negligible resistance) and then in a liquid, the impedance difference can be related to the liquid's viscosity, enabling the latter to be determined conveniently.

Ultrasonic flowmeter. The apparent frequency of an utrasonic wave travelling in a medium moving relative to the transducer in a direction parallel to that of the wave, differs from the vibration frequency of the transducer because of the Doppler effect (see RADAR). The frequency shift is directly related to the medium's velocity, and hence, if the frequency shift can be measured, the medium's velocity can be calculated. This principle has been applied to the measurement of fluid flow rates.

Medical applications. The use of X-rays has been well-established for many years for medical investigations (see DIAGNOSIS). X-rays, however, suffer from two defects—it is difficult to delineate soft tissues of the human body with them, and their use is not advisable in the early stages of pregnancy. Ultrasonic waves, however, are reflected by some soft tissues and, as far as is known, cause no harmful effects if the ultrasonic intensity is sufficiently low. In medicine, the main application of ultrasonics has been as a flaw detector in such applications as detecting shifts in the midline of the brain and investigations of the fetus. Fetal echoes are obtainable many weeks before the fetal skeleton is visible by radiography (see also THERAPEUTICS).

HIGH-POWER APPLICATIONS

The effects produced by high-energy ultrasonic waves are normally irreversible and arise from cavitation (see below), intense mechanical stresses, or intense localized heating.

If the ultrasonic pressure exceeds the ambient (normal average) pressure in a liquid, the pressure in the liquid will fall below zero at the ultrasonic wave pressure trough, or point of minimum pressure. If this occurs, a process known as cavitation takes place; the liquid ruptures and forms small cavities, which—if they have a suitable radius—will expand as the pressure rises and then, as the pressure starts to fall, will become unstable and collapse very rapidly. At the end of the collapse, the gas within the cavity will be highly compressed (measurements indicate pressures of several hundreds of atmospheres); these high pressures will be relieved by the radiation of shock waves. These intense shock waves can cause liquids to mix that normally would not do so—such as oil and water; they can break up giant molecules such as polymers, proteins, and viruses; force dirt and grease off surfaces for cleaning purposes; break up cells; and initiate chemical reactions. The violent agitation caused by cavitation has also been used to improve the quality of electrodeposited copperplate and the quality of optical glass by irradiating the glass, when melted, with high-power ultrasonic energy.

The rapid vibration of a gas or liquid under the influence of intense ultrasonic waves causes a net attractive force to develop between particles suspended in the fluid. In addition, small, light particles will take up more of the fluid's motion than large, heavier ones. This difference in motion will increase the chance of collisions between the

particles. If the particles coalesce (adhere) on collision, irradiation by ultrasonic waves provides a means of coagulating the suspended particles. This has found applications in the removal of suspended particulate matter, as in the cleaning of factory exhaust gases.

Another useful application of intense ultrasonic waves is the ultrasonic soldering iron. The iron is designed to be a magnetostrictive transducer. The rapid vibration at its tip removes oxide layers from the surface of the metal to be soldered and not only improves the quality of the soldering but also permits the soldering of materials otherwise difficult to solder, such as aluminum.

Ultrasonics in brain surgery

Intense ultrasonic waves have also found an application in medicine, particularly in brain surgery. Four beams of ultrasonic energy are beamed into the brain through holes cut in the skull. The intensity of each beam is insufficient to cause damage, but when combined at some point within the brain the total intensity is sufficient to heat a small region to a high enough temperature to destroy the tissue that the surgeon wants destroyed. This technique has been used successfully in the treatment of Parkinson's disease.

INFRASONICS

Infrasonic waves are those whose frequencies are nominally below the lower limit of human hearing. In recent years, however, evidence has been accumulating that waves with frequencies down to one cycle per second can be detected by human beings, provided the intensity is sufficiently high. The detection process, not yet fully understood, is believed to be a disturbance of the inner ear leading to dizziness. These waves are generated wherever a large high-speed flow of air occurs into, or around, an enclosed box or room. Of particular current interest is their effect on automobile drivers driving with open windows. Some microphones operate down to these frequencies and can be used to detect the presence of infrasonic waves.

Other sources of infrasonic waves of even much lower frequency (sometimes below one cycle per second) are earthquakes and tidal motion. Earthquakes require special detectors that usually consist of a large, well-sprung mass acting as an inertial element, the movement of which relative to the Earth is monitored, either by a pen drawing onto a chart mounted on the Earth or by a light beam falling onto photographically sensitive paper. When the Earth moves, the chart moves with it, but the inertial mass remains stationary and, therefore, the deflection of the trace on the chart indicates the motion of the Earth relative to the stationary mass. For portable use in seismographic surveys, the inertial mass is formed by a well-sprung magnet, between whose poles is situated a coil connected to the Earth. The motion of the Earth relative to the magnet induces a voltage in the coil proportional to the speed of relative motion (see also SEISMOGRAPH).

Use in underground exploration

Underground explosions are used to generate infrasonic waves. From the traces provided by several seismometers of the paths traversed by the waves, the properties of the underlying rocks can be evaluated. This technique is used extensively in mineral and oil surveys. Recently, extremely sensitive seismometers have been employed to monitor infrasonic waves produced by underground nuclear explosions as part of the implementation of the nuclear test ban treaty.

Earthquakes are the main source of naturally occurring infrasonic waves. The main shock is often preceded by smaller shocks; by detecting these preliminary waves it may be possible to develop an early-warning system for large earthquakes. A similar early-warning system has been suggested for volcanic eruptions, which are usually preceded by seismological activity.

Undersea Exploration

Ocean exploration is a scientific pursuit involving numerous disciplines. The efforts of oceanographers, who go to sea regularly to expand man's knowledge, have been supported by innovative engineering and technology. The pace of discovery is, to a certain degree, regulated by the rate of scientific innovation (see also the article OCEANS AND SEAS).

The practical value of ocean exploration has long been established by those countries that exploit the sea's natural resources, transport goods and people across its surface, or maintain their national security by controlling its lanes. Investigations of the sea are expanding both in scientific scope and total effort.

By the 1970s ocean-exploration achievements were strongly dependent on new platforms and instruments, and included manned descent to the deepest undersea point (35,800 feet [10,740 metres]); a submerged circumnavigation of the world; transits beneath the North Pole and the Arctic ice cap; discovery of major new features of the sea floor, including a 40,000-mile-long (60,000-kilometre) mountain-range system under the Atlantic, Indian, and Pacific oceans; observation of major ocean-current systems; and evidence of major historical changes in the sea and the basins that contain them. All of these accomplishments can be traced to new instruments and vehicles with capabilities not available to earlier investigators. Sixty ships from 40 nations were combined during the International Geophysical Year in 1957–58, demonstrating the feasibility of carrying out oceanographic studies on a massive scale.

HISTORY OF UNDERSEA EXPLORATION

The 19th century. *Beginnings of oceanography.* Modern oceanography began in the mid-1800s when Matthew Fontaine Maury, an American naval officer, assembled and analyzed the qualitative observations and simple measurements of waves, winds, and currents gathered routinely by 19th-century mariners. He spent a lifetime compiling charts of major currents, prevailing winds, and storm tracks. Updating these valuable charts continues to be a regular routine for modern mariners and oceanographers. Primitive measuring devices and simple estimates have been replaced by accurate instruments on special

ships and buoys; they provide continuous records that relate all data to specific geographical positions.

Marine biology exploration got its initial impetus at about the same time. The Englishman Edward Forbes was one of the first to make combined use of the related sciences now called oceanography. Using a naturalist's dredge, he discovered that ocean-bottom geology and marine life were closely related. His dredging revealed that the shape of the bottom was varied and as complex as that known on the continents. He noted too that the chemistry and physics of the sea influenced the type and quantity of animals and plants in a given locality. Though recognized by most as the father of modern marine biology, Forbes also introduced a fundamental interdisciplinary approach to oceanography.

One of Forbes's best known hypotheses, however, was later refuted. Reasoning that sunlight was necessary for plant photosynthesis and that animals needed plants for food, he suggested that no life could exist more than 1,800 feet below the ocean surface. Though contrary evidence, based on retrieval of lines and cables from great depths with plant and animal life clinging to them, appeared many times through the years, Forbes's theory was not everywhere discarded until 1960. In that year, Jacques Piccard of Switzerland and the United States navy lieutenant Don Walsh, from within the protective shell of the bathyscaphe "Trieste," at a depth of 35,800 feet, witnessed life in the form of a flat fish, a medusa, and a shrimp.

HMS "Challenger" expedition and subsequent research. The general lack of knowledge of the deep sea and the practical need for the successful laying of expensive transoceanic cables led a British professor, William B. Carpenter, to initiate the greatest oceanographic project of the 19th century, one that marked the beginning of oceanography as an integrated science. A committee established by the Royal Society wrote out a comprehensive deep-sea exploration program, and the Admiralty made HMS "Challenger" available for a four-year around-the-world expedition.

Oceanographers, until recent years, have had to make do with ships and platforms constructed originally for purposes other than ocean research. The "Challenger" was such a vessel, but was also one of the most substantial of its time. A fully-rigged corvette of 2,306 tons with auxiliary steam power, she compared favourably with modern vessels in oceanographic service. Her crew and scientists sailed around the globe, logged 68,890 nautical miles through all the major oceans, and gathered data and samples from waters of all depths and at almost all latitudes. From December 7, 1872, to May 24, 1876, she amassed a wealth of information requiring 20 years for compilation in 50 thick quarto volumes.

The success of the "Challenger" led to a series of other national oceanographic expeditions during the rest of the century. Each added valuable information to the fundamental discoveries of the British. The American marine zoologist Alexander Agassiz, for example, amassed an unprecedented 10,000 miles (16,000 kilometres) in tropical seas to map more lines across deep-sea basins and make more deep soundings than had all other scientific expeditions combined. Agassiz' proficiency as an engineer provided solutions to the problems associated with cable tensioning and winding. He designed a double-edged bottom trawl that worked equally well regardless of which edge hit the bottom. He invented remote opening and closing devices for tow nets to eliminate any uncertainty of the depth at which specimens were captured.

Oceanography in Monaco

Prince Albert of Monaco sent his own fleet of yachts on numerous expeditions. Each ship was fully equipped for deep-sea research; many of the devices deployed were on display in the early 1970s at the Musée Océanographique de Monaco. Among the Prince's engineering contributions were huge baited traps, special nets and trawls for use at various depths, and a system of underwater electric lights to attract fish. His most famous innovation (in 1885 and still in use) was the mass use of copper floats, with instructions in nine languages, to track major currents in the Atlantic.

The 20th century. By the beginning of the 20th century, oceanography was firmly established, but primarily within institutions devoted to the biological sciences. By the 1930s, small seashore laboratories were established by virtually every European country.

The practical value of oceanographical techniques was demonstrated in World War II. Acoustical devices, for example, were successfully employed in locating submarines. They were also used for wave forecasting and reconnoitring beaches in advance of landings. During the immediate postwar period, theoretical studies enabled oceanographers to translate water-temperature and salinity data into water-flow data (speed and direction), thereby providing subsurface water movement tracking. The currents could not be observed directly, however, until the 1950s, when improved technology appeared in two forms: a special marker buoy to identify deepwater currents, and the modern echo sounder to provide a continuous silhouette of the sea floor over which a ship is passing (see also SONAR; HYDROGRAPHIC CHARTING).

The echo sounder, however, at times would show a sea-floor depth of a few hundred feet when the true bottom was actually several thousand feet below. No physical explanation seemed plausible for this newly discovered phenomenon until a zoologist surmised that the echoes might come from vast populations of marine organisms—a hypothesis that is now universally accepted. Evidence indicating the specific organisms causing the echoes had to await development of deep-submersible technology. In the 1960s the deep-diving platform bathyscaphe "Trieste" and the submersible "Alvin" viewed and photographed large concentrations of these organisms.

TYPES OF PROGRAMS AND RESEARCH BODIES

National institutions, universities, and private industry. The national oceanographic program in most countries is a combined effort by government laboratories and academic institutions, with the government providing most of the funds and general coordination. The benefits of such exploration are shared by many segments of the national economy: natural-resources exploitation, transportation, national defense, and recreation. Nations on all continents have oceanographic programs. Some examples are the Zoological Station of Algeria; the Argentine Antarctic Institute; the Institute of Fisheries Research in Varna, Bulgaria; the Korea Central Fisheries Experimental Station; and the Oceanographic Laboratory of the Institute of French Oceania. The United States government has numerous laboratories, including the important station at Woods Hole, Massachusetts. Many universities maintain laboratories; an example is the Scripps Institution of Oceanography of the University of California, San Diego.

Private enterprise, particularly the petroleum industry, has become a significant participant in oceanographic exploration. Since the late 1940s, petroleum firms have developed their own oceanographic fleets and specialized instruments. The industry's special requirements have been fulfilled by innovative platform designs, sampling and measuring techniques, and handling facilities. The disciplines of geology and geophysics have benefitted most from the industry's activities. Markedly improved seismic techniques for acquiring, compiling, and processing data, from which three-dimensional models of subbottom geological features could be made, have significantly aided geologists. Improved ship designs, open-sea anchoring techniques, ship control, navigation aids, and new tools and techniques have been adopted by the scientific oceanographer.

Involvement of marine fisheries

Marine fisheries have been closely allied to oceanography for many decades, and the industry has turned to the biological oceanographers for information about the marine environment. In contrast to the petroleum industry, the fishing industry has not established a significant private research capability, but has adopted engineering advances developed for other purposes.

International organizations. *United Nations.* The principal international oceanographic organization is the Inter-governmental Oceanographic Commission of the

United Nations Educational, Scientific and Cultural Organization (UNESCO), founded in 1961. UNESCO also operates an Office of Oceanography that provides staff support to the commission and conducts some activities of its own. Such activities as the recent International Indian Ocean Expedition and the International Tropical Atlantic Expedition were sponsored by the commission. The International Hydrographic Bureau, Monaco, assists in the standardization and dissemination of ocean survey data. The World Meteorological Organization and the Food and Agriculture Organization are also concerned with oceanographic problems that relate to meteorology and fisheries.

In the early 1970s the integrated Global Ocean Station System was being planned by the Inter-governmental Oceanographic Commission to monitor and predict the state of the oceans, a project that included many elements of the World Weather Watch of the World Meteorological Organization; coordination procedures were established. The commission also had international coordinating responsibility for the Pacific Tsunami Warning System, a system that was designed to warn of extraordinarily high waves created by seismic disturbances or underground volcanoes. Other international organizations had the responsibility for such additional activities as the Ocean Station Vessel Program and the International Ice Patrol.

International Council of Scientific Unions. The principal nongovernmental world body providing a forum for all sciences is the International Council of Scientific Unions, whose marine-science groups are the Scientific Committee on Oceanic Research and the former International Union of Geodesy and Geophysics, now called the International Association for the Physical Sciences of the Ocean (IAPSO). The council established the World Data Center (WDC) system in 1957 to assemble and make available the data collected by the observational programs of the International Geophysical Year (see below). That network of data centres was continued on a permanent basis by international agreement. One group, or subcentre, of offices is located in the United States; another in the Soviet Union; and still others are located in Australia, Japan, and various countries in western Europe. Establishing WDCs at several locations ensures against catastrophic destruction of a single centre, is convenient geographically and provides easy communication for workers in different parts of the world. Each country in which a component of the system is located is responsible for its financial support.

World Data Center system

International Geophysical Year. A major international scientific effort that included many oceanographic disciplines was the International Geophysical Year in 1957–58. Its principal fields of study were aurora and airglow, cosmic rays, geomagnetism, glaciology, gravity, ionospheric physics, longitudes and latitudes, meteorology, oceanography, seismology, solar activity, and nuclear radiation, all of which are global in nature. The project involved organizing ocean expeditions; collecting, reducing, and tabulating data; and exchanging this information among data centres and making it available to the scientific community.

In addition to the establishment of the World Data Centers, the effort also contributed to the organization of such continuing programs as those of the Scientific Committee for Antarctic Research and the Scientific Committee on Oceanic Research. The oceanographic and other findings of the International Geophysical Year were published in 48 volumes entitled *Annals of the International Geophysical Year.*

Deep-Sea Drilling Project. The Deep-Sea Drilling Project, sponsored by the United States National Science Foundation, began in the summer of 1968 with the objective of learning about the origin and history of the Earth through the study of samples obtained from previously inaccessible sites. Sediment and rock cores were obtained from the ocean floor at depths of 20,000 feet, and holes were drilled in the bottom to depths of thousands of feet. Ocean-bottom sediments from land erosion and from the remains of microscopic marine organisms provided fresh insights into the origin and movement of the Earth's crust (see also MARINE SEDIMENTS).

Barbados Oceanographic and Meteorological Experiment (Bomex). The point of contact between the atmosphere and the sea is the scene of a complex and continuous exchange of energy, water, gases, and particulates. Most of the heat received from the Sun is stored in the tropical ocean between 30° south and 30° north latitude. Since the Earth loses heat by radiation almost uniformly at all latitudes, heat must be transported from equatorial regions to higher latitudes. Though scientists know that the atmosphere, not the ocean, carries this heat, very little more is known about the process. For that reason, the Barbados Oceanographic and Meteorological Experiment (Bomex) was set up.

Bomex involved 12 ships, 28 aircraft, and 1,500 men from the United States, Canada, and Barbados. The project focussed on the exchange of energy between the ocean and the atmosphere and on the vertical and horizontal spreading of the energies within each medium. One goal was to broaden scientific understanding of basic processes of energy exchange at low altitudes. The site selected was a 300-mile square just east of Barbados, an area where energy exchange between the atmosphere and the ocean is particularly significant. Extensive and detailed measurements were taken of temperature structures, turbulent stresses, wind stresses, growth and dissipation of kinetic energy, radiant energy exchange, chemical exchange, and other phenomena. Instruments were deployed from ships, aircraft, buoys, rockets, and stable platforms. Much new information was obtained suggesting considerable revision of theories concerning the sea-to-air interface.

International Decade of Ocean Exploration (1970–80). In recognition of the rapidly growing significance of ocean resources and the increasing importance of an understanding of ocean processes, Pres. Lyndon Johnson of the United States proposed on March 8, 1968, that the nations of the world join together in a concerted, long-term cooperative program of ocean exploration. He proposed an initial ten-year period of expanded collaborative effort to be designated the International Decade of Ocean Exploration.

The decade 1970 to 1980 was conceived to be a period of intensified collaborative planning, development of national capabilities, and execution of worldwide programs of oceanic research and resource exploration. Because of the size, complexity, and variability of the marine environment, scientific investigations of vast scope are necessary if the limited knowledge of this environment is to increase within a reasonably short interval. At the same time, excellence, experience, and capabilities in marine science and technology are shared by many nations. Hence, a broad program of ocean exploration can best be carried out through a cooperative effort by many nations.

In the early 1970s most nations gave most of their financial support to programs close to their own shores, such as exploration of the continental shelf and of their coastal fishery stocks. Even though nations are moving farther out to sea every year, much of the world's ocean exploration activity will probably continue to be this type of coastal activity.

Advances in marine science and technology depend critically upon the effective flow of information from data collectors to data consumers. As more sophisticated data-processing equipment comes into use, particular attention will be given to the compatibility of national data systems. Standardization of data collection techniques and common procedures for calibrating oceanographic instruments may also help make data useful on a broad basis.

Data exchange and compatibility

RESEARCH AND EXPLORATION VESSELS

Surface vessels. The traditional platform for oceanographic research has, until recent years, been described as any sturdy, seaworthy vessel capable of carrying oceanographic winches and a variety of measuring and sampling devices. In the 1950s a fleet of research ships designed

specifically for oceanography began appearing. Their varied characteristics reflected the design requirements of their respective owners. The international listing exceeded 500 in the early 1970s. All ocean vessels, usually over 70 metres (230 feet) in length, are operated by large academic institutions or government agencies. Smaller vessels are used for coastal work and are operated by virtually all oceanographic groups.

Shipboard equipment and facilities. The fundamental requirement for an oceanographic vessel is stability. The more stable the platform, the greater is the number of working days possible under adverse weather and sea conditions. In addition to stability, the ability to remain on station with a minimum amount of drift is necessary. Thus, a deep-draft vessel, with a minimum height above water level (freeboard) to avoid excessive wind forces, is desirable. Other basic requirements include adequate deck working space and machinery, laboratory facilities, cruising range, and living accommodations for the scientists and crew. Other desirable features include control of the ship's direction at very slow speeds and while stopped, and the ability to proceed silently (by use of batteries) for periods up to 12 hours.

Deck space and machinery. Open and uncluttered deck space facilitates handling the numerous pieces of large oceanographic equipment. Essential deck machinery includes winches, booms, and cranes, usually of special design. The largest winch is used for anchoring at great depths for periods ranging from a few hours to a month; its steel-wire rope is from 20,000 to 35,000 feet long. This winch may also assist in bottom dredging, towing large midwater trawls, taking large bottom cores, and obtaining samples of seawater for radioactive carbon analysis.

Deep-sea anchoring winch

The most commonly used oceanographic winch is of medium size, with 20,000- to 30,000-foot lengths of stainless-steel-wire rope. It operates at high speeds and has a variety of uses: for water-sampling bottles, current meters, underwater cameras, small coring devices, small dredges, plankton nets, various temperature-measuring instruments, and other equipment. One of the smallest is the bathythermograph winch. It is used to lower the bathythermograph, a recording thermometer capable of registering temperature against depth down to 900 feet. In shallow water the winch, with a specially designed device called a "scoopfish," takes small bottom samples. Mechanical current meters and vertical hand plankton nets are lowered from the bathythermograph winch.

Laboratory facilities. An oceanographic ship requires several laboratory spaces. A deck laboratory, for instrument preparation and operation and some analyses, is usually located near the oceanographic winch. Other laboratory spaces are needed for performing chemical, biological, and geological analyses, installing electronic recording equipment, and for photographic developing and printing. In addition, of course, space for offices and drafting rooms and for dry storage of oceanographic equipment and samples must be provided. Laboratory spaces are, by design, flexible. As one surface ship may serve a variety of scientists or disciplines within a short period of time, a vessel needs to be available for multipurpose missions. Portable laboratories that can be deck-loaded offer the convenience of being available for outfitting on shore, precluding losses of valuable ship time.

Portable laboratories

Fixed platforms. The need for long-term investigations with fixed equipment has led to the construction and installation of fixed towers in moderate depths of water (Figure 1). Three such towers are actively used: the Naval Undersea Research and Development Center tower near San Diego, California, and two Naval Ship Research and Development Laboratory towers near Panama City, Florida.

Moored platform. For long-term measurements at selected sites, platforms that support instruments at desired depths are moored to the ocean floor. Large oceanographic buoys and their associated sensors are classified as platforms. The largest is a moored, 40-foot-diameter platform that can measure and record 100 separate channels of data, sending the data on command by radio to shore stations thousands of miles away. Both short-term and long-term memory devices store collected data, the long-term for periods of up to one year. This buoy was used, for example, as a master in an array of buoys moored between Hawaii and Alaska in the North Pacific, collecting their measurements and transmitting them to shore.

Sea Spider is a submerged buoy intended to provide stable support for underwater instruments at depths up to 20,000 feet. A model experimentally placed in 2,600 feet (800 metres) of water by the Woods Hole (Massachusetts) Oceanographic Institution exhibited movements of less than three feet, essentially equal to or better than the accuracy of its position. A system of installation in 19,000 feet of water was under way in the early 1970s.

The United States Naval Arctic Research Laboratory at Point Barrow, Alaska, operates numerous field stations, including research platform stations on ice islands. Temporary stations are located on ice floes. One such ice-island station drifted approximately 5,000 miles in four years from near Point Barrow, through the Arctic Ocean, almost over the North Pole, and through the Greenland Sea to a point near Iceland, where it was evacuated. A permanent station has been occupied for many years on Fletcher's Ice Island. Research conducted from ice stations covers nearly every aspect of oceanography. Airborne observations, including the distribution and dynamics of pack ice, have supplemented their findings.

Ice floe stations

Floating instrument platform (FLIP). Developed under sponsorship of the United States Navy, FLIP (Figure 2) is an unusual vessel, the first of its kind. Built in 1962 to fulfill a need for an extremely stable and yet mobile platform from which accurate acoustical measurements could be made at sea, FLIP is a long pole-shaped platform towed in the horizontal position to the research area. On station, ballast tanks in the after two-thirds of the 355-foot vessel are flooded. As the stern gradually sinks, the prow rises. Ultimately the vessel is completely vertical with approximately 55 feet of prow above water and pointed skyward. As the hull is only 12½ feet in diameter

some distance above and below the waterline, the rise and fall of the waves cause a very small percentage change in the displacement. Consequently, the vertical motions that do occur are extremely small compared with those of a conventional ship.

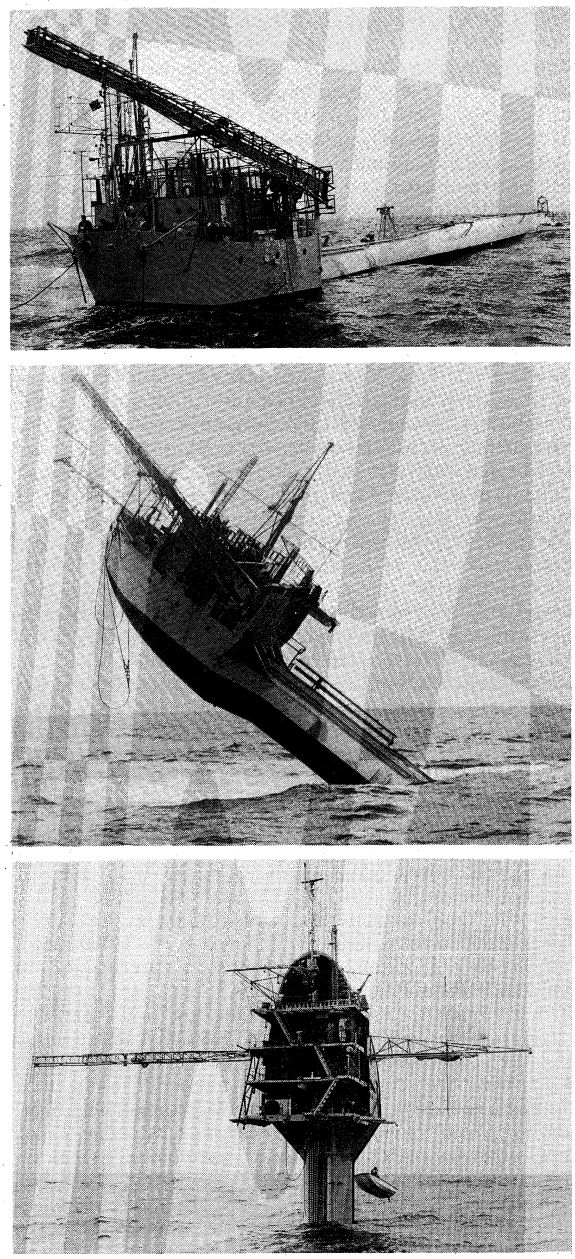

Figure 2: *Floating instrument platform (FLIP).*
The platform has no motive power of its own but is towed in the horizontal position (top) to the research area, then "flipped" (centre) to the vertical position by flooding its ballast tanks. Fifty-five feet (16.5 metres) of prow show above water in the vertical position (bottom), affording scientists a stable platform from which to carry out oceanographic research.

Stability, coupled with the unusually deep draft in the vertical position, makes FLIP an ideal platform for many sea experiments. Oceanographic instruments may be mounted anywhere along the submerged hull. By use of precision equipment, the location, depth, and orientation of the instruments may be determined and controlled to a higher precision than can be achieved with any other platform. Although first developed for acoustical experiments, FLIP has found many other uses since it was placed in operation on August 15, 1962. Operations have included experiments or studies of wave attenuation, sound propagation, sound-scattering or sound-reverberation measurements, seismic wave recording, wave-pressure and wave-acceleration measurements, meteorological work, and measurement of internal waves.

FLIP has no propulsion power of its own other than two small orientation propellers that rotate the vessel about its vertical axis. Three diesel generators supply electrical power for all ship and scientific needs. Practical tow speeds for FLIP vary up to about ten knots (nautical miles per hour) in the horizontal position. It is sometimes towed slowly in the vertical position for station keeping or small changes in position.

Submersibles. The descent of the bathyscaphe "Trieste" to 35,800 feet (10,740 metres) in 1960 was a major event in the deep-submersible field. The family of vehicles that has evolved since ranges in size from small one-man submarines for exploration of the continental shelf to vehicles capable of routine operation at great depths. In the continuing development of deep-sea research vehicles, the goal is to operate safely at any depth. In the early 1970s materials were being fabricated and tested, and techniques of life support, navigation, communications, bottom mapping, photography, direct viewing, and in-place measuring were being studied to improve vehicle capability. New methods of providing power for propulsion and life support at great depths were also under investigation.

A major advance in the evolution of deep submersibles was "Alvin," a vehicle built for ocean science and operated by the Woods Hole Oceanographic Institution. It has been successful in working at depths down to 6,000 feet (see SUBMARINE).

Aircraft and satellites. Major advances have been made in the use of aircraft for obtaining operational oceanographic information. With the development of air-dropped bathythermographs, aircraft can obtain information on subsurface layers as well as on the surface. Lasers as airborne remote sensors can take profiles of polar sea ice and of the ocean surface. In the North Pacific, expendable bathythermographs were dropped from planes every 25 miles along a great circle line approximately 1,800 miles long in 12 monthly transits to study temperature as a function of depth, position, and time. Because each transit was completed in about eight hours, records of the temperature profile and approximate sound-velocity structure (*i.e.*, the rate at which sound would pass through ocean water at different temperatures) were provided for a vast area of the Pacific at monthly intervals.

Many acoustical and seismological measurements, including those of propagation loss, ambient noise, and sediment sound speed and thickness, have been made successfully by employing sonobuoys (buoys incorporating sonar equipment) from aircraft. Use of aircraft is a logical step toward use of satellites to obtain oceanographic observations globally; satellite navigation systems, with their accurate positioning devices, have already influenced ocean science research. Current measurements made from an ice platform, itself in motion, have been improved by accurate position data, permitting determination of rate of drift.

Telemetering data by satellite

The use of satellites for telemetering oceanographic data from buoy systems has been successfully demonstrated. Sound signals from hydrophones deep in the Pacific Ocean and depth measurements from a research ship were transmitted continuously for several hours via satellite to the United States Navy Underwater Sound Laboratory in New London, Connecticut, where the data were processed for frequency content and amplitude one-fourth second after being transmitted. Such a system is ideally suited for transmitting underwater acoustic signals used for a variety of scientific purposes: subbottom profiling, depth readings necessary for charting the ocean bottom, and measurements of the Earth's gravitational and magnetic fields. A dramatic development has been the possibility of collecting useful ocean data from remote platforms in space. Earth-orbiting satellites have demonstrated a capability for collecting and transmitting oceanographic data and acting as data communications relays. The TIROS, NIMBUS, and ESSA series of

satellites, for example, have demonstrated operational capability for providing useful global photographs showing clouds and limited indications of sea ice; other applications were under development in the early 1970s.

Buoys and other unmanned units. Buoys serve as effective instrument platforms that can remain unattended at a given location for extended periods. Buoy design was still under active development in the early 1970s. Simple can and spar buoys, decked-over skiffs, boat-shaped hulls, and giant saucer-shaped buoys are a few examples of unmanned buoys. Extra large spar buoys with excellent vertical stability have been created to serve oceanographers.

Remote underwater manipulator (RUM). The remote underwater manipulator (RUM) is a remotely controlled, tracked, sea-floor work vehicle with mechanical arms and pincers developed as a research tool. Areas of particular interest are remote manipulation, navigation, cable telemetry systems, ambient-pressure-exposed electronics, and environmental and mechanical design considerations. Design depth for the RUM vehicle is 10,000 feet. Its hull, tracks, and suspension system are those of a surplus United States Marine Corps vehicle rifle platform. Equipment includes two television cameras, a scanning sonar, an acoustic transponder navigation system, and numerous other instruments to monitor operational conditions. The manipulator can work off either side or to the rear of the vehicle and is capable of exerting 50 pounds (20 kilograms) of force in any direction at full arm's length. Two tethered swimming platforms called CURV and RUWS offer similar features.

Towed instrument platforms. To explore the details of sea-floor topography and related characteristics, instrumented vehicles commonly called FISH (fully instrumented submersible housing) are towed by a research ship. A network of bottom-mounted acoustic transponders (two-way sonars) is used to provide precise navigational information. The FISH usually consists of a pressure resistant enclosure to protect the electronic gear. Instrument sensors are mounted in various locations on the outside.

Communication between the vehicle and the ship's laboratory is provided by a single coaxial electrical conductor in the core of the tow cable, even while the winch is running. The cable is also used to transmit power to the vehicle.

Precise navigation in a survey area is aided by acoustic transponders dropped from the ship at random locations at the beginning of the operation. With the transponders, some of which are recoverable, the towed vehicle and the ship can be located in relation to the network to an accuracy of 30 feet. Their usable range is from five to ten miles.

A FISH system is a powerful research tool for studying details of the sea floor. By virtue of its complex of instruments and the precision of its acoustic transponder navigation system, magnetic, topographic, subsurface sediment, and photographic data may be closely correlated to identify features of special interest and to increase understanding of the processes of formation of the sea floor.

TECHNIQUES AND EQUIPMENT

Basic methods and equipment of oceanographic measurement. Oceanographic observations are made from a surface ship while either under way or on station or at anchor. Those taken while under way are generally limited to meteorological and bathythermographic observations with occasional shallow-water bottom sampling. For special surveys, hull-mounted recording devices for obtaining continuous data of water temperature, salinity, and conductivity are used. The greater portion of oceanographic work at sea is carried out while lying to on an oceanographic station.

Outboard from most oceanographic winches is a platform, with an A-frame over it. From the A-frame a metre wheel is usually suspended as well as a special block that will quickly receive a cable. The amount of oceanographic wire that passes over the metre wheel in or out is registered on dials, indicating the depths to which the lead-weighted wire has been lowered. The wire is used, variously, for carrying water-sampling bottles with attached thermometers to desired depths or to make a series of plankton tows, or for a lowering of an underwater camera or a coring device to the bottom.

The time needed to take a series of observations in water about 13,000 feet deep is about seven hours. If a large coring device, such as the half-ton Ewing piston corer (see below), were lowered by the anchoring winch to that depth, it would take some five hours to lower and raise it for a single core. Many observations can be taken simultaneously, however. Thus, bathythermograph lowerings, surface plankton tows, subsurface-visibility measurements, wave measurements with the electric wave staff (described below), and the associated meteorological observations all can be taken while other lowerings are in progress without adding to the time on station.

While steaming to the next station, measurements of currents and sea-floor echo soundings may be taken. Equipment and instruments are cleaned, the samples stored, preparations for operations at the next station made, and work is started on computing and analyzing the data obtained.

Water-sampling bottles. Seawater is collected from various depths by means of specially adapted water-sampling bottles, the first of which was invented by the English chemist Robert Hooke in 1611. More than 50 types have been developed since. The types of bottles in general use, however, have been reduced to those few proved capable of withstanding rigorous working conditions. The most universal water sampler, the Nansen bottle, is a modification of one developed in the latter part of the 19th century by the Norwegian Arctic explorer and oceanographer Fridtjof Nansen. It is a metal water sampler with a 1.25-litre capacity, intended to bring an uncontaminated water sample from a desired depth to the surface. Nansen bottles are made of brass, with the exterior parts chromium plated and the interior silver or tin plated to provide resistance to seawater. The exterior is painted yellow to increase visibility.

In 1936 the International Association of Physical Oceanography proposed the following standard depths at which observations should either be taken directly or the data adjusted by interpolation from the distribution at other levels. The standard depths, in metres below the sea surface, are: 10, 20, 30, 50, 75, 100, 150, 200, (250), 300, 400, 500, 600, (700), 800, 1,000, 1,200, 1,500, 2,000, 2,500, 3,000, 4,000, and thence every 1,000-metre interval to the bottom. The depths in parentheses are optional. (One metre equals about 3.3 feet.)

Standard observation depths

Other temperature-measuring devices and seawater samplers have been developed. A few such instruments are the bathythermograph, the salinity–temperature-depth recorder, the conductivity–temperature-indicator recorder, and the microthermal depth recorder. The Nansen bottle still maintains a high level of usage, as all of these other instruments are limited to relatively shallow-depth operations.

The bathythermograph. The bathythermograph is an instrument for obtaining a permanent, graphic record of water temperature at various depths as it is lowered and raised in the ocean. It can be used while the ship is under way. A depth element in the instrument drives a smoked-glass slide at right angles to a stylus, which in turn is driven by a thermal element consisting of copper tubing filled with an organic liquid, xylene, that expands and contracts, transmitting pressure to a stylus. Thus, a continuous record of both temperature and pressure (or depth) is charted. The trace, or record, scribed by the stylus, is read by comparing it with a grid individually calibrated for each instrument.

Techniques and equipment of physical oceanography. Physical oceanography includes the study of tides, currents, sea and swell, temperatures, densities, origin and circulation, sound propagation, optical transparency, sea ice, and other physical properties of seawater (see also OCEANS AND SEAS).

Of major importance is the acquisition of knowledge on surface and subsurface currents: whence they originate, their speed and direction, and their influence on other

oceanic factors. Determinations of subsurface currents may be made by direct measurements with current meters (see below) or by mathematical computations from the densities of the masses of water under study. Density is a function of the temperature and salinity of water under a given pressure; these two variables provide basic information required to determine sound propagation and patterns, both vertically and horizontally, in seawater.

Depth information

Depth information is an essential part of every oceanographic expedition and is a fundamental reference for all sampling. The echo sounder is an electronic instrument that automatically and continuously measures ocean depth by transmitting and receiving acoustic sound pulses. Echo sounders that can generate strong acoustic pulses can penetrate not only large water columns but also sedimentary sea-floor deposits and record layering to depths of several tens of metres.

The use of high-energy electrical discharges underwater has directly augmented the echo sounder. Acoustic energy generated in this manner, sufficient to produce strong echoes from well below the bottom of the sea, extends the oceanographer's capacity for identifying subbottom structures, such as salt domes and potential oil-producing geologic structures, hundreds of metres below the sea floor. Models constructed from seismic profile surveys provide three-dimensional information about the sea floor. Deep-sea drilling sites are most often selected on the basis of seismic surveys. Drilling cores provide confirming evidence for the conjectured forecasts of what would be discovered by drilling in a given location.

Temperature. Oceanographers require thousands of temperature readings. The measure of seawater temperature both vertically and horizontally continues to be of great importance to oceanographers exploring the subtleties of ocean currents and physical forces related to them. For measuring the temperature of surface water, a conventional, highly accurate mercury thermometer is used.

For measuring temperatures below the surface to all depths in the sea, a simple mechanical scheme was devised in 1874 for capturing and maintaining the temperature reading taken at depth. Two thermometers, one pressure protected and one unprotected, are mounted in a frame that can be inverted on demand. The design is such that when the thermometers are inverted, the mercury column breaks at a certain point. The amount of mercury remaining in a graduated capillary portion of the thermometer is then read to indicate temperature at the point of inversion. Traditionally, the reversing thermometers are cable lowered to approximate depth, and the unprotected thermometer used to provide precise depth. The probable depth error for such measurements is about 0.5 percent. Reversing thermometers continue to be a standard device for oceanographers throughout the world.

Temperature–salinity measurements

Exploratory activities of physical oceanography profit from temperature–salinity measurements. Water masses can be classified on the basis of their temperature–salinity characteristics. A series sample of water, plus an accurate temperature measurement for each, provides one of the most valuable tools in physical oceanography. A temperature–salinity diagram can be constructed and anomalies easily recognized. Water masses so characterized are traceable over great distances and at varying depths, providing information on currents and water mass mixing.

Measuring waves. Internal waves are similar to the commonly observed surface waves but occur at the point of contact between layers of water of different densities rather than at the sea–air boundary. Until recently, observations of deepwater waves were limited to visual data. Recently developed electrical wave staffs and pressure-operated wave indicators now provide recorded data for analyses. The success of long- and short-range wave forecasting is dependent upon the number of observers reporting and the accuracy of the observations.

The electric wave staff records wave heights and periods at sea. It consists of three lengths of watertight aluminum tubing, a circular steel damping disk, a recorder, a transformer–rectifier circuit, electrical cables, floats, retrieving lines, and balancing weights. The upper section of tubing, called the step-resistance gauge, has 36 contact points and a connection for the electrical cable at the top. The remaining two sections of tubing provide proper buoyancy to the gauge so that it will float vertically with one-half of its length exposed. Below the end of the lower tube is suspended the damping disk, the function of which is to provide weight to keep the staff vertical and to damp the tendency of the staff to rise and fall with the passing waves. The wave water rising and falling along the step-resistance gauge increases and decreases the resistance in the gauge at successive contact points. This variation in resistance is transmitted to the recorder aboard ship and a record of the wave height and period is made. Observations are made when the ship is lying to; the wave-staff assembly is put overboard to windward so that the drift of the ship will be away from the staff.

Observations of transparency, light penetration, scattering, and colour are aided by the use of photoelectric cells that are lowered to various depths. Such studies assist in the determination of currents and provide clues to biological conditions.

Meteorological oceanography. The interaction of sea and air and the influence of one medium upon the other make up another important part of oceanographic studies. Prevailing winds in certain areas affect ocean currents, while in other areas the air temperatures are tempered by the sea surface. Solar radiation affects the heat budget (the sum of all Earth heat gains and losses) and influences biological conditions. Thus, the types of meteorological information that must accompany all oceanographic observations include air temperatures, humidity, wind direction and speed, atmospheric pressure, cloud types and amount, and visibility, along with the oceanographic variables of sea-surface temperature, wind waves, and swell.

Currents. Surface ocean currents are a portion of a thin veneer overlying other currents that do not usually match the surface currents in any way. Probably more types of instruments are used for measuring currents than for any other single oceanographic operation. Although many types have been developed, most are limited in use either by cost or design. A simple, rugged, and accurate instrument that can indicate weak as well as strong current speed, direction, and depth is still one of the most important needs of oceanographic instrumentation. The types may be divided into three broad categories: free floating, shallow water, and shipboard. The free-floating category includes drift bottles, dye marks, and floats that can be observed from ship, shore, or aircraft. Shallow-water instruments include those attached to piers, buoys, or beacons or placed on the bottom in near-shore areas at more or less set depths. Shipboard types include instruments that can be operated when the ship is under way and those used when the ship is anchored. Representative instruments of the shallow-water and shipboard categories are described below.

Current-measuring devices

Surface-current measurements when under way are often taken by the geomagnetic electrokinetograph, which records the electrical potential developed by the movement of an electrolyte (ocean current) through a magnetic field (the Earth's) at depths of more than 100 fathoms (600 feet). A matched pair of electrodes mounted 300 feet apart on a two-conductor cable is trailed about three ship lengths behind the stern, and thus away from the magnetic influences of the ship. The geomagnetic electrokinetograph makes observations of the potential difference between the electrodes along the ship's course and at right angles to it. These potential differences are caused by the motion of the water through the Earth's magnetic field and are mathematically related to the set and drift of the ship and to the electrodes.

Another device that gives the speed and direction of ocean current at any depth is the Ekman current meter, developed by Vagn Walfrid Ekman, a Swedish scientist. This meter consists of an impeller, or screw, and shaft connected to a set of dials. The number of shaft revolutions per unit of time is read from the dials on the main body of the meter. A reservoir of bronze balls is connected by a narrow tube to a compass box containing a compass needle. Below the needle is the compass-ball recepta-

cle, which is divided into 36 chambers, each representing 10° of azimuth. As the impeller rotates, the balls fall, one at a time, onto the top of the compass needle, which guides them into one or another of the chambers, depending on the heading of the current meter. This gives the direction toward which the current is flowing.

The current meter is lowered on either the oceanographic or bathythermograph wire. The impeller is locked while lowering or hoisting. A small metal device known as a messenger is sent down the wire, unlocks the impeller, and sets the meter in operation. A second messenger is sent down later to lock the impeller and stop the meter before hoisting. Valid measurements cannot be made with an Ekman current meter unless the ship or buoy from which it is suspended is anchored.

The Roberts radio current meter, an instrument designed specifically to record subsurface current speeds accurately while simultaneously indicating the direction of the flow, consists of a buoy from which one to three meters may be suspended; an automatic radio-transmitting system within the buoy; and a ship- or shore-based radio-receiving monitoring system that can monitor up to 15 meters. The buoys usually are anchored in bays, rivers, channels, or other relatively shallow areas. Meters have been operated successfully at depths as great as 8,000 feet from anchored ships.

Water transparency and light absorption. The physical relationships governing the penetration and absorption of light, the colour, and the transparency of the sea are of prime importance to physical and biological oceanography. Such measurements are taken with three general types of instruments: the submarine photometer, the hydrophotometer, and the Secchi disk.

The submarine photometer detects and records directly, in footcandles, the light at the surface and at all depths down to approximately 500 feet. Through the use of filters, observations are made in the infrared and ultraviolet ranges of the spectrum. The hydrophotometer has a self-contained constant light source that allows greater latitude in observation. It may be used at any time of day or night and will measure finer graduations of transparency. The Secchi disk, designed to measure water transparency, is dependent upon the available illumination, which varies with the time of day, cloud formation, and amount of cloud cover. To a circular plate, or disk, usually of wood painted a flat white, a graduated line is secured, and the disk is lowered into the water from the shaded side of the ship until it is just visible. Then the depth in metres is noted, and lowering is continued until the disk can no longer be seen. At that point the disk is slowly raised until it is barely visible. The depth reading of this point is then averaged with the reading obtained on lowering and is recorded. The greater the depth reading, the more transparent is the water.

Techniques and equipment of chemical oceanography. Chemical oceanography is concerned with determining the various constituents of seawater and their distribution. The salinity of seawater is of major importance in computing its density and determining currents as well as sound velocities. Analyses of nutrient concentration (*e.g.*, phosphate, nitrate, silicate), the pH (acidity), and the content of dissolved gases (oxygen and carbon dioxide) provide information that aids in determining age, origin, and movement of water masses and their influences upon marine life. One of the more rapidly expanding areas of interest in chemical oceanography is the study of dissolved gases in seawater. New, very sensitive analytical methods that can be used aboard ship permit rapid accumulation of data on the distribution of dissolved gases. Analysis of such data is useful in tracing ocean-mixing processes, in studying the production of gases in the ocean, and in elucidating the natural cycles of atmospheric pollutants.

Studying dissolved gases in seawater

New and improved methods of trace-element analysis are being developed for use on shipboard. An electrochemical technique, for example, provides a means of investigating unexplained fluoride concentration anomalies in certain parts of the deep ocean, the possible influence of submarine volcanism in causing such anomalies, and the physical chemistry of fluoride ions in seawater involving complex formation by elements such as magnesium. It is now possible to detect 25 parts per 1,000,000,000 of fluoride in seawater.

The utilization of seawater trace constituents has enabled scientists to identify water masses and to trace currents. By using characteristic chemical tags of water masses, water in the Caribbean Sea has been identified as of South Atlantic origin.

Chlorinity and salinity of seawater. Determining the chlorinity of seawater is of fundamental importance to oceanography. The ratios of concentrations of several major constituents of seawater are virtually constant with the concentration of chlorinity. Of these, salinity is probably the most important.

Chlorinity is briefly defined as the number of grams of chlorine, bromine, and iodine contained in one kilogram of seawater, assuming that the bromine and iodine are replaced by chlorine. Salinity is the total weight of dissolved solids, in grams, found in one kilogram of seawater, and may be determined from the concentration of chlorinity.

Titration of chloride, the basic process for nearly all measurements of salinity in oceanographic work, is used extensively around the world, both ashore and at sea. Chlorinity is determined by adding a solution of silver nitrate of a known strength to a sample of seawater until enough is added to produce the same reaction as with standard seawater. The difference in the amounts added gives the degree of salinity. To ensure worldwide uniformity in chlorinity and salinity determinations, the International Council for the Exploration of the Sea prepared a universal reference, *Eau de Mer Normale* ("standard seawater"), in 1902. A new primary standard, prepared in 1937 and having a chlorinity of 19.381 parts per 1,000, is used to determine the chlorinities of all batches of standard seawater.

The concept of standard seawater

Oxygen content of seawater. The concentration of dissolved oxygen in seawater may vary from supersaturation near the surface, where photosynthetic activity by the phytoplankton is very high, to no oxygen in stagnant basins or deep fjords. The values, therefore, may be anything from zero to ten millilitres or more per litre of seawater.

The analysis for dissolved oxygen in seawater is important for numerous reasons: it aids in the interpretation of biological processes taking place in the ocean; it is finding increased use in studies of oceanic currents and mixing processes; and it is sometimes used as an index for detecting malfunctional sampling equipment and erroneous values.

Techniques and equipment of marine geology. The ocean floor has the same general character as the land areas of the world: mountains, plains, channels, canyons, exposed rocks, and sediment-covered areas. Because sound propagation is markedly affected by the ocean bottom and subbottom, extensive measurements have been made by means of an evolving series of geological or geophysical instruments of increasing precision and discrimination. These methods are providing increasingly accurate data on bottom topography and roughness that aid in understanding reflection loss at the bottom as a function of composition, roughness, frequency, and grazing angle. Investigators are using deep-ocean photography in conjunction with precision echo soundings to make detailed studies of bottom roughness and sediment structure.

Analysis and classification of marine sediments. Marine sedimentation embraces that phase of oceanography that is related to the deposition, composition, and classification of organic and inorganic material found on the ocean floor. Various sampling devices are utilized to obtain bottom sediments. Once obtained, samples are packed and shipped to a sedimentation laboratory to be analyzed and classified. Analysis of marine sediments generally includes the determination of size, shape, and percentage of component particles; identification of minerals and ratio of light to heavy minerals; wet density; pH (acidity–alkalinity); and calcium carbonate content.

Biological and ecological studies emphasize the animal population as well as the environmental factors determined by temperature, depth, type of sediment, and geographic location.

Bottom sediments are classified according to composition. Samples may be composed of terrigenous material (formed by the erosive action of rivers, tides, and currents), material from surface or submarine volcanoes, organic matter, inorganic material, and extraterrestrial matter. Size of the component materials may range widely, and it is used as a further, more detailed classification characteristic. From thousands of reported classifications and collected samples, bottom sediment charts are prepared (see also MARINE SEDIMENTS).

Bottom sediment charts

Geological sampling: coring devices. Marine sediments are collected by means of three basic categories of bottom samplers: coring tubes, snappers, and dredges. Coring devices are essentially steel tubes that are driven into the ocean floor. A typical coring device consists of interchangeable core tubes, a main body of streamlined lead weights, and a tailfin assembly that directs the corer in a vertical line normal to the bottom; all three components are referred to as the main weight. The amount of sediment collected by coring devices depends upon the length of the corer, size of the main weight, and penetrability of the bottom.

Designed to obtain cores up to about four feet in length, the small, lightweight Phleger corer takes only samples of the upper layers of the sea bottom. Coring tubes 12 and 36 inches in length, plus a main body weight, an upper tube, check valve, and tailfin assembly, account for an overall length of three to five feet for the Phleger corer.

Kullenberg and Ewing corers are representative of the piston corer. A closely-fitting piston attached to the end of the lowering cable is installed inside the coring tube just above the core catcher. When the coring tube is driven into the ocean floor, friction will exercise a downward pull on the core sample. The hydrostatic pressure on the ocean bottom, however, exerts an upward pressure on the core that will work against a vacuum being created between the piston and the top of the core. The piston, in effect, provides a suction that overcomes the frictional forces acting between the sediment sample and the inside wall of the coring tube. The complete assembly of the Kullenberg corer and releaser gear weighs about 400 pounds. The Ewing piston core is even larger, with coring tubes approximately 20 feet in length; one, two, or three lengths may be coupled together by connecting sleeves to obtain cores up to about 60 feet.

Small bottom samplers. Bottom samplers of the second category, clamshell snappers, are used to obtain small samples of the superficial layers of bottom sediments. They are of two general types: one, about 30 inches long and weighing about 60 pounds, is ruggedly constructed of stainless steel. The cast stainless steel snapper jaws, closed by heavy arms actuated by a strong spring and lead weight, trap about a pint of bottom material. The other type is smaller; it is called a mud snapper and is about 11 inches long and weighs three pounds. The jaws are cast bronze and are actuated by a spring.

Orange peel bucket samplers are for collecting bottom materials in shallow waters. A small hook attached to the end of the lowering wire supports the sampler as it is lowered and also holds the jaws in the open position. When contact is made with the bottom, the sampler jaws sink into the sediment and the wire tension is released, allowing the hook to swing free of the sampler. Upon hoisting, the wire takes a strain on the closing line, which closes the jaws and traps a sample.

The underway bottom sampler, or scoopfish, is designed to sample rapidly without stopping the ship. It is lowered from the bathythermograph winch in depths less than 100 fathoms (600 feet) from a ship under way at speeds not over 15 knots. The sampler weighs 11 pounds (five kilograms) and can capture samples ranging from mud to coral.

Dredges. The third major category of bottom sampler is the dredge. Bottom dredging operations require very sturdy gear, particularly when dredging for rock samples. A dredge is constructed of steel plate and is one foot deep, two feet wide, and three feet long. The forward end is open, but the aft end has a heavy grill of round steel bars that is designed to retain large rock samples. When finer sized material is sought, a screen of heavy hardware cloth is placed over the grill.

Techniques and equipment of biological oceanography. Biological oceanography is concerned with both plant and animal life in the sea. Animal life is divided into three general groups—the benthos (bottom living), the nekton (swimming), and the plankton (wanderers—the floating and drifting life). The plankton are further divided into phytoplankton (plant forms) and zooplankton (animal forms). Little is known of the life cycles of most marine life. Oceanographers are interested in the distribution of plankton populations, from both quantitative and qualitative points of view (see also PLANKTON).

Underwater sea life

Some of the most commonly used of oceanographers' samplers are plankton nets and midwater trawls. Nets have a mesh size capable of sieving micro-organisms such as zooplankton and phytoplankton from water; the trawls have a net-mesh size that permits plankton to pass through but filters out larger forms. Some nets can be used only when a ship is stopped or at anchor, while others take samples while a ship is under way. Plankton nets are further diversified in construction to allow sampling at one or several depths.

Plankton nets can be subdivided into qualitative and quantitative samplers. A qualitative sampler sieves organisms from the water without measuring the volume of water that has passed through it. A quantitative sampler does measure the volume, and hence the concentration of the organisms in a unit volume of water can be determined.

The midwater trawl is a specially designed net for rapid trawling at great ocean depths and at such a speed that active, fast-swimming fish are unable to swim out of the net once caught. Ships towing a certain type of trawl can travel as fast as five knots.

Clarke-Bumpus quantitative plankton sampler. The Clarke-Bumpus sampler is unique in that it can take an uncontaminated sample from any desired depth while simultaneously estimating the filtered volume of the seawater. The device is equipped with a flow meter to which an impeller is geared so that the number of revolutions made by the impeller can be recorded by a counter. By reading the counter, the volume of water that has passed through the sampler can be determined. A shutter opens and closes on command, admitting water and spinning the impeller while filtering out zooplankton and phytoplankton. When the impeller is stopped by closing the shutter, the sample can be raised without contamination from plankton in the overlying water strata.

The midwater trawl. To counteract the tendency of an ordinary net to surface behind the towing vessel, the Isaacs-Kidd midwater trawl (Figure 3) utilizes an inclined-plane surface rigged in front of the net entrance to act as a depressor. In form it is essentially an asymmetrical cone with a pentagonal mouth opening and a round, closed end. Within the net, an additional netting is attached as a lining. A steel ring (or rings) is fastened in the end of the net to maintain the tubular shape. A large perforated can is fastened by draw strings on the end of the net to retain the sample in a relatively undamaged condition.

Biological sound recordings. Major studies are under way on the acoustical properties and behaviour of marine organisms. Some organisms contribute to the background noise by their own acoustic signal emissions. Organisms that passively affect various electronic systems are the large mammals, schools of fish, and plankton that scatter sound and thus appear as false targets or background reverberation or that attenuate the acoustic signal.

Oceanic biologists record and analyze sounds produced by marine animals, their geographic and temporal distribution, and their behaviour as it relates to sound production. Concentrated effort has been made to identify sounds of biological origin. Some fish and invertebrates

make up layers of acoustic-scattering material that may exhibit daily vertical movement related to diurnal changes in light. The acoustical and biological properties of these layers have been studied for many years by

scientists of several nations, partly because of their military importance in interfering with underwater target detection. They have made repeated examinations of the same regions of the oceans in order to discover, for example, seasonal rhythms and evidence of the geographic range of the scatterers.

Marine biology in the laboratory. The description and classification of marine organisms continues to be an active field as hundreds of new species are collected each year. Advances in biochemistry, physiology, animal behaviour, and other fundamentally shore-based investigations are being emphasized as new equipment and techniques evolve.

Laboratory experiments involving biochemical studies on marine plants and animals have resulted in the isolation of chemicals that have antiviral, antimicrobial, cancer-inhibiting, nerve-blocking, or heart-stimulating properties. Some of these chemicals have potential pharmacological value, as shown by biotoxins from poisonous shellfish and pufferfish that are 200,000 times more powerful in blocking nervous activity than are drugs such as curare currently used for this purpose. Recent investigations of sponges have unexpectedly revealed a unique material, an arabinosyl nucleoside, that is apparently highly effective in the treatment of certain virus infections and leukemia in laboratory animals. Other products from sponges also show a broad spectrum of antimicrobial effects.

Potential new drugs from the sea

Many sea cucumbers, starfish, and their relatives produce highly toxic mixtures of steroid glycosides, a group of chemicals that includes the powerful cardiac drug digitalis, which is obtained from a terrestrial plant. Steroid glycosides from these marine organisms have suppressed growth of several different kinds of tumour in experimental animals and may provide leads toward the chemotherapy of malignant tumours.

RECENT ADVANCES AND FUTURE TRENDS

Important oceanographic prospects lie in increased drilling and core-sampling capabilities provided by improved technology. The "Glomar Challenger" (Figure 4), a 10,500-ton vessel built on the basis of the technology available in the 1960s, can maintain an exact position for days and weeks at a time by means of an acoustical beacon dropped to the sea floor, hydrophone reception of the beacon's signals, shipboard computer calculations, and four special propulsion units. The ship is stabilized against roll by a gyroscopically controlled system, so that drillers can effectively control, even in heavy seas, the 23,000 feet of drill pipe carried. A powerful drilling derrick operates through the bottom of the ship, extracting cores of extraordinary length from depths of thousands of metres, thus making available for study clues to the

history of oceans, climates, mountain building, volcanic eruptions, life and evolution, and the movements of sea floor and continents.

The "Glomar Challenger" used the latest navigation aids, including satellite observations and the various electro-magnetic systems such as shoran and Lorac. These have made possible the positioning of oceanographic vessels with a precision heretofore impossible.

Among the important practical benefits that promise to accumulate from more sophisticated oceanographic research are more efficient use of the potential marine food supply, new sources of pharmacological materials, and mineral resources, including not only oil and gas but hard minerals. Salt, bromine, and magnesium are already being economically extracted, and submerged placer deposits on the inner edge of the continental shelf may presently be exploited. The seabed may also yield coal, potash, phosphatic rock, iron ore, bauxite, and possibly metallic vein deposits. Coal has already been mined from onshore shafts or artificial islands off the coasts of Canada, the United Kingdom, Japan, and Taiwan. The nodules and crusts that rise in certain places in the deep ocean contain manganese, copper, cobalt, and nickel. Rich brines have been discovered on the floor of the Red Sea.

Electronic sensors, communications systems, and data storage and analysis systems are in the forefront of the new instrumentation becoming available to oceanography. Far from replacing men, however, such aids only increase man's capabilities and therefore value. Manned habitats and diver-transport systems will permit scientists to work routinely at great depths; operations at 2,000 feet appear feasible. Undersea tunnel drilling and a new technology for mating submersibles to a sea-floor shaft entrance may provide a completely independent sub-sea-floor installation for extended geophysical studies.

The immense efforts involved in the design of such submersibles as "Aluminaut," "Alvin," "Trieste," and "Deepstar" in the 1950s and 1960s demonstrated the problems and the promise of such vessels. As obstacles are overcome, the oceanographer will have increased mobility to go where he wishes, at many depths, and with greater convenience and safety.

Unidentified Flying Objects

Although sightings of unusual phenomena in the sky have been reported since ancient times, an extraordinary outburst of such sightings in the late 1940s and over the next two decades created a sharp scientific controversy, centred in the U.S., but extending around the globe. The term UFO, short for "unidentified flying object," was introduced in 1953 by the U.S. Air Force. An earlier term, "flying saucer," is still widely used in Australia, South America, and Europe, while in the Soviet Union the Russian equivalent of "flying sickle" is used. The term UFO is not restricted to saucer-shaped objects nor even to objects in the sky, and in general refers simply to any sighting the observer could not understand, even though it may have been later identified.

History. A series of radar detections coincident with visual sightings near the National Airport in Washington, D.C., in July, 1952, led the U.S. government to establish a panel of scientists headed by H.P. Robertson, a physicist of the California Institute of Technology, and including engineers, meteorologists, physicists, and an astronomer. The thrust of public and governmental concern was indicated by the fact that the panel was organized by the Central Intelligence Agency (CIA) and was briefed on U.S. military activities and intelligence, and that its report was originally classified Secret. Later declassified, the report revealed that 90 percent of UFO sightings could be readily identified with astronomical and meteorological phenomena (bright planets, meteors, auroras, ion clouds) or with aircraft, birds, balloons, searchlights, hot gases, and other terrestrial phenomena, sometimes complicated by unusual meterological conditions.

The publicity given to early sightings in the press doubtless helped stimulate further sightings not only in the U.S. but in western Europe, the Soviet Union, Australia, and elsewhere. A second panel organized in February 1966 reached conclusions similar to those of its predecessor. This left a number of sightings admittedly unexplained, and in the mid-1960s a few scientists and engineers, notably James E. McDonald, a University of Arizona meteorologist, and J. Allen Hynek, a Northwestern University astronomer, concluded that a small percentage of the most reliable UFO reports gave definite indications of the presence of extraterrestrial visitors.

This sensational hypothesis, already promoted in newspaper and magazine articles, met with prompt resistance from other scientists. The continuing controversy led in 1968 to the sponsorship by the U.S. Air Force of a study at the University of Colorado under the direction of

Lenticular clouds over São Paulo, Brazil, exemplify natural phenomena that can be easily mistaken for "flying saucers."

E.U. Condon, a renowned physicist. The Condon Report, "A Scientific Study of UFO's," was reviewed by a special committee of the National Academy of Sciences and released in early 1969. A total of 37 scientists wrote chapters or parts of chapters for the report, which covered investigations of 59 UFO sightings in detail, analyzed public-opinion polls, and reviewed the capabilities of radar and photography. Condon's own "Conclusions and Recommendations" firmly rejected "ETH"—the extraterrestrial hypothesis—and declared that no further investigation was needed.

This left a wide variety of opinions on UFOs. A large fraction of the U.S. public, and a few scientists and engineers, continued to support ETH. A middle group of scientists felt that the possibility of extraterrestrial visitation, however slight, justified continued investigation, and still another group favoured continuing investigation on the grounds that UFO reports are useful in sociopsychological studies. These varying views and attitudes were expressed at a symposium held by the American Association for the Advancement of Science, in December 1969.

REPORTED UFO SIGHTINGS AND EVENTS

U.S. Air Force Project

Official records. In 1948 the U.S. Air Force began to maintain a file of UFO reports called Project Blue Book. By 1969 the project had recorded reports of 12,618 sightings or events, each of which was ultimately classified as "identified" with a known astronomical, atmospheric, or artificial phenomenon, or as "unidentified," including cases in which information was insufficient. In 1969, following the Condon Report, Project Blue Book was discontinued. The only other official and fairly complete records of UFO sightings were maintained in Canada, where they were transferred in 1968 from the Canadian Department of National Defense to the Canadian National Research Council and placed under the supervision of Peter Millman, a meteoriticist. The Canadian records totalled about 750 in 1969. Less complete records were maintained in Britain, Sweden, Denmark, Australia, and Greece, and were usually destroyed after five years.

Press reports. Press reports have been worldwide, including a number from the Soviet Union. But though such reports reflect a general public concern, they tend to emphasize the sensational and are not properly evaluated. No comprehensive summary of press reports has yet been made, but they seem to have followed an eastward-moving geographic trend starting with the first widely publicized "flying saucer" sighting in the western U.S. in 1947. Many press reports of sightings on the U.S. East Coast in the early 1950s were followed by reports from Britain, France, the Soviet Union, Australia, and on to the U.S. West Coast in the 1960s. In the 1960s there were many sightings of UFOs "taking off" from the ground, a shift from saucer shapes to cigar shapes in the images reported, and a number of reports of effects on the electrical systems of automobiles. Many authorities believe that mass-media coverage of UFOs both stimulated more reports of sightings and encouraged a change to more dramatic events and differently shaped images. A series of feature articles in an Argentine newspaper in 1968 was promptly followed by a number of sightings in Buenos Aires and other cities.

Types of UFO reports. UFO reports varied widely in reliability, as judged by the number of witnesses, whether the witnesses were independent of each other, by the observing conditions (fog, haze, illumination, etc.), and by the direction of sighting. Typically, the witness who reported a sighting considered the object extraterrestrial in origin, or possibly a military vehicle, but certainly under intelligent control, a conclusion usually based on apparent formation-flying of multiple objects, unnatural motions seemingly centred on a target, or arbitrary alterations in direction, brightness, and motion.

That the unaided human eye plays tricks bordering on hallucinations is well known. A bright light, such as the planet Venus, often appears to move, although a clamped telescope or a sighting bar shows it to be fixed. Visual impressions of distance are also highly unreliable, being based on assumed size. Reflections from windows and eyeglasses can provide superimposed views. Optical defects can turn point sources of light into apparently saucer-shaped objects. Such optical illusions, and the psychological desire to interpret visual images, are known to account for many visual UFO reports. Radar sightings, while more reliable in certain respects, fail to discriminate between physical objects and meteor trails, tracks of ionized gas, rain, or thermal discontinuities. Even "contact events"—in which activities besides sighting were reported—have been found most frequently to involve dreams or hallucinations; the reliability of such reports depended heavily on whether there were two or more independent witnesses.

Radar sightings

Sightings and reports may be conveniently classified in four broad categories, for each of which selected examples are given below:

1. Visual sightings in daytime (some photographed);
2. Visual sightings at night (a few photographed);
3. Radar sightings;
4. Close encounters or physical evidence.

The absence of a given explanation does not necessarily mean that the example constitutes evidence favouring the ETH. It merely means that no explanation is known.

Examples of daytime sightings. Many of these sightings have been identified with the planet Venus, from its known position in the sky.

Louisville, Kentucky, Jan. 7, 1948. At 1:15 PM the State Highway Patrol reported a flying saucer to the Godman Air Force Base, where the base commander and several other persons saw the object. A group of four USAF F-51 aircraft arrived at the base and three were directed by the control tower toward the UFO. One pilot saw it and started a rapid climb toward it; the other two fighter pilots remained behind and lost radio contact with the first just after he reported that he would climb to 20,000 feet altitude. He had no oxygen equipment and was killed when his plane crashed without further communication half an hour later. The first USAF investigation concluded that the pilot saw Venus, which was in the direction of his sighting, but later discussion suggests that it was a 100-foot "Skyhook" balloon being tested by the U.S. Navy. (This uncertainty is typical of early UFO identifications, and led to greater USAF effort in Blue Book.)

Newton, Illinois, Oct. 10, 1966, 5:20 PM CST. A woman and five children witnessed the slow passage of a metallic object past their farm home. Observing conditions were excellent, with clear, dry weather. The object was first seen by the children, ages four through nine years. The mother responded to the children's call and joined them in the yard, walking parallel with the object's motion. The object moved slowly and uniformly in a westerly direction, at walking speed, approximately 50 feet

above the ground. Abruptly turning its nose up and moving rapidly upward, it disappeared from sight in one or two seconds. An analysis of the reported sighting suggested a cigar-shaped spheroid approximately 20 feet long and eight feet in diameter, possibly of aluminum, with longitudinal seams, a small dorsal fin at the rear, and a rectangular, black aperture near the front. A brownish-gold design was observed on the lower rear portion. The object was surrounded by a bluish haze that contained luminous bubbles or sparks. No sound was heard except for an unusual vibrating noise perceived for a few seconds when the object was nearest.

Seventy minutes later, under dark-sky conditions, an elliptical blue light of the same colour and shape was seen moving in the same general direction by a witness seven miles from the first sighting.

Tremonton, Utah, July 2, 1952. At 11:10 AM, a Navy Chief Warrant Officer with his wife and two children was driving along State Highway 30 when they saw a group of strange white objects above the eastern horizon. The officer stopped the car, estimated that there were 12 to 14 of the objects, and photographed them for several minutes, using a 16-mm movie camera. He was sure that the UFOS were large objects at high altitude. Analysis of the film showed that they might have been sea gulls at 2,000 feet distance; at 50,000 feet they would have been moving at 300 miles per hour, executing maneouvers impossible for aircraft known in 1952.

Socorro, New Mexico, April 24, 1964. A patrolman reported that at 6 PM he sighted a "blue flame" about 2,000 feet off Highway 7A. He drove along a ranch road to within 200 feet of a 20-foot hemispherical object standing on four legs near an abandoned shack where he earlier thought he had seen two people dressed in white. As he approached, the UFO took off with a loud roar, apparently emitting a blue jet flame, and climbed in a southwesterly direction away from the highway. There were no other witnesses, although the observer had radioed another patrolman for assistance when he left the highway. After recovering from his fright, the observer located four deep impressions in the soft ground where he said the UFO stood. There were two smaller impressions where a ladder had led to a door seen by the observer.

Examples of nighttime sightings. Many of these sightings have been identified with planets, bright stars, meteors, and airplanes. Some may be explained by the refraction of light in layers of warm air hundreds of feet above the observer, allowing him to see surface lights high in the sky.

Montgomery, Alabama, July 24, 1948, 2:45 AM. A pilot and copilot in the cockpit of an airline passenger plane at 5,000 feet altitude, en route from Houston to Boston, saw a dull-red object approaching on a collision course. During the next ten seconds it veered slightly to the right, passed the plane on the right at high speed, then seemed to pull up, and disappeared in the clouds overhead. One passenger on the right side of the plane glimpsed the bright light as it flashed by. There was no disturbance of the plane. The pilots described the object as cigar-shaped, about 100 feet long, with two rows of lighted windows, a dark blue glow underneath, and a red-orange jet flame about 50 feet long behind it. They estimated the closest approach to be less than a mile. Authorities concluded that the object was probably a distant meteor.

Dexter, Michigan, March 21–22, 1966. A farmer and several of his friends reported coloured lights that landed in a swamp, where they later saw a "pyramid-shaped object" with lights rippling eerily across its surface in the dark. The next night, several girls at a nearby college reported three large coloured lights moving up and down in a "synchronized" way, and two other co-eds reported a glowing disc in the swamp.

The lights have been interpreted as glowing marsh gas, or will-o'-the-wisp. The faint, fingerlike, glowing methane is often seen low on the ground on damp nights, and is well known to result from decaying vegetation, but its appearance did not fit the large coloured balls seen "landing" in the swamp. This case was lampooned extensively by the U.S. press.

Examples of radar sightings. Radar measures the distance to a UFO and the direction, which may be affected by refraction of the radio beam in the atmosphere. Several effects can give false radar echoes: electronic interference, reflections from ionized layers or clouds, and reflections from regions of higher temperature or humidity, as in a cumulus cloud. A simultaneous radar detection and visual sighting in the same direction is the most reliable—but not certain—evidence of a physical object.

Lakenheath, England, Aug..13, 1956, 11:00 PM–3:30 AM. Two RAF ground radar stations detected several objects moving at high speed on a clear moonlit night. One was tracked by the first radar as going at about 3,000 miles per hour westward at 4,000 feet altitude; simultaneously, tower operators reported a bright light passing overhead toward the west, and the pilot of an aircraft at 4,000 feet over the airfield saw the bright light streak westward underneath him. The second radar station, alerted by the first, detected a stationary target at about 20,000 feet altitude that suddenly went north at 600 miles per hour. It made several sudden stops and turns. After 30 minutes an RAF fighter was called in and made airborne-radar contacts with the object over Bedford (just north of Cambridge, England). Suddenly the object moved around behind the fighter plane, both being tracked by ground radar. The fighter pilot could not "shake" the object. A second plane was called in but never made contact, and all radar contacts were then lost. Several other radar targets were tracked in the same area and several other small moving lights were seen, but all disappeared at 3:30 AM.

This is believed to be one of the best established and most puzzling of the unexplained cases.

Colorado Springs, Colorado, May 13, 1967, 3:40 PM. The weather was overcast with scattered rain and sleet showers and gusty winds. As an airliner came in for a landing, the ground radar detected an object beyond it at about twice the range. As the plane landed, the object pulled to the east and passed low over the airport (at 200 feet altitude, about 1.5 miles from the control tower). The tower operators, alerted by the radar operation, saw and heard nothing. The pilot of another aircraft, three miles behind the first, saw nothing when asked to look.

Examples of close encounters or physical evidence. These include foot impressions described above in Socorro, New Mexico, circular burned patches in fields, and melted patches in road pavement, possibly due to jet take-off. It is barely possible that strong magnetic fields or plasma clouds of ions produced by a UFO could affect the electrical components of an automobile.

Methuen, Massachusetts, Jan. 20, 1967, after dark. Three people were driving northeast on a street bordered by woods, fields, and a few houses. They reported that on reaching the top of a hill they suddenly came upon a straight string of bright red lights moving along the roadside at an altitude of 500–600 feet. When they were almost broadside to the lights, which then were hovering, the object to which they were apparently attached swung around to reveal four distinct lights in a perfect trapezoid. Two red lights formed the top and two white lights formed the base. The red lights resembled a hot electric-stove burner. A reflecting metal was seen about the lights. The centre of the trapezoid was dark. When the driver pulled over to the side of the road directly broadside to the object, his car engine, lights, and radio failed completely. The driver tried to start the car again, but was unsuccessful. No noise was heard as the object began moving slowly and then shot away at great speed in a southwest direction. The driver was then able to start the car, and the lights and radio worked perfectly.

Ubatuba, São Paulo, Brazil, Sept. 10, 1957, 12 noon. Three fishermen saw a flying saucer diving into the sea at high speed. Just before reaching the water, it turned sharply upward and exploded into "thousands of fiery fragments." The fishermen picked up several of these fragments, which fell on the beach, and sent them in an anonymous letter to a Rio de Janeiro newspaper. A Brazilian government laboratory did a chemical analysis and announced that the metal was "magnesium of higher purity than attainable in purification techniques known to

man." The impurities detected were zinc, strontium, and other trace metals totalling about 0.15 percent. Analysis, however, soon showed that industrial magnesium in the U.S. is a good deal purer (less than 0.002 percent impurities). The abundance of strontium was unusual, however, and may lend some weight to the claim that the Ubatuba fragments were from an extraterrestrial space vehicle.

Southern New Hampshire, Sept. 19, 1961, 11 PM to 2 AM. A couple returning to Boston via Lancaster and Concord saw a large disk-shaped object and felt obliged to stop and walk over to it. Their stories, recorded separately under hypnosis by a psychiatrist in Boston in 1964, were consistent and told of their being taken aboard the flying saucer, undressed, and examined by a group of humanoids. Later, psychologists concluded that this widely publicized case was a hallucination by the woman, transmitted to her husband so thoroughly that he "remembered" it as real, even under hypnosis.

Role of hallucination

CONTINUING ACTIVITIES

In accordance with the conclusions and recommendations from the 1969 Condon Report, the U.S. Air Force terminated its Project Blue Book study of UFOs in December 1969. Several groups of American scientists claim, nevertheless, that the UFO phenomenon warrants further study; and groups in other countries are continuing their studies of UFOs. These studies are of three types:

1. Detailed analysis of reported cases similar to the examples cited above, often called "soft data" because they depend on the reliability of witnesses. The goal is to identify new physical phenomena or to confirm the extraterrestrial hypothesis.
2. Systematic collection of "hard data" by networks of cameras, or radar sets or other instruments that cover a broad area nearly 100 percent of the time without the questionable reliability of eyewitnesses. The goal is often associated with studies of meteors, auroras, or other atmospheric phenomena.
3. Statistical studies of past reports to establish definite psychological and sociological patterns. The duration of the UFO phenomenon—over 20 years—puzzles psychologists because mass hysteria has never been so long enduring or so widespread.

It is claimed by many experts that type 1, detailed analyses of soft data, will not produce new information, although some scientists hold that an exceptionally good sighting may occur and lead to significant conclusions.

Instrumental developments. There are at least two new instrumental developments than can provide hard data for type 2 studies: "all-sky" camera networks and TV cameras in artificial satellites. The first of these is typified by the Prairie Meteorite Network of 64 automated cameras in groups of four at 16 stations spaced about 140 miles (225 kilometres) apart to cover about 500,000 square miles (1,500,000 square kilometres) of the U.S. Midwest centred on Steinauer, Nebraska. This network is operated by the Smithsonian Astrophysical Observatory in Cambridge, Massachusetts, for the purpose of observing meteors and locating meteorites soon after impact. Each camera is programmed to make four three-hour exposures each night, and the 9x9-inch film (totalling 3.6 acres per year) is quickly scanned for nearly straight meteor tracks. Except for about 200 films used in connection with the Condon Report to check UFO reports, the Prairie Network films have not been scanned for irregular UFO tracks or images, a job that would require at least 30 persons working full time.

Prairie Meteorite Network

Single all-sky cameras, photographing about 80° down from the zenith on all sides, are used for broad sky-brightness measures but do not have sufficient resolution to detect UFOs. A large number were operated by international cooperation during 1957–58, and two or three are operated continuously in Czechoslovakia. The Canadians started operating a meteorite network similar to the Prairie Network in 1970, but their films have not been scanned for UFOs.

The National Aeronautics and Space Administration operates several artificial satellites equipped with optical TV cameras that radio image-data to ground-based receivers. Two sets of satellites record cloud patterns for weather prediction, and they might detect bright, high UFOs. Other optical satellites used for astronomical observations look outward and have a very small chance of detecting small objects. Similarly, the telescopes used by astronomers at observatories all around the world have little chance of photographing a passing UFO.

Two radar networks covering most of the United States and Canada are operated jointly by the U.S. and Canadian (civilian) Aviation Administrations and by the North American (military) Air Defense Command. Together, they track every airplane, balloon, rocket, satellite, or other moving object; but the task of sorting out UFOs from full-time records of the millions of other objects tracked each day would require an expensive and very special computer. It is probable that most of the radar targets not associated with scheduled aircraft, known balloon launches, and known rocket firings would be thunderstorms, air currents, and other complex meteorological phenomena; and a systematic search for UFOs would require hundreds of weather specialists.

Statistical studies. The statistical studies of type 3 could be undertaken by psychologists if the UFO reports filed by Project Blue Book or other groups are systematized and recorded on punch cards or tape for use in an electronic computer. The difficulty here lies in the wide variety and incomplete nature of UFO soft data. None of the files contains *all* sightings, and the record of any one sighting usually omits several points of significance to sociological or psychological studies.

The sample of over 12,000 sightings is, however, large enough so that in the early 1970s psychologists were planning to sort the records into broad categories that could be statistically corrected for incompleteness and used to study mass hysteria, hysterical contagion, and possible causes of hallucination. Some of the hallucinations associated with UFO reports may be related to the so-called Isakower syndrome, wherein a drowsy person visualizes scenes of his remote past, which would account for apparitions and misidentifications.

Response of the public. Psychologists are also interested in the strong emotions aroused by UFOs among the witnesses who sighted them, the public who read about them, and the scientists who evaluate reports. In addition to defending the validity of their reports, witnesses are usually somewhat "shaken" by their sightings, a reaction similar to that of religious experiences. The witnesses, however, are seldom active in organizing UFO study groups or in writing books and articles.

Public reaction ranges from excited curiosity to ridicule. The excitement is probably related to the extraterrestrial hypothesis, exemplified by the strong public interest since 1900 in possible intelligent life on Mars. Some of the emotion may derive from religious beliefs about terrestrial man's place in the universe or from ancient myths about the supremacy of angels over ordinary men. It often involves fear of extraterrestrial visitors.

The evidence for these psychological reactions is displayed in the 50 books and over 250 magazine articles written in the U.S. about UFOs since the first flying saucer was reported in 1947. U.S. public interest was indicated by some 30 UFO clubs and societies that sprang up in the 1950s and '60s. There were signs that this public interest was diminishing following publication of the Condon Report and the termination of Project Blue Book in 1969. The number of newspaper articles on UFOs significantly declined to a fraction of its peak of 1966.

The reaction of physical scientists has been centred on reluctance to change their systems of belief based on current physics and astronomy. The basic philosophical question raised by UFO reports is one of reality. Because of the confusing variety of evidence and the doubtful reliability of most reports, it has been difficult to apply accepted criteria of physical reality to UFOs themselves, but the psychological UFO phenomenon is certainly real.

Uniformitarianism

Uniformitarianism is a point of view held by scholars who accept the principle of the uniformity of nature as a basis for their investigations. This principle has been stated in many ways, most commonly in the form, "The present is the key to the past." In the context of the history of science, uniformitarianism is the name of a geological doctrine that developed in opposition to the doctrine of catastrophism during the late 18th century and thereafter. The meaning and usefulness of the principle of uniformity, no less than the identification and analysis of points at issue during the debate between the uniformitarians and the catastrophists of the 19th century, are matters on which no consensus has yet been reached.

Sir Charles Lyell (1797–1875) was the leader of the uniformitarian school of geological thought in the last century. His monumental *Principles of Geology* (3 vol., 1830–33) was based upon the hypothesis that "the ancient changes of the animate and inanimate world, of which we find memorials in the Earth's crust, may be similar both in kind and degree to those which are now in progress." William Whewell (1794–1866), reviewing the second volume of the *Principles* in 1832, conceded that the same *kinds* of geological changes now in action, namely those related to erosion and deposition of sediment and to dislocations attending earthquakes, apparently have operated in the distant past. But he questioned the assumption of uniformity in the average *rates* of changes past and present. "Have the changes which have led us from one geological state to another been, on a long average, uniform in their intensity," Whewell asked, "or have they consisted of paroxysmal and catastrophic action, interposed between periods of comparative tranquility? These two opinions will probably for some time divide the geological world into two sects, which may perhaps be designated as the Uniformitarians and the Catastrophists." Because catastrophism was the more popular view in the 1830s, it is useful to examine that doctrine first, in order to identify the issues that the uniformitarians were attacking.

The doctrine of catastrophism. The catastrophism of the early 19th century gained much of its authority and respectability from the writings of the French scientist and statesman Georges Cuvier (1769–1832). A master of vertebrate paleontology and comparative anatomy, Cuvier made detailed studies of the large quadrupeds whose bones are preserved in strata of Cenozoic age around Paris. In the younger alluvial deposits he found remains of rhinoceros, hippopotamus, tapir, elephant, and mastodon. With the exception of the mastodons, Cuvier could classify most of these fossils as exinct species of modern genera. The underlying and older strata of Tertiary age, however, yielded remains of pachyderms and other vertebrate animals that belong to extinct genera. In the alternating deposits of marine and freshwater origin, which are characteristic of the Tertiary System in the Paris Basin, Cuvier found, moreover, that each formation has its distinctive suite of vertebrate fossils. To explain these discontinuities in the record of ancient life, Cuvier invoked the agency of recurrent catastrophies.

The views of Cuvier and Buckland

As envisioned by Cuvier, the catastrophic episodes that divided the history of the Earth into chapters were brief, convulsive, and lethal. Sudden changes in the level of land and sea were attended by the upheaval and dislocation of strata to form ranges of mountains, by the flooding of continents, and by abrupt changes of climate. Whole races of organisms were supposedly wiped out; terrestrial animals drowned, and marine life was left stranded as parts of the ocean's floor were uplifted. Following each convulsion, the normal order of nature was restored and the Earth was repopulated by organisms that had somehow survived the ordeal. Cuvier estimated that the last catastrophe took place 5,000 to 6,000 years ago when a deluge covered all areas previously inhabited by man. The few surviving men and other animals then propagated and spread over the lands left dry after this flood subsided.

In England William Buckland (1784–1856) was the leading geologist of the 1820s and the chief advocate of catastrophism. Buckland's investigations concentrated upon the vertebrate fossils which he collected from the Kirkdale Cave of Yorkshire and more than 20 other caves in England and on the Continent. Buckland collected a Quaternary fauna that included bones of hyenas, lions, tigers, elephants, and hippopotamuses. He interpreted the layers of clastic sediment covering the uppermost bone beds as aqueous deposits laid down by Noah's flood. This most recent catastrophe was but one example in Buckland's mind of many such convulsions that left their records in the rocks and that offer "proofs of an overruling Intelligence continuing to superintend, direct, modify, and control the operations of the agents which He originally ordained." The belief that the normal operations of nature have been repeatedly suspended by direct intervention of a supernatural agency was one of the tenets of catastrophism that the uniformitarians specifically rejected.

A second point at issue revolved around the doctrine of progressive development of organic species. This doctrine was based on the paleontological evidence that lower orders of life are preserved as fossils in the oldest strata and are followed by progressively higher orders in successively younger rocks. Invertebrate animals evidently appeared on the Earth long before the vertebrates; in the vertebrate succession the oldest were fishes, after which came in turn the amphibians, reptiles, mammals and birds, and finally man. Many catastrophists interpreted this record as the unfolding of a divine plan. Following the destruction of numerous species during catastrophic episodes they held that the Earth was replenished with new and higher forms of life. The doctrine of progressive development was supported by many outstanding geologists of the 19th century, including W.D. Conybeare, Hugh Miller, Roderick Murchison, and Adam Sedgwick. To the extent that successive creations implied supernatural interventions, the uniformitarians rejected the doctrine on principle, but for many years Lyell also denied the evidence that the doctrine was intended to explain.

In the catastrophist view, the folded and fractured strata of mountain chains, in which former marine sediments now stand thousands of metres above sea level, seemed to call for forces greater by many orders of magnitude than any manifest in nature today. "Do not vertical strata prove rapid elevation?" Whewell asked. Great thicknesses of coarse sandstone, conglomerates, and breccias, which occur at intervals throughout the stratigraphic column, were taken as evidence for ages of violent aqueous action. Beds in which the fossilized remains of marine animals and terrestrial plants were mingled seemed to attest the destructiveness and confusion of paroxysmal events. Whole mountains of igneous rock exist, and the magma that formed these masses must have burst through the Earth's crust. The widespread veneer of alluvium upon the continents was thought to record the force of the last great deluge, which also excavated gorges and canyons as the waters subsided.

Uniformitarianism according to Hutton, Playfair, and Lyell. The initial thrust of Lyell's attack upon catastro-

phist geology, beginning in 1830, was directed against the proposition that the natural course of events that followed the creation of the Earth has been interrupted time and again by supernatural causes. Lyell was willing to concede that the earth was divinely created, but he insisted that the subject of "first causes" lay beyond the reach of geology. If the reconstruction of the Earth's history is to be pursued on scientific grounds, geologists are constrained to invoke only secondary and naturalistic causes: the causes presently in operation.

Lyell's methodology

One of the prejudices that has persistently retarded the progress of geology, Lyell contended, is the tendency to undervalue greatly the duration of geologic time. Compressing a lengthy sequence of geological events into a span of time that is unreasonably short can indeed cause these to unfold in a manner that might seem miraculous.

> We should be warranted in ascribing the erection of the great pyramid to superhuman power, if we were convinced that it was raised in one day; and if we imagine, in the same manner, a mountain chain to have been elevated, during an equally small fraction of the time which was really occupied in upheaving it, we might be justified in inferring that the subterranean movements were once far more energetic than in our own times. We know that one earthquake may raise the coast of Chile a hundred miles to the average height of about five feet. A repetition of two thousand shocks of equal violence might produce a mountain chain one hundred miles long and ten thousand feet high. Now, should only one of these convulsions happen in a century, it would be consistent with the order of events experienced by the Chileans from the earliest times; but if the whole of them were to occur in the next hundred years, the entire district must be depopulated, scarcely any animals or plants could survive, and the surface would be one confused heap of ruin and desolation.

The above quotation well illustrates Lyell's method. To account for the origin of some geological phenomenon or some feature of the landscape he appealed to processes now operating in a modern geographic setting. By assuming that these same processes will operate over long intervals of time, he showed how these might produce results similar to the phenomena under investigation.

For example, it is not uncommon to find in Mesozoic and younger strata certain sequences in which fossilized parts of terrestrial animals and plants are mingled with the remains of marine organisms. Those sequences were sometimes interpreted by the catastrophists as evidence of supranatural convulsions. As a more reasonable if less spectacular alternative, Lyell suggested that strata of this kind must today be forming off the delta of the Mississippi River. He described how this great river, during its stages of flood, annually sweeps into the sea:

> sand and finer matter . . . together with the wreck of countless forests and the bones of animals which perish in the inundations. When these materials reach the Gulf of Mexico, they do not render the waters unfit for aquatic animals; but on the contrary, the ocean here swarms with life. . . . Yet many geologists, when they behold the spoils of the land heaped in successive strata, and blended confusedly with the remains of fishes, or interspersed with broken shells and corals . . . . they read in such phenomena the proof of chaotic disorder, and reiterated catastrophes, instead of indications of a surface as habitable as the most delicious and fertile districts now tenanted by man.

Deep valleys excavated in solid rock were often cited by the catastrophists as evidence of the torrential scouring action exerted upon the land by the retiring waters of the Noahian Deluge. Lacking any evidence to the contrary, Lyell assumed that these valleys had been cut by the long-continued erosive action of the streams that now occupy them. Thus, to explain the gorge below Niagara Falls, Lyell appealed to the recurrent undermining of the limestone lip and the sweeping away of the fallen debris by the river below. Historical reports indicated that the falls had receded upstream by about 50 yards (46 metres) during a period of 40 years. At this rate of recession, he argued, nearly 10,000 years would have been required for the excavation of the gorge above Queenstown, seven miles (13 kilometres) downstream. Lyell later increased his earliest estimate of the age of the gorge more than threefold but regarded all figures for age as no more than approximations, subordinate to the general proposition that "the river supplies an adequate cause for executing the whole task thus assigned to it, provided we grant sufficient time for its completion."

Lyell's uniformitarian method owed much to the writings of his predecessors, James Hutton (1726–97) and John Playfair (1748–1819) in particular. Hutton's *Theory of the Earth*, published first as an essay in 1788 and expanded to a two-volume work in 1795, developed the idea that the Earth functions essentially as a heat machine. The agents of erosion, particularly streams, wear down the continents over long periods of time. The sediments spread from the wasting continents are periodically upheaved to form new continents by the expansive force of subterranean heat. These new or rejuvenated continents in turn waste away until the next cycle of uplift and deformation. In the record of the rocks, Hutton saw an apparently endless sequence of such cycles that afforded "no vestige of a beginning, no prospect of an end." Although he was willing to concede that the Earth was divinely created as an abode suitable for man and other organisms, he invoked no supernatural causes to explain the workings of the terrestrial heat machine once it had been set in motion. As for the length of time that has elapsed since the world was formed, Hutton was only certain that it must be vast beyond human comprehension. "Time," he wrote, "is to nature endless and as nothing." Playfair, in his *Illustrations of the Huttonian Theory of the Earth* (1802), summarized, elaborated upon, and defended Hutton's views in a work of grace and clarity.

Lyell incorporated into his synthesis Hutton's views on the immensity of geologic time, the idea that past changes in the configuration of the Earth can be explained in terms of natural causes now in action, and the idea that great changes in the Earth's configurational aspects may be accomplished by a series of small changes operating over long periods of time. Unlike Hutton, Lyell held that the elevation of continents and the formation of folded mountain chains were accomplished no less gradually than the wearing down of the continents by erosion.

19th-century debate. Lyell's uniformitarian synthesis was attacked on theological, philosophical, and scientific grounds. Most of the counterarguments are summarized in Whewell's *Philosophy of the Inductive Sciences* (2nd ed., 1847). Whewell insisted that there must be "a Providential as well as a Natural Course of Things." The assumption that known causes have always operated at their present rates is philosophically unsound and scientifically suspect.

> Whether the causes of change do act uniformly;—whether they oscillate only within narrow limits;—whether their intensity in former times was nearly the same as it now is;—these are precisely the questions which we wish Science to answer to us impartially and truly. . . .

The theory of constant change through virtually infinite time is untenable because the Earth cannot be a perpetual motion machine, regardless of whether the motive power be mechanical or chemical. The paleontological record unequivocally shows that in the course of geological history hosts of new species have appeared in an orderly succession, but nothing in the Lyellian theory can explain the creation of new species by "causes now in action."

Despite these and other criticisms, Lyell did not yield. In two successive presidential addresses delivered before the Geological Society of London in 1850 and 1851, he defended the position that he had set forth 20 years earlier in the first edition of his *Principles*. Granting that the deformation of strata in the Alps is spectacular, he argued that it is no more intense, nor more extended geographically, than may be observed in mountain chains that were deformed far earlier in geologic time. There is no evidence to be drawn from folded mountains, therefore, that the Earth's orogenic energy has diminished with time. Granted that deposits of rounded pebbles measuring more than one kilometre in thickness have been found in the Alps, do not deposits of this kind require long periods of time for their accumulation if each pebble is to be rounded by attrition before its burial? As for the "theory of successive development of organisms," Lyell questioned

both the adequacy of the empirical evidence offered in support of it and the progressionist interpretation of this evidence. The fossil record is so incomplete and so little known that it affords no conclusive evidence as to the time when the major groups of plants and animals first appeared on the Earth, he argued. Fossilized remains of birds, for example, are paleontological rarities in general; for this reason it cannot be deemed impossible to find birds in strata as old as the Carboniferous. Even accepting the record as it stands, there is no evidence of progressive development: the conifers of the Carboniferous were as highly organized as any in the plant kingdom; the marine invertebrate animals of the Silurian were as perfect as their counterparts in existing seas; and the record of mammals during the Tertiary Period shows no advance from earliest Tertiary times to the present.

Significance of organic evolution

As the debate between the uniformitarians and catastrophists developed, the question as to the progressive development of organisms through time became the central issue. Lyell's position, as originally stated in the early 1830s and long maintained thereafter, was that organic species are stable, susceptible to extinction, but incapable of alteration. This viewpoint was shaken when, in April of 1856, Charles Darwin first outlined his hypothesis of natural selection to Lyell in a private conversation. Four years later, following the publication of the Darwin-Wallace papers on natural selection in 1858 and Darwin's *Origin of Species* in 1859, Lyell confessed in his private journal that Darwin's hypothesis seemed more probable than the theory of miraculous creation. But nine more years were to pass before Lyell would become a confessed convert, at the age of 72, to Darwin's theory of evolution.

Much has been written about Darwin's indebtedness to Lyell and the doctrine of uniformitarianism, but it is important to recognize that strict Lyellian uniformitarianism was at the outset anti-evolutionary. Naturalism, gradualism, and the long scale of geological time were the ingredients of uniformitarianism that were essential to Darwin's synthesis. The evolution of organic species through the mechanism of natural selection substituted causes now in action for supernatural causes. Darwin denied great and sudden changes in the modification of organic species, preferring to believe that major changes in the organic world are the summation of a host of minute mutations. This gradualism, in turn, required a very long, if indefinite, span of geological time.

Against the catastrophists and the uniformitarians, who were prodigal of time despite their doctrinal differences, William Thomson (Lord Kelvin, 1824–1907) launched an attack beginning in 1862. Kelvin revived, this time in formidable mathematical terms, Whewell's contention that the Earth could not be a perpetual motion machine. Kelvin's argument rested upon two interrelated assumptions: the heat of the Earth is residual from its original molten state, and the matter of the Earth is chemically inert. Reasoning from the laws of thermodynamics, Kelvin concluded in 1899 that the Earth is probably no older than 24,000,000 years. Kelvin's estimates were soon discredited by the discovery of radioactivity, which in turn led to the dating of terrestrial events as ancient as 3.5×10^9 years.

Modern status of uniformitarianism. The guiding principle of uniformitarianism, the principle of the uniformity of nature, is somewhat ambiguous. As S.J. Gould has pointed out, most of the many and diverse formulations of the uniformity principle fall into two classes: those

Substantive versus methodological uniformity

descriptive of the history of nature (substantive uniformity) and those descriptive of the procedures by which scientists investigate the history of nature (methodologic uniformity). Lyell's assumption that the laws of nature are unchanging through time and space is procedural or methodologic. On the other hand, his assertion that the rates of geologic change through time also are invariant over the long term is a substantive statement, subject to testing like any other scientific hypothesis.

Certain critics maintain that substantive uniformitarianism is disproved: theoretically on the ground that the terrestrial heat machine cannot have maintained a steady state throughout the 4.6×10^9 years or so during which the Earth presumably has been in operation, and empirically on the ground that the paleontological record shows wide variations in the rate of extinction and generation of species through time. Methodologic uniformitarianism, it has been asserted, is no more than the logical principle of simplicity applied to the causes of geologic change: naturalistic causes of change, other than those in operation at present, should not be invented without necessity. In other words, substantive uniformitarianism is outmoded and methodologic uniformitarianism is common to all scientific investigation and not unique to geology.

It is unlikely that these criticisms will be acceptable to all scientists and philosophers of science. Substantive uniformitarianism can no longer be entertained in any authoritarian sense but will probably continue to serve as a point of departure in arriving at first approximations of the time required for the deposition of sedimentary formations, the development of landforms, and the origination of other geological features. Methodologic uniformitarianism, in G.G. Simpson's terms, is the proposition that the inherent properties of matter and energy throughout the universe remain constant through time and space. So stated, this principle seems basic to the historical sciences: astrohistory, geohistory, and biohistory.

Unitarians and Universalists

Unitarians and Universalists are religious groups who trace their heritage to certain unorthodox theological views in the early church and the Reformation period. They formed their respective churches in Hungary, Romania, and Poland in the 16th century and in England, the United States, and other countries in the 18th and 19th centuries. Believing that God is One, they deny the deity of Christ and the doctrine of the Trinity.

Unitarian or Unitarian-Universalist churches exist today in three regions: North America, Britain, and central Europe, with only a few small groups elsewhere. The International Association for Liberal Christianity and Religious Freedom (founded in 1900) links them with liberal churches and with liberal groups within other churches, notably in Holland, Switzerland, West Germany, Czechoslovakia, India, and Japan. Universalist churches are found mainly in the United States; in 1961 they merged with the Unitarians to form the American Unitarian Universalist Association.

There are about 1,100 Unitarian-Universalist congregations in the United States, Canada, and Iceland; about 300 in the British Isles, including the allied Non-Subscribing Presbyterian Church of Ireland; 250 in Hungary, Romania, Czechoslovakia, and West Germany; and about 100 elsewhere. Membership totals perhaps 300,000, but like-minded groups, in the International Association, bring the number to over 2,000,000. Unitarians assert

that there are many members of orthodox churches who are "Unitarian without knowing it."

Though their views have been influenced by past development and change, modern American Unitarians see themselves as freed from tradition and committed to open inquiry and to advancing scientific truth, rather than to Christian origins. Unitarians in other lands view themselves similarly, but are more attached to a liberal Protestant tradition. They believe that religion is universal rather than specifically Christian, and their International Association includes liberal non-Christians in India and Japan.

Historical development. *Unitarian and Universalist views in the early church.* The New Testament contains a variety of doctrines about the status of Jesus Christ. One of them is that he was a man adopted by God to proclaim the coming kingdom. The Ebionites, an early Jewish-Christian sect that called Jesus the Son of man and the true prophet, believed that he was a man who was miraculously endowed and who became the Messiah ("anointed one") because he obeyed the Jewish law. Several early Christian theologians (*e.g.*, Clement of Alexandria and Origen) of the 2nd and 3rd centuries—who were influenced by Middle Platonism with its concern (mainly religious) for the problem of the one and the many; *i.e.*, what is really one—viewed God as the Eternal One and Christ as the divine Logos ("Word") who was the image of God and who enabled man to become one with God.

Arius and Arianism

Arius, a 4th-century priest of Alexandria, in teaching that Christ was the Son of God only as a created being and not coequal or coeternal with God, precipitated the Arian controversy; his views (declared heretical at the Council of Nicaea in 325) became, for a time, the official theology in the eastern Roman Empire and among the Goths. But Athanasius, the orthodox opponent of Arius, said that a subordinate Christ could not save man. The ecumenical councils of Nicaea and Chalcedon (451) firmly established the doctrine of the Trinity and the doctrine that Christ was the God-man. Thus, Arianism, an early form of Unitarianism, was anathematized (formally denounced) by the orthodox bishops.

Origen, the great Alexandrian theologian of the 3rd century, taught that all would be restored to God on the Last Day, a prefiguring of Universalism. But orthodoxy eventually affirmed the finality of heaven and hell, and the concept of the universal restoration (or the *apokatastasis pantōn*) was held to be heretical, though other early Christian theologians as individuals taught that there would be a universal salvation.

Unitarianism in the Reformation period. Most Reformers (*e.g.*, Luther, Calvin, Zwingli) reaffirmed Christian orthodoxy, but there were also liberal, radical, and rationalist Reformers who extended their ideas. Devout Italians, in a revival of Platonism (a Greek philosophical system), exalted reason (the *logos*) as the divine spark in man. Declared heretics, they fled from the Roman Catholic Inquisition to Calvin's Geneva, but there found a Protestant orthodoxy that was equally strict. Michael Servetus, a Neoplatonic Unitarian—*i.e.*, one who denied the Trinity because of an acceptance of the ineffable One as the basis of reality—was burned at Geneva in 1553. His death caused Sebastian Castellio, a liberal humanist, to plead for religious toleration. Others who denied the Trinity were burned or exiled. Some Anabaptists (radical Reformers) also were anti-Trinitarian. In the midst of these controversies, such Reformers as Kaspar Schwenckfeld urged latitude in religion.

Unitarianism in eastern Europe

Some Italians found refuge in Poland, then a land of toleration, where the Minor Reformed Church (Polish Brethren) with a Unitarian theology was founded in 1565. Inspired by Faustus Socinus, an Italian exile who arrived at Cracow in 1579, the minor church flourished for half a century. The Polish Socinian Church was destroyed in the 17th century by the Counter-Reformation. Its exiled ministers and nobility and its publications (*Bibliotheca Fratrum Polonorum*, 8 folio vols., Amsterdam 1656/1665–69) influenced radical thought in Holland and England.

Unitarianism (or anti-Trinitarianism) became influential in Transylvania, the eastern portion of the old Kingdom of Hungary, under the encouragement of Georgius Blandrata (or Giorgio Biandrata), an Italian court physician to the Polish-Italian bride of the king, John Sigismund (died 1571). He encouraged Ferenc Dávid, bishop of the Reformed Church in Transylvania and court preacher—who had been successively Catholic, Lutheran, and Calvinist—to preach anti-Trinitarian sermons. In 1568, at the Diet of Torda, the king granted wide religious toleration, one of the earliest such toleration decrees in Christian history, and Dávid became head of the Unitarian churches. Three years later the Unitarians were granted legal recognition. In opposition to Blandrata, however, Dávid denied that prayers could be addressed to Christ, and after a trial and conviction as an innovator, he died (1579) in prison. His church still exists. It is the world's oldest Unitarian Church. Its congregations were divided after World War I into two separate organizations—one in Hungary and the other in Romania—as a result of the Treaty of Trianon (1920) that divided the old Austro-Hungarian Empire.

Unitarianism in the British Isles. An English translation of the Polish Socinian catechism was publicly burned in London in 1614 and 1652, and John Biddle, an English Socinian, was exiled to the Scilly Isles. Under the English monarchs Elizabeth and James I some Unitarian Anabaptists were burned, and later General Baptists adopted unorthodox views of Christ that were similar to those of Unitarians. Also, some Anglican clergy published Unitarian pamphlets, arousing controversy within the Anglican Church, leading to the Arian theology of Samuel Clarke, who denied the essential divinity of Christ.

The mainstream of British Unitarianism, as of American, however, grew out of Calvinist Puritanism. Calvin's doctrine of the absolute providential rule of God, the scientist Isaac Newton's picture of a mathematically regular universe, and the philosopher John Locke's plea for common sense and open discussion greatly influenced the Presbyterian, or "moderate," party among the Dissenters in the English Church. They preached God as the sole creator and ruler of the world, best worshipped by a moral life, with Christ as his messenger, whose authority was authenticated by his miracles and resurrection—the so-called Arian scheme. Many Dissenting preachers, challenged to define their faith in orthodox terms, would use only the words of Scripture, which gave them greater freedom. But the evangelical revival, led by John Wesley, caused a renewal of orthodoxy, and the Dissenters split into orthodox and liberal factions.

The rise of English "Unitarian Christianity"

Joseph Priestley, a scientist and Dissenting minister, began to preach overt "Unitarian Christianity": Jesus as man, though unique in his miracles and resurrection; God as all-powerful and all-knowing; the primacy of reason and morals; and scientific determinism, materialism, and political reform. Many old Presbyterian congregations, diminished in number by the success of the evangelical (or Methodist) revival initiated by John Wesley, became Unitarian. Other groups joined them: Anglican reformers at Cambridge University, vainly petitioning Parliament to relax "subscription" in the Church of England—including Theophilus Lindsey, who in 1774 opened a Unitarian chapel in London with a modified Anglican liturgy modelled on that of Samuel Clarke; some General Baptists, resisting an evangelical revival in 1770; and some early 19th-century seceders from Methodism. The English Unitarians—by the early 19th century a small body struggling against penal laws that were enacted against heresy and nonconformity—were strong in Parliament, local government, the professions, and social reform. In 1825 they established the British & Foreign Unitarian Association. Their tenure of Puritan chapels and endowments was challenged in the courts. Though some were lost, the rest were saved by the Dissenters' Chapels Act (1844), which recognized tenure and change.

In Scotland in the 18th century, leaders of the national (Presbyterian) church were liberal, encouraging the English Arians; later, however, came an orthodox revival. The few Scottish Unitarian churches were of radical

origin. In Ireland the former Presbyterian clergyman Thomas Emlyn suffered persecution as a Socinian; and in 1725 and 1828 trouble over "subscription," or acceptance of the Westminster Confession of faith (of 1646) in the Presbyterian Church led to the founding of the Non-Subscribing Presbyterian Church of Ireland, with an Arian doctrine.

Crisis in English Unitarianism

About 1840 a crisis arose among English Unitarians; Priestley's rationalism was challenged by a new leader, James Martineau, who pleaded for deeper feeling, and for a faith based on intuition rather than on argument and the Bible. He opposed the name "Unitarian" as sectarian and divisive, preferring "Free Christian," or even "Presbyterian." He wanted comprehension within a liberal national church, not denominational propaganda. Partly as a result of Unitarian efforts, penal laws were repealed, and many Unitarians became prominent in commerce and public life. The latter half of the 19th and early part of the 20th centuries was, for Unitarians, an age of church building, large congregations, and social idealism. In 1928 the two English Unitarian groups (the denominationalists and the liberals) were united in the General Assembly of Unitarian and Free Christian Churches.

Unitarianism in the United States. American Unitarianism developed more slowly out of the Congregational churches of eastern Massachusetts, which rejected the revivalism of the 18th-century preachers George Whitefield and Jonathan Edwards. Over against the revivalists, some Congregational ministers preached moderation, stressing reason and morals, and were protected from controversy by congregational autonomy. Charles Chauncy, for 60 years minister of the First Church, Boston, led in deprecating controversy. In 1783 King's Chapel, Boston (Episcopal), became Unitarian, with a modified Anglican liturgy like Lindsey's in London. Unitarian congregations were organized at Portland and Saco (Maine) in 1792. In 1803 conflict arose between liberals and conservatives over the appointment of a professor of theology at Harvard University, and unwillingly the moderates found themselves labelled Unitarian. Legal battles over church property left the Unitarians in possession of churches founded by their Puritan ancestors in and around Boston. In 1825, on the same day as its British counterpart, the American Unitarian Association was founded, with headquarters in Boston. The American Unitarian Church thus founded claims five presidents of the United States and many leading figures in literature, education, social reform, and public life.

The founding of the American Unitarian Association

As in England, there was a theological crisis about 1840. William Ellery Channing of Boston challenged the orthodox doctrine of the atonement and taught the loving fatherhood of God. Sparked by the "Divinity School Address" (1838) of Ralph Waldo Emerson, the Transcendentalist Movement, the so-called flowering of New England, shook American Unitarianism and exploded beyond it. It shattered rationalist, biblical Unitarianism—now grown conservative—and replaced it with intuitional religion and social idealism. When Unitarianism spread to the newly opened Middle West, its religious fundamentals changed to human aspiration and scientific truth, rather than Christianity and the Bible. In 1866 a Free Religious Association was founded to assert free thought over against the conservative Boston tradition. In 1900 the Americans took the lead in founding the International Association for Liberal Christianity and Religious Freedom. In the 1920s "humanism"—a nontheistic, antisupernatural Unitarianism—arose and influenced even those Unitarians who did not accept it. Fellowships, informal groups with lay leadership, were founded in almost every American state and among Americans abroad. In 1961 Unitarians merged with Universalists in a new united church, the American Unitarian Universalist Association.

Universalism in America and in Britain. Universalism (a belief in the final restoration of all things to God, and a denial of everlasting hell) was first preached in America by George de Benneville, a French mystic who came to America in 1741, and his disciple Elhanan Winchester, and by the former English Methodist John Murray, who founded the first Universalist Church in 1779. Murray was a follower of the Welsh revivalist preacher James Relly, who taught that all men will be saved because they share the holiness of Christ. The teaching was partly Calvinist, partly mystical. Hosea Ballou gave American Universalism its definitive form: belief in the fatherhood of God, the brotherhood of man, the moral authority of Jesus, and earthly life as a time of perfecting man for heaven. In 1830-60 Universalism had much popular success, challenging the hellfire preaching of orthodox revivalism. Universalist churches were founded in many states, and also in Scotland and Japan. Elhanan Winchester founded a Universalist Church in London in 1793, and made missionary journeys in southern England. He was succeeded by William Vidler, who allied with the Unitarians. Another English Universalist group, the Freethinking Christians, also was Unitarian. Universalist ideas spread among British Unitarians. There was also an unsuccessful revolt against "eternal punishment" in the Church of England in the mid-19th century.

The Unitarian-Universalist merger, 1961. In the 19th century, U.S. Unitarians and Universalists shunned one another; they used different religious terminologies, and appealed to different social groups. As viewed by one another, Unitarians were "insufficiently Christian," and Universalists "made light of sin." But they came to have similar ideas about God, Christ, man, and social reform, and learned to cooperate. After negotiation, a merger took place in 1961 establishing the American Unitarian Universalist Association. The Universalists were legally organized on a state basis and the Unitarians in geographical regions that did not coincide, but this difficulty was solved. It was soon overshadowed by the demands of black militant Unitarians for radical social change in the U.S., appealing with some success to the liberal idealism of Unitarians and Universalists.

Beliefs, practices, and organization. Among Universalists and Unitarians there is no official formula of belief, and much variety. Development of beliefs, as already noted, went through several stages—Neoplatonic mysticism, Socinianism, moderate Calvinism, the Arian scheme, Priestley's moralistic determinism, and Martineau's intuitionism. In America there was a development from liberal Congregationalism to Channing's optimism, and on to Transcendentalism, to the Unitarianism of the Middle West, based on moral idealism rather than solely upon the Bible, and then to humanism. A great change came in the 19th century when, in Martineau's words, Unitarians came to see God "not as First Cause prefixed to the scheme of things, but as Indwelling Life pervading it" (his preface to the 2nd ed. of J.J. Taylor, *A Retrospect of the Religious Life of England*, 1876); one result of this view is the Unitarian concept of humanism, which is agnostic about God and emphasizes the human condition and scientific progress. According to the U.S. Unitarian historian E.M. Wilbur, Unitarian history shows a steady drive toward freedom, reason, and tolerance. Unitarians have been especially responsive to the spirit of the age in which they live, and have been leaders and transmitters of current thought. They vary from liberal-traditional to extreme modernist. Though humanism is widely accepted, many Unitarians and Universalists, especially outside the U.S., are theistic and Christian. Most German Unitarians are humanists.

Stages of Unitarian and Universalist belief

All have inherited Protestant (Calvinist and Anglican) forms of worship, but some experiment considerably. Transcendentalism, as a movement within U.S. Unitarianism, produced many fine hymns, now in many English-language Christian hymnbooks. Of the Christian sacraments, Baptism is usually practiced as a simple dedication of infants, and the Lord's Supper is celebrated by the more traditional Unitarians and Universalists as a memorial. Preaching is especially important, and in some groups a lecture is the dominant part of the meeting. Besides the Bible, the sacred scriptures of other religions and other inspiring writings are often used.

In polity, most Unitarians and Universalists are congregational; each congregation is self-governing, uniting

with others in district and national assemblies on a voluntary basis. The Irish churches follow a presbyterian form of church government under a general synod, and the churches in Hungary and Romania are headed by bishops, each with a lay curator. The International Association for Religious Freedom (so named since 1969) is purely consultative.

United Arab Emirates

Seven tiny emirates strung out along the eastern Persian Gulf coast of the Arabian Peninsula together form the United Arab Emirates (Ittiḥād al-Imārāt al-ʿArabīyah). Formerly known as the Trucial States, Trucial Oman, or the Trucial Sheikhdoms, they are bordered by Qatar on the northwest, Saudi Arabia on the west and south, and Oman on the east and northeast. Most of the union's area of 32,300 square miles (83,650 square kilometres) is occupied by Abu Dhabi, which lies along the mainland coast. The six other emirates are clustered on the Ru'us al-Jibāl that separates the Persian Gulf from the Gulf of Oman; they are Dubai, Ajman, Sharjah, Umm al-Qaiwain, Ras al-Khaimah, and Fujairah. The total population of some 197,000 is concentrated on the peninsula and along the coast. Upon formation of the union, in 1971, the town of Abu Dhabi was chosen as the national capital for a period of five years, after which a new capital would be built on the border between Abu Dhabi and Dubai emirates.

Physical features

The landscape and environment. Nearly the entire union is desert, containing broad patches of sand and numerous salt flats. Along the eastern portion of the peninsula, the northern extension of the al-Ḥajar mountains offers the only other major relief feature. Steep on all sides, the mountains rise to 10,000 feet (3,000 metres) in some places. The Persian Gulf coast is broken by shoals and dotted with islands that offer shelter to small vessels. There are, however, no natural deepwater harbours. The coast of the Gulf of Oman is more regular, and there are three natural harbours: Dibbah, Khawr al-Fakkān, and Kalbā'.

The climate is hot and dry. Rainfall averages only three to four inches annually, and the summer heat may reach 114° F (46° C) in some places. The mean January temperature is 65° F (18° C), while in July it reaches 92° F (33° C). In midwinter and early summer seasonal winds known as the *shamāl* blow from the north and northwest, bearing dust and sand.

Because of the desert climate, vegetation is scanty and largely limited to the low shrubs that offer forage to nomadic herds. In the oases, date palms are raised together with alfalfa. Food grains include wheat, barley, and millet. Fruits are popular, and al-Buraymī oasis in Abu Dhabi is famous for its mangoes. Animal life is mostly restricted to domesticated camels, sheep, and goats. The gulf waters offer schools of mackerel, groupers, tuna, and porgies, as well as sharks and occasional whales.

The people. Most of the union's 185,000 inhabitants are Arabs who adhere to the Sunnī and Shīʿah sects of Islām. Many of the Bedouins who once roamed the interior in search of pasturage for their flocks have migrated to the towns. In the al-Ḥajar mountains are several groups of isolated peoples, including the Shiḥūḥ. A blue-eyed people of unknown origin, the Shiḥūḥ live in caves, practice subsistence agriculture, and are nominal adherents of Islām. The national language of the United Arab Emirates is Arabic. The towns contain immigrant populations from India, Pakistan, and Iran.

Settlements

Most of the population is concentrated in the towns of the peninsula. They include Dubayy (Dubai town), ash-Shāriqah (Sharjah town), ʿUjmān (Ajman town), and Umm al-Qaywayn (Umm al-Qaiwain town) on the Persian Gulf and Dibbah, Khawr al-Fakkān, and Kalbā' on the Gulf of Oman. Towns in Abu Dhabi include Abū Ẓaby (Abu Dhabi town) on an island off the coast, aṭ-Ṭarīf on the coast, and al-Buraymī oasis near the border with Oman. A new group of towns known as al-ʿAyn was constructed in the oasis in the late 1960s.

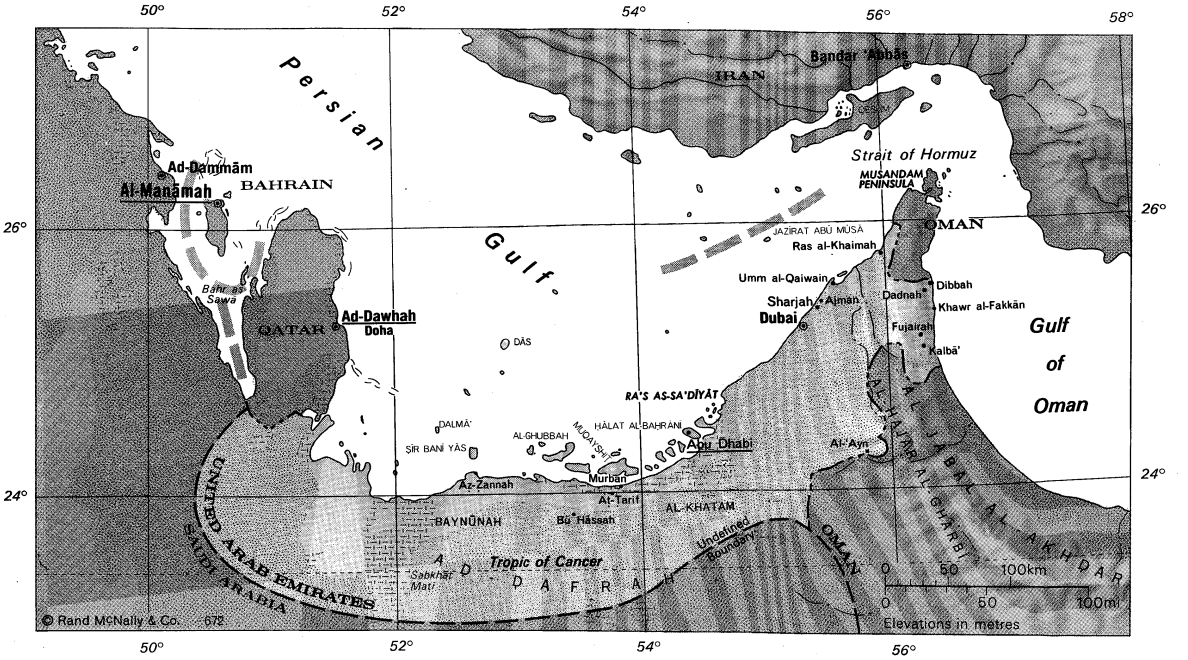
The economy. The union's economy is dominated by the oil boom in the Abu Dhabi and Dubai emirates. The richest of the emirates is Abu Dhabi, which is also the richest political unit per capita in the world. With a population of about 70,000, it had an income in 1972 of $420,000,000.

Oil reserves



Oil was first discovered in Abu Dhabi in 1958. The largest concessions are held by the Abu Dhabi Marine Areas Ltd. (ADMA), which is owned by British and French interests. One of the main offshore fields is located in Umm Shaif, 80 miles (130 kilometres) into the Persian Gulf and 20 miles from Dās island. The field is connected by a submarine pipeline to the separating facilities, storage tanks, and tanker berths on the island. The field at Zakhum (Zakum), 40 miles southeast of Umm Shaif, is also joined by pipeline to Dās. Al-Bunduq offshore field is shared with neighbouring Qatar but is operated by ADMA. A Japanese company has struck oil at Mubarraz, 70 miles west of Abu Dhabi town, and other offshore concessions are held by United States companies.

Onshore oil concessions are held by the Abu Dhabi Petroleum Company, which is owned by Iraqi, United States, and Canadian interests. Bab Dome field at Murban, 60 miles southwest of Abū Ẓaby, and the Bū Ḥassah field, 25 miles southwest of Murban, are connected by pipeline to aẓ-Ẓannah on the coast. Other onshore concessions are held by Japanese companies.

In the early 1970s Dubai had one offshore oil field at Fateh. Operated by a United States company and its subsidiary, the Dubai Petroleum Company, it is known as the Three Pyramids of Dubai. The oil is pumped into three steel storage tanks placed on the seabed that are shaped like inverted champagne glasses. By the early 1970s, oil had not been discovered in the other emirates.

A national oil company was proposed in the early 1970s. It would be funded by the union government and public subscription and would distribute oil products, run a proposed petrochemical complex, and attain oil concessions of its own.

Agriculture is concentrated in the two mountain enclaves of Ajman and in the mountains of Fujairah. The Arid Lands Research Centre at Saʿdīyāt, Abu Dhabi, experiments with the raising of vegetables in the desert with water obtained from a desalinization plant. There are also agricultural projects at al-Buraymī oasis and in Ras al-Khaimah. Marine fishing at Umm al-Qaiwain is fairly extensive; it is proposed that the fisheries be developed on an industrial level.

UNITED ARAB EMIRATES

There is little industry in the union. The five oilless states, especially Ajman, produce stamps mainly for philatelists. Boats and fish traps are built in Ajman, and there are ship-repair facilities at ash-Shāriqah; but plans existed in the early 1970s to develop Dubayy industrially with factories, assembly plants, and a possible dry dock for oil tankers.

Upon formation of the union there were two currencies in circulation—the Bahrain dinar in Abu Dhabi and the Qatar-Dubai rial elsewhere. In the early 1970s the creation of a Gulf dinar, at par with the Bahrain dinar, was proposed. There is no central bank, and numerous banks, mostly foreign-owned, were licensed by the individual emirates.

Trade patterns

Trade is important in Dubai and Sharjah. Dubayy is a free port on the Persian Gulf. Its creek has been dredged, and a modern harbour has been built nearby at Port Rashīd that is equipped with 15 berths and 12 transit sheds. Sharjah's trade centres upon the port of Khawr al-Fakkān on the Gulf of Oman. It is a centre for the smuggling of gold from the United Kingdom to India and Pakistan.

Exports are dominated by oil, more than 40 percent of which is sold to western Europe and 20 percent to Japan. Imports include foodstuffs and beverages, machinery, building materials, fuel and oil, arms and ammunition, drilling materials, and consumer goods. Major trading partners are Japan, the United Kingdom, Switzerland, the United States, India, West Germany, Pakistan, China, The Netherlands, and Hong Kong.

Transportation. There are no railways in the union, and the developing road system is concentratred along the coast. Abū Ẓaby is linked to the mainland by a bridge that is then connected to al-'Ayn and al-Buraymī oasis by a four-lane highway. In the early 1970s construction was under way to connect Abū Ẓaby to Dubayy with an 80-mile road and to connect the capital to Qatar. There were also proposals for a road that would run across the mountains from the Gulf of Oman to the Persian Gulf and for a 40-mile coastal road on the east to Oman. Air services are provided by the airports at Abū Ẓaby, Dubayy, and ash-Shāriqah.

Government structure

Administration and social conditions. The union government was still developing in the early 1970s. The highest governmental authority is the Supreme Council, which is composed of the rulers of the seven emirates. The president, vice president, and premier of the union are appointed by the Supreme Council. A proposed Cabinet is to serve as the executive branch of the government; it also is to be appointed by the Supreme Council. The proposed legislature will be composed of eight members each for Abu Dhabi and Dubai, six members for Sharjah and Ras al-Khaimah and four members for each of the remaining emirates. Abu Dhabi's armed forces are to form the nucleus of the union's army.

Education is free, and facilities are to be developed by the former Abu Dhabi Education Ministry. Medical services are concentrated in Dubai, which contains four hospitals and four child-welfare clinics. Hospital services are free; there is little private medical practice, and most people are treated in hospital out-patient clinics. The union set a goal of one doctor for every 1,000 people, to be reached by the mid-1970s; most of the doctors will be expatriates. There are also two small hospitals in Ajman and a medical mission in Sharjah.

Cultural life. The union has declared itself part of the greater Arab world, and its culture is that of Islām. The people are divided into tribal groups united under the patriarchal emirates of each of the union members.

The news media are concentrated in Dubayy. There is one Arabic weekly newspaper and two daily news bulletins printed in English. The Ṣawt as-Sāḥil (Voice of the Coast) broadcasts daily radio programs from Dubai in Arabic and English. Television programs are received in Dubai from Kuwait and are rebroadcast to the other union members.

Prospects for the future. A group of poor, separate emirates in the 1950s, the union members are now joined together for both administrative and development purposes. The wealth of Abu Dhabi and Dubai is to be shared among all the emirates, and the continued flow of oil promises a rapid entry into the 20th century. Long-range problems centre about current economic planning: the union intends to develop trade and industry, rather than continuing its reliance on a diminishing resource. Along with economic development, the Supreme Council was working out plans in the early 1970s that would also encompass progress in health, education, and welfare services. If controlled economic planning continues, it is hoped that the union will present the world with a model of cooperation toward the advancement of all.

United Kingdom

Situated in northwestern Europe, lying to the north of France and west of The Netherlands and Denmark, the United Kingdom comprises Great Britain (the island consisting of England, Scotland, and Wales) and Northern Ireland (that portion of the island of Ireland made up of the six counties of Antrim, Down, Armagh, Tyrone, Fermanagh, and Londonderry, and also known as Ulster), together with numerous small islands. The total area of the United Kingdom (known popularly, if not quite accurately, as Britain) is 94,512 square miles (244,786 square kilometres), including 1,190 square miles of inland water.

England and Scotland, it has often been observed, were fortunate in being ruled by centralized monarchies from very early times; and the United Kingdom still enjoys the benefits attributed to a constitutional monarchy. In modern history what Shakespeare described as "this scept'red isle" has resisted invasion by Spain, France, and the Germany of Adolf Hitler. Its "moat" is the English Channel. As islanders, none of whom lives more than about 75 miles from the coast, the British have, over the centuries, taken naturally to the sea. This circumstance has made of them a nation of overseas venturers who, in their time, have held in fee India and the Spice Islands. An English navigator, James Cook, was the first European to take formal possession of part of Australia, and Arthur Phillip, of the Royal Navy, was governor of the first settlements there. English-speaking peoples now control the vast resources of North America, and in the 19th and early 20th centuries large parts of Africa were within the British colonial system.

The British Empire and Commonwealth

During the 20th century the British Empire has been converted into a self-governing Commonwealth, and the Commonwealth finally into independent political units. One of the greatest imperial experiments in the history of the world has thus been changed into a free association of peoples. Britain stood alone again as an island off the northwest of Europe until 1971, when the decision of its Parliament to join the European Economic Community seemed to many to open for it a new destiny.

Britain's economy is remarkable for the fact that it has to import the vast majority of its raw materials. Coal, agricultural products, and traces of iron ore are its only indigenous wealth, for the value of gas and oil from North Sea drilling is still uncertain. Since its population (some 55,000,000 in the early 1970s) constitutes one of the biggest import markets for food and other essentials, there is a perpetual struggle to export sufficient goods to balance the external-payments account. In the 18th and 19th centuries Britain was among the first of the European countries to undergo an industrial revolution, which brought with it a leadership in the field of commerce and industry. It also brought a train of social problems, to the solution of which a state sickness- and unemployment-insurance system, first introduced by the Liberal statesman David Lloyd George in 1911, and a free health service and education system are contributing.

Apart from the events surrounding the political separation of Ireland in the early 20th century, Britain, since the Middle Ages, has had one major civil war, that of the mid-17th century in the time of Charles I and Oliver Cromwell. This, with the subsequent settlement made when William III replaced James II in 1689, decided that the British monarchy should be constitutional and not dictatorial.

The British constitution is largely unwritten. Also, there is no separation of the powers (that is, of the legislature and executive), a concept that the United States Constitution, for example, derived from the 18th-century French philosopher Charles-Louis de Montesquieu. The British legislature and the executive mix freely together, ministers sitting and answering for their policy in both Houses of Parliament. The government can be overturned by an adverse vote in the House of Commons. The judiciary remains independent, the judges being irremovable except through age. One exception is the Lord Chancellor, who sits as chairman of the House of Lords and speaks on behalf of the government, of which he is a member.

The legislature is bicameral, but the powers of the House of Lords, once equal to those of the House of Commons, have been cut drastically since the controversies early in the 20th century. The Lords can now only delay a bill for a few months, but they have unique powers of amendment and revision of bills. Members of the Lords are hereditary and life peers, the latter being equivalent in this sphere to aldermen in local government. Recent attempts further to reform or abolish the House of Lords have come to naught.

Two-party government

The unwritten constitution of the United Kingdom depends for its proper functioning on the existence of two strong rival political parties. These are at present the Conservative and Labour parties. Earlier in history, the Conservatives, or Tories, and the Whigs, later to develop into the Liberal Party, were in rivalry. It has been proved that a strong government and a strong opposition between them guarantee the preservation of liberty of speech, thought, action, and worship. It is understood that the political parties have certain fundamentals in common, namely, respect for the monarchy, care for the defense of the realm, the maintenance of personal liberty through the system of habeas corpus, whereby no one can be kept in prison without trial, and the principle of equality before the law. There is also broad agreement on the main aspects of social policy.

As the Neapolitan admiral Francesco Caracciolo remarked, England has 60 different religious sects, but only one sauce. In England the established church is the Church of England, of which the Queen is head; in Scotland the established church is the Presbyterian Church of Scotland. In Wales and Northern Ireland there is no established church. The Roman Catholics are well represented numerically, and there is a variety of free churches: Congregational, Baptist, Unitarian, and Quaker. The only specific clerical representatives in Parliament are the bishops of the Anglican Church, who sit in the House of Lords.

The characteristics of the British constitution derive primarily from England, because historically England conquered and to some extent imposed its institutions on Wales and Ireland. Scotland, united with England under one monarchy from 1603 and joined in full constitutional union since 1707, has kept certain of its own distinctive practices, especially in the field of law. All of its four component countries have brought to the United Kingdom traditions of vigorous independence of thought, speech, and worship. Scotland's sons have made a vast contribution to the island's history, and Edinburgh, the Scottish capital, called the Athens of the North, was, in the 18th and early 19th centuries, particularly prominent as a centre of literature and the arts. Britain's long association with Ireland has provided the larger country with a series of great statesmen and soldiers, such as Viscount Castlereagh, foreign secretary after the Napoleonic Wars, and the Duke of Wellington, victor of Waterloo. When the Irish Free State became independent in 1921, the majority of the peoples of the six northern counties wished to remain as part of the United Kingdom and were provided with their own government at Stormont. The Welsh have contributed much to British artistic life, especially in connection with music; and their coal helped to further the Industrial Revolution and Britain's economic power. (Bu.)

The land

Great Britain, the island comprising England, Scotland, and Wales, forms, together with numerous smaller islands, an archipelago that is as irregular in shape as it is

diverse in its natural heritage. This latter circumstance stems largely from the nature and disposition of the underlying rocks, which are westward extensions of European structures, with the shallow waters of the Strait of Dover and the North Sea concealing former land links. Northern Ireland—which politically completes the United Kingdom—is a westward extension of the rock structures of Scotland, breached by the narrow North Channel. Northern Ireland, too, has a very diverse natural environment.

On a global scale, this natural endowment covers a small area—approximating that of Oregon, in the United States, or the African nation of Guinea—and its internal diversity, accompanied by rapid changes of often beautiful scenery, may perhaps convey to visitors from larger countries a striking sense of compactness and consolidation. The peoples who, over the centuries, have made their way to, and hewed an existence from, this Atlantic extremity of Eurasia have put their own imprint on the environment, with the ancient and distinctive palimpsest of their field patterns and settlements complementing the natural diversity.

THE NATURAL ENVIRONMENT

Topography. The traditional division of Great Britain into a Highland and Lowland zone is still meaningful. A line running from the mouth of the River Exe, in the southwest, to that of the Tees, in the northeast, is a crude expression of this division. The course of the 700-foot contour, or of the boundary separating the generally older rocks of the north and west from the younger southeastern strata, provide more appropriate indications of the extent of the Highlands.

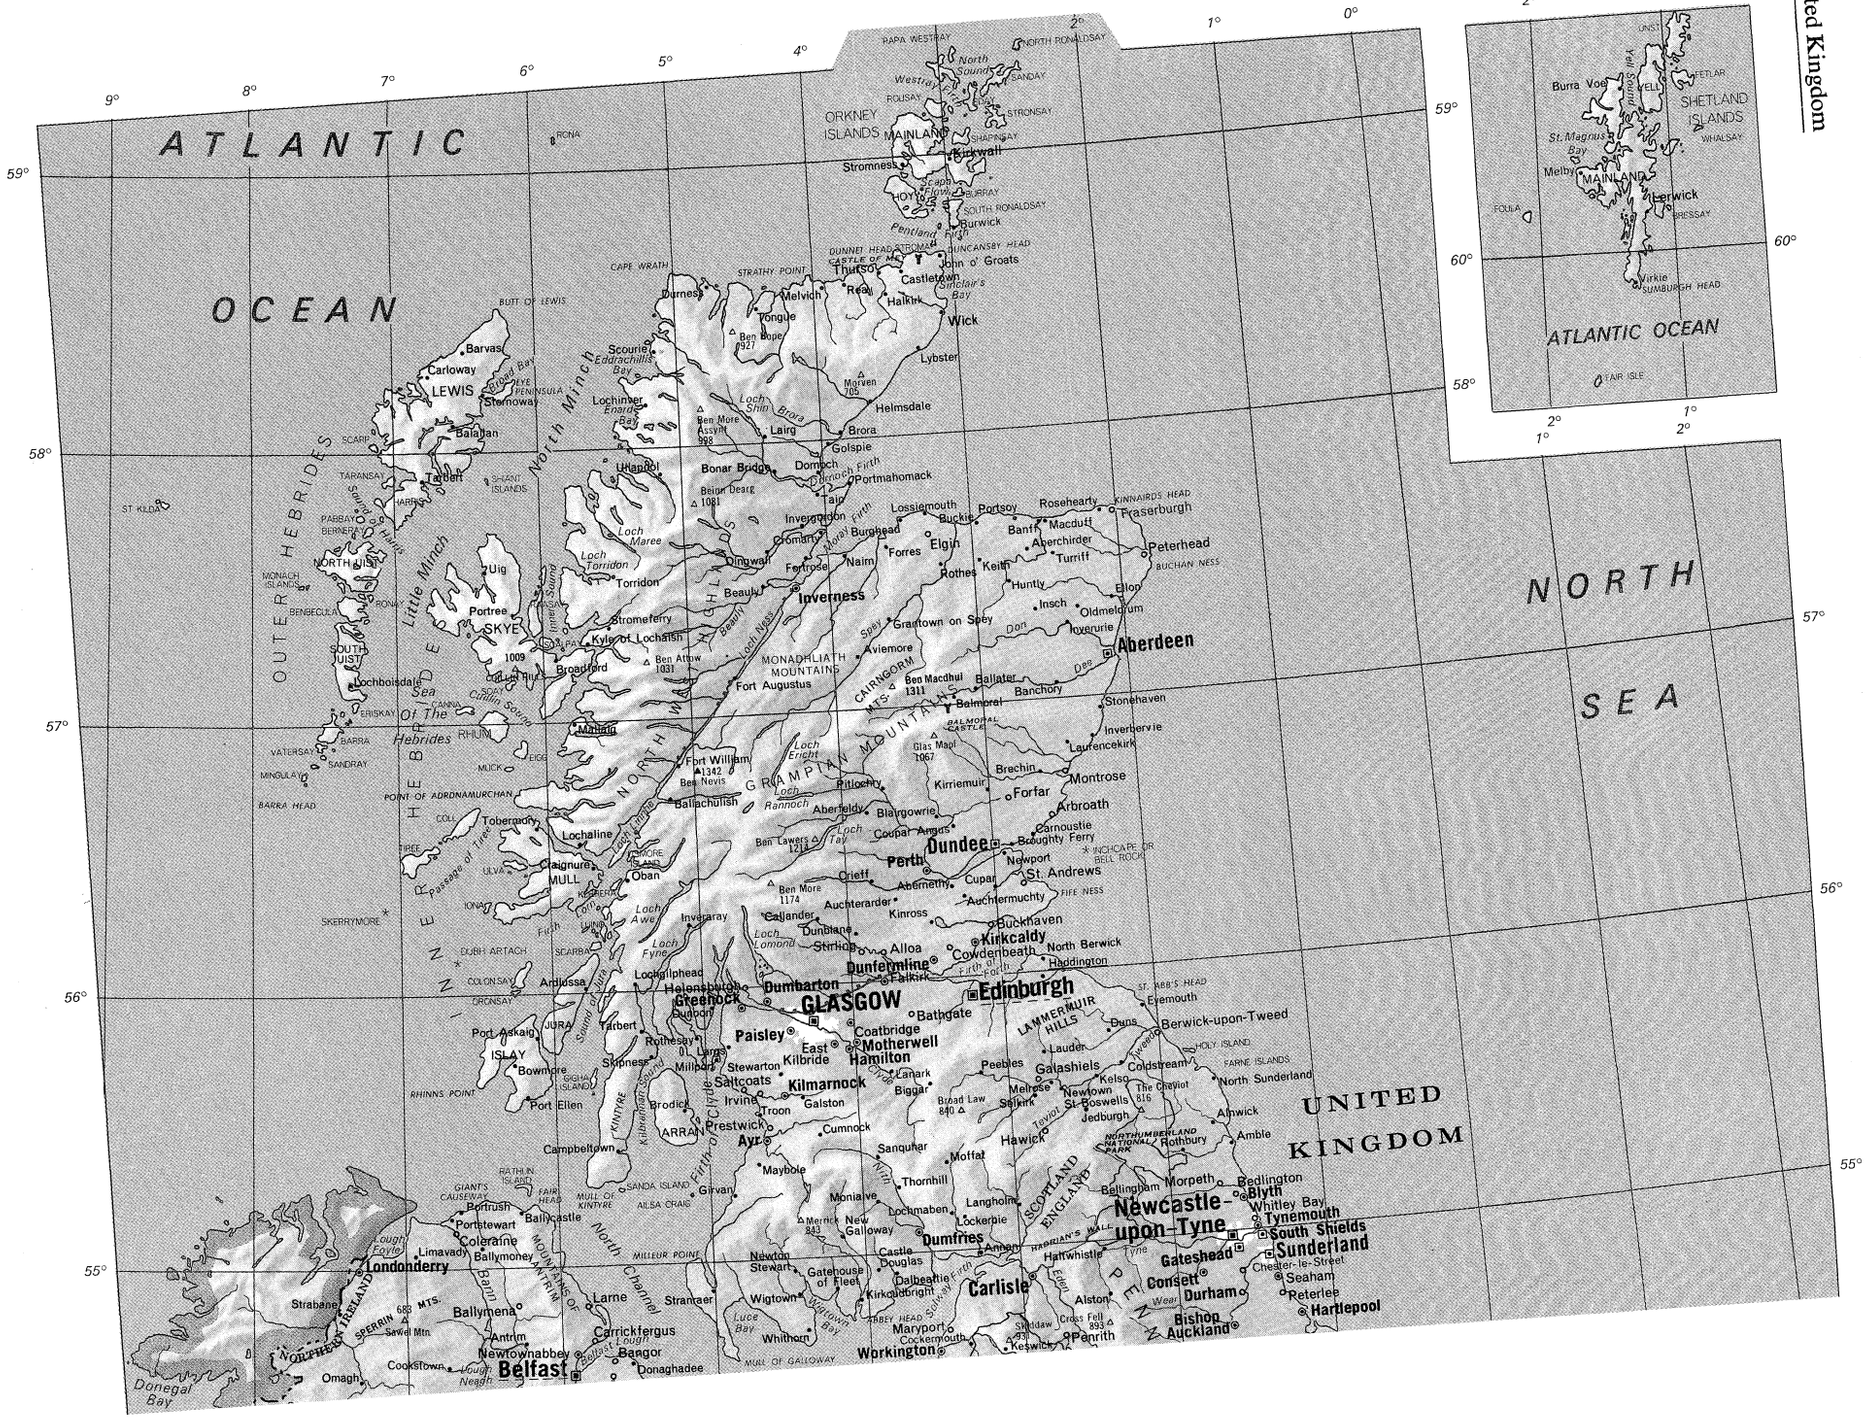
The Tees–Exe Line

The Highland zone. Even in terms of geological time, the creation of the Highlands was a long process, yet altitudes, compared with European equivalents, are low, with the highest summit, Ben Nevis, only 4,406 feet (1,342 metres) above sea level. In addition, the really mountainous areas above 2,000 feet often lie in smooth profiles against the changing skies, reminders of the effects of former periods of erosion.

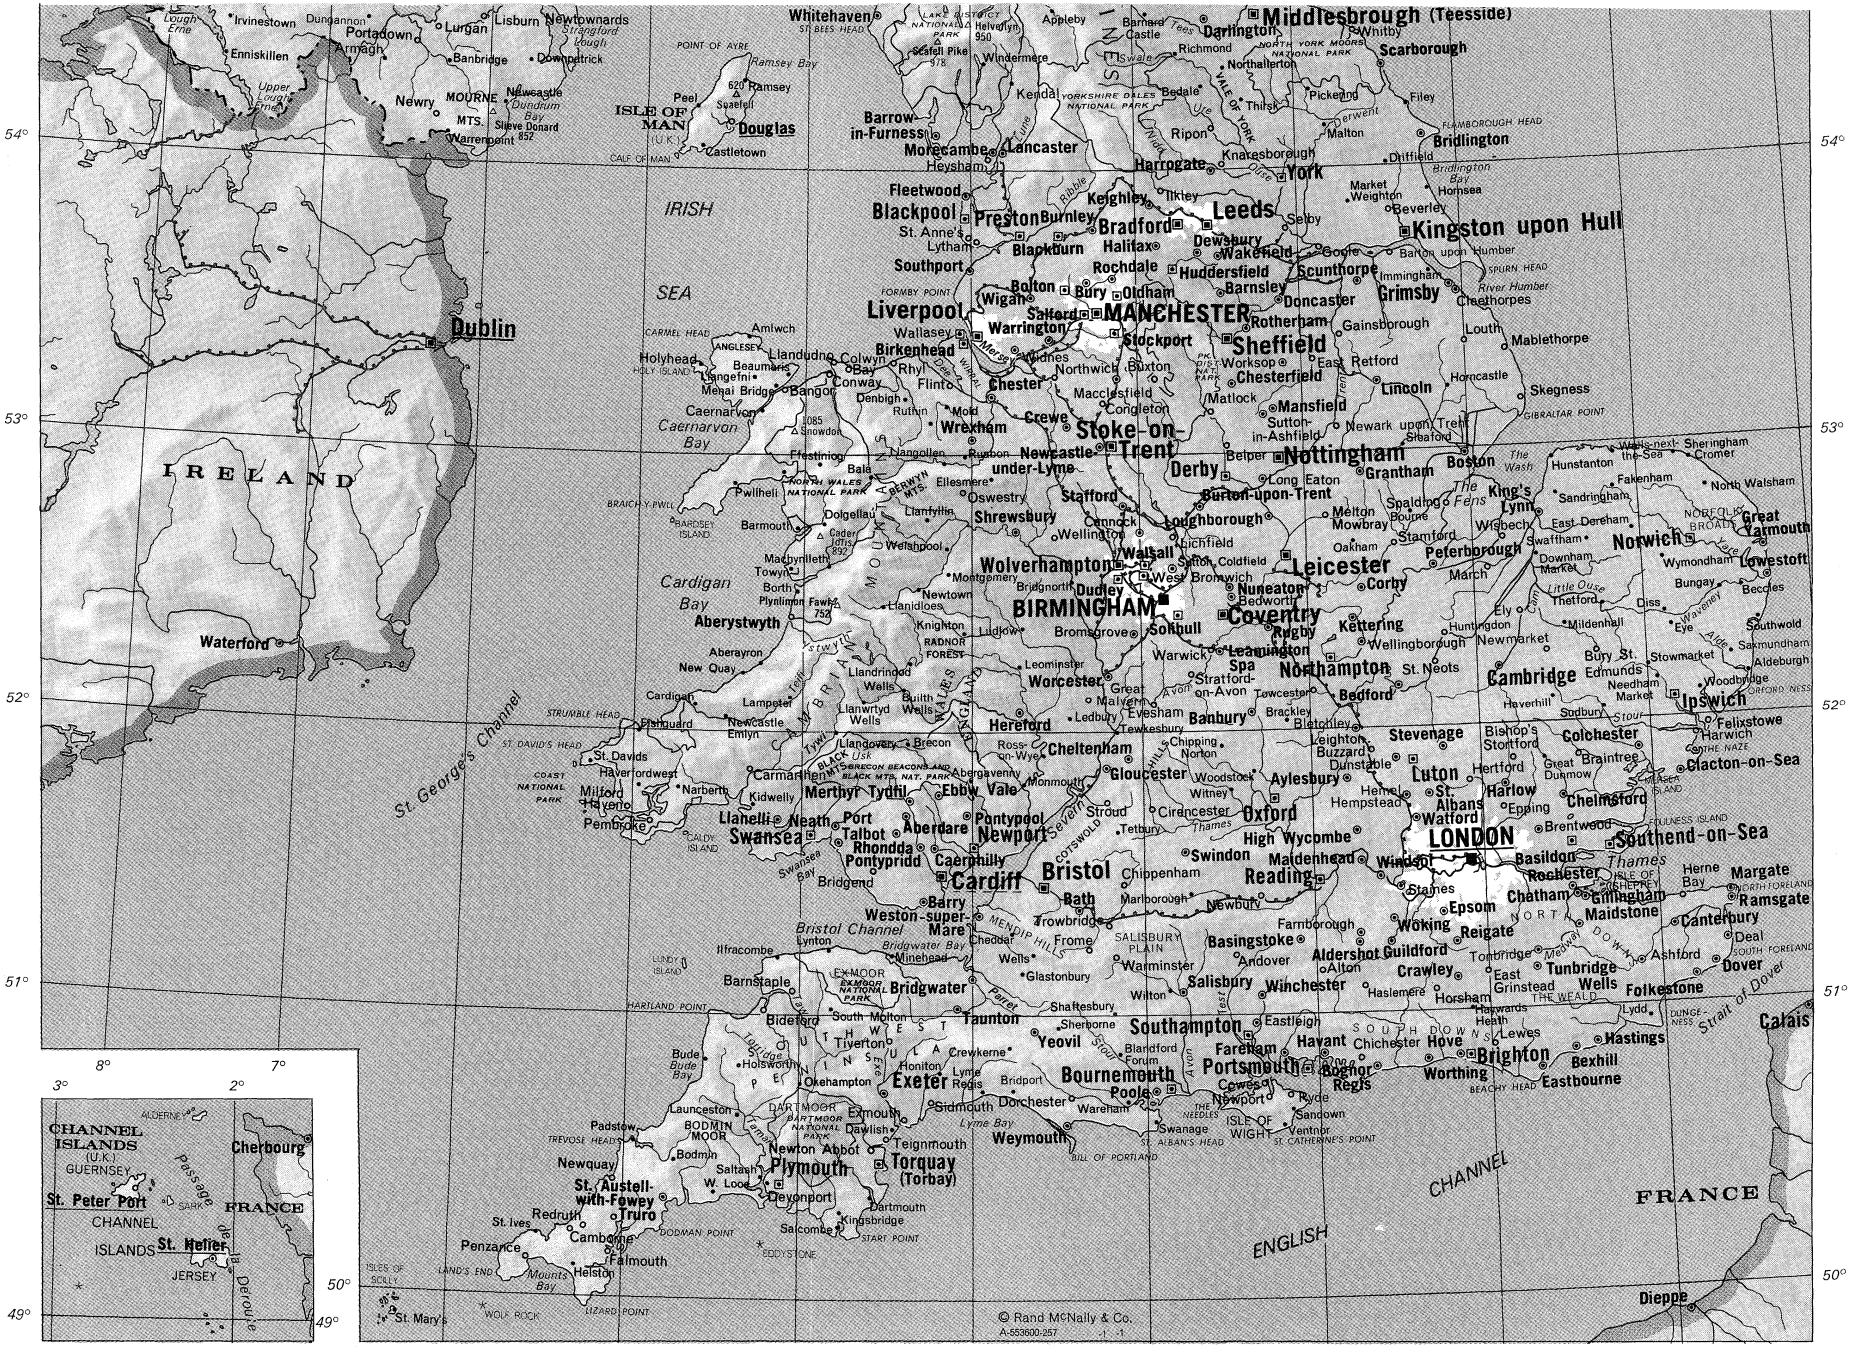
Scotland's three main topographic regions follow the northeast to southwest trend of the ancient underlying rocks. The northern Highlands and the Southern Uplands are separated by the intervening rift valley, or subsided structural block, of the Central Lowlands. The core of the Highlands is the elevated, worn-down surface of the Grampians, 2,000–3,000 feet above sea level, with the Cairngorm Mountains rising to over 4,000 feet. This majestic mountain landscape is furrowed by numerous wide valleys, or straths, and occasional large areas of lowland, often fringed with long lines of sand dunes, add variety to the east. The Buchan peninsula, the Moray Firth estuarine flats, and the plain of Caithness—all low-lying areas—contrast sharply with the mountain scenery and show more mellow outlines than do the glacier-scoured landscapes of the west, where northeasterly-facing hollows, or corries, separated by knife-edge ridges and deep glens, sculpture the surfaces left by erosion. The many freshwater lochs further enhance a landscape of wild beauty. The linear Glen More, where the Caledonian Ship Canal now threads a chain of lakes, is the result of a vast structural sideways tear in the whole mass of the Northwest Highlands. To the northwest of Glen More stretch most of the counties given over to agricultural small holdings, or crofts; settlement is intermittent and mostly coastal, a pattern clearly reflecting the pronounced dissection of a highland massif that has been scored and plucked by the Ice Age glaciers. Many sea-drowned, glacier-widened, river valleys (fjords) penetrate deeply into the mountains, the outliers of which rise from the sea in stately, elongated peninsulas or emerge in hundreds of offshore islands.

Landscapes of the Scottish Highlands

In comparison with the northern Highlands of Scotland, the Southern Uplands present a more subdued relief, the land nowhere rising above 2,790 feet. The main hill masses are the Cheviots, which rise to 2,676 feet, while Merrick and Broad Law reach just above the 2,700-foot contour line. Broad plateau surfaces, separated by numerous dales, are again characteristic of these uplands, and in the west most of the rivers flow across the prevailing northeast-southwest trend, following the general slope of the plateau, toward the Solway Firth. Bold masses of granite and the rugged imprint of former glaciers occasionally impart a mountainous quality to the scenery. In the east, the valley network of the Tweed and its many tributaries forms a broad lowland expanse between the Lammermuir and Cheviot Hills.



The Central Lowlands are bounded by great regular structural faults. The northern boundary with the Highlands is a wall-like feature, but the boundary with the Southern Uplands exhibits a linear topographic form only near the coast. This vast trench is by no means a continuous plain, for high ground—often formed of sturdy, resistant masses of volcanic rock—meets the eye in all directions, rising above the low-lying areas that flank the rivers and the deeply penetrating estuaries of the Firth of Clyde and the Firth of Forth.



In Northern Ireland, structural extensions of the Scottish Highlands reappear in the generally rugged mountain scenery and in the peat-covered summits of the 2,240-foot Sperrin Mountains. The uplands of County Down and County Armagh are the western continuation of the Southern Uplands but rise only in limited areas over 500 feet, the one important exception being the Mourne Mountains, a lovely cluster of granite summits, the loftiest of which, Slieve Donard, rises to 2,796 feet within two miles of the sea. Compared with that of the Scottish Central Lowlands, Northern Ireland's structure has been complicated by the outpouring of basaltic lavas to form a huge plateau, much of which is occupied by the shallow Lough Neagh, the largest freshwater lake in the British Isles.

Northern Ireland extensions of the Scottish Highlands

The Highland zone of England and of Wales consists, from north to south, of four broad upland masses: the Pennines, the Lake District, Wales, and the South West Peninsula. The Pennines are usually considered to end in the north along the River Tyne gap, but the surface features of the Northumberland Fells are in many ways similar to those of the northern Pennines. The general surface of the asymmetrically arched backbone (anticline) of the Pennines is remarkably smooth, because many of the valleys, though deep, occupy such a small portion within the total area that the windswept moorland between them appears almost featureless. This is particularly true of the landscape around Alston, in Cumberland, which, cut off by faults on its north, west, and south sides, stands out as an almost rectangular block of high moorland plateau with isolated peaks (known to geographers as monadnocks), rising up above it. Farther south, the Pennine plateau is cut into by deep and scenic dales, their craggy sides formed of Millstone Grit, beneath which lie streams stepped by waterfalls. The most southerly part of the Pennines is a grassy upland, in places over 2,000 feet above sea level, but it is characterized by the dry valleys, steep-sided gorges, and underground streams and caverns of a limestone-drainage system rather than the bleak moorland that might be expected at this altitude. At lower levels, the larger dales are more richly wooded, the trees standing out against a background of rugged cliffs of white-gray rocks. On both Pennine flanks, older rocks disappear beneath younger layers, and the uplands merge into flanking coastal lowlands.

The famous Lake District, celebrated in poetry by William Wordsworth and the other "Lake poets," is an isolated, compact mountain group to the west of the Pennines. The tough slate rocks of the northern portion have been cut into many deep gorges, separated by narrow ridges and sharp peaks. Greater expanses of level upland, formed from thick beds of lava and the ash thrown out by ancient volcanoes, are found to the south. Although Scafell Pike, at 3,210 feet, and Helvellyn, at 3,117 feet, are high for Britain, the volcanic belt is largely an irregular upland, traversed by deep, narrow valleys. Nine rivers, flowing out in all directions from the centre of this uplifted dome, form a classic radial drainage pattern. The valleys, often occupied by long, narrow lakes, have been

widened to a U-shape by glacial action, which has also etched corries from the mountainsides and deposited the heaps of debris known as moraines.

The Welsh Massif

The core of the principality of Wales is formed by a highland block, clearly defined by the sea except on its eastern side, where a sharp break of slope often marks the transition to the English plain. Cycles of erosion have several times worn down its ancient and austere surfaces; many topographic features may be attributed to glacial processes; some of the most striking scenery owes much to former vulcanism. The mountain areas above 2,000 feet are most extensive in North Wales, in Snowdonia and its southward extensions, Cader Idris and the Berwyn mass. With the exception of Plynlimon and the Forest of Radnor, central Wales lacks similar high areas, but the monadnocks of South Wales—notably the Black Mountains and the Brecon (Brecknock) Beacons—again stand out in solitary splendour above the upland surfaces. Three of these are distinguishable: a high plateau of 1,700 to 1,800 feet; a middle peneplain, or worn-down surface, of 1,200 to 1,600 feet; and a low peneplain of 700 to 1,100 feet. These smooth, rounded, grass-covered moorlands present a remarkably even skyline. Below 700 feet lies a further series of former wave-cut surfaces. Several valleys radiate from the highland core to the coastal regions. In the west these lowlands have provided a haven for traditional Welsh culture, but the deeply penetrating eastern valleys have channelled anglicizing influences into the highland. A more extensive lowland—physically and structurally an extension of the English plain—in the southeast borders the Bristol Channel. The irregularities of the 600-mile Welsh coast exhibit differing adjustments to the pounding attack of the sea.

The South West peninsula

The South West—England's largest peninsula—has six locally conspicuous uplands: Exmoor, where Dunkery Beacon reaches 1,707 feet; the wild, granite uplands of Dartmoor (High Willhays; 2,039 feet); Bodmin Moor; St. Austell (Hensbarrow); Carnmenellis; and the spectacular extremity of Land's End. Granite reappears above the sea in the Isles of Scilly, 28 miles further southwest. Despite this variation in general elevation, the landscape, like that of so many other parts of the United Kingdom, has a quite marked uniformity of summit heights, with a high series occurring between 1,000 and 1,400 feet; a middle group between 700 and 1,000 feet; and coastal plateaus ranging between about 200 and 400 feet. A network of deep, narrow valleys alternates with flat-topped, steplike areas rising inland. The South West derives much of its renowned physical attraction from its peninsular nature, for, in addition to magnificent drowned estuaries created by sea-level changes, the coastline is unsurpassed for its diversity.

The Lowland zone. Gauged by the 700-foot contour, the Lowland zone starts around the Solway Firth in the northwest, with a strip of low-lying ground extending up the fault-directed Vale of Eden. Southward, the narrow coastal plain bordering the Lake District broadens into the flat, glacial-drift-covered Lancastrian lowlands, with their slow-flowing rivers. East of the Pennine ridge, the lowlands are continuous, save for the limestone plateau north of the River Tees and, to the south, the North York Moors, with large, exposed tracts over 1,400 feet. South again lies the wide Vale of York, which the broad lower Trent Valley links to the younger rocks of the Midland Plain, terminating against the Welsh Massif on the west. The lowland continues southward along the flat landscapes bordering the lower River Severn, becomes constricted by the complex Bristol–Mendip upland, and opens out once more into the extensive and flat plain of Somerset. The eastern horizon of much of the Midland Plain is the scarp face of the Cotswolds, part of the discontinuous outcrop of limestones and sandstones that arcs from the Dorset coast across the heart of England, continuing in the Cleveland Hills as far as the north Yorkshire coast. The more massive limestones and sandstones give rise to noble, 1,000-foot-high escarpments, yet the dip slope is frequently of such a low angle that the countryside resembles a dissected plateau, passing gradually on to the clay vales of Oxford, White Horse, Lincoln, and Pickering. The flat, often reclaimed landscapes of the Fenlands are also underlain by these clays, and the next scarp, the western-facing chalk outcrop (cuesta), undergoes several marked directional changes in the vicinity of the Wash, a shallow arm of the North Sea.

Eastern chalklands and vales

The chalk outcrop is a more conspicuous and continuous feature than its sandstone and limestone predecessor: it begins in the north with the open rolling country known as the Yorkshire Wolds, where heights of 750 feet are reached; is breached by the River Humber; and then continues in the Lincolnshire Wolds. East of the Fens the outcrop, or cuesta, is very low, barely attaining 150 feet, but it then rises gradually to the 807 feet reached in the attractive Chilterns, a ridge interrupted by several wind gaps, or former river courses; the Thames alone actually cuts through it, in the Goring Gap. Where the dip slope of the chalk is almost horizontal, as is the case in the open Salisbury Plain, the landscape is that of a large dissected plateau, of 350 to 500 feet. Only the main valleys contain rivers, and most of the tributary valleys are dry.

The chalk outcrop continues into Dorset, but in the south the chalk has been folded along west-to-east lines. Downfolds, subsequently filled in by geologically recent sands and clays, now floor the London and Hampshire basins. The former, an asymmetrical synclinal, or structurally downwarped, lowland rimmed by chalk, is occupied mainly by gravel terraces and valley-side benches and has relatively little floodplain; the latter is similarly cradled by a girdle of chalk, but the southern rim, or monocline, has been cut by the sea in two places to form the scenic Isle of Wight.

Between these two synclinal areas rises the anticlinal, or structurally upwarped, dome of the Weald region of Kent and Sussex. The arch of this vast geological upfold has long since been eroded away, and the bounding chalk escarpments of the North and South Downs (uplands so named because of their open, rolling, treeless grassland) are therefore inward facing and enclose a concentric series of exposed clay vales and sandstone ridges. Eaten into by the waters of the English Channel, a dazzling succession of chalk cliffs faces the European mainland, 21 miles distant at the narrowest point.

The main watershed

Drainage. The main water parting in Great Britain runs from north to south, keeping well to the west until the basin of the River Severn. Westward-flowing streams attain the Atlantic in relatively short reaches, and the Clyde in Scotland, the Eden and Mersey in northwest England, and the Welsh Dee, Teifi, and Tywi are the only significant rivers. The drainage complex that debouches into the Severn Estuary covers a large area in central and eastern Wales and the greater part of seven English counties. Thereafter, the Bristol Avon and the Parret catchments take the water parting somewhat to the east, but subsequently, with the exception of the Taw–Torridge valleys, it runs very close to the west coast in Devon and Cornwall.

The rivers draining east from the main water parting are longer, several coalescing into wide estuaries. The fast-flowing Spey, Don, Tay, Forth, and Tweed of eastern Scotland run generally across impermeable rocks, and their discharges increase rapidly after rain. From the northern Pennines, the Tyne, Wear, and Tees flow independently to the North Sea, but thereafter significant estuary groupings occur. A number of rivers drain into the Humber, including, after it leaves the Pennines, the important Trent. To the south, another group of rivers enters the Wash after sluggishly draining a large flat countryside. The big drainage complex of the Thames dominates South East England; its source is in the Cotswolds, and, after being joined by many tributaries as it flows over the Oxford Clay, the mainstream breaches the chalk escarpment in the Goring Gap. A number of tributaries add their discharges farther downstream, and the total drainage converging on the Thames Estuary exceeds 4,000 square miles. The rivers flowing into the English Channel are mainly short, as are those in Northern Ireland, with the exceptions of the Erne, Foyle, and Bann.

Soils. The regional pattern of soil formation can be correlated usefully with local variations of relief and climate. Although changes are gradual and can be complicated by local factors, a division of Britain into four climatic regimes (see below *Climate*) goes far to explain the distribution of soils.

On those loftier parts of the Highland zone, particularly in Scotland, experiencing a cold, wet regime of more than 40 inches (1,000 millimetres) rainfall and less than 47° F (8° C) mean temperature annually, blanket peat and peaty podzol soils, the organic surface layer of which rests on a gray, leached base, are found. A similarly wet regime, but with a mean annual temperature exceeding 47° F, obtains over most of the remainder of the Highland zone, particularly on the lower parts of the Southern Uplands, the Solway Firth–Lake District area, the peripheral plateaus of Wales, and most of South West England. These areas are covered by acid brown soils and weakly podzolized associates. On the lower lying areas within the Highland zone, more particularly in eastern Scotland and the eastern flanks of the Pennines, a relatively cold, dry regime gives rise to soils intermediate between the richer brown earths and the podzols.

Over the whole of the Lowland zone, which also has a mean annual temperature above 47° F (8° C) but less than 40 inches of rain, leached brown soils are characteristic. Calcareous, and thus alkaline, parent materials are widespread, particularly in the southeast, and so acid soils and podzols are confined to the most quartz-laden parent materials. In Northern Ireland, above about 460 feet, brown earths are replaced by semipodzols, and these grade upslope into more intensively leached podzols. This is particularly the case in the Sperrins and the Mournes, but, between them in the Lough Neagh lowland, rich brown earth soils are extensively developed.

Climate. The climate of the United Kingdom, a perennial topic of conversation within the country, is broadly determined by its setting within the pattern of the atmosphere's general circulation and its position in relation to the form and distribution of land and sea. Regional diversity does exist, but the boundaries of major world climatic systems do not pass through the country. Britain's marginal position between the European landmass to the east, and the ever-present, relatively warm Atlantic waters to the west, ensures the modification of both the thermal and moisture characteristics of the principal types of air reaching British shores. These, according to their source regions, are Arctic, polar, and tropical, and, by their route of travel, may in each case be maritime or continental. For much of the year the weather is dominated by the sequence of disturbances within the midlatitude Westerlies that bring in mostly polar-maritime, and, occasionally, tropical-maritime air.

Air-mass characteristics

In winter, occasional high-pressure areas to the east allow biting Arctic or polar-continental air to sweep over Britain. All these atmospheric systems tend to fluctuate rapidly in their paths and to vary both in frequency and intensity throughout the seasons of the year and also from year to year for any given season. Variability contributes much to the character of British weather, and extreme conditions, though rare, can be very important for the life of the country.

The westerly maritime derivation of so much of the air reaching the country in winter creates a temperature distribution that does not reflect latitudinal differences. Thus the north-to-south run of the 40° F (4° C) January isotherm, or line of equal temperature, from the coast in northwest Scotland right down to the Isle of Wight betrays the moderating influence of the winds blowing off the Atlantic Ocean. In summer, polar-maritime air is less common, and a nine-degree difference of latitude and distance from the sea assume more importance, with temperatures increasing from north to south and from the coast inland. Above-average temperatures are usually associated with tropical-continental air, particularly in anticyclonic, or high-pressure, conditions. These southerly or southeasterly airstreams can bring to southern England heat waves with temperatures of more than 90° F (32° C). In spring and autumn a variety of airstreams and temperature conditions may be experienced, and changing patterns of sun and shadow enhance the natural seasonal beauty of the landscape.

Rainfall patterns

Rain-producing atmospheric systems arrive from a westerly direction, and some of the bleak highest summits of the Highland zone can receive as much as 200 inches (5,100 millimetres) of driving rainfall a year. East Anglia and the Thames Estuary, in contrast, can expect as little as 20 inches (500 millimetres). Rain is fairly well distributed throughout the year: June, on the whole, is the driest month all over Britain; May is the next driest in the east and centre of England, but April is drier in parts of the west and north. The wettest months are usually October, December, and August, but in any particular year almost any month can prove to be the wettest, and the association of Britain with seemingly perpetual rainfall (a concept popular among foreigners) is based on a germ of truth. Some precipitation falls as snow, and the average number of days with snow falling can vary from as many as 30 in blizzard-prone northeast Scotland to as few as five in South West England.

Vegetation and animal life. Except for northern Scotland, the highest hills of the north and west, the saturated fens and marshes, and the seacoast fringes, the natural vegetation of the British Isles was deciduous summer forest dominated by oak. The hand of man has, however, lain long and heavy on this heritage, and only scattered woodlands and the areas of wild or seminatural vegetation lie outside the enclosed cultivated fields. Few of these fine moorlands and heathlands, wild though they may appear, can lay claim to any truly natural plant communities: nearly all show varying degrees of adjustment to grazing, swaling (controlled burning), or other activities. Woodland now covers a little less than 7 percent of the country, and, though the State Forestry Commission has been most active since its creation in 1919, by far the greater part of this woodland remains in private hands. The largest areas of woodland are now to be found in northeast Scotland; Kielder in Northumberland; South East England; Monmouthshire; and Breckland in Norfolk.

Flora of the moorlands and heathlands

The moorlands and heathlands occupy about a third of the total area of the United Kingdom. They consist of the possibly true Arctic–Alpine vegetation on some mountain summits in Scotland and the much more extensive peat moss, heather, bilberry, and the thin *Molinia* and *Nardus* grass moors of the Highland zone. A similar vegetation exists on high ground in eastern Northern Ireland and on the Mournes, with considerable areas of peat moss vegetation on the mountains of Antrim. In the Lowland zone, where light sandy soils are found, the vegetation is dominated typically by the common heather—the deep purple of which adds a splash of colour to the autumn countryside—but sometimes by bilberry or bell heather. A strip of land immediately bordering the coastline has also largely escaped the attention of man and his animals, so that patches of maritime vegetation can frequently be found in approximately their natural state.

The survival of the wild mammals, amphibians, and reptiles of the United Kingdom depends on their ability to come to terms with the changing environment and to protect themselves from the attacks by their enemies—the most dangerous being man. British mammals survive in a greater range of habitats than do amphibians and reptiles. Most of the former larger mammals have become extinct, but red deer survive in the Scottish Highlands and on Exmoor, and roe deer in the wooded areas of Scotland and southern England. The carnivore mammals (badgers, otters, foxes, stoats, and weasels) thrive in most rural areas; also widely distributed are the rodents (rats, squirrels, mice) and the insectivores (hedgehogs, moles, shrews). Rabbits are widespread and their numbers are again increasing in spite of the outbreak, in the 1950s, of the disease known as myxomatosis. The other nocturnal vegetarian, the brown hare, is found in open lowland country, while the mountain hare is native to Scotland. The amphibians are represented by three species of newt and five species of frogs and toads, while reptiles consist of three species of snakes, of which only the adder is venomous, and three species of lizard. There are no snakes in Northern Ireland.

THE HUMAN IMPRINT ON THE LAND

Traditional regions. When a long view is taken of the slow possession of Britain by its peoples, it seems an inescapable conclusion that the man–land relationship probably reached its greatest intimacy late in the 18th century: communications at this time were good enough to bind the community into a unity but were not yet so good as to destroy the sense of belonging to a specific locality, as well as to a particular nation, Scotland, England, Wales, or Ireland. Generations of toiling hands had won the necessities of life from the landscape, and generations of tongues had shaped the national languages and dialects for the expression of local things. The regional character of British life is still recognizable, but its heyday has passed. The consciousness of being a Northern Irelander, a Scot, a Welshman, or a Cornishman—to say nothing of the rivalry between a North and South Walian, or a Highland and Lowland Scot—is as marked as is the obvious geographical identity of these parts of the Highland zone.

The conditions of regional awareness

Within England nine traditional regions are to be distinguished. The North Country province, including the present counties of Durham, Northumberland, Cumberland, and northern Westmorland, formed, after the Anglo-Saxon settlement of the mid-5th to late 6th century AD, the central part of the Anglian Kingdom of Northumbria. Later, it became an area whose life, over a period of centuries, was dominated by border warfare with Scotland; this strengthened its regional traditions and folklore. With the coming of the Industrial Revolution, the region's wealth in coal and iron gave it great advantages that later were to enhance its traditions of independence and initiative. The county of Yorkshire, finally dismembered in the administrative reorganization of the 1970s, has existed as a northern unit in varying degrees since Roman times, and the cohesion given to it when it became the Danish Kingdom of York was maintained until the Council of the North—a prerogative court established in Tudor times to ensure the fair administration of English common law—was abolished in 1641. The growth of the wool-textile industry in the West Riding wrought major changes in the rural economy, but, in spite of this and the variety in the landscape, the sense of being a Yorkshireman is still a reality. Across the Pennines, on the other hand, it would be difficult to find a time before the Industrial Revolution when Lancaster formed a unit, yet there now exists a Lancastrian tradition and dialect, as well as a provincial entity. These stem from a certain physical unity and from the cohesion imposed by the long dominion of the cotton industry. The English Midlands are

really divisible into two regions: a West Midland province, which has become conscious of its identity since the emergence of Birmingham as a regional capital, and, in contrast, the East Midland province, with a greater physical and historic—but much less economic—unity.

Norfolk, Suffolk, and Cambridgeshire and Isle of Ely make up the ancient Kingdom of East Anglia. This is an agricultural province. In this respect it forms a marked contrast with its London-dominated neighbour, South East England, which in size and density of population is the largest English region. The Hampshire Downs form the core of Wessex, a province with that well-marked regional consciousness and patriotism that is so vividly depicted in the writings of the novelist Thomas Hardy. The eastern side of the Severn Estuary, together with the Somerset Levels, has become known as the West of England, a province which looks to the old city of Bristol as its centre. The completion of the elegant Severn Bridge, as part of the motorway system, is tending to unify both sides of the Severn Estuary into a Severnside region.

Patterns of rural settlement. The forms and patterns of settlement are remarkably varied in the United Kingdom and reflect not only the physical variety of the landscape but also the successive movements of peoples arriving as settlers, refugees, conquerors, or traders from continental Europe. The social and economic advantages that led folk to cluster and, on the other hand, the equally strong desire for separateness on the part of some individuals are apparent in settlement forms from very early times, and so regional contrasts in the degree of dispersion and nucleation are frequent.

Highland-zone hamlets

The single farmstead, together with many survivals of the old clachan (cluster or hamlet), interspersed with the occasional village and small town, is still characteristic of much of the Highland zone. Radical alteration has nevertheless occurred in some nucleated settlement patterns: in Wales the breakup of hamlets began in the later Middle Ages as a result of the related processes of consolidation and enclosure that accompanied the late medieval decline in the numerical strength of the bond (feudally tied) population. This trend was reinforced by the Black Death of 1349, which spread quickly among the inhabitants of lowly status. Many surviving bondsmen took advantage of the turmoil caused by the nationalistic uprising led by Owen Glendower (Welsh Owain Glyndŵr) to escape their servile obligations by flight, and thus many Welsh hamlets fell into decay by 1410, when the rebellion was crushed. In Scotland great changes accompanied the Highland clearances in the mid-18th century; in Northern Ireland, as late as the 1880s, many clachans disappeared as part of a deliberate policy of reallocating land to new dispersed farmsteads. Great changes are also to be seen in the Lowland zone, where the swing to individual ownership or tenancy from the medieval custom of landholding in common brought about not only dispersion and deserted villages but also the enclosure of fields by hedges and walls. Nucleations remain remarkably stable features of the rural landscape of Britain, and linear, round, oval, and ring-shaped villages survive, many with their ancient greens still held in common by the community.

Urban settlement. By any standards Britain must be regarded as the most urbanized of countries, for towns are not only particularly expressive of the national way of life but are also unusually significant elements in the geography of the country. The greatest overall change in settlement was, in fact, the massive urbanization that accompanied Britain's early industrial development. The increasing percentage of employees in offices and service industries ensures continued contemporary urban growth. Of every ten people in the United Kingdom, almost eight now live in towns, four of them in one of the eight major urban groups, or conurbations. The Greater London conurbation, the greatest port, the largest centre of industry, the most important centre of office employment, and the capital city, is by far the largest of these. The need for accommodating business premises has involved the displacement of population from inner London, and this, in part, has led to the designation of nine New Towns outside the ten-mile-wide Green Belt, which surrounds London's built-up area, and two more distant "overspill" towns.

The role of Greater London

Large conurbations have also formed on or near the exposed coalfields. The extensive built-up area of the West Midlands conurbation (with a population of almost 2,800,000) is dominated by Birmingham, but the industrial Black Country—named for its formerly polluted skies and grimy buildings—has also several large and flourishing towns. In the Manchester conurbation, with an equivalent number of inhabitants, urbanization accompanied the mechanization of the cotton-textile industry. Across the Pennines, similar mechanization of wool textiles created the West Yorkshire conurbation, the home of over 2,000,000 people, with Leeds and Bradford as its twin centres. Tyneside and the Central Clydeside conurbation are also located on coalfields, the latter housing about one-third of Scotland's 5,000,000 people. Merseyside is not on the Lancashire coalfield, but it has close economic links with it. In Northern Ireland, only Belfast may be considered a major conurbation.

In addition to these large metropolitan areas, there are many minor conurbations and large towns, a large number of which are strung out along the coast.

With so much urban and suburban concentration, the problems of air, water, and noise pollution have become subjects of much concern in the United Kingdom. Considerable progress has been made with the air-pollution question as a result of changes in fuel usage and the operation of clean-air legislation, which has led to the establishment of smoke-control areas in most cities and towns. Pollution of the rivers remains a large problem, particularly in the highly industrialized parts of the United Kingdom, but vigilance and control on the part of the river authorities, research done by the Water Pollution Research Laboratory, and general public concern for the environment are encouraging features of contemporary Britain. Several statutory and voluntary organizations support measures to protect the environment; they have as their aim the conservation not only of the countryside's natural amenity and beauty but that of the towns and cities also.

The people

LINGUISTIC AND ETHNIC GROUPS

All the traditional languages spoken in the United Kingdom are descended from a common Aryan, or Indo-European, original, a tongue so ancient that, over the centuries, it has split into a variety of languages, each with its own peculiarities in sounds, grammar, and vocabulary. A separate idiom in what became the United Kingdom was initiated when peoples from the Continent were cut off, in their new homes, from regular intercourse with their continental kindred.

Of the surviving languages the earliest to arrive were the two forms of Celtic: the Goidelic (from which Irish Gaelic, Manx, and Scottish Gaelic are derived) and Brythonic, from which are descended the old Cornish language and modern Welsh. Among the contemporary Celtic languages Welsh is the strongest: more than a quarter of the total population of the principality are able to speak it, but there are still extensive interior upland areas and regions facing the Irish Sea where the percentage rises to 70 percent and more. Scottish Gaelic is at its strongest among the inhabitants of the Islands and is still heard in the nearby Northwest Highlands. As only about 1.6 percent of Scotsmen are able to speak it, it has long since ceased to be a national language, and even in the northwest, where it remains the language of religion, business, and social activity, Gaelic is losing ground. In Northern Ireland very little Gaelic is spoken; similarly Manx is now used by very few individuals indeed, although as late as 1870 it was spoken by about half the people of the Isle of Man. Cornish became extinct in the early 18th century.

Germanic language links

The second link with Indo-European is through the ancient Germanic group of languages, two branches of which, North Germanic and West Germanic, were des-

tined to make contributions to the English language. Modern English is derived mainly from the four Germanic dialects spoken by the Angles, Saxons, and Jutes (who all arrived in Britain in the 5th century AD) and by the Danes, whose long series of raids began about 790. The Humber became an important linguistic as well as geographical boundary, and the English-speaking portion of what became England was divided into a Northumbrian and a Southumbrian province (in which the most important kingdoms were Mercia, Wessex, and Kent). In the 8th century, Northumbria was foremost in literature and culture, followed, for a short time, by Mercia; finally Wessex remained the linguistic centre until the time of King Edward the Confessor. The Normans, although also of Viking stock, were at first regarded as much more of an alien race than the Danes. Under the Norman and Angevin kings, England formed part of a continental empire; and the prolonged connection with France retained by its new rulers and landlords made a deep impression on the English language. An Anglo-French hybrid speech developed and remained the official language, sometimes even displacing Latin in public documents, until the mid-14th century. Many additions to English have been made since that date, but the Normans were the last important linguistic group to enter Britain.

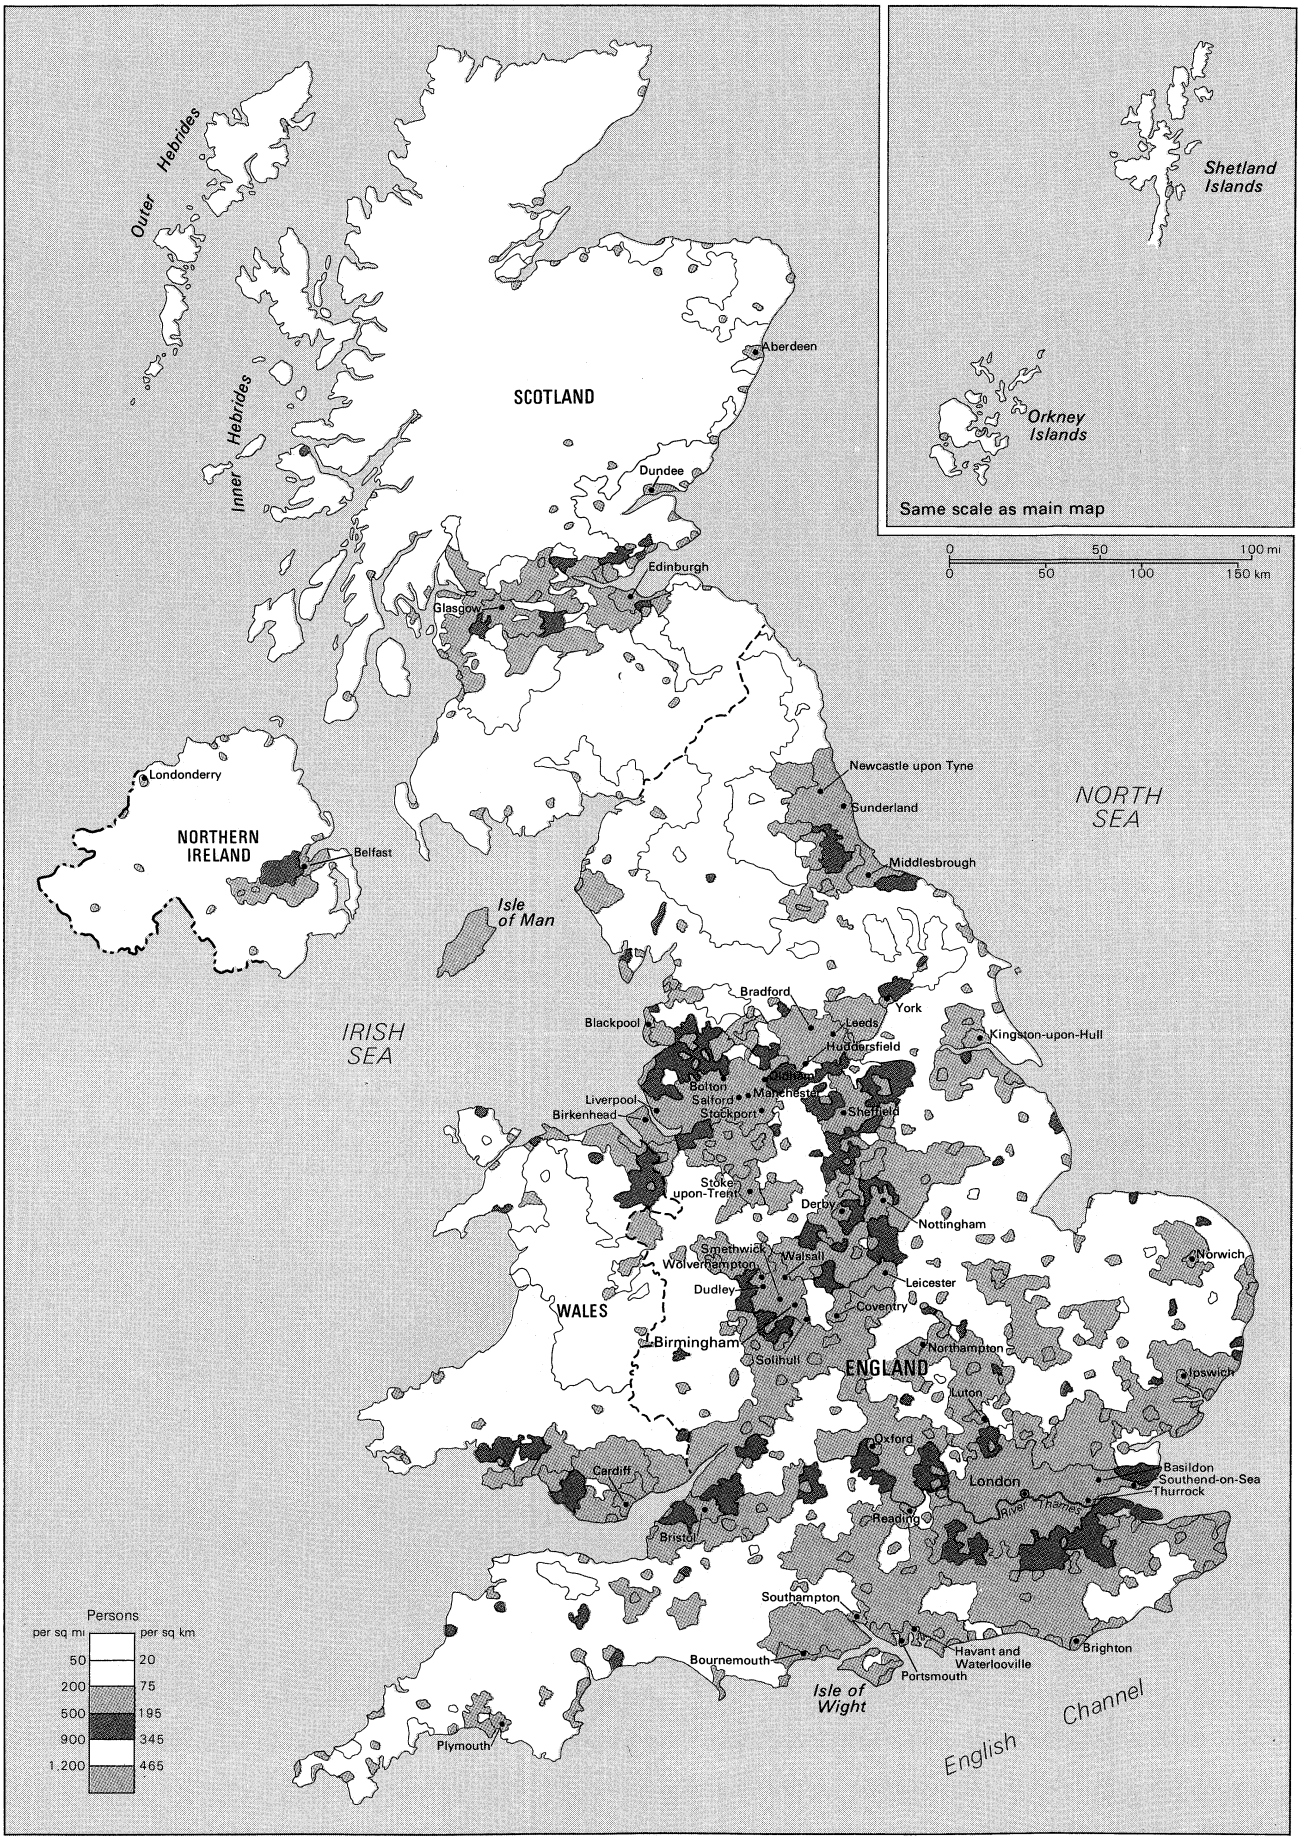
RELIGIOUS GROUPS

The various Christian denominations in the United Kingdom have emerged from the schisms that divided the church. The greatest of these occurred in England in the 16th century, when Henry VIII rejected the absolute supremacy of the pope. This break with Rome facilitated the adoption of some Protestant tenets and was the foundation of the Anglican Church, still the established church of England. In Scotland, the Reformation gave rise to a church governed by a presbytery—a body composed of ministers and laymen—rather than by bishops, as was the case in England. Roman Catholicism in Ireland as a whole was almost undisturbed by these events, but what became Northern Ireland came strongly under the influence of the Anglican and Presbyterian churches. In the 17th century further schisms divided the Church of England; these were associated with the rise of the Puritan movement, which, with its desire for simpler forms of worship and government, led to a proliferation of nonconformist churches, such as those of the Baptists and the Congregationalists; the Society of Friends (Quakers) also originated at that time. Religious revivals of the mid-18th century gave to Wales a form of Protestantism closely linked with the Welsh language; Calvinistic Methodism is still the most powerful religious influence in the principality. The great evangelical revivals of the 18th century, associated with John Wesley and others, led to the foundation of Methodist churches, particularly in the industrial areas; northeastern England and Cornwall still have the largest percentages of adherents to this denomination. In the 19th century the Salvation Army and various fundamentalist sects grew from minor schisms. That century also saw the introduction of sects from the United States as well as a marked increase in the number of Jews in Britain. The first Jewish community to be established in Britain since their expulsion in 1290 had been created in London during the 17th century, and in the 19th century they also settled in many of the large provincial cities. Over half the number of British Jews live in London and the rest are essentially members of urban communities. In the 20th century, immigrants from India and Pakistan have introduced various Eastern religions into the United Kingdom, but their places of worship are, for the most part, found only in the largest cities.

The Judaic and Eastern traditions

It is difficult to characterize and describe this variety of beliefs and their distribution in the United Kingdom, since the statistics for the various denominations are collected separately and on widely differing bases. The generalized description of England as Anglican, Scotland as Presbyterian, Wales as Calvinistic Methodist, and Northern Ireland as Protestant remains useful so long as it is remembered that each country contains large minority groups adhering to other Christian denominations and that a large proportion of the population is, in effect, agnostic.

DEMOGRAPHIC TRENDS



General factors. At any time, the basic factors governing population changes are the relation of births to deaths and of immigration to emigration. Since the making, in 1086, of the Domesday Survey, a detailed compilation that enables the earliest reasonable estimate of population to be made, at least of England's population (the survey did not cover other areas), the number of people has been increasing. This has been in spite of some setbacks, by far the most serious of which was the Black Death in the mid-14th century, in which it is estimated that about one-third of the population died. There is little concrete data, however, concerning variation in these rates until 1801, when the first official census was taken. The assumption is that a population of about 2,000,000 lived in what became the United Kingdom during the 11th century and that this figure increased to about 12,000,000 by 1801. This slow growth rate, in contrast with that of more modern times, resulted mainly from the fact that a high birth rate was accompanied by an almost equally high death rate. Family monuments in old churches show many examples of men whose "quivers were full" but whose hearths were not crowded. It is estimated that, in the first half of the 18th century, three-quarters of the children born in London died before they reached puberty. Despite the appalling living conditions it produced, the Industrial Revolution resulted in an acceleration of the birth rate; gradually the greater medical knowledge, improved nutrition, and concern for public health that characterized the 19th century bore fruit in a lessened mortality rate. The birth rate also continued to rise, until it reached 35.5 per thousand in 1871; since that time, except during the years immediately following World Wars I and II, it declined and, throughout the 1950s, steadied at around 16 per thousand. During the 1960s it rose again, to 18.5 and fell back to about 16.2 per thousand by the early 1970s. This marked decline in the birth rate since the late 19th century was due in part to the spread of deliberate methods of family planning. Over the same period the death rate declined from 22.3 per thousand in 1871 to a steady 11.6 per thousand 100 years later. When the birth and death rates are considered together, the margin of births over deaths shows an overall increase in population. While the death rates remained high, a population of low average age was being formed; but, as the death rates fell, each successive census showed a gradual increase in the proportion of elderly people.

First official census

In the contemporary United Kingdom, death rates differ between the sexes and also show variations from region to region, reflecting the response of people to the totality of their cultural and physical environments. As men are likely to follow more dangerous pursuits than women do and adjust less well to retirement, male death rates are normally higher. The principal regional difference is between the generally low death rates in southeastern and eastern counties and the high rates in northern and western Britain. Rates for males are distinctly high in parts of Lancashire, West Yorkshire, Lowland Scotland, northeastern England, South Wales, the West Midlands, and London, while for females the five major areas of high-mortality experience are southern Scotland, northern and northwestern England, Wales, and parts of Northern Ireland. For both sexes Cambridgeshire and the Isle of Ely, Rutland, Huntingdonshire, Oxfordshire, West Sussex, and Hampshire are the counties, and Canterbury, Oxford, and Bath the towns, with the most favourable mortality experience.

Regional variations in death rates

Immigration and emigration. Although historical records make reference to emigration to North America in the 17th and 18th centuries, there is little quantitative information about such movements before the middle of the following century. The greatest numbers appear to have left Great Britain in the 1880s and between 1900 and the outbreak of World War I. Emigration, particular-

ly to Canada and Australia, continued at a high rate after the war until 1930, when unfavourable economic conditions in the British Empire and in the United States reversed the movement. The same years also saw an influx of refugees from Europe. After World War II, both inward and outward movements reached considerable dimensions. Emigration to the Commonwealth and, to a smaller degree, to the United States continued, but, until 1951, the net migration balance of the United Kingdom with the rest of the world was not thought to be large.

After 1957 the immigration of black and other non-white ("New Commonwealth") people from such developing nations as the West Indies, India, and Pakistan became significant, and, from that year until 1962, there was a net migration gain. The immigrants came, it was held, to find work in the buoyant prosperity Britain enjoyed in the 1960s. Despite efforts to achieve racial integration, observers have held that both the white and non-white communities in Britain tend to see themselves as distinct and different, but not necessarily separate—a neutral relationship for which the term "social pluralism" has been coined. As in many other countries, race relations nevertheless continued to present problems throughout the 1960s and early 1970s. During fiscal 1965–70, suitably adjusted migration statistics, based on a sample survey of passenger movements between the United Kingdom and overseas countries, suggest that the gross migrant movements from all sources show a net loss averaging about 44,500 per year. These losses result from an average net loss per year of 145,000 United Kingdom residents and of a little more than 2,000 people from the white "Old Commonwealth" (Australia, Canada, New Zealand), balanced against a net gain per year of an average of 24,000 aliens, of 52,000 non-white, or "New Commonwealth" citizens, and of 26,000 Irish. Non-white ("coloured") Commonwealth immigrants and their families were estimated to number about 1,300,000 by the early 1970s. About 60 percent of the immigrants have flocked to the areas—Greater London and the Birmingham conurbation—where opportunities for employment are greatest. In the latter half of 1972, there was a great influx of Ugandan Asians holding British passports into the United Kingdom.

Racial factors in migrant movements

Migration within the United Kingdom has at times reached sizable dimensions. Until 1700, the small population was thinly distributed and largely rural and agricultural, much as it had been in medieval times. From the mid-18th century, scientific and technological innovations created the first modern industrial state, while, at the same time, agriculture was experiencing technical and tenurial changes, and revolutionary improvements in transport made easier the movement of materials and men. As a result, by the first decade of the 19th century, a previously mainly rural population had been largely replaced by a nation of industrial workers and town dwellers. The rural exodus was a long process; the breakdown of communal farming started before the 14th century; and, subsequently, enclosures advanced steadily, especially after 1740, until, a century later, open fields had virtually disappeared from the landscape. Many of the landless agricultural labourers so displaced were attracted to the better opportunities for employment and the higher wage levels existing in the growing industries; their movements, together with those of the surplus population produced by the contemporary rapid rise in the birth rate, resulted in a high volume of internal migration, taking the form of a townward movement.

Industry, as well as the urban centres that inevitably grew up around it, was increasingly located on the coalfields, while the railway network, which grew rapidly after 1830, enchanced the nodality of many towns. The migration of people, especially young people, from the country to industrialized towns took place at an unprecedented rate in the early railway age, and such movements were relatively confined geographically. Migration from agricultural Ireland provided an exception, for, when the disastrous potato disease of 1845-46 led to widespread famine, large numbers moved to Britain to become the urban workers of Lancashire, Clydeside, and London. The rural exodus continued, but on a greatly reduced scale, after 1901.

Soon after World War I, new interregional migration flows commenced when the formerly booming 19th-century industrial and mining districts lost much of their economic momentum. Declining or stagnating heavy industry in Clydeside, northeastern England, South Wales, and parts of Lancashire and Yorkshire swelled the ranks of the unemployed, and the consequent outward migration became the drift south to the relatively more prosperous Midlands and south of England. This movement of people continued until it was arrested by the relatively full employment conditions that obtained soon after the outbreak of World War II. In the 1950s, opportunities for employment improved with government-sponsored diversification of industry, and this did much to reduce the magnitude of the prewar drift to the south. The decline of certain northern industries—coal mining, shipbuilding, and cotton textiles in particular—had nevertheless reached a critical level by the middle 1960s, and the emergence of new growth points in the West Midlands and southeastern England made the drift to the south a continuing feature of British economic life. In addition population has increased significantly in the East Midlands and around the great estuaries such as the Bristol Channel, Southampton Water, Merseyside, and Teesside.

The distribution of population. The population of the United Kingdom including the crown dependencies at the 1971 census was about 55,522,000, the densities per square mile ranging from 935 in England and 339 in Wales to 280 in Northern Ireland, and 172 in Scotland. These overall figures express the middle position between the extremes of densely settled cities and towns and the almost uninhabited mountains and moorlands. Approximately 80 percent of the population of England and Wales live in towns, with the corresponding figure at 70 percent in Scotland and 55 percent in Northern Ireland.

Urban areas. Dominant in the distribution is the widespread urban development centred on the Greater London conurbation (7,379,000), but strong metropolitan influences extend to large marginal towns such as Chatham, Luton, Bedford, Southend, and nine planned New Towns. Railway electrification has encouraged a further movement of dormitory areas outward from Central London, while good road and rail communications foster links between the metropolis and the coast to the south: as far as passenger traffic is concerned, Southampton (215,000) has long operated as an outport for London, while the minor conurbation of Brighton offers seaside amenities and a place for the retirement of the more affluent Londoners. Portsmouth (197,000) and Bournemouth (153,000) are two more large elements in the complex of urban settlements along the south coast.

All the other large concentrations of population are

Industrial conurbations

found in the great industrial conurbations, and all are located on or near the coalfields. Placed in the centre of England and Wales, a few miles to the south of what was the Roman Watling Street but is now the central "grand thoroughfare" for road and rail traffic is the West Midland conurbation of Birmingham and the Black Country. Nearly half of the almost 2,800,000 people in the conurbation live in Birmingham and its two satellites, Solihull and Sutton Coldfield, and the remainder live in 21 other small and medium-sized towns. The official name for the northern conurbation, which has Manchester as its centre, was South East Lancashire, an inappropriate title, since the continuous built-up area spreads deep into Cheshire. By the early 1970s, the conurbation (renamed Greater Manchester) was the home of over 2,700,000 people, with Manchester (541,000), Salford (over 131,000), and Bolton (154,000) the largest elements within it. Only a few miles to the southwest is the Merseyside conurbation (1,659,000), but it is unlike the other provincial conurbations in that its expansion is due mainly to the enlargment of its large centre, Liverpool (607,000), and Birkenhead (138,000) on the south bank of the Mersey Estuary. On the eastern flanks of the Pennines, the high-density West Yorkshire conurbation of over 2,050,000 people consists of a large number of industrial settlements, with Leeds (495,000) and Bradford (294,000) dominant. Many settlements are strung out over the countryside in a southerly direction, making an almost continuous belt of high population density all the way round the Pennines as far as its junction with the West Midland conurbation. Within this belt lie the large and important cities of Sheffield (520,000), Rotherham (85,000), Chesterfield (70,000), Nottingham (almost 300,000), Derby (nearly 220,000), and Leicester (284,000).

Two further major population groupings, those of Northeast England and South Wales–Bristol, are located on coalfields with their own independent access to the sea. The main urban concentrations in northeastern England lie alongside the Tyne, Tees, and Wear rivers, while in South Wales–Bristol the population is concentrated in the striking, long, terraced rows in the many narrow mining valleys and on the coast of Swansea Bay and Severnside. In both areas the port cities of Bristol (over 425,000), Cardiff (278,000), and Swansea (173,000) dominate the scene. Third in rank numerically among the cities of Britain is Glasgow, with a population of almost 900,000; together with seven other large burghs it forms the Central Clydeside conurbation of almost 2,000,000 people. High densities, however, continue northeastward toward the Firth of Forth, on the shores of which lies Edinburgh, with nearly 450,000 inhabitants. Aberdeen (about 180,000) is the only really large settlement outside the Central Lowlands. In Northern Ireland the only area with a high density of population extends from the southeast corner of Lough Neagh to the shores of Belfast Lough, where Belfast and its vicinity house nearly half a million people.

Rural patterns. Outside these urban groupings lie the rural areas of the United Kingdom in which about 23 percent of the population reside. The pattern of high relief bears a very close relationship to the low density of population, particularly in the Highland zone, where there are extensive areas of very thin rural population.

Depopulation problems

These uplands have for a long time been losing people by migration, especially of young people, and this can produce a difficult situation culturally, socially, and economically, when an increasingly elderly population is thinly spread in scattered farms. Hydroelectric schemes, afforestation, and the development of the tourist industry have improved the economy of some of these upland areas, while rural electrification and better roads, together with the increase in car ownership, have all helped to mitigate the rigours and isolation of life in these remote parts. The attractiveness of town life is still great, however, and the downward trend in the population of upland zones continues.

In the Lowland zone, on the good agricultural land, a pattern of country towns, villages, hamlets, and dispersed farms can give a dense rural population, but densities rise even higher as the distinction between urban and rural settlement becomes blurred. This is particularly the case where the homes of a motorized people fill in the spaces between the old nuclei, so that long-distance commuters become the neighbours of local rural workers.

The demographic outlook. Tentative projections of the future peopling of the United Kingdom forecast a population of about 57,700,000 in 1981, rising to over 63,000,000 in the year 2001. Population is likely to continue to grow around many of the conurbations, although increasing emphasis on the rehabilitation of their centres, particularly inner London, may help to avert the current downward spiral in social conditions that seems to afflict the large city centres of the Western world. Attempts to reduce the nationwide trend toward an ever increasing concentration of population in South East England now seem to have met with some success, for there was, in 1970, a very small net outward migration from the region, while the projected natural increase in the area's population, though it remains high up to the year 1999, has nevertheless been revised downward. (W.Ra.)

The national economy

The United Kingdom occupies a unique position in the world economy. The dominant industrial nation of the 19th century, it has, during the 20th century, seen its markets and its position in the world whittled away by other developed countries, especially by the United States, the nations of western Europe, and, more recently, Japan. Part of this relative decline has been due to the increasing industrialization of other countries, but a more fundamental reason has been the maintenance of the national role as sterling-area banker, necessitating restrictions on any domestic growth that might precipitate balance-of-payments deficits, loss of confidence in sterling, and consequent outflows of currency. The United Kingdom growth rate has thus compared poorly with that of other industrial countries, and, at the start of the 1970s, annual growth in gross national productivity, at just under 3 percent, was the lowest among comparable members of the Organisation for Economic Co-operation and Development (OECD). This slow growth rate has, in turn, retarded the British standard of living, as measured in terms of disposable income per head, to a level considerably lower than those in the United States, Canada, Sweden, and the Federal Republic of Germany and slightly lower than those in Italy and France.

Economic growth in the 1970s

Given favourable conditions, the potential for United Kingdom growth, relative to that of other countries, is nevertheless large. An increasing proportion of world trade is in manufactured goods, and thus the British industrial sector, already providing a larger proportion of such trade relative to its population size than any other country except Japan, is in a favourable position to take advantage of increased growth in world trade. By the beginning of the 1970s, exports to other countries of western Europe already exceeded those to the Commonwealth, even before Britain joined the European Economic Community (EEC) in January 1972. The extent to which the country would remain the focal point of Commonwealth trade also remained uncertain, for Australia, among other countries, was loosening its old ties with the former imperial homeland and turning to new trading partners such as Japan.

THE EXTENT AND DISTRIBUTION OF NATURAL RESOURCES

Mineral resources. Unlike most developed countries, the United Kingdom has very few natural mineral resources. With the exception of iron ore, virtually all metallic ores have to be imported, and even the proportion of home-produced iron ore, mined mainly in eastern England, and with an average 27 percent iron content, is decreasing. There are also small quantities of west coast ore with 48 percent average iron content. Annual consumption exceeded 30,000,000 tons, of which about a third was home produced, by the 1970s. Minerals in which the nation is self-sufficient are sand and gravel, chalk, limestone, salt, slate, china clay, and, most important, coal. Production of coal, however, has been decreasing rapidly

since the early 1950s, mainly because competition from other energy sources, such as oil, has increased, and also because easily worked seams have been exhausted. In 1961, 180,000,000 tons of coal were produced; a decade later the figure was 147,000,000, of which nearly 3,000,000 tons were exported. Government policy has been to close the many small, uneconomical pits and to hold production at about 120,000,000 tons by the mid-1970s, using only the most efficient pits.

Of the more than 90,000,000,000 tons of crude oil consumed annually, only a tiny fraction, coming mainly from small fields in the Midlands, is home produced. The 1960s search for natural gas in the North Sea revealed large reserves of oil, and production of oil from the continental shelf was likely to begin in 1975. It remains to be seen whether large-scale extraction could be economical, a situation that would certainly improve the balance of payments and the economy as a whole. Natural gas from the North Sea has been entering the country since 1962. A controlled licensing system over the 100,000 square miles of the British claim area is operated by the Ministry of Power. The gas comes from West Sole and Leman Bank, which produced just under 1,400,000,000 cubic feet per day in 1971. Exploration continues, and larger quantities might be available by the late 1970s.

Natural gas

Hydroelectric resources. Although rainfall in the mountainous areas is high, the topography does not provide ideal conditions for hydroelectric schemes, and by the 1970s power from such schemes accounted for only about 2 percent of all electric power generated. The majority of hydroelectric stations are found in the north of Scotland, where more than 1,000 megawatts are generated by some 54 stations, most of which use high-level water storage and have their own catchment areas. A pumped storage plant with a capacity of 400 megawatts operates at Cruachan, Loch Awe, and a further 300-megawatt plant at Foyers, Loch Ness, was to be completed in 1974. Other stations operate in the south of Scotland (122 megawatts) and in Wales (469 megawatts), the latter group including a 360-megawatt station at Ffestiniog.

SOURCES OF NATIONAL INCOME

Agriculture. The two main features that distinguish British agriculture from that of other western European and industrialized countries are, first, the small proportion of the total population (2 percent of those in civil employment) engaged in the industry and, second, its advanced degree of mechanization. With one tractor for every 35 acres of arable land, Britain has one of the heaviest tractor densities in the world. Agriculture accounts for about 3 percent of the total gross national product (GNP) and utilizes about 47,000,000 acres, with arable and rough grazing land accounting for about 18,000,000 and 16,000,000 acres respectively, and permanent grass accounting for the remainder. The arable area is decreasing slightly, while that under permanent grass is increasing, changes brought about mainly by government-support policies. Individual holdings numbered about 422,000 in the early 1970s, slightly more than half of which were operated part-time. Half of the total agriculture output was then attributable to about 42,000 large holdings, while, of the remainder, about 66,000 were thought to be commercially viable. Some 112,000 holdings were too small to operate profitably; the government policy is to encourage amalgamations. The average size of a full-time farm is about 160 acres. In Northern Ireland there are about 63,000 holdings, almost all of which are owner occupied, but some 40 percent of these are either very small or let on a seasonal basis, so that the number of agricultural businesses is around 37,000, half of which are part-time, with an average size of from 40 to 70 acres.

Total British agricultural output by the early 1970s was just over £2,000,000,000, the main contribution being from crops (19 percent), livestock (36 percent), livestock products (31 percent), and horticulutral products (12 percent). Of the farm crops, wheat and potatoes each accounted for almost a quarter, barley for about a third, and sugar beet for about 11 percent. Cattle and calves accounted for 40 percent of livestock output, pigs for over 30 percent, poultry for just under 20 percent, and sheep and lambs for 10 percent. Milk and milk products comprised over two-thirds, and eggs nearly one-third, of livestock products.

The British government is intimately concerned with agriculture, since it has been considered a matter of national interest to maintain a stable, efficient food-producing industry, with the lowest possible prices consistent with reasonable incomes for those involved. An agricultural-support policy, required by the Agricultural Act of 1947, enabled the government to provide guaranteed prices for the main agricultural products and, if necessary, to impose minimum prices for imports. Annual reviews determined guaranteed prices over a 12-month period, and deficiency payments, related to the difference between the market price and the guaranteed price, were made to producers. The government also gave extensive production grants for improvements to land, crops, livestock, and equipment and was also empowered to meet up to 50 percent of the approved costs of voluntary amalgamation of small farms into commercial units. By the early 1970s this system was in the process of being changed to one whereby import duties would be levied on temperate-zone foodstuffs coming into the country, thus raising the internal-market prices for similar British food and so stimulating further home production. The funds collected from the levies were to be used to provide price-deficiency payments on those home products whose prices fall below the guaranteed minimum. This change would bring agricultural policy in the United Kingdom closer into line with that of the EEC. The difference between the old farm-support system and the policy of maintaining high market prices followed in the EEC was nevertheless a major problem in the United Kingdom's application to join the Common Market. It was thought that adoption by the United Kingdom of the EEC's common agricultural policy would increase farm incomes and agricultural output by between 3 and 10 percent, but, at the same time, security and a basis for forward planning would be lost.

Government support for agriculture

Forestry. Productive woodland occupies about 6.5 percent of the total United Kingdom land area; scrubs and old felled areas increase this to nearly 8 percent, the large area of unproductive woodland being largely the result of neglect of work during World Wars I and II. Ownership is divided about evenly between the Forestry Commission and private landlords. Replanting progresses at the annual rate of about 87,000 trees, most of which are Sitka spruce, lodgepole pine, Scotch pine, and Norway spruce. The home timber industry provides for only about 10 percent of the country's needs, and most of its produce is low-grade when compared with that imported from Scandinavia and elsewhere.

Fishing. In 1971 over £93,000,000 worth of fish was landed in the United Kingdom, of which nearly 92 percent was wet (*i.e.*, nonshell) fish. Of this total, about 47 percent were cod, 20 percent haddock, 8 percent plaice, and 6 percent herring; the 8 percent shellfish were mainly mussels and oysters. The industry is especially important to Scotland, the fishing fleet of which numbered over 2,600 ships in 1971, while that of England and Wales numbered about 3,200. Over the previous decade the size of the Scottish fleet had declined by over 15 percent and that of the English and Welsh by 13 percent. This is in part due to rationalization—bigger vessels are being used for freezing the catch.

The weight of landed fish by the early 1970s was over 1,100,000 tons annually, an increase of 43 percent over the figure for ten years earlier. Exports of fish are a minor, but rapidly increasing, factor in the industry's economy, having doubled over the 1960s. The white fish industry covers three areas: distant water, near and middle water, and inshore fisheries. There are over 160 distant water vessels, operating from Hull, Grimsby, and Fleetwood, while near and middle water vessels number about 350. The industry employs about 18,000 people.

Government aid to the fishing industry consists of grants and loans toward purchase and improvement of vessels

and equipment. Subsidies are given according to the class of vessel used, with the white fish trade receiving the most support. There are no subsidies for shellfish. There is also a subsidy related to the operating efficiency of vessels.

Mining and quarrying. This is a rapidly declining sector of the national economy, its output having dropped by more than 20 percent during the 1960s. During the same period, output per head nevertheless increased by almost the same proportion. The decline is due mainly to the running down of the coal industry (see below *Energy*). Mining and quarrying of other materials predominantly concerns sand and gravel (over 100,000,000 tons annually by the early 1970s), limestone (over 85,000,000 tons), and clays, shale, and igneous rock (about 35,000,000 tons each).

Principal mining and quarrying products

Manufacturing. The manufacturing sector is a vital element in the economy, employing nearly 9,000,000 people; that is, 35 percent of the total labour force. It contributes nearly 35 percent of the total GNP and its production rose by over a quarter during the 1960s. Industries with the highest growth rates tend to be those involved in advanced technology; examples are the chemical industries, instrument and electrical engineering, and those concerned with the by-products of coal and petroleum. Declining sectors are shipbuilding and leatherwork, falling, respectively, by 15 percent and 6 percent in the same period. This decline occurred because other countries were more competitive, mainly through the availability of cheaper labour. In terms of output and work force, the engineering and electrical-goods industry was, in the early 1970s, the largest manufacturing industry, employing 26 percent of the total manufacturing labour force of 8,900,000 and contributing 18 percent of the gross manufacturing output. The textile, leather, and clothing industries employed 14 percent of the labour force, and contributed 1 percent of its total output, while the vehicle industry employed well over 9 percent of the sector total and contributed more than 10 percent of gross output.

Iron and steel industry

A key supply industry to the manufacturing sector is the iron and steel industry. Re-nationalized in 1967, the British Steel Corporation combines 13 major steel companies producing over 90 percent of the country's total crude-steel output, which in 1971 was 26,600,000 tons. Capital expenditure, which up to the early 1960s was concentrated on increasing capacity, especially in strip-mill expansion, was in the early 1970s aimed at improving efficiency. As a result, the country now has some of the most modern converter- and electric-furnace plants in Europe.

Investment in manufacturing industry is vital to economic growth, and it increased a third, to over £1,800,000, during the 1960s. Of the total investment in the manufacturing sector, over two-thirds is spent on new plants and machinery. In the early 1970s the low level of industrial investment was a matter of serious concern.

Energy. The structure of national energy production has altered radically since the early 1950s. At that time, indigenous coal provided nearly 90 percent of total power requirements. Since then, the coal industry has contracted dramatically, and its competitors have become much more important; so much so that, by the early 1970s, little more than 39,200,000,000 therms, or 47 percent of total gross energy consumption, was provided by coal itself. Oil provided the bulk of the remainder, dwarfing the contributions of nuclear energy, gas, and hydroelectric power. Electricity-generating capacity in the early 1970s was nearly 62,000 megawatts, an increase of over 80 percent on the figure a decade earlier. The most significant recent change has been the increase in the use of oil power, the production of which doubled between 1955 and 1960 and virtually doubled again during the 1960s. The most radical change, in terms of future impact, has been the switch to nuclear energy. The United Kingdom has been a pioneer in this field, its use of electricity generated by nuclear plants exceeding, by 1970, that of the rest of the world put together. It was expected that, by the mid-1970s, as much as 25 percent of the total public electricity supply would come from nuclear sources. The electricity authorities themselves operate nine nuclear-powered "magnox" stations, with total output of 4,500 megawatts. These stations, using early, less sophisticated reactors were developed between 1955 and 1970; a second expansion with advanced gas-cooled reactors, began production in 1970 and was expected to contribute 8,000 megawatts by 1976. These latest plants were to use enriched uranium dioxide fuel encased in stainless steel, a development of the magnox system. The Atomic Energy Authority, which directs nuclear research, has three stations producing electricity, with a total capacity of 128 megawatts. The former AEA stations at Calder Hall, in Cumberland, and Chapelcross, Dumfriesshire (both 198 megawatts), are now owned and operated by British Nuclear Fuels Ltd.

Nuclear energy

The use of gas as a source of energy has also greatly increased, the total available at gasworks increasing by over two-thirds in the 1960s, to 6,300,000,000 therms. Most is now oil-based, the proportion of coal-based gas having declined rapidly during the 1960s. The remainder of available gas comes from privately owned coke ovens and oil refineries. Annual growth rates in overall consumption stood at around 12 percent in the early 1970s, when the gas industry was engaged in a major transformation of its equipment in order to cope with expanded production of natural gas, expected to reach 3,000,000,000 cubic feet per day by 1975. This transformation took place especially in the domestic market, which accounted for three-fifths of total demand.

Finance. The United Kingdom has one of the globe's oldest, most extensive, and most highly developed financial systems, and for many purposes London is still the financial centre of the Western world, sharing in the convulsions and crises that afflicted the international monetary system in the late 1960s and early 1970s. The hub of this system is the Bank of England, established in 1694 and nationalized in 1946. Its main function is to act as banker to the government, to the private banks, and to overseas central banks. Externally, it administers exchange control and operates the Exchange Equalisation Account, which is used to maintain within certain set limits the exchange rate of sterling against other currencies. Internally, the bank acts as the sole note-issuing authority in England and Wales (Scottish and Northern Ireland banks have their own limited issuing right), the issue being virtually all fiduciary (*i.e.*, dependent for its value on public confidence or securities) since almost all the gold backing for issue has been transferred to the Exchange Equalisation Account. The bank works in close contact with the government, especially over the control of monetary policy, in which it acts as the government's executive arm in giving directives to the commercial banks. The major policy instrument is control of bank rate, which is the rate at which the bank will lend money as lender of last resort to the discount houses. The country's whole interest-rate structure is based either on a fixed relationship to bank rate or on expectations about its possible movements. In many circumstances movements in bank rate can in fact have considerable effect on the money supply and on the cost of borrowing. The bank also manipulates the supply of money by open-market operations on the money and gilt-edged (government stock) markets. It can affect the policy of the commercial banks by issuing directives on the level of lending and credit regarded as permissible, and it can extract from them special deposits over and above those already held at the bank as liquid assets.

The Bank of England

The commercial bank group consists of six London clearing banks, which carry on virtually all commercial banking in England and Wales, three Scottish clearing banks, and two Northern Ireland banks. All have numerous branches. Certain Bank of England regulations affect the operation of the commercial banks; their holdings of coin, notes, and balances at the Bank of England must be kept at 8 percent of total deposits, and the minimum ratio for liquid assets is 28 percent. Between 1951 and 1958 advances varied between 26 and 30 percent of total deposits, but since then they have averaged 40 to 50 percent.

Banking in the City

This comprehensive banking system is integrated with complex and sophisticated capital and discount markets, which are based in the City of London, a small area of old London that retains its global pre-eminence as a commercial and financial centre. The importance of the City has been based on the United Kingdom's position as banker for the sterling area; this has meant that substantial funds are held in the City for overseas sterling countries and are utilized, together with funds from many nonsterling countries, in various financial transactions to the City's and its customers' advantage. A major recent trend has been for London banks to receive large deposits of dollars, which are then re-lent, creating the Eurodollar market.

The Stock Exchange

Many other important institutions operate in the City; among them the Stock Exchange, the largest of the eight in the nation. About 9,000 securities with an enormous total value were quoted on the London Stock Exchange by the early 1970s. There are numerous insurance companies, dominated by the international insurance market of Lloyds; shipping companies; the merchant banks and discount houses; foreign banks; life assurance offices; building societies; and many of the world's major commodity markets. The various activities of the City make a large contribution to the United Kingdom's favourable balance on invisible trade transactions.

Foreign trade. With less than 2 percent of the world's population, the United Kingdom entered the 1970s as the world's third largest trading nation, taking over 11 percent of the total trade and 8 percent of the export trade in manufactured goods. With few natural resources of its own, the country relies on imports for nearly half of its food and for most of its raw materials. In order to earn the foreign exchange needed to pay for these, exports value about one-fifth of the total national GNP. Although the terms of trade with the rest of the world have tended, since the late 1950s, to be favourable to the United Kingdom, adverse movements in 1963 and 1964 were repeated in the late 1960s, prompting a pessimistic interpretation of the ultimate effects of the devaluation of the pound carried out in 1967.

The rate of growth of imports has been erratic compared with that of exports, mainly because of their changing composition. Over the 1960s, imports increased in volume by almost a half. The proportion of foodstuffs, drink, and tobacco decreased, although the absolute amounts imported increased. Imports of basic raw materials, including fuels, exhibited a similar decline, falling from over a third of the total in the early 1950s to barely a quarter in 1971, while imports of semimanufactures have tended to increase, as developing countries turn to processing their raw materials before exporting them. Crude petroleum and lubricants are the largest single commodity import, accounting for more than 10 percent of total import value. Finished manufactured goods have shown the greatest percentage rise in recent years, from 7 percent in 1957 to 23 percent in 1971, the steepest rise being in capital goods. Exports have also risen rapidly, at a steady rate of about 5 percent per annum in the early 1960s and fluctuating greatly in the latter part of the decade between 10 and 25 percent. More than five-sixths of total exports are in manufactured goods, and, by 1971, 45 percent of the total was engineering goods. Machinery, both electrical and mechanical, vehicles, tractors, and scientific instruments are the major components of this sector, while chemicals are a rapidly growing export. Sectors in relative decline include textiles and metal manufactures other than machinery.

Trade with western Europe

The sources and destinations of United Kingdom trade include every country in the world, but the trend is for a relatively larger percentage of all trade to be carried out with western Europe. Just prior to British entry to the EEC, exports to western Europe were almost 40 percent of total exports; those to EEC countries accounted for 21 percent, and those to the European Free Trade Association (EFTA) for 15 percent. Conversely, trade with the sterling area and the Commonwealth has relatively declined, exports reaching only 28 percent of the total in 1971. Imports from these areas have similarly declined. Despite the increased importance of western Europe in the country's trade, the U.S. remains its major single customer, the source in 1971 of 11 percent of imports and the recipient of 12 percent of exports.

Considered year by year, visible imports are greater than visible exports, although the gap has, until recently, been largely covered by such invisible exports as shipping, civil aviation, financial services, travel, and tourism. During the 1960s, however, a continuous balance-of-payments deficit grew up, eventually leading to the devaluation of the pound in 1967. The consequent government-sponsored export drive achieved considerable success, and by mid-year 1971 pressure on sterling had eased. There was some uncertainty in 1970 and 1971 as to whether the favourable trade situation could be maintained in the face of continuing domestic and international inflation.

MANAGEMENT OF THE ECONOMY

The private sector. The British economy is a good example of a mixed economic system, for the public and private sectors claim almost equal shares of the GNP. The relationship between government and the private sector varies to some extent, according to whether a Conservative or a Labour government is in power; the former tends to allow the private sector to succeed or fail according to its own resources and energy, while the latter usually intervenes more actively, bolstering up failing sectors and also initiating new projects. Within such a system, and given an international situation beyond its control, a government can clearly impose no overall plan, but it is able to indicate to private industry the lines of expansion that it believes necessary and, to some extent, force it along them. The main ways in which a government influences industry are by its fiscal and monetary policies, by its control of the level of public expenditure, and by provision of government contracts, services, information, and advice. These operate mainly to affect aggregate demand, supply, investment, and savings. Equally effective is the two-pronged policy of encouraging investment and counteracting relatively high unemployment in the more depressed areas, forcing development away from the prosperous and congested areas of the Midlands and the South East. Under the Labour government of 1964-70, investment incentives took the form of grants of varying sizes. The Conservative government of the early 1970s operated a system of investment allowances, by which 60 percent of capital expenditure could be written off in the first year and 25 percent of the remainder in succeeding years. In development areas free depreciation was allowed. Other development inducements included the provision of ready-built factories, building grants, and assistance with planning. For manufacturing industries in development areas, a selective employment tax, introduced by the Labour government in 1966 and originally scheduled to be abolished by the Conservatives in 1974, was refunded; firms were also granted a 37.5 percent premium and a regional employment premium of £1.50 per head on their employees. Among the government bodies concerned with the private sector is the National Economic Development Council, which runs committees to study and promote productivity in some 21 separate industries. The Monopolies Commission and the Restrictive Practices Court (Department of Employment and Productivity) operate to ensure that agreements entered into by companies do not jeopardize the public interest.

Help for development areas

The public sector and the role of government. About 10 percent of the total British labour force works for statutory bodies directly controlling public corporations, which operate major industries and services in the public interest. These include the Bank of England, the Post Office, the British Broadcasting Corporation (BBC), the major airlines, the Atomic Energy Authority, the coal, gas, electricity, and steel industries, and the railway, docks, waterway, and freight services. Although not part of government departments, these bodies are under varying degrees of control by them. Responsibility for management nevertheless lies with the boards and staff of each public corporation, not with the minister of the gov-

ernment department concerned. Some bodies are self-supporting, while others receive Exchequer grants. The minister appoints the chairman and members of the board and can direct the general running of the corporation; but he does not interfere in day-to-day operations. In the early 1970s it was the aim to achieve a higher degree of financial self-support than that of the 1960s. Capital expenditure is met by loans from the Exchequer if it cannot be met from internal funds. Financial targets vary from 12.4 percent gross return to a mere break-even, the test discount rate applied for investment being 8 percent. Consumer interests are usually looked after by consumers' councils, which deal with complaints and suggestions and can make representations to the boards of the ministers concerned.

Consumers' councils

Between 1956 and 1966 the public sector accounted for around 40 percent of fixed investment, reaching some 48 percent in the early 1970s. This was divided between public corporations, the central government, and local authorities. The share taken by local government has recently increased, while that of the central government has diminished.

Taxation. Total national taxation receipts for the financial year April 6, 1971, to April 5, 1972, an average example for the early 1970s, were estimated at £16,217,000,000 and were produced by three major forms of taxation: on income, on capital, and on expenditure. Considerable reform of the structure of taxation, outlined in the 1971 budget, is due to come into effect in subsequent years.

Taxes on income. Although accurate comparisons are not feasible because of differences in taxation methods, costs of living, and social security benefits and payments, it is generally thought that personal taxation in the United Kingdom is among the highest in the world. On a single person's earned income of £30,000, for example, the effective total rate of income tax and surtax was 60.7 percent before, and 60.5 percent after, the 1971 budget. Income taxes include personal income tax, surtax, and corporation tax. In 1972 the standard rate of personal income tax, estimated to produce 41 percent of total tax receipts, was 38.75 pence in the pound sterling; this was applied to an individual's total income after deduction of personal, earned-income, marriage, children's, and various other allowances or reliefs. Until April 1, 1972, a married couple's income was aggregated and treated as the husband's income, but thereafter the wife was free to choose either aggregation or a separate tax evaluation. Surtax, estimated to produce 2.17 percent of total tax receipts in 1972-73, is an additional graduated tax payable on personal incomes, which, after certain allowable deductions have been made, including earned-income relief and a further deduction of up to £2,000 on earned income, exceeds £3,000. Reforms of personal taxation planned to come into effect in 1973 were to include the replacement of income tax and surtax by a single, graduated tax. This would be constructed in terms of earned income, a broad band of which would be charged at a provisional rate of 30 percent; higher rates would apply to higher income groups, rising to a top rate of 75 percent on an earned income over £20,000. Higher rates would also be applied to unearned income above a certain level, but, as one of the major aims of the reform is to ease the burden on this income, its lower levels will attract only the new earned-income rate.

Corporation tax, estimated to produce 8.06 percent of total tax receipts in 1972–73, is a company income tax on profits. The 1972 budget proposed that, effective April 1973, an imputation system should be introduced.

Taxes on capital. Taxes on capital are estate duties, popularly called death duties, and capital gains tax, estimated to account, respectively, for 2.5 percent and 1.2 percent of total tax receipts in 1972–73. The former is applicable at death on estates of over £15,000; above this sum the rate ranges from 25 to 75 percent. Capital gains tax is payable on disposal of assets; with companies the profits occurring from such disposals are liable to corporation tax, while for individuals the rate is generally 30 percent. The sale of a person's principal private residence, chattels worth less than £1,000, goods with a predictable life of shorter than 50 years, gifts to charities, and certain securities are not subject to the tax.

Capital gains tax

Taxes on expenditure. Taxes on expenditure include customs and excise duties, applying mainly to tobacco, hydrocarbon oil, and alcoholic drinks, estimated to account, respectively, for 7, 9, and 6.5 percent of total 1972–73 tax receipts. Another tax on expenditure is purchase tax, which is applied to a wide range of goods, usually consumer goods, at two different rates which can be varied by the Chancellor of the Exchequer for up to a year at a time, under the so-called regulator system. It was estimated to account for 8.1 percent of total 1972–73 receipts. Other taxes on expenditure are betting taxes and motor-vehicle-license charges.

A selective employment tax (SET), was introduced in 1966 that fell into none of the three major tax categories noted above. Designed mainly to encourage the transfer of labour from service to manufacturing industries, it was, from July 1971, charged on employers at a rate of £1.20 pence per week for every man employed, and £0.60 pence for every woman. Manufacturing employers in developing areas got a refund, together with two premiums, while those not in developing areas and employers in nationalized industries, in transport and communications, agriculture, and the extractive industries receive the refund but no premiums. From April 1, 1973, SET was to be replaced by a value-added tax at the rate of 10 percent on the supply of goods and services and on importation of goods subject to certain exceptions. From that date, a tax on new and imported cars would be levied at 10 percent of the wholesale value.

Employers' associations and trade unions. The main employers' organization is the Confederation of British Industry (CBI), which deals with all industrial matters affecting employers. In close contact with the government, the public, and other interested parties, it includes more than 1,400 different employers' organizations, of which about 90 are nationwide. These are the bodies that negotiate most of the important collective agreements with trade unions.

Labour in nearly all industries and occupations is organized, to a varying extent, into trade unions. Total membership by the early 1970s exceeded 10,000,000 divided among over 500 unions, of which some two dozen accounted for almost three-quarters of all members. Just over half the total number of trade union members were in the nine unions with a membership of more than 250,000. Membership at the beginning of the 1970s was increasing most rapidly among white-collar workers, largely because manual labourers, skilled and unskilled, were earlier organized into unions. Most unions belong to the Trades Union Congress (TUC), the central body of the movement. The TUC is empowered to mediate between unions, to comment on wage claims, and to deal with unauthorized or unconstitutional strikes. It is nonpolitical, but unions may set up a political fund financed by a membership levy, from which anyone may opt out. Most unions have such a fund, used to support the Labour Party.

Trades Union Congress

Industrial relations in the United Kingdom were going through fundamental changes in the early 1970s. For many years previously, agreements between employers and unions had been only exceptionally enforceable by law, and the conditions surrounding such agreements were often archaic, complex, and liable to considerable misunderstanding. As a result, although the official figures for strikes were not as bad as those in many countries, enormous harm was done in the late 1960s and early 1970s by numerous unrecorded unofficial strikes. The Conservative government, in 1971, passed an Industrial Relations Act, aimed at modernizing the structure of industrial relations. By it the registrar of trade unions was given additional powers, and a National Industrial Relations Court was set up to adjudicate on "unfair" industrial practice, both on the unions' and on the employers' side. Registered unions were obliged to define precisely who is entitled to call a strike against employment contracts, which are, under the act, legally enforceable unless

The changing context of industrial relations

the signatories specifically state that they shall not be so. Those not legally entitled to strike are liable for damages. Registered unions are held responsible for the activities of their members; if the National Industrial Relations Court decides that a union has helped or condoned the activities of an unregistered group, that union's funds will be put at risk, and the ultimate sanction is the threat of deregistration. The act is expected to eliminate the closed shop, by which unionists demand that nonunion workers be excluded from the factory or work group.

Contemporary economic problems and policies. The period since World War II has witnessed continuous expansion in the British economy, rising standards of living, high industrial production, and generally low unemployment. There has also been a fundamental disequilibrium in the balance-of-payments situation, whereby imports have tended to rise faster with national income than have exports. The situation has been aggravated by the United Kingdom's position as banker to the sterling area, which meant that any loss of confidence in the strength of sterling vis-à-vis other currencies, such as might be prompted by a continual balance-of-payments deficit, immediately led to outflows of sterling with consequent further loss of confidence. In such circumstances it would be impossible to maintain the exchange rate without further reducing gold reserves. Until 1967, it had been the policy of successive governments to attack this problem by reducing the rate of growth of demand through restrictive fiscal and monetary policies whenever the balance-of-payments deficit seemed seriously increasing. Thus, interest rates would rise and foreign currencies be attracted back to the United Kingdom. Such action restricted growth rates and increased unemployment, however, and the potential of the economy remained seriously unexploited.

In 1967 the government finally recognized that the prolonged overvaluation of sterling created a fundamental flaw in the economy, and the pound was devalued. In order to benefit from this action, resources had to be diverted from the domestic to the export market as quickly as possible, and the measure of success achieved is shown by the fact that between 1967 and 1971 the balance of exports over imports changed from a deficit of £225,000,000 to a surplus of £299,000,000. The price paid in this achievement was high; the increase in domestic output was extremely small, and unemployment soared to a 1971 level of 3.6 percent (excluding Northern Ireland) compared with an average level of 1.7 percent in the 1960s.

The problem inherited by the Conservative government in 1970 was thus that of maintaining progress in the balance of payments while at the same time encouraging growth rates commensurate with the productive potential of the economy as a whole. Its task was made more difficult by a rapid rise in the number of damaging strikes in many key export industries, which inevitably gave Britain the reputation of an unreliable provider of goods. At the same time industrialists, both British and foreign, showed a marked reluctance to invest in the United Kingdom at anything like the rate required to parallel the growth in demand and to maintain production at a level high enough to keep unemployment at an acceptable level. Inflation, a problem throughout the world, became particularly serious in the United Kingdom, where, in the year 1971, it was in the region of 13 percent. It was aggravated by many wage claims put in by unions in order to meet and anticipate an ever-increasing cost of living. Although the balance-of-payments problem had, by the early 1970s, been solved for at least the short term, this had thus been achieved only at the cost of a high rate of inflation, combined with serious stagnation and rising unemployment. In this period wage and price increases were so high that it seemed possible that a disastrous form of hyperinflation could develop. This sort of inflation had never occurred in Britain, although it was common in many countries between World Wars I and II and in some developing countries in the 1950s and 1960s. The various methods used by the government to restrict or counter wage claims, all of which depended for success on voluntary union agreement to conform to wage-rise norms strictly related to productivity growth, had met with little real success by mid-1971; it remained to be seen what could be achieved by means of the controversial Industrial Relations Act. This was expected to produce a slow but sure change in the high rate of wage increases, reducing them from the 10–15 percent level typical of 1971 to something around 5–7 percent or more, where productivity deals could be made. The act also provides for any wage contracts made to remain legally binding for a longer period of time; although, therefore, official strikes may occur when the time limit runs out, the United Kingdom's liability to damaging unofficial strikes should, hopefully, be reduced, thus encouraging investment. Provided that such renewed investment in fact takes place, the growth rate in the GNP for the early 1970s might reach nearly 4 percent, reducing unemployment to less than 2 percent. In such a situation the government would be in a much stronger position to deal with more peripheral economic problems such as those of the traditionally depressed areas. Attention could also be given to the restructuring of several older industries and to improving equipment for the social and educational services. Such an outcome was rendered even more vital by Britain's joining the EEC, in which the rewards could be spectacular for a prosperous United Kingdom with a sound economic growth rate but in which difficulties would be multiplied if the economy remained stagnant and inflationary. Transportation

THE OVERALL SYSTEM

Main transportation routes. Most of the heaviest British passenger and freight loads travel along the main English commercial axis running from London, through Birmingham, to Liverpool and Manchester. Along this route, that of the Roman Watling Street and the famous Scottish civil engineer Thomas Telford's London to Holyhead Road, now lie the principal electrified trunk rail line, the M.1 and M.6 motorways, the Grand Union Canal, the principal internal air corridor, and the main natural-gas and petroleum pipelines. This axis has extensions: northward as the west coast route to Scotland; westward through North Wales to Holyhead, the principal port for travel to Dublin; and southward from London to the south coast and the prospective Channel Tunnel. London and Liverpool–Manchester are by far the largest freight ports, as well as the largest centres of population and industry. Major transport arteries have developed linking them with other cities and regions in Britain.

The English commercial transport axis

The role of public transportation. Apart from traffic covering the main intercity routes, most urban and interurban public transportation of both people and freight is in decline. Despite the growing population and the consequent increase of production and consumption, the amount of freight moved by railways fell from an annual 500,000,000 tons before 1914 to little more than 200,000,000 tons in the early 1970s. In the same period the number of passengers carried fell from 1,300,000,000 to nearly 824,000,000. Although urban populations have steadily increased, public passenger traffic in towns and cities had been declining by a few percent per annum for many years even before the 1960s, when spiralling fare increases and diminished services accelerated the annual falloff rate to between 3 and 5 percent. Ownership of private cars has been increasing consistently since the 1920s, except during World War II and periods of economic depression, at a little under 10 percent per annum. By 1971 about 225 private cars were registered for every 1,000 persons; this was estimated to be about half the anticipated saturation level for private car ownership, a status that, unless checked by changes in taste or policy, would be reached by the end of the 20th century. By 1971 more than 75 percent of total passenger mileage was made in privately owned vehicles.

Transportation policy. The near-crisis conditions that have developed for the publicly owned road, rail, and waterways transportation systems and the seriously congested state of most main roads have brought the problem of transportation under closer public scrutiny in recent

years. In the face of the need to maintain some form of passenger-transport services despite declining demand and consequent increasing losses, some practical attempts to cut costs, especially labour costs, have been made. Some one-man buses have been introduced into service; in London the new Underground Victoria Line has automated trains, and automated ticket collection is being introduced in underground stations.

Automation in urban transport

Government policy for the national transport undertakings has varied according to whether the government is Conservative or Labour. The Conservatives practice a fairly strict commercialism: they closed uneconomical services in the early 1960s and proposed, in the early 1970s, to end the subsidization of commuter rail travel. Labour has tended to recognize the social value of many of the country's public transport services and, in the late 1960s, was paying considerable subsidies to the British Railways Board.

A policy statement that preceded the 1968 Transport Act showed government acceptance of the movement away from rail traffic and from public transport in general. It cleared the way for the railways to concentrate on providing the services for which they are best suited; that is to say, intercity passenger trains, city commuter services, and trainload freight. By the terms of the act, previously competing bus and rail passenger services in many city regions were placed under the operational control of unified passenger transport authorities, which were required to coordinate services and balance operating costs against revenues supplemented by local taxation. The act incorporated most of the bus undertakings that were not municipally owned into a National Bus Company, operating in ten areas, and, in 1969, control of London Transport (buses and underground railways) was vested in the Greater London Council. In 1970 the Conservatives decided to strengthen the main private airline by the transfer to it of some routes previously served by the state airlines.

INTERNAL COMPONENTS

Roads. Since 1914, the importance of roads for freight and passenger movement has been growing steadily, and, in the early 1970s, road travel accounted for 90 percent of all passenger movement within the United Kingdom. Roads provide excellent coverage of most of the country, except in the thinly populated areas of the Highland zone. Most roads are of minor status, however, and less than 5 percent of total United Kingdom road mileage consists of trunk roads—the major routes—that are the financial responsibility of the central government. These trunk roads, together with principal roads, a classification embracing a further 10 percent of the total, carry the major intercity and intertown flows in the regions.

Despite the reconstruction, sometimes to high standards, of many roads, serious traffic congestion and low travel speeds, to say nothing of pollution problems, are normal on most of the principal roads that carry two-directional traffic. Motorways and other roads that carry the two opposing streams of traffic on separated (dual) roadways are usually less congested, but in some areas, particularly near cities, these too are becoming overloaded. The United Kingdom, containing more than 70 registered vehicles per mile of road, has a higher vehicle density than any other country.

Motorways

The United Kingdom's motorway, or freeway, building program got under way only in the 1950s. The first substantial length of motorway in Britain, the M.1, came into service in 1959, and the first 1,000 miles of such roads were due to be completed in the early 1970s. By the early 1970s motorways linked London with the Midlands, the northwest, and the Scottish border by the west coast route; with the West Yorkshire cities; and with Bristol and South Wales. An east–west trans-Pennine motorway, linking Liverpool and Manchester with Leeds and Hull, was under construction, and further motorways were planned to serve the south coast of England. In Scotland there was a Glasgow–Edinburgh–Stirling triangle of motorways, and in Northern Ireland some 40 miles of motorway radiated from Belfast. The motorways relieve pressure on other roads, creating a better environment for local traffic.

Most of the motorways in existence in the early 1970s were national routes, connecting London with the regions and the regions with one another. A second group of motorways, more regional in character and designed to duplicate and relieve existing heavily loaded interurban routes, was also taking shape: some were urban motorways, created to ease the acute problems of traffic congestion in the nation's older cities.

Capital expenditure on new roads and major reconstructions, amounting to about three-fifths of total central and local government roadwork expenditure, was expected to rise with the increasing use of road transport. In 1970 the Ministry of Transport, shortly before its merger into the Department of the Environment, published a strategy for a 20-year development of a national, interurban network of main roads with dual roadways but not necessarily motorways, or even new routes. The program was to be correlated with plans for the economic development of the regions.

Railways. The 1960s and early 1970s have seen changes in Britain's railway system perhaps unequalled since the first 20 years of railway development in the early 19th century. At its peak in 1914 the railway system had about 20,000 miles of routes and carried nearly 1,300,000,000 passengers and more than 500,000,000 tons of freight annually. It was controlled by some 120 competing companies, which had, between them, a virtual monopoly of inland traffic. Passenger traffic remained stable between World Wars I and II, but there was a steady loss of freight traffic to road transport. Nationalized in 1947 by the Railway Executive established under the British Transport Commission, the railways were run in much the same way as before. Steam, replaced by diesel power in the 1950s and by electric power in the 1960s, disappeared entirely in 1968.

Rail nationalization

A major investigation into the commercial viability of the system, undertaken in 1962, showed that a large number of routes, services, and stations were uneconomical, half the route mileage carrying insignificant freight and passenger traffic and half the stations handling only 2 percent of traffic. By the end of 1970, route mileage had been reduced to almost 12,000 and the number of stations from 7,000 in 1961 to fewer than 2,900, less than one-quarter of which handled freight. Specialization of services, undertaken as a result of the 1968 Transport Act, resulted in an increase of trunk trainload freight, of intercity express passenger trains, and the suburban commuter services. Unprofitable miscellaneous traffic was transferred to a new National Freight Corporation, and technological improvements were also made. Track reconstruction, the introduction of long, continuously welded rails, and new signalling all combined to improve comfort, safety, and speeds. Following main-line electrification and track reconstruction between, for example, London (Euston) and Liverpool–Manchester, many daily trains have scheduled journey speeds of 80 miles (130 kilometres) per hour, with top speeds of 100 miles per hour, which reduce the pre-electrification journey time by one-third. In 1971 the decision was taken to extend the electrification of the London to Liverpool–Manchester line to the whole of the main west coast line to Glasgow. For specialized freights, liner trains have been introduced: these function as indivisible units and operate on regular schedules at express-passenger-train speeds. Inland container bases are connected by liner train to the port container berths, and the use of these sealed, easily handled bulk containers is having an increasing impact on the carriage of goods to and from ports.

In their development of high-speed track, signalling, and rolling stock, British railways are among the most modern in the world. By the early 1970s, the railway's research division had an advanced passenger train, planned for speeds of 125-150 miles per hour, in the development stage. This project has aroused considerable international interest; because of these speeds railways can compete with air travel for journeys of up to about 350 miles.

Inland waterways. Most of Britain's canals are 18th- or early 19th-century narrow-boat canals. Though not without scenic attraction, except in the grimy industrial regions, canals have been at a commercial disadvantage ever since railways were first built, and their traffic has so dwindled that, by the early 1970s, they were carrying less than 0.5 percent of the total inland freight tonnage.

The Caledonian Canal

One of Britain's more interesting canals is the Caledonian, another early-19th-century engineering feat by Telford. Linking Loch Ness to Loch Linnhe and the Moray Firth, it allows small vessels to traverse the "waist" of Scotland and so avoid the Pentland Firth passage.

Almost the whole of the 2,000 miles of navigable rivers and canals in Britain, together with their small estuarine ports, were nationalized in 1947 and came under the control of the British Waterways Board. One exception is the Manchester Ship Canal, open to deep-sea vessels, which allows ships of up to 10,000 tons to travel 30 miles inland from the Mersey Estuary to Manchester.

The 1968 Transport Act introduced a new function for many of the noncommercial canals. They were to become amenity waterways for cruising and recreation and thus take on a new and important role in a more leisure-oriented society. Service facilities and amenity clubs are increasing, and some attempt is being made to include canal frontages in urban redevelopment.

In the early 1970s more than half the board's revenue came from the sale of water, a function of canals that had scarcely begun to be exploited adequately. This, with their importance for land drainage and their new leisure role, constitutes the foreseeable future use of the canals.

Pipelines. The increasing demand for oil and oil products, coupled with the growing congestion in road transport and the discovery of natural gas in the North Sea, led during the 1960s to a development of pipelines for the transport of oil and gas. Two major systems are operated: one by the Gas Council for the distribution of natural gas and the other by the petroleum industry for that of oil and oil products.

Gas. The first high-pressure gas pipeline was commissioned in 1964 to distribute imported liquefied natural gas from the port terminal at Canvey Island, near London, to the industrial Midlands. Discovery of the major North Sea natural-gas fields in 1965–66, which according to a 1971 report could hold gas reserves of 50,000,000,000,000 cubic feet, meant that very large indigenous supplies of natural gas would become available, and it was decided to supply this form of gas to all parts of Britain as quickly as possible, to replace coal gas. The Gas Council constructed a large-diameter high-pressure pipeline between London and Manchester, together with feeders from the natural-gas-field landing points on the east coast. This link was to be connected eventually to Bristol and South Wales, and, through West Yorkshire, to Newcastle and Glasgow. In the early 1970s the system could supply an annual total of 2,000,000,000 cubic feet, at a pressure of 1,000 pounds per square inch, to the 12 existing area gas boards. These could regulate the pressure to feed their supergrids, high-pressure grids, and local grids for industrial and domestic supplies.

The London and Manchester pipeline

Oil. The history of oil pipelines is rather longer, dating from the wartime oil supply lines of the 1940s. These were subsequently extended with the commission of new refineries on the River Thames, Southampton Water, and the River Humber. In the early 1970s pipelines for the transmission of petroleum interconnected the major refineries on the Thames, Merseyside, Southampton, the Severn, and the Humber, also supplying inland distribution terminals. The building of further lines from the refineries to new deepwater-tanker terminals at Milford Haven and Anglesey was under consideration. Some of the pipelines transport crude oil from port to refinery; most are used to convey refined white oils to inland distribution centres, but some move other oil products between refineries and centres of the petrochemical industries.

Other materials. Pipelines have been used to a limited extent for conveying material other than liquid hydrocarbons. A 57-mile pipeline carries chalk slurry from quarries at Dunstable, in Bedfordshire, to a cement works at Rugby, in the Midlands, while, in the early 1970s, experiments were being made in the moving of coal by pipeline. The development of pipelines as an important form of transport is likely to continue as experience in this area increases and industries become more integrated.

EXTERNAL FUNCTIONS

Seaports. Ownership of the majority of commercial seaports in Britain was vested in the British Transport Docks Board by the 1962 Transport Act. Half of Britain's imports and exports are nevertheless handled by the major independent ports, particularly those on the Rivers Mersey and Thames. The traffic of the docks of the British Transport Docks Board is mainly of the cross-Channel, short-haul variety, serving Ireland, the offshore islands, and the closer continental ports, as well as British coastwise traffic.

The association of shipping lines with individual ports has led to a tendency for traffic with particular parts of the world to become associated with one particular port. Thus, Tilbury, part of the Port of London, is associated with the Australasian passenger trade, Liverpool with that to Canada, West Africa, and the Far East, and Southampton with the North and South American and South African trades. During the 1960s, however, much of the deep-sea passenger-liner traffic was transferred to Southampton, which is exceptional among ports of the British Transport Docks Board in that it is developing a major traffic role comparable with that of Liverpool and London. Much of its success is due to its geographical location, its peculiar double-crested tide, which obviates the need for enclosed water docks, and to a history of good labour relations. Although other major ports have made considerable investments to equip themselves to handle container-freight traffic, it appears that much of this trade will also go through Southampton.

The role of Southampton

Of the total annual traffic through Britain's seaports (332,000,000 tons at the beginning of the 1970s), more than two-thirds is fuels, mainly petroleum. The combined ports of the British Transport Docks Board handled a total of over 86,000,000 tons, about 30 percent of which was in coastwise traffic. Of the independent ports, the Port of London Authority and other ports on the Thames, the major sea gateway to Britain, carry about 80,000,000 tons of traffic annually, three-quarters of which is fuels, but also with major imports of cereals, sugar, wood, wood pulp, and paper. The ports on the River Mersey (Liverpool, Manchester, and Garston) together handle 25,000,000 tons of petroleum and about 20,000,000 tons of nonfuel traffic, with cereals, sugar, and iron ore as the most important commodities imported.

A National Ports Council was set up in 1964 to control major port investment and to produce a national ports plan. Impending changes in world trade and methods of sea transportation are likely to effect radical structural changes in the United Kingdom port system, some berths or docks becoming redundant or inadequate to handle the new-style, mainly container, traffic and larger vessels.

Airways. Britain is linked with the rest of Europe and other continents by state-owned airlines. A number of subsidiary and independent companies also operate airlines. Most world airlines use London's Heathrow Airport, making it one of the busiest in the world; in 1970 it dealt with more than 270,000 aircraft movements and 15,700,000 passengers. It is, in fact, the world's busiest airport for international passengers, carrying some 12,600,000 in 1970. It is supported by the smaller subsidiary airports of Gatwick to the South, Southend on the east, and Luton and Stanstead to the north. In 1970 Heathrow and Gatwick together handled over 50 percent of the 32,000,000 international passengers passing through the seaports and airports of the United Kingdom, as well as 10 percent by value of the country's visible imports and exports. By far the greatest passenger traffic at Heathrow is with the European continent, just over 50 percent in 1970, compared with some 18 percent domestic traffic and 15 percent with North America. Traffic with other continents was much smaller.

The role of Heathrow Airport

Domestic air traffic is comparatively light, since distances between the principal cities are small, and air travel offers scant saving in travel time. Each major city region, nevertheless, has its airport, with passenger services to London accounting for about 18 percent of the traffic. Special networks serve the offshore islands and some cross-country routes. Few of the provincial airports have significant international links other than cross-Channel, the exceptions being Manchester and Prestwick (Glasgow), which both have a moderate level of traffic services to North America.

The British Airport Authority administers Heathrow, Gatwick, Stanstead, Edinburgh, and Prestwick. Since 1967 it has been investing more than £9,000,000 per annum in Heathrow and increasingly large amounts in Gatwick. By the early 1970s Heathrow had almost reached its capacity limit for aircraft movements. Although Gatwick was being expanded, the high rate of increase of air traffic, generally exceeding 10 percent per annum and usually doubling over about a seven-year period, made a third major airport for London, to be located at Foulness, an urgent necessity. Administration and social conditions

THE STRUCTURE OF GOVERNMENT

Constitutional framework. Britain is a constitutional monarchy and a parliamentary democracy. Its permanent head of state is the reigning king or queen, and the head of government is the prime minister, who derives his position from the fact that he is leader of the political party that currently possesses, or can command, a majority in the House of Commons.

Sources of the constitution

The British constitution is partly unwritten and wholly flexible. Its basic sources are legislative enactments of Parliament, such as the Act of Settlement, 1701, and decisions made by courts of law. Matters for which there is no formal law, as, for instance, the resignation of office by a government, are determined by important conventions of the constitution, based on precedent, but always open to development or modification. The main elements in the constitution are the legislature, the executive, and the judiciary; and government, in the most general sense, involves all three, with many functions overlapping, since there is no separation of powers. Sovereignty resides in Parliament, which comprises the monarch, referred to as the Crown, the hereditary and appointive House of Lords, and the elected House of Commons acting in concert, and is expressed in its legislative enactments. These are therefore binding on all, although the liberty of the individual subject, secured in essence by the rule of law, is, in practice, exemplified by the right of the private individual to contest in the courts the legality of any action under a specific statute.

All political power is concentrated in the prime minister and his Cabinet, and the monarch must act on their advice. Members of the Cabinet are chosen by the prime minister from among his own political party in Parliament. Most Cabinet ministers are heads of such government departments as the Home Office or the Foreign Office. The prime minister's authority over his Cabinet colleagues has tended to increase, and some decisions previously within the competence of the Cabinet as a whole are now made by the prime minister alone. A clear example of this development occurred in 1918, when the right to dissolve Parliament and fix the date of an election passed by tacit consent from Cabinet to prime minister. The prime minister can also, on occasion, alone or with one or two colleagues, make decisions without consulting the Cabinet. A prime minister has nevertheless been overruled by his Cabinet on many occasions, right up to the present day; and, in order to exercise fully his enhanced powers, he must, as a rule, carry his Cabinet with him. The prime minister also appoints about 25 ministers not in the Cabinet, and about 50 junior ministers.

Powers of the Cabinet

The Cabinet exercises the sovereignty of Parliament because, as it is drawn from, and supported by, the party that has a majority in the House of Commons, it can effectively control legislation. The royal right of veto has not been exercised since the early 18th century, and the once coequal legislative power of the hereditary House of Lords was reduced in 1911 to a mere right of temporary delay. The Cabinet plans, drafts, and lays before Parliament all important bills, including the budget, using its majority to get them through Parliament with reasonable dispatch. While the Cabinet thus controls the lawmaking machinery, it is also subject to Parliament, in the sense that it must expound and defend its policy in debate.

Administrative decisions of the Cabinet are implicitly and immediately obeyed and carried out by the entire executive apparatus, both civil and military. The mechanism by which its decisions, always in exercise of already existing statutory powers or of the reserve powers of the Crown or, exceptionally, requiring retrospective parliamentary authorization, are converted into executive action is the Cabinet secretariat, which grew up after World War I. Besides preparing the agenda of the Cabinet and circulating all relevant papers to members, the secretariat records the conclusions of the Cabinet in such a form that the government departments concerned can speedily carry them into effect.

Within the United Kingdom, Scotland has a distinct legal system based on Roman law; much of Wales is bilingual, and in some parts Welsh is the first language. Both regard themselves as nations on a par with England. England itself is divided by dialect and sentiment into regions that are in varying degree conscious of their own identity. Northern Ireland has a Parliament (located at Stormont) and a Cabinet that (under a United Kingdom act in 1920) have autonomy in purely domestic affairs. The powers of the Stormont Parliament were suspended for a year by the United Kingdom government in London in March 1971, a step necessitated by the continuing crisis in Northern Ireland.

Compared with other countries, the United Kingdom is, to a high degree, homogeneous. Practically everyone speaks English; the electoral system is uniform; the same legal system prevails throughout England, Wales and Northern Ireland; three-quarters of the population live within daily travelling distance of the centres of six conurbations.

Local government. Local government is also homogeneous. Although its roots stretch back to a period before the Norman Conquest in 1066, it was established on its present uniform basis between the years 1835 and 1888. Local authorities are subordinate corporations formed by acts of Parliament or charters. Their powers, which are executive as well as legislative and which include the levying and appropriating of financial rates, derive from statute and from judicial interpretation. Local government bodies in England, Wales, Northern Ireland, and Scotland include county (shire) councils, whose area of jurisdiction in the main follows that of the corresponding geographical counties but excludes county-borough areas; county borough councils, established in some large boroughs having a population of 100,000 upward; ordinary borough (or, in Scotland, burgh) councils; and urban district or rural district councils (in Scotland, district councils). County councils and county borough councils consist of a chairman, aldermen, and councillors; borough councils of a mayor, aldermen, and councillors; and urban and rural district councils of a chairman and councillors. In Scotland burgh councils consist of a provost, bailies, and councillors.

Local government officials

Many local-government responsibilities are subsidized, and to some extent supervised, by the central government, but local authorities are proud and careful of their independence. They are organized into national associations capable of making potent representations to the government of the day.

A royal commission was set up in 1966 to examine the system of local government; its report in 1969 formed the basis of government proposals, issued in February 1971, for a reorganization of local government planned to take effect in England and Wales in April 1974 and in Scotland in 1975. An almost uniform two-tier system is envisaged, which will largely extinguish the existing extensive powers wielded by borough councils. A large reduction in the number of local government authorities will be effect-

ed, and there are to be 59 new larger areas, called counties in England and Wales and called regions in Scotland. These, in turn, will be subdivided into districts. The new English county areas will, in the main, follow the historic county boundaries, but each new Scottish region will take in two or more of the original shires. Both counties and districts will have separate elected councils, and proposals for representation at parish or community levels within both rural and urban districts are under consideration.

Districts will be responsible for local services, such as housing and refuse collection, the larger areas for major services such as police, education, and social works; but, in six new English metropolitan counties to be formed in areas of extensive urban development, responsibility for education and social services will be given to the district councils. This follows the practice already current in London. The government of London, reformed in 1963, when its boundaries were enlarged to include 610 square miles and a population of about 7,750,000 and responsibilities were divided between the Greater London Council and 32 London borough councils, will not be further altered. Many existing boroughs or burghs, including the Scottish cities of Edinburgh, Glasgow, Aberdeen, and Dundee, often with a long history of civic autonomy, will thus lose to their respective county or region control of services such as education.

London government

The final form of British local government may be affected by the report of another royal commission, on the constitution, set up in 1969 and reported in 1971. The Conservative Government's proposals provided for a two-tier structure in which there would be two distinct forms of local authority—county councils, and district or borough councils—each with its own statutory duties and obligations.

Government proposals for reform of local government in Northern Ireland, including a reduction to 17 of the number of local authorities and abolition of the plural "company" vote, (*i.e.*, the right of an elector to vote in respect to business premises owned by him) were made in December 1967 and July 1969.

The political process. *Elections.* Voters in Britain vote in parliamentary and local government elections. The former are either general elections, in which a whole new House of Commons is chosen, or by-elections, which occur when a sitting member has died or has resigned. All other public posts are filled by appointment.

Each member of the House of Commons represents one parliamentary constituency. Constituency boundaries are drawn so that they are all roughly the same size in population—about 50,000 people. They are divided into wards and other units for the election of local government councillors. Periodically, a commission recommends to Parliament any boundary changes that may seem necessary because of shifts of population.

Registration of electors is compulsory and is carried out annually by the state. Candidates for election to Parliament or a council are chosen by the local parties. There is no primary system, on the United States model, and there could not well be any, since the timing of general elections is unpredictable.

The House of Commons is elected, not for a fixed, but for a maximum term—reduced in 1911 from seven to five years. At any time during this five years, the prime minister has the right to dissolve Parliament and call a general election. The use of this power for party advantage is checked by the probability of public resentment at such a manoeuvre. A government returned with a majority is expected to govern for the major part of the five-year life of Parliament. It is accepted that Parliament may be dissolved at any time in about the last year and a half of its life, and it rarely runs its full five years.

Duration of Parliament

An early election is, however, acceptable if the prime minister and Cabinet emerge from a general election with less than a working majority—that is, one of about 20 seats—in which case the paramount need for effective government justifies an election. This is especially so if the government majority is so slim that it might be lost altogether should a handful of by-elections run against the government.

Only three weeks' notice of a general election need by law be given, and expenses of parliamentary candidates are strictly limited by law. These provisions and the uncertainty about the timing of an election produce campaigns of unusual brevity and inexpensiveness.

Political parties. A two-party political system has existed in Britain since the late 17th century, and the two rival groups have always respectively embodied, in some form related to the main issues of the day, the conservative and radical elements in human character. This two-party system, which predominates despite the existence of minority parties such as the extremely small Communist Party, or the rump of the historic Liberal Party, is one of the most outstanding features of British politics and has done much to produce a history of firm and decisive government.

The two-party system

The political system and the nature of the great parties themselves have been shaped by the special role of the Cabinet as the centre of political authority. Control of the Cabinet has long been the prize and object of British politics, fought for from the early 18th century by Whigs against Tories, later by Liberals against Conservatives, and now by Labour against Conservatives. The practice of simple majority voting, which had always prevailed, and the final establishment of single member constituencies of uniform population size have tended to exaggerate the majority of the winning party and thus to eliminate third parties. On occasions when the two-party system has been disturbed, these factors have helped to restore it. If one of the giant parties has been, temporarily, in abeyance, two rival groups have thus usually developed among members of the predominant party and have contended for control of the Cabinet. A new party only rises to power by displacing another, as happened when Labour superseded the Liberals in the first half of the 20th century.

Progressive widening of the franchise from the early 19th century (the vote is now given to all at the age of 18) made it increasingly necessary to organize mass parties in the country in order to win a clear and firm majority of parliamentary seats in a general election. But, equally, the parties in the country depended on their representatives in Parliament and, in particular, on those who, as members of the Cabinet, drafted and introduced bills to carry through the parties' legislative programs. Thus the parliamentary parties not only became indissolubly linked with the national parties but inevitably dominated them. There grew up in the 20th century one of the most distinctive features of the British party system, namely the choice by the parliamentary parties of leaders who were then automatically accepted as leaders of the national parties.

The growth and maintenance of a mass two-party system, together with the uncertainty of the timing of a general election, produced the British phenomenon of the Opposition. Each party when out of office has to organize and conduct itself so as, if possible, to win the next general election. The decisive characteristic of the Opposition is that it is a viable alternative government, ready at any time to take office. The leader of the Opposition is paid an official salary as such.

The Opposition

Government and Opposition are ranged against each other in daily battle in Parliament. The perpetual conflict between them has caused national political issues to dominate, increasingly, local elections, while ensuring that the two main parties themselves remain continuously alert and disciplined. In the last resort the two-party system depends upon its acceptance by the British voters and upon their readiness to find satisfaction in and through one of the two major parties and to reject independent candidates or those of third parties.

The participation of the citizen. Fundamentally, the right of the citizen to participate in public affairs is exercised when he casts his vote in parliamentary or local elections. He can also participate in the political field by becoming a paid-up member or a voluntary worker for the party of his choice. Further participation in affairs of state can take the form of support of particular causes and attempts to urge Parliament to further them; or,

more often effectively, of protest outside the field of electoral politics against actions or proposed actions of the government. Vested interests and pressure groups nevertheless play a relatively small part in British parliamentary life. The disciplined two-party system means that a member's loyalty to a party normally transcends loyalty to an interest and that he is more conscious of the authority of the party whips than of the influence of pressure groups or vocal minorities. Members are not subjected to massive campaigns of letters and telegrams.

Political protest movements

Movements of protest have been endemic in British history and have been associated with many major reforms. In the 20th century, although no less frequent in occurrence, they have perhaps been more fragmented and less likely to be effective. Movements of protest against nuclear weapons and against the war in Vietnam were organized in the 1960s. Students also staged sit-ins in universities and committed some acts of violence; but, in comparison with student demonstrations in other like countries, their activities were on a small scale. Nationalist movements exist in Scotland and Wales. Supporters of the Welsh movement have organized protests to further the use of the Welsh language, and have on rare occasions resorted to sabotage, such as the blowing up of pipelines carrying water from Welsh lakes to English cities. Each of these movements secured the election of a member of Parliament in the 1966–70 Parliament, but both of these men lost their seats. In Northern Ireland a civil rights movement has in recent years worked for the ending of discrimination against the Roman Catholic minority. The result of civil violence led to the dispatch of troops from Britain. Since 1970 a number of British soldiers have been killed by snipers. Northern Ireland is the only part of the United Kingdom where tear gas has ever been used by the authorities. Violence—with many civilian casualties—continued in the early 1970s.

Trade unions directly challenged the authority of the state in the general strike of 1926. That experience convinced them that strikes for political ends would always be defeated by the government, backed by considerable popular support. They also realized that such strikes were incompatible with parliamentary democracy, in that they would usurp or frustrate the electoral processes that make possible the constant criticism and ultimate replacement of a government. Since 1926, the trade unions, which participate in politics by supporting the Labour Party by their funds, have thus used industrial action solely in furtherance of the economic interests of their members. Strikes in 1971 against the Conservative government's Industrial Relations Bill were "in token" only; the stated determination of some unions to refuse to register, as would be required when the bill became law, came close to political action but was within their legal rights under the law.

Britain has a long history of participation by the private citizen in voluntary work outside party politics. Unpaid justices of the peace, besides hearing cases, discharge many administrative functions such as the annual licensing of public houses (bars) and betting shops. The welfare services run by central and local government are reinforced by a great deal of voluntary help.

JUSTICE

Judges are irremovable and appointed. There is no election to judicial office. The Bench, as it is known, is recruited from practicing lawyers and never from people in public or elected office. The courts alone declare the law; but any act of Parliament is accepted by them as part of the law. No court can declare a statute invalid.

An accused person is presumed innocent until proved guilty. The courts strictly enforce the law of contempt to prevent newspapers or television from prejudicing by comment the trial of the accused before a jury. Accused persons and litigants in civil actions are entitled to legal aid paid by the state on a scale varying with their income. Two-thirds or more of persons in criminal cases are granted legal aid.

Legal aid

Criminal and civil cases. About 90 percent of criminal cases are tried and determined by justices of the peace, who act as unpaid magistrates, or in towns and some other places by stipendiary (paid) magistrates who are trained lawyers. Magistrates' courts sit in about 1,000 places in England and Wales and are therefore within comparatively easy reach of everyone. The remaining 10 percent of more serious crimes also come in the first place before a magistrate's court. The police must bring an arrested person within 24 hours before a magistrate, who alone decides whether he shall be remanded on bail or in custody. If they so find, they commit him for trial by a judge and jury. In 1967 an act of Parliament enabled jurors to give a majority verdict in criminal cases; the majority must be at least 10–2. Hanging for murder was abolished in 1965.

The vast majority of civil actions are tried in local county courts before paid judges. Their jurisdiction is limited by the nature of the action and by the amount of money at stake. In both these respects the jurisdiction of the courts has been steadily widened. County courts sit in over 370 places.

Higher courts. Partly in an effort to reduce delays in the hearing of criminal cases, which had been running at about four and one-half months, the higher courts were radically reorganized by an act of Parliament in 1971. As a result, the Supreme Court of Judicature now consists of the Appeal Court; the High Court of Justice with civil jurisdiction; and the Crown Court, for criminal work above the level handled by the magistrates' courts. High Court and Crown Court move between the major centres of population. The High Court hears the most important and difficult criminal and civil cases; criminal cases of less importance are tried by the Crown Court.

Appeals

Appeals in both civil and criminal matters lie from the High and Crown Courts to the Appeal Court. This court can give leave, in cases of great legal importance, for a final appeal to the judges in the House of Lords.

THE ARMED FORCES

Supreme responsibility for national defense rests with the prime minister and the Cabinet. The secretary of state for defense formulates and proposes defense policy. His ministry, created in 1970 by a merger of the three original service ministries, has responsibility for all the armed forces. The secretary of state is advised by the chief of defense staff aided by the three service chiefs.

Both the cost and strength of the forces have been reduced. Between 1966 and 1971 the proportion of the gross national product devoted to defense fell from 6.6 to 5.8 percent. At the beginning of the 1970s the Defence Budget ran over £2,850,000,000 and service manpower at 372,000 (Army, 180,000; Royal Air Force, 110,000; Royal Navy, 82,000). The armed forces are wholly raised by voluntary recruitment.

In the late 1960s military commitments east of Suez were drastically reduced, and the defense effort was concentrated in and around Europe. The prime function of the armed forces became participation in the North Atlantic Treaty Organization (NATO). At the beginning of the 1970s, more than 60,000 men were deployed in Germany and nearly 25,000 in the Mediterranean area; 37,000 were at sea with the navy, mainly in European or Atlantic waters; 259,000 were stationed in Britain, including major units in Northern Ireland acting in aid of the civil authorities. The British contribution to the Western nuclear deterrent rests with the four Polaris submarines of the Royal Navy.

SERVICES

Educational services. The government operates no schools, employs no teachers, prescribes no textbooks or curricula; nor does it control universities. There is, however, a central Department of Education and Science headed by a minister who is responsible to Parliament and who is usually in the Cabinet.

Prime responsibility for managing schools is in the hands of elected local education authorities, which allocate children among schools and appoint and pay teachers. Head teachers (principals) enjoy a high measure of independence; they cannot be given instructions on textbooks or

teaching methods. Local education authorities plan and build schools, of which there were about 19,000 at the beginning of the 1970s. They also meet the greater part of the cost of some 10,000 voluntary schools—those maintained by religious bodies. The authorities receive a central-government grant of 60 percent of their expenditure.

Secondary schools. The Education Act of 1944 established free and compulsory secondary education from 11 to 15 years old. In 1972 the school-leaving age was raised to 16.

By the terms of the act, children were allocated by examination at the age of 11 either to grammar schools, which prepared them for universities, or to secondary modern schools, from which they generally went into industry. In November 1964 the Labour government announced a reorganization of secondary education on comprehensive lines to end this segregation. All children were to go to comprehensive schools.

Comprehensive schools

Independent schools exist outside the public system. Chief of these are about 300 free-paying public schools, half of which are for girls.

Universities. Some 30 percent of the United Kingdom's 18–20-year-olds go on to some form of higher education. Britain has 44 universities, 16 of which were founded after World War II. Almost the whole cost is met by the government. The money is given to the University Grants Committee, an independent body that deals directly with the universities.

Universities are wholly independent, arrange their own courses of study and research, and appoint their own staff. They also decide about the admission of students. Recently students in some universities have achieved some measure of representation on the governing councils. Universities are relatively small: none except London has over 15,000 students; many have fewer. Although the number of places has risen rapidly, at the beginning of the 1970s, of about 120,000 annual applicants, fewer than 65,000 were admitted; some 7,000 of these were non-British, 2,000 coming from the United States.

The staff–student ratio is under 1:10—the lowest in the world. The failure rate in British universities is 13 percent (compared with 40 percent in France and the United States).

Most of those who fail to gain entry to a university go to some other form of higher education. Local education authorities maintain about 700 colleges providing mainly technical and commercial courses: some of these institutions award degrees of university level. There are also nearly 170 colleges of education for the training of teachers, who can also gain degrees.

All students are entitled to grants varying with the income of their parents: 260,000 were in receipt of grants at the end of the 1960s.

The Open University

In January 1971 the Open University—something unique of its kind in the world—was launched. It provides for adults who missed the chance of university education, and it uses television, radio, and local study and lecture courses. Applicants have to be accepted for a number of places limited at any one time by the availability of teachers. Degrees are awarded as at any university.

Health and welfare services. *The National Health Service.* A complete national health service began to operate on July 5, 1948. Every man, woman, and child is entitled to medical treatment of every kind, free at the moment of need. The only exceptions are a number of charges that meet part of the cost of dental work, spectacles, and prescribed medicines. All these charges are remitted for children, old-age pensioners, and people below a certain income level. The charges meet 4 percent of the cost of the National Health Service. The service is voluntary: doctors may, if they wish, take only fee-paying patients, but 98 percent of general practitioners (numbering 24,000 in England and Wales at the beginning of the 1970s) were in the service, as were almost all the 10,000 or so dentists. Some 2,500 hospitals provided entirely free treatment. A small number have opted out of the service—most of them run by religious orders or maintained for special groups, as in the case of the Italian, Jewish, and trade-union hospitals. Private nursing homes are permitted, but they must be registered.

The normal doctor–patient relationship is maintained. A patient can freely choose or change the doctor with whom he is registered, and a doctor may decline to have a patient on his list. A doctor receives from the state a basic practice allowance, payments for ancillary staff, and a capitation grant for each patient on his list, limited to a maximum of 3,500. He receives a higher fee for every patient over 65, for night visits, and for practicing in an underdoctored area. He can also take private patients.

Some of the total cost of the National Health Service comes from central or local government.

General management and discipline of the family practitioner service is exercised by about 150 local bodies, half of the members of which are appointed by doctors, dentists, and pharmacists. Hospitals are supervised by 20 regional boards, which receive government grants and are responsible for planning and building hospitals.

The local authorities have a legal obligation to provide maternity and child-welfare services, home nursing, health visiting, domestic help for those in need, and the care and aftercare of illness, including mental disorder. They organize ambulance services and build and maintain health centres.

Social security. The social security system makes up a vital part of the welfare services. It, too, was established in 1948 and is based on compulsory insurance. Some 25,000,000 employees pay, by law, a weekly contribution, which is supplemented by a charge upon the employer. The state meets the balance of the cost.

In return for his contribution, every employee is entitled to a retirement pension (at 65 for men and at 60 for women) and to cash benefits in unemployment or sickness. The duration of these benefits depends on the number of contributions paid.

Retirement pension

Should these be exhausted, the employee can draw supplementary benefit, as can anyone whose income falls below a certain level, even if in work. Supplementary benefit depends upon a means test, and the cost is borne wholly by the state. It also meets the entire cost of family allowances for all children after the first so long as they remain in full-time education.

The total cost of the social services to central and local government was £9,750,000,000 for the year 1971–72 alone.

A beginning has been made in changing this system of flat contributions and flat benefits to one based on a percentage of wages.

In 1965 a statutory system of redundancy or severance pay was introduced. An employee who loses his job through no fault of his own receives a lump-sum payment. The cost is met in part by his employer and in part out of a fund made up by a levy on all employers.

Housing. Local authorities have a legal obligation to see that housing in their area is adequate. This they fulfill mainly by building houses and apartments (flats) for rent. The central government lays down mandatory minimum standards, and local authorities maintain waiting lists and allocate houses according to need. The cost is met in part by government subsidies, in part by rents collected from the tenants, and in part by contributions from local taxation. Since 1971 local authorities have had a statutory duty to operate rent rebates. They must charge their tenants the true economic rent and make rebates to those whose income falls below a certain level. Local authorities can make grants up to 50 percent of the cost, up to a certain limit, of improving privately owned houses, for instance by the installation of a bathroom.

Local authorities own and administer about one-third of the 19,000,000 houses in the country; half that total are owner occupied, and the remainder are rented from private landlords. In the quarter century since the end of World War II, some 7,000,000 dwellings have been built by private and public enterprise. It is estimated that almost another 4,000,000 must be put up before Britons are properly housed. Since the war, 200,000 new dwellings have been constructed in 32 New Towns that have been built or are being built. They are at a considerable dis-

New Towns

tance from the conurbations and are carefully planned with separate industrial areas and traffic-free precincts.

The whole country is now subject to town and country planning by eight regional boards, which control where new building or the substantial alteration of existing structures may be undertaken.

Police services. There is in Britain no national police force nor any minister exclusively responsible for the police. Each provincial police force is maintained by a police authority—a committee elected by a number of local authorities—which determines the establishment of the force and provides and maintains buildings, vehicles, and other equipment. It also appoints and dismisses the chief constable, who, however, has sole right of appointment, promotion, discipline, and deployment of his force and who alone decides police action in individual cases.

The home secretary is the police authority for the Metropolitan Police in London. Broadly, the commissioner in charge of the Metropolitan Police has status similar to that of a chief constable. The famous Scotland Yard (the criminal investigation department of the Metropolitan Police) helps other police forces on request and handles the British business of the International Criminal Police Organization (Interpol).

The supervisory powers of the home secretary over the police forces of the country have been steadily extended by acts of Parliament. In 1856 he was empowered to appoint officials to inspect all police forces; those forces certified by the Home Office to be efficient received a government grant, which now amounts to 50 percent. In 1919 the home secretary was given the right to make regulations dealing with pay, pensions, and conditions of service. In 1964 he was further empowered to compel the amalgamation of police forces, and, by 1970, the number of police forces had been reduced by one-third, to 67. These are further grouped into eight regions for the provision of forensic-science laboratories, wireless services, criminal records, and crime squads.

The total strength of the police force in the United Kingdom was about 107,000 in the early 1970s. In addition, chief constables appoint special constables, unpaid volunteers who can be called upon to act as auxiliaries to the police. Police authorities appoint and pay 5,000 traffic wardens, who have limited powers in relation to parking offenses and the direction of traffic.

Traffic wardens

The British police wear a uniform that is nonmilitary in appearance. Their only regular weapon is a short wooden truncheon, which they keep out of sight and which may not be employed except in self-defense or to restore order. Police engaged on dangerous missions may carry firearms for that specific occasion.

SOCIAL CONDITIONS

Wages and cost of living. By 1970 weekly earnings of full-time manual workers averaged £28 a week, and, over the previous five years, earnings of all workers increased by almost a half, and the retail-price index by over a quarter, giving, over this period, a 20 percent rise in the standard of living.

The best measure of the cost of living is a combination of the general index of retail prices with the consumer price index. For the economically troubled 1960–70 period, this indicated a nearly 50 percent rise in the cost of living, and, on these figures, the average real standard of living rose in that decade by about 17 percent.

Averages of these kinds are significant, but they conceal many important variations. Workers in the most powerful trade unions tended to do better than the average, while those on fixed incomes, for example, found them eroded by an inflation not far short of 50 percent in ten years. All social security benefits, including retirement pensions, are reviewed about every second year and increased in an attempt to make good any increase in the cost of living.

Health conditions. Improved standards of living and the steady extension of free medical services till they covered the whole population are reflected in the vital statistics for England and Wales.

Deaths from tuberculosis, for example, fell by 90 percent between 1938 and the mid-1960s, while deaths from diphtheria have virtually disappeared as a result of free and nearly universal vaccination of children. Between 1947 (the year before the introduction of the National Health Service) and 1970, infant mortality fell by 57 percent to 18.5 per 1,000. Over the same period maternal mortality fell by 86 percent, to 0.18 per 1,000. Decreases in mortality rates are due, in part, to lengthened life expectancy—itself an index of a nation's health conditions.

Britain is one of the few countries that is free from rabies. This is partly because it is an island. Wildlife cannot invade it from other countries, and all cats and dogs brought into the country are compulsorily quarantined for a period of nine months.

The Clean Air Act of 1956 enables local authorities to establish smokeless zones in which the emission of smoke from all chimneys is prohibited. By 1968 smoke-control orders affected 3,500,000 premises, including 1,700,000 in London, which can now claim to be the cleanest great city in the world, almost entirely free from smog.

Smokeless zones

Social and economic division. By 1971 total personal income before tax was about £47,000,000,000, equivalent to £855 a year to every man, woman, and child in the land. In 1969 the actual distribution of income before tax was as follows: 7,000 people had incomes of over £20,000 a year; 16,600,000 had incomes under £1,000 a year; 2,250,000 had incomes under £250 a year. These extreme inequalities were mitigated by direct taxation, which reduced the total income of all those earning £20,000 a year gross from £221,000,000 to £56,000,000 a year.

The distribution of the ownership of wealth (that is, of property and capital) remains unequal: 14,000,000 people owned net wealth of over £1,000, and their total net wealth was £89,000,000,000; some 20,000 individuals, or about 0.15 percent of all these wealth owners, owned almost 8 percent of this total.

Educational divisions tend to accentuate the social divisions caused by the distribution of net income and wealth. Their original economic class still to a considerable extent determines the chances of access of young people to higher education, and this in turn is the main avenue to socially approved and better rewarded careers.

Educational divisions

Reform and reorganization is, nevertheless, steadily mitigating, indeed reversing, the divisive effects of the educational system. The introduction of grants for all students and the spread of comprehensive schools have markedly increased the proportion of students of working class origin in higher education. These educational changes, together with the rise in the real incomes of workers, has carried much farther the social fluidity that, in varying degree, has for centuries characterized British society.

(P.G.W.)

Cultural life and institutions

Widespread changes in the United Kingdom's cultural life have occurred since 1945. The most remarkable was perhaps the emergence first of Liverpool, then of London in the 1960s as a world centre of popular culture. The capital soon became a mecca for pleasure-seekers of all varieties, replacing, for many of them, the perennial popularity of Paris. The Beatles were only the first and best known of the many British rock-music groups to bring new dimensions to the musical tastes of Europe and the Americas. British designers for a time led the world as innovators of new styles of dress for both men and women, and the brightly coloured, often extreme, oufits sold in Carnaby Street and King's Road shops perhaps became more symbolic of Britain than the traditionally staid tailoring of Savile Row and neighbouring streets, while flea markets as sources of bizarre clothing flourished in many large towns, particularly London. The long-established addiction of the British to betting and gambling was recognized in the easing of legal restrictions during the 1960s, which led to the establishment of casino-style gambling in London and other large cities, as well as to a boom in horse-racing betting shops.

The new cultural milieu

More traditional fields also have experienced renewed vigour. In the decade after World War II, the British film

industry came of age and set a standard of excellence that, by and large, it has maintained. The steady stream of productions on London and provincial stages includes many new works by a large group of dramatists who are nearly as well represented on stages from New York to Melbourne, Australia. Beginning in the 1930s, Britain has enjoyed an eminence as well in the visual arts, most notably in sculpture, in which a sense of the organic unity of form and material asserted itself.

The social settings of the arts

Underlying these changes were several important social developments. Most evident was the rising standard of education, the school-leaving age having been extended from 15 to 16. Increasingly large numbers of pupils were going on to higher education with a major expansion in the number of universities and other institutions of higher education. By the early 1970s, Britain had 44 universities as compared with 17 in 1945. Within the schools, especially since the early 1960s, new emphasis was placed on creative activity and play. In society in general there was an increase in leisure, and, until the late 1960s, steady employment and improved wages for younger workers markedly increased people's capacity to take part in all kinds of culture and recreation.

During this same period, successive governments have shifted their policies toward the arts. The Arts Council, formed in 1946, provides widespread support for many kinds of contemporary creative and performing arts. This has coincided with a great expansion of the cultural market, mainly commercial, and of audiences and viewers for the arts generally. The ordinary person's life was greatly changed by the more sophisticated standards of design in domestic equipment and home furnishing and decoration—as well as the impact of television and radio. These changes have been accompanied by continuous argument about their nature and bearings and about the effects on the arts of an expanded audience. A clash of tastes and values between generations and, to some extent, between social classes has been sharp, and the quality of the national life increasingly has been judged —favourably and unfavourably—in terms of current work in the arts. By comparison with any earlier period, this is a unique situation in Britain.

DEVELOPMENTS IN THE ARTS

A notable postwar development has been proliferation of festivals involving one or several of the arts, of which the Edinburgh International Festival of Music and Drama is only the most ambitious. In the late 1960s the popular arts began to follow suit, and in 1970 a huge three-day "pop festival" took place on the Isle of Wight.

Literature. Books reached a majority public in Britain for the first time during the 1950s, and well over 30,000 new titles were appearing annually by the 1970s. Paperbacks, introduced in the 1930s, transformed all previous ideas of the extent of the reading public. Since World War II, the novel, social reporting, and criticism have attracted major attention. The several new movements in poetry have included vigorous revival of live readings for audiences, a movement perhaps sparked largely by the Welshman Dylan Thomas. Commercially, however, the many new little magazines often have had difficulty in surviving, and the financial situation of all but a few best selling authors has not improved in the proportion that might be expected from an enlarged readership.

The performing arts

Theatre. During the 20th century, the number of theatres in Britain has fallen to less than one-half of those existing in 1900, and the financial situation of the living theatre has been and remains precarious. At the same time, there has been continuous dramatic experiment, principally in the "little theatres" and in independent experimental companies, from the revival of verse drama in the 1930s and 1940s, through Joan Littlewood's Theatre Workshop in the 1950s and early 1960s, and to the English Stage Company at the Royal Court Theatre, London, from the 1950s onward. Many writers have turned back to the theatre or have developed through it: the work of John Arden, Arnold Wesker, John Osborne, and Harold Pinter is only the best known. In the 1950s a number of writers—playwrights, novelists, and critics—who were dubbed collectively as "the angry young men" brought a new thrust of social criticism to British letters, perhaps most clearly evident in Osborne's *Look Back in Anger* (performed 1956). In 1968, after theatre censorship by the lord chamberlain ended, for a time the most obvious beneficiary of the new freedom was eroticism, though the resulting wave of staged nudity, often gratuitous, often proved unarousing. The National Theatre Company began in 1963, and a National Theatre is being built on the south bank of the Thames in Central London. The Royal Shakespeare Company, based at Stratford-on-Avon and in London, has been vigorous and generally successful and, like other new developments, is supported by the Arts Council. Such avant-garde ventures as theatre clubs of the restaurant cellar type and London's short-lived Arts Laboratory helped to ferment a counter-West End climate that, however, often shared orthodox theatre's preoccupation with sex and politics as subject matter, while breaking some new ground in the development of often anarchic, experimental, theatre techniques. The many provincial theatres and companies—some of them new, such as those at Coventry and Nottingham—provide further assurances of the continued vitality of this traditionally richest of British arts.

Music. Music has gained a vast new public in Britain since the 1930s, at first through the influence of radio and, more recently, through the great expansion of record buying. Concerts draw substantial audiences in many of the larger towns, but the financial situation of orchestras has remained precarious and requires regular subsidy. There is also a continuing shortage of adequate concert halls in many towns. In the same period, there has been a remarkable expansion of popular music. In the 1960s, British rock groups acquired international fame, providing models for similar groups in virtually every city of the world.

Opera. Before 1945 it had proved very difficult to establish a permanent English opera company, and most singers and even choruses had come from abroad. New arrangements for a national opera theatre were developed at Covent Garden in London, between 1945 and 1947, and there is now a world-renowned resident company. In addition to the international repertory, new English-language operas by such composers as Benjamin Britten, Sir William Walton, and Michael Tippett have been performed. Though audiences are substantial, the heavy deficit has to be met partly by an Arts Council grant. Standards of performance and production have made Covent Garden one of the world's great opera houses. The Sadler's Wells Company, performing usually in English and undertaking more extensive tours in Britain and abroad, in 1968 moved to a larger London theatre, the Coliseum. The English Opera Group, associated with the Royal Opera Company, presents works of smaller scale, a number of them new and experimental.

Covent Garden

Ballet. English ballet enjoys a high international esteem both for its direction and dancing. In 1956 the Sadler's Wells Ballet, formed in 1931 under Ninette de Valois, became the Royal Ballet. From 1945 it was based at Covent Garden, where it is backed up by a Theatre Ballet and the Royal Ballet School. The company has won the highest reputation, both in the classical repertory and in the production of new works by English choreographers and composers. London's Festival Ballet has a mainly classical repertory, while the Ballet Rambert, a leading pioneer in English ballet since 1930, has returned to the experimental role of its earlier years. In spite of a shortage of suitable provincial theatres, a limited touring program is maintained by most companies.

Film. British film art has been affected radically by the decline in attendances, by its exposure to the climate of the American market, and by what is widely regarded as a restrictive distribution system. In the late 1940s a series of social comedies made by Ealing Studios, such as *Kind Hearts and Coronets* and *Passport To Pimlico*, brought international acclaim to the British film industry. The most valuable new work has come, however, from relatively short-lived independent companies. Among important directors are Tony Richardson, Lindsay Anderson,

Joseph Losey, Karel Reisz, Ken Loach, and Ken Russell. The nearness of film studios to the London stages has allowed directors and actors to pursue careers in both mediums to an extent unknown in the United States. A new school of actors emerged in the production of genre films based on working class and provincial life. It was at its finest in the late 1950s and early 1960s. Important films have been made in Britain by major foreign directors, including the Italian Michelangelo Antonioni and the Frenchman Jean-Luc Godard. Organizational difficulties have severely restricted British film makers, and many of the younger generation have turned to the experimental work of the underground cinema, which is exhibited mainly by the many thriving film societies or on television.

Painting and sculpture. The revival of the visual arts in Britain that began in the 1930s was effected largely through the work of the generation of painters born between 1890 and 1910: Ben Nicholson, Ivon Hitchens, Victor Pasmore, Sir Stanley Spencer, John Piper, and Graham Sutherland. They have been followed by such artists as Francis Bacon, John Minton, John Craxton, John Bratby, David Hockney, and Bridget Riley. Among sculptors, Henry Moore and Barbara Hepworth were followed by Reg Butler, Kenneth Armitage, Lynn Chadwick, Elisabeth Frink, and Anthony Caro. Public interest was stimulated by sponsored exhibitions both in the national galleries and throughout the country and by the acquisition of new works of art for many public buildings and developments. Public sponsorship of individual artists has been undertaken, but commissions and purchases are now more common. Experiment among the younger generation has been not only in the pop-art field and in the use of new materials but also in the interaction between art and industrial design.

Design. A wide field of design, ranging from architecture to dress fashions, has experienced a remarkable growth of confidence and experiment. Though most apparent in inexpensive everyday objects—gaily coloured paper bags, for example—it shows up as well in furniture, textiles, pottery, toys, and, above all, clothes. Many young artist-designers now choose to work not only in the industrial field but in that part of it producing for the mass market. Since the late 1950s, the look of Britain, not only in the capital but very widely in the provinces, has been changed quite remarkably by their efforts, though a heavy legacy of bleak and dull industrial townscape still survives. Glass and steel skyscrapers owing their genesis to the modern international style of architecture have risen virtually alongside buildings echoing a centuries-older Britain.

Industrial and commercial arts

Much of the excitement of this new work has been reflected in the art colleges, where controversies about the relations between art and design and about the proper place of art and design in the educational complex date at least from the 19th century. Public interest in design is fostered by the Council of Industrial Design, a government-grant-aided body established in 1944, which runs selective and changing displays of well-designed domestic products in London and Glasgow, maintains a Design Index of more than 10,000 well-designed products, and promotes good design standards in industrial equipment.

THE MASS MEDIA

The communications media—press, publishing, broadcasting, and entertainment—provide mass coverage in Great Britain, but their scale varies from the multi-million audiences for television, radio, and national newspapers to the small minority audiences for local papers, specialist periodicals, or experimental theatre and film that may count their following in a few thousands or even hundreds. Though the mass media have been subject to the economic trends toward concentration in large single-ownership groups, variety has been preserved in the expression of political views and the satisfaction of cultural tastes. A tradition of editorial independence is recognized in newspaper groups, which give substantial freedom to the running of each of their newspapers and periodicals. This philosophy of independence extends to the state-owned British Broadcasting Corporation (BBC) and also to the Independent Television News (ITN), the news service that supplies the commercial television companies. It is well understood that broadcasting and the press, whether publicly or privately owned, will resist political pressures from government. The BBC, with a monopoly of radio until 1972, and with two out of three television channels, has been in practice as critically independent of government as has privately owned broadcasting media. A similar philosophy animates the work of the Arts Council, to which the government allocates a flat sum to cover all its work—with no strings attached. The Arts Council chooses its beneficiaries and distributes funds to a large number of organizations and individuals, so that creative independence may be preserved.

The tradition of editorial independence

The press. The structure of the British newspaper industry is derived from the dense population and the availability of a closely knit rail network, which has enabled newspapers published in London to sell all over the country the next morning. Hence a sharp division has emerged between national newspapers and the regional and local press. Both in sales and reputation, the national papers dominate. Within the national-newspaper business, a distinction has grown up between popular papers with multi-million circulation, and quality papers with relatively small sales. Four populars account for about 85 percent of the total morning paper circulation. In both groups, competition for circulation and advertising has been acute in a market in which total sales have been declining since the late 1950s, and some advertising has been diverted to television. With continuously escalating labour costs in the printing industry, the financial viability of some of the most prestigious papers, such as *The Times, The Guardian,* and *The Observer* has been precarious. Both *The Times* and *The Guardian* have been run at a heavy loss, covered by the profits of other papers in their respective companies.

Though many national papers have been in difficulties and some have disappeared in recent years, the British remain among the world's most avid newspaper readers, buying more than 460 copies for every 1,000 population in the early 1970s. There are more than 130 regional daily papers, most of them evening papers and almost all of them benefiting from a monopoly situation in their own area. There are more than 1,000 weekly magazines, ranging from some popular women's magazines with circulations around the 2,000,000 mark down to a host of small specialist magazines. A loss in sales of mass-circulation women's weeklies has been accompanied by gains in some monthly magazines.

The financial insecurity of many newspapers was to some extent aggravated by excessive dependence on advertising revenue. From 1970, however, the sale price of most newspapers was substantially increased, in some cases doubling within a period of two years. Dependence on advertising, however, did not in general make newspapers subservient to advertisers. Competition among the populars, already tending to concentrate on entertaining news such as sports, crime, and human interest at the expense of the less compelling serious news, led, however, to an aggressive exploitation of sex interest. The standards of the British press were watched over by the Press Council, which had little influence in matters of taste but helped to secure the basic traditions of factual accuracy and fairness.

The variety of the newspaper and periodical press was sustained by some of the newer and relatively cheap printing techniques, which made it possible for fringe interests to publish their own papers cheaply and provided scope for the "underground press," which was probably rather more successful in outraging conventional opinion than influential in spreading its views of a "dropout," or alternative, society.

Broadcasting. A monopoly of both radio and television broadcasting was in the hands of the BBC, established as an independent public corporation in 1927, until the establishment of the Independent Television Authority (ITA) in 1954 to provide the facilities for a number of commercial television program companies. In 1972 the ITA became the Independent Broadcasting Authority (IBA) with responsibility also for commercial radio. The

The BBC and ITA

BBC draws its revenue from license fees (on a scale fixed by the government) from persons owning receiving sets. The IBA owns transmitters that it leases to the commercial program companies, which obtain their revenue from selling advertising time. The BBC operates two television channels and the IBA one (with a second projected). Since 1970 all three have been in colour. Until 1972 the BBC had a monopoly of radio, operating national radio programs and a number of local stations. From 1972 Parliament authorized the creation of local commercial radio stations financed by advertising. The BBC's four programs were Radio 1 (mostly popular music), Radio 2 (mostly light music), Radio 3 (mostly classical music, and some programs of an intellectual content in the tradition of the BBC's famous Third Programme), and Radio 4 (mostly news, current affairs, and speech programs). In its second television channel the BBC has tended to put programs of above-average intellectual and cultural interest—competition that the IBA commercial channel meets with its own cultural programs. The BBC also operates a comprehensive external service, broadcasting around the world in 40 languages, as well as a world service in English 24 hours a day.

The BBC has won an international reputation for the impartiality and objectivity of its news services. The concept of public-service broadcasting requires the BBC to inform, to educate, and to entertain. As a public service, the BBC must maintain a fair balance in political argument and must not express political views of its own. Similar requirements have been placed on the IBA. Both the BBC and the IBA supply educational programs for schools and for adult studies. The Open University, offering degree courses to people without formal academic qualifications who work at home, is based on educational programs broadcast by the BBC backed by correspondence courses.

Both the BBC and IBA are public bodies that in the last resort can be controlled by the government, and Parliament can alter the terms of their authority. The government has the statutory power to veto a broadcast, but this power has never been exercised, and the BBC and the IBA program companies are not interfered with in the day-to-day management of their affairs. Furthermore, on such rare occasions as the Suez crisis of 1956, when governmental pressure has been brought to bear on the BBC, the broadcasters successfully have asserted their independence. There have been complaints by politicians, however, that individual broadcasting producers sometimes have misused their power, and objections by politicians partly account for the disappearance of political satire, which floundered during the mid-1960s, from the BBC. Some viewers have complained persistently about what they consider to be the BBC's "permissive" attitude to sex.

POPULAR PURSUITS

Statistically it could be argued that the British have become a nation of television watchers. Almost every family has a television set. Viewing is said to average about four hours a day, and audiences for the most popular programs exceed 20,000,000. Nevertheless, a good many British pursuits are what they used to be. With most people working a five-day week and an eight-hour day, or thereabouts, there is time for gardening, going round to the pub for a drink and gossip, fishing, walking, looking after the pets (dogs, cats, rabbits, white mice, what-have-you), filling in the football pools in the hope of winning a fortune, fixing this and that in the home with a do-it-yourself kit, playing the latest pop records, and so on—predominantly, it is safe to say, home-based pursuits. An outing in the car is a growing weekend habit, and the British have been learning to eat out more than they did, but most of the time (when they are not at work) they are to be found at home. (Ed.)

Prospects for the future

The period following World War II saw the final dissolution of the British Empire; one by one, former colonies were granted independence until Britain stood more really alone even than it had been in the short period in 1940, when it was the only power effectively at war with Hitler's Germany. The resultant loss of control of a vast network of ports and airports of strategic and military value across the world drastically reduced Britain's weight in international deliberations, while the transfer to some new nations of ownership of the production of raw materials in their countries, as in the case of Zambia copper and Ceylon (now Sri Lanka) tea, contributed to Britain's endemic economic troubles. Thus, the history of Britain as a world power seemed almost to be ended. Its membership in the European Economic Community (EEC), made effective by its formal adherence (on January 22, 1972) to the Treaty of Rome, did open to the country a new sphere of influence and provide the chance for the development of a new role in the world. The world is divided into large economic and political blocs: the Soviet Union, the United States, the EEC, Japan, and China; as part of one of these blocs, Britain should be both more secure and more able to make worthwhile contributions to world developments than if it had contributed alone.

Significance of EEC membership

It is important that Britain's leaders expect that, after joining the EEC, Britain's links with its independent Commonwealth of Nations will be no less close and intimate than in the past. This applies particularly to its family relationship with the former dominions of Canada, Australia, and New Zealand. Britain will also maintain its ties with the countries of the Indian subcontinent, with countries in Africa that were formerly British colonies, and with other countries, such as Singapore and Malaysia. Its "special relationship" with the United States is expected to continue. All these ties will continue to enhance Britain's reputation as a world power, but increases in its real influence are likely to derive primarily from the opportunities for increased commerce and industrial strength from which it is hoped the country will be able to profit as a member of the EEC.

It is hoped by its leaders that the economic benefits occurring to Britain from membership in the EEC will favourably affect its investment and employment position and create a better economic growth rate. As a member of the EEC, Britain is more likely to attract international investment, particularly in advanced industrial and technological concerns, which generate the greatest expansion of exports. Such expansion should help employment, and it was hoped that, in time, the high rate of unemployment (about 1,000,000 persons were out of work early in 1972) would be reduced to the level generally prevailing in the countries of western Europe. Although Britain at the time of joining the EEC had a strong balance-of-payments position, its membership should ease the general problems of sterling as an international currency, and currency support may well be developed in a European as well as in a world context.

Britain also has every reason to hope for a better growth rate as a member of the EEC; and it is from such an increase that the country's immense social-service budget and its unrivalled National Health Service must be financed. It is, therefore, not only hoped that the level of prosperity will rise but that continued and improved help for the aged and infirm may be guaranteed. Britain is proud of—and determined to maintain—its social services and its educational record. In 1972 considerable extra financial support was being given to the primary-school range of education, and, in due course, with planned expansion of higher education, the proportion attending courses at universities, institutes of technology, or technical colleges is expected to approach a little more closely that of students receiving higher education in the United States.

Prospects in education

In joining the EEC, Britain will have the opportunity to take part in a unique political experiment. With its long history of parliamentary democracy and its record of tolerance, ability to compromise, and ingenuity, Britain has much to offer, and the experience of its excellent civil service should enable it to assist in solving the EEC's administrative problems. In facing the future, whether of a confederation of nations or of the more

remote possibility of a European federal state, Britain will presumably be unwilling to prejudice the existence of its monarchy or the independence of its Parliament. All treaties involve some degrees of abrogation of sovereignty, but Britain will be ready to sign conventions and treaties in the confidence that its island sovereignty will not be essentially impaired.

In the future, Britain will lend the aid of its armed forces to European as well as to North Atlantic Treaty Organization (NATO) defenses. With France it will continue to possess nuclear energy and weapons.

By widening its boundaries under the Treaty of Rome, Britain will have unique opportunities to mingle its culture with that of Europe. A strong and more homogeneous Europe will be to the advantage of the developing countries. There is probably no problem in the world more severe or poignant than that of the wide discrepancy in wealth and well-being between the rich and poor nations. An increased investment and growth rate will give Britain the opportunity to maintain and, if possible, increase its overseas-aid programs. (Bu.)

United Nations

The name United Nations was adopted during World War II to denote the nations allied in opposition to the so-called Axis powers—Germany, Italy, and Japan—and later adopted as the name of the postwar world organization. The term first achieved worldwide prominence when the Declaration of the United Nations was signed by 26 states on January 1, 1942, setting forth the war aims of the Allied powers.

The first major step toward the formulation of a permanent organization was taken at the Dumbarton Oaks Conference, a meeting of diplomatic experts of the Big Four powers (U.S., U.K., U.S.S.R., China) held August 21–October 7, 1944, at Dumbarton Oaks, an estate in Washington, D.C. The proposals developed at the meeting did not represent a complete plan of organization. Furthermore, the United States and the United Kingdom became stalemated with the Soviet Union on two essential issues: (1) on the voting system of the proposed Security Council, which later became famous as the "veto problem"; (2) on membership because the Soviet Union demanded seats in the General Assembly for all of its constituent republics. Roosevelt, Churchill, and Stalin finally resolved these two issues at the Yalta Conference and also agreed that the new agency would include a trusteeship system to succeed the League of Nations mandate system.

The Dumbarton Oaks proposals, as modified at the Yalta Conference, thus formed the basis of negotiations at the United Nations Conference on International Organization (UNCIO), which convened at San Francisco on April 25, 1945, and drafted the Charter of the United Nations (UN). The Charter was signed on June 26 and entered into force on October 24, 1945, by which time the Big Four, France, and a majority of the other signatories had deposited their ratifications.

San Francisco Conference

The San Francisco Conference was attended by representatives of the 46 states that had signed the Declaration of the United Nations. Four other states (Ukrainian S.S.R., Belorussian S.S.R., Argentina, and Denmark) were admitted during the conference. Poland, not present at the conference, was permitted to become an original member of the UN, which thus began with 51 members.

The San Francisco Conference was the first major international conference for two millenniums not dominated by Europe. Not only was it remote from Europe geographically but only nine continental European states west of the U.S.S.R. were represented. The 21 American republics, seven Near Eastern states, six Commonwealth nations, three Soviet republics, two Far Eastern, and two African states represented all parts of the world. Nine enemy states (Germany, Italy, Japan, Hungary, Austria, Romania, Bulgaria, Finland, and Thailand), eight neutral states (Switzerland, Spain, Portugal, Sweden, Ireland, Afghanistan, Iceland, and Yemen), and Poland, which was unable to organize a government until the conference was over, were not represented.

The international Secretariat provided interpreters and translators and distributed documents and speeches daily in the five official languages (English, French, Spanish, Russian, and Chinese). The chairmanship of the plenary sessions rotated among the Big Four. The private consultations of the Big Four, to which France was later added, exerted a greal deal of influence. The rule of unanimity, usually adopted by political conferences, was abandoned. Measures could be carried in committees, commissions, and plenary sessions by a two-thirds vote.

Political issues arose, especially between the Western powers and the U.S.S.R., over the admission of Ukrainian S.S.R., Belorussian S.S.R., and Argentina; the recognition of a government of Poland; and the extension of the great-power veto in the Security Council to discussion as well as to recommendations and decisions. These controversies were settled by compromises. The issues concerning domestic jurisdiction versus international competence for the protection of human rights and the promotion of economic and social welfare, the status of colonial areas and of regional and defense arrangements, and great-power dominance versus the equality of states involved other groupings. In these matters the small states, the Oriental states, and the Latin American states succeeded in obtaining modifications of the Dumbarton Oaks proposals. (Q.W.)

PURPOSES AND MEMBERSHIP

The first article of the Charter outlines the purposes of the organization, declaring that the primary objective of the United Nations is the maintenance of international peace and security. The organization is also dedicated to the development of friendly relations among nations, based on the principle of equal rights and self-determination of peoples; to the achievement of international cooperation in solving international economic, social, cultural, or humanitarian problems; and to serving as a centre for harmonizing the actions of nations in the attainment of these common ends. Some of the basic principles of the United Nations, as outlined in Article 2 of the Charter, are the following: the United Nations is based on the sovereign equality of its members; disputes are to be settled by peaceful means; members undertake not to use force or the threat of force in contravention of the purposes of the United Nations; each member must assist the organization in any action it takes under the Charter; and states that are not members of the United Nations are required to act in accordance with these principles insofar as necessary for the maintenance of international peace and security. Article 2 also stipulates that, except to take enforcement measures, the organization shall not intervene in matters within the domestic jurisidiction of any state.

Original members

The original members of the United Nations were Argentina, Australia, Belgium, Belorussian S.S.R., Bolivia, Brazil, Canada, Chile, China, Colombia, Costa Rica, Cuba, Czechoslovakia, Denmark, Dominican Republic, Ecuador, Egypt, El Salvador, Ethiopia, France, Greece, Guatemala, Haïti, Honduras, India, Iran, Iraq, Lebanon, Liberia, Luxembourg, Mexico, The Netherlands, New Zealand, Nicaragua, Norway, Panama, Paraguay, Peru, the Philippines, Poland, Saudi Arabia, South Africa, Syria, Turkey, Ukrainian S.S.R., Union of Soviet Socialist Republics, United Kingdom, United States, Uruguay, Venezuela, and Yugoslavia.

New members are admitted to the United Nations on recommendation of the Security Council and by a two-thirds vote of the General Assembly. They must be peace-loving states that accept the obligations contained in the Charter and be able and willing to carry out these obligations. The requirement of concurrence of the permanent members of the Security Council was for many years a serious obstacle to the admission of new members. By 1950 only nine of 31 applicants had been admitted: Afghanistan, Iceland, Sweden, Thailand (all in 1946);

Pakistan, Yemen (1947); Burma (1948); Israel (1949); and Indonesia (1950).

A number of efforts had been made by the General Assembly to break the deadlock. In the tenth assembly session (1955) there was wide support for a "package deal" sponsored by 29 members under the leadership of Canada. Though it became necessary to drop Japan and Mongolia from the package, the proposal was approved by the Security Council in modified form, and the General Assembly voted to admit 16 new members: Albania, Austria, Bulgaria, Cambodia, Ceylon, Finland, Hungary, Ireland, Italy, Jordan, Laos, Libya, Nepal, Portugal, Romania, and Spain.

In its 11th session (1956–57) the General Assembly voted to admit Ghana, Japan, Morocco, The Sudan, and Tunisia. The Federation of Malaya (later Malaysia) was admitted in 1957. In 1958 the Egyptian and Syrian delegations consolidated into one, representing the United Arab Republic (U.A.R.); in December 1958 Guinea became a member.

In September 1960, 16 nations were admitted: Cameroon, Central African Republic, Chad, Cyprus, Dahomey, Gabon, Ivory Coast, Malagasy Republic, Mali, Niger, Republic of Congo, Democratic Republic of the Congo (former Belgian Congo), Senegal, Somalia, Togo, and Upper Volta. Nigeria was admitted in October 1960 and Sierra Leone in September 1961. In October 1961 Syria, having seceded from the U.A.R., resumed its separate membership; Mongolia and Mauritania were admitted in October 1961 and Tanganyika in December. Rwanda, Burundi, Jamaica, and Trinidad and Tobago were admitted in September 1962, followed by Algeria and Uganda in October. Kuwait was admitted in May 1963 and Zanzibar and Kenya in December, bringing the membership to 113. When Tanganyika and Zanzibar in April 1964 signed an agreement to unite under the name of Tanzania, the total was reduced to 112. With the admission of Malawi, Zambia, and Malta in December 1964, the total membership reached 115.

Indonesia, by letter of January 21, 1965, informed the United Nations that it was withdrawing from the organization, but on September 19, 1966, it sent another letter stating that it was resuming "full cooperation." Without formalities Indonesia resumed participation in the activities of the UN as if it had never been absent.

Singapore, The Gambia, and Maldives were admitted to membership in September 1965. In 1966 Guyana, Botswana, Lesotho, and Barbados were admitted. Southern Yemen was admitted in 1967; Mauritius, Swaziland, and Equatorial Guinea in 1968; Fiji in 1970; and Bahrain, Bhutan, Oman, Qatar, and the United Arab Emirates in 1971. At the end of 1971 the membership was 132.

With UN membership approaching universality, another problem confronted the organization: that of the large number of leftover fragments of empire. If all of these small territories, of which there were more than 50, should become members of the UN, the effectiveness of the organization would be seriously diminished. With the preponderant voting or political power in the General Assembly resting with the small states, the big states may be tempted to ignore the United Nations and resort to big-power politics. Secretary General U Thant in his 1967 annual report drew attention to the difficult problem of the role that "microstates" should attempt to play in world politics. Some of them find it a strain to maintain representations at the headquarters of the United Nations. Thant suggested the desirability of limiting membership on the basis of ability to carry out the responsibilities of membership and raised the question of some form of associate membership in the organization for these very small states.

The question of Chinese representation

The question of China's representation in the UN was before the General Assembly at every session since 1950, when India introduced a resolution declaring that the Communist regime was entitled to representation in the assembly. This resolution failed by a vote of 33 to 16, with ten abstentions—largely because of the opposition led by the United States. For twenty years, efforts to bring the People's Republic of China into the organization and, concurrently, to expel the representatives of Nationalist China on Taiwan were consistently frustrated. Finally, in 1971, the United States acquiesced to the idea of admitting Communist China to the Security Council and General Assembly if, at the same time, Nationalist China could retain a seat in the General Assembly. This compromise failed. The General Assembly on October 25, 1971, voted 76 to 35, with 17 abstentions and three members absent, to admit the representatives of the People's Republic and to wholly remove the Nationalist representatives. Nationalist China's permanent Security Council seat was also given to Communist China.

PRINCIPAL ORGANS

The United Nations has six principal organs: General Assembly, Security Council, Economic and Social Council, Trusteeship Council, International Court of Justice, and Secretariat.

General Assembly. This is the only body in which all of the UN members are represented. A member may send as many as five representatives, but each member has only one vote. Decisions on substantive questions are taken by a majority or by a two-thirds vote, depending on the importance of the matters involved. Procedural questions are decided by majority vote.

Article 10 and the role of the General Assembly

Through its deliberative, supervisory, financial, and elective functions the General Assembly occupies a central position in the functioning of the United Nations. Its role as a deliberative organ is based in articles 10–14 of the Charter. Article 10 states that the General Assembly may discuss and make recommendations on "any questions or any matters within the scope of the present Charter or relating to the powers and functions of any organs provided for in the present Charter."

In performing its supervisory functions, the General Assembly exercises control over the activities of UN organs in the economic and social fields and in dealing with the problems of non-self-governing territories. It receives annual reports from the secretary general, Security Council, Economic and Social Council, and Trusteeship Council and may make recommendations to these organs. The Economic and Social Council and the Trusteeship Council operate under the authority of the General Assembly. The assembly approves trust agreements and through the Trusteeship Council supervises the administration of trust territories. It exercises general supervision and control over the operations of the Secretariat. The financial power of the assembly is exercised through its control over the budget of the United Nations and the scale of assessments levied on members.

In its elective capacity, the General Assembly chooses all the members of the Economic and Social Council and the elective members of the Security Council and Trusteeship Council. Along with the Security Council, it also participates in the election of judges of the International Court of Justice and the appointment of the secretary general. The assembly shares with the Security Council the power to propose amendments to the Charter as well as the right to convene a conference for the purpose of revising the charter.

During its first ten years the General Assembly progressively increased in importance as an organ of deliberation and political influence. At the same time the influence and the effectiveness of the Security Council declined because of the inability of the permanent members to cooperate. The broad language of articles 10, 11, and 14 of the Charter permitted the role of the General Assembly to increase far beyond what was originally envisaged, and most of its members encouraged this increase. Members consequently became more and more concerned with ways and means of strengthening the assembly, in organization and procedure, so that it could more effectively handle its growing responsibilities.

The assembly convenes annually, but its rules also permit the calling of special sessions on short notice. It works through a complex structure of main committees, procedural committees, standing committees, and subsidiary and ad hoc bodies.

Security Council. The Charter assigns the Security Council primary responsibility for maintenance of international peace and security. The council consisted originally of 11 members—five permanent members (Nationalist China, France, the United Kingdom, the U.S.S.R., and the United States) and six nonpermanent members elected by the assembly for two-year terms. In 1965, when an amendment to the Charter was ratified, the council became a 15-member body consisting of the original five permanent members and ten nonpermanent members. The latter were to be chosen as follows: five from African and Asian states, one from eastern European states, two from Latin-American states, and two from western European and other states. The presidency is held by each member in turn for one month. In selecting nonpermanent members the assembly must not only strive for an equitable geographical distribution but must also consider the contribution of members to the maintenance of international peace and security. From the beginning, nonpermanent members of the Security Council were elected with a view to giving representation to certain regions or groups of states. This practice ran into increasing difficulty as the number of UN members increased, and there were not enough seats on the Security Council to distribute among the groups and regions desiring representation.

Under the Charter, members of the UN agreed to carry out the decisions of the Security Council. This agreement refers primarily to decisions pertaining to the maintenance of international peace and security under Chapter VII of the Charter. The council may investigate any dispute that might threaten international peace and security, but it can make recommendations only for its peaceful settlement. The council may, however, require members of the UN to apply various sanctions against any state that the council has found guilty of a threat to the peace, breach of the peace, or act of aggression (Article 39), or of failing to "perform the obligations incumbent upon it under a judgment" of the International Court of Justice (Article 94). Recommendations for the regulations of national armaments may also be made by the council (Article 26).

Procedural and substantive voting in the Security Council

On procedural matters, decisions by the council are made by an affirmative vote of any nine (seven until 1965) of its members. On substantive matters, including the investigation of a dispute and the application of sanctions, nine (seven until 1965) affirmative votes (including those of the five permanent members) are required, but in practice a permanent member may abstain without impairing the validity of the decision. A vote on whether a matter is procedural or substantive is itself a substantive question. Because the council is required to function continuously, each member is represented at all times at UN headquarters.

Economic and Social Council. The Economic and Social Council is charged with directing and coordinating the complex system of economic, social, humanitarian, and cultural activities of the United Nations. Its 27 members (18 before 1965) are elected by the General Assembly for three-year terms with the possibility of re-election. Although the Economic and Social Council has no permanent members, states the participation of which is considered necessary to the work of the council have been regularly re-elected. When the membership of the council was increased in 1965 it was provided that seven of the additional members would represent African and Asian states, one would represent a Latin-American state, and one a western European or other state.

The Economic and Social Council meets at least twice a year; it is directed by the Charter to carry on studies and make recommendations for the promotion of international cooperation in economic and social matters. It may prepare draft conventions for submission to the assembly and call international conferences.

The council is assisted in its work by commissions organized on functional or geographical bases. The functional commissions, including an economic, a social, and a human rights commission, carry out studies in their fields and otherwise assist the council in the performance of its duties. They formulate resolutions, recommendations, and international conventions on which the council and General Assembly take action. Four regional commissions—for Europe, Asia and the Far East, Latin America, and Africa—that were established to deal with specific regional economic problems assumed roles of considerable importance both as advisory organs and as organs with important operational responsibilities.

Trusteeship Council. Acting under the authority of the General Assembly, the Trusteeship Council supervises the administration of trust territories by the administering states. The council is composed of UN members who administer trust territories; the permanent members of the Security Council not administering trust territories; and as many other nonadministering members elected by the assembly for three-year terms as are necessary to ensure an equal number of administering and nonadministering members in the total membership of the council. The Trusteeship Council is authorized to send visiting inspection missions into the trust territories, to receive and examine petitions, to consider reports submitted to it annually by the administering authorities, and to make recommendations with respect to all the matters coming within its purview. The council is required to submit annual reports on its activities to the General Assembly.

International Court of Justice. The court, popularly known as the World Court, is the principal judicial organ of the United Nations, and its statute is an integral part of the Charter. The 15 judges of the court are elected by the General Assembly and the Security Council voting independently. No two judges may be nationals of the same state. The main forms of civilization and the major legal systems of the world are to be represented on the court. Judges serve for nine years and are eligible for re-election. The seat of the court is The Hague, The Netherlands.

The jurisdiction of the court comprises "all cases which parties refer to it and all matters specially provided for in the Charter of the United Nations or in treaties and conventions in force." By formal declaration, states may accept the compulsory jurisdiction of the court in specified categories of disputes. The court may give advisory opinions at the request of the General Assembly or the Security Council or at the request of other organs and specialized agencies authorized by the General Assembly (see INTERNATIONAL COURT OF JUSTICE).

Secretariat. The Secretariat is headed by the secretary general, who is appointed by the General Assembly upon the recommendation of the Security Council. At the beginning of its first session in 1946, the General Assembly chose Trygve Lie of Norway for a term of five years, which was extended in 1950 for three more years. This extension was bitterly opposed by the U.S.S.R., and in November 1952 Lie resigned. In April 1953 Dag Hammarskjöld of Sweden succeeded him and was re-elected in 1957. In September 1961 Hammarskjöld was killed in an airplane crash in Northern Rhodesia. After a period of controversy, during which the U.S.S.R. proposed that the Secretariat be headed by a three-member committee, the powers agreed upon the choice of U Thant of Burma. In December 1966 Thant was unanimously elected to a second term. When he resigned at the end of 1971, Dr. Kurt Waldheim of Austria was elected to succeed him for a five-year term.

The UN secretary general

In addition to being the chief administrative officer of the United Nations, the secretary general also has important political functions, being specifically charged with bringing before the organization any matter that threatens international peace and security (see also below, *Administration*).

MAINTENANCE OF INTERNATIONAL PEACE AND SECURITY

Settlement of disputes. The preamble to the Charter begins with the declaration that the peoples of the United Nations are determined "to save succeeding generations from the scourge of war"; and Article 1 places the maintenance of international peace and security first among the purposes of the organization, followed by the development of "friendly relations among nations" and the achievement of "international cooperation in solving international problems of an economic, social, cultural, or humanitarian character." In the long run the secondary

purposes may be more important than the first, but it is only in peace that the United Nations can function to achieve the secondary purposes.

The primary responsibility for the maintenance of international peace and security is placed on the Security Council. The founders realized that without basic agreement among the great powers on important international issues there could be no effective cooperation in the maintenance of peace or the application of sanctions against an aggressor. For this reason the Charter provided that substantive decisions would require the unanimous vote of the five permanent members of the Security Council. But this requirement means that when there is disagreement on substantive matters among the big powers the Security Council is unable to act. It was assumed by those who drafted the Charter that the five great powers who were given permanent membership in the council would cooperate in security matters. This assumption proved false. Almost immediately there developed a sharp rift between the Soviet Union and the Western powers; and the Soviet Union, being in a minority, resorted to frequent use of the veto to prevent what it considered adverse action by the council.

Articles 11–12 and the role of the General Assembly

With a stalemate in the Security Council, members of the United Nations began to look to the General Assembly. Article 11, paragraph 2, of the Charter authorizes the General Assembly to "discuss any questions relating to the maintenance of international peace and security" and to "make recommendations with regard to any such questions to the state or states concerned or to the Security Council or to both." This broad authorization is restricted somewhat by the provision of Article 12, that, "while the Security Council is exercising in respect of any dispute or situation the functions assigned to it in the present Charter, the General Assembly shall not make any recommendations with regard to that dispute or situation unless the Security Council so requests." Whereas these provisions grant the assembly a broad secondary role, there exists a very important difference between the two bodies. The Security Council can make decisions that bind all the members, whereas the General Assembly can only make recommendations.

Because the Soviet representative was absent from the Security Council in protest against the allegedly illegal representation of China on that body by the Nationalist government, the Security Council was able to take prompt action against the North Korean forces when they attacked South Korea in June 1950. After a few weeks, however, the Soviet representative returned to the council, and further action by that body to deal with the Korean situation was blocked by Russian vetoes. To enable it to carry out its peace-keeping function more effectively, the General Assembly in November 1950 adopted the Uniting for Peace Resolution proposed by the United States. It provided for immediate consideration by the General Assembly of a threat to the peace, breach of the peace, or act of aggression, with a view to recommending collective measures, including the use of armed force when necessary, "if the Security Council, because of lack of unanimity of the permanent members, fails to exercise its primary responsibility." The resolution established a Peace Observation Commission to "observe and report on the situation in any area where there exists international tension the continuance of which is likely to endanger the maintenance of international peace and security." It also established a Collective Measures Committee to "study and report on methods which the Assembly might use in strengthening international peace and security."

1950 Uniting for Peace Resolution

In carrying out its responsibility the Security Council must first seek to bring about a pacific settlement of disputes, in accordance with Chapter VI of the Charter. If the parties to a dispute that threatens the peace fail to settle it by peaceful means of their own choice, the Security Council must call upon them to settle it. The council may investigate any dispute or situation in order to determine whether its continuance is likely to endanger international peace and security. Any state, whether it is a member of the UN or not, may bring any such dispute or situation to the attention of the Security Council or the General Assembly. At any stage of the dispute or situation the Security Council may recommend appropriate procedures or methods of adjustment, and if the parties fail to settle the dispute by peaceful means the Security Council may recommend terms of settlement.

Whenever the Security Council determines that a threat to the peace exists or that a breach of the peace or act of aggression has taken place, it may decide upon measures to be taken to meet the situation. The Charter envisages the application of graduated measures, from economic and diplomatic sanctions to action by air, sea, and land forces. By subscribing to the Charter, all the members undertook to place at the disposal of the Security Council armed forces and facilities for military sanctions against aggressors or disturbers of the peace; but this provision did not become operative because no agreements to give it effect were concluded.

During the first 20 years of its life, a large number of disputes and situations involving the maintenance of peace came before the Security Council and the General Assembly, reflecting the unsettled conditions in the world after World War II. The United Nations succeeded in helping to settle some of them, such as the removal of Soviet troops from northern Iran in 1946; others remained unsolved and were a continuing concern of the Security Council and the General Assembly. Because most of these disputes have involved actions taken by nations acting outside, as well as within, the United Nations, the detailed histories of each will not be found in the present article. For references to these disputes, see RELATED ENTRIES under UNITED NATIONS in the *Ready Reference and Index.*

Regulation of armaments. The Charter places responsibility on the Security Council for preparing and submitting plans for the regulation of armaments. The General Assembly may discuss and recommend principles governing "disarmament and the regulation of armaments." The word regulation has been interpreted to include making armaments available for United Nations purposes as well as limiting or reducing armaments used for national purposes. The development of the atomic bomb during World War II created a situation in which it seemed to the United States and other governments that the international control of atomic energy demanded consideration even in advance of any perfection of collective security arrangements. Consequently, the first act of the United Nations was to establish the Atomic Energy Commission in January 1946 to prepare plans for the control of atomic energy. In December 1946 the General Assembly adopted a resolution providing for the urgent consideration of the control of atomic weapons and other weapons of mass destruction and for the regulation and reduction of all armaments and armed forces.

Atomic Energy Commission

The Atomic Energy Commission began its deliberations in June 1946. It soon became apparent that there was complete disagreement between the United States and the U.S.S.R. The commission submitted reports to the Security Council in 1946, 1947, and 1948. The majority of the members of the commission called for international managerial control or ownership of atomic-energy facilities, international inspection by a proposed international atomic development authority, and the elimination of the veto from enforcement provisions of the agreement. The majority also insisted that the control system should be in operation before the existing stockpile of atomic bombs was destroyed. The Soviet Union, however, took an opposite view. It refused to agree to international ownership and to the kind of international inspection demanded by the majority; it demanded that the veto be applicable to enforcement measures under the plan and that the destruction of atomic stockpiles accompany the establishment of a control system. The commission recorded an impasse in negotiations in its 1948 report, though some agreement had been reached on matters of detail.

To deal with armaments other than weapons of mass destruction, the Security Council organized the Commission for Conventional Armaments, but progress in this field was also blocked by disagreement between the U.S.S.R. and the Western powers. Although the commis-

sion and the General Assembly in 1949 approved a plan whereby each state would submit full information to the commission on its conventional armaments and armed forces, the refusal of the U.S.S.R. to accept the plan prevented any implementation. By early 1950 it was clear that a hopeless deadlock had been reached.

Disarmament Commission

In January 1952 the assembly voted to merge the Atomic Energy Commission and the Conventional Armaments Commission into a Disarmament Commission, thus recognizing the interdependence of the various elements of the problem. The Disarmament Commission, which consisted of the members of the Security Council and Canada, was directed to prepare proposals for the regulation, limitation, and balanced reduction of all the armed forces and armaments; for the elimination of major weapons adaptable to mass destruction; and for the effective international control of atomic energy to ensure its use for peaceful purposes only. The development of atomic and hydrogen weapons by the U.S.S.R. fundamentally altered the terms of the problem of the regulation and reduction of armaments and resulted in important changes in national positions. In spite of vigorous efforts to achieve constructive results through the commission and the General Assembly itself, little progress was made.

In his annual report to the 12th General Assembly, which convened in 1957, Secretary General Hammarskjöld stated that the year had witnessed "most sustained and intensive efforts by the members of the disarmament subcommittee to find common ground." Instead of attempting to work out a comprehensive, detailed, general disarmament plan there was a shift toward efforts to obtain a limited "first step" agreement. After over a decade of stalemate there was some hope that a limited agreement might be possible. Much attention was devoted to means of preventing surprise attacks; the United States urged acceptance of the Eisenhower "open skies" proposal for aerial inspection and exchange of military blueprints; the U.S.S.R. supported the Bulganin plan of ground observation posts at strategic centres. No agreement resulted. In 1957, however, the International Atomic Energy Agency was established to promote the peaceful uses of atomic energy.

World public opinion, as expressed in the General Assembly, continued to exert pressure on the great powers to resume negotiations for disarmament. A Ten-Nation Disarmament Committee, composed of five members from eastern Europe and an equal number from the West, began deliberations in March 1959, but negotiations soon reached an impasse. The committee was enlarged to 18 members by the addition of neutral countries, but one member, France, did not participate. Both the U.S.S.R. and the Western powers declared that general and complete disarmament was their goal, but little agreement was reached on how to achieve that goal. The Western approach was primarily military: a step-by-step movement toward a carefully inspected and controlled system of disarmament. The Soviet approach was primarily political: an agreement for complete and total disarmament within a few years. The General Assembly in 1961 adopted a resolution declaring the use of nuclear or thermonuclear weapons to be contrary to international law, to the UN Charter, and to the laws of humanity.

An important step toward disarmament was achieved by the Nuclear Test-Ban Treaty signed on August 5, 1963, by the Soviet Union, the United Kingdom, and the United States. This agreement—to which over 100 states later adhered—prohibited nuclear tests or explosions in the atmosphere, in outer space, and under water, but not underground. (China and France, both atomic powers, did not sign the treaty.)

Treaty on the Peaceful Uses of Outer Space

In June 1966 the Soviet Union and the U.S. submitted draft space treaties to the UN. The legal subcommittee of the UN Committee on the Peaceful Uses of Outer Space, assigned to reconcile the two drafts, on December 8 produced a historic document: it prohibited countries that ratified it from placing nuclear arms or other weapons of mass destruction in orbit, on the moon, or on other bodies in space and required nations to use the moon and other celestial bodies for peaceful purposes only. The General Assembly approved the treaty unanimously. Signature and ratification by UN members and nonmembers were to follow. After more than six years of negotiation, the Soviet Union and the United States reached an agreement on a draft of a treaty to ban the further spread of nuclear weapons. By resolution of June 12, 1968, the General Assembly commended the draft and urged members to ratify it.

Revision of the Charter. In accordance with Article 109, a proposal to call a conference to review the Charter was placed on the agenda of the General Assembly at its tenth session in 1955. The assembly decided that such a conference should be held at some appropriate time in the future, but no date was set. Three specific proposals for Charter amendment were urged by a number of Latin American states as early as 1956: to increase the number of nonpermanent members of the Security Council, to increase the membership of the Economic and Social Council, and to increase the number of judges on the International Court of Justice. As the membership of the United Nations rose to more than 100, the demand for enlargement of the councils became more insistent; some regions, particularly Africa, felt they were not given adequate representation.

The General Assembly adopted, on December 17, 1963, a resolution proposing an amendment to the Charter to enlarge the Security Council to 15 (by increasing the number of nonpermanent members to ten) and to raise the membership of the Economic and Social Council to 27. Under the proposed revision, decisions of the Security Council on procedural matters would require an affirmative vote of any nine members, and decisions on all other matters would require nine affirmative votes, including those of the five permanent members. The proposed amendment provided for the geographic distribution of the seats of the nonpermanent members as follows: Africa and Asia, five; eastern Europe, one; Latin America, two; western Europe and other regions, two. The Soviet Union, which previously had opposed any amendment to the Charter so long as China was barred from the United Nations, changed its position and was the first of the permanent members of the Security Council to ratify the proposed revision. By September 1965 the two amendments had been ratified.

DEVELOPMENT OF INTERNATIONAL LAW

International Law Commission

In November 1947 the General Assembly established the International Law Commission of 15 members to make recommendations for the progressive development and codification of international law. In setting up the commission, the General Assembly directed it to formulate the principles of international law recognized at the Nuremberg trial of Nazi war criminals and to prepare a draft code of offenses against the peace and security of mankind.

In 1950 the commission submitted its formulation of the Nuremberg principles, which covered crimes against the peace, war crimes, and crimes against humanity. The commission presented to the assembly in 1951 draft articles on offenses against the peace and security of mankind, which enumerated 12 crimes against international law, including any act of aggression, threat of or preparation for aggression, annexation of territory, and genocide. The commission also prepared a draft declaration on the rights and duties of states.

The commission made studies of the possibility of codifying certain branches of international law, giving priority to the law of treaties and the law of the sea (see INTERNATIONAL LAW). It also prepared a study on the legal aspects of reservations to multilateral conventions. Draft conventions were prepared on statelessness, the peaceful settlement of disputes, the law of the sea, diplomatic relations, consular relations, and the law of treaties. The commission was also concerned about the subjects of arbitral procedure and international criminal jurisdiction. After the commission has completed a draft convention it submits it to the General Assembly, which may either convene an international conference to draw up formal conventions based on the draft or merely commend the

text to the states. A conference to consider the draft convention on the law of the sea was held at Geneva in 1958; conferences held at Vienna in 1961 and 1963 completed conventions on diplomatic relations and optional protocols on the acquisition of nationality and the compulsory settlement of disputes and on consular relations. The commission in 1966 completed a draft convention on the law of treaties, which was placed before a conference meeting in split sessions in 1968 and 1969.

During its first two decades the UN made considerable effort to arrive at an acceptable definition of aggression. The San Francisco Conference, the International Law Commission, and special committees set up by the assembly all sought an agreement on such a definition but failed. Failure to reach agreement on the definition of aggression delayed progress on the drafting of certain conventions. The commission was engaged in preparing draft conventions on special diplomatic missions, relations between states and intergovernmental organizations, state responsibility, and succession of states and governments.

The General Assembly also set up two special committees to promote the development and codification of international law—one on the principles of international law concerning friendly relations of states and another on international trade law.

ECONOMIC AND SOCIAL COOPERATION

A major purpose of the United Nations is "to achieve international cooperation in solving international problems of an economic, social, cultural, or humanitarian character, and in promoting and encouraging respect for human rights and for fundamental freedoms for all without distinction as to race, sex, language, or religion." The General Assembly, the Economic and Social Council, the Secretariat, and the specialized agencies are the organs primarily responsible for action in this field. An important part of this aspect of UN activity consists of research, publication of reports, and rendering technical assistance to governments. The United Nations has no authority to legislate or to enforce measures of economic and social cooperation; it can only make recommendations, which the member governments may or may not follow.

Major UN annual publications

The United Nations has rendered a valuable service by publishing carefully prepared statistical data and surveys of economic and social developments. Among the more significant of its yearly publications are the *World Economic Report*, the *Statistical Yearbook*, the *Demographic Yearbook*, and the *Yearbook on Human Rights*.

Economic reconstruction. The devastation of large areas of the world and the dislocation of normal economic relations during World War II resulted in the need for concerted measures of relief, rehabilitation, and reconstruction. The United Nations Relief and Rehabilitation Administration, established in 1943, did much to alleviate the situation. To assist in dealing with regional problems the Economic and Social Council in 1947 established the Economic Commission for Europe and the Economic Commission for Asia and the Far East. Similar commissions were established for Latin America in 1948 and for Africa in 1958.

Technical assistance. A modest program of technical assistance to the less developed countries was undertaken in 1946 when the General Assembly passed a resolution calling for the establishment of machinery in the Secretariat for giving such aid. The Expanded Program of Technical Assistance was approved by the General Assembly in 1949. It is financed by voluntary contributions from members. Pledges are made at an annual conference.

Financing economic development. The United Nations gave a great deal of consideration to ways and means of making capital available to less developed countries for financing projects that were not self-liquidating or that did not meet the International Bank's requirements for loans. In 1954 the General Assembly recommended that both capital-importing and capital-exporting countries examine their policies and practices with a view to encouraging the flow of private capital. In April 1955 the Bank submitted to its members the draft charter of the International Finance Corporation, to come into operation as soon as ratified by 30 states and as soon as 75 percent of $100,000,000 capital had been subscribed. The corporation was to make direct loans to private enterprises without government guarantees and was to be allowed to make loans for other than fixed returns. The charter entered into force on July 20, 1956.

International Development Association

In 1960 the International Development Association was established as an affiliate of the International Bank. It was created to make loans to less developed countries on terms that were more flexible than bank loans. It was authorized to finance any project "which will make an important contribution to the development of an area or areas concerned, whether or not the project is revenue producing or directly productive."

To assist in the financing of non-self-liquidating development projects a proposal was submitted to the General Assembly for a Special United Nations Fund for Economic Development (SUNFED). The General Assembly in 1957 unanimously adopted a resolution to set up a separate fund to provide systematic assistance in fields essential to technical, economic, and social development of less developed countries. The Special Fund began operations in 1959 with Paul G. Hoffman as the managing director.

The Expanded Program and the Special Fund had similar goals, but they were different in structure and operation. The Special Fund put greater emphasis on the preevaluation of projects; about one-third of its expenditures were allocated for surveys and feasibility studies. Nevertheless, because of the similarity of functions there was a growing demand for a merger of the Expanded Program and the Special Fund. This merger was effected in 1965 under the name United Nations Development Programme.

Trade and development. The less developed countries contended that the terms of international trade were against them. They complained that the prices of the manufactured goods they had to import from industrialized countries were high, whereas the prices of the primary commodities that they produced for export were low, thus frustrating their efforts to obtain more rapid growth. Although they became parties to the General Agreement on Tariffs and Trade (GATT), they were critical of it, insisting that more was required than the application of the most-favoured-nation principle and the mere reduction of tariffs. They demanded a conference to consider means for the removal of obstacles to the trade of developing countries.

UNCTAD

A United Nations Conference on Trade and Development (UNCTAD) met in Geneva in the early months of 1964, chiefly to consider the trade needs of the developing countries, and established the following items: a continual United Nations Conference on Trade and Development to promote international trade, especially with a view to accelerating economic development; a Trade and Development Board composed of 55 members elected by the conference; a permanent and full-time Secretariat; and a secretary general to be appointed by the UN secretary general with the confirmation of the General Assembly. This UNCTAD has proposed a variety of means, such as agreements on commodity trade and tariff rates favouring exports of developing countries.

Refugees. The International Refugee Organization (IRO) was established in 1946 to take over the refugee functions of the United Nations Relief and Rehabilitation Administration, which expired in 1947. The IRO was successful in resettling, repatriating, transporting, and maintaining more than 1,000,000 European refugees. Because the IRO was conceived as a short-term emergency organization, it was abolished in 1952 and replaced by a new refugee structure. A United Nations High Commissioner for Refugees was appointed and was directed to act under the Convention Relating to the Status of Refugees, drawn up by the Economic and Social Council and approved by the General Assembly in 1951. An Advisory Committee on Refugees was appointed by the council in 1951 to assist the high commissioner. The assembly in 1957 voted to continue the office of UN high commissioner for refugees for five years from January 1959, and in 1963 and

1968 voted to extend it for five-year periods (to 1974). The assembly appealed to member governments to aid Chinese refugees in Hong Kong and urged them to meet the critical need for funds for Arab refugees.

Commission on Human Rights

Human rights. The General Assembly in 1948 adopted the Universal Declaration of Human Rights, which was prepared by the Commission on Human Rights. In 1948 the commission began to draft a Covenant of Human Rights that, upon ratification by governments, would become legally binding upon them. Wide differences in economic and social philosophies hampered efforts to achieve agreement on a common text, but finally a Draft Covenant on Economic, Social, and Cultural Rights and a Draft Covenant on Civil and Political Rights were completed in 1954 and submitted to the General Assembly for its consideration. The years of work by the Commission on Human Rights culminated in the adoption in 1966 by the General Assembly of the International Covenant on Civil and Political Rights, the International Covenant on Economic, Social and Cultural Rights, and the Optional Protocol to the Covenant on Civil and Political Rights, but by the middle of 1972 neither covenant had been ratified or acceded to by the 35 states necessary for its entry into force. In the general field of human rights, the assembly also concerned itself with discrimination against citizens of India, the policy of apartheid in South Africa, and violations of the civil-rights provisions of peace treaties by Hungary, Romania, and Bulgaria. The General Assembly in 1962 established a Special Committee on Apartheid and recommended that member states break off diplomatic relations with South Africa and apply economic sanctions against it. In 1963 the General Assembly adopted a Declaration on the Elimination of all Forms of Racial Discrimination, and in 1965 it approved an international convention on the same subject, which then went before the member states for signature and ratification.

Commission on Narcotic Drugs

Control of narcotics. The Commission on Narcotic Drugs was authorized by the assembly in 1946 to carry out the functions entrusted by international conventions to the League of Nations Advisory Committee on Traffic in Opium and Other Dangerous Drugs. The agreements, conventions, and protocols on the control of narcotic drugs concluded in 1912, 1925, 1931, and 1936 were amended in a draft protocol approved by the assembly in November 1946 and subsequently came into force among its signatories. In addition to re-establishing the pre-World War II system of narcotics control, which had suffered from the dislocations of the war, the UN concerned itself with new problems resulting from the development of synthetic drugs. Efforts were made to simplify the system of control by drafting one convention incorporating all the agreements in force. (L.M.G./A.Va.)

Specialized agencies. The League of Nations provided a focal point for intergovernmental organizations and also for the growing network of nongovernmental agencies. Following World War II, the United Nations became a kind of "roof organization" for the major enterprises in systematic international cooperation. In accordance with its Charter, the UN entered into coordinating agreements with intergovernmental agencies operating in economic, social, cultural, educational, health, and related fields. In the second half of the 20th century the roster of specialized agencies affiliated with the United Nations included the following: Inter-Governmental Maritime Consultative Organization (IMCO); International Labour Organisation (ILO); United Nations Educational, Scientific and Cultural Organization (UNESCO); Food and Agriculture Organization (FAO); International Civil Aviation Organization (ICAO); International Bank for Reconstruction and Development (World Bank); World Health Organization (WHO); International Telecommunication Union (ITU); Universal Postal Union (UPU); World Meteorological Organization (WMO); International Atomic Energy Agency (IAEA); International Development Association (IDA); and the International Finance Corporation (IFC). The Economic and Social Council, acting under the Charter of the United Nations, endeavoured to maintain a consultative relationship with practically 300 nongovernmental organizations, virtually every one of them international in scope.

General structure of UN agencies

The general structure of each specialized agency follows a common pattern. Each agency has a general conference in which all the members are represented, and the conference elects an executive body that is charged with initiating proposals and carrying out decisions of the general conference. Each agency also has a permanent secretariat headed by a director. Many agencies have regional subcommissions operating in various parts of the world. Some of the specialized agencies were in existence before the United Nations was organized; some were in the process of establishment during World War II; and some agencies were organized under the auspices of the United Nations. (Ed.)

International Labour Organisation. The ILO is an example of an official international institution now affiliated with the UN but existing before World War II. In 1919, the Peace Conference of Paris, fearful of social revolution, set up a commission for international labour legislation headed by Samuel Gompers, president of the American Federation of Labor. The commission put aside the more ambitious claims for a body with legislative authority and proposed a body with powers of recommendation to national governments for action by them, in composition a tripartite body in which half the representation would be by governments, and one-fourth each by labour and by employers. The peace conference adopted these proposals and, by inserting them in the Treaty of Versailles, thereby set up the ILO.

In its first decade the ILO was concerned primarily with its research efforts; with the definition and promotion of proper minimum standards of labour legislation for adoption by member states; and with "mutual education" and some forms of collaboration among worker, employer, and government delegates and the office professional staff. During the 1930s the ILO sought ways to combat worldwide unemployment and economic depression. Its proposals of extensive international public works never influenced national decision makers.

After 1945, the "Cold War," the breakup of European colonial empires, and the claims of the developing nations placed new tasks in the foreground for an organization the membership of which was no longer chiefly that of European, economically developed states but increasingly that of the less developed states. The ILO's major emphases shifted therefore to the area of human rights and to technical assistance and other work of an operating character in the interest of the less developed countries of Asia, Africa, Latin America, and Europe itself. The ILO's ideal has been universality of membership. It admitted Germany in 1919, long before the League of Nations did. Some nations—Brazil and, for a time, Japan—remained in the ILO after resigning from the League. Others became members of the ILO without joining the League or the UN. The United States, aloof from the League, joined the ILO in 1934. After World War II the ILO admitted the German Federal Republic and Japan in 1951. But South Africa was practically forced out of the organization because of its racial policies. Post-World War II amendments made it easier to join the ILO. Members of the UN do not have automatic membership in the ILO, as did League members, but they may become members simply by filing a declaration accepting the obligations of the ILO constitution. Nonmembers of the UN must be accepted by a vote of two-thirds of the conference, including that of two-thirds of the government delegates. By the end of 1971 the ILO had 119 members.

Membership of the ILO

The International Labour Office is the secretariat of the organization and its research staff. By 1970 it had international civil servants from more than 90 nations, including technical-assistance experts on temporary missions, working in Geneva, or in the field, all over the world. Their work was made possible by the ILO's own budget plus funds from other sources, chiefly UN Development Program funds. Some idea of the ILO's manifold activities may be gleaned from its current *Catalogue of Publications;* most widely used are the monthly *International Labour Review* and the *Year Book of Labour Statistics.*

In 1962 there opened under ILO auspices—but with its own endowment fund—an International Institute for Labour Studies at Geneva, concerned with leadership training, especially for the developing countries, and with long-range research (in contrast to the ILO's own service-oriented research). Three years later the ILO, in cooperation with the Italian government, opened an International Centre for Technical and Vocational Training in Turin, which began to emphasize management training for different types of enterprises, including cooperatives, in the developing nations. (V.R.L.)

International Bank for Reconstruction and Development and International Monetary Fund. Two complementary, but separate, organizations, the International Bank (better known as the World Bank) and the International Monetary Fund (IMF), had their origin in wartime preparations for postwar international financial and economic cooperation that culminated in the United Nations Monetary and Financial Conference held in July 1944 at Bretton Woods, New Hampshire, and attended by 44 nations. The principal purposes of the World Bank, set forth in its articles of agreement (charter), may be summarized as follows: (1) To assist in the reconstruction and development of its member countries by facilitating the investment of capital for productive purposes, thereby promoting the long-range growth of international trade and improvement of standards of living. (2) To promote private foreign investment by guarantees of and participations in loans and other investments made by private investors. (3) When private capital is not available on reasonable terms, to make loans for productive purposes out of its own resources or funds borrowed by it.

World Bank

The World Bank came into existence on December 27, 1945, when its articles of agreement were signed by 29 governments. The Bank officially began operations at its headquarters in Washington, D.C., in June 1946. By 1972 the Bank had 119 member countries. The largest of these, in terms of capital subscribed, were the United States, the United Kingdom, West Germany, France, India, Canada, and Japan. Also among the Bank's members were many other countries such as Iceland, Israel, Lebanon, Ceylon (now Sri Lanka), Indonesia, Afghanistan, Libya, Lesotho, Somalia, Ghana, Yugoslavia, and all the Latin-American republics except Cuba.

The World Bank's charter authorized it to engage in the following types of financing: it may lend funds directly, either from its capital funds or from funds that it borrows in private investment markets; it may guarantee loans made by others; or it may participate in such loans. Loans may be made to member countries directly or to any of their political subdivisions or to private business or agricultural enterprises in the territories of members. When the member government in whose territory the project is located is not itself the borrower, however, this member government must guarantee the loan.

The World Bank obtains its funds for loans from paid-in capital subscription, from borrowings in the capital markets of the world, and from net earnings. Sales to investors of portions of the Bank's loan portfolio and repayments of loans to the Bank, while representing only a recovery of funds originally derived from one of the above sources, have the same effect as new capital in that they reduce the amount the Bank would otherwise have to obtain from other sources. The capital markets of the world provide the largest amount of funds for loans. By the late 1960s the Bank's outstanding funded debt amounted to over $4,000,000,000. Loan funds available from other sources were $2,000,000,000 from paid-in capital subscriptions, about $1,000,000,000 from operations, and about $4,000,000,000 from repayments and sales of loans.

Because the World Bank is primarily a source of long-term loan capital, its resources have been used largely to assist in the financing of investments for which large amounts of long-term loan capital are required and for which this method of financing is appropriate. For this reason, a large part of the Bank's portfolio consists of loans to publicly and privately owned utilities, such as undertakings for the generation and distribution of electric power, railroads, ports and inland waterways, airlines and airports, telecommunications, and pipelines.

The International Monetary Fund was designed to stabilize international monetary rates. It came into existence in March 1946 after the ratification and appropriation of funds by national governments had been completed, but the Fund was not actually opened until March 1947, and the first transactions were made in May of that year. Operating funds of the IMF are subscribed by member governments. Each member has a quota, of which an amount equal either to 25 percent of the quota or 10 percent of the member's holdings of gold and U.S. dollars, whichever is smaller, is subscribed in gold and the remainder in national currency. The IMF was designed to stabilize exchange rates by assisting members over temporary difficulties in their international balance of payments. It does so partly by consultation and technical advice, but also by allowing members to purchase from it with their own national currencies the gold or foreign exchange they need. In principle not more than 25 percent of the member's quota may be purchased in any one year, but in an emergency this limit may be, and often is, waived. Not more than 125% of the quota may be purchased in all. Charges begin at ½% for the first 25% for the first year, rising by ½% for each additional year, with a limit of 5%. Members may arrange standby credits to use as and if necessary. If demands for any currency outrun the IMF's resources it may be declared scarce and rationed. Members may then impose discriminatory exchange controls against it. Members are required to repurchase the excess of their own currencies over their quotas within an agreed period (three to five years) as their balances improve. Members agree not to alter the exchange value of their currencies (except once by no more than 10 percent) without prior IMF agreement.

International Monetary Fund

The expansion of world trade, however, coupled with a succession of international financial crises, created a demand for additional reserves that could be used in settlement of international balances. In October 1969 the IMF voted to distribute a total of $9,500,000,000 in Special Drawing Rights. These served, in effect, to enlarge members' quotas without any additional subscription either in gold or in national currencies, and thus to create a base for new credit expansion. But demands upon international liquidity continued to increase. A realignment of currencies agreed upon in December 1971 included an effective 11 percent devaluation of the U.S. dollar and the upvaluation of other major currencies. Another realignment came after the U.S. announced a new devaluation of 10 percent in February 1973. A number of countries allowed their currencies to "float"—*i.e.*, to change in value according to market conditions and without formal announcement. (J.H.A./J.B.C./Ed.)

Food and Agriculture Organization. The FAO, first of the permanent specialized agencies of the United Nations to be founded after World War II, came into formal being in October 1945 with the signing of its constitution at a conference held in Quebec City. The immediate factor leading to its foundation was the Conference on Food and Agriculture convened at the request of Pres. Franklin D. Roosevelt at Hot Springs, Virginia, in 1943. In 1951 the organization was transferred from its temporary headquarters in Washington, D.C., to a permanent seat in Rome.

The ideas underlying foundation of the new organization came from two sources. First was the International Institute of Agriculture founded in Rome in 1905. The IIA had been designed to protect farmers against the effects of sudden slumps and gluts and was, therefore, concerned with information about market trends and agricultural statistics. Second was the League of Nations, which in the period immediately before World War II had been interested in problems of nutrition and their relationship to health. Both the IIA and the League, however, had been principally concerned with the more advanced countries, whereas in the foundation of the FAO several of the new and developing countries took great interest and played an active part.

Basis of FAO

Because FAO was in part an answer to the question of

feeding vast populations in the countries the economics of which had been seriously disrupted by World War II, it was natural that the first few years should be devoted to trying to help bring about a rapid increase in the world's overall supplies of food. At the same time the member countries had an eye on the possible emergence of surpluses of some commodities in certain countries should the distribution system break down or should needy governments not be able to pay for the food they required. Finally, an appreciation of the rapid rise in population in virtually all the parts of the world in the immediate postwar period added urgency to the organization's work.

With the creation of the United Nations Expanded Program of Technical Assistance, further extrabudgetary sums became available for FAO's field operations and from 1950 onward an increasing number of countries received technical assistance from FAO under the terms of that fund. The range of projects covered all of the FAO's activities in agriculture, nutrition, forestry, fisheries, and economics.

Most of the experts working under the technical-assistance program were on individual assignments, advising governments concerned on specific problems. FAO also helped its member governments through regional projects, including widespread plant and animal disease control schemes, such as the desert locust-control program in the Arabian Peninsula; projects for the eradication of rinderpest; and creation of a European commission for the control of foot-and-mouth disease. A broad educational program was also in continual operation, with training centres and seminars in many subjects and a fellowship program run in connection with the assignment of technical-assistance experts.

These programs were implemented by various publications and reports of a technical nature, including the *Plant Protection Bulletin*, comprising the work of a worldwide reporting service on plant diseases and quarantine regulations. A parallel informational service for animal diseases included an annual overall summary of developments in the subject field as well as periodical reports. The FAO-sponsored monthly bulletin of agricultural statistics and allied yearbooks on production and trade in agriculture, fisheries, and forest products were standard works in their fields.

United Nations Educational, Scientific and Cultural Organization. The historical roots of UNESCO lie in the intellectual cooperation efforts of the League of Nations and in the 1945 UN founding conferences at San Francisco and London, at which scholars who wanted to help increase the flow and exchange of knowledge drafted the organization's program.

UNESCO's activities were intended to be facilitative; through conferences, seminars, and publications, through the promotion of research and exchange of information and knowledge, and through technical advisory services, it was to assist, support, and seek to complement national efforts of member states. The significance of its activities in the life of any individual nation is limited. Even the allocation of the total budget among the neediest members would provide small amounts compared to what is spent by the countries themselves. The real effect is to be measured by the influence of internationally formulated standards of excellence, by the effectiveness of scholarly communication and exchanges, and by the quality of technical assistance provided.

Administration of UNESCO

UNESCO is administered by a director general and an international civil service of about 1,500 persons, subject to advice and direction from an executive board of 30 (originally 18) elected by the General Conference and designated by individual member states. Its permanent headquarters are in Paris. The constitution provides for national citizen advisory commissions in member states. The activities of UNESCO are coordinated with those of other UN agencies by the UN Economic and Social Council and by the policies of their respective member states. UNESCO's membership, 44 in 1945, had reached 127 by 1972.

Emphasis has been placed upon strengthening international professional (nongovernmental) organizations in education, science, and culture; establishing clearinghouses for the exchange of information; and promoting international professional conferences, symposia and seminars, and publication of scholarly abstracts. A Universal Copyright Convention and an Agreement on the Importation of Educational, Scientific, and Cultural Materials were drafted and submitted for ratification by member states. The necessity of extending communication, within the fields of UNESCO's interest, to include relatively less developed areas of the world produced at first only modest projects. Among these were in the Science Cooperation Offices in Montevideo, Uruguay, Cairo, New Delhi, and Djakartar, Indonesia; assistance for developing public library resources in certain emerging countries; fellowships for study in more highly developed areas of the world; studies and conferences on illiteracy; and some pilot projects in so-called fundamental education.

Although UNESCO's contributions have been mainly indirect, exceptions have been the annual *Study Abroad*, a comprehensive index to foreign study opportunities; a few seminars for teachers on methods to increase international understanding; the multivolume *Scientific and Cultural History of Mankind* (1963–); some modest promotion of social science research into national character and the nature of race; a project urging member states to increase understanding between Asia and the West; and some efforts to promote international exchanges in the arts.

UNICEF

United Nations Children's Fund. The General Assembly established the United Nations International Children's Emergency Fund (later styled the UN Children's Fund but still officially called UNICEF) in December 1946 to provide for the emergency needs of children in devastated areas. Financed by contributions from member states, UNICEF was effective in helping to feed destitute children in more than 50 countries; preventing such diseases as tuberculosis, whooping cough, and diphtheria; and providing for children's clothing and other needs. In 1953 it was made a permanent UN organization. (Ed.)

World Health Organization. WHO, established in 1948, is a specialized agency of the United Nations designed to further international cooperation for improved health conditions. WHO inherited from the Health Organization of the former League of Nations, set up in 1923, and from the International Office of Public Health at Paris, established in 1909, various international duties relative to epidemic control, quarantine measures, and the standardization of drugs. Under its constitution, however, WHO is given a much broader mandate—to promote the attainment of "the highest possible level of health" by all peoples. Health is defined positively as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity," and good health is held to be fundamental to world peace and security.

The membership of WHO consists of sovereign states and non-self-governing territories, their number growing from 26 in 1948 to 133 in 1972. The organization is financed primarily from annual contributions made by member governments on the basis of relative capacity to pay. The regular annual budget expanded in the first decade from $5,000,000 to more than $30,000,000, the largest contributor being the United States, which provided approximately one-third. In addition, after 1951 WHO was allocated substantial resources from the expanded technical-assistance program of the UN. Grants for special purposes have been also made to WHO from time to time by private foundations and individual governments.

The work of WHO embraces three fairly distinct categories of activities:

Activities of WHO

1. The provision of central clearinghouse and research services. As an example, information about the occurrence of pestilential disease anywhere in the world is broadcast over an international radio network to national health authorities, seaports, airports, and ships at sea. In 1952, 13 outdated international sanitary agreements were

replaced by a codified set of international sanitary regulations designed to standardize quarantine measures without interfering unnecessarily with trade and air travel across national boundaries. The central WHO Secretariat also issues numerous publications, sets statistical standards, and keeps member countries informed of the latest developments in use of vaccines, cancer research, nutritional discoveries, control of drug addiction, and health hazards of nuclear radiation.

2. Measures for the control of epidemic and endemic disease. This category consists chiefly of mass campaigns promoted by WHO against communicable diseases. These campaigns, some of them conducted with the cooperation of the United Nations Children's Fund, have been dramatically successful in reducing the incidence of tuberculosis, malaria, and venereal disease in the more backward regions of the globe. The organization launched a worldwide campaign for the complete eradication of malaria. Considerable progress was also made by WHO in attacking such diseases as cholera, yellow fever, yaws, and trachoma. Among the techniques employed in these campaigns are nationwide vaccination programs, instruction in the use of antibiotics and insecticides, the improvement of laboratory and clinical facilities for early diagnosis and prevention, assistance in providing pure water supplies and sanitation systems, and health education for rural communities. In 1963 WHO established an Expert Advisory Panel on Air Pollution to study methods of measuring and analyzing atmospheric pollutants.

3. Efforts to strengthen and expand the public health administrations of member nations. As its program developed, WHO set as its most important task the strengthening of national and local health services, especially in Africa, Asia, and Latin America. In furthering this vital objective, a wide variety of devices are utilized. The organization provides technical advice to governments on request in the preparation of long-term national health plans; sends out to the field international teams of experts to conduct surveys and demonstration projects; helps set up local health centres; offers aid in the development of national training institutions for medical and nursing personnel; makes available teachers for on-the-spot short-course training experiments; and makes travelling fellowship awards to doctors, public health administrators, nurses, sanitary inspectors, and laboratory technicians. DEPENDENT AREAS

The United Nations maintained concern for people residing in non-self-governing territories on two different levels: (1) under principles and procedures developed for making administering states internationally accountable for the treatment of their non-self-governing territories and (2) under the United Nations trusteeship system.

Non-self-governing territories. Under Article 73 of the Charter, members of the United Nations responsible for administering non-self-governing territories agreed to ensure the people of such territories just treatment, protection against abuses, and advancement toward self-government. They also agreed to transmit to the secretary general technical information concerning the economic, social, and educational conditions in their territories. In 1947 the General Assembly created a special committee to receive and analyze information on these territories and to make recommendations to the administering authorities on the basis of information received. Attempts of the committee to obtain political information on territories from the administering states met with resistance. Only Australia, The Netherlands, New Zealand, and the United States transmitted such information, the other administering states contending that the Charter did not require the transmission of political information.

There was considerable controversy over the question as to which territories were non-self-governing and when they ceased to be non-self-governing. France soon stopped transmitting information on a number of territories on the ground that they had either become self-governing or had become an integral part of France. Later Great Britain ceased to send information on Malta and Ghana, the United States on the Panama Canal Zone and Puerto Rico, Denmark on Greenland, and The Netherlands on Surinam and the Antilles. Administering states claimed the sole right to decide whether Article 73 (e) did or did not apply to one of their territories, but this position was challenged by the assembly, which in 1952 adopted a resolution containing a list of factors to serve as a guide in deciding whether a territory had obtained a full measure of self-government. In 1947 the committee received information on 74 territories with about 215,000,000 inhabitants; by 1956 this had declined to 55 territories with 115,000,000 inhabitants. In 1963 the committee was dissolved, and its functions were transferred to a Special Committee on Colonialism that had been created in 1961.

The anticolonial movement in the United Nations reached a high point in 1960 when the General Assembly adopted a resolution sponsored by 43 Afro-Asian states. This resolution, called the Declaration on the Granting of Independence to Colonial Countries and Peoples, condemned "the subjection of peoples to alien subjugation, domination, and exploitation" and declared that "immediate steps shall be taken . . . to transfer all powers" to the peoples in the colonies "without any conditions or reservations, in accordance with their freely expressed will and desire . . . in order to enable them to enjoy complete independence and freedom. . . ." The declaration was adopted 89–0 (with 9 abstentions).

Declaration on the Granting of Independence to Colonial Countries and Peoples (1960)

Spain, Portugal, South Africa, and Southern Rhodesia were the chief targets of the anticolonial drive. Spain and Portugal had refused to transmit information on their overseas territories on the ground that they were not dependencies but provinces enjoying constitutional equality with the provinces in the homeland. Southern Rhodesia was a peculiar case; the situation in South Africa was somewhat similar, except that South Africa was completely independent. Hostility toward South Africa, Southern Rhodesia, and Portugal on the part of the other African countries became intense. By 1965 the age of colonialism was about over. There remained a number of dependent territories, some of them isolated islands, that seemed too poor or too small to stand alone as political entities. How the principles of the declaration were to be applied to them became a difficult question. In many colonial areas to which self-government had been granted the basic social and economic problems remained unsolved, and all of them looked to the UN for help in gaining the strength needed to make them truly independent countries. The breakup of the colonial empires and the greatly enlarged membership of the UN modified the political structure of that organization and enabled the small states to play an important role in world politics. (L.M.G./A.Va.)

Trusteeship system. The trusteeship system of the UN, the successor to the mandates system of the League of Nations, was established on the principle that colonial territories wrested from defeated enemies should not be annexed by any victorious nation but should be administered by mandatory or trust power under international supervision until they were able to determine their own future status.

Eleven such territories taken from Germany, Italy, and Japan were brought under the trusteeship system after 1945. Other colonial territories could have been voluntarily brought under the system by Article 77 of the UN Charter, but no such action was taken. With the attainment of independence by Togo, British Cameroons, French Cameroun, Somalia, Tanganyika, Western Samoa, Ruanda-Urundi, and Nauru, only the trust territories in the Pacific area—New Guinea and the Pacific Islands—remained under trusteeship. Failure to utilize the trusteeship system for other colonial areas has been attributed to two principal developments: (1) after 1945 many colonies attained independence without being made subject to the trusteeship system, and (2) the colonial powers were reluctant to bring their colonial territories under the system because of the critical and even hostile attitude shown in the debates of the United Nations toward any form of colonial relationship.

Differences between the mandate and trusteeship systems

The UN trusteeship system differed in two important respects from the mandates system of the League of Nations. The first difference was the provision that facilitated the submission of petitions from inhabitants of the trust territory or from any other source. In addition, the Charter provided that a petitioner might appear in person to present his case orally before the Trusteeship Council or the General Assembly. Tens of thousands of written petitions were submitted to the United Nations. Indeed, the flood of petitions was sometimes so great that it was difficult to work out a procedure for handling them efficiently and expeditiously. The second basic innovation that differentiated the trusteeship system from the mandates system was the Charter provision for periodic visits by UN missions to the trust territories. In practice, each territory was visited by such a mission every three years. The purpose of the missions was to supplement information provided in the annual reports of the administering authorities and to provide what were regarded as objective and impartial evaluations of the conditions in each territory. Each visiting mission was composed of two persons drawn from administering countries and two from nonadministering countries, accompanied by five or six members of the UN Secretariat. The two members from administering countries were not drawn from among the nationals of the country administering the territory to be visited.

A Trusteeship Council was established by the Charter under the authority of the UN General Assembly. The council was empowered to consider reports made to it by the administering authorities, accept and examine petitions in consultation with the appropriate administering authority, provide for periodic visiting missions to the respective trust territories, and take such other actions as might be in conformity with the terms of trusteeship agreements between each administering authority and the General Assembly or, in the case of a strategic trust territory, with the Security Council.

The Trusteeship Council was to consist of an equal number of members administering trust territories and members not administering such territories, provided all of the permanent members of the Security Council were also to be members of the Trusteeship Council. To keep the council in balance there were to be as many nonadministering members elected for three-year terms as would be necessary to ensure that the council was equally divided between the administering and nonadministering members.

All of the former mandatory powers entered into UN trusteeship agreements after 1945 except South Africa, which refused to enter into such an agreement for the mandated territory of South West Africa. The United States became a member of the Trusteeship Council both by virtue of the fact that it was a permanent member of the Security Council and because it negotiated an agreement with the UN regarding the Pacific Islands, which it had taken from Japan in World War II. In 1950 Italy became a member of the Trusteeship Council by assuming responsibility for the administration of Somalia for a period of ten years and accordingly ceased to be a member of the council in 1960 when Somalia became an independent member of the United Nations. In 1960 France ceased to be an administering power when the trust territory of French Cameroun became independent, but France retained its membership on the Trusteeship Council as a nonadministering member because it was a permanent member of the Security Council.

Strategic areas

The UN Charter (Article 82) provided that certain areas, which might include part or all of a trust territory, could be designated as strategic areas. This provision was placed in the Charter in 1945 on the initiative of the United States, and in 1947 a strategic trusteeship agreement was concluded between the United States and the United Nations that placed the Pacific Islands (the Marshalls, Marianas, and Carolines) under the trusteeship system. All of the other trust agreements were made between the administering authority and the General Assembly but that for the Pacific Islands was made with the Security Council. In practice, however, there was no appreciable difference in the way the two types of territories were handled within the system. In the agreement with the Security Council the United States provided that it might close off any area for security reasons. This provision was never put into effect, and the United States freely permitted UN visiting missions to go through the territory and agreed that the Trusteeship Council should examine the annual reports on political, economic, and social conditions in the territory. (O.B.G.)

ADMINISTRATION

Finances. The secretary general must submit an annual budget including estimated expenditures to the General Assembly for approval. The Charter stipulates that the expenses of the organization shall be borne by members as apportioned by the General Assembly. The Committee on Contributions prepares a scale of assessments for each member, based on the general economic level and capacity of each state, and this scale is submitted to the General Assembly for approval. The United States is the largest contributor, but a few members make a larger per capita contribution. The U.S. assessment began at 49 percent of the total but, at the request of the United States government, this figure was steadily reduced until in 1963 it was 32 percent.

The normal operating expenses of the United Nations increased from $19,000,000 in 1946 to over $200,000,000 for 1972. When the cost of the special programs, specialized agencies, and peace-keeping operations was added to the regular budget, the total annual cost of the United Nations system became much greater. The special programs are financed by voluntary contributions of the members of the United Nations, and the specialized agencies have their own budgets. The rapid increase in membership after 1955 did not help UN finances, for most of the new members were economically weak. Nearly all of them needed help, and their financial contributions to the UN were minimal.

Personnel. The Secretariat of the United Nations, serving under the secretary general, influences the day-to-day work of the organization to a degree that is not indicated by the words of the Charter. This influence is largely a result of the fact that the members of the Secretariat are permanent expert officials. The staff is recruited on a merit basis, with regard to equitable geographical distribution. Members of the organization are required to take an oath of loyalty to the United Nations and are not permitted to receive instructions from member governments.

A United Nations Field Service and a United Nations Panel of Field Observers were organized by the assembly in 1949. The Field Service looks after the safety of UN missions in many parts of the world, and the Panel of Field Observers assists the various missions in supervising truces and observing plebiscites. Both are under the supervision of the secretary general.

Privileges and immunities. A General Convention on Privileges and Immunities of the United Nations, approved by the General Assembly in February 1946 and accepted by most of the members except the United States, asserted that the UN possesses juridical personality. The convention also provided for such matters as immunity from legal process of the property and officials of the United Nations. An agreement between the UN and the U.S., signed in June 1947, defined the privileges and immunities of the UN headquarters in New York.

Headquarters. The General Assembly decided during the second part of its first session in New York to locate its permanent headquarters in that city. John D. Rockefeller, Jr., gave land for a building site in Manhattan. Temporary headquarters was established at Lake Success on Long Island, New York. The permanent Secretariat building was completed and occupied in 1951. The building providing accommodations for the General Assembly and the councils was completed and occupied in early 1952.

The design of the UN flag, adopted in 1947, consists of the official emblem of the UN in white centred on a light-blue background. The Assembly designated October 24 as United Nations Day. (L.M.G./A.Va.)

United States of America

The foremost nation in the Western Hemisphere in population and economic development, the United States of America is in form a federal republic comprising 50 states. It is often referred to simply as the United States and, colloquially, as America. The 48 conterminous states occupy the central one-third of the North American continent, bounded on the west by the Pacific Ocean, on the north by Canada, on the east by the Atlantic Ocean, on the south by Mexico and arms of the Atlantic and Pacific. The newest states, Alaska and Hawaii, lie at the northwestern extremity of the continent and in the mid-Pacific, respectively.

Location and general character of the nation

The total area of the nation is 3,615,122 square miles (9,363,123 square kilometres), making it the fourth largest nation in the world in area (after the Soviet Union, Canada, and China), while its de facto 1972 population of some 208,837,000 made it the fourth most populous (after China, India, and the Soviet Union). Such outlying possessions as the Virgin Islands and the U.S. trust territories in the Pacific, and such politically related entities as the Commonwealth of Puerto Rico added 12,940 square miles (33,514 square kilometres) and 3,026,690 persons (1970) to these figures.

The major characteristic of the United States is probably its great variety. Its physical environment ranges from the Arctic to the subtropical, from the moist rain forest to the arid desert, from the bald mountain peak to the flat prairie stretching beyond all horizons. Its people probably comprise a wider range of racial, ethnic, and cultural types than any other nation. Quite apart from the presence of surviving American Indians and the descendants of slaves brought from Africa, the nation shows the effects of having taken in some 35,000,000 immigrants from around the world between the declaration of national identity in 1776 and the imposition of immigration quotas in 1921. Its natural resources, though becoming depleted or seriously polluted in some areas, continued to sustain an economic life that is more diversified than any other on Earth, providing the majority of its people with an unrivalled standard of living and richness of material choice. And, although it seemed still to offer its people opportunities for unparalleled personal advancement and wealth in the second half of the 20th century, it contained areas of poverty and blight in both urban and rural areas that were becoming an increasing threat to the social and political fabric of the nation.

I. The natural landscape

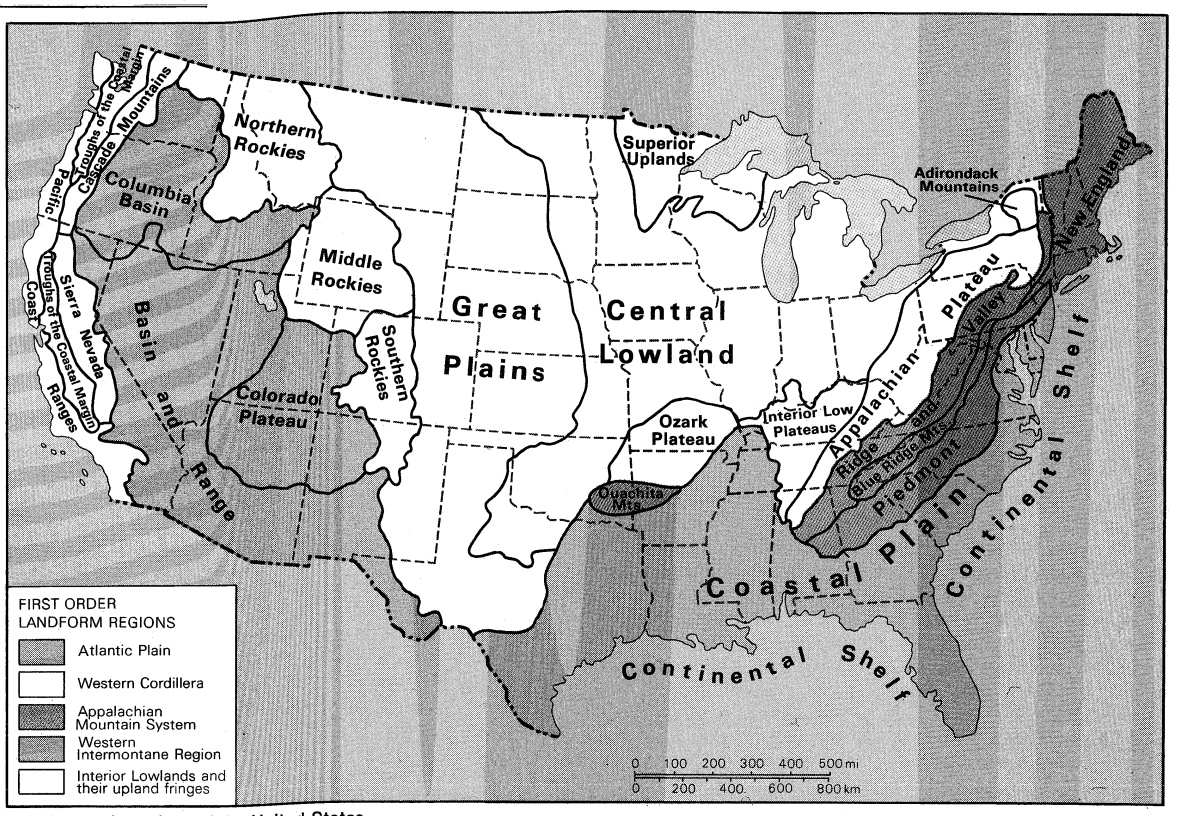
The two great sets of elements that mold the physical environment of the United States are, first, the geological, which determines the main patterns of landforms, drainage, and mineral resources and influences soils to a lesser degree; and, second, the atmospheric, which dictates not only climate and weather but also in large part the geographic distribution of soils, plants, and animals. Although climatic and geologic processes are not wholly independent of one another, each produces on a map patterns that are so profoundly different that essentially they comprise two separate geographies. Since this portion of the article covers only the conterminous United States, see also ALASKA; HAWAII; and PUERTO RICO.

LANDFORMS AND MINERALS



The grand geological pattern

The centre of the conterminous United States is a great sprawling interior lowland, reaching from the ancient shield of central Canada on the north to the Gulf of Mexico on the south. To east and west, this lowland rises first gradually, then abruptly, to mountain ranges that divide it from the sea on both sides. The two mountain systems differ drastically. The Appalachians on the east are low, almost unbroken, and in the main set well back from the Atlantic. From New York City to the Mexican border stretches a low Coastal Plain, whose swampy and convoluted shoreline merges almost imperceptibly with the ocean. Southward, the plain grows wider, swinging westward in Georgia and Alabama to truncate the Appalachians along their southern extremity and separate the interior lowland from the Gulf.

West of the Central Lowlands is the mighty Cordillera, part of the global mountain system that entirely rings the Pacific Basin. The Cordillera encompasses fully one-third of the United States, with an internal variety commensurate with its size. At its eastern margin lie the Rocky Mountains, a high, diverse, and discontinuous chain that stretches from New Mexico to the Canadian border. The Cordillera's western edge is a Pacific coastal chain of rugged mountains and inland valleys, the whole rising spectacularly from the sea without benefit of a coastal plain.

Finally, pent between the Rockies and the Pacific chain is a vast intermontane complex of basins, plateaus, and isolated ranges, so large and remarkable that they merit recognition as a region separate from the Cordillera itself. These regions—the Interior Lowlands and their upland fringes, the Appalachian Mountain system, the Atlantic Plain, the Western Cordillera, and the Western Intermontane Region—contain so much variety that they require further division into 24 major subregions (see accompanying map).

The Interior Lowlands and their upland fringes. Andrew Jackson is supposed to have remarked that the United States begins at the Alleghenies, implying that only west of the mountains, in the isolation and freedom

Physiographic regions of the United States.

of the great Interior Lowlands, could people finally escape Old World influences and become truly American. Whether or not the lowlands constitute the cultural core of the nation is debatable; there can be no doubt, however, that they comprise the geological core and in many ways the geographical core as well.

The midcontinent of the nation

This enormous region rests upon an ancient, much-eroded platform of complex crystalline rocks that have lain undisturbed by major orogenic (mountain-building) activity for over 600,000,000 years. Over much of central Canada, these old rocks are exposed at the surface and form the continent's single largest topographic region, the formidable and ice-scoured Canadian Shield.

In the United States, most of the crystalline platform is concealed under a deep blanket of sedimentary rocks. In the far north, however, the naked shield extends into the United States far enough to form two small but distinctive landform regions: the rugged and occasionally spectacular Adirondack Mountains of northern New York; and the more subdued but austere Superior Uplands, of northern Minnesota, Wisconsin, and Michigan. As in the rest of the shield, glaciers have stripped soils away, strewn the surface with boulders and other debris, and obliterated preglacial drainage systems. Most attempts at farming in this region have been abandoned, but the combination of a comparative wilderness in a northern climate, clear lakes, and white-water streams have turned both areas into seasonal vacationlands.

Mineral wealth in the Superior Uplands is legendary. Iron lies near the surface and close to the deepwater ports of the lower Great Lakes. Iron is mined both north and south of Lake Superior, but most famous are the colossal deposits of Minnesota's Mesabi Range, known for more than a century as one of the world's richest and a vital element in America's rise to industrial power. In spite of recent depletion, the Minnesota and Michigan mines still yield 80 percent in value of the nation's iron and about 10 percent of the world's supply.

South of the Adirondacks and Superior Upland lies the boundary between crystalline and sedimentary rocks; abruptly, everything is different. The core of this sedimentary region—quite literally the heartland of the United States—is the great Central Lowland, which stretches for 1,500 miles from New York state to central Texas and north another 1,000 miles to the Canadian province of Saskatchewan. To some, the landscape may seem dull, for heights over 2,000 feet are unusual, and truly rough terrain is almost unknown. Landscapes are varied, however, largely as the result of glaciation that directly or indirectly affected most of the region. North of the Missouri–Ohio river line, the advance and readvance of continental ice left an intricate mosaic of boulders, sand, gravel, silt, and clay and a complex pattern of lakes and drainage channels, some abandoned, some still in use. The southern part of the Central Lowlands is quite different, covered mostly with wind-borne loess that subdued the already low relief to nearly billiard-table flatness. Elsewhere, especially near major rivers, postglacial streams carved the loess into rounded hills, and visitors have aptly compared their billowing shapes to the waves of the sea. Above all, the loess produces soil of extraordinary fertility. As the Mesabi iron is the foundation of the United States' industrial wealth, the nation's agricultural prosperity is rooted in Middle Western loess.

The plateaus surrounding the midcontinent

The Central Lowlands resemble a vast saucer, rising gradually to higher lands on all sides. Southward and eastward, the land climbs gradually to three major plateaus. Beyond the reach of glaciation to the south, the sedimentary rocks have been raised into two broad upwarps, separated from one another by the great valley of the Mississippi River. The Ozark Plateau lies west of the river and occupies most of southern Missouri and northern Arkansas; on the east, the Interior Low Plateaus dominate central Kentucky and Tennessee. Except for two nearly circular patches of rich limestone country—the Nashville Basin of Tennessee and the fabled racehorse country of the Kentucky Bluegrass—most of both plateau regions is sandstone uplands, intricately dissected by streams. Local relief runs to several hundreds of feet in most places, and visitors to the region must travel winding roads along narrow stream valleys. Not many take the trouble, however, for soils are poor and mineral resources scanty.

Eastward from the Central Lowlands, the Appalachian Plateau—a narrow band of dissected uplands that strongly resembles the Ozark Plateau and Interior Low Plateaus in steep slopes, wretched soils, and endemic poverty—forms a transition between the interior plains

and the Appalachian Mountains. Usually, however, the Appalachian Plateau is considered a subregion of the Appalachian Mountains, partly on grounds of location, partly because of geologic structure. Unlike the other plateaus, where rocks are warped upward, the rocks here form a long narrow basin, wherein bituminous coal has been preserved from erosion. This Appalachian coal, like the Mesabi iron that it complements in American industry, is extraordinary. Extensive, thick, and close to the surface, it has stoked the furnaces of northeastern steel mills for decades and helps explain the huge concentration of heavy industry along the lower Great Lakes.

The Great Plains

The western flanks of the Interior Lowlands are the Great Plains, a region of awesome bulk that spans the full distance between Canada and Mexico in a swath nearly 500 miles wide. The Great Plains were built by successive layers of poorly cemented sand, silt, and gravel—debris laid down by parallel east-flowing streams from the Rocky Mountains. Seen from the east, the surface rises inexorably from about 2,000 feet near Omaha, Nebraska, to over 6,000 feet at Cheyenne, Wyoming, but the climb is so gradual that popular legend holds the Great Plains to be flat. True flatness is rare, although the High Plains of west Texas, Oklahoma, Kansas, and eastern Colorado come very close. More commonly, the land is broadly rolling, and parts of the northern plains are sharply dissected into "badlands."

The main mineral wealth of the Interior Lowlands derives from fossil fuels, scarcely surprising in a region underlain by sedimentary rocks. Coal occurs in structural basins protected from erosion—high-quality bituminous in the Appalachian, Illinois, and west Kentucky basins; and poorer bituminous and lignite in the eastern and northwestern Great Plains. Petroleum and natural gas have been found in nearly every state between the Appalachians and the Rockies, but the Midcontinent Fields of west Texas, the Texas Panhandle, Oklahoma, and Kansas surpass all others in the Interior Lowlands. Aside from small deposits of lead and zinc, metallic minerals are of little importance.

The Appalachian Mountain system. The Appalachians dominate the eastern United States and separate the Eastern Seaboard from the interior with a belt of subdued uplands that extends 1,500 miles from northeastern Alabama to the Canadian border. They are old and very complex mountains, the eroded stumps of much greater ranges. Present topography results from prolonged erosion that has differentially carved weak rocks away, leaving a skeleton of resistant rocks behind as highlands. Geologic differences are thus faithfully reflected in topography. In the Appalachians, these differences are sharply demarcated and elegantly arranged, so that all the major subdivisions except New England lie in strips parallel to the Atlantic and to one another.

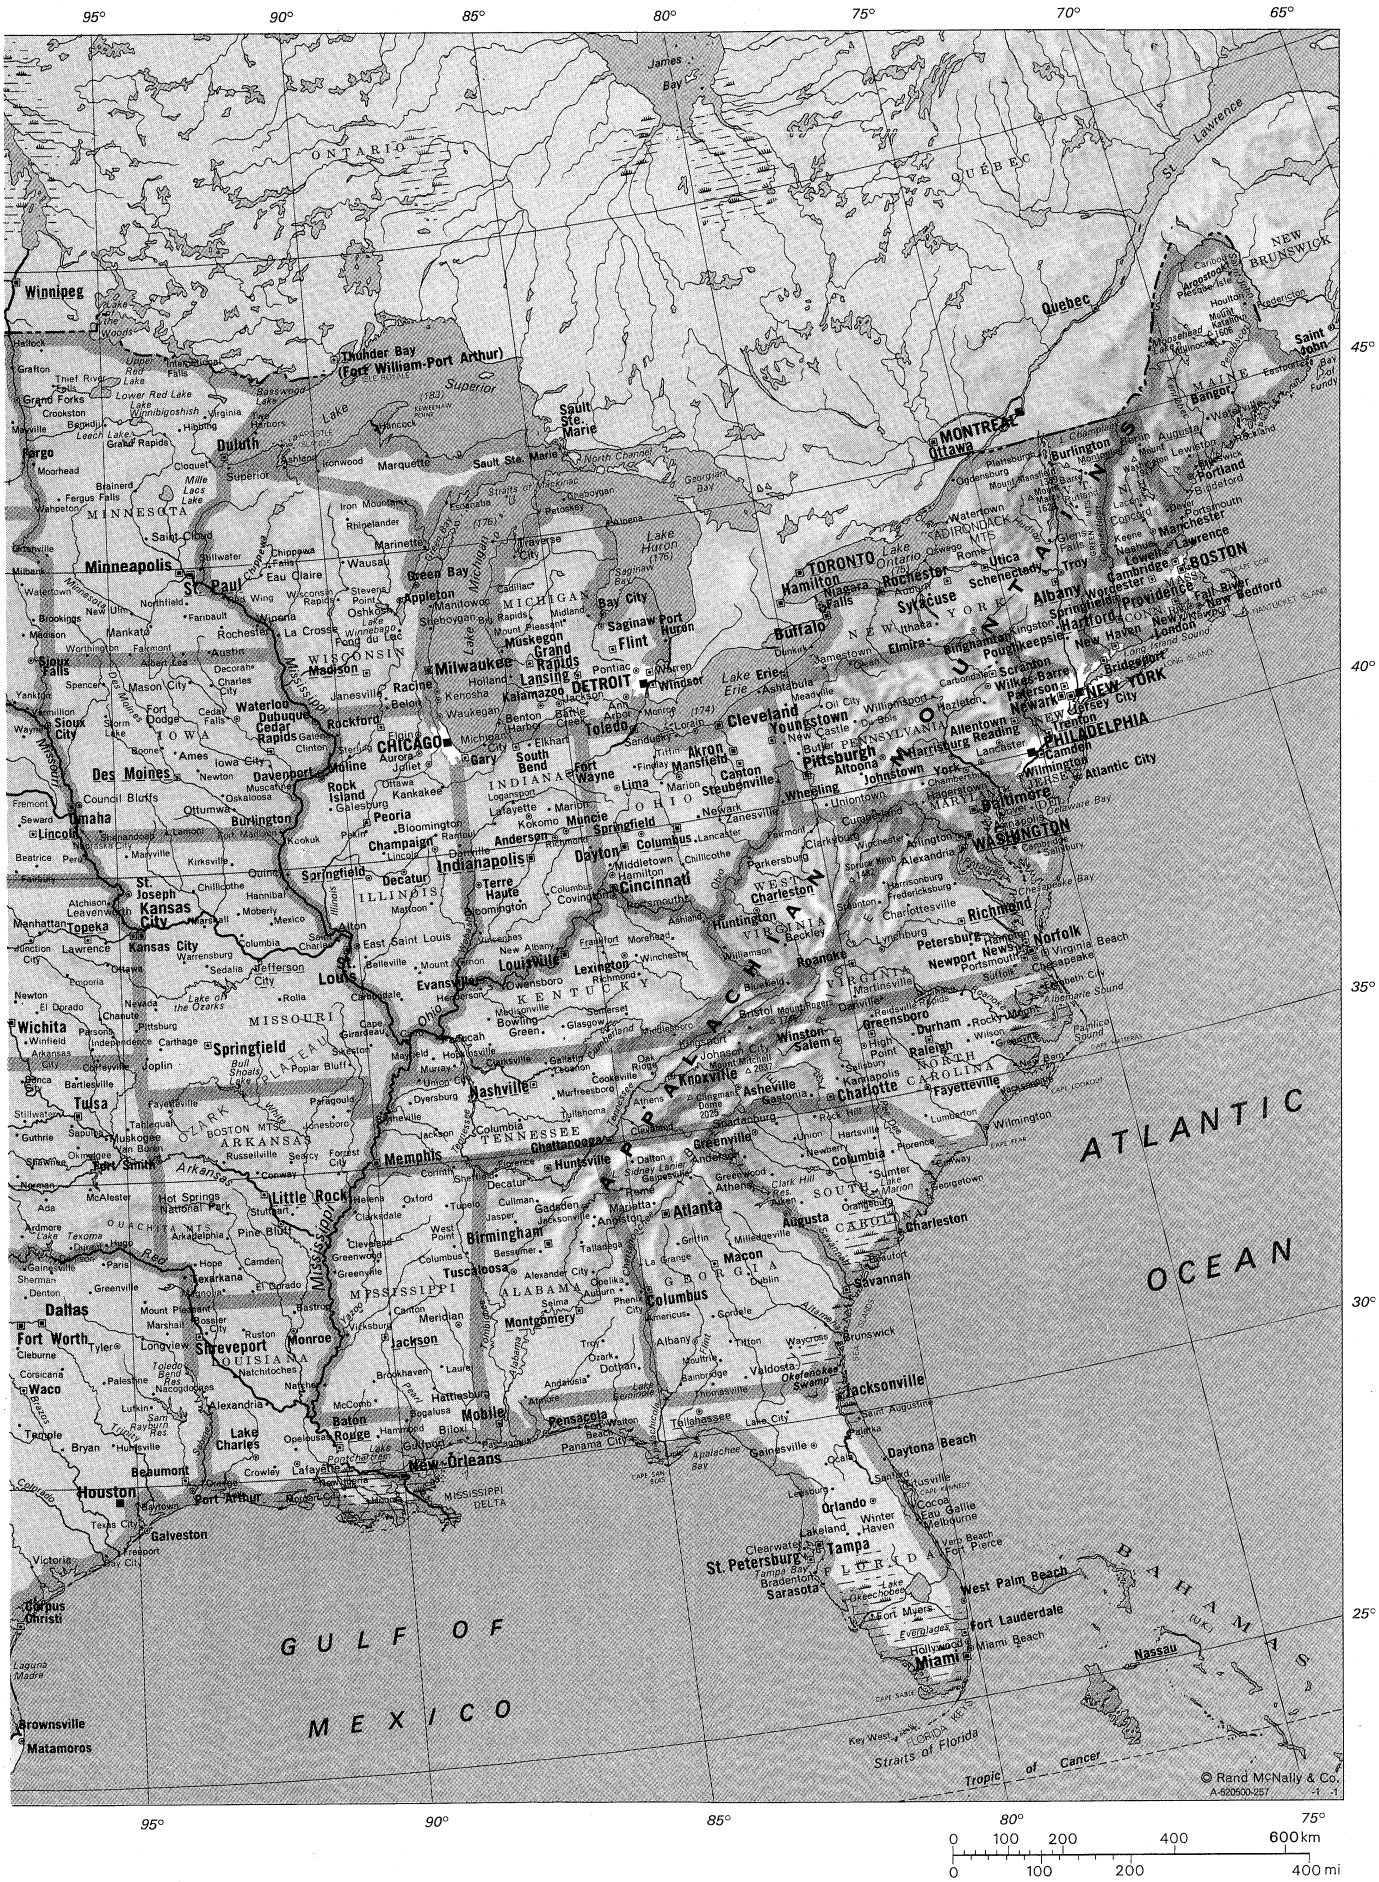
The core of the Appalachians, both geologically and geographically, is a belt of complex metamorphic and igneous rocks that stretches from Alabama to New Hampshire. The west side of this belt forms the long slender rampart of the Blue Ridge Mountains, containing the highest elevations in the Appalachians (Mt. Mitchell, North Carolina, 6,684 feet [2,037 metres]) and some of its most handsome mountain scenery. On its seaward side, the Blue Ridge descends in an abrupt and sometimes spectacular escarpment to the Piedmont, a well-drained, rolling land—never quite hills, never quite a plain. Before the settlement of the Middle West, the Piedmont was the most productive agricultural region in the United States, and several Pennsylvania counties still consistently report some of the highest farm yields per acre in the nation.

West of the crystalline zone, away from the axis of geologic deformation, sedimentary rocks have escaped metamorphism but are compressed into tight folds, like a rug that has slid and crumpled on a slippery floor. Erosion has carved the upturned edges of these folded rocks into the remarkable Ridge and Valley country of the western Appalachians. Seen from the air, this region looks as if some cosmic rake had been dragged 1,000 miles the length of the Appalachian system. Long linear ridges characteristically stand about 1,000 feet from base to crest and run for tens of miles, paralleled by broad open valleys of comparable length. In Pennsylvania, ridges run unbroken for great distances, occasionally turning abruptly in a zigzag pattern; by contrast, the southern ridges are broken by faults and form short parallel segments that are lined up like magnetized iron filings. By far the largest valley—and one of the most important routes in North America—is the Great Valley, an extraordinary trench of shale and limestone that runs nearly the entire length of the Appalachians. It provides a lowland passage from the middle Hudson Valley to Harrisburg, Pennsylvania and on southward where it forms the Cumberland and Shenandoah valleys, one of the main paths through the Appalachians since pioneer times. In New England it is floored with slates and marbles and forms the Valley of Vermont, one of the few fertile areas in an otherwise mountainous region.

Topography very much like that of the Ridge and Valley occurs in the Ouachita Mountains of western Arkansas and eastern Oklahoma, an area generally thought to be a detached continuation of Appalachian geologic structure, the intervening section buried beneath the sediments of the lower Mississippi Valley.

The New England mountain systems

The glaciated New England section of the Appalachians is divided from the rest of the chain by an indentation of the Atlantic. Although almost completely underlain by crystalline rocks, New England is laid out in north–south bands, reminiscent of the southern Appalachians. The rolling, rocky hills of southeastern New England are not dissimilar to the Piedmont, while, farther northwest, the rugged and lofty White Mountains are an obvious New England analogue to the Blue Ridge. (Mt. Washington, New Hampshire, at 6,288 feet [1,917 metres] is the highest peak in the northeastern United States.) And the westernmost ranges—the Taconics, Berkshires, and Green Mountains—exhibit a strong north–south lineation like the Ridge and Valley. Unlike the rest of the Appalachians, however, glaciation has scoured the crystalline rocks much like those of the Canadian Shield, so that New England is best known for its picturesque landscape, not its fertile soil.



Typical of diverse geologic regions, the Appalachians contain a great variety of minerals. Only a few occur in quantities large enough for sustained exploitation, notably iron in Pennsylvania's Blue Ridge and Piedmont and the famous granites, marbles, and slates of northern New England. In Pennsylvania, the Ridge and Valley region contains one of the world's largest deposits of anthracite coal, once the basis of a thriving mining economy; now most of the mines are shut, oil and gas having replaced anthracite as the major fuel for heating U.S. homes.

The Atlantic Plain. The eastern and southeastern fringes of the United States are part of the outermost margins of the continental platform, repeatedly invaded by the sea and veneered with layer after layer of young, poorly consolidated sediments. Part of this platform now lies slightly above sea level and forms a nearly flat and often swampy Coastal Plain, which stretches from Cape Cod to and beyond the Mexican border. Most of the platform, however, is still submerged, so that a band of shallow water, the Continental Shelf, parallels the whole Atlantic and Gulf coasts of the United States, in some places reaching 250 miles out to sea.

Coastal uplifts and depressions

The Atlantic Plain slopes so gently that even slight crustal upwarping can shift the coastline far out to sea at the expense of the Continental Shelf. The peninsula of Florida is just such an upwarp; nowhere in its 400-mile length does the land rise more than 350 feet above sea level; much of the southern and coastal areas rise less than ten feet and are poorly drained and dangerously exposed to Atlantic storms. Correspondingly, downwarps can result in extensive flooding. North of New York City, for example, the weight of glacial ice depressed most of the Coastal Plain beneath the sea, and the Atlantic now beats directly against New England's rock-ribbed coasts. Cape Cod, Long Island, and a few offshore islands are all that remain of New England's drowned Coastal Plain.

Another downwarp lies perpendicular to the Gulf coast and guides the course of the Lower Mississippi. The river, however, has filled with alluvium what otherwise would be an arm of the Gulf, forming a great inland salient of the Coastal Plain called the Mississippi Embayment.

South of New York, the Coastal Plain gradually widens, but ocean water has invaded the lower valleys of most coastal rivers and turned them into estuaries. The greatest is Chesapeake Bay, merely the flooded lower valley of the Susquehanna and its tributaries, but there are literally hundreds of others. Offshore a line of sandbars and barrier beaches stretches intermittently the length of the Coastal Plain, hampering entry of shipping into the estuaries but providing the crowded eastern United States with a marine playground over 1,000 miles long.

Poor soils are the rule on the Coastal Plain, though rare exceptions have formed some of America's most famous agricultural regions—for example, the citrus country of central Florida's limestone uplands and the Cotton Belt of the Old South, once centred on the alluvial plain of the Mississippi and belts of chalky black soils of east Texas, Alabama, and Mississippi. The Atlantic Plain's greatest natural wealth derives from petroleum and natural gas trapped in domal structures that dot the Gulf coast of east Texas and Louisiana. Onshore and offshore drilling have revealed colossal reserves, and Louisiana alone produces one-fourth of the nation's crude oil and one-fifth of the natural gas in the world.

The Western Cordillera. West of the Great Plains, the United States seems to become another world, a craggy land whose skyline is rarely without mountains—totally different from the open plains and rounded hills of the East. On a map, the alignment of the two main chains—the Rockies on the east, the Pacific ranges on the west—tempts one to assume a certain geological and hence topographic homogeneity. Nothing could be further from the truth, for each chain is divided into widely disparate sections.

Diversity of the Rocky Mountain chains

The Rockies are typically diverse. The Southern Rockies comprise a disconnected series of lofty elongated upwarps, their cores made of granitic basement rocks, stripped of sediments, and heavily glaciated at high elevations. In New Mexico and along the western flanks of the Colorado ranges, widespread volcanism and deformation of colourful sedimentary rocks have produced rugged and picturesque country, but the characteristic central Colorado or southern Wyoming range is impressively austere rather than spectacular. The Front Range west of Denver is prototypical, rising abruptly from its base to rolling alpine meadows between 11,000 and 12,000 feet. Peaks appear as low hills perched on this high-level surface, so that Colorado, for example, boasts 53 mountains over 14,000 feet but not one over 14,500.

The Middle Rockies occupy most of west central Wyoming. Most of the ranges resemble the granitic upwarps of Colorado, but thrust faulting and volcanism have produced varied and spectacular country to the west, some of which is included in Grand Teton and Yellowstone national parks. Much of the region, however, is not mountainous at all but consists of extensive intermontane basins and plains—largely floored with enormous volumes of sedimentary waste eroded from the mountains themselves. Whole ranges have been buried, producing the greatest gap in the whole Cordilleran system, the Wyoming Basin—which is, in fact, an intermontane peninsula of the Great Plains. As a result, the Rockies have never posed an important barrier to east–west transportation in the United States; all major routes, from the Oregon Trail to interstate highways, funnel through the basin, essentially circumventing the Rockies.

The Northern Rockies contain the most varied mountain landscapes of the Cordillera, reflecting a corresponding geologic complexity. The region's backbone is a mighty series of batholiths—huge masses of molten rock that slowly cooled below the surface and were later uplifted. The batholiths are eroded into rugged granitic ranges, which, in central Idaho, compose the most extensive wilderness country in the conterminous United States. East of the batholiths and facing the Great Plains, sediments have been folded and thrust-faulted into a series of linear north–south ranges, a southern extension of the spectacular Canadian Rockies. Although elevations run 2,000 to 3,000 feet lower than the Colorado Rockies (most of the Idaho Rockies lie well below 10,000 feet), increased rainfall and northern latitude have encouraged glaciation—here as elsewhere a sculptor of handsome alpine landscape.

The Pacific mountain chains

The western branch of the Cordillera directly abuts the Pacific Ocean. This coastal chain, like its Rocky Mountain cousins on the east flank of the Cordillera, conceals bewildering complexity behind a facade of apparent simplicity. At first glance, the chain consists merely of two lines of mountains with a discontinuous trough between. Immediately behind the coast is a line of hills and low mountains—the Pacific Coast Ranges. Farther inland, averaging 150 miles from the coast, the line of the Sierra Nevada and the Cascade Range includes the highest elevations in the conterminous United States. Between these two unequal mountain lines is a discontinuous trench, the Troughs of the Coastal Margin.

The apparent simplicity disappears under the most cursory examination. The Pacific Coast Ranges actually contain five distinct sections, each of different geologic origin, each with distinctive topography. The Transverse Ranges of Southern California are a crowded assemblage of barren island-like ranges, with peak elevations over 10,000 feet but sufficiently separated by plains and low passes that travel through them is easy. From Point Conception to the Oregon border, however, the main California Coast Ranges are entirely different, resembling the Appalachian Ridge and Valley region, with low linear ranges that result from erosion of faulted and folded rocks. Major faults run parallel to the low ridges, and the greatest—the notorious San Andreas Fault—was responsible for the earthquake that destroyed San Francisco in 1906. Along the California–Oregon line, everything changes again. There, the wildly rugged Klamath Mountains represent a western salient of interior structure reminiscent of the Idaho Rockies and the northern Sierra Nevada. In western Oregon and southwestern Washington, the Coast Ranges are also different—a gentle, hilly land carved by streams from a broad arch of marine deposits interbedded with tabular lavas. Finally, in the northernmost part of the Coast Ranges and the remote northwesternmost corner of the conterminous United States, a domal upwarp has produced the Olympic Mountains, whose serrated peaks tower nearly 8,000 feet above Puget Sound and the Pacific and whose upper slopes still support the largest active glaciers in the United States outside Alaska.

East of the Coast Ranges, the Troughs of the Coastal Margin contain the only extensive lowland plains of the Pacific margin—California's Central Valley, Oregon's Willamette Valley, and the half-drowned basin of Puget Sound in Washington state. Parts of an inland trench that extends great distances along the east coast of the Pacific, similar valleys occur in such diverse areas as Chile and the Alaska Panhandle. Blessed with better than average soils, easily irrigated, and freely accessible from the Pacific, these valleys have enticed settlers for over a century and have become the main centres of population and economic activity for much of the West Coast.

The Cascades and Sierras

Still farther east rise the two highest mountain chains in the conterminous United States—the Cascades and the Sierra Nevada. Aside from elevation, geographical continuity, and spectacular scenery, however, the two ranges differ in almost every important respect. Except for its northern section, where sedimentary and metamorphic rocks occur, the Sierra Nevada is largely made of granite, part of the same batholithic chain that creates the Idaho Rockies. The range is grossly asymmetrical, the result of massive faulting that has gently tilted the western slopes toward the Central Valley but has uplifted the eastern side to confront the interior with an awesome escarpment nearly two miles high. At high elevation, glaciers have scoured the granites to an astonishing gleaming white, while on the west the ice has carved spectacular valleys such as the Yosemite. The loftiest peak in the Sierras is Mt. Whitney, which, at 14,494 feet (4,418 metres), is the highest mountain in the contiguous 48 states. The upfaulting that produced Mt. Whitney is accompanied by downfaulting that formed nearby Death Valley, at 282 feet (86 metres) below sea level the lowest point on the North American continent.

The Cascades as well are made of volcanic rock, in northern Washington granitic like the Sierras, but for the rest, formed from relatively recent lava outpourings of dun-coloured basalt and andesite. The Cascades are in effect two ranges. The lower, older range is a long belt of upwarped lava, rising unspectacularly to elevations between 6,000 and 8,000 feet. Perched above the "low Cascades" is a chain of lofty quiescent volcanoes that punctuate the horizon with magnificent glacier-clad peaks. The highest is Mt. Rainier, whose 14,410 feet (4,392 metres) are all the more dramatic for rising from near sea level.

The Western Intermontane Region. The Cordillera's two main chains enclose a vast intermontane region of arid basins, plateaus, and isolated mountain ranges that stretches from the Mexican border nearly to Canada and extends 600 miles from east to west. This enormous territory contains three huge subregions, each with a distinctive geologic history and its own striking topographic personality.

Nestled against the west flanks of the Southern Rockies, the Colorado Plateau comprises an extraordinary island of geologic stability set in the turbulent sea of Cordilleran tectonic activity. Stability was not absolute, of course, so that parts of the plateau are warped and injected with volcanics, but in general the landscape results from the erosion by streams of nearly flat-lying sedimentary rocks. The result is a mosaic of angular mesas, buttes, and steplike canyons intricately cut from rocks that often are vividly coloured. Large areas of the plateau are so improbably picturesque that they have been set aside as national preserves. The Grand Canyon of the Colorado River is merely the most famous of several dozen such areas.

West of the plateau and abutting the Sierra Nevada's eastern escarpment lies the barren, arid Basin and Range, among the most remarkable topographic provinces of the United States. Rocks of great complexity have been broken by faulting, and the resulting blocks have tumbled, eroded, and been partly buried by alluvial debris that has accumulated in the desert basins at their feet. The eroded blocks form mountain ranges that are characteristically several tens of miles long, several thousand feet from base to crest, with peak elevations only occasionally much over 10,000 feet, and almost always aligned roughly north–south. The basins are typically floored with alluvium and sometimes salt.

The third intermontane region, the Columbia Basin, is literally the last, for in some parts its rocks are still being formed. Its entire area is underlain by innumerable tabular lava flows that have flooded the basin between the Cascades and Northern Rockies to undetermined depths. The volume of lava must be measured in thousands of cubic miles, for the flows blanket large parts of Washington, Oregon, and Idaho and in southern Idaho have drowned the Northern Rocky Mountains in a basaltic sea. Where the lavas are fresh, as in southern Idaho, the surface is often nearly flat, but more often the floors have been trenched by rivers—conspicuously the Columbia and the Snake—or by glacial floodwaters that have carved an intricate system of braided canyons in the remarkable Channeled Scablands of eastern Washington. In surface form, the eroded lava often resembles the topography of the Colorado Plateau, but the gaudy colours of the Colorado are replaced here by the sombre black and rusty brown of weathered basalt.

Minerals of the cordillera

Most large mountain systems are sources of varied mineral wealth, and the American Cordillera is no exception. Metallic minerals have been taken from most crystalline regions and have furnished the United States with both romance and wealth—the Sierra gold that provoked the 1849 Gold Rush, the fabulous silver lodes of western Nevada's Basin and Range, and gold strikes all along the Rocky Mountain chain. Today, however, industrial metals are far more important, copper and lead among the base metals and the more exotic molybdenum, vanadium, and cadmium, mainly useful in alloys.

In the Cordillera, as elsewhere, the greatest wealth stems from fuels. Most major basins contain oil and natural gas, conspicuously the Wyoming Basin, the Central Valley of California, and the Los Angeles Basin. The Colorado Plateau, however, has yielded some of the most interesting discoveries of recent years —considerable deposits of uranium and colossal occurrences of oil shale. Oil from the shale, however, probably could not be economically removed without widespread strip mining, and correspondingly large-scale damage to environment. Finally, and still more recently, wide exploitation of low-sulfur bituminous coal has been initiated in the Four Corners area of the Colorado Plateau, and open-pit mining has already devastated parts of this once pristine country as completely as it has in the ravaged Appalachian Plateau of West Virginia.

WATERWAYS

As befits a nation of continental proportions, the United States possesses an extraordinary network of rivers and lakes, including some of the largest and most useful in the world. In the humid East, they provide an enormous mileage of cheap inland transportation; westward, most rivers and streams are unnavigable but are heavily used for irrigation and power generation. Both East and West, unfortunately, have traditionally used lakes and streams as public sewers, and most large U.S. waterways are laden with vast poisonous volumes of industrial, agricultural, and human wastes.

The Eastern systems. Chief among U.S. rivers is the Mississippi, which, with its great tributaries, the Ohio and the Missouri, drains most of the midcontinent. It is one of the world's great inland waterways, navigable to Minneapolis nearly 1,200 airline miles from the Gulf of Mexico. Its eastern branches, chiefly the Ohio and the Tennessee, are also navigable for great distances. From the west, however, many of its numerous Great Plains tributaries are too seasonal and choked with sandbars to be used for shipping. The Missouri, for example, though longer than the Mississippi itself, was essentially without navigation until recently, when a combination of large dams, locks, and continual dredging has opened the river to considerable barge traffic.

The Mississippi and Great Lakes waters

The Great Lakes–St. Lawrence system comprises the second half of the world's greatest network of inland waterways, for it is connected to the Mississippi–Ohio by canals. No description of the Great Lakes is possible without superlatives, for the five lakes (four of which are shared with Canada) constitute by far the largest freshwater lake group in the world and carry a larger tonnage of shipping than any other. The three main barriers to navigation—the St. Marys Rapids, at Sault Ste. Marie; Niagara Falls; and the rapids of the St. Lawrence—are all bypassed by locks, whose 27-foot draft lets ocean vessels penetrate 1,300 miles into the continent, to Duluth and Chicago.

The third group of Eastern rivers drains the coastal strip along the Atlantic and Gulf of Mexico. Except for the Rio Grande, which rises west of the Rockies and flows 1,900 circuitous miles to the Gulf, few of these coastal rivers measure more than 300 miles, and most flow in an almost straight line to the sea. Except in glaciated New England and in arid southwest Texas, most of the larger coastal streams are navigable for some distance.

The Pacific systems. West of the Rockies, nearly all of United States' rivers are strongly influenced by aridity. In the deserts and steppes of the intermontane basins, most of the scanty runoff disappears into interior basins only one of which, the Great Salt Lake, holds any substantial volume of water. Aside from a few minor coastal streams, only three large river systems manage to reach the sea—the Columbia, the Colorado, and the San Joaquin–Sacramento system of California's Central Valley. All three are exotic: that is, they flow for considerable distances across dry lands from which they receive no water. Both the Columbia and Colorado have carved awesome gorges, the former through the sombre lavas of the Cascades and the Columbia Basin, the latter through the brilliantly coloured rocks of the Colorado Plateau. These gorges lend themselves to easy damming, and the once wild Columbia has been turned into a stairway of placid lakes whose waters irrigate the arid plateaus of eastern Washington and power one of the world's largest hydroelectric networks. The Colorado is less extensively developed, and recent proposals for new dam construction have met fierce opposition from those who want to preserve the spectacular beauty of the river's canyon lands.

CLIMATE AND ITS EFFECTS

Climate affects human habitats both directly and through its influence on vegetation, soils, and wildlife. In the United States, however, the natural environment has been altered drastically by nearly four centuries of European settlement, not to mention many thousand years of Indian occupancy.

But, wherever land is abandoned, "wild" conditions return rapidly, achieving over the long run a dynamic equilibrium among soils, vegetation, and the inexorable strictures of climate. Thus, though Americans have created an artificial environment of continental proportions, the United States, in fact, can be divided into a mosaic of bioclimatic regions, each distinguished by peculiar climatic conditions and each with a potential vegetation and soil that eventually would return in the absence of man. The main exception to this generalization applies to fauna, so grossly altered that it is almost impossible to know what sort of animal geography would redevelop in a United States if man were removed from the scene.

Climatic controls. The pattern of U.S. climates is largely set by three primary geographic controls: (1) the location of the conterminous United States almost entirely in the middle latitudes; (2) its position with respect to the continental landmass and its fringing oceans; and (3) the nation's gross pattern of mountains and lowlands. Each of these operates to determine the character of air masses and their changing behaviour from season to season.

The conterminous United States lies entirely between the Tropic of Cancer and 50° N latitude, a position that confines Arctic climates to the high mountaintops and genuine tropics to a small part of southern Florida. By no means, however, is the climate literally temperate, for the middle latitudes are notorious for extreme variations of temperature and precipitation.

Climatic impact of latitude, landforms, and oceans

The great size of the North American landmass tends to reinforce these extremes. Since land heats and cools more rapidly than water, places distant from an ocean tend to

exhibit "continental" climates; that is, they alternate between extremes of hot summers and cold winters, in contrast to the "marine" climates, which are more equable. Most U.S. climates are markedly continental, the more so because the Cordillera effectively confines the moderating Pacific influence to a narrow strip along the West Coast. Extremes of continentality occur near the centre of the continent, and North Dakota has seen ranges between a summer high temperature record of 121° F (49° C) and a winter low of −60° F (−51° C). Moreover, the general eastward drift of air over the United States carries continental temperatures all the way to the Atlantic coast. Bismarck, North Dakota, for example, exhibits a great annual temperature range; Boston, on the Atlantic but largely exempt from its influence, has a lesser but still continental range; but San Francisco, which is under strong Pacific influence, has only a small summer–winter differential.

The Western Cordillera confines not only Pacific temperatures to the coastal margin but also the Pacific rainfall. The Coast Ranges are high enough to make a local rain shadow in their lee, but the main barrier is the great rampart of the Sierra Nevada and Cascades. Rainy on their western slopes, barren on the east, this mountain crest forms one of the sharpest climatic divides in the United States.

The rain shadow continues east to the Rockies, leaving the entire Intermontane Region either arid or semi-arid, except where isolated ranges manage to capture leftover moisture at high altitudes. East of the Rockies, the westerly drift brings mainly dry air, and as a result the Great Plains are semi-arid. Still farther east, humidity increases owing to the frequent incursion from the south of warm, moist, and unstable air from the Gulf of Mexico, which produces more precipitation in the United States than the Pacific and Atlantic oceans combined.

Although the landforms of the Interior Lowlands have been termed dull, there is nothing dull about their weather conditions. Gulf air can flow northward across the Great Plains, uninterrupted by topographic barriers, but continental Canadian air flows south by the same route, and, since these two air masses differ in every important respect, the collisions often produce disturbances of monumental violence. Plainsmen and Middle Westerners grow accustomed to unexpected displays of furious weather—tornadoes, blizzards, hailstorms, precipitous drops and rises in temperature, and a host of other spectacular meteorological displays, sometimes dangerous but seldom boring.

The march of the seasons. Most of the United States is marked by sharp differences between winter and summer. In winter, when temperature contrasts between land and water are greatest, a huge mass of frigid, dry Canadian air spreads far south over the midcontinent, bringing cold, sparkling weather to the interior and generating great cyclonic storms where its leading edge confronts a shrunken mass of warm Gulf air to the south. Although such cyclonic activity occurs throughout the year, it is most frequent and intense during the winter, parading eastward out of the Great Plains to bring the Eastern states practically all their winter precipitation. Temperatures differ widely, depending largely on latitude. Thus, New Orleans, at 30° N latitude, and International Falls, Minnesota, at 49° N, have respective January temperature averages of 55° F (13° C) and 3° F (−16° C). In the north, therefore, precipitation comes as snow, often driven by furious winds; farther south, cold rain alternates with sleet and occasional snow. Southern Florida is the only dependably warm part of the East, though "polar outbursts" have been known to bring temperatures below 0° F (−18° C) as far south as Tallahassee. The main uniformity of Eastern weather in wintertime is the expectation of continual change.

Nationwide seasonal variations

Winter climate on the West Coast is very different. A great spiralling mass of relatively warm, moist air spreads south from the Aleutian Islands of Alaska, its semipermanent front producing gloomy overcast and drizzles that hang over the Pacific Northwest all winter long, occasionally reaching Southern California, which receives nearly all of its rain at this time of year. This Pacific air brings mild temperatures along the whole coast; the average January day in Seattle ranges between 33° and 44° F (1° and 7° C), in Los Angeles between 45° and 64° F (7° and 18° C). In Southern California, however, rains are separated by long spells of fine weather, and the whole region is a winter haven for those seeking refuge from less agreeable weather patterns. The Intermontane Region is similar to the Pacific coast, but with much less rainfall and a somewhat wider range of temperatures.

Summer sees a reversal of the air masses, and east of the Rockies the change resembles the summer monsoon of Southeast Asia. As the midcontinent heats up, the cold Canadian air mass weakens and retreats, pushed north by an aggressive mass of warm, moist air from the Gulf. The great winter temperature differential between North and South disappears as the hot, soggy blanket spreads from the Gulf coast to the Canadian border. Heat and humidity are naturally most oppressive in the South, but northern latitude brings small comfort. Houston expects its normal July day to reach 92° F (33° C), with relative humidity averaging near 75 percent, but Minneapolis, over 1,000 miles north, is only slightly cooler and less humid.

Since the Gulf air is unstable as well as wet, convectional and frontal summer thunderstorms are endemic east of the Rockies, accounting for a majority of total summer rain. These storms usually drench small areas with short-lived, sometimes violent downpours, so that crops in one Middle Western county may prosper, those in another shrivel in drought, and those in yet another are flattened by hailstones. Relief from the humid heat comes in the north from occasional outbursts of cool Canadian air; small, but more consistent relief is found through influences from the Great Lakes and high elevations in the Appalachians. East of the Rockies, however, U.S. summers are distinctly uncomfortable, and air conditioning is viewed today as a desirable amenity in any Eastern city.

Again, the Pacific regime is different. The moist Aleutian air retreats northward, to be replaced by mild, stable air from over the cool subtropical Pacific, and except in the mountains the Pacific coast is nearly rainless, though often foggy. Meanwhile, a small but potent mass of dry hot air raises temperatures to blistering levels over much of the intermontane Southwest. In Yuma, Arizona, for example, the normal July day reaches 108° F (42° C), while nearby Death Valley, California, holds the national record, 134° F (57° C). During its summer peak, this scorching air mass spreads from the Pacific margin as far as Texas on the east and Idaho to the north, turning the whole interior basin into a summer desert.

Over most of the United States, as in most continental climates, spring and autumn are agreeable but disappointingly brief. Autumn is particularly idyllic in the East, the romantic Indian summer of ripening corn and brilliantly coloured foliage, of mild days and frosty nights. The shift in dominance between marine and continental air masses, however, spawns furious weather in some regions. Along the Atlantic and Gulf coasts, for example, autumn is the season for hurricanes—the American equivalent of Southeast Asian typhoons—which rage northward from the Gulf and Caribbean to visit havoc along the Coast as far north as New England. The Mississippi Valley holds the dubious distinction of recording more tornadoes than any other area on Earth. These violent storms are usually focussed on relatively small areas and are confined largely to springtime.

The bioclimatic regions. Three first-order bioclimatic zones encompass most of the conterminous United States —regions in which climatic conditions are similar enough to dictate similar conditions of mature (zonal) soil and potential climax vegetation (*i.e.*, the assemblage of plants that would grow and reproduce indefinitely given stable climate and average conditions of soil and drainage). These are the Humid East, the Humid Pacific Coast, and the Dry West. In addition, the boundary zone between the Humid East and the Dry West is so large and

important that it constitutes a separate region, the Humid-Arid Transition. Finally, because the Western Cordillera contains an intricate mosaic of climatic types, largely determined by local elevation and exposure, it is useful to distinguish the Western Mountain Climate. The first three zones, however, are very diverse and require further breakdown, producing a total of ten main bioclimatic regions. For two reasons, the boundaries of these bioclimatic regions are much less distinct than boundaries of landform regions. First, climate obviously varies from year to year, especially in boundary zones, whereas landforms do not. Second, regions of climate, vegetation, and soils coincide generally but sometimes not precisely. Boundaries, therefore, should be interpreted as zonal and transitional, rarely as sharp lines in the landscape.

Indistinctness of climatic boundaries

For all of their indistinct boundaries, however, these bioclimatic regions have strong and easily recognized identities. Such regional identity is strongly reinforced when a particular area falls entirely within a single bioclimatic region and at the same time a single landform region. The result—as in the Piedmont South, the central Middle West, or the western Great Plains—is a landscape with an unmistakable regional personality.

The Humid East. The largest and in some ways the most important of the bioclimatic zones, the Humid East was where the Europeans first settled, tamed the land, and learned the new ways that were to make them American. In aboriginal times, nearly all this territory was forested, a fact of central importance in American history that profoundly influenced both soils and wildlife. As in most of the world's humid lands, soluble minerals have been leached from the earth, leaving a great family of soils called pedalfers, rich in relatively insoluble iron and aluminum compounds.

Both forests and soils, however, differ considerably within this vast region. Since rainfall is ample and summers warm everywhere, the main differences result from the length and severity of winters, which determine the length of growing season. Winter, obviously, differs according to latitude, so that the Humid East is sliced into four great east–west bands of soils and vegetation, with progressively more amenable winters as one travels southward. These changes occur very gradually, however, and the boundaries therefore are extremely subtle.

Climatic sub-regions of the Eastern U.S.

A Sub-Boreal Forest Region is the northernmost of these bands. Only a small and discontinuous part of the United States, it represents the tattered southern fringe of the vast Canadian taiga—a scrubby forest dominated by evergreen needle-leaf species that can endure the ferocious winters and reproduce during the short, erratic summers. Average growing seasons are below 120 days, though Newberry, Michigan, has recorded frost-free periods lasting as long as 161 days and as short as 76. What soils survived the scour of glaciation are miserably thin podzols—heavily leached, highly acid, and often interrupted by extensive stretches of bog. Most attempts at farming in the region long since have been abandoned.

Farther south lies a Humid Microthermal Zone of milder winters and longer summers. Large broadleaf trees begin to crowd out the evergreens, producing a mixed forest of greater floristic variety and economic value and famous for its brilliant autumn colours. As the forest grows richer in species, sterile podzols give way to more productive gray-brown podzolic soils, stained and fertilized with humus. Although winters are warmer than the Sub-Boreal zone, and although the Great Lakes help temper the bitterest cold, January temperatures ordinarily average below freezing, and a winter without a few subzero days is uncommon. Everywhere, the ground is solidly frozen and snow covered for several months of the year.

Still farther south are the Humid Subtropics. The region's northern boundary is one of the United States' most portentous climatic lines, the approximate northern limit of a 180–200-day growing season, the outer margin of cotton growing, and, hence, of the Old South. Most of the South lies in the Piedmont and Coastal Plain, for higher elevations in the Appalachians cause a peninsula of Northern mixed forest to extend as far south as northern Georgia. The red-brown podzolic soil, once moderately fertile, has been severely damaged by overcropping and burning. Thus much of the region that ordinarily sustains a rich, broadleaf-forest flora in fact supports poor pinewoods. Throughout the South, summers are hot, muggy, long, and disagreeable; Dixie's "frosty mornings" bring a welcome respite in winter.

The southern margins of Florida contain the conterminous United States' only real tropics, an area in which frost is almost unknown. Hot, rainy summers alternate with warm and somewhat drier winters, with a secondary rainfall peak during the autumn hurricane season—altogether a typical monsoonal regime. Soils and vegetation are mostly immature, however, since southern Florida rises so slightly above sea level that substantial areas, such as the Everglades (*q.v.*), are swampy and often brackish. Peat and sand frequently masquerade as soil, and much of the vegetation is either salt-loving mangrove or sawgrass prairie.

The Humid Pacific Coast. The western humid region differs from its eastern counterpart in so many ways as to be a world apart. Much smaller, it is crammed into a narrow littoral belt to the windward of the Sierra–Cascade summit, dominated by mild Pacific air, and chopped by irregular topography into an intricate mosaic of climatic and biotic habitats. Throughout the region, rainfall is extremely seasonal, falling mostly in the winter half of the year. Summers are droughty everywhere, but the main regional differences come from the length of drought—from two months in humid Seattle to nearly five months in semi-arid San Diego.

Western Washington, Oregon, and Northern California lie within a zone that climatologists call Marine West Coast. Winters are raw, overcast, and drizzly—not unlike northwestern Europe—with subfreezing temperatures restricted mainly to the mountains, upon which enormous snow accumulations produce local alpine glaciers. Summers, by contrast, are brilliantly cloudless, cool, and with frequent foggy intervals along the Coast and somewhat warmer in the inland valleys. This mild marine climate produces some of the world's greatest forests, enormous straight-boled evergreen trees that furnish the United States with much of its commercial timber. Mature soils are typical of humid midlatitude forest lands, a moderately leached gray-brown podzol.

The United States' Mediterranean-like climes

Toward the south, with diminishing coastal rain the moist marine climate gradually gives way to California's tiny but much publicized Mediterranean regime. Although mountainous topography introduces a bewildering variety of local environments, scanty winter rains are quite inadequate to compensate for the long summer drought, and much of the region has a distinctly arid flavour. For much of the year, cool, stable Pacific air dominates the Coast, bringing San Francisco its famous fogs and Los Angeles its infamous smoggy temperature inversions. Inland, however, summer temperatures reach blistering levels, so that in July, while Los Angeles expects a normal daily maximum of 76° F (24° C), Fresno expects 100° F (38° C) and is climatically a desert. As might be expected, Mediterranean California contains a huge variety of vegetal habitats, but the commonest perhaps is the chaparral, a drought-resistant, scrubby woodland of twisted hard-leafed trees, picturesque but of little economic value. Soils are similarly varied, but most are light in colour and rich in soluble minerals, qualities typical of subarid soils.

The Dry West. In the United States, to speak of dry areas is to speak of the West. It covers an enormous region beyond the dependable reach of moist oceanic air, occupying the entire Intermontane area and sprawling from Canada to Mexico across the western part of the Great Plains. To Americans nurtured in the Humid East, this vast territory across the path of all transcontinental travellers has been harder to tame than any other—and no region has so gripped the national imagination as this fierce and dangerous land.

In the Dry West, nothing matters more than water. Thus, though temperatures may differ radically from

place to place, the really important regional differences depend overwhelmingly on the degree of aridity, whether an area is extremely dry and hence desert or whether it is semi-arid and therefore steppe.

The Great American Desert

Americans of the 19th century were preoccupied by the myth of a Great American Desert, which supposedly occupied more than one-third of the nation. True desert in fact is confined to the Southwest, with patchy outliers elsewhere, all without exception located in the lowland rain shadows of the Cordillera. Vegetation varies between nothing at all (a rare circumstance confined mainly to salt flats and sand dunes) to a low cover of scattered woody scrub and short-lived annuals that burst into flamboyant bloom after rains. Soils are usually thin, light coloured, and overrich with mineral salts. In some areas, wind erosion has removed fine-grained material, leaving behind desert pavement, a barren veneer of broken rock.

Most of the West, however, lies in the semi-arid region, in which rainfall is scanty but adequate to support a thin cover of short bunchgrass, commonly alternating with scrubby sagebrush. As in the desert, soils fall into the large family of the pedocals, rich in calcium and other soluble minerals, but here, in a slightly wetter environment, enriched with humus from decomposed grass roots. Under proper management, these chestnut-coloured steppe soils can prove very fertile.

Weather in the West resembles that of other dry regions of the world, often extreme, violent, and reliably unreliable. Rainfall, for example, obeys a cruel natural law: as total precipitation decreases, it becomes more undependable. John Steinbeck's novel *The Grapes of Wrath* describes a family enticed to the arid frontier of Oklahoma during a wet period, only to be driven out by the savage drought of the 1930s that turned the western Great Plains into the great American Dust Bowl. Temperatures also fluctuate convulsively within short periods, and high winds are infamous throughout the region.

The Humid-Arid Transition. East of the Rockies, all climatic boundaries are gradational. None, however, is so important nor so imperceptibly subtle as the boundary zone that separates the Humid East from the Dry West and that alternates unpredictably between arid and humid conditions from year to year. Stretching from Texas to North Dakota in an ill-defined band between the 95th and 100th meridians, this transitional region deserves separate recognition, partly because of its great size, partly because the fine balance between surplus and deficit rainfall produces a unique and valuable combination of soils, flora, and fauna. The native vegetation, insofar as it can be reconstructed, was prairie, the legendary sea of tall, deep-rooted grass now almost entirely tilled and planted to grains. Soils, often of loessial derivation, include the enormously productive chernozem ("black earth") in the north, with reddish prairie soils of nearly equal fertility in the south. Throughout the region, temperatures are severely continental, with bitterly cold winters in the north and scorching summers everywhere.

The prairies

The western edge of the prairie fades gradually into the shortgrass steppe of the High Plains, the change a function of diminishing rainfall. The eastern edge, however, represents one of the few major discordances between a climatic and biotic boundary in the United States, for the grassland penetrates the eastern forest in a great salient across humid Illinois and Indiana. Many scholars believe this part of the U.S. prairie was artificially induced by repeated Indian burning and consequent destruction of the forest margins.

The Western Mountain climates. Throughout the Cordillera and Intermontane regions, irregular topography shatters the grand bioclimatic pattern into an intricate mosaic of tiny regions that differ drastically according to elevation and exposure. No small- or medium-scale map can accurately record such complexity, and mountainous parts of the West are said, noncommitally, to have a "mountain climate." Lowlands are usually dry, but increasing elevation brings lower temperature, decreased evaporation, and—if a slope faces prevailing winds—greater precipitation. Soils vary wildly from place to place, but vegetation is fairly predictable. From the desert or steppe of intermontane valleys, a climber typically ascends into parklike savanna, then through an orderly sequence of increasingly humid and boreal forests until, if the range is high enough, he reaches timberline and Arctic tundra. The very highest peaks are snow-capped, although permanent glaciers rarely occur outside the cool humid highlands of the Pacific Northwest.

Animal life. With most of North America, the United States lies in the Nearctic faunistic realm, a region containing an assemblage of species similar to Eurasia and North Africa but sharply different from the tropical and subtropical zones to the south. Main regional differences correspond roughly with primary climatic and vegetal patterns. Thus, for example, the animal communities of the Dry West differ sharply from those of the Humid East and from those of the Pacific coast. Because animals tend to range over wider areas than plants and because they migrate, faunal regions are generally coarser than vegetal regions and harder to delineate sharply.

The animal geography of the United States, however, is far from a natural pattern, for European settlement produced a series of environmental changes that grossly altered the distribution of animal communities. First, many species were hunted to extinction or near extinction, most conspicuously, perhaps, the American bison, which ranged by the millions nearly from coast to coast but now lives only in zoos and wildlife preserves. Second, habitats were upset or destroyed throughout most of the country—forests cut, grasslands plowed and overgrazed, and migration paths interrupted by fences, railroads, and highways. Third, certain introduced species found hospitable niches and, like the English sparrow, spread over huge areas, often pre-empting the habitats of native animals. Fourth, though their effects are not well understood, chemical biocides such as DDT were used for so long and in such volume that they are believed at least partly responsible for catastrophic mortality rates among large mammals and birds, especially predators high on the food chain. In consequence, many native animals have been reduced to tiny fractions of their former ranges or exterminated completely, while other animals, both native and introduced, have found the new anthropocentric environment well suited to their needs, with explosive effects on their populations. The coyote and several species of deer are among the animals that now occupy much larger ranges than they once did. (P.F.L.)

Disruption of natural patterns of animal life

II. Patterns of settlement and cultural development

Although the land was occupied and much affected by diverse Indian cultures over many millennia, these pre-European settlement patterns have had virtually no impact upon the contemporary nation—except locally, as in parts of New Mexico. A benign habitat permitted a huge contiguous tract of settled land to materialize across nearly all the eastern half of the United States and within lesser, but still substantial, patches of the West. Climate, physiography, soils, plant cover, and drainage were such that access or occupance was difficult only locally—with the result that reasonably pure wilderness is a rare phenomenon in the United States today. The vastness of the land, the scarcity of labour, and the abundance of migratory opportunities in a land replete with raw physical resources contributed to exceptional human mobility and a quick succession of ephemeral forms of land use and settlement. Although the handiwork of man is everywhere visible in the grossly altered environments, human endeavour has been largely exploitative and destructive. Most of the pre-European landscape in the United States was so swiftly and radically altered that it is difficult to conjecture intelligently about its earlier appearance.

Factors affecting use of the land

For further details on settlement and cultural patterns, see the articles on the individual U.S. states and on the major cities.

RURAL AND URBAN AMERICA

The overall impression of the settled portion of the U.S. landscape, rural or urban, is one of disorder, of lack of coherence, even in areas of strict geometric sur-

vey. Indeed, the individual landscape unit is seldom in visual harmony with its neighbour, so that, however sound in design or construction the single structure may be, the general effect is untidy. These attributes have been intensified by the acute individualism of the American, vigorous speculation in land and other commodities, a strongly utilitarian attitude toward the land and the treasures above and below it, and government policy and law. Further, the landscape is remarkable for its emphasis upon transportation facilities, which are often critical in determining both form and function.

Another special characteristic of U.S. settlement, one that became obvious only by the mid-20th century, is the convergence of rural and urban modes of life. The farmsteads—and rural folk in general—have become increasingly citified, and agricultural operations have become ever more factory-like, while the metropolis grows more and more gelatinous, unfocussed, and pseudo-bucolic along its vague but rapidly spreading margins.

Rural settlement. Patterns of rural settlement everywhere and always tell much about the history, economy, society, and minds of those who create them as well as about the land itself. The essential design of rural activity in the United States bears a strong family resemblance to that of other neo-European lands, such as Canada, Australia, New Zealand, South Africa, Argentina, or Siberia —places that have undergone rapid occupation and exploitation during recent times by vigorous immigrants intent upon short-term development and enrichment. In all such areas, under novel social and political conditions and with a relative abundance of territory and physical resources, ideas and institutions derived from a relatively stable medieval or early-modern Europe have undergone major transformation. Further, these are nonpeasant countrysides, alike in thus far having failed to achieve the intimate symbiosis of man and habitat, the humanized rural landscapes characteristic of many relatively dense, stable, earthbound communities in parts of Asia, Africa, Europe, and aboriginal Latin America.

Comparative rural patterns: U.S. and elsewhere

Early models of land allocation. From the beginning, the prevalent official policy of the British (except between 1763 and 1776) and then of the new U.S. government was to promote agricultural and other settlement, to push the frontier westward as fast as physical and economic conditions permitted. The British crown's grants of large, often vaguely specified tracts to individual proprietors or companies enabled the grantees, in turn, to draw settlers by the sale or lease of land at attractive prices or even by outright gift.

Of the numerous attempts at group colonization, the most notable effort was the theocratic yet collectivist New England town that flourished, especially in Massachusetts, Connecticut, and New Hampshire, during the first century of settlement. The town, the basic unit of government and comparable in area to townships in other states, allotted both rural and village parcels to single families by group decision. The residences of farmers and all others were concentrated in a central village. This quasi-communal system broke down before the end of the colonial era, although the village persisted as an amoeba-shaped entity straggling along converging roads, neither fully rural nor agglomerated in form. The only latter-day settlement experiment of notable magnitude to achieve enduring success was a series of Mormon settlements in the Great Basin region of Utah and adjacent states, with their tightly concentrated farm villages reminiscent of the New England model. Many other efforts were, or are being, made along ethnic, religious, or political lines, but success has been at best brief and fragile.

Creating the national domain. With the coming of independence and after complex negotiations, the original 13 states surrendered to a new national government nearly all their claims to the unsettled western lands beyond their boundaries. Some tracts, however, were reserved for disposal to particular groups. Thus the Western Reserve of northeastern Ohio gave preferential treatment to natives of Connecticut, while the military tracts in Ohio and Indiana were used as bonus payments to veterans of the Revolution.

A federally administered national domain was created, to which the great bulk of the territory acquired in the 1803 Louisiana Purchase and later beyond the Mississippi and in 1819 in Florida was consigned. The only major exceptions were the public lands of Texas, which were left within that state's jurisdiction, such earlier French and Spanish land grants as were confirmed, often after tortuous litigation, and some Indian lands. In sharp contrast to the slipshod methods of colonial land survey and disposal, the federal land managers expeditiously surveyed, numbered, and mapped their territory in advance of settlement, beginning with Ohio in the 1780s, then sold or deeded it to settlers under inviting terms at a number of regional land offices.

The design universally followed in the new survey system (except within the French, Spanish, and Indian grants) was a simple, efficient rectangular scheme. Townships were laid out as square blocks, six by six miles in size, oriented with the compass directions. Thirty-six sections, each one square mile, or 640 acres, in size, were designated within each township; and public roads were established along section lines and, where needed, along half-section lines. At irregular intervals, offsets in survey lines and roads were introduced to allow for the Earth's curvature. Individual property lines were coincident with, or parallel to, survey lines, and this pervasive rectangularity generally carried over into the geometry of fields and fences or the townsites later superimposed upon the basic rural survey.

The establishment of townships

This all-encompassing checkerboard pattern is best appreciated from an airplane window over Iowa or Kansas. There, one sees few streams or other natural features or few diagonal highways or railroads interrupting the triumphant squareness of the landscape. A systematic rectangular layout, rather less rigorous in form, also appears in much of Texas and those portions of Maine, western New York and Pennsylvania, and southern Georgia pioneered from the 1780s onward.

Distribution of rural lands. Over the past two centuries, Congress has enacted a series of complex schemes for distribution of the national domain: the Homestead Act of 1862, which offered title to 160 acres to individual settlers, subject only to residence for a certain period and the making of minimal improvements, is only the most famous of these. The legal provisions have varied with time as the nature of farming technology and the remaining lands have changed, but their clear intention has been to flesh out the Jeffersonian ideal of a republic peopled by yeoman farmers owning and tilling economically self-sufficient properties.

The program succeeded well in providing private owners with almost all choice lands, aside from parcels reserved for schools and various township and municipal uses. Just over one-third of the national territory is still owned by the federal government, about one-half of this in Alaska. Nearly all, however, aside from that used by government agencies, is in the West and is unsuited for intensive agriculture or grazing because of the roughness, dryness, or salinity of the terrain, but much federal land is leased out for light grazing or for timber cutting.

Patterns of farm life. During the classic period of U.S. rural life, around 1900, the typical American lived or worked on a farm or was economically dependent upon farmers. In contrast to rural life in many other parts of the world, the farm family lived on an isolated farmstead some distance from town and often from farm neighbours; its property averaged less than one-quarter square mile. This farmstead would vary in form and content with local tradition and economy. In particular, barn types were localized—for example, the tobacco barns of the South, the great dairy barns of Wisconsin, or the general-purpose forebay barns of southeast Pennsylvania —as were modes of fencing. In general, however, the farmstead contained dwelling, barn, storage and sheds for small livestock and equipment, a small orchard, and kitchen garden. A woodlot might be found in the least accessible or least fertile part of the farm.

The U.S. farm around 1900

Successions of such farms were connected with one another and with the towns by means of a dense, usually

rectangular lattice of roads, largely unimproved at the time. The hamlets, villages, and smaller cities were arrayed at relatively regular intervals, with size and affluence determined in large part by presence and quality of rail service or status as county seat. But, among a population that has been historically rural, individualistic, and anti-urban in bias, many a service normally located in urban places might be found in a rustic setting. Thus much retail business was transacted by means of itinerant peddlers; the post office and many small shops for the fabrication, distribution, or repair of some basic items were often located in isolated farmsteads.

Social activity also tended to be widely dispersed among numerous rural churches, schools, or grange halls; and the climactic event of the year might well be the county fair, political rally, or religious encampment—again on a rural site. Not the least symptomatic sign of the strong tendency toward spatial isolation are the countless family burial plots or community cemeteries so liberally distributed across the countryside.

Regional small-town patterns. There has been and still is much regional variation among smaller villages and hamlets. Unfortunately, such phenomena have received relatively little attention from students of U.S. culture or geography. The distinctive New England village, of course, is generally recognized and cherished: a loose clustering of white frame buildings, including a church (more often than not Congregationalist or Unitarian), town hall, shops, and stately homes with tall shade trees around the central green or commons, a grassy expanse that may contain a bandstand and monuments or a flower bed. Derivative village forms were carried westward to several sections of the northern Middle West.

Town morphologies in the rural U.S.

Less widely known but equally distinctive is the town morphology characteristic of the Midland, or Pennsylvanian, culture area and most fully developed in southeastern and central Pennsylvania and Piedmont Maryland. It differs totally from the New England model in density, building materials, and general appearance. Closely packed, often contiguous buildings—mostly brick, but sometimes stone, frame, or stucco, which may be either shops or residences or both—abut directly on a sidewalk, often paved with brick and usually thickly planted with maple, sycamore, or other shade trees. Characteristically, such towns are linear in plan, have only one or two principal streets, and may radiate outward from a central square lined with commercial and governmental structures.

The most characteristic U.S. small town was the one whose pattern was evolved in the Middle West. Its simple scheme was usually platted on the grid plan. Functions are rigidly segregated spatially, with the central business district, consisting of closely packed two- or three-story brick buildings, limited exclusively to commercial and administrative activity and usually quite desolate in the evenings. The residences, generally set well back within spacious lots, are peripheral in location, as are most rail facilities, factories, or warehousing.

Even the modest urbanization represented by the small town came late to the South. Most usual urban functions long were spatially dispersed—almost totally so in early Chesapeake Bay country or North Carolina—or were performed entirely by the larger plantations dominating the economic life of much of the region. When city and town began to materialize in the 19th and 20th centuries, they tended to follow the Middle Western model in layout.

Although quite limited in geographical area, the characteristic villages of the Mormon and Hispanic-American districts contain much of interest. The former uncompromisingly followed the ecclesiastically imposed pattern of a grid plan composed of perfectly square blocks, each with perhaps only four very large house lots, and the block surrounded by extremely wide streets. Those villages in New Mexico whose population and culture were derived from Old Mexico were often built according to the standard Latin American plan. The distinctive feature is a central plaza dominated by a Roman Catholic church and encircled by low stone or adobe buildings.

The rural–urban transition. *Weakening of the agrarian ideal.* The United States has had little success in achieving or maintaining the family-farm ideal. Through purchase, inheritance, leasing, and other means of dubious legality, smaller properties have been merged into much larger entities. In 1964, when average farm size had grown to 352 acres, those farms containing 2,000 or more acres accounted for about 42 percent of all farmland and 12 percent of cropland harvested, although comprising less than 2 percent of all farms. At the other extreme were those 63 percent of all farms containing less than 180 acres and reporting less than 19 percent of cropland harvested. Succeeding years have intensified this trend toward fewer but larger farms.

The huge, heavily capitalized "neoplantation," essentially a factory in the field, is especially conspicuous in parts of California, Arizona, and the Mississippi Delta, but examples can be found in any state. There are also many smaller but intensive operations calling for large investments and advanced managerial skills. This trend toward large-scale, capital-intensive farm enterprise has been paralleled, of course, by a sharp drop in rural farm population—a slump from the all-time maximum of around 32,000,000 in the early 20th century to 9,400,000 in 1971; but even in 1940, when farm folk still numbered more than 30,000,000, nearly 40 percent of farm operators were tenants, and another 10 percent were only part owners.

As the absolute, as well as the relative, size of the truly agrarian open-country and small-town population of the United States has dwindled in recent years, so too has its immediate impact lessened, though less swiftly, in economic and political matters. The real strength of the rural United States, however, remains in the realm of image and myth rather than in mundane material fact. Although the United States has become a highly urbanized, technologically advanced society far removed in daily life from cracker barrel, barnyard, corral, or logging camp, Americans have gravitated, sometimes reluctantly, to the big city; and in the deeply internalized daydreams and mythological assumptions that guide basic sociopolitical decisions, the lingering memory of a rapidly vanishing agrarian small-town America glows brightly. This is revealed not only in the works of some of the better contemporary novelists, poets, and painters but also throughout the popular arts: in movies, television, soap opera, folklore, country-and-western music, political oratory, and in much leisure-time activity.

The mythology of small-town America

Impact of the motor vehicle. Since about 1920, more genuine change has occurred in U.S. rural life than during the preceding three centuries of European experience in North America. Although the basic explanation is the profound social and technological transformation engulfing most of the world, the most immediate agent of change has been the internal-combustion engine. The auto, truck, bus, and paved highway have more than supplanted a moribund passenger-railroad system. While many a local rail depot has been boarded up and scores of secondary lines have been abandoned, hundreds of thousands of miles of old dirt roads have been paved, and a vast system of multiple-lane, limited-access interstate highways is under construction to connect all sizable cities in a single nonstop network. The net result has been a shrinking of the mile, a great extension of effective circulatory space for the individual driver, rural or urban. In balance, the total population of small towns has remained about the same. Those towns with strategic locations with respect to highways and urban opportunity have prospered; the less fortunate are wounded or dying, and, if the residents linger on for the sake of relatively cheap housing, the downtown businesses are often extinct.

Highways and human settlement

As the United States has become increasingly wheel borne, the visual aspect of the rural U.S. has altered drastically. The highway has become the central physical fact, and many of the functions once confined to town or city now stretch mile after mile along major roads (see below).

Reversal of the classic rural dominance. The metropolitanization of U.S. life has not been limited to

city, suburb, or exurb; it has now involved nearly the entirety of the inhabited rural United States and its people. The result has been the decline of local crafts and regional peculiarities, quite visibly in terms of such items as farm implements, fencing, silos, and housing and in many everyday commodities such as clothing or bread. In other ways, to an extent not yet fully realized, the countryside is now economically at the mercy of the city.

The city dweller is a dominant patron for products other than those of field, quarry, or lumber mill; and city location now determines patterns of rural economy rather than the reverse. During weekends and the vacation seasons, swarms of city folk stream out to second homes in the countryside, to campgrounds, ski trails, beaches, boating areas, or hunting and fishing tracts. For many large rural tracts, recreation is the principal source of income and employment; and such areas as northern New England and Upstate New York are now in essence playgrounds and sylvan refuges for the more affluent citizens of the multiple metropolises.

The larger cities reach far into the countryside for their vital supplies of water and energy; there is an increasing reliance upon distant mine-mouth power plants for electrical power; and they have gone far afield in seeking out rural dumps for their evergrowing excretion of garbage and trash.

The greater part of the rural population of the nation now lives within daily commuting range of a sizable city. This enables many a farm resident to stick to the farm while working part- or full-time at a city job and prevents the drastic decline in rural-farm population that has occurred in remoter parts of the country. Similarly, many a small town within the shadow of the metropolis, with fewer and fewer farmers to service, has stabilized or even increased its wealth and population and preserved its outward appearance while actually undergoing a drastic shift in function by becoming a dormitory satellite whose residents—some natives; others, migrants from the city in quest of a placid, simpler environment—work within accessible cities or suburbs.

Urban settlement. The United States has moved rapidly from an emphatically rural past into an overwhelmingly urban present. In so doing, it has followed the same general path that other advanced nations have travelled and one along which the contemporary developing nations have begun to hasten. Three-quarters of the population live clustered within officially designated urban places and "urbanized areas" (which account for less than 2 percent of the national territory), and at least another 15 percent in dispersed residences are actually urban in economic or social orientation.

Classic patterns of siting and growth. Although at least 95 percent of the population was rural throughout the colonial period and for the first few years of independence, cities were crucial elements in the settlement system from the earliest days. Boston, New Amsterdam (New York City), Jamestown, Charleston, and Philadelphia were founded at the same time as the colonies they served. Like nearly all other North American colonial towns of consequence, they were ocean ports. Until at least the beginning of the 20th century, the historical geography of U.S. cities has been intimately related with that of successive transportation systems. The location of successful cities with respect to the areas they served, as well as their internal structure, was determined largely by the nature of these systems.

Evolving functions of U.S. cities

The colonial cities acted as funnels for the collection and shipment of farm and forest products and other raw materials from the interior to trading partners in Europe, the Caribbean, or Africa and for the return flow of manufactured goods, immigrants, and other locally scarce items. Essentially marts and warehouses, they gave only minimal attention to social, military, educational, or religious functions. The inadequacy and costliness of overland traffic dictated sites along major ocean embayments or river estuaries; the only pre-1800 non-ports worthy of notice were Lancaster and York, Pennsylvania, and Williamsburg, Virginia. With the populating of the interior and the spread of a system of canals and improved roads, such new cities as Pittsburgh, Cincinnati, Buffalo, and St. Louis mushroomed at junctures between various routes or at which modes of transport were changed. Older ocean ports, such as New Castle, Delaware; Newport, Rhode Island; Charleston, South Carolina; Savannah, Georgia; and Portland, Maine, whose locations prevented them from serving large hinterlands tended to stagnate.

From about 1850 to 1920, the success of new cities and the further growth of older ones were related critically to their location within the totally triumphant new steam railroad system and to how effectively they could dominate a large tributary territory. Such waterside rail hubs as Buffalo, Toledo, Chicago, and San Francisco gained population and wealth rapidly, while such new offspring of the rail era as Atlanta; Indianapolis; Minneapolis; Fort Worth, Texas; and Tacoma, Washington, also grew lustily. Much of the rapid industrialization of the 19th and early 20th centuries occurred in places already favoured as to water or rail transport systems; but in some instances, such as in the cities of northeastern Pennsylvania's anthracite region, some New England mill towns, and the textile centres of the Carolina and Virginia Piedmont, manufacturing was the principal cause of rapid urbanization and the consequent attraction of transport facilities. The mining of gold, silver, copper, coal, iron, and, more recently, gas or oil led to rather ephemeral centres—unless these places were able to capitalize on local or regional advantages other than minerals.

A strong early start, whatever the initial economic base may have been, was often the key factor in interurban competition. With sufficient early momentum, urban capital and population would tend to expand almost automatically in a circular and cumulative process. The point is illustrated perfectly by the larger cities of the northeastern seaboard, from Portland (Maine) through Baltimore. The nearby physical wealth is poor to mediocre, and they are now far off-centre on the national map; but a prosperous mercantile beginning, good land and sea connections with distant places, and a rich local accumulation of talent, capital, and initiative were sufficient to bring about the growth of the world's largest concentration of industry, commerce, and people.

New factors in municipal development. The pre-1900 development of the U.S. city was almost completely a chronicle of the economics of the production, collection, and distribution of physical commodities and basic services in relation to geography, but recent decades have seen striking deviations from this pattern. The physical determinants of urban location and growth have given way to social factors. Increasingly, those older cities faring best and the more successful newer ones are oriented toward the more advanced modes for the production and consumption of services, specifically the knowledge, managerial, and pleasure industries. The largest cities are becoming more dependent upon corporate headquarters, communications, and the manipulation of information for their sustenance. Washington, D.C., is the most obvious example of a metropolis in which government and ancillary activities have been the spur for vigorous growth; but almost all the state capitals have displayed a similar demographic and economic vitality. Further, those urban centres containing a major college or university have enjoyed remarkable expansion during the past generation.

With the coming of relative affluence and abundant leisure among the masses and a decrease of labour input in industrial processes, an entirely new breed of cities has sprouted across the land: those that cater to the pleasure-seeker, vacationer, and the retired—for example, the young, flourishing cities of Florida or Nevada and many a place in California, Arizona, Colorado, and other states.

With the coming of the automobile as a means of personal transportation, about the time of World War I, the U.S. city was catapulted into a radically new period, both quantitatively and qualitatively, in the further evo-

lution of physical form and function. Previously, the size, density, and internal structure of the city were constrained by the limitations of the pedestrian and early mass-transit systems. Only the well-to-do could afford horse and carriage or a secluded villa in the countryside. Cities were relatively small and compact, with a single clearly defined centre, and grew by accretion along their edges, without any significant spatial hiatuses, except where commuter railroads linked outlying towns and suburbs to the largest of metropolises. Workers living beyond the immediate vicinity of their place of work had no choice but locate within reach of the few horse-drawn omnibuses or the later electric street railways.

Effect of the automobile on urban development

The universality of the automobile, even among the less affluent, and the parallel proliferation of service facilities and highways greatly loosened and fragmented the U.S. city, almost literally exploding and splattering it over surrounding rural lands. Older, formerly autonomous towns were swallowed up, grew swiftly, and became satellites of the larger city. Multitudes of new suburbs and subdivisions arose with single-family homes on lots much larger than had been possible for the ordinary householder in the city. These were almost totally dependent on the highway for the flow of commuters, goods, and services, and many were located in open country in splendid isolation, separated by tracts of farmland, brush, or forest from other such developments. At the major interchanges of the limited-access highways, a new form of agglomerated settlement has sprung up: the service station, motel, restaurant, and other establishments for a mobile clientele. Such satellite communities are especially noteworthy in the environs of such larger cities as Philadelphia, New York, Detroit, and Chicago.

The new look of "the metropolitan area." The outcome has been a broad, ragged, semi-urbanized belt of land surrounding each city, large or small, and quite often melting imperceptibly into the suburban–exurban halo encircling a neighbouring metropolitan centre. A great sameness exists in the makeup and general appearance of all such tracts: the planless intermixture of scraps of the old rural landscape with the fragments of the scattered metropolis; the randomly distributed subdivisions or single homes; the vast shopping centres, the large commercial cemeteries, drive-in theatres, junkyards, and golf courses and other recreational enterprises; and the regional or metropolitan airport, often with its own cluster of factories, warehouses, or travel-oriented businesses. The traditional city—unitary, concentric in form, with a single well-defined middle—was replaced by a relatively amorphous, polycentric metropolitan sprawl.

Present-day inner cities

The inner city of the larger U.S. metropolitan area, now as in the past, displays the basic traits common to the larger centres of all advanced nations. A central business district, almost always the oldest section of the city, is surrounded by a succession of roughly circular zones, each distinctive as to economic and social–ethnic character. The symmetry of this scheme is distorted by the irregularities of surface and drainage or the effects of radial highways and railroads. Land is most costly and hence land use most intensive, toward the centre. Major business, financial and governmental offices, department stores, and specialty shops dominate the downtown, which is usually fringed by a band of factories and warehouses. The outer parts of the city, like the suburbs, are mainly residential.

With some exceptions—*e.g.*, new, large apartment complexes in downtown Chicago—people do not reside in the downtown areas, and there is a steady downward gradient in population density per unit area (and more open land and single-family residences) as one moves from city centre toward open country. Conversely (again with some exceptions), there is a rise in income and social status with increasing distance from the core. The sharply defined immigrant neighbourhoods of the 19th century generally persist in somewhat diluted form, though specific ethnic groups may have shifted their location. Recent migrant groups, notably Southern blacks and Latin Americans, often dominate the more decrepit of the inner-city residential districts.

Individual and collective character of U.S. cities. U.S. cities, more so than the small-town or agrarian landscape, are more the product of period than of place. The relatively venerable centres of the Atlantic Seaboard—Boston; Philadelphia; Baltimore; Albany, New York; Chester, Pennsylvania; Alexandria, Virginia; or Georgetown (a district of Washington, D.C.), for example—are virtual replicas of the fashionable European models of their youth rather than the fruition of a regional culture—as New Orleans and Santa Fe, New Mexico, reflect other times and regions. The townscapes of Pittsburgh, Detroit, Chicago, and Denver speak of national modes of thought and the technologies of their formative years, just as Dallas, Texas; Las Vegas, Nevada; San Diego; Tucson, Arizona; and Albuquerque, New Mexico, proclaim the values and gadgetry of the present, rather than any local distinctiveness. Only when strong-minded city founders instituted a highly individual plan and their successors managed to preserve it—as, for example, in Savannah, Georgia; Washington, D.C.; and Salt Lake City—or when there is a happy match of a spectacular site with an appreciative populace—as in San Francisco or Seattle, Washington—does a genuine individuality seem to emerge. Some such identity may also be developing where immigration has been highly selective, as appears to be happening in such places as Miami; Phoenix, Arizona; and Los Angeles.

Political fragmentation and lack of planning

As a group, U.S. cities differ from others in both kind and degree. The political structure of the nation, the social inclinations of the people, and the strong outward surge of urban development have led to an unparalleled political fragmentation of metropolises that socially and economically are relatively cohesive units of their own. The fact that a single metropolitan area may sprawl across numerous incorporated towns and cities, several townships, and two or more counties and states has a major impact upon both its appearance and the way it functions. Not the least of these effects is a dearth of overall physical and social planning (or its ineffectuality when attempted), and the rather chaotic, inharmonious appearance of both inner-city and peripheral zones painfully reflects the absence of any strong collective conscience concerning such matters.

The U.S. city is a place of sharp transitions in both time and space. Construction, demolition, and reconstruction go on almost ceaselessly, with little thought given to preserving traces of the past. From present evidence, it would be impossible to guess that New York City and Albany date from the 1620s or that Detroit was founded in 1701. Preservation and restoration do occur, but generally only when it makes sense in terms of tourist revenue. Physical and social blight has reached epidemic proportions in the older slum areas of the inner city; but, despite the recent wholesale razing of such areas and the subsequent urban-renewal projects (often as apartment or commercial developments for the affluent), the belief is becoming widespread that the ills of the U.S. city are, in fact, incurable, especially with the increasing flight of capital, tax revenue, and the more highly educated, affluent elements of the population to suburban sanctuaries and the spatial and political polarization of whites and non-whites.

In the central sections of U.S. cities, physical evidence abounds of the weakness of any sense of history, of the dominance of the engineering mentality, and of the credo that the business of the city is business. Commercial and administrative activities are paramount, and usually there is little room for the church buildings or for parks or other nonprofit enterprises. The role of the cathedral, so central in the medieval European city, is filled by a U.S. invention serving both utilitarian and symbolic purposes, the skyscraper. Some cities have felt the need for other bold secular monuments; hence the Jefferson Memorial Arch looming over St. Louis, Seattle's Space Needle, and Houston's Astrodome. Future archaeologists may well conclude from their excavations that American society was ruled by an oligarchy of highway engineers and bulldozer operators. The great expressways converging upon, or looping, the downtown area and the

huge amount of space devoted to parking lots and garages are even more impressive than the massive surgery executed upon the vitals of U.S. cities a century ago to hack out room for railroad terminals and marshalling yards.

Altered landforms and landscapes of the city

Within many an urban site, there has been such gross physical transformation of shoreline, drainage systems, and land surface as would be difficult to match elsewhere in the world. Thus, in their physical lineaments, Manhattan and inner Boston bear scant resemblance to the landscapes seen by their initial settlers; the surface of downtown Chicago has been raised several feet above its former swamp level, the city's lakefront extensively reshaped, and the flow of the Chicago River reversed; and present-day Los Angeles, which has become a byword for environmental vandalism, has its concrete arroyo bottoms, terraced hillsides and landslides, and its own man-induced microclimate.

The super-cities of the United States. In the unprecedented outward sprawl of urban settlement, the United States has created some novel settlement forms, for the quantitative change has been so great as to induce qualitative transformation. The conurbation—a territorial coalescence of two or more good-sized cities whose peripheral zones have grown together—may have first appeared in early-19th-century Europe. There are major examples in Great Britain, the Low Countries, and West Germany, as well as in Japan.

Megalopolis: concept and forms

Nothing elsewhere, however, rivals in sheer size and complexity the aptly named megalopolis, that super-city of more than 30,000,000 inhabitants stretching along the Atlantic Seaboard from southern Maine to central Virginia. Other large conurbations include, in the Great Lakes region, one centred on Chicago and containing large slices of Illinois, Wisconsin, and Indiana; another based in Detroit, embracing large parts of Michigan and Ohio and reaching into Canada; and a third stretching from Buffalo through Cleveland and back to Pittsburgh. All three are reaching out toward one another and will shortly form another megalopolis, one that, in turn, may soon be grafted onto the seaboard megalopolis by way of a corridor through central New York state.

Also worthy of note is the huge Southern California conurbation reaching from Santa Barbara, through a dominating Los Angeles, to the Mexican border. A lesser counterpart exists as a solid strip of urban territory lining the eastern shore of Puget Sound. Quite exceptional in form is the slender linear multi-city occupying Florida's Atlantic coastline, from Jacksonville to Miami, and the loose swarm of medium-sized cities clustering along the Southern Piedmont, from south central Virginia to Atlanta.

One of the few predictions that seem safe in so dynamic and innovative a land as the United States is that, unless some severe and painful controls are placed on land use by powerful governmental agencies, the shape of the urban environment will be increasingly megalopolitan: a small set of great constellations of polycentric urban zones, each complexly interlocked socially and physically with its neighbours.

TRADITIONAL REGIONS OF THE UNITED STATES

The differences among U.S. "traditional regions," or "culture areas," tend to be slight and shallow as compared with such areas in most older, more stable countries. The muted, often subtle nature of interregional differences can be ascribed to the relative newness of U.S. settlement, a perpetually high degree of mobility, a superb communication system, and the galloping centralization of economy and government. It might even be argued that some of these regions are quaint vestiges of a vanishing past, of interest only to antiquarians.

Yet, in spite of the nationwide standardization in many departments of U.S. thought and behaviour, the lingering effects of the older culture areas do remain potent. Indeed, in one instance, that of the South, the differences helped to precipitate the gravest political crisis and bloodiest military conflict in the nation's history. And more than a century after the Civil War, the South remains a powerful entity in political and social terms, and its peculiar status is formally recognized in religious, educational, athletic, and literary circles.

Even more intriguing is the appearance of a series of essentially 20th-century regions. The Southern Californian is the largest and most distinctive, and its quite special culture has yet to reach full bloom. Similar trends are visible in southern Florida, in the burgeoning Texas identity, and probably in the more ebullient segments of New Mexico and Arizona as well. At the metropolitan level, it is difficult to believe that such aggressively narcissistic cities as San Francisco, Las Vegas, Dallas, Tucson, and Seattle are becoming like all other American cities. In any event, a detailed examination would show significant if sometimes subtle interregional differences in terms of language, religion, diet, folklore, folk architecture and handicrafts, political behaviour, social etiquette, and any number of other cultural categories.

The hierarchy of culture areas. A multi-tiered hierarchy of culture areas might be postulated for the United States; but the most interesting levels are, first, the nation as a whole and, second, the five to ten large subnational regions, each comprising parts or the entirety of several states. A remarkably close coincidence exists between the political United States and the cultural United States. Crossing into Mexico, the traveller negotiates a passage across a cultural chasm. If the contrasts are less dramatic between the two sides of the U.S.–Canadian boundary, they are nonetheless real, especially to the Canadian. The cultural barrier has been eroded along only a single major segment of the international frontiers: that reaching from northern New York state to Aroostook County, Maine. There, a vigorous demographic and cultural invasion by French-Canadians has gone far toward eradicating international differences.

Relation of political and cultural boundaries

If the international boundaries act as a cultural container, the interstate boundaries are curiously irrelevant. Even when the state enjoyed a strong autonomous early existence—as happened with Massachusetts, Virginia, or Pennsylvania—subsequent economic and political forces have tended to wash away such initial identities. Actually, it could be argued that the existence of 48 conterminous states is anachronistic in the context of contemporary socio-economic realities, not to mention cultural forces. Partially convincing cases might be built for equating Utah and Texas with their respective culture areas because of exceptional historical and physical circumstances or perhaps Oklahoma, given its very tardy European occupation and unique status as dumping ground for the relict Indian tribes of the East. In most instances, however, the states either contain two or more distinctly different culture areas or fragments thereof or are part of a much larger single culture area. Thus sharp North–South dichotomies characterize California, Missouri, Illinois, Indiana, Ohio, and Florida, while Tennessee advertises that, in fact, there are really three Tennessees. In Virginia, the opposing cultural forces were so strong that actual fission took place in 1863 (with the admission to the Union of West Virginia) along one of those rare interstate boundaries that approximate a genuine cultural divide.

Indefinite relation of cultures and economies

Much remains to be learned about the cause and effect relations between economic and culture areas in the U.S. If the South or New England could at one time be correlated with a specific economic system, this is no longer easy to do. Cultural systems appear to respond more slowly to agents of change than do economic or urban systems. Thus the American Manufacturing Belt, a core region for many social and economic activities, now spans major parts of three traditional culture areas—New England, the Midland, and the Middle West—and the northern fringes of a fourth, the South. And the great urban sprawl, from southern Maine to central Virginia, blithely ignores the steep relict cultural slopes still visible in its more bucolic tracts.

The cultural hearths. The culture areas of the modern United States are European in origin, the result of importing European colonists and ways of life and the sub-

sequent interactions among and within social groups and with a novel set of habitats. In the large picture, the aboriginal cultures remain territorially insignificant. In the Southwestern and the indistinct Oklahoman subregions, the Indian element merits consideration only as one of several ingredients making up the regional mosaic. With minor exceptions, the map of contemporary U.S. culture areas can be explained in terms of the genesis, development, and expansion of the three principal colonial cultural hearths along the Atlantic Seaboard. Each was basically British in character, but their personalities remain distinct because of, first, different sets of social and political conditions during the critical period of first effective settlement and, second, localized physical and economic circumstances. The cultural gradients between them tend to be much steeper and the boundaries more distinct than is true for the remainder of the continent.

New England. New England was clearly the dominant region during the century of national expansion following the American Revolution and not merely in terms of demographic or economic expansion. In social and cultural life—in education, politics, theology, literature, science, architecture, and the more advanced forms of mechanical and social technology—the area exercised its primacy. New England was the leading source of ideas and styles for the nation from about 1780 to 1880; it furnishes an impressive example of the capacity of strongly motivated communities for rising above the constraints of a parsimonious environment.

The character of early New England

During the first two centuries of its existence, New England was unusually homogeneous in its population characteristics. With rare exceptions, the British immigrant stock shared the same religion (Congregationalist), language, social organization, and general outlook. Over the years a distinctive regional culture took form, most noticeably in terms of dialect, town morphology, and folk architecture. The personality of the people also took on a regional coloration both in folklore and in actuality: there is a sound basis for the belief that the New England Yankee is self-reliant, thrifty, inventive, and highly enterprising. The massive influx of the foreign-born that began in the 1830s diluted and altered the New England identity, but much of its early personality survived.

By virtue of location, wealth, and seniority, the Boston metropolitan area has acted as the functional hub for all of New England both culturally and economically. This sovereignty is shared to some degree, however, with two other old centres, the lower Connecticut Valley and the Narragansett Bay region of Rhode Island.

The early westward demographic and ideological expansion of New England was so persistent that it is justifiable to call New York, northern New Jersey, northern Pennsylvania, and much of the Upper Middle West "New England Extended." Further, the energetic endeavours of New England whalers, merchants, and missionaries resulted in a perceptible imprinting of population or culture or both in Hawaii, various other Pacific isles, and scattered points in the Caribbean. New Englanders were also active in the Americanization of early Oregon and Washington, with results visible to this day. Later, the overland diffusion of New England natives and practices meant a recognizable New England flavour not only for the Upper Midwest, from Ohio to the Dakotas, but also more dilutely in the Pacific Northwest in general.

The South. By far the largest of the three primordial Anglo-American culture areas, the South is also the most aberrant with respect to national norms—or slowest to accept them. Indeed, the South has been so distinct from the non-South in almost every observable or quantifiable feature and so fiercely jealous of its peculiarities that for some years the question of whether it could maintain political and social unity with the non-South was in serious doubt. These differences are observable in almost every realm of human activity, including rural economy, dialect, diet, costume, folklore, politics, architecture, social customs, and recreation. Only during the 20th century can an argument be made that it has achieved a decisive convergence with the rest of the nation, at least in terms of economic behaviour and material culture.

Southern deviation from the U.S. mainstream

An early, persistent deviation from the national mainstream probably commenced during the first years of settlement. The settlers of the South were almost purely British, not outwardly different from the British, Welsh, or Scots-Irish who flocked to New England or the Midland but almost certainly distinct in terms of motives and social values and more conservative in retaining the rurality and the family and social structure of premodern Europe. The vast importation of African slaves was surely a factor, as was a degree of interaction with the aborigines that was missing farther north. And certainly the unusual (for northwest Europeans) pattern of economy, settlement, and social organization, in part a matter of a starkly unfamiliar physical habitat, may have prompted a deviation from other culture areas.

In both origin and spatial structure, the South has been characterized by diffuseness. In the search for a single cultural hearth, the most plausible choice is the Chesapeake Bay area and the northeastern corner of North Carolina, the earliest area of recognizably Southern character. Early components of Southern population and culture also arrived from other sources. A narrow coastal strip from North Carolina to the Georgia–Florida border and including the Sea Islands is decidedly Southern in flavour, yet it stands apart self-consciously from other parts of the South. Though colonized directly from Great Britain, it had also significant connections with the West Indies, in which relation the African cultural contribution was strongest and purest. The cities of Charleston and Savannah, which nurtured their own quite special civilizations, dominated this subregion in every sense. Similarly, French Louisiana received elements of culture and population—to be stirred into the special Creole mixture—not only from a putative Chesapeake Bay hearth area but also indirectly from France, French Nova Scotia, the French West Indies, and Africa. In the case of south central Texas, the Teutonic influx was so heavy that a special subregion can quite properly be designated.

It would seem, then, that the Southern culture area may be an example of convergent, or parallel, evolution of a variety of elements arriving along several paths but subject to some single general process that could mold one larger regional consciousness and way of life.

Because of its slowness in joining the national technological mainstream, the South can be subdivided into a much greater number of subregions than is possible for any of the other older traditional regions. Those described above are of lesser order than the two principal Souths, variously called Upper and Lower (or Deep) South, Upland and Lowland South, or Yeoman and Plantation South.

The two Souths

The former, which comprises the southern Appalachians, the upper Appalachian Piedmont, the Cumberland and other low interior plateaus, and the Ozarks and Ouachitas, was colonized culturally and demographically from two sources—the Chesapeake Bay hearth area and the early Midland; it is most emphatically white Anglo-Saxon Protestant in character. The latter area, which contains a large Afro-American population, includes the greater part of the South Atlantic and Gulf coastal plains and the lower Appalachian Piedmont. Its early major influences came principally from the Chesapeake Bay area, with only minor elements from the coastal Carolina–Georgia belt, Louisiana, or elsewhere. The division between the two subregions remains distinct from Virginia to Texas, but each region can be further broken down. Within the Upland South, the Ozark segment might legitimately be detached from the Appalachian; and, within the latter, the proud and prosperous Kentucky Bluegrass, with its emphasis on tobacco and thoroughbreds, certainly merits special recognition.

Toward the margins of the South, the difficulties in delimiting subregions become greater. The outer limits themselves are a topic of special interest. There seems to be more than an accidental relation between these limits and various climate factors. The fuzzy northern boundary, definitely not associated with the conventional Mason and Dixon Line or the Ohio River, seems most closely associated with length of frost-free season or with

Southern culture and climate

temperature during the winter months. As the Southern cultural complex was carried to the West, it not only retained its strength but became even more intense, in contrast to the experience of New England and the Midland. But the South finally fades away as one approaches the 100th meridian, with its critical decline in annual precipitation. The apparent correlation of the cultural South with a humid subtropical climatic regime is an old but provocative one.

The Texas subregion is so large, unmistakable, vigorous, and self-assertive that it presents some vexing classificatory questions. Is Texas simply a subordinate fraction of the Greater South, or has it now acquired so strong and divergent an identity that it can be denoted a new first-order region? It is conceivable that a major region is being born in a frontier zone in which several distinct cultural communities confront one another and in which the mixture has bred the vigorous, extroverted, aggressive Texas personality so widely celebrated in song and story. Similarly, peninsular Florida is either within or juxtaposed to the South but without being unequivocally part of it. In this case, an almost empty territory began to receive significant settlement only after about 1890; and, if like Texas, most of it came from the older South, there were also vigorous infusions from elsewhere.

The Midland. The significance of this region has not been slighter than that of New England or the South, but its characteristics are the least conspicuous to outsiders as well as to its own inhabitants—reflecting, perhaps, its centrality in the course of U.S. development. The Midland (a term not to be confused with Middle West) comprises portions of the following Middle Atlantic and Upper Southern states: Pennsylvania, New Jersey, Maryland, and Delaware. Serious European settlement of the Midland began a generation or more after that of the other major cultural nodes and after several earlier, relatively ineffectual trials by the Dutch, Swedes, Finns, and British. But once begun late in the 17th century by William Penn and associates, the colonization of the area was an instant success. Within southeastern Pennsylvania this culture area first assumed its distinctive form: a prosperous, sober, industrious agricultural society that quickly became a mixed economy as mercantile and later industrial functions came to the fore. By the middle of the 18th century, much of the region had acquired a markedly urban character, resembling in many ways the more advanced portions of the North Sea countries. In this respect, at least, the Midland was well ahead of neighbouring areas to the north and south.

Polyglot nature of the Midland culture

It differed also in its polyglot ethnicity. From almost the very beginning, the various ethnic and religious groups of the British Isles were joined by immigrants from the European mainland. This diversity has, if anything, grown through the years—and promises to persevere indefinitely. The mosaic of colonial ethnic groups has persisted in much of Pennsylvania, New York, New Jersey, and Maryland, as has the remarkable variety of more recent nationalities and churches in coalfields, company towns, cities large and small, and many a rural tract. Much the same sort of ethnic heterogeneity is to be seen in New England, the Middle West, and a few other areas, but the Midland still stands out as perhaps the most polyglot region of the nation.

The Teutonic element has always been notably strong, if irregularly distributed, in the Midland, accounting for more than 70 percent of the population of many townships. Had not the Anglo-American culture finally proved supreme, the area might well be designated as Pennsylvania German.

Considerations of physiography and migrational history carried the Midland culture area into the Maryland Piedmont; and, although its width tapers quickly below the Potomac, it reaches into parts of Virginia and West Virginia, with traces legible far down the Appalachian zone and into the South in general.

The northern half of the greater Midland region (the New York subregion, or New England Extended) cannot be assigned unequivocally to either New England or this Midland. Essentially it is a hybrid formed mainly from two parental strains of almost equal potency: New England and the post-1660 British element moving up the Hudson Valley and beyond. In addition, there has been a persistent, if slight, residue of early Dutch culture and some subtle filtering northward of Pennsylvania influences. Within the New York subregion apparently occurred the first major intra-American blending and fusion of regional cultures, especially within the early-19th-century "Burned-Over District," in and near the Finger Lakes and Genesee areas of central and western New York state. This locality, the seedbed for a number of important social innovations, was a major staging area for westward migration and quite possibly a chief source for the people and notions that were to build the Middle Western culture area.

Toward the west, the Midland retains its integrity for only a short distance—certainly no further than eastern Ohio—as it becomes submerged within the Middle West. Still, its significance in the genesis of the Middle West or of the national culture cannot be belittled. Its very success in projecting its image upon so much of the country may have rendered the source area less visible. As both name and location suggest, the Midland is intermediate in character in many respects, as between New England and the South. Moreover, its residents are much less concerned with, or conscious of, its existence (excepting the "Pennsylvania Dutch" caricatures) than is true for the other regions, and, in addition, the Midland lacks their strong political and literary traditions, though it is unmistakable in its distinctive townscapes and farmsteads.

The newer culture areas. *The Middle West.* No such self-effacement exists in the Middle West, that large triangular region justly regarded as the most nearly representative of the national average. Everyone within or outside the Middle West knows of its existence, but no one is certain where it begins or ends. The older apex of the eastward-pointing triangle appears to rest around Pittsburgh, while the two western corners melt away somewhere in the Great Plains, possibly in southern Manitoba in the north and southern Kansas in the south. The eastern terminus and the southern and western borders are broad, indistinct transitional zones.

This historical geography of the Middle West remains largely unstudied, but it seems plausible that this culture region was the progeny of all three colonial regions and that the fertile union took place in the upper Ohio Valley. The early routes of travel—the Ohio and its tributaries, the Great Lakes, and the low, level corridor along the Mohawk and the Lake Ontario and Lake Erie coastal plains—converge upon Ohio. There, the people and cultural traits from New England, the Midland, and the South were first funnelled together. Thence there would seem to have been a fanlike widening of the new hybrid area into the West as pioneer settlers worked their way frontierward.

Contrasts of Upper and Lower Middle West

Two major subregions are readily discerned, the Upper and Lower Middle West. They are separated by a line roughly approximating the 41st parallel, one that persists as far west as Colorado in terms of speech patterns and indicates differences in regional provenance in ethnic and religious terms as well. Much of the Upper Middle West retains a faint New England bouquet, although Midland influences are probably as important. A rich mixture of German, Scandinavian, Slavic, and other non-WASP elements has greatly diversified a stock in which the British element usually remains dominant and the range of church denominations is great. The Lower Middle West, except for the relative scarcity of Negroes, tends to resemble the South in its predominantly Protestant and British makeup. Local exceptions include areas of Catholic and non-WASP strength, but on the whole the subregion tends to be more nativistic in inclination than most other parts of the nation.

The problem of "the West." The foregoing culture areas account for roughly the eastern half of the conterminous United States. A genuine dilemma exists in classifying the remaining half. The concept of an "American West," strong in the popular imagination, is reinforced constant-

ly by romanticized cinematic and TV images of the cowboy. It is tempting to accept the widespread Western livestock complex as somehow epitomizing the full gamut of Western life, but, although the cattle industry may have accounted for more than one-half of the active Western domain as measured in acres, it employed only a relatively small fraction of the total population. As a single subculture, it cannot bear the burden of representing the total regional culture.

It is not clear whether a genuine, single, grand Western culture region exists. Unlike the East, in which settlement is virtually continuous through space and in which culture areas and subregions abut and overlap in splendid confusion, the eight major and many lesser nodes of population in the western United States are all oasis-like, separated from one another by wide expanses of nearly uninhabited mountain or arid desert. The only obvious properties these isolated clusters have in common are, first, the recent intermixture of several strains of culture, primarily from the East but with additions from Europe, Mexico and East Asia, and, second, except for one subregion, a general modernity, having been settled in a serious way no earlier than the 1840s. Some may be viewed as inchoate, partially formed cultural entities; the others have acquired definite personalities but are difficult to classify as first-order or lesser order culture areas at this time.

There are three (or, possibly, four) major tracts in the western United States that reveal a genuine cultural identity: the Upper Rio Grande region; the Mormon region; Southern California; and Northern California. (To this group one might add the anomalous Texan and Oklahoman subregions, which may adhere to the South, to the West, or to both).

Upper Rio Grande and Mormon regions

The term Upper Rio Grande region was coined to denote the oldest and strongest of the three sectors of Hispanic-American activity in the U.S. Southwest, the others having been Southern California and portions of Texas. Although focussed upon the valley of the Upper Rio Grande, the region also embraces segments of Arizona and Colorado as well as other parts of New Mexico. European communities and culture have been present there in strength, with only one interruption, since the late 16th century. The initial sources were Spain and Mexico, but after 1848 at least three distinct strains of Anglo-American culture were increasingly well represented—the Southern, Mormon, and a general undifferentiated northeastern U.S. culture—plus a distinct Texan subcategory. For once, this has occurred without obliterating the aboriginal folk, whose culture endures in various stages of dilution, from the strongly Americanized or Hispanicized to the almost undisturbed.

The general mosaic is a fabric of aboriginal, Anglo, and Hispanic elements, and all three major groups, furthermore, are complex in character. The aboriginal component embraces the Navajo, Pueblos, and several smaller groups, each of which is quite distinct from the others. The Hispanic element is also diverse—modally Mexican mestizo, but ranging from pure Spanish to nearly pure pre-Spanish aboriginal.

The Mormon region is expansive in the religious and demographic realms, though it has ceased to expand territorially as it did in the decades after Utah's settlement in 1847. Despite its Great Basin location and an exemplary adaptation to environmental constraints, this cultural complex appears somewhat non-Western in spirit: the Mormons may be in the West, but they are not entirely of it. Their historical derivation from the Middle West and from ultimate sources in New York and New England is still apparent, along with the generous admixture of European converts to their religion.

Here again, as in New England, the power of the human will and an intensely cherished abstract design have triumphed over an unfriendly habitat. The Mormon way of life is expressed in many recognizable ways in the settlement landscape and economic activities within a region more homogeneous internally than any other U.S. culture area.

In contrast, the Northern California region has yet to gain its own strong cultural coloration. From the beginning of the great 1849 Gold Rush, the area drew a thoroughly diverse population from Europe and Asia as well as the older portions of the United States. Whether the greater part of the Northern California region has produced a culture amounting to more than the sum of the contributions brought by immigrants is questionable. San Francisco, the regional metropolis, may have crossed the qualitative threshold. An unusually cosmopolitan outlook that includes an awareness of the Orient stronger than that of any other U.S. city, a fierce self-esteem, and a unique townscape may be symptomatic of a genuinely new, emergent local culture.

Northern and Southern California regions

The Southern California region is the most spectacular of the Western regions, not only in terms of economic and population growth but also for the luxuriance, regional particularism, and general avant-garde character of its swiftly evolving cultural pattern. Until the coming of a direct transcontinental rail connection in 1885, the region was remote, rural, and largely inconsequential. Since then, the invasion by persons from virtually every corner of North America and by the foreign-born has been massive and, until the late 1960s, apparently ceaseless. A loosely articulated series of conurbations has encroached upon what little is left of arable or habitable land in the Coast Ranges and valleys from Santa Barbara to the Mexican border.

Although every significant ethnic and racial group and every other U.S. culture area is amply represented, there is reason to suspect that a process of selection for certain kinds of people, attitudes, and personality traits may have been at work at both source and destination. Certainly the region is aberrant from, or perhaps in the vanguard of, the remainder of the nation. One might view Southern California as the super-American region or the outpost of a rapidly approaching postindustrial future; but, in any event, its cultural distinctiveness, in visible landscape and social behaviour, is evident to all. Southern California in no way approaches being a "traditional region," or even the smudged facsimile of such, but rather the largest, boldest experiment in creating a "voluntary region," one built through the self-selection of immigrants and their subsequent interaction.

Emergent culture areas of the West

The remaining identifiable Western regions—the Willamette Valley of Oregon, the Puget Sound region, the Inland Empire of eastern Washington and adjacent tracts of Idaho and Oregon, central Arizona, and the Colorado Piedmont—can be treated jointly as potential, or emergent, culture areas, still too close to the national mean to display any cultural distinctiveness. In all are evident the arrival of a cross section of the national population and the growth of regional life around one or more major metropolises. A New England element is noteworthy in the Willamette Valley and Puget Sound regions, while a Hispanic-American component appears in the Colorado Piedmont and central Arizona. Only time and further study will reveal whether any of these regions, so distant from the historic sources of U.S. population and culture, can engender the capacity or will for an independent cultural existence. (W.Ze.)

III. The people of the United States

As they entered the 1970s, a majority of the people of the United States had achieved a relatively high level of material comfort, prosperity, and security. They appear to be, however, in a bad and divided mood. They were worried about crime, racial injustice, urban decay, the war in Vietnam, environmental pollution, narcotics, alienation among the young, and the high cost of living. Moreover, they were unhappy: to a public-opinion-poll question that asked "Do you believe that life is getting better or worse in terms of happiness?" nearly half (49 percent) of the respondents, who live in the country in which the standard of living is the highest in the world, glumly answered "worse."

Social unrest and tensions and divisions among its citizens were, such attitude surveys showed, the major causes of this general malaise. Many Americans perceived these as caused by the failure of U.S. society to extend

what is traditionally called the "American dream" equally to all its people, particularly to those who were members of minority groups. The traditional spirit of U.S. society had characterized the nation as a democratic "land of opportunity," in which social, political, economic, and religious freedom prevail, one man is as good as another, and every man can achieve if only he will.

A shared belief in such egalitarian ideals is often seen as being perhaps the strongest bond that has united Americans, and the fact that the nation has not achieved equality for all troubles the American soul. More than half of all Americans say, according to opinion polls, that they "often feel bad" about the poverty and hunger that exist in the United States. One in three says he "often feels bad" about the treatment of Negroes and the American Indian. Nearly two out of three agree that "Until there is justice for minorities, there will not be law and order" in the United States.

Social pluralism and the "melting-pot" myth

The population of the United States is the most widely diverse of any nation in the world. It is possible to create pictures of statistically "typical" Americans—the average U.S. voter, for example, is a 47-year-old housewife who lives in the outskirts of Dayton, Ohio, and whose husband works as a machinist. Far more typical, however, is the fact that, on a recent summer Sunday in Chicago, three queens were being crowned: one by the Polish National Alliance, another by the Scandinavian Midsummer Night Festival, and a third to lead the annual Puerto Rican Independence Day parade. The United States is not homogeneous; it is a pluralistic

society, a nation of groups. The long cherished belief that the United States has been a great "melting pot" in which people from all nations and cultures have blended into what are called "Americans" is a myth. In the early 1970s a strong trend among United States minorities, black and white, to organize groups to press for social change made the American people increasingly conscious of the characteristics of the various ethnic and racial groups that make up the population of the United States.

THE MIX OF PEOPLES

The "old-stock" Americans. Until about 1860, the population of the United States was relatively homogeneous. It was overwhelmingly white, Anglo-Saxon (the majority had come originally from the British Isles), and Protestant. Of the 5,000,000 European immigrants who had entered the United States between 1820 and 1860, nine out of ten were from England, Ireland, or Germany. With the exception of some of the Irish Catholics, these early immigrants, many of whom were barely distinguishable from the native stock, were easily assimilated by the English Protestant United States.

After the Civil War, however, ever larger numbers of immigrants began to arrive from the countries of central and southeastern Europe: Italy, the Balkans, Poland, and Russia. This vast group of newcomers, some 30,000,000 of them from 1860 to 1920, flooded the U.S. cities. Most were non-English, non-Protestant, and markedly different in culture and language from the older Americans. The immigrants established their own neighbourhoods and rapidly developed ethnic societies, clubs, newspapers, and theatres; and their living areas became distinctive cultural and social enclaves within the larger U.S. society.

The immigrants, however separate, were not denied access to the mainstreams of U.S. life. It was an open society, and those with ability and intelligence usually achieved success—and some achieved greatness.

The old-stock English Protestants who remained the dominant U.S. cultural group came, in time, to be defined by the fact that they were not immigrants or the descendants of recent immigrants. Today, the term WASP (for White Anglo-Saxon Protestant) is frequently used to describe all those—including such groups as the Dutch and Scots-Irish—whose assimilation has become so complete that the national origins of their families have become merely a memory. They comprise about 45 percent of the U.S. population.

The "Yankee Patricians" among them still retain a firm grip on the U.S. social order. They are predominant in the headquarters of large corporations, banks, insurance companies, law offices, and educational, cultural, and philanthropic institutions. Many other less affluent old-stock white Protestants are concentrated in the rural areas of the United States and in the South.

The "ethnics." The term ethnics was coined in the early 1970s to describe the 40,000,000 Americans of Polish, Italian, Lithuanian, Bohemian, Slovakian, and other extraction, most of whom live in the northern and Middle Western cities. They are Catholic, middle-class (with incomes ranging from $7,000 to $11,000 per year), and most are workers, either part of the blue-collar labour force or holders of low-level white-collar jobs.

Group identity of the white "ethnics"

The neighbourhoods in which most of them still live have their roots in the many "Little Italys" and "Polish Hills" established by the immigrants. Their strong ethnic ties are apparent in the pattern of their lives: spouses, friends, neighbours, fellow churchmembers, and even co-workers are usually also Polish or Italian or Slovakian.

Their ethnic group identity is not, however, merely a holdover from the era of mass immigration. It is based not only upon a common cultural heritage but also on the fact that the group has common interests, needs, and problems in the present-day United States. Concentrated in the inner cities, the white ethnics are intimately affected by high crime rates, deteriorating municipal services, inferior schools, and urban unrest. They fear losing their jobs and neighbourhoods to blacks. Neither rich nor poor, they anxiously watch their purchasing power being diminished by inflation and rising taxes.

As the children and grandchildren of immigrants, they have been taught to believe that the road to success in the United States is achieved through individual effort. They believe in equality of opportunity and self-improvement, and they attribute poverty to the failing of the individual and not to inequities in society. This attitude makes them largely unsympathetic to the demands of Negro groups, to student protest (which they tend to view as the antics of spoiled children of the rich), and to the peace movement, which they regard as un-American, especially since their own sons, who did not attend college, made up a large percentage of the fighting force in Vietnam.

As the ethnics became more vocal in the early 1970s, the public became aware of the problems and concerns of the urban ethnic minorities and stopped dismissing them as merely "racist" or "uneducated." Ethnic groups began to be included in the planning and administration of social-welfare programs of government or foundations, and an ethnic identity was no longer looked upon as somehow un-American and vaguely shameful. It had become legitimate to be an "ethnic."

The blacks. The civil-rights movement that gained momentum in the early 1960s awakened the nation's conscience to the fact that black Americans, who constitute 11 percent of the population, had long been denied first-class citizenship. By 1970, despite government poverty programs and equal-opportunity laws that outlawed discrimination in education, housing and employment, blacks remained clearly unequal partners in U.S. society. Their median family income was only 64 percent that of whites. Half of all white families had incomes over $10,000, while only 24 percent of black families had reached that income level. About one in three black persons had an income below the poverty line, as compared to one in ten whites. Although 62 percent of the whites had completed high school, only 40 percent of the adult blacks had done so. Blacks represented 11 percent of the labour force, yet held only 5 percent of the better paying jobs. Two out of five black men remained in low-paid service, labouring, or farm occupations. The black population nonetheless had made important advances between 1960 and 1970. Their share of the higher paying jobs had increased by 72 percent. Median income had increased 100 percent. Black college enrollment had almost doubled.

Militancy among the blacks

The civil-rights movement prior to the mid-1960s was largely middle-class and interracial; it had used nonviolence and passive resistance to change discriminatory laws and practices, primarily in the South. It aimed for an integration of blacks into U.S. life. For the militants who later arose from the urban poor in the North and West, separatism replaced integration as the primary objective. The militants rejected the U.S. cultural mainstream and spoke instead of black pride, of "soul," of Afro-American history and culture. Instead of attempting to bring change through the moral persuasion of white governmental bodies and institutions, the militants aimed for black autonomy and community control. They turned their attention to developing black political organizations that would give them a position of bargaining strength and political control over their own communities. Most frightening to whites, the militants rejected nonviolence and proclaimed the need for self-defense to protect themselves from police harassment in the city ghetto. The militant movement was strongest among the young; and, as the nation moved into the 1970s, urban high schools had become centres of black protest, with students demanding community control of the schools and the development of educational programs relevant to black history and black needs.

There were strong indications that the majority of blacks generally support the more militant posture. The militants' concern with the daily problems of ghetto living speaks directly to the three out of five blacks who live in inner-city areas. Moreover, sociological studies and

public-opinion polls made subsequent to riots and demonstrations indicate that, though deploring violence and destruction, blacks generally view militant-type activities as useful and legitimate forms of protest.

The Spanish-Americans. Persons with Spanish surnames make up about 5 percent of the American population. About half of them are of Mexican origin, the descendants of ancestors who settled in areas that were once part of Mexico. A majority of these still live in Arizona, California, Colorado, New Mexico, and Texas. Another 16 percent of the Spanish-Americans are of Puerto Rican origin; they are concentrated in New York City. Six percent are fairly recent immigrants of Cuban origin who have settled in or near Miami.

Although the Spanish-Americans have experienced less outright discrimination than the blacks, they, like the blacks, have a generally lower economic and educational level than the rest of the population. Family income is only 70 percent that of white families. They are only half as likely to hold white-collar jobs as the rest of the population and are twice as likely to be unemployed, and they have about 3½ years less education than the average American. Although four out of five Spanish-Americans were born in the United States or the Commonwealth of Puerto Rico, Spanish is the main language in about half of the homes. The continued use of Spanish indicates the strength of the bonds that tie Spanish-Americans together.

After generations of quiet acceptance and near-invisibility, Mexican-Americans began to organize in the 1960s. Following the example of black activism, Mexican-Americans formed groups in the barrios of such large cities as Los Angeles and Denver and in the southern Texas towns in which they often constituted a majority. Their major goals were greater political representation through which they might gain better health, housing, and municipal services, bilingual school programs, and a better education for their children.

The Indians. The 800,000 Indians, the only Americans who can truly be called native, are the group that has been least integrated into U.S. society. The Indian population is concentrated in Oklahoma, Arizona, New Mexico, California, and North Carolina.

Cultural isolation of the American Indian

The Indian reservations, on which more than 40 percent of all Indians still live, are enclaves of deep poverty and social distress. In 1971 the median Indian family income was about $4,000 compared with the national figure of $9,867; since Indian families tend to be large, most lived near destitution. Four out of ten Indian children do not finish high school, and many of those who do lag behind the national educational norms by several years. Substandard, unsanitary, and overcrowded housing conditions are reflected in the fact that their death rates from tuberculosis and from dysentery are, respectively, four and five times that of the nation as a whole. Their infant mortality rate is more than 40 percent higher than the overall U.S. rate; their average age at death is about 20 years younger than the rest of the population.

The physical and social isolation of the reservation has caused a cultural hiatus that has left Indians unprepared educationally and culturally to take part in the urbanized, technical United States. The poverty and frustration of life on the reservation prompted sizable numbers of Indians to migrate to large cities, especially Los Angeles and Chicago. In such environments they possessed neither the occupational skills nor the cultural background necessary to sustain themselves, and social workers reported a high percentage of family disintegration, alcoholism, and suicide among them. By 1972, a few "red-power" Indian groups had begun to organize to call attention to their condition and press for change.

The Oriental Americans. The Oriental population of the United States consists of Japanese, Chinese, and Filipinos, the great majority of whom live in the cities of California and in Hawaii. Like other ethnic groups, the Oriental Americans have established their own urban neighbourhoods, the most famous of which is San Francisco's Chinatown. The Oriental Americans are not "problem minorities": strong family ties, cultural pride, respect for authority, and an emphasis on education have brought them extraordinary success in the United States. Despite severe discrimination and internment during World War II, the Japanese Americans have achieved educational and employment levels that are substantially higher than those of the white population.

Religious groups. Churches and synagogues in the United States claimed 131,000,000 members in 1970. Of these, more than 48,000,000, nearly 24 percent of the population, were Roman Catholics, and about 5,900,000 were Jews. The Protestant sects reported membership of about 72,000,000; unlike the Catholics and Jews, however, they count children as members only after they are confirmed. Nine out of ten churches in the United States are Protestant, with the largest groups being the Baptists, Methodists, Lutherans, and Episcopalians.

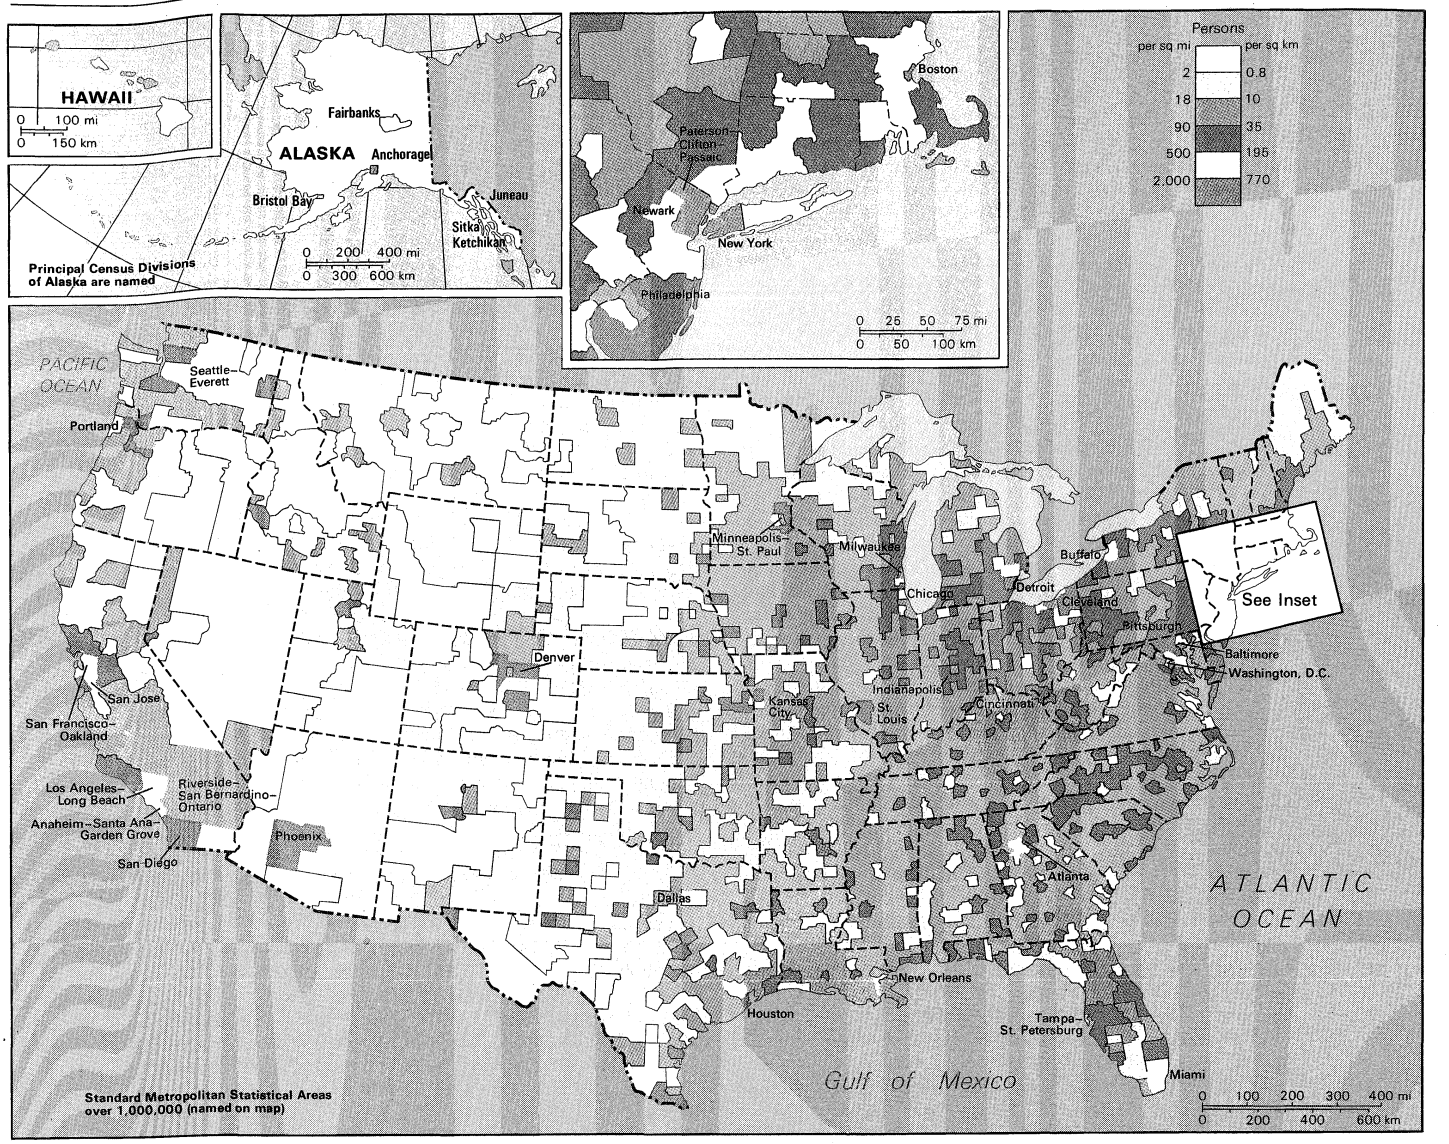
Catholics are, by and large, members of the working class. Jews are predominantly white-collar workers (75 percent), followed in percentage terms by Episcopalians (57) and Baptists (26). Two-thirds of all Methodists are farm workers or labourers.

Religious intermarriage is still not common: Protestants marry other Protestants 80 percent of the time; Catholics marry other Catholics 80 percent of the time; and Jews marry other Jews 95 percent of the time.

DEMOGRAPHIC FIGURES AND TRENDS

Population growth. The 203,211,926 citizens of the United States counted in the 1970 census represented a 13.3 percent increase over the 1960 population, but it was the second lowest percentage increase of any decade in U.S. history. Only in the 1930s, the decade of the Great Depression, when the increase was 7.3 percent, had the nation grown at a slower rate.

Population projections for the year 2000



Projections of the population in the year 2000 range from 251,000,000 to 300,000,000. National surveys of birth expectations suggest that, on the average, families are settling on the two-child family as most desirable. If women continue to have children at about the rate of the early 1970s, the population in the year 2000 will be 280,000,000. If environmental concerns, more effective contraceptive methods, legalized abortion, and other factors have the result of permanently reducing the birth rate to 2.11 children per woman—the rate, reached in 1972, at which population exactly replaces itself—the population in the year 2000 will be only 271,000,000 and will level off at 276,000,000 in 2037.

Mortality rates. Americans can expect to live until about age 71. This average life expectancy is nearly double that of many underdeveloped countries. The death rate per 1,000 population is about 9.3, about half the world death rate of 18.

Death rates have remained stable in the United States since 1950. The dramatic decreases of the first half of the 20th century, during which the death rate dropped from 17.2 in 1900 to 9.6 in 1950, were the result of medical discoveries in the area of immunology and the antibiotic drugs. Currently, the major causes of death are the chronic diseases of old age, such as heart disease, and cancer. Barring a major medical breakthrough in curing or preventing such diseases, substantial decreases in overall death rate are unlikely.

Death, however, does not strike all Americans equally. On the average, the life expectancy of blacks is seven years shorter than that of whites. Comparative mortality rates at various ages for non-white males are consistently 30 to 50 percent higher than those of white males. Such differences have narrowed considerably in recent years as blacks have experienced increases in their general standard of living and of medical care.

Infant mortality rates—the number of deaths under one year of age per 1,000 live births—reached a low of 19.2 in 1971, due largely to advances in prenatal and infant health care. Infant mortality rates as low as 11.7 and 12.7 have been achieved in Sweden and The Netherlands, respectively, indicating that U.S. rates remain far from an irreducible minimum. Despite narrowing racial differentials, the non-white infant mortality rate remains one-half higher than the white.

Population density of the United States.

Declining birth rates

Birth and fertility rates. The United States entered the 1970s with the lowest birth rate in its history, a decline that was not anticipated by demographers. In 1970 the number of births per 1,000 population was 18.2; in October 1972, however, it was down to 15.6. In the 1970s, the children who were born during the post-World War II "baby boom" from 1947 to 1957 were reaching childbearing age; it was not expected that this increase in the size of the childbearing population would result in an increase in the birth rate.

That the birth rate showed a decline instead of the predicted increase was attributed mainly to such factors as a rise in the knowledge of contraception and its use and the legalization of abortion by the United States Supreme Court. Several sociocultural factors may also have combined to cause a decline in the willingness or desire to have children, among them an increasing concern with the effect of overpopulation on the quality of the environment; the women's liberation movement, which led more women into the work force; and the increasing emphasis placed by young people on humanistic values, which may have begun a movement toward more carefully planned childbearing than in previous generations.

Birth rates are not uniform for all groups. The nonwhite birth rate is about 50 percent higher than the white, and the highest birth rate occurs for women between the ages of 20 and 29. Socio-economic level is also a factor: in general, as family income and educational levels rise, the number of children declines. Religion also influences fertility, with the Roman Catholics and the more fundamentalist Protestant sects, notably the Baptists, having the highest birth rates and averaging about 50 percent more children than the Jews and more liberal Protestant groups.

Migratory trends. Few populations are as mobile as that of the United States, where 20 percent of the people move every year. Westward expansion continued: between 1960 and 1970, the Western states grew by 24.1 percent, the largest increase of any region in the nation. The Negro migration from the South, which began after World War I, had by 1970 so altered the distribution of the black population that only slightly more than half of all American Negroes were living in the South. The proportion had been two-thirds as recently as 1950.

Immigration of blacks accounted for one-third of the growth of inner-city populations between 1960 and 1970. Blacks represented one-fifth of the population of central cities by 1970 and were in the majority in four major cities—Washington, D.C.; Newark, New Jersey; Gary, Indiana; and Atlanta, Georgia. The population of seven other major cities was more than 40 percent black.

The United States became a suburban nation in 1970, with 75,600,000 people living in the suburbs, 63,800,000 in the central cities, and 63,200,000 in rural areas. During the 1960s the suburban rings about the cities increased in population by 27 percent, whereas the cities themselves

grew by only 6 percent. Although 762,000 blacks had moved to the suburbs during the decade, along with 12,500,000 whites, the suburbs remained 95.5 percent white in 1970. The farm population was down to 10,000,000 persons (less than five percent of the total population), the lowest percentage in the history of the nation.

Immigration. The era of mass immigration came to an abrupt end soon after World War I, when the Immigration Act of 1924 established an annual quota, later fixed at 150,000 immigrants (1929). The act also established the national origins system, which was to characterize national immigration policy until 1968. Under it, quotas were established for each country based on the number of persons of that national origin who were living in the United States in 1920. The quotas had the effect of reducing drastically the flow of immigrants from southeastern Europe—who, since they were still relatively recent arrivals in the United States, formed only a small percentage of the population in 1920—and of discriminating in favour of the countries of northwestern Europe. Under this system Great Britain, Ireland, and Germany were allotted more than 70 percent of the quota, an allotment that rarely was filled.

Quota system of immigration

The quota system was liberalized in December 1965, and in 1968 it was finally abolished in favor of a first-come, first-served policy. An annual ceiling of 170,000 immigrant visas for nations outside the Western Hemisphere was established, with 20,000 the maximum allowed to any one nation. A ceiling of 120,000 was set for persons from the Western Hemisphere.

The new policy radically changed the pattern of immigration. In 1965, the last year during which the old national-origins system was still in effect, Mexico, Canada, and Great Britain topped the list of countries sending immigrants to the United States. By 1971, the last two had been displaced by nine other countries. The number of Philippine immigrants was nine times larger in 1971 than in 1965; the number of Chinese, nearly four times larger; the number of Koreans, almost seven times larger; and the number of persons from India, 25 times larger. Of the 3,300,000 immigrants who entered the United States between 1960 and 1970, nearly 14 percent were non-white. (Jo.N./T.K.F.)

IV. The national economy

By a very wide margin, the United States is the world's greatest economic power, measured in terms both of Gross National Product (GNP) and of GNP per capita. While precise comparisons among countries are difficult, in 1969 GNP per capita in the U.S. was more than twice that of the industrialized countries of western Europe.

Economic power of the U.S.

This position of the United States is partly a reflection of its richness in natural resources. In 1970, the U.S., with less than 6 percent of the world's population, produced 25 percent of the world's output of coal, 21 percent of its crude petroleum, 25 percent of its copper, and 12 percent of its iron ore. In 1970 the agricultural sector produced 46 percent of the world's maize, 21 percent of its beef, pork, mutton, and lamb, and 13 percent of its wheat. The U.S. owes much more, however, to its developed industry. In the 1960s U.S. industrial production was still increasing more rapidly than that of most other countries. Between 1965 and 1970 it grew by 18 percent; this represented an average annual growth rate in gross domestic product of 3.3 percent, and a per capita growth rate of 2.3 percent. (Gross domestic product [GDP] is the total of goods and services produced in a country. GNP is GDP plus net factor income from abroad, which can be a minus quantity.) The latter rate may be compared with a rate of 4.0 percent in the Federal Republic of Germany, 4.9 percent in France, 1.9 percent in the United Kingdom, 2.6 percent in Canada, and 11.5 percent in Japan.

Despite its relative self-sufficiency, the U.S. is the most important single factor in world trade by virtue of the sheer size of its economy. In 1971 its exports represented about 14.0 percent of the world total, while those of West Germany, United Kingdom, and Japan were, respectively, about 12.5 percent, 7.2 percent, and 7.7 percent. The U.S. market also accounted for 13.9 percent of world imports in 1971, compared with West Germany's 10.5 percent, the U.K.'s 7.3 percent, France's 6.5 percent, and Japan's 6.0 percent.

The United States impinges on the economy of the rest of the world not only as a trading power but also as a source of investment capital. The book value of direct investments abroad by U.S. firms amounted to $78,100,000,000 at the end of 1970. This investment was a dominant factor in the economies of Canada and many Latin American countries; $22,800,000,000 in Canada and $12,200,000,000 in Latin America (predominantly Venezuela, Brazil, and Mexico). U.S. investments in Europe, valued at $24,500,000,000 at the end of 1969 ($8,000,000,000 in the U.K.), were concentrated in high-technology growth areas.

NATURAL RESOURCES

Mineral resources. The U.S. is the world's major petroleum-producing nation, accounting for about one-fifth of world output. Its proved petroleum reserves at the end of 1971 amounted to 38,063,000,000 barrels, including reserves offshore from Texas, Louisiana, and California. This represented 10.9 times the amount extracted in 1971, whereas at the end of 1960, proved reserves, at 31,613,000,000 barrels, had been equivalent to 12.3 times annual production. But, while the ratio of production to reserves worsened throughout most of the 1960s, it seemed likely to be improved by major oil discoveries in Alaska. In 1971 Texas accounted for 35.2 percent of U.S. production (1,220,000,000 barrels), and its proved reserves represented over 34 percent of the national total. Next most important in terms of 1971 production was Louisiana (948,000,000 barrels), followed by California (359,000,000 barrels).

Oil and gas reserves

Important reserves of natural gas exist, estimated to amount to 290,746,000,000,000 cubic feet of recoverable gas at the end of 1970, an increase of 10.2 percent over the figure for 1960 despite a large increase in annual offtake throughout the 1960s. Proved recoverable reserves represented 13.3 times production at the end of 1970, compared with 20.7 times at the end of 1960. The state producing the most natural gas in 1970 was Texas, with over 38 percent of national output and nearly 37 percent of proved recoverable reserves. Its output of 8,358,000,000,000 cubic feet was followed by those of Louisiana (7,788,000,000,000), Oklahoma (1,595,000,000,000), and New Mexico (1,139,000,000,000).

Coal deposits are concentrated largely in eastern parts of the country. Total production of bituminous coal and lignite in 1970 was 602,932,000 tons, of which 349,868,000 tons were mined in West Virginia, Kentucky, and Pennsylvania—the last-named state also producing the country's only anthracite (9,729,000 tons in 1970). Illinois produced 65,119,000 tons of coal in 1970 and Ohio 55,351,000 tons. Iron ore is mined predominantly in the Great Lakes region; there has been a long-term shift away from the mining of hematite, which accounted for 89 percent of output in 1950 but only 46 percent in 1970, toward the mining of magnetite. Iron-ore production declined marginally in the 1950s and 1960s, while demand for it grew, with the result that in 1970 over 40 percent of demand was met by imports.

The U.S. also has important reserves of copper, lead, and zinc. Copper production is concentrated in the mountainous states of the West. In 1971, nearly 54 percent of copper-mining output came from Arizona and 17 percent from Utah; most of the rest was mined in Montana, Nevada, and New Mexico. In the 1950s and 1960s the grade of the ore mined became lower. Zinc mining is more scattered than that of copper; just over 22 percent of production in 1971 came from Tennessee, nearly 13 percent from New York, and 12 and 8 percent from Idaho and Colorado, respectively. Lead mining is concentrated in Missouri, which accounted for 75 percent of the output in 1971. Other metals mined in the U.S. are gold, silver, molybdenum, manganese, tungsten, bauxite, uranium, vanadium, and nickel. Important nonmetallic minerals produced are phosphates, potash, and sulfur.

Land and water resources

Biological resources. Of a total land area of 2,264,000,000 acres, about 47 percent were devoted to farming in 1969. Cropland, including fallow, comprised 17.1 percent of the land area in 1969 and grassland pasture 23.8 percent. Tobacco is produced in the Southeast and cotton in the South and Southwest; California is noted for its vineyards and citrus groves; the Middle West is the centre of corn (maize) and wheat farming, while dairy herds are concentrated in the Northern states; and the Southwestern and Rocky Mountain states support large herds of livestock.

Total forest land amounted to 753,549,000 acres at the beginning of 1970. Of this, 499,697,000 acres were in commercial forest land, defined as economically available land producing or capable of producing industrial timber. The area with most forest land was the West, with 355,169,000 acres, including 119,051,000 acres in Alaska, but the total commercial area was only 129,254,000 acres. The South had 211,885,000 acres of forest land, 192,542,000 of them commercial, and the North 186,495,000 of which 177,901,000 were commercial. The nation's growing stock of timber, excluding cull trees, amounted, at the beginning of 1970, to 431,874,000,000 cubic feet of softwood and 217,005,000,000 cubic feet of hardwood. Over half of the hardwood was located in the North. Of total commercial forest land, 73 percent was in private ownership, and 21 percent was owned or controlled by the federal government, the remainder being under the control of state and local administrations.

Hydroelectric resources. The U.S. had 1,176 hydroelectric power stations in 1971. Although this was fewer than in 1950 (1,458) and 1960 (1,331), installed hydroelectric capacity had grown from 18,000,000 kilowatts in 1950 to 32,000,000 kilowatts in 1960 and 56,000,000 in 1971, an annual average growth rate of almost 6 percent. Much unused potential remained. In 1967 the Federal Power Commission estimated that only one-quarter of the potential waterpower was being used. Hydroelectric resources are heavily concentrated in the Pacific and Mountain regions, which together accounted for 57 percent of the installed capacity in 1970. Alaska, where installed hydroelectric capacity was only 77,000 kilowatts in 1970, is estimated to have nearly one-quarter of the nation's unrealized potential capacity.

SOURCES OF NATIONAL INCOME

Changing structure of agriculture

Agriculture, forestry, and fishing. Despite the enormous output of U.S. agriculture, the sector of agriculture, forestry, and fishing produced altogether only 3.0 percent of the net national income in 1971 and 4.1 percent in 1960. Farm productivity grew at a very rapid rate, enabling a smaller labour force to produce more than ever before. Farm manpower fell from 7,485,000 in 1960 to 4,708,000 in 1970, a drop of 37.1 percent, but over the same period the index of farm output (1967 = 100) rose from 90 to 111, a gain of 23.3 percent. This was made possible by an improvement of 82.1 percent in farm output per man-hour. The high rate of growth in farm productivity was important to the overall growth of the economy, in that over a decade it released 2,800,000 people for employment in other sectors. It was accompanied and to a large extent made possible by a marked concentration of farm holdings. While in 1960 there were 3,962,000 farms, with an average 297 acres per farm, in 1971 there were about 2,876,000 farms with an average of 389 acres. Thus, the average size of farms had increased by nearly one-third in a decade, while the number had decreased by more than one-quarter. Farms of more than 1,000 acres accounted for 54.4 percent of all farmland in 1969 and for 48.7 percent of all cropland harvested.

The 1960s saw a considerable increase in the yields of most important crops. The 1961–65 average for maize, at 66.3 bushels per acre, was nearly 30 percent higher than that for 1956–60, and the yield rose further to 86.8 bushels in 1971. For the same periods—1956–60, 1961–65, and 1971—the yields per acre for other crops were as follows: wheat 23.4 bushels, 25.3 bushels, and 33.8 bushels; oats, 39.7 bushels, 45.2, and 55.7; grain sorghums 32.4 bushels, 45.0, and 53.9; cotton, 434 pounds, 491, and 442; rice, 3,265 pounds, 3,892, and 4,638; soybeans, 23.2 bushels, 24.2, and 27.6; tobacco, 1,591 pounds, 1,921, and 2,078. The general improvement in yields was accompanied by an increase in the use of commercial fertilizers of more than 50 percent in seven years.

The U.S. is second only to the Soviet Union as a producer of timber. Production amounted to 36,639,000,000 board feet in 1971, made up of 30,283,000,000 board feet of softwoods and 6,356,000,000 board feet of hardwoods; the principal trees cut in the first category were Douglas fir and southern yellow pine, and, in the second category, oak. Domestic consumption of timber products has been growing faster than national production; imports rose from less than 4,000,000,000 board feet in 1960 to more than 7,000,000,000 in 1971.

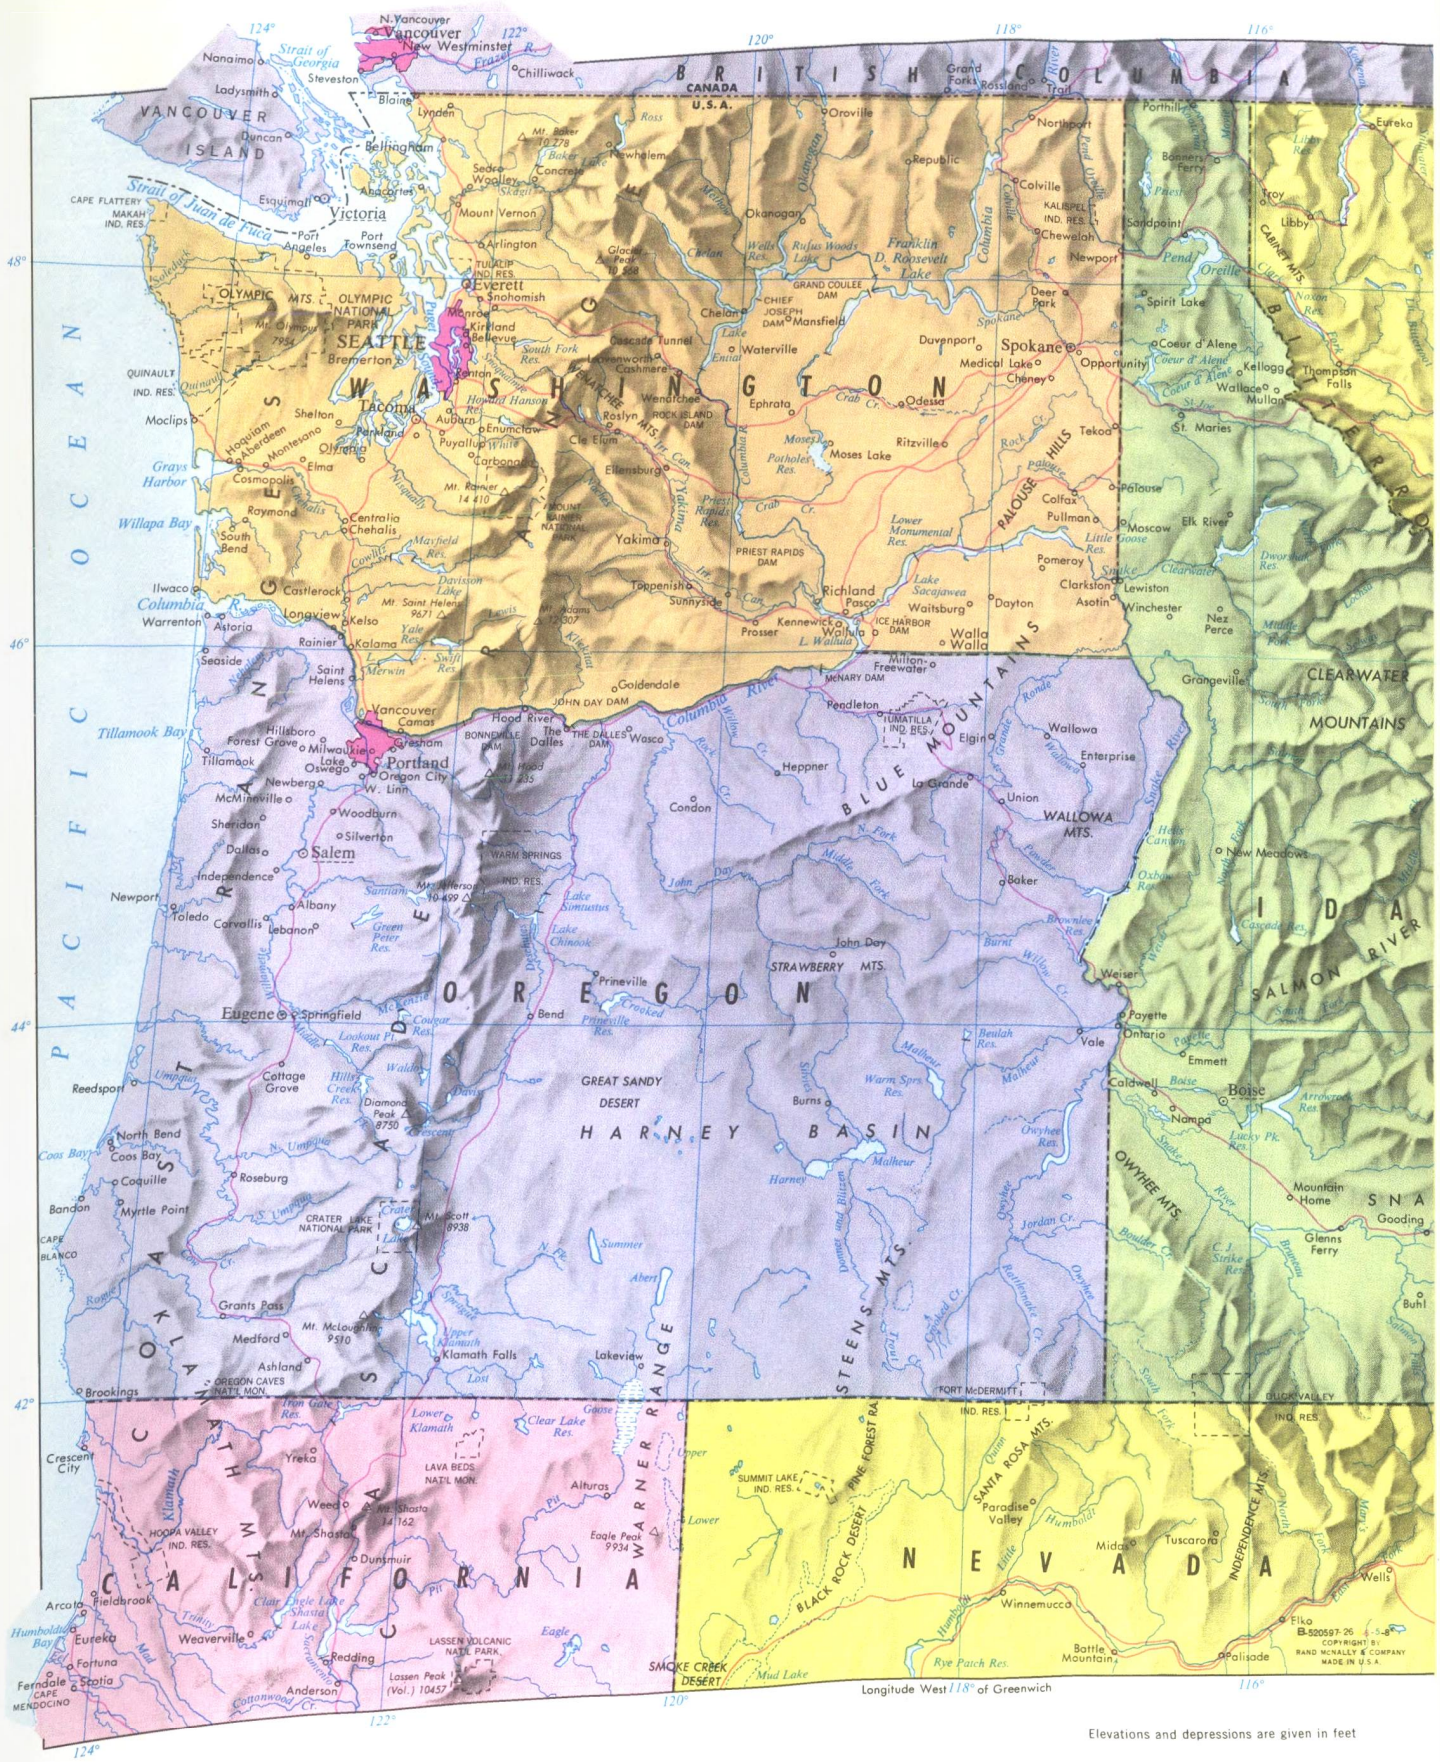
In terms of the weight of its fishing catch, the U.S. was the fourth most important country in the world in 1970, after Peru, Japan, and Norway. Fish for human consumption accounted for 50.5 percent of the tonnage landed in 1960, but this proportion had dropped to 48.3 percent in 1970. Nearly half the 1970 catch, in terms of value, consisted of shellfish.

Declining importance of mining

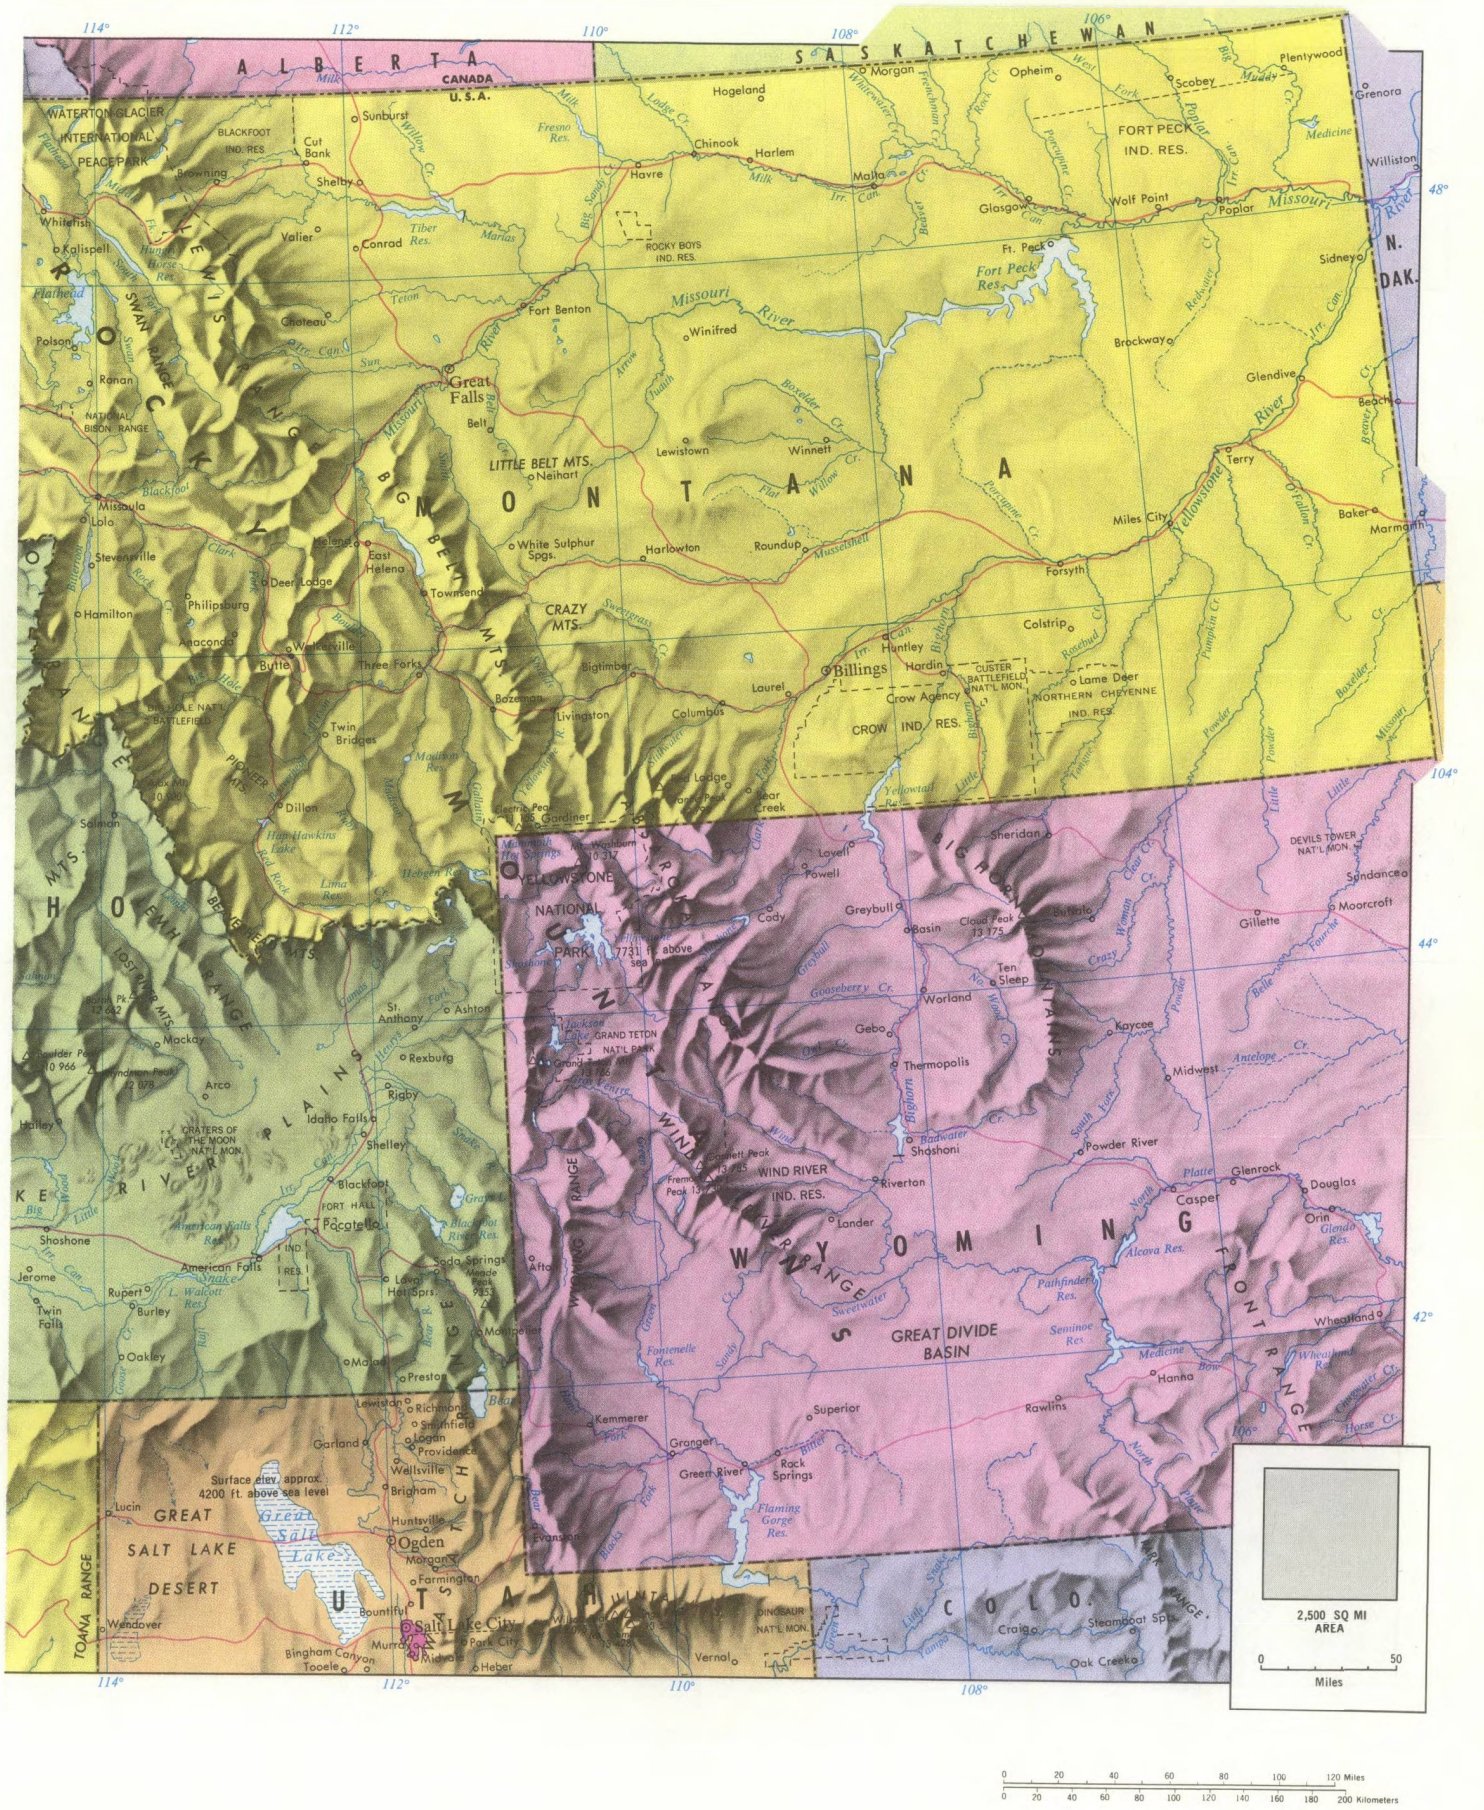
Mining and quarrying. Less than 2 percent of the national income now comes from mining and quarrying, despite the fact that the U.S. is a major world producer of a number of metals and of coal and petroleum. Mineral production showed a modest rise of 3.7 percent a year throughout the 1960s, being faster for fuels (3.6 percent a year) than for metals (2.7 percent a year).

Coal. The late 1960s saw something of a recovery in coal production, which had fallen from an average of 616,000,000 tons in the 1940s to an average of 483,000,000 tons in the 1950s and to 474,000,000 in 1961–65 but averaged 574,000,000 in the five years 1966–70. The recovery owed something to the rise in exports of coal, from 36,500,000 tons in 1960 to 71,000,000 by 1970. The main source of demand for coal, however, remained the electricity-generating industry, where consumption rose by 9.7 percent a year between 1950 and 1960 and by 7.6 percent in the period 1960–70. This helped to offset the stagnation of sales to the manufacturing sector and the really drastic fall in household deliveries (from 84,400,000 tons in 1950 to 12,000,000 in 1970). Total domestic consumption rose by 3.3 percent a year in the period 1960–70. The coal industry underwent a massive increase in productivity: output per man almost doubled in the 1950s, from 1,239 tons a year in 1950 to 2,453 in 1960, and subsequently rose to a level of 4,296 tons a year in 1970.

Petroleum. The output of crude petroleum in 1971 was 3,478,000,000 barrels, compared with 1,974,000,000 in 1950 and 2,575,000,000 in 1960. The number of wells producing natural gas rose rapidly in the late 1950s and early 1960s, from 64,900 at the end of 1950 to 90,761 at the end of 1960 and 117,496 at the end of 1970. Total consumption of natural gas reached 22,046,000,000,000 cubic feet in 1970, having risen since 1960 at an average annual rate of 6.9 percent.



Iron, copper, zinc, lead. Production of iron ore amounted to 82,298,000 tons in 1971, a level below that of 1950. Copper mining, by contrast, expanded considerably in the 1960s, the 1971 output being 41.9 percent higher than that of 1960. Zinc-mine output fluctuated considerably from year to year, but the 1971 figure of 492,000 tons (recoverable content) was 19.5 percent below that of 1965 and 21.0 percent below that of 1950. The statistics for mine production of recoverable lead showed a clearer trend, declining between 1950 and 1960 from 431,000 tons to 247,000 and recovering in the early 1970s to 573,000 tons. Domestic mine production is not, however, the principal source of supply of lead, since even in 1971 it was outstripped by recovery of lead from scrap (587,000 tons), while lead imports, in the form of both ore and metal, amounted to 265,000 tons.



Manufacturing. Manufacturing output grew in the 1960s at roughly the same rate as the economy as a whole. Between 1960 and 1971 the index of manufacturing production increased by 60.6 percent, at an average

annual rate of 5.1 percent, compared with 3.7 percent between 1950 and 1960. The increase was slightly higher for durable manufactures, slightly lower for nondurables. This rate of growth was made possible by two factors: an average annual increase of 3.2 percent in output per man-hour in manufacturing (compared with 2.2 percent during the 1950s) and an increase of just over 2 percent a year in the manufacturing labour force (compared with an increase of only 1 percent a year in the 1950s). The increase in output per man-hour was in part a function of the increased level of capital investment in the 1960s. Manufacturing accounted for 26.6 percent of the net national income in 1971.

Leading sectors in manufacturing

The total value added by manufacturing (*i.e.*, the value of production less the cost of materials, supplies, and overhead) was $298,000,000,000 in 1970. One of the most important sectors in terms of value added was the manufacture of transportation equipment ($28,900,000,000 or 9.7 percent of the total in 1970). Of this, motor vehicles and equipment accounted for roughly half. Sales of passenger cars from U.S. factories amounted to 6,547,000 in 1970 and 8,585,000 in 1971, while the corresponding figures for trucks and buses were 1,692,000 in 1970 and 2,053,000 in 1971. The nonelectrical machinery industry accounted for 10.6 percent of value added by manufacturing in 1970 and the output of electrical machinery for 9.3 percent. These two sectors enjoyed a high growth rate in the 1960s, averaging 9.4 percent annually (1960–70), compared with 7.6 percent for fabricated metal products, 4.8 percent for primary metals, and 5.2 percent for motor vehicles and parts.

Steel production was 120,443,000 tons in 1971, compared with 99,282,000 in 1960; nearly 20 percent of all shipments of steel-mill products in 1970 went to the automotive industry and another 11 percent to the construction industry. The chemical industry showed rapid growth during the 1960s, its production increasing at an average annual rate of 11.5 percent between 1960 and 1971. Against these high-flying industries must be set several the growth of which was below average; in textiles, the average was 4.5 percent a year; in food and beverages, only 4.0 percent a year; and in apparel, 4.6 percent a year.

The ownership of many industries in the U.S., as in other countries, is highly concentrated. In the production of motor vehicles and parts, 79 percent of the value added by the industry in 1966 was accounted for by the largest 4 producers and 83 percent by the largest 8. In aircraft, 67 percent of the value added was accounted for by the largest 4 companies in the industry and 88 percent by the largest 8. In terms of value of shipments, the corresponding figures for the aircraft engines and parts industry were 58 and 77 percent, respectively; for oil refining, 32 and 57 percent; for paper mills, 28 and 40 percent; radio and TV receivers, 48 and 68 percent; cigarette production, 81 and 100 percent; pharmaceuticals, 24 and 41 percent. Litigation by the federal government under the antitrust laws may have helped to prevent significant increases in concentration in many individual industries, but the rise of "conglomerates"—corporations with interests in diverse industries—increased the concentration of ownership overall. Thus, the largest 50 companies accounted for 25 percent of the total value added in manufacturing in 1966, compared with 17 percent in 1947; the largest 200 companies accounted for 42 percent of value added, compared with 30 percent in 1947.

Military orders were of considerable importance to industry in the 1960s. According to the U.S. Department of Labor, 8.7 percent of all those working in private manufacturing industry in 1970 were in employment generated by the Department of Defense. This meant that certain industries and geographic areas were particularly sensitive to reductions in defense spending. In 1968, for example, 6.2 percent of the total labour force in California was in defense-generated employment.

Energy. Energy consumption in the U.S. reached 68,810,000,000,000 British thermal units (BTU) in 1970, rising by an annual average of 4.7 percent in the period 1960–70. (The growth rate over the period 1950–70 was 4.4 percent a year.) Expressed in terms of an equivalent amount of coal, the 1970 figure represented a per capita consumption of 11.1 tons. The corresponding figure for the world as a whole was 1.9 tons; for Japan, it was 3.2 tons; for western Europe, 3.8; for the Soviet Union, 4.4; and for Canada, 9.1. U.S. energy consumption was equal to 33.3 percent of total world energy production in 1970.

Changes in the composition of energy supplies

Major changes occurred in the composition of energy supplies in the 1950s, when the share of soft coal and anthracite dropped from 37.8 to 23.2 percent, while that of natural gas rose from 20.3 to 31.6 percent and that of crude petroleum from 37.2 to 41.6 percent. Change in the 1960s was slower; the share of soft coal and anthracite continued to decline, falling to 18.2 percent in 1971, while that of natural gas rose to 36.5 percent. Electricity from water power and nuclear fission accounted for 2 percent of total energy consumption in 1971.

Oil and gas. Petroleum production rose on the average by 2.7 percent a year throughout the 1950s and by 3.3 percent a year between 1960 and 1971. In the latter year it was 3,478,000,000 barrels, compared with total domestic consumption of 5,041,000,000 barrels. The balance was made up by natural-gas-plant liquids (291,000,000) and imports (1,247,000,000). The U.S. had become slightly less self-sufficient in petroleum production since 1950, when domestic supplies of crude oil accounted for 91.9 percent of the total, as compared with 87.8 percent in 1970. The oil industry is protected from foreign competition by a quota system.

Natural-gas production rose much more rapidly than that of crude petroleum, by an average of 9.4 percent in the 1950s and by 6.5 percent a year between 1960 and 1970. The number of residential consumers of natural gas rose from 16,900,000 in 1950 to 31,100,000 in 1960, reaching 38,600,000 in 1970, while industrial and commercial consumers increased from 1,300,000 in 1950 to 2,600,000 in 1960 and 3,300,000 in 1970.

Coal. Although coal lost ground relatively to petroleum and natural gas in the steadily expanding energy market, its use increased in absolute terms: its 22.9 percent share of the domestic energy market in 1970 represented 613,000,000 tons, compared with 454,200,000 tons in 1950 and 330,400,000 tons in 1960. Consumption rose further in 1970 to 517,000,000 tons, of which electric-power utilities took 320,000,000 tons.

Electricity. The output of electricity reached 1,718,000,000,000 kilowatt-hours in 1971, compared with 842,000,000,000 in 1960, representing an average rate of increase of 8.7 percent a year. The sources of electric energy changed considerably in the 1950s and 1960s. In 1950, coal provided 47.1 percent of the electric energy, increasing its share to 53.6 percent in 1960 and decreasing to 44.3 percent in 1971. The importance of hydroelectric power fell sharply, from 29.2 percent in 1950 to 19.3 percent in 1960 and only 16.5 percent in 1971. Oil provided 10.3 percent of the electricity in 1950 and 13.5 percent in 1971, while natural gas, which provided only 13.5 percent of the energy in 1950, provided 23 percent in 1970. Total installed capacity was 367,400,000 kilowatts in 1971, compared with 186,000,000 in 1960. About three-quarters of the electricity sold to the public was produced by privately-owned companies. The rest came from facilities owned cooperatively, municipally, and by the federal government.

Financial services. Under the Federal Reserve System, central banking functions are exercised by 12 Federal Reserve banks, each serving an important area of the country, supervised by a Board of Governors in Washington, D.C. The governors are appointed by the president, subject to confirmation by the Senate, but are by no means invariably in accord with the administration's views on economic policy—in contrast to the formal dependence of the Bank of England on the treasury in the United Kingdom. The Federal Reserve System regulates bank credit and the money supply by changes in the rediscount rate charged on loans to member banks, by changes in the reserve requirements imposed on commercial banks, and by open-market operations in government

The capital market

securities. The Treasury is not, however, without influence on the working of the monetary system; it influences market interest rates through its management of the national debt, while, by changing its own deposits with the Federal Reserve banks, it can affect the volume of credit.

Laws hindering the formation of branch banks have led to a proliferation of individual commercial banks, of which there were 13,687 at the end of 1971. Of these, 5,727 accounting for nearly 80 percent of total deposits with commercial banks, were members of the Federal Reserve System. Banks incorporated under national charter—4,599 at the end of 1971—must be members of the system, while banks incorporated under state charters may become members, though only about 14 percent of them have done so. Member banks must maintain minimum legal reserves with a Federal Reserve bank, ranging from 10 to 22 percent of their net demand deposits in the case of banks in reserve cities and from 7 to 14 percent in the case of country banks. Member banks must also deposit between 3 and 10 percent of their time (savings) deposits with a Federal Reserve bank.

In addition to commercial banks, there are 490 mutual savings banks and 5,500 savings and loan associations or building societies. Other financial intermediaries include insurance companies, with enormous assets, and finance companies dealing mainly in consumer credit. The federal government sponsors other credit agencies in the fields of housing and farming.

Security ownership is widespread; in the 1960s the number of shareholders rose from 13,000,000 to 31,000,000 in 1970. The market value of listed shares held by private individuals at the beginning of 1970 was almost two-thirds of the estimated total; the other third was held by institutions—pension funds, insurance companies, bank trust departments, mutual funds, etc.—which accounted for about half of the trading on the New York exchanges. New York has two organized stock exchanges, the New York Stock Exchange and the American Stock Exchange. The former trades in 1,830 of the most important securities and the latter in 1,200 other securities. There are, however, subsidiary New York markets: one in which members of the two exchanges sell unlisted stocks across the counter; another in which firms that are not members sell listed stocks across the counter without commission, taking a jobber's profit rather than a broker's; and a third in which institutions bypass the exchanges and deal directly with one another. The latter has been a cause of growing concern to the two exchanges.

A total of $105,200,000,000 was raised on the domestic capital market in 1971. Corporations raised $12,961,000,000 with issues of preferred and common stock, and $32,100,000,000 with bond issues. The U.S. government raised $17,300,000,000 (compared with a record amount of $19,400,000,000 four years earlier) and other noncorporate borrowers, principally government agencies and state and local governments, raised $43,000,000,000.

Foreign trade. International trade plays a relatively small part in the U.S. economy, as compared with the foreign trade of other major industrial countries. In 1971 imports of goods and services were equivalent to 7.0 percent of Gross National Product, while exports of goods and services represented 7.1 percent. Nevertheless, the sheer size of the economy makes the U.S. a major factor in world trade: in 1971 the U.S. absorbed 14 percent of total world imports and contributed 14 percent of total world exports, making it in both respects the most important single trading country.

Changes in imports and exports

U.S. imports rose at an average annual rate of 15.7 percent throughout the 1960s, reaching $40,000,000,000 by 1970. In 1970 nearly three-quarters of the imports were drawn from the developed countries of the world, compared with less than 60 percent in 1960, an illustration of the extent to which the growth in world trade in the 1960s was predominantly among the industrialized countries. The same point emerges from a consideration of the commodity composition of U.S. imports. In 1970, 60 percent of U.S. imports consisted of manufactures, compared with only 40 percent at the beginning of the decade. Imports of food and raw materials grew much more slowly in the 1960s than total imports. This is partly explained by the increased use of domestically produced substitutes for imports of natural rubber and textile fibres. At the same time, there were dramatic increases in imports of manufactures, particularly of machinery and transport equipment.

While U.S. imports grew faster than world imports in the 1960s, U.S. exports rose more slowly than world exports. They totalled $42,600,000,000 in 1970. This represented a sharp drop in the massive trade surpluses that had been recorded in the early 1960s and was one reason for the growing difficulties in the balance of payments. The proportion of exports going to the developed nations rose during the 1960s, from 64 percent in 1960 to 69 percent in 1970. The largest single export market in 1970 was Canada ($9,100,000,000, or nearly one-fifth of total exports), followed by Japan ($4,700,000,000), West Germany ($2,700,000,000), and the U.K. ($2,500,000,000).

The compositon of exports changed during the 1960s to give greater weight to manufactures, in particular to machinery and transport equipment. In 1970 manufactured exports accounted for over 59 percent of the total, compared with 53 percent in 1960. Exports of food and raw materials remained of some importance, however.

One factor assisting the U.S. balance of trade in the 1960s was a shift in the terms of trade. Taking the years 1957–59 as a baseline, the unit value of U.S. exports had risen 16.5 percent by 1969, while the unit value of its imports had risen only 7.2 percent—representing an 8.7 percent improvement in the terms of trade over that period.

MANAGEMENT OF THE ECONOMY

Government and private enterprise. Government plays only a small direct part in economic activity in the U.S., where it is restricted to the United States Postal Service, the uranium enrichment facilities of the U.S. Atomic Energy Commission, and market activities such as those of the Tennessee Valley Authority. Enterprises that are often in public hands in other countries, such as railways, airlines, and telephone systems, are run privately in the U.S.

A principal effort of the government has been the fostering of competition through enforcement of the antitrust laws. These are designed to combat collusion among companies with respect to prices, output levels, or market shares and, where feasible, to prevent mergers that significantly reduce competition. The 1969 merger between The Standard Oil Co. (Ohio) (Sohio) and a subsidiary of The British Petroleum Co. Ltd., for example, was challenged by the Department of Justice and allowed to go through only when Sohio agreed to exchange stations in Ohio for others elsewhere in the country, thus fostering competition in gasoline retailing. So-called conglomerate mergers, between corporations in unrelated industries, which accounted for 82 percent of all combinations in the period 1966–68, had not come within the purview of the antitrust laws. There was strong sentiment at the end of the 1960s for opposing such mergers among the 200 largest manufacturing companies or any merger by one of them with a leading producer in a highly concentrated industry, on the ground that conglomerates were able to switch the profits of one market to subsidize price wars in others, thus reducing competition in the long run, and were also able to require suppliers of one industry in the group to buy from others, on the principle of reciprocity, thus again potentially excluding competitors.

Fiscal and monetary policy

The major area of government regulation of economic activity is through fiscal and monetary policy. The small-scale recession of 1970–71, for example, was the result of a decision to restrict the growth of the money supply in an effort to control inflation. Reductions in federal income tax rates played an important part in initiating the boom of the 1960s. The government also exerts considerable leverage on certain sectors of the economy as a purchaser of goods, notably in the aircraft and aerospace industries.

Proposals for governmental controls of prices and in-

comes were a source of much controversy in the 1960s and early 1970s. Between 1962 and 1966 the Kennedy and Johnson administrations established so-called guideposts for wages and prices in an effort to prevent the economic upswing from leading to inflation. These were to be followed voluntarily rather than enforced by regulation, but there were instances in the 1960s when the prospect of major price increases in important industries brought down on the manufacturers concerned a heavy weight of what was euphemistically called "moral persuasion" on the part of the President. The strong inflationary trend of the late 1960s and early 1970s led the Nixon administration to more radical intervention in the summer of 1971. A three-month freeze on wages and prices was imposed in August, followed in November by the establishment of a Pay Board and a Price Commission that were to set limits on subsequent increases.

Another field in which the government regulates private economic activity is farming. It endeavours to support farm incomes through direct payments to farmers, controls on output, price supports, and the provision of storage and marketing facilities. In 1971 direct payment to farmers cost $3,200,000,000. One disadvantage of the system is that payments are related to farm output, so that the benefit has often gone to the larger commercial farms rather than to those the income level of which was the main object of governmental concern.

Rates of income taxation

Taxation. Nearly all of the federal government's revenues come from taxes. By far the most important source of tax revenue is the personal income tax, which yielded 42.5 percent of total federal receipts in the fiscal year 1972–73. The effective rate of tax in 1972 on the income of a married couple with two dependents varied from 2.0 percent if they had an income of $5,000 a year to 17.0 percent if their income was $25,000—at which income level a single person without dependents paid an effective rate of 18.8 percent. The 17.0 percent rate in 1972 would have been 19.0 percent in 1964 and 21.3 percent in the period between 1954 and 1963, while the 2.0 percent rate would have been 6.5 in 1964 and 8.4 percent between 1954 and 1963. Marginal tax rates in 1966 in the various income brackets—*i.e.*, the rate applicable to the top dollar of income taxable at normal and surtax rates—were 18.4 percent in the $5,000–$10,000-a-year bracket, 32.8 percent in the $20,000–$50,000 bracket, and 57.3 percent in the $100,000–$500,000 bracket; the marginal rate on incomes of over $1,000,000 was 58.2 percent.

Corporate income taxes yielded 16.2 percent of total federal receipts in the 1972/73 fiscal year. The tax was levied at a rate of 48 percent. Excise duties yielded only 7.4 percent of the total federal revenue, but this was offset by the fact that the individual states levy their own excise and sales taxes. Federal excises rest heavily on alcohol, gasoline, and tobacco. Another major source of revenue in the 1972/73 fiscal year was social-insurance taxes and contributions, which yielded 28.8 percent of total revenue. There are also estate and gift duties, yielding 1.9 percent of the total in 1972/73.

Federal tax receipts rose rapidly in the later years of the 1960s, partly because the prevailing inflation brought compensatory wage and salary increases that resulted in higher marginal rates of taxation. Total federal revenue rose in the five years from fiscal 1967 to fiscal 1972 by 32.2 percent, but the net yield of individual income taxes rose by nearly 41 percent. In contrast, the net yield of the corporation income tax declined by 13 percent over the same period—an indication of how severely the monetary squeeze of 1969 and the ensuing fall in demand had affected corporate profits.

Trade unions. The labour force in the U.S. is not highly organized. Total union membership in 1970 (excluding Canadians who are members of U.S. unions) was 19,381,000, of whom 15,978,000 belonged to unions affiliated with the American Federation of Labor-Congress of Industrial Organizations (AFL-CIO), the nationwide federation of unions. Of the total nonagricultural labour force, 27.9 percent in 1968 belonged to unions; in 1960 the comparable figure had been 31.4 percent. About 46 percent of wage and salary earners in manufacturing belonged to unions in 1966. The unionized proportion in mining and quarrying was over 50 percent, in contract construction just over 75 percent; but, in wholesale and retail trade and the service industries, it reached only about 10 percent. The biggest unions in 1970 were the International Brotherhood of Teamsters, Chauffeurs, Warehousemen, and Helpers of America, with 1,829,000 members, the United Automobile Workers (1,486,000), and the United Steel Workers of America (1,200,000). Most unions in manufacturing bargain on a plant- or company-wide scale, although the older unions, such as those of the carpenters and the electricians, bargain by crafts. Settlements negotiated by the unions do not necessarily set the pattern for the movement of wage rates in general. There have been periods when negotiated settlements secured wage increases rather lower than the rate at which wage rates were rising overall.

Although the freedom to strike is hedged about with legislative provisions for "cooling-off" periods and in some cases compulsory arbitration, the major unions are able and willing to embark on long strikes. In 1971 there were 5,100 stoppages causing the loss of 47,400,000 man-days, of which 2,598 stoppages were about general wage claims. Some 1,473 stoppages lasted for longer than 30 days.

Contemporary economic policies. The first economic concern of President Nixon's administration was to bring under control the inflation it inherited from the previous administration; the inflation had been caused in large measure by rapidly increasing military expenditures from the war in Vietnam, coupled with a reluctance to forgo higher expenditures on domestic programs. The problem, in the government's view, was not simply that the economy had veered briefly into excessive expansion, but rather that it was entering its fourth successive year of inflation, which itself served to generate expectations of further inflation that would make the reattainment of reasonable price stability difficult. President Johnson's administration had imposed a 10 percent surcharge on income taxes at the end of June 1968, swinging from a budget deficit of $25,000,000,000 in the fiscal year ending that month to an estimated surplus of $3,200,000,000 in the 1968/69 fiscal year. The Nixon administration began by adopting a policy of balanced budgets and a tight money supply, hoping that a decline in economic activity would put a stop to inflation. The resulting recession, however, was accompanied by continued increases in prices. In response to mounting criticism of its economic policies, the administration decided in mid-1971 to swing over to direct controls on prices and wages (see above), while at the same time attempting to stimulate the economy by giving tax concessions to business and consumers and allowing the federal budget to remain in deficit.

Anti-inflationary policy

Trade and financial policies

The summer of 1971 also saw a major shift in foreign-trade policy. In previous years, under the Trade Expansion Act of 1962, the government had taken part in a series of tariff negotiations with other industrialized countries known as the Kennedy Round. In exchange for tariff concessions by its main trading partners, the U.S. had agreed to tariff cuts averaging 35 percent, to be made in five annual installments beginning on January 1, 1968. Subsequently, strong pressures developed in some industrial circles and in Congress for a more protectionist stance. President Nixon, for example, gave an election pledge in 1968 to restrict entry of Japanese textiles to the U.S. market if Japan proved unwilling to limit them voluntarily. Proposals were made in Congress to impose quota restrictions on the entry of other products that were underselling domestically produced goods. Other tensions arose with the countries of the European Economic Community (EEC; Common Market) over the more protectionist aspects of the EEC's common agricultural policy, which hindered U.S. exports, and over the EEC's policy of signing preferential agreements with Mediterranean countries. Impatience was also expressed at the protectionist policies of Japan. To the difficulties in trade was added a severe international financial crisis resulting from continued deficits in the U.S. balance of payments.

In August 1971 President Nixon called upon the major trading partners of the U.S. to revalue their currencies upward, on the ground that the dollar, as the currency in terms of which all others were expressed, could not be unilaterally devalued. He also announced that the U.S. was suspending the free convertibility of the dollar into gold and imposing restrictions on imports—including a 10 percent surcharge on those covered by tariff legislation.

In December 1971 a realignment of currency rates was agreed in Washington, D.C., involving an 8.57 percent increase in the dollar price of gold and a further revaluation of the Deutsche Mark, yen, guilder, Belgian franc, and Swiss franc. During 1972, continuing (and increasing) balance of trade deficits, combined with other monetary pressures, led to a second devaluation of the dollar (by 10 percent) in February 1973.

Problems and prospects. The problems facing the U.S. economy in the early 1970s were similar to those of other highly industrialized countries. One of them was the question whether high levels of employment could be maintained without inflation or whether the quest for price stability would require damping down economic growth and incurring unacceptable amounts of unemployment—a course that the congressional elections of 1970 indicated would be dangerous to the party in power.

Public concern with environmental pollution also increased at the beginning of the 1970s, leading many to question whether economic growth could continue at previous rates without disastrous consequences to plant and animal life, including human life. It became apparent that serious efforts to deal with the side effects of industrial development would require new economic and social policies. Any slowing in the rate of economic growth, however, would in itself create problems. As the *Economic Report of the President* for 1970 pointed out, the probable increase in federal expenditure arising from existing commitments and policies would be sufficient in coming years to absorb virtually all the additional revenues the government would receive even if growth resumed at a rate of 4.3 percent per annum by 1973. A slower rate of growth would therefore mean reducing the claims on the federal budget, most likely in the area of social policy.

TRANSPORTATION

The mobility of the population

The economic and social complexion of life in the United States mirrors the nation's extraordinary mobility. It may be that no other people on Earth allocate so many resources and so much of their time and attention to moving and getting things moved. A pervasive transportation network has helped bring together in the vast geographic expanse of the country a surprisingly homogeneous and close-knit social and economic environment. This freedom to move explains in large measure the dynamism of the U.S. economy. Mobility has made possible vast metropolises, spreading suburbs, a lengthening radius of commuter travel, the dispersal of shops and industry, and the growing millions of nonfarm rural residents who constitute a new kind of urbanization without community. Mobility has also had destructive effects. It has accelerated the decay of the old urban areas, multiplied traffic congestion, intensified the pollution of the environment, undermined the public-transportation systems, and made recluses of those who lack automobiles.

A view of the continental United States from a spacecraft would show 3,000,000 square miles (8,000,000 square kilometres) of land etched by 3,700,000 miles (6,000,000 kilometres) of roads and streets. The network of roads is thickest on the eastern seaboard, along the Mississippi and Ohio valleys, and on the Pacific coast. Over this network in 1971 moved 111,000,000 motor vehicles—92,000,000 passenger cars and 19,000,000 trucks and buses. In addition, there are 344,000 miles of railway track, 176,000 miles of intercity pipelines, 142,000 miles of airways, and 25,000 miles of navigable waterways on the rivers and Great Lakes. Together these systems make it possible to provide 9,000 ton-miles of freight transportation per year for each inhabitant. The number of persons employed in the transportation services and in their supporting equipment and supply industries exceeds the combined population of Norway and Sweden.

Methods of passenger travel. The overriding factor in the nation's mobility is the automobile. Eighty-three percent of all families own at least one car, and 28 percent own two or more. It is possible to eat a meal, attend the theatre, or make a bank deposit without getting out of one's car, and only slightly more effort is required to spend the night at a motel or to visit a shopping centre where business caters to a wheeled clientele. Millions work in suburban factories far from any means of public transportation, where getting the job requires having a car.

Importance of the automobile

The increase in car ownership has exceeded the rising output of goods and services and far outstripped the growth of population. Taking 1950 as 100, the index of gross national product in 1969 was 205, the index of population 133, and the index of auto registration 213. At the same time, the city transit systems have undergone a sharp decline: between 1950 and 1971 the number of bus and subway rides taken annually dropped from 17,000,000,000 to 7,000,000,000, despite a great increase in urban population.

The purposes of automobile riding were revealed in a survey of the Baltimore metropolitan area in the early 1960s. It showed that 38 percent of all trips were for the purpose of getting to work, and 9 percent were for personal business. Shopping accounted for 16 percent of the total trips and social or recreational travel for an equal proportion. Another 10 percent of the riding was to school (Wilbur Smith and Associates, *Baltimore Metropolitan Area Transportation Study* [1964]).

While seven out of ten trips in metropolitan areas are made by car, public transit and rail commuter lines play an important role in the most populous cities. From 70 to 90 percent of home-to-work travel in the rush hours is by public carrier in such large centres as Boston, Philadelphia, Chicago, and New York. On an average day 26,000,000 people in the United States patronize local buses and subways. Only 15 percent of U.S. workers walk to their jobs.

The automobile also dominates intercity travel patterns. According to a Census Bureau survey in 1967, of those making trips of 100 miles or more, 86 percent go by car. Of the remainder, 3 percent go by bus, 8 percent by air, and 1 percent by railway. When intercity travel by public carrier is measured in terms of passenger miles, however, the figure for air travel is three times the total of rail and bus transportation combined, because trips by air are much longer than by bus or rail.

Household budgets reflect the travel picture. Out of every consumer dollar spent for travel in 1968, 93 cents went for automobiles and their upkeep. The remaining seven cents was spent on public carriers, divided almost equally between intercity transportation and carriers serving urban areas. In other words, only 3.2 cents out of the transportation dollar was spent on non-automobile transportation in cities. Since nearly one-third of this amount was taxi fares, the urban public transportation systems, including the commuter railroads, received only 2.2 cents of the transportation dollar.

Railroads as bulk carriers

Freight transportation. Railroads still play an important part in freight transportation between cities. In 1970 they carried 41 percent of the total domestic ton-miles of freight, compared with 22 percent carried by pipelines, 21 percent by truck, and 16 percent by the inland waterways and on the Great Lakes. The railways carry a preponderance of heavy bulk materials, while trucks carry the lighter and more valuable goods. The result is that trucks get the lion's share of the intercity freight dollar: 73 cents, compared with only 14 cents for the railways. Altogether, the volume of freight traffic in the United States in 1970 amounted to 1,900,000,000,000 ton-miles, or about two ton-miles for every dollar of gross national product.

The transportation bill. The total freight bill paid by Americans in 1968 amounted to $75,000,000,000, of which $55,000,000,000 was for trucking. Outlays for passenger travel totalled $97,000,000,000 of which $83,000,000,000 was spent on private automobiles.

Government expenditures for basic transport facilities in 1970 totalled nearly $23,000,000,000, about one-third supplied through the federal government and two-thirds by the states and localities. The major outlay was for roads, on which nearly $20,000,000,000 was spent; the remaining $3,000,000,000 was shared by all other transportation media. A little less than $2,000,000,000 was spent on airways and airports. The most spectacular part of the government program was the ongoing 42,000-mile Interstate Highway System, a national network of multiple-lane dual expressways connecting 48 states and 90 percent of all cities of 50,000 population or more. This $50,000,000,000 system, begun in the 1950s, was to be completed by 1974, when it would carry 20 per cent of the nation's motor traffic. It would be possible to drive from coast to coast on the Interstate network without stopping for a traffic light.

Policy issues. The automobile age has brought some unpleasant consequences, including traffic congestion and air pollution. Some efforts were being made at various governmental levels in the early 1970s to adapt the transportation system to the changing needs of society. These included a new program of aid for urban transit in hope of providing an attractive alternative for automobile commuters. New federal safety requirements for passenger cars were aimed at reducing the highway death toll (nearing 60,000 per year), and new engines and fuels were being developed to reduce air pollution. Efforts were directed to making transportation investment decisions more responsive to community desires. Bans were beginning to be imposed on cars on the downtown streets in some large cities.

The U.S. Congress gave recognition to the urgency of transportation problems in 1965 by establishing a Department of Transportation in the federal government. The country was entering a new era of jumbo jets, vertical- and steep-take off airplanes, high-speed ground transport, computerized freight systems, automated highways, and new power sources. Many believed that the central question was how to arrive at a compromise between the desire to be urbanized and motorized and the desire to remain civilized. (W.O.)

V. Administration and social conditions

THE STRUCTURE OF GOVERNMENT

The national government. The United States Constitution sets up and defines a federal system of government in which certain powers are delegated to the national government and all other powers fall to the states. The national government consists of executive, legislative, and judicial branches designed to check and balance each other, all interrelated and overlapping yet each quite distinct.

Since the Constitution came into effect in 1788, there have been 26 amendments to it. The first ten, known as the Bill of Rights, established certain individual liberties. Notable among the other amendments are the 13th, 14th, and 15th, which abolished slavery and declared former slaves citizens with the right to vote; the 19th, which effected female suffrage; and the 17th, which provided for the direct election of United States senators. Amending the Constitution requires a proposal by a two-thirds vote in Congress or by a national convention, followed by ratification by three-fourths of the state legislatures or state conventions.

The executive and legislative branches

The executive branch of the government is headed by the president, whose formal responsibilities include those of chief executive, treaty maker, commander in chief of the army, and head of state. In practice, they have grown to include the drafting of legislation, the formulation of foreign policy, personal diplomacy, and leadership of his political party. The members of the president's Cabinet —the secretaries of State; Treasury; Defense; Interior; Agriculture; Commerce; Labor; Health, Education and Welfare; Housing and Urban Development; Transportation; and the Attorney General—are defined in the 25th amendment as "the principal officers of the executive departments," but much power has come to be exercised by presidential aides who are not in the Cabinet. Thus, the president's Executive Office includes the Office of Management and Budget, the National Security Resources Board, the Council of Economic Advisers, the National Security Council, and the Office of Defense Mobilization.

The legislative branch of the government is the Congress, which has two houses: the Senate and the House of Representatives. Powers granted Congress under the Constitution include the power to levy taxes, borrow money, regulate interstate commerce, declare war, seat members, discipline its own membership, and determine its rules of procedure.

The House of Representatives is chosen by direct vote of the electorate in each state, the number of representatives allotted to each state being based on population. Members must be 25 years old, inhabitants of the states from which they are elected, and previously citizens of the United States for at least seven years. It has become practically imperative, though not constitutionally required, that they be inhabitants of the districts that elect them. They serve for a two-year period. The speaker of the House, who is chosen by the majority party, presides over debate, appoints members of select conference committees, and performs other leading duties. The parliamentary leaders of the two parties are the majority floor leader and the minority floor leader; they are helped by party whips who maintain contact between the leadership and the members of the House. Bills introduced by members in the House of Representatives are received by the standing committees, which meet in private executive session and can amend, expedite, delay, or kill the bills. The committee chairmen attain their positions on the basis of seniority, a criterion that is increasingly challenged. Among the most important committees are those on Appropriations, Ways and Means, and Rules. The Rules Committee, traditionally conservative, has great power to determine which bills will be brought to the floor of the House for consideration.

Each state elects two senators. Senators must be at least 30 years old, inhabitants of the state from which they are elected, and previously citizens of the United States for at least nine years. Each term of service is for six years, and

terms are so arranged that one-third of the members are elected every two years.

The Senate has 16 standing committees, among which the most prominent are those on Foreign Relations, Finance, Appropriations, and Government Operations. Debate is almost unlimited and may be used to delay the vote on a bill indefinitely. Such a delay is known as a filibuster and can be brought to an end only if two-thirds of the Senate agree. Treaties made by the president with other governments must be ratified by a two-thirds vote of the Senate.

The judicial branch

The United States Supreme Court, the third, or judicial, branch of the government, interprets the meaning of the Constitution and of federal laws. It consists of nine justices (including the chief justice) appointed for life by the president with the consent of the Senate. It has appellate jurisdiction for the lower courts and from state courts of last resort if a federal question is involved. It has original jurisdiction over cases involving foreign ambassadors, ministers, consuls, and cases to which a state is a party.

Three types of cases commonly reach the Supreme Court: cases involving litigants of different states, cases involving the interpretation of federal law, and cases involving the interpretation of the Constitution. Six judges consider each case, and a majority vote of the whole court is decisive; a tie vote sustains a lower-court decision. Often the minority judges will write a dissenting report.

The Supreme Court has often been criticized for its decisions. In the 1930s a conservative court overturned much of Pres. Franklin D. Roosevelt's New Deal legislation. In the area of civil rights it has received criticism from various groups at different times. After a 1954 ruling against school segregation, Southern political leaders attacked it harshly. Later, they were joined by Northern conservatives. During the 1960s a number of decisions involving the pretrial rights of prisoners came under attack on the ground that the court had made it difficult to convict criminals.

Below the Supreme Court is the U.S. Court of Appeals. Special courts handle property and contract damage suits against the United States (U.S. Court of Claims), review customs rulings (U.S. Customs Court), and apply the uniform Code of Military Justice (U.S. Court of Military Appeals). Each state has at least one federal district court and at least one federal judge. District judges are appointed for life by the president with Senate consent. Appeals from district-court decisions are carried to the Court of Appeals.

State and municipal governments. The governments of the 50 states have structures closely paralleling those of the federal government. Each state has a governor, a legislature, and a judiciary. Each state has its own constitution.

All state legislatures but one have two houses, Nebraska's being unicameral. Traditionally, state legislatures have been dominated by rural representatives who are not always sympathetic to the needs of growing urban areas. State judicial systems are based upon elected justices of the peace, above whom come the major trial courts, often called district courts, and appellate courts. In addition, there are probate courts concerned with wills, estates, and guardianships. Most state judges are elected

State governments have a wide array of functions, encompassing agriculture and conservation, highway and motor-vehicle supervision, public safety and correction, professional licensing, regulation of intrastate business and industry, and certain aspects of education, public health, and welfare. These activities require a large administrative organization, headed by the governor. In most states there is also a lieutenant governor, not always of the same party as the governor, who serves as the presiding officer of the Senate. Other elected officials include the secretary of state, state treasurer, state auditor, attorney general, and superintendent of public instruction.

Municipal governments are more diverse in structure than state governments. There are three basic types: mayor–council governments, commission governments, and council–manager governments. In the first type, the mayor and the council are elected; the council is nominally responsible for formulating city ordinances, which the mayor enforces; often the mayor controls the actions of the council. Boston, New York, Philadelphia, Chicago, and Seattle have the mayor–council type of city government. In the commission type, voters elect a number of commissioners each of whom serves as head of a city department; the presiding commissioner is generally the mayor. Des Moines and New Orleans have commission governments. In the council–manager type, an elected council hires a city manager to administer the city departments. The mayor, elected by the council, simply chairs it and officiates at important functions. Over 2,200 cities had adopted the manager plan by 1968.

The three types of municipal government

Political parties. There are two major political parties in the U.S., the Democratic Party and the Republican Party. Other parties have occasionally challenged these two but without permanent success. One reason for their failure is that to win a national election, a party must appeal to a broad base of voters and a wide spectrum of interests. The two major parties tend to be moderate in their programs, and, in fact, there is usually little difference between them. Each has a conservative wing, and each has a wing that is considered liberal. The conservative Democrats are more conservative on racial issues than their Republican counterparts; the liberal Democrats are more radical on economic issues than the liberal Republicans. The national parties exist mainly to contest presidential elections every four years, and, in between their quadrennial national conventions, they are little more than loose alliances of state and local party organizations.

The political process

In elections for president, voters actually choose among electors committed to the support of a particular candidate. Each state is allotted one electoral vote for each senator and representative in Congress. This is called the electoral-college system.

At the state level, political parties reflect the diversity of the population. Large urban centres are likely to support a Democratic ticket, whereas rural areas, small cities, and suburban areas tend to vote Republican. In many states the rural areas and smaller towns control the state legislatures, even though the more populous city areas provide the greater proportion of tax revenue. A Supreme Court ruling in 1964 sought to remedy this situation by ordering states to reapportion their legislatures more according to population. Some states have traditionally given majorities to one particular party. The 11 Southern states of the old Confederacy have until recently voted almost solidly for Democratic candidates; in Maine and South Dakota the Republicans more often won.

Municipal political parties have a pyramidal structure based, at the lowest level, on districts or precincts. The leaders of these units are responsible to ward leaders, who form the governing body of the municipal party. All of these party functionaries are responsible for getting their voters to the polls at election time, often on the basis of a return for services rendered. It is to them after all, that voters have gone with requests for better municipal services, jobs, and assistance in minor difficulties. One route to political office for the ordinary citizen has been through the organization: belonging to a neighbourhood party club, helping to raise funds, getting out the vote, watching the polls, and gradually rising through the system to committeeman, city councilman, representative to the state legislature, or—depending on chance, talent, political expediency, and a host of other factors—to higher positions.

Decline of local autonomy

As society has become increasingly urban, politics and government have become more and more complex. Many problems of the cities, including the problems of transportation, housing, education, health, and welfare, can no longer be handled entirely on the local level. Since even the states do not have the necessary resources, the cities have been forced to turn to the federal government for assistance.

Armed forces. The military forces of the U.S. consist of the army, navy, marines, air force, and coast guard, under the umbrella of the Department of Defense with its headquarters in the Pentagon building in Arlington, Virginia. Military personnel numbered over 3,600,000 in 1971, and the military budget exceeded $78,000,000,000. Since a large part of it is spent on matériel and research and development, military programs may have considerable economic and political impact.

The influence of the military also extends to other countries through various multilateral and bilateral treaties for mutual defense and military assistance. In the early 1970s the U.S. had military bases in Africa, Asia, Europe, and Latin America.

The armed forces in the early 1970s were made up of conscripts as well as career personnel and volunteers. Under the Military Selective Service Act of 1967 (Public Law 90–40), all men between 18 and 26 years of age were required to register for service, although provisions were made for the physically handicapped, conscientious objectors, and others in special circumstances. The equity of the draft provisions was increasingly questioned, however, and in the early 1970s a completely volunteer service began to be created. The four armed services also maintain reserve forces that may be called upon in time of war. Each state has a National Guard consisting of reserve groups subject to call at any time by the governor of the state.

THE SOCIAL SECTOR

Education. The interplay of local, state, and national programs and policies is nowhere more evident than in the field of education. Historically, education has been considered the province of the state and local governments. Of the more than 2,500 colleges and universities, only one—Howard University in Washington, D.C.—is considered a federal institution. (The U.S. also administers the College of the Virgin Islands.) For years, however, the federal government has been involved in education at all levels, beginning in 1872 with the grant of public lands to the states for the purpose of establishing agricultural and mechanical arts colleges. There are 68 of these land-grant colleges. Additionally, the federal government supports school lunch programs, administers Indian education, makes research grants to universities, underwrites loans to college students, finances education for veterans, and prepares teaching materials. In 1971 the Office of Education administered $11,400,000,000 in federal school aid. Whether the government should also give assistance to private and parochial (religious) schools has been widely debated. The Supreme Court has ruled that direct assistance to parochial schools is barred by the First Amendment to the Constitution, which states that "Congress shall make no law respecting an establishment of religion," although this has not been extended to the use of textbooks and so-called "supplementary educational centres."

Colleges and universities

Entry to colleges and universities in the U.S. is still closely correlated with family income. In the 1968–69 academic year about 20 percent of college-age children of families with incomes up to $3,000 attended college. The figure was about 30 percent in the case of families with incomes of $3,000 to $4,000, 50 percent for families with incomes between $7,500 and $10,000, and 85 percent for those with incomes of $15,000 and over.

Elementary and secondary education

The amount of education received by the general population has increased over the years. In 1940, among persons 25 years of age and older, only 24.5 percent had completed high school; in 1960, 41.1 percent; and in 1970, 55.2 percent had completed high school. The figure was higher for whites (57.5 percent in 1970) than for blacks (33.8). Of the general population in 1970, only 13.4 percent had completed fewer than eight years of school and only 5.3 percent fewer than five years.

Although responsibility for elementary education still rests primarily with local government; it is increasingly affected by state and national policies. The 1964 Civil Rights Act, for example, required federal agencies to cut off financial aid to school districts that are not racially integrated. This raised difficult problems for the school systems of some Northern cities where blacks were living in largely segregated enclaves, requiring children to be transported long distances to nonsegregated schools.

Current trends in education are toward meeting the needs of a complex society: preschool programs; nongraded, multilevel classrooms; classes in the community; summer and night schools; increased facilities for exceptional children; and a general restructuring of traditional mores to improve education of the culturally deprived and the disaffected student.

Welfare and health services. For all its wealth, poverty remains a reality for many persons in the United States. In 1960 an estimated 28,300,000 whites and 11,500,000 non-whites were at or below what was considered the poverty level by government statisticians. In 1971 the total was 25,600,000, of whom 4,300,000 were 65 or older, and 8,400,000 were children under 14. About 60 percent of the poor were in homes in which there was a full or part-time wage earner. Of the others, 80 percent were too old or handicapped to work, while 15 percent were mothers of young children. The states provide assistance to the poor in varying amounts. In the late 1960s, state assistance ranged from approximately $2,400 a year for a family of four to as low as $600. The U.S. Department of Agriculture subsidizes the distribution of low-cost food to the poor through the state and local governments.

The poor

Increasing public concern with poverty and welfare led to new federal legislation in the 1960s. Work, training, and rehabilitation programs were established in 1962 for welfare recipients. Between 1965 and 1969 the Office of Economic Opportunity set in motion a host of programs: the Head Start program for preschool children, the Neighborhood Youth Corps, the Teacher Corps, and the Manpower Training and Development program for unemployed workers. In 1969 the Nixon administration proposed among other measures, a sliding scale of payments for workers earning less than the poverty level. The plan would require all able adult family members to accept work or training when possible and would provide day-care centres to free mothers for work.

Persons who have been employed are eligible for retirement pensions under the federal social security program established in the 1930s. Many employers also provide additional retirement benefits, as well as health insurance and life insurance, usually based on contributions by both the employer and the worker. In 1970 about 90 percent of those employed, or 80,600,000 persons, were covered by Social Security. In addition, 29,700,000 persons were covered by private pension plans.

The provision of medical and health care is the second largest industry in the United States. In 1970 about 7 percent of the gross national product, amounting to over $300 per person, was spent in this field. There were, nevertheless, many inadequacies in medical services, particularly in rural and poor areas. The number of practicing physicians for every 100,000 persons was about 164 in 1970, ranging from 78 in Mississippi to 234 in New York State.

Financing of health care

About one-sixth of the population, including members of the armed forces and their families, receive medical care paid for or subsidized by the federal government. Many people are not covered by any form of health insurance. In 1965 some medical care was provided for the aged under the federal Social Security program, but most health insurance is on a private basis.

Of the total amount spent on medical and health care in 1970, 37 percent or $26,724,000,000 came from government sources. The federal Department of Health, Education and Welfare through its National Institutes of Health supports over 40 percent of the biomedical research in the U.S. Grants are made also to researchers in clinics and medical schools.

Infant mortality was 19.8 per thousand in 1970. Life expectancy at birth was 74.0 years for females and 66.6 for males.

Housing. About 68,627,000 housing units existed in the United States in 1970, of which more than 64,000,000

Quality of housing

were occupied. For the country as a whole, there were about 2.7 persons per occupied unit, as compared with 3.4 in 1960 and 3.8 in 1940. Over 90 percent of the occupied housing units had hot running water, flush toilets, and bathing facilities inside. About 70 percent of them were single-family houses, and a majority of the remainder were in structures containing two, three, or four units. Most houses in the United States are of wood construction, though often covered with shingles or brick veneer.

Housing, like health, was long considered a private rather than public concern. The growth of urban slums led many municipal governments to enact stricter building codes and sanitary regulations. In 1934 the Federal Housing Administration was established to make loans to institutions that would build low-rent dwellings. In 1945, Congress authorized the building of 810,000 housing units by public housing authorities. In 1949 it provided large sums in loans and grants to local communities for slum clearance and redevelopment. The continued deterioration of housing conditions in large cities led in 1968 to new federal legislation to subsidize the building of 26,000,000 new units in ten years, 6,000,000 of which were to be low-cost.

Efforts to reduce the slums in large cities by developing low-cost housing in other areas have been resisted by property owners. For many years the restrictive covenant, by which property owners pledged not to sell to certain racial or religious groups, served to bar those groups from many communities. A 1948 Supreme Court decision declared covenants unenforceable; a 1962 executive order by President Kennedy prohibited discrimination in housing built with federal aid; and many states and cities have adopted fair-housing laws and set up fair-housing commissions. All these efforts, however, have had little effect upon the black ghettos in large cities.

Law enforcement. The enforcement of law in the United States has traditionally been centred in the hands of local police officials. The bulk of the work is done by patrolmen, detectives, and policewomen in the cities and by sheriffs and constables in rural areas. Many of the state governments also have law-enforcement agencies, and all of them have highway-patrol systems for traffic-law enforcement. Crimes that come under federal jurisdiction (for example, those committed in more than one state) are the responsibility of the Federal Bureau of Investigation (FBI), which also provides assistance through fingerprint identification and technical laboratory services to state and local law-enforcement agencies.

Crime rates rose in the 1960s, and law enforcement became a major political issue in the early 1970s. In 1966 the federal government began encouraging state coordinating councils composed of local police, prosecutors, courts, and corrective officers—a trend that was strengthened by the omnibus Crime Control and Safe Streets Act (Public Law 90–351). Other measures taken to combat crime included enlarging police departments and raising the level of competence in police work.

Living levels. The decade of the 1960s saw a continued improvement in the level of living of much of the U.S. population. Average family incomes in 1970 dollars rose from $6,962 in 1960 to $9,867 in 1970. The incomes of Negro families in the latter year averaged about 63 percent of the incomes of white families, as compared with 55 percent in 1960. Food consumption, although accounting for a smaller part of the consumer's dollar than formerly, continued to increase. Daily per capita food consumption was about 3,290 calories in 1970, one of the highest levels in the world. The consumption of wheat flour and fluid milk declined; the consumption of meat increased from about 161 pounds per person (73 kilograms) in 1960 to 185 pounds in 1970.

The latter part of the 1960s and the beginning of the 1970s were shadowed by price inflation that approached a rate of 6 percent a year—considered high in the U.S.—and also by increased unemployment. The latter fell more heavily upon blacks than upon whites and was especially severe among young people under 20 years of age.

VI. Cultural life and institutions

THE CULTURAL MILIEU

The dominant fact of cultural life in the United States during the 20th century has been rapid and continual change brought about by such factors as population growth, technological development, urbanization, and the press of world events. By the middle decades of the 20th century, the principal question was whether change was producing a more unified, homogeneous, and standardized culture or a culture increasingly divided and fragmented into sometimes conflicting parts.

Trends toward uniformity. With the advent of commercial television at midcentury, it was generally believed that cultural life would be increasingly shaped by the techniques and requirements of mass cultural institutions. According to this view, the major media of communications—television, radio, motion pictures, national magazines, and phonograph-record companies, operating principally in New York City and Los Angeles—would produce an overwhelming proportion of the entertainment and information available to the public. Such cultural production, it was argued, would inevitably be controlled by the commercial need to appeal to the largest possible audience and to sell advertised goods and services. The result would be a growing cultural uniformity throughout the country at a level of lowest-common-denominator mediocrity, wiping out ethnic and regional differences and confining the creation and preservation of "high culture"—literature, the fine arts, classical music and opera, philosophy and social thought—to a small, educated elite.

Homogenizing influences of mass communications and institutions

Certainly, some part of these pessimistic predictions came true in U.S. cultural life at midcentury. In a period of rapid communications and nationwide consolidation of corporate industry, regional variations in such facets of cultural life as architecture, language, popular entertainment, and style of dress unquestionably diminished. It was possible to travel west across the country in a few hours and find in Arizona or Oregon shops and restaurants with the same names, buildings, and products, as well as television channels and movie theatres with the same programs, that had been left behind in Virginia or Connecticut. Few other countries had attained such unity of cultural life over so vast a territory and so large a population.

The counter-cultures. In this period of increasing standardization of cultural life, however, a countertrend began that opposed the process of unification with a process of fragmentation. In its origins, this countermovement consisted very little in a conscious effort to resist the development of mass culture, in the form, for example, of a bohemian colony of nonconformists. Rather, its sources came from movements of social change and political opposition, the renewed civil-rights movement of the early 1960s, and the opposition to the growing United States' military involvement in Vietnam in the latter half of that decade. As groups formed around issues and developed identities through the struggles, a consciousness emerged not merely of political disagreement but also of cultural difference. The movement for civil rights became a movement for black power, dividing rather than uniting black and white people. Middle class college and university students, shifting their concern from civil rights to the antiwar movement as the United States became more deeply involved in Southeast Asia, developed a sense of youth culture and adopted the phrase generation gap and the slogan "never trust anyone over 30." By the end of the 1960s, the term counter-culture was commonly used as a loose umbrella covering a variety of alternatives to the traditional norms of cultural life.

The counter-culture differed significantly from the alternative cultures of other eras. Past alternative cultures had accepted high culture as their standard against the alleged mediocrity or commercialism of the mass. They were minority cultures founded on appreciation and creation of literature and other fine arts. This facet of cultural alternative was not entirely missing from the counter-culture that began in the 1960s, but it was not its central

aspect. The new focus was on opposing the norms of conventional culture, including the class and aesthetic distinctions reflected in the idea of high culture. Its most publicized symbols were "hippies," long-haired young people who popularized the use of marijuana and hallucinogenic drugs, rock music, and communal life-styles.

Impulses toward increased cultural fragmentation

The fragmentation of cultural life continued to take new forms. Black power for Negroes became red power for American Indians, brown power for Chicanos and other Spanish-speaking people, women's liberation as a new form of feminism, gay liberation for homosexuals. In all these cases the rhetoric of "power" and "liberation" implied a pride and self-confidence in racial, ethnic, sexual, and ultimately cultural differences. It marked a new form of consciousness among minority groups in the cultural life of the United States, a militancy arising from the assertion of group solidarity and the distinctive traits and appearances of the group. Only a few years before, members of minority groups had been striving to adapt themselves as much as possible to a unified mode of cultural behaviour in grooming, dress, work habits, and recreation. By the early 1970s such efforts at acculturation had proven so effective that many of the old ethnic, nationality, and religious distinctions among white Americans had lost their emotional force. White Americans of the middle classes, whatever their country of origin or form of worship, were described as a "silent majority" of "middle Americans," marked by an increasing resistance to social and cultural change. But it remained to be seen how much cohesion this group possessed, whether political or economic differences would take on growing importance as cultural differences waned. There were signs, moreover, that the new minority consciousness was also affecting the older European ethnic allegiances, causing a revival of ethnic awareness and assertion among groups nominally part of the undifferentiated "middle Americans."

The roots of the startling and unexpected trend toward cultural differentiation have been traced to several causes. One useful explanation centres on the practical impossibility of attaining a single standardized cultural life in the United States. This viewpoint holds that differences in ethnic and racial background and in sexual and cultural experience are real and that the effort to deny them led to social and cultural tensions that exploded in cultural conflict and self-assertion. It would be better, according to this view, to foster cultural pluralism in the United States and encourage groups and individuals to create their own cultural lives based on their differences and also their inevitable relation within the shared activities of national life.

Another explanation finds the cause of cultural divergence paradoxically in the very technologies that make a unified culture possible. This view asserts that the new electronic technologies of computers, artificial Earth satellites, and television have created a revolution in communications and in culture. They make possible an instantaneous transmission of information to any part of the world. Instant communications thereby pose a double challenge to traditional centralized and large-scale organizations. People are learning to think in global terms, as part of a single Earth system. At the same time, transnational technologies encourage people to re-examine their cultural identities. One result has been the desire to reformulate cultural life in smaller, more distinctive units.

Such theories may help to explain many of the contradictory features of the new cultural movements in the United States. Although the counter-culture has an explicitly anti-technological ideology, its members often extol the products of mass-technological culture, including movies, television, records, and tapes. The distinctive styles and languages of the minority cultures are projected across the nation through the media and are adopted, imitated, or commercialized for mass cultural use. Information made available by the new technologies has convinced many that technological growth is leading the society to ecological disaster. An ecology movement has developed that opposes further technological expansion and fosters the trend toward smaller cultural units. In the early 1970s cultural life in the United States continued to be marked by rapid change, emphasizing new relationships among people and between people and their environment.

THE STATE OF THE VARIOUS ARTS

New forces and forms. The technological, economic, social, and intellectual factors underlying cultural change obviously affect the work of artists and entertainers in the United States, as well as the audiences and status of the various arts. But the relationship of the arts to the structure of culture has always been an ambiguous one, with artists sometimes anticipating or prefiguring cultural change in their works and at other times reflecting or documenting such changes. In either case, the arts in recent years have been deeply involved with the transformations shaping cultural life in the United States.

Literature. This involvement may be readily seen in literature, the form of artistic expression in which U.S. artists first received worldwide recognition. Fiction and poetry have traditionally been mediums that members of minority groups have used to express their sense of life in the United States. Burdened and blessed with a double consciousness, at once insider and outsider to the mainstream of cultural life in the United States, the minority-group writer has a special perspective that can illuminate aspects of the national culture inaccessible to others. After World War II, writers from regional and ethnic minorities thus played significant roles in sensing and interpreting U.S. life through fiction and poetry. Southerners were prominent among U.S. writers, including William Faulkner, Eudora Welty, Robert Penn Warren, Katherine Anne Porter, Flannery O'Connor, and Walker Percy; in the 1950s, Jewish writers came to the fore in literary life, among them Saul Bellow, Norman Mailer, Bernard Malamud, Philip Roth, and Allen Ginsberg.

Literary perspectives of the U.S. minorities

In the mid-1960s, as a counterpart to the civil-rights movement, it appeared that blacks would become the latest minority to take a leading part in U.S. literature. Black novelists such as James Baldwin and Ralph Ellison had already become prominent, and Ellison's *Invisible Man* (1952) was considered by many critics the outstanding U.S. novel of the quarter century following World War II. But, as the civil-rights movement turned to black power, the writers who expressed the black perspective on U.S. culture were not novelists but militant activists who wrote essays, memoirs, and polemics. Such works as *The Autobiography of Malcolm X* (1965), Eldridge Cleaver's *Soul on Ice* (1968), and George Jackson's *Soledad Brother* (1970) claimed for nonfiction the imaginative force and depth that the literary public had been accustomed to finding only in poetry and fiction.

Literature of cultural alienation and protest

The predominance of nonfiction among black writers was one part of a general movement in the U.S. literary community to reassess the traditions and future of literature. Many of the functions of literature as a source of description and information seemed to have been taken over by the communications media and the social sciences. The question was asked, "Is the novel dead as an art form?" Some writers responded to the challenge by proclaiming a new form, the "nonfiction novel," and at least one masterwork was produced in this form, Norman Mailer's *The Armies of the Night* (1968). Other writers, such as John Barth and Donald Barthelme, experimented with new forms, emphasizing fiction as a source of fantasy rather than fact. Such genre forms as the science-fiction novels of Kurt Vonnegut, Jr., were taken more seriously, but so too were novels of social realism such as those of Joyce Carol Oates. Literature, like other aspects of cultural life, was in a state of change.

The visual arts. While the perspectives of minority groups helped to shape the development of U.S. literature, the advance of technology played a similar role for painting and sculpture. Until around 1960, however, trends in general cultural life, technological or otherwise, seemed to bear little relation to the practice of the visual arts in the United States. In the aftermath of World War II, U.S. painting came for the first time to take a dominant position in the world art scene in the style of abstract

expressionism, which took as its subject matter not a rendering of natural forms but rather the formal properties of the artistic mediums—line and colour; the textures of paint, wood, or stone; purely geometric form; and the like—and the subjectivity of the artist. In the early 1960s, however, a sudden shift occurred in the climate of the New York art world, in which most of the leading U.S. artists lived and exhibited. Amid considerable publicity and controversy, a new style came to the fore called Pop art, a style that seemed to celebrate—at least to present—the banal objects of U.S. commercial, technological, and popular culture: comic strips, advertisements, soda bottles, soup cans, trademarks, billboards, hamburgers, automobiles, telephones, and much more.

Deification of technology and the banal

When the furor over Pop art subsided, it became apparent that the new style was a continuation of abstract expression in a new form, stressing the abstract and formalist qualities of the old and discarding the subjective and psychological expressionism. Instead of taking the self as subjects, Pop artists such as Andy Warhol, Roy Lichtenstein, or Claes Oldenburg turned to everyday life and the objects around them, abstracting such objects from their environment and presenting them almost as icons. The motives and goals of the Pop artists varied widely, some aiming toward satire or parody, others professing admiration for the culture from which they drew their subjects. The central tendency, however, was formalist, asserting the impersonality of the artist and his or her indifference to the subject except as a form to enable viewers to see in ways they had not before.

The abstract tradition was carried forward more directly into the 1960s in Minimal art, a style of stark geometric forms, shapes, and colours practiced by such older artists of the New York school as Barnett Newman and Mark Rothko and carried forward by younger painters such as Frank Stella. Later in the decade, as the fashion of Pop art began to wane, many artists became increasingly interested not only in the products of modern technology as subject matter but also in technology itself as a medium for artistic creation. An exhibition at the Museum of Modern Art in New York, "The Machine as Seen at the End of the Mechanical Age," publicized the ways in which 20th-century artists depicted and used technology in their work. The Los Angeles County Museum of Art—one of the many newer museums around the country that were becoming increasingly active participants in art rather than passive repositories—carried the process a step further, developing collaboration between artists and business firms specializing in advanced technology; in 1971, it exhibited the art works that were created in this program.

The theatre. Much of the expressionism and subjectivity that was excluded from painting and sculpture in the 1960s was channelled into new forms of theatre, sometimes called "happenings" or "assemblages." These were performances involving several mediums, including music, film, sound and light effects, materials, live acting, and often the audience as well. Arising from the works and teachings of the composer John Cage, the new theatre practiced an aesthetic of chance and indeterminacy, aiming at times toward the elimination of distinctions between art and life. One composition by Cage called for musicians to maintain 4 minutes and 33 seconds of silence, allowing incidental sounds, coughing in the audience, or outdoor noises to become the "music."

Similar innovations occurred in the drama, though not quite such extreme breaks with traditional forms. The dominance of Broadway over conventional theatrical production of drama, comedy, and musicals continued to give way to regional theatre as well as to Off-Broadway theatre in New York, a development of the 1950s, and Off-Off-Broadway, a more experimental theatre that emerged in the 1960s. Many of the new playwrights expressed the same fascination as the Pop artists with the artifacts and myths of popular culture and the U.S. past, and they tried to infuse them with a similar iconographic objectivity and mystery. Two plays presenting such themes, Arthur Kopit's *Indians* and Howard Sackler's *The Great White Hope*, were first produced at the Arena Stage in Washington, D.C., and later moved to Broadway; other works, such as Jean-Claude van Italie's *America Hurrah* and the short plays of Sam Shepard, originated Off-Off-Broadway under the auspices of the La Mama Experimental Theatre Company and other small theatres. The coming together of high culture and popular culture in the theatre reached a new level in the late 1960s with *Hair,* the first rock musical, followed in 1971 by *Jesus Christ Superstar,* a rock musical based on a rock-opera record album.

Theatrical investigations of U.S. mythologies

Musical activity. No other art form was more popular in the 1960s than rock music. Its origins, as with so much of the art of mid-20th-century U.S. culture, lay both in popular and folk cultures and in technology. Rock music drew on the traditions of country folk songs, black urban blues, and the rhythm-and-blues and rock-and-roll popular music of black performers such as Little Richard and whites such as Elvis Presley in the 1950s. It adapted its roots to the new technology of electric instruments. Rock evolved from similar American sources both in the United States and Great Britain and first made its impact felt in the mid-1960s through a group from Liverpool, the Beatles, and the U.S. performer Bob Dylan.

Rock grew in popularity in the latter years of the 1960s as a counterpart to the emergence of the youth and counter-cultures. The rock sound was often music of social and political protest, and the youthful culture that grew up around rock musicians was in the vanguard of unorthodox hairstyles and dress styles, communal living, and drug use. The high point of the rock-music culture perhaps occurred in the summer of 1969, when the Woodstock Music and Art Fair, an outdoor rock concert in Bethel, New York, featuring many of the leading musical groups, attracted several hundred thousand young spectators who lived together and listened to music in harmonious mass community for two or three days. Many young people for a time called themselves the "Woodstock generation" or citizens of "Woodstock nation."

The "rock generation": Woodstock and afterward

In the early 1970s, however, some of the bloom had come off the rock generation. The murder of a spectator by Hell's Angels at a Rolling Stones concert, the deaths of leading rock musicians Jimi Hendrix and Janis Joplin, the latter from a drug overdose, the virtual retirement of Bob Dylan, and the breakup of the Beatles marked a more somber end to the possibility of a utopian community through rock culture. But the quality of musical inventiveness and performance remained high among other groups and individuals, continuing one of the most remarkable periods of innovation in the history of U.S. popular music.

Motion pictures. The popularity of rock music and the celebrity of rock musicians began in the late 1960s to rival the appeal of motion pictures and their stars in earlier decades of mass popular culture. The movies had dominated the popular arts and entertainment from the 1920s until shortly after World War II, when the advent of television and new uses of leisure time for sports and recreation began to cut down their audience. Rapidly increasing production costs, the breakup of the studio system, with its emphasis on star performers and its virtual control of production and distribution of films, and the retirement of important creative workers continued to weaken the Hollywood-based U.S. motion-picture industry in the 1950s and 1960s, although the work of a new generation of foreign film makers developed an audience for movies as a form of high culture. In 1967, however, two striking critical and commercial successes seemed to revive the fortunes of U.S. motion pictures—director Arthur Penn's *Bonnie and Clyde*, a film that skillfully fashioned a myth of the U.S. past, and Mike Nichols' *The Graduate*, a satire on contemporary youth and the "generation gap."

Both films appealed particularly to young people, and the motion-picture industry discovered the importance of "youth culture" for consumption of entertainment products. Proclaiming that youth were a "film generation" as well as a "rock generation," the industry began making

films aimed specifically at the youth market. The strategy paid off handsomely with Dennis Hopper's *Easy Rider* (1969), a film featuring drugs, motorcycles, and conflict between long-haired youth and rural red-necks, backed by a soundtrack of popular rock songs. But neither the youth market nor "youth culture" as a subject halted the decline of motion-picture attendance. In 1971, one of Hollywood's worst years at the box office, the one subject above all others that seemed to draw audiences to movies was nostalgia for the U.S. past, expressed in such films as Peter Bogdanovich's *The Last Picture Show*.

Audiences. If the arts and entertainment were deeply implicated in forms of cultural change, perhaps nowhere was this more apparent than in the way culture was disseminated to the general population. In the long run, it may be recognized that the mid-20th-century decades in the United States were years of cultural revolution brought about by communications technology. Beginning with television around 1950, followed rapidly by paperbound books, long-playing records, multiple reproductions of art works, transistors, tape recorders, and other innovations, technology made possible an unprecedented inexpensive mass production of art and entertainment products. A steadily increasing enrollment in colleges and universities during these years brought a far greater proportion of the U.S. population into contact with instruction in the history, criticism, and techniques of the arts and also, for the first time, with professional performances of music, dance, and drama and exhibitions of painting and sculpture.

The democratization of the arts

The consequences of such a historic democratization of culture remained a subject of much debate. Some critics saw largely negative results, pointing to the commercialization of "high culture" and a concomitant turning of artists into celebrities and art styles into fads and fashions that change before they can develop; to continuing weaknesses in the educational system, suggesting that culture has not penetrated much beyond its usual minority audience; and to the precarious survival of many cultural institutions. Others, recognizing such criticisms, nevertheless contended that democratization of culture, spreading information about society and the arts to new sectors of the population, belied the prediction that mediocrity and homogeneity would be the result and led to the dramatic transformation of attitude and expectation affecting U.S. society at all its levels.

Mass culture, with its opposing tendencies toward standardization and differentiation, remained in the early 1970s the central fact of artistic life in the United States. Some artists and entertainers were directly employed in mass-culture industries—motion pictures, recording, and television. Others used the technology of mass culture—audiotape and videotape, film, and electronics—in their artistic creation. And, in all fields, the artifacts and myths of mass popular culture were a major subject of artistic exploration and treatment. Historically, the boundary between folk traditions and commercial culture had always been ambiguous in the United States. Artists born in the 20th-century urban United States, re-creating their own roots, found a new modern folklore emerging from older manifestations of commercial mass culture. The notion grew that rapid social and cultural change makes today's new thing tomorrow's antique, an icon to enshrine as art and probe as a subject for cultural self-understanding.

CULTURAL INSTITUTIONS

Leadership and support for such cultural institutions as museums, symphony orchestras, and theatres in the United States has come traditionally from individual and private sources. In the 1950s and 1960s, however, local, state, and federal government began to play a larger role in the planning and financing of cultural institutions. Nowhere was this public expenditure more significant for cultural life than in the expansion and transformation of colleges and universities.

Educational–cultural complexes. In response to the growing need for a skilled work force, state legislatures and the federal government contributed to a swift development of higher education in the United States. Older public universities added new departments and schools; teacher-training colleges became full-scale universities; and two-year junior colleges became four-year institutions. Hundreds of new junior colleges were founded and many new four-year and graduate institutions as well. States such as New York and Massachusetts developed almost entirely new systems of public higher education and states such as California, with a traditionally strong system, vastly expanded their institutions and resources. The number of students attending degree-granting institutions more than doubled.

Universities continue to function as institutions in which the cultural heritage of the past is preserved and transmitted to a new generation, but, in this period of growth, many universities also took on new roles as centres in which the arts were performed, exhibited, and created. As part of their task of teaching skills as well as knowledge, universities added active writers, composers, musicians, painters, sculptors, and other artists and performers to their staffs. A number of schools established or expanded museum, music, and theatre programs as the means of training students and also improving the cultural environments of their cities and states. Among the most notable examples of such programs was the Tyrone Guthrie Theater associated with the University of Minnesota, which became nationally known for the quality of its stagings and performances. The new cultural activities of universities served in important ways to decentralize cultural production in the United States and make live performances of the arts available to a far wider audience.

Expanding role of the university in the arts

Government support for the arts also took the form of aid and planning for new cultural centres in the nation's cities. During the period of extensive urban renewal in the 1950s and 1960s, many cities sought to concentrate or revive their cultural institutions by constructing centres for cultural activity in inner-city locations. New York established the Lincoln Center for the Performing Arts, with facilities for opera, theatre, music, film, and other arts, and Los Angeles developed its Music Center. In 1971 the federally sponsored John F. Kennedy Center for the Performing Arts was opened, to mixed critical reception, in Washington, D.C.

Areas of friction and instability. In the late 1960s, both privately and publicly supported cultural institutions became increasingly involved in the cultural and social issues of the larger society. Although the cultural activities of universities were not directly affected by the political controversies and turmoil on many college campuses, the resulting cutbacks in state aid and private donations placed a strain on the financing of higher education that curtailed the growth or even threatened the survival of many cultural programs. Museums and cultural centres in inner cities suffered declines in attendance and revenues because patrons became reluctant to enter high-crime areas in which they were located.

Declining financial support for the arts

At the same time, a number of groups made demands directly on cultural institutions. In several cities, symphony-orchestra musicians and museum employees organized labour unions to press demands for better wages and working conditions. Some painters and sculptors in New York, recognizing the major role museums play in developing cultural tastes, fashioning reputations and critical judgments of artists, and influencing the prices of their works, demanded a share in setting museums' policies. Minority groups protested land acquisition by cultural institutions, their indifference to minority cultures and artists, high prices, and their isolation from minority patrons. The Metropolitan Museum of Art's unprecedented photographic show in New York, Harlem on My Mind, was one effort to respond to such protests.

Above all, the problem for cultural institutions was one of finding continued financial support. The recession of the early 1970s caused both governments and private donors to reduce their assistance. Museums and libraries were forced to lay off employees and cut back their acquisitions and hours of service, and in some cases there seemed little alternative to closing entirely. At a time when the resources of cultural institutions had reached their highest levels of quality and breadth in the history

of the United States, many such institutions were plagued by financial difficulties that could only be solved by changes in national economic conditions that were beyond their control.

THE COMMUNICATIONS MEDIA

The development of media for communicating news, entertainment, and commercial advertising since midcentury has been primarily shaped by the two dominant factors of contemporary cultural life: technological change and the emergence of minority cultures. Television has become the major medium, surpassing newspapers, magazines, and radio and profoundly influencing the structure of their institutions. With its production centralized in three commercial networks, television has been less affected by minority interests than the other mediums, but technological innovations within television itself may provide more opportunities for minority expression.

Printed media and radio. The impact of television struck newspapers at the same time that the growth of suburbs and satellite cities around urban centres began to reshape the needs and desires of newspaper readers. With the loss of advertising revenue to television and of readership to suburban newspapers, the big-city dailies were seriously hurt. During the 1950s and 1960s, scores of major urban newspapers ceased operation, leaving most large U.S. cities with no more than one morning and one afternoon newspaper. Since the ownership is often in one company, a diversity in editorial point of view or content was usually lacking. At the same time, the growing number of suburban papers led to a small net gain in the number of newspapers in the United States. Most of these, however, were smaller and often less ambitious, and observers noted a trend toward less independent reporting and an increasing reliance on nationwide press services for national and international news.

Realignments within newspaper and magazine publishing

When the counter-culture and minority cultures emerged in the mid-1960s, their members perceived that the national press was indifferent or hostile to their activities. They responded by founding newspapers and magazines of their own, an "underground press" that rapidly attained a solid place in the communicatons field, appealing to youth and minority audiences and aided by advertising revenues from record companies. *Ramparts* and *Rolling Stone*, two San Francisco-based magazines, emerged from the "underground press" and gained readerships of several hundred thousand persons.

Television had similar effects on general magazines and radio. Those magazines edited for a broad common denominator of readers tended to suffer from competition with television, and *Collier's*, *The Saturday Evening Post*, *Life*, and *Look* were among the major general-readership periodicals that ceased publication. At the same time, smaller magazines, edited for a specialized audience, thrived by reaching audiences and providing services that competing media could not offer. Radio was most directly affected by television, giving up almost entirely its variety programming and concentrating on music for teen-age audiences. A new trend in radio broadcasting in the late 1960s was the "talk shows," featuring conversations between listeners and announcers or guests in the studio. Thus, the development of television had the long-range effect of loosening the structure of other media and permitting increasing diversity of communications—although increases in printing costs and postal rates in the early 1970s were causing difficulties for periodical publishers and threatening to reduce the number of specialized and minority magazines.

The television industry. Within the television industry itself, however, just the opposite development occurred. Television production rapidly became concentrated in three major networks, whose uniformity of programming seemed to bear out the fears of the critics of mass culture that standardization and the lowest common denominator of cultural communication would result from the growth of mass media.

By the early 1970s, about 95 percent of U.S. homes had television receivers, and the very size of the potential audience—virtually the entire U.S. population—made television a medium different from any other in U.S. history. Commercial advertisers paid large sums of money to advertise their products in the evening "prime-viewing" time, and a one-half-hour network entertainment show cost several hundred thousand dollars to produce. These high costs of production and advertising time led the television industry to place great emphasis on national ratings of audiences, the number of persons believed to be watching a show. Shows that did not get high ratings were dropped after a few weeks or a season, and successful shows were widely copied. Original and innovative programming gave way to a standard television schedule featuring movies, sports, celebrity talk shows, and genre programs adapted from other media—soap operas, comedies, westerns, and mysteries.

Efforts were made to increase the variety and quality of programming through the National Educational Television network, broadcast largely on ultrahigh-frequency (UHF) wavelengths, and a federally financed Public Broadcast Laboratory. The potentially most important trend of the 1970s, however, was cable television, carried to homes on wires rather than through the atmosphere. Cable TV was expected to increase vastly the number of channels available to viewers and, according to regulations of the Federal Communications Commission, to provide opportunities for community-controlled channels and programming.

Counterbalances to commercial mediocrity

VII. Problems and prospects

As the United States entered its third century as an independent republic, the problems and challenges of the future occupied its citizens more deeply than the celebration of 200 years of national history. Many Americans expressed the belief that the social and environmental foundations not only of the United States but of the entire world were endangered unless fundamental changes could be made in institutions, policies, and attitudes. Others decried such pessimism, as they called it, and predicted a future of continued national power and growth in harmony with the development of the nation in the past. This future orientation, of course, had been a characteristic of U.S. values and perspectives from the earliest colonial settlements. But, in the last third of the 20th century, the future seemed more problematic and troubling than at almost any other time in the nation's history. The United States at its bicentennial faced at least two principal concerns that were unique in its experience: it was forced to seek a new conception, a new ideology for its role and purpose as a major national power in world affairs, and it had to decide how to limit the destruction and preserve the quality of its human and natural environment.

Throughout its history, operating on a partly religious and partly secular foundation, the United States has proclaimed its mission to improve the world, its Manifest Destiny to expand in territory and power and to bring to less fortunate nations the benefits of U.S. political and economic systems and moral values. Although the policies generated by this impulse have often been controversial, not until the undeclared counterinsurgency war in Indochina, the longest military conflict on foreign soil in U.S. history, was the validity of this basic U.S. world view widely questioned. It became clear that many of the world's peoples, particularly in the largely non-white and underdeveloped nations of Africa, Asia, and Latin America, did not want to adopt U.S. systems and, above all, did not want to be forced to conform to U.S. world-power objectives, which they considered merely a 20th-century version of traditional Western imperialism. Although it seemed improbable that the United States would (or could) withdraw from its role as a world power, it began to appear more and more likely that the country might have to choose between (1) a world role based purely on self-interest, without the justification of a moral mission and with the prospect of continuing internal dissent, or (2) the forging of a new relationship of cooperation rather than conflict with the aspirations of peoples throughout the world.

Similarly, the dream of U.S. destiny was an expectation

of expansion in territory, in resources, in population, and in material well-being. It was perhaps no coincidence that the questioning of U.S. destiny as a world power was accompanied by an increasing awareness of the threat of unlimited growth. For the first time in U.S. history, a considerable part of the population came to recognize that irreplaceable land, water, and mineral resources were being used up at rapid rates, that uncontrolled development had deteriorated the environment, and that continued unplanned growth could lead to social crisis and personal suffering. The United States began to tackle the difficult problems of how to conserve and improve its natural resources, how to protect and enhance the lives of human beings, and, above all, how to plan and make choices without the sustaining ideology of continued growth and expansion in all facets of national life.

Necessity for revising national values

More than most nations in world history, the United States justified its development, its acquisition of land and power, and its treatment of its citizens by reference to an overriding purpose that was larger than mere national concerns—a universal moral purpose to transform the world into its own image. In the last third of the 20th century, the nation was learning that there were limits to its power and its growth. How the people of the United States, their leaders, and their institutions would respond to that knowledge was the great question for the third century of national existence. The country had grown more organized and bureaucratized at its higher levels, at the same time becoming more disordered in its cities and communities, more fragmented in its values and group allegiances. Few people were able to say whether further organization, on the one hand, or decentralization and fragmentation, on the other, would prove the more effective means of forging a just and humane internal order, world role, and system of values for the United States.

BIBLIOGRAPHY

The land: Although no treatment of the contemporary American landscape has yet appeared that is comprehensive and adequate for both town and countryside, several items do provide useful introductions to the topic. DAVID LOWENTHAL, "The American Scene," *Geogrl. Rev.*, 58:61–88 (1968), skillfully sets forth several basic themes apparent in the visual landscape and the American's attitude toward it. A serviceable description of many current landscape features and a manual for their improvement is available in CHRISTOPHER TUNNARD and BORIS PUSHKAREV, *Man-Made America: Chaos or Control?* (1963); while a more pessimistic assessment of the situation is given in IAN NAIRN, *The American Landscape: A Critical View* (1965). Rural land use is treated in terms of both historical development and modern physical pattern in FRANCIS J. MARSCHNER, *Land Use and Its Patterns in the United States* (1959). The historical geography of open-country and village settlement in the early Atlantic Seaboard is discussed in GLENN T. TREWARTHA, "Types of Rural Settlement in Colonial America," *Geogrl. Rev.*, 36: 569–596 (1946); and the same area and topic, along with much else, is dealt with in HENRY GLASSIE, *Pattern in the Material Folk Culture of the Eastern United States* (1968). Both these publications are also valuable in the study of traditional regions. For a concise but substantial survey of the townscapes of the nation and their evolution, see CHRISTOPHER TUNNARD and HENRY HOPE REED, *American Skyline* (1955). JOHN W. REPS, *The Making of Urban America: A History of City Planning in the United States* (1965), is a masterly account in word and map of the development of urban street patterns and related matters. Two exemplary presentations of the geography and history of specific metropolitan areas may be found in JEAN GOTTMANN, *Megalopolis: The Urbanized Northeastern Seaboard of the United States* (1961); and HAROLD M. MAYER and RICHARD C. WADE, *Chicago: Growth of a Metropolis* (1969). The only general discussion of the traditional regions of the country and related subjects is WILBUR ZELINSKY, *The Cultural Geography of the United States* (1973). Of the several general texts covering the human geography of the continent, perhaps the most stimulating and informative is J. WREFORD WATSON, *North America, Its Countries and Regions* (1967). Two atlases that are indispensable for the serious study of any aspect of the American human or physical scene are CHARLES O. PAULLIN and JOHN K. WRIGHT, *Atlas of the Historical Geography of the United States* (1932); and the UNITED STATES GEOLOGICAL SURVEY, *The National Atlas of the United States of America* (1970). Although several sections of the country lack adequate monographic treatment, there are commendable volumes for a few areas, notably: RUPERT B. VANCE, *Human Geography of the South,* 2nd ed. (1968); HANS KURATH (ed.), *Linguistic Atlas of New England,* 3 vol. (1939–43); D.W. MEINIG, *Imperial Texas* (1969) and *Southwest: Three Peoples in Geographical Change, 1600–1900* (1971).

General physical geography: CHARLES B. HUNT, *Physiography of the United States* (1967), is solid and well illustrated, though geology receives disproportionate attention. An excellent brief summary comprises the first three chapters of J. WREFORD WATSON'S lucid and authoritative *North America, Its Countries and Regions* (1967), which includes a useful bibliography. (*Landforms and geology*): The standard work on American landforms is W.D. THORNBURY, *Regional Geomorphology of the United States* (1965), superbly illustrated with maps, diagrams, and air photos, an excellent bibliography, and balanced discussions of controversial questions. NEVIN FENNEMAN, *Physiography of Western United States* (1931) and *Physiography of Eastern United States* (1938), are exhaustive and still standard references. An authoritative treatment of American tectonics is PHILIP B. KING, *The Evolution of North America* (1959). The effects of Pleistocene glaciation are exhaustively analyzed in a collection of scholarly essays, H.E. WRIGHT, JR., and D.G. FREY (eds.), *The Quaternary of the United States* (1965). (*Maps of landforms*): Overwhelmingly the best depiction of American landforms is ERWIN RAISZ, *Landforms of the United States,* 6th rev. ed. (1957). The UNITED STATES GEOLOGICAL SURVEY, *Tectonic Map of the United States Exclusive of Alaska and Hawaii* (1962), is invaluable. Essential for understanding Northeastern landscapes are the *Glacial Map of the United States East of the Rocky Mountains* (1959), showing the main deposits of continental ice; and *Pleistocene Eolian Deposits of the United States, Alaska, and Parts of Canada* (1952), which maps the location of glacially-derived loess and sand; both are published by the Geological Society of America. For small areas, excellent large topographic maps and air photos are available for most of the country from the United States Geological Survey. (*Mineral resources*): Basic data on mineral deposits, production, exports, and imports are collected by the United States Bureau of Mines and published annually in the *Minerals Yearbook.* (*Climate*): U.S. climate and its role in human affairs is intelligently treated in the classic *Climate and Man,* the *1941 Yearbook of Agriculture,* which contains numerous maps and statistical data. Excellent atlases of American climate include C.W. THORNTHWAITE, *Atlas of Climatic Types in the United States, 1900–1939* (1941), including detailed maps that show the annual variations over 40 years; STEPHEN S. VISHER, *Climatic Atlas of the United States* (1954), with more than 1,000 maps showing every aspect of American weather and climate; and the UNITED STATES DEPARTMENT OF COMMERCE, ENVIRONMENTAL DATA SERVICE, *Climatic Atlas of the United States* (1968), a careful and authoritative assemblage of maps and selected statistics in paperback. (*Vegetation and animal life*): HENRY A. GLEASON and ARTHUR CRONQUIST, *The Natural Geography of Plants* (1964), is a highly readable and beautifully illustrated introduction to plant ecology and geography, with heavy emphasis on North America. An authoritative regional treatment of U.S. plant and animal ecology is VICTOR E. SHELFORD, *The Ecology of North America* (1963). The most honoured treatment of American forests is E. LUCY BRAUN, *Deciduous Forests of Eastern North America* (1950). The best medium-scale map of U.S. vegetation patterns is A.W. KUCHLER'S authoritative "Natural Vegetation," in E.B. ESPENSHADE (ed.), *Goode's World Atlas,* 13th ed. (1970). (*Soils*): C.F. MARBUT, "Soils of the United States," pt. 3 of the *Atlas of American Agriculture* (1935), remains an authoritative description of American soil geography. *Soils and Men* (1938) and *Soil* (1957), contain a wide variety of useful information. All three works are issued by the United States Department of Agriculture.

The people: *The Statistical Abstract of the United States,* published annually by the BUREAU OF THE CENSUS, is the standard summary of statistics on the social, political, and economic organization of the United States. The Census Bureau also published *Historical Statistics of the United States,* 2 vol. (1960–65), which contain similar data from colonial times to 1962. For interpretation of demographic data, see EDWARD G. STOCKWELL, *Population and People* (1968); and RICHARD M. SCAMMON and BEN J. WATTENBERG, *The Real Majority* (1970); for analysis of national values and their historical development, D.W. BROGAN, *The American Character* (1944); and SEYMOUR MARTIN LIPSET, *The First New Nation* (1963); for contemporary attitudes and opin-

ions, ALBERT H. CANTRIL and CHARLES W. ROLL, JR., *Hopes and Fears of the American People* (1971); for history of the era of mass immigration, 1860–1920, OSCAR HANDLIN, *The Uprooted* (1951); and for an examination of contemporary American minority groups, NATHAN GLAZER and DANIEL P. MOYNIHAN, *Beyond the Melting Pot*, 2nd ed. (1970).

The Economy: General surveys of the U.S. economy include SHEPHARD B. CLOUGH and THEODORE F. MARBURY, *The Economic Basis of American Civilization* (1968); EDWARD F. DENISON, *The Sources of Economic Growth in the United States and the Alternatives Before Us* (1962); CHARLES H. HESSION, *The Dynamics of the American Economy* (1956); UNITED STATES ECONOMIC DEVELOPMENT ADMINISTRATION, *Regional Economic Development in the United States* (1967); EMMA WOYTINSKY, *Profile of the U.S. Economy: A Survey of Growth and Change* (1967). Trends in production and employment are analyzed in CLOPPER ALMON, *The American Economy to 1975: An Interindustry Forecast* (1966); EDITORS OF FORTUNE, *Markets of the Seventies: The Unwinding U.S. Economy* (1968); NATIONAL INDUSTRIAL CONFERENCE BOARD, *The Consumer of the Seventies* (1969); UNITED STATES BUREAU OF LABOR STATISTICS, *Patterns of U.S. Economic Growth: 1980 Projections of Final Demand, Interindustry Relationships, Output, Productivity, and Employment* (1970); and the UNITED STATES NATIONAL GOALS RESEARCH STAFF, *Toward Balanced Growth: Quantity with Quality* (1970). Issues of economic policy are treated in GEORGE L. BACH, *Making Monetary and Fiscal Policy* (1971); COMMITTEE FOR ECONOMIC DEVELOPMENT, *Fiscal and Monetary Policies for Steady Economic Growth* (1969); WALTER W. HELLER, *New Dimensions of Political Economy* (1966); ARTHUR M. OKUN, *The Political Economy of Prosperity* (1970); MELVILLE J. ULMER, *The Welfare State, U.S.A.: An Exploration in and Beyond the New Economics* (1969); and the PRESIDENT'S TASK FORCE ON ECONOMIC GROWTH, *Policies for American Economic Progress in the Seventies* (1970). Various points of view are in NEIL W. CHAMBERLAIN (ed.), *Contemporary Economic Issues* (1969); and WALTER W. HELLER (ed.), *Perspectives on Economic Growth* (1968).

Transportation: WILFRED OWEN, EZRA BOWEN, and the EDITORS OF LIFE, *Wheels* (1967), a book on the technological development of transport throughout history and on proposed scientific innovations to help solve future problems; WILFRED OWEN, *The Metropolitan Transportation Problem*, rev. ed. (1966), an analysis of the transportation problems and traffic congestion of American cities concluding that future solutions lie to a major degree in the design of the city and urban region; GEORGE M. SMERK (ed.), *Readings in Urban Transportation* (1968), a varied collection of essays by widely known authors in the field.

Administration and social conditions: The contemporary political and social milieus are analyzed in an avalanche of publications expressing every conceivable philosophy of government and social management; few have yet been able to achieve the necessary distance, in time or sentiment, for unaffected analysis of the structure or functioning of U.S. government, politics, or social dynamics. A few, however, can provide a valuable beginning. In government and politics, the *United States Government Organization Manual* (annual), offers a broad overview of the federal structure; while the *Congressional Record* and the *Congressional Quarterly* provide closer views of the public record of the federal legislature. Other basic books on government include AARON WILDAVSKY and NELSON W. POLSBY (eds.), *American Governmental Institutions* (1968); PETER WOLL, *American Government: Readings and Cases*, 2nd ed. (1965); and ROBERT A. GOLDWIN (ed.), *A Nation of States* (1963). Among the more penetrating insights into the complexities of politics are JOSEPH R. FISZMAN (ed.), *The American Political Arena*, 2nd ed. (1966); FRED I. GREENSTEIN, *The American Party System and the American People* (1963); the series by THEODORE WHITE begun with *The Making of the President, 1960* (1961) and continued to cover subsequent presidential elections; RICHARD M. SCAMMON and BEN. J. WATTENBERG, *The Real Majority: How the Silent Center of the American Electorate Chooses Its President* (1970), based on studies of voting behaviour in 1968; and SHIRLEY CHISHOLM, *Unbought and Unbossed* (1970). The U.S. military is studied in terms of its politics in ADAM YARMOLINSKY, *The Military Establishment* (1971). The political and social structures are bridged in C. WRIGHT MILLS, *Power Elite* (1956); while other studies probing special areas of politico-social concern include BARBARA and JOHN EHRENREICH, *American Health Empire: Power, Profits, and Politics* (1970); MICHAEL HARRINGTON, *The Other America* (1962), a study of poverty in the U.S.; JANE JACOBS, *The Death and Life of Great American Cities* (1961), an inquiry into the structuring and destruction of the city; HARRY M. CAUDILL, *Night Comes to the Cumberlands* (1963), a historical survey of the development of poverty in the southern Appalachians; and ROBERT C. COLES on rural poor and effects of their migrations to the city. For social statistics see the *Statistical Abstracts of the United States* (annual).

Cultural life: A good way to begin the study of cultural life and institutions in the United States is through MARSHALL MCLUHAN, *Understanding Media: The Extensions of Man* (1964). Although McLuhan's works have been highly controversial, no writer has done more to stimulate awareness of the role of media in modern culture. A broad introduction to the "counter culture" is THEODORE ROSZAK, *The Making of a Counter Culture: Reflections on the Technocratic Society and Its Youthful Opposition* (1969). Information about minority cultures and movements must be found primarily in their polemical writings. Interesting discussions of all phases of contemporary literature, including nonfiction, journalism, and the theatre, as well as poetry and fiction, appear in ELIZABETH JANEWAY (ed.), *The Writer's World* (1969). A useful survey of Pop art is LUCY R. LIPPARD *et al.*, *Pop Art* (1966); while two books by MICHAEL KIRBY cover multimedia experiments, *Happenings* (1965) and *The Art of Time: Essays on the Avante-Garde* (1969). Rock music is explored in CARL BELZ, *The Story of Rock* (1969). A valuable study of the television industry is LES BROWN, *Television: The Business Behind the Box* (1971); while a more historical treatment of radio and television is ERIK BARNOUW, *A History of Broadcasting in the United States*, 3 vol. (1966–70). The magazine *Saturday Review* (weekly), provides a broad survey of social and cultural aspects of American life.

THE EUROPEAN BACKGROUND

The English colonization of North America was but one

chapter in the larger story of European expansion throughout the globe. The Portuguese, beginning with a voyage to Porto Santo off the coast of West Africa in 1418, were the first Europeans to promote overseas exploration and colonization. By 1487 the Portuguese had travelled all the way to the southern tip of Africa, establishing trading stations at Arguin, Sierra Leone, and El Mina. In 1497 Vasco da Gama rounded the Cape of Good Hope and sailed up the eastern coast of Africa, laying the groundwork for Portugal's later commercial control of India. By 1500, when Pedro Álvares Cabral stumbled across the coast of Brazil en route to India, Portuguese influence had expanded to the New World as well.

Though initially lagging behind the Portuguese in the arts of navigation and exploration, the Spanish quickly closed that gap in the decades following Columbus' (see COLUMBUS, CHRISTOPHER) voyages to America. First in the Caribbean and then in spectacular conquests of New Spain and Peru, they captured the imagination, and the envy, of the European world.

French settlement

France, occupied with wars in Europe to preserve its own territorial integrity, was not able to devote as much time or effort to overseas expansion as Spain and Portugal. Beginning in the early 16th century, however, French fishermen established an outpost in Newfoundland, and in 1534 Jacques Cartier began exploring the Gulf of St. Lawrence. By 1543 the French had ceased their efforts to colonize the northwest portion of the New World. In the last half of the 16th century, France attempted to found colonies in Florida and Brazil; but each of these efforts failed, and by the end of the century Spain and Portugal remained the only two European nations to have established successful colonies in America.

The English, although anxious to duplicate the Spanish and Portuguese successes, nevertheless lagged far behind in their colonization efforts. The English possessed a theoretical claim to the North American mainland by dint of the 1497 voyage of John Cabot off the coast of Nova Scotia, but in fact they had neither the means nor the desire to back up that claim during the 16th century. Thus it was that England relied instead on private trading companies, which were interested principally in commercial rather than territorial expansion, to defend its interests in the expanding European world. The first of these commercial ventures began with the formation of the Muscovy Company in 1554. In 1576–78 the English mariner Martin Frobisher undertook three voyages in search of a Northwest Passage to the East. In 1577 Sir Francis Drake made his famous voyage around the world, plundering the western coast of South America en route.

The voyages of Sir Humphrey Gilbert

A year later Sir Humphrey Gilbert, one of the most dedicated of Elizabethan imperialists, began a series of ventures aimed at establishing permanent colonies in North America. All of his efforts met with what was, at best, limited success. Finally, in September 1583, on what would prove to be his final voyage, Gilbert, with five vessels and 260 men, disappeared in the North Atlantic. With the failure of Gilbert's voyage, the English turned to a new man, Sir Walter Raleigh, and a new strategy—a southern rather than a northern route to North America—to advance England's fortunes in the New World. Raleigh's efforts to found a permanent colony off the coast of Virginia, although they did finally fail with the mysterious destruction of the Roanoke Island colony in 1587, awakened popular interest in a permanent colonizing venture.

During the years separating the failure of the Roanoke colony and the establishment in 1607 of the English settlement in Jamestown, English propagandists worked hard to convince the public that a colony in America would yield instant and easily exploitable wealth. Even men like the English geographer Richard Hakluyt were not certain that the Spanish colonization experience could or should be imitated but hoped nevertheless that the English colonies in the New World would prove to be a source of immediate commercial gain. There were, of course, other motives for colonization. Some hoped to discover the much sought after route to the Orient in North America. English imperialists thought it necessary to settle in the New World in order to limit Spanish expansion. Once it was proven that America was a suitable place for settlement, some Englishmen would travel to those particular colonies that promised to free them from religious persecution. There were also Englishmen, primarily of lower and middle class origin, who hoped the New World would provide them with increased economic opportunity in the form of free or inexpensive land. These last two motives, while they have been given considerable attention by historians, appear not to have been so much original motives for English colonization as they were shifts of attitude once colonization had begun.

SETTLEMENT

Virginia. The leaders of the Virginia Company of London, a joint-stock company in charge of the Jamestown enterprise, were for the most part wealthy and well-born commercial and military adventurers eager to find new outlets for investment. During the first two years of its existence, the Virginia colony, under the Charter of 1607, proved an extraordinarily bad investment. This was principally due to the unwillingness of the early colonizers to do the necessary work of providing for themselves and to the chronic shortage of capital for supply of the venture.

A new charter in 1609 significantly broadened membership in the Virginia Company, thereby increasing temporarily the supply of capital at the disposal of its directors; but most of the settlers continued to act as though they expected the Indians to provide for their existence, a notion that the Indians fiercely rejected. As a result, the enterprise still failed to yield any profits and the number of investors again declined.

The crown issued a third charter in 1612 authorizing the company to institute a lottery to raise more capital for the floundering enterprise. In that same year John Rolfe harvested the first crop of a high-grade and therefore potentially profitable strain of tobacco. At about the same time, with the arrival of Sir Thomas Dale in the colony as governor in 1611, the settlers gradually began to practice the discipline necessary for their survival, though at an enormous personal cost.

The administration of Sir Thomas Dale

Dale carried with him the "Laws Divine, Morall and Martial," which were intended to supervise nearly every aspect of the settlers' lives. Each person in Virginia, including women and children, was given a military rank, and his duties were spelled out in minute detail. Penalties imposed for violating these rules were severe: those who failed to obey the work regulations were to be forced to lie neck and heels together all night for the first offense, whipped for the second, and sent to a year's service in the galleys for the third. The settlers could hardly protest against the harshness of the code, for that might be deemed slander against the company—an offense punishable by service in the galleys or by death.

Dale's Code brought order to the Virginia experiment, but it hardly served to attract new settlers. To increase incentive the company, beginning in 1618, offered 50 acres of land to those settlers who could pay their transportation to Virginia and a promise of 50 acres after seven years of service to those who could not pay their passage. Concurrently, the new governor of Virginia, Sir George Yeardley, issued a call for the election of representatives to a House of Burgesses, which was to convene in Jamestown in July 1619. In its original form, the House of Burgesses was little more than an agency of the governing board of the Virginia Company, but it would later expand its powers and prerogatives and become an important force for colonial self-government.

Despite the introduction of these reforms, the years from 1619 to 1624 proved fatal to the future of the Virginia Company. Epidemics, an Indian massacre in 1622, and internal disputes took a heavy toll on the colony. In 1624 the crown finally revoked the charter of the company and placed the colony under royal control.

Virginia made a crown colony

The introduction of royal government into Virginia, while it was to have important long-range consequences, did not produce an immediate change in the character of the col-

ony. The economic and political life of the colony continued as it had in the past. The House of Burgesses, though its future under the royal commission of 1624 was uncertain, continued to meet on an informal basis; by 1629 it was officially re-established. The crown also grudgingly acquiesced to the decision of the Virginia settlers to continue to direct most of their energies to the growth and exportation of tobacco. By 1630 the Virginia colony, while not prosperous, at least showed signs that it was capable of surviving without royal subsidy.

Maryland. Maryland, Virginia's neighbour to the north, was the first English colony to be controlled by a single proprietor rather than by a joint-stock company. George Calvert (Lord Baltimore) had been an investor in a number of colonizing schemes before being given a grant of land from the crown in 1632. Baltimore was given a sizable grant of power to go along with his grant of land; he had control over the trade and political system of the colony so long as he did nothing to deviate from the laws of England. Baltimore's son Cecilius Calvert took over the project at his father's death and promoted a settlement at St. Mary's on the Potomac. Supplied in part by Virginia and buoyed by their own crop of corn in the very first year, the Maryland colonists managed to prosper from the beginning.

The colony was intended to serve at least two purposes. Lord Baltimore, a Roman Catholic, was anxious to found a colony where Catholics could live in peace, but he was also eager to see his colony yield him as large a profit as possible. From the outset Protestants outnumbered Catholics, although a few prominent Catholics tended to own an inordinate share of the land in the colony. Despite this favouritism in the area of land policy, Lord Baltimore was for the most part a good and fair administrator.

Following the accession of William and Mary to the English throne, however, control of the colony was taken away from the Calvert family and entrusted to the royal government. Shortly thereafter the crown decreed that Anglicanism would be the established religion of the colony. In 1715, after the Calvert family had renounced Catholicism and embraced Anglicanism, the colony reverted back to a proprietary form of government.

The New England Colonies. Although lacking a charter, the founders of Plymouth in Massachusetts were, like their counterparts in Virginia, dependent upon private investments from profit-minded backers to finance their colony. The nucleus of that settlement was drawn from an enclave of English émigrés in Leyden, Holland. These religious "Separatists" believed that the true church was a voluntary company of the faithful under the "guidance" of a pastor and tended to be exceedingly individualistic in matters of church doctrine. Unlike the settlers of Massachusetts Bay, the Pilgrims chose to "separate" from the Church of England rather than to reform it from within.

In 1620, the first year of settlement, nearly half the settlers died of disease. From that time forward, however, and despite decreasing support from English investors, the health and the economic position of the colonists improved. The Pilgrims soon secured peace treaties with most of the Indians around them, enabling them to devote their time to building a strong, stable economic base rather than diverting their efforts toward costly and time-consuming problems of defending the colony from attack. Although none of their principal economic pursuits—farming, fishing, and trading—promised them lavish wealth, the Pilgrims in America were, after only five years, self-sufficient.

Mayflower Compact

Although the Pilgrims were always a minority in Plymouth, they nevertheless controlled the entire governmental structure of their colony during the first four decades of settlement. Before disembarking from the "Mayflower" in 1620, the Pilgrim founders, led by William Bradford, demanded that all 41 adults aboard sign a compact promising obedience to the laws and ordinances drafted by the leaders of the enterprise. Although the Mayflower Compact has been interpreted as an important step in the evolution of democratic government in America, it is a fact that the compact represented a one-sided arrangement, with the settlers promising obedience and the Pilgrim founders promising very little. Although nearly all the male inhabitants were permitted to vote for deputies to a provincial assembly and for a governor, the colony, for at least the first 40 years of its existence, remained in the tight control of a few men. After 1660 the people of Plymouth gradually gained a greater voice in both their church and civic affairs, and by 1691, when Plymouth colony was annexed to Massachusetts Bay, the Plymouth settlers had distinguished themselves by their quiet, orderly ways.

The Puritans of Massachusetts Bay, like the Pilgrims, sailed to America principally to free themselves from religious restraints. Unlike the Pilgrims, the Puritans did not desire to "separate" themselves from the Church of England but, rather, hoped by their example, to reform it. Nonetheless, one of the recurring problems facing the leaders of the Massachusetts Bay Colony was to be the tendency of some, in their desire to free themselves from the alleged corruption of the Church of England, to espouse "separatist" doctrine. When these tendencies or any other hinting of deviation from orthodox Puritan doctrine developed, those holding them were either quickly corrected or expelled from the colony. The leaders of the Massachusetts Bay enterprise never intended their colony to be an outpost of toleration in the New World; rather, they intended it to be a "Zion in the wilderness," a model of purity and orthodoxy, with all backsliders subject to immediate correction.

John Winthrop and Massachusetts Bay

The civil government of the colony was guided by a similar authoritarian spirit. Men like John Winthrop, the first governor of Massachusetts Bay, believed that it was not the duty of the governors of society to act as the direct representatives of their constituents but rather to decide, independently, what measures were in the best interests of the total society. The original charter of 1629 gave all power in the colony to a General Court composed of only a small number of shareholders in the company. On arriving in Massachusetts, many disenfranchised settlers immediately protested against this provision and caused the franchise to be widened to include all church members. These "freemen" were given the right to vote in the General Court once each year for a governor and a Council of Assistants. Although the Charter of 1629 technically gave the General Court the power to decide on all matters affecting the colony, the members of the ruling elite initially refused to allow the freemen in the General Court to take part in the lawmaking process on the grounds that their numbers would render the court inefficient.

In 1634 the General Court adopted a new plan of representation whereby the freemen of each town would be permitted to select two or three delegates and assistants, elected separately but sitting together in the General Court, who would be responsible for all legislation. There was always tension existing between the smaller, more prestigious group of assistants and the larger group of deputies. In 1644, as a result of this continuing tension, the two groups were officially lodged in separate houses of the General Court, with each house reserving a veto power over the other.

Despite the authoritarian tendencies of the Massachusetts Bay Colony, a spirit of community developed there as perhaps in no other colony. The same spirit that caused the residents of Massachusetts to report on their neighbours for deviation from the true principles of Puritan morality also prompted them to be extraordinarily solicitous about their neighbours' needs. Although life in Massachusetts was made difficult for those who dissented from the prevailing orthodoxy, it was marked by a feeling of attachment and community for those who lived within the enforced consensus of the society.

Many New Englanders, however, refused to live within the orthodoxy imposed by the ruling elite of Massachusetts, and both Connecticut and Rhode Island were founded as a by-product of their discontent. The Rev. Thomas Hooker, who had arrived in Massachusetts Bay in 1633, soon found himself in opposition to the colony's restric-

Connecticut and Rhode Island

tive policy regarding the admission of church members and to the oligarchic power of the leaders of the colony. Motivated both by a distaste for the religious and political structure of Massachusetts and by a desire to open up new land, Hooker and his followers began moving into the Connecticut Valley in 1635. By 1636 they had succeeded in founding three towns—Hartford, Windsor, and Wethersford. In 1638 the separate colony of New Haven was founded, and in 1662 Connecticut and Rhode Island merged under one charter.

Roger Williams, the man closely associated with the founding of Rhode Island, also fled Massachusetts because of his objections to the arbitrary nature of Massachusetts government. Williams, however, was in some ways more rigid in his approach to religious polity than those Puritans he criticized. His own strict criteria for determining who was regenerate, and therefore eligible for church membership, finally led him to deny any practical way to admit anyone into the church. Once he recognized that no church could insure the purity of its congregation, he ceased using purity as a criterion for membership. Though this train of logic ultimately led him to adopt a position that subsequent generations labelled "democratic," the fact is that the principal source of Williams' policy of religious libertarianism was his very extremism in Calvinist orthodoxy.

The unpopularity of Williams' views forced him to flee Massachusetts Bay for Providence in 1636. In 1639 William Coddington, another dissenter in Massachusetts, settled his congregation in Newport. Four years later Samuel Gorton, another minister banished from Massachusetts Bay because of his differences with the ruling oligarchy, settled in Shawomet (later renamed Warwick). In 1644 these three communities joined with a fourth in Portsmouth under one charter to become one colony called Providence Plantation in Narragansett Bay. The early settlers of New Hampshire and Maine were also ruled by the government of Massachusetts Bay. New Hampshire was permanently separated from Massachusetts in 1692, although it was not until 1741 that it was given its own royal governor. Maine remained under the jurisdiction of Massachusetts until 1820.

The Middle Colonies. New Netherland, founded in 1624 on Manhattan Island by the Dutch West India Company, was but one element in a wider program of Dutch expansion in the first half of the 17th century. The English captured New Netherland in 1664; it was renamed New York, after James, duke of York, brother of Charles II, and was placed under the proprietary control of the Duke. In return for an annual gift to the King of 40 beaver skins, the Duke of York and his resident Board of Governors were given extraordinary discretion in the ruling of the colony. Although the grant to the Duke of York made mention of a representative assembly, the Duke was not legally obliged to summon it and in fact did not summon it until 1683. The Duke's interest in the colony was chiefly economic, not political, but most of his efforts to derive economic gain from New York proved futile. Indians, foreign interlopers (the Dutch actually recaptured New York in 1673 and held it for more than a year), and the success of the colonists in evading taxes made the proprietor's job a frustrating one.

Dominion of New England

In February 1685 the Duke of York found himself not only proprietor of New York but also king of England, a fact that changed the status of New York from that of a proprietary to a royal colony. The process of royal consolidation was accelerated when, in 1688, the colony was made part of the ill-fated Dominion of New England. In 1691, Jacob Leisler, a German merchant living on Long Island, led a successful revolt against the rule of the deputy governor, Francis Nicholson. The revolt, which was a product of dissatisfaction with a small aristocratic ruling elite and a more general dislike of the consolidated scheme of government of the Dominion of New England, served to hasten the demise of the dominion.

Pennsylvania, in part because of the liberal policies of its founder, William Penn, was destined to become the most diverse, dynamic, and prosperous of all the North American Colonies. Penn himself was a liberal, but by no means radical, English Whig. His Quaker faith was marked not by the religious extremism of some Quaker leaders of the day but rather by an adherence to certain dominant tenets of the faith—liberty of conscience and pacifism—and by an attachment to some of the basic tenets of Whig doctrine. William Penn sought to implement these ideals in his "holy experiment" in the New World.

Penn received his grant of land along the Delaware River in 1681 from Charles II. The "first frame of government" proposed by Penn in 1682 provided for a council and an assembly, each to be elected by the freeholders of the colony. The council was to have the sole power of initiating legislation; the lower house could only approve or veto bills submitted by the council. After numerous objections about the "oligarchic" nature of this form of government, Penn issued a second "frame of government" in 1682 and then a third in 1696, but even these did not wholly satisfy the residents of the colony. Finally, in 1701, a Charter of Privileges, giving the lower house all legislative power and transforming the council into an appointive body with advisory functions only, was approved by the citizens. The Charter of Privileges, like the other three frames of government, continued to guarantee the principle of religious toleration to all Protestants.

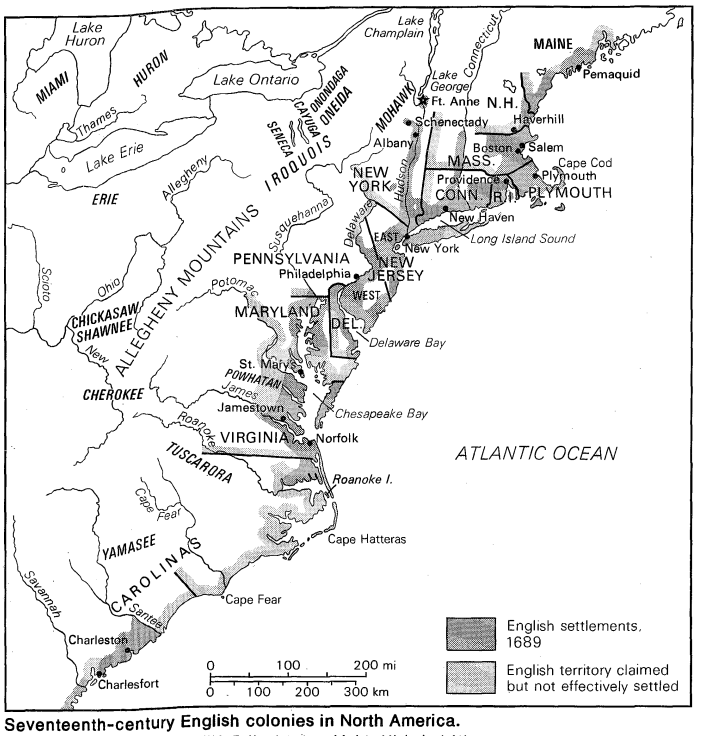
Pennsylvania prospered from the outset. Although there was some jealousy between the original settlers (who had received the best land and important commercial privileges) and the later arrivals, economic opportunity in Pennsylvania was on the whole greater than in any other colony. Beginning in 1683 with the immigration of Germans into the Delaware Valley and continuing with an enormous influx of Irish and Scots-Irish in the 1720s and 1730s, the population of Pennsylvania increased and diversified. The fertile soil of the countryside, in conjunction with a generous government land policy, kept immigration at high levels throughout the 18th century. William Penn's sons, John, Richard, and Thomas, although they ultimately converted back to Anglicanism, continued their father's policies of religious toleration after his death in 1718.

New Jersey

New Jersey remained in the shadow of both New York and Pennsylvania throughout most of the colonial period. Part of the territory ceded to the Duke of York by the English crown in 1664 lay in what would later become the colony of New Jersey. The Duke of York in turn granted that portion of his lands to John Berkeley and George Carteret, two close friends and allies of the King. In 1665 Berkeley and Carteret established a proprietary government under their own direction. Constant clashes, however, developed between the New Jersey and the New York proprietors over the precise nature of the New Jersey grant. The legal status of New Jersey became even more tangled when Berkeley sold his half interest in the colony to two Quakers, who in turn placed the management of the colony in the hands of three trustees, one of whom was William Penn. The area was then divided into East Jersey, controlled by Carteret, and West Jersey, controlled by Penn and the other Quaker trustees. In 1682 the Quakers bought East Jersey. A multiplicity of owners and an uncertainty of administration caused both colonists and colonizers to feel dissatisfied with the proprietary arrangement, and in 1702 the crown united the two Jerseys into a single royal province.

When the Quakers purchased East Jersey, they also acquired the tract of land that was to become Delaware, in order to protect their water route to Pennsylvania. That territory remained part of the Pennsylvania colony until 1704, when it was given an assembly of its own. It remained under the Pennsylvania governor, however, until the Revolution.

The Carolinas and Georgia. The English crown had issued grants to the Carolina territory as early as 1629, but it was not until 1663 that a group of eight proprietors —most of them men of extraordinary wealth and power even by English standards—actually began colonizing the area. The proprietors hoped to grow silk in the warm



climate of the Carolinas, but all efforts to produce that valuable commodity failed. Moreover, it proved difficult to attract settlers to the Carolinas; it was not until 1718, after a series of violent Indian wars had subsided, that the population began to increase substantially. The pattern of settlement, once begun, followed two paths. North Carolina, which was largely cut off from the European and Caribbean trade by its unpromising coastline, developed into a colony of small to medium farms. South Carolina, with close ties to both the Caribbean and Europe, produced rice and, after 1742, indigo for a world market. The early settlers in both areas came primarily from the West Indian colonies. This pattern of migration was not, however, as distinctive in North Carolina, where many of the residents were part of the spillover from the natural expansion of Virginians southward.

The Fundamental Constitutions

The original frame of government for the Carolinas, the Fundamental Constitutions, drafted in 1669 by Anthony Ashley Cooper (Lord Shaftesbury) with the help of the philosopher John Locke, was largely ineffective because of its restrictive and feudal nature. The Fundamental Constitutions was abandoned in 1693 and replaced by a frame of government diminishing the powers of the proprietors and increasing the prerogatives of the provincial assembly. In 1729, primarily because of the proprietors' inability to meet the pressing problems of defense, the Carolinas were converted into the two separate royal colonies of North and South Carolina.

The proprietors of Georgia, led by James Oglethorpe, were wealthy philanthropic English gentlemen. It was Oglethorpe's plan to transport imprisoned debtors to Georgia where they could rehabilitate themselves by profitable labour and make money for the proprietors in the process. Those who actually settled in Georgia—and by no means all of them were impoverished debtors—encountered a highly restrictive economic and social system. Oglethorpe and his partners limited the size of individual landholdings to 500 acres, prohibited slavery, forbade the drinking of rum, and instituted a system of inheritance that further restricted the accumulation of large estates. The regulations, though noble in intention, created considerable tension between some of the more enterprising settlers and the proprietors. Moreover, the economy did not live up to the expectations of the colony's promoters. The silk industry in Georgia, like that in the Carolinas, failed to produce even one profitable crop.

The settlers were also dissatisfied with the political structure of the colony; the proprietors, concerned primarily with keeping close control over their utopian experiment, failed to provide for local institutions of self-government. As protests against the proprietors' policies mounted, the crown in 1753 assumed control over the colony; subsequently, many of the restrictions that the settlers had complained about, notably that prohibiting slavery, were lifted.

IMPERIAL ORGANIZATION

British policy toward the American Colonies was inevitably affected by the domestic politics of England; since the politics of England in the 17th and 18th centuries were never wholly stable, it is not surprising that British colonial policy during those years never developed along clear and consistent lines. During the first half century of colonization, it was even more difficult for England to establish an intelligent colonial policy because of the very disorganization of the Colonies themselves. It was nearly impossible for England to predict what role Virginia, Maryland, Massachusetts, Connecticut, and Rhode Island would play in the overall scheme of empire because of the diversity of the aims and governmental structures of those colonies. By 1660, however, England had taken the first steps in reorganizing her empire in a more profitable manner. The Navigation Act of 1660, a modification and amplification of a temporary series of acts passed in 1651, provided that goods bound to England or to English colonies, regardless of origin, must be shipped only in English vessels; that three-fourths of the personnel of those ships be Englishmen; and that certain "enumerated articles," such as sugar, cotton, and tobacco, be shipped only to England, with trade in those items with other nations prohibited. This last provision hit Virginia and Maryland particularly hard; although those two colonies were awarded a monopoly over the English tobacco market at the same time that they were prohibited from marketing their tobacco elsewhere, there was no way that England alone could absorb their tobacco production.

Navigation Acts

The 1660 act proved inadequate to safeguard the entire British commercial empire and in subsequent years other navigation acts were passed strengthening the system. In 1663 Parliament passed an act requiring all vessels with European goods bound for the Colonies to pass first through English ports to pay customs duties. In 1673 Parliament, in order to prevent merchants from shipping the enumerated articles from colony to colony in the coastal trade and then taking them to a foreign country, required that merchants post bond guaranteeing that those goods be taken only to England. Finally, in 1696 Parliament established a Board of Trade to oversee Britain's commercial empire, instituted mechanisms to insure that the colonial governors aided in the enforcement of trade regulations, and set up vice admiralty courts in America for the prosecution of those who violated the Navigation Acts. The effectiveness of Britain's commercial policy is not altogether clear. It is certain that a significant amount of trade occurred in violation of that policy. The most recent investigations suggest, however, that by the end of the 17th century the Navigation Acts were being enforced successfully and that these acts did, in fact, constitute a significant economic burden for the American colonists.

In addition to the agencies of royal control in England, there were a number of royal officials in America responsible not only for aiding in the regulation of England's commercial empire but also for overseeing the internal affairs of the Colonies. The weaknesses of royal authority in the politics of provincial America were striking. In some areas, particularly in the corporate colonies of New England during the 17th century and in the proprietary colonies throughout their entire existence, direct royal authority in the person of a governor responsible to the crown was nonexistent. The absence of a royal governor in those colonies had a particularly deleterious effect on the enforcement of trade regulations. In fact, the lack of royal control over the political and commercial activities of New England prompted the Board of Trade to over-

turn the Massachusetts Bay Charter in 1684 and to consolidate Massachusetts, along with the other New England colonies and New York, into the Dominion of New England. After the colonists, aided by the turmoil of the Revolution of 1688 in England, succeeded in overthrowing the dominion scheme, the crown installed a royal governor in Massachusetts to protect its interests.

Powers of the royal governors

In those colonies with royal governors—the number of those colonies grew from one in 1650 to eight in 1760—the crown possessed a mechanism by which to insure that royal policy was enforced. The Privy Council issued each royal governor in America a set of instructions carefully defining the limits of provincial authority. The royal governors were to have the power to decide when to call the provincial assemblies together, to prorogue, or dissolve, the assemblies, and to veto any legislation passed by those assemblies. The governor's power over other aspects of the political structure of the colony was just as great. In most royal colonies he was the one official primarily responsible for the composition of the upper houses of the colonial legislatures and for the appointment of important provincial officials, such as the treasurer, attorney general, and all colonial judges. Moreover, the governor had enormous patronage powers over the local agencies of government. The officials of the county court, who were the principal agents of local government, were appointed by the governor in most of the royal colonies. Thus, the governor had direct or indirect control over every agency of government in America.

THE GROWTH OF PROVINCIAL POWER

Political growth. The distance separating England and America, the powerful pressures exerted on royal officials by Americans, and the inevitable inefficiency of any large bureaucracy all served to weaken royal power and to strengthen the hold of provincial leaders on the affairs of their respective colonies. During the 18th century, the colonial legislatures gained control over their own parliamentary prerogatives, achieved primary responsibility for legislation affecting taxation and defense, and ultimately took control over the salaries paid to royal officials. Provincial leaders also made significant inroads into the governor's patronage powers. Although theoretically the governor continued to control the appointments of local officials, in reality he most often automatically followed the recommendations of the provincial leaders in the localities in question. Similarly, the Governor's Councils, theoretically agents of royal authority, came to be dominated by prominent provincial leaders who tended to reflect the interests of the leadership of the lower house of assembly rather than those of the royal government in London.

Thus, by the mid-18th century most political power in America was concentrated in the hands of provincial rather than royal officials. These provincial leaders undoubtedly represented the interests of their constituents more faithfully than any royal official, but it is clear that the politics of provincial America were hardly democratic by modern standards. In general, both social prestige and political power tended to be determined by economic standing; and the economic resources of colonial America, though not as unevenly distributed as in Europe, were nevertheless controlled by relatively few men.

In the Chesapeake societies of Virginia and Maryland, and particularly in the regions east of the Blue Ridge Mountains, a planter class came to dominate nearly every aspect of those colonies' economic life. These same planters, joined by a few prominent merchants and lawyers, dominated the two most important agencies of local government—the county courts and the provincial assemblies. This extraordinary concentration of power in the hands of a wealthy few occurred in spite of the fact that a large percentage of the free adult male population (some have estimated as high as 80 to 90 percent) was able to participate in the political process. The ordinary citizens of the Chesapeake society, and those of most colonies, nevertheless continued to defer to those whom they considered to be their "betters." Although the societal ethic that enabled power to be concentrated in the hands of a few was hardly a democratic one, there is little evidence, at least for Virginia and Maryland, that the people of those societies were dissatisfied with their rulers. For the most part they believed that their local officials ruled responsively.

In the Carolinas a small group of rice and indigo planters monopolized much of the wealth. As in Virginia and Maryland, the planter class came to constitute a social elite. As a rule the planter class of the Carolinas did not have the same long tradition of responsible government as did the ruling oligarchies of Virginia and Maryland, and, as a consequence, they tended to be absentee landlords and governors, often passing much of their time in Charleston, away from their plantations and their political responsibilities.

The western regions

The western regions of both the Chesapeake and Carolina societies displayed distinctive characteristics of their own. Ruling traditions were fewer, accumulations of land and wealth less striking, and the social hierarchy less rigid in the west. In fact, in some western areas antagonism toward the restrictiveness of the east and toward eastern control of the political structure led to actual conflict. In both North and South Carolina armed risings of varying intensity erupted against the unresponsive nature of the eastern ruling elite. As the 18th century progressed, however, and as men accumulated more wealth and social prestige, the societies of the west came more closely to resemble those of the east.

New England society was more diverse and the political system less oligarchic than that of the South. In New England the mechanisms of town government served to broaden popular participation in government beyond the narrow base of the county courts.

New England town meetings

The town meetings, which elected the members of the provincial assemblies, were open to nearly all free adult males. Despite this, a relatively small group of men dominated the provincial governments of New England. As in the South, men of high occupational status and social prestige were closely concentrated in leadership positions in their respective colonies; in New England, merchants, lawyers, and to a lesser extent clergymen made up the bulk of the social and political elite.

The social and political structure of the Middle Colonies was more diverse than any region in America. New York, with its extensive system of manors and manor lords, often displayed genuinely feudal characteristics. The tenants on large manors often found it impossible to escape the influence of their manor lords. The administration of justice, the election of representatives, and the collection of taxes often took place on the manor itself. As a consequence, the large land-owning families exercised an inordinate amount of economic and political power.

The "Great Rebellion of 1766"

The "Great Rebellion of 1766," a short-lived outburst directed against the manor lords, was a symptom of the widespread discontent among the lower and middle classes. By contrast, Pennsylvania's governmental system was more open and responsive than that of any other colony in America. A unicameral legislature, free from the restraints imposed by a powerful governor's council, allowed Pennsylvania to be relatively independent of the influence of both the crown and the proprietor. This fact, in combination with the tolerant and relatively egalitarian bent of the early Quaker settlers and the subsequent immigration of large numbers of Europeans, made the social and political structure of Pennsylvania more democratic but more faction ridden than that of any other colony.

Population growth. The increasing political autonomy of the American Colonies was a natural reflection of their increased stature in the overall scheme of the British Empire. In 1650 the population of the Colonies had been 52,000; in 1700 it was 250,000 and by 1760 it was approaching 1,700,000. Virginia had increased from 54,000 in 1700 to approximately 340,000 in 1760. Pennsylvania had begun with 500 settlers in 1681 and had attracted at least 250,000 people by 1760. And America's cities were beginning to grow as well. By 1765 Boston had reached 15,000; New York City, 16,000–17,000; and Philadelphia, the largest city in the Colonies, 20,000.

African slaves

Part of that population growth was the result of the involuntary immigration of African slaves. During the 17th century, slaves remained a tiny minority of the population. By the mid–18th century, after Southern colonists discovered that the profits generated by their plantations could support the relatively large initial investments needed for slave labour, the volume of the slave trade increased markedly. In Virginia the slave population leaped from 2,000 in 1670 to 23,000 in 1715 and reached 150,000 on the eve of the Revolution. In South Carolina it was even more dramatic. In 1700 there were probably no more than 2,500 blacks in the population; by 1765 there were 80,000–90,000, with blacks outnumbering whites by about two to one.

One of the principal attractions to the immigrants who moved to America voluntarily was the availability of inexpensive arable land. The westward migration to America's frontier—in the early 17th century all of America was a frontier, and by the 18th century the frontier ranged anywhere from 10 to 200 miles from the coastline—was to become one of the distinctive elements in American history. English Puritans, beginning in 1629 and continuing through 1640, were the first to immigrate in large numbers to America. Throughout the 17th century most of the migrants remained English; but beginning in the second decade of the 18th century, a wave of Germans, principally from the Rhineland Palatinate, arrived in America: by 1770 some 225,000–250,000 Germans had emigrated to America, more than 70 percent of them settling in the Middle Colonies, where generous land policies and religious toleration made life more comfortable for them. The Scots-Irish and Irish immigration, which began on a large scale after 1713 and continued past the Revolution, was more evenly distributed. By 1750 both Scots-Irish and Irish could be found in the western portions of nearly every colony. The French Huguenots, unlike most other groups immigrating to America, tended to be skilled and reasonably affluent when they first arrived.

Economic growth. Provincial America came to be less dependent upon subsistence agriculture and more on the cultivation and manufacture of products for the world market. Land, which initially served only individual needs, came to be the fundamental source of economic enterprise. The independent yeoman farmer continued to exist, particularly in New England and the Middle Colonies, but most settled land in North America by 1750 was devoted to the cultivation of a cash crop. New England turned its land over to the raising of meat products for export. The Middle Colonies were the principal producers of grains. By 1700 Philadelphia exported more than 350,000 bushels of wheat and over 18,000 tons of flour annually. The Southern Colonies were, of course, even more closely tied to the cash crop system. South Carolina, aided by British incentives, turned to the production of rice and indigo. North Carolina, although less oriented toward the market economy than South Carolina, was nevertheless one of the principal suppliers of naval stores. Virginia and Maryland steadily increased their economic dependence on tobacco and on the London merchants who purchased that tobacco; and for the most part they ignored those who recommended that they diversify their economies by turning part of their land over to the cultivation of wheat. Their near-total dependence upon the world tobacco price would ultimately prove disastrous, but for most of the 18th century Virginia and Maryland soil remained productive enough to make a single-crop system reasonably profitable.

Predominance of cash crops

As America evolved from subsistence to commercial agriculture, an influential commercial class increased its power in nearly every colony. Boston was the centre of the merchant elite of New England, who not only dominated economic life but also wielded social and political power as well. Merchants like James De Lancey and Philip Livingston in New York and Joseph Galloway, Robert Morris, and Thomas Wharton in Philadelphia exerted an influence far beyond the confines of their occupations. In Charleston the Pinckney, Rutledge, and Lowndes families controlled much of the trade that passed through that port. Even in Virginia, where a strong merchant class was nonexistent, those people with the most economic and political power were those commercial farmers who best combined the occupations of merchant and farmer. And it is clear that the commercial importance of the Colonies was increasing. During the years 1700–10, approximately £265,000 sterling was exported annually to Great Britain from the Colonies, with roughly the same amount being imported by the Americans from Great Britain. By the decade 1760–70, that figure had risen to more than £1,000,000 sterling of goods exported annually to Great Britain and £1,760,000 annually imported from Great Britain.

CULTURAL AND RELIGIOUS DEVELOPMENT

Colonial culture. America's intellectual attainments during the 17th and 18th centuries, while not inferior to those of the nations of Europe, were nevertheless of a decidedly different character. It was the techniques of applied science that most excited the minds of Americans, who, faced with the problem of subduing an often wild and unruly land, saw in science the best way to explain, and eventually to harness, those forces around them. Ultimately this scientific mode of thought might be applied to the problems of civil society as well, but for the most part the emphasis in colonial America remained on science and technology, not politics or metaphysics. Typical of America's peculiar scientific genius was John Bartram of Pennsylvania, who collected and classified important botanical data from the New World. The American Philosophical Society, founded in 1744, is justly remembered as the focus of intellectual life in America. Men like David Rittenhouse, an astronomer who built the first planetarium in America; Cadwallader Colden, the lieutenant governor of New York, whose accomplishments as a botanist and as an anthropologist probably outmatched his achievements as a politician; and Benjamin Rush, a pioneer in numerous areas of social reform as well as one of colonial America's foremost physicians, were among the many active members of the Society. At the centre of the American Philosophical Society was one of its founders, Benjamin Franklin, who (in his experiments concerning the flow of electricity) proved to be one of the few American scientists to achieve a major theoretical breakthrough but who was more adept at the kinds of applied research that resulted in the manufacture of more efficient fireplaces and the development of the lightning rod.

American Philosophical Society

American cultural achievements in nonscientific fields were less impressive. American literature, at least in the traditional European forms, was nearly nonexistent. The most important American contribution to literature was neither in fiction nor in metaphysics but rather in such histories as Robert Beverley's *History and Present State of Virginia* (1705) or William Byrd's *History of the Dividing Line* (1728–29, but not published until 1841). The most important cultural medium in America was not the book but the newspaper. The high cost of printing tended to eliminate all but the most vital news, and thus local gossip or extended speculative efforts were sacrificed so that more important material such as classified advertisements and reports of crop prices, could be included. Next to newspapers, almanacs were the most popular literary form in America, Franklin's *Poor Richard's* being only the most famous among scores of similar projects. Not until 1741 and the first installment of Franklin's *General Magazine* did literary magazines begin to make their first appearance in America. Most of the 18th-century magazines, however, failed to attract subscribers, and nearly all of them collapsed after only a few years of operation.

Art and drama

Art and drama, though flourishing somewhat more than literature, were nevertheless slow to achieve real distinction in America. America did produce one good historical painter in Benjamin West and two excellent portrait painters in John Copley and Gilbert Stuart; but it is not without significance that all three men passed much of their lives in London, where they received more attention and higher fees.

The Southern Colonies, particularly Charleston, seemed

to be more interested in providing good theatre for their residents than did other regions, but in no colony did the theatre approach the excellence of that of Europe. In New England, Puritan influence was a roadblock to the performance of plays, and even in cosmopolitan Philadelphia the Quakers for a long time discouraged the development of the dramatic arts.

If Americans in the colonial period did not excel in achieving a high level of traditional cultural attainment, they did manage at least to disseminate what culture they had in a manner slightly more equitable than that of most nations of the world. Newspapers and almanacs, though hardly on the same intellectual level as the Encyclopédie produced by the European Philosophes, probably had a wider audience than any European cultural medium. The New England Colonies, although they did not always manage to keep pace with population growth, pioneered in the field of public education. Outside of New England, education remained the preserve of those who could afford to send their children to private schools. The existence of privately supported but tuition-free charity schools and of some of the more inexpensive "academies" made it possible for the children of the American middle class to receive at least some education. The principal institutions of higher learning—Harvard (1636), William and Mary (1693), Yale (1701), Princeton (1747), Pennsylvania (a college since 1755), King's College (1754, now Columbia), Rhode Island College (1764, now Brown), Queen's College (1766, now Rutgers), and Dartmouth (1769)—served the upper class almost exclusively.

Public education

The "Great Awakening." A series of religious revivals known collectively as the "Great Awakening" swept over the Colonies in the 1730s and the 1740s. Its impact was first felt in the Middle Colonies, where Theodore J. Frelinghuysen, a minister of the Dutch Reformed Church, began preaching in the 1720s. In New England, in the early 1730s, men such as Jonathan Edwards, perhaps the most learned theologian of the 18th century, were responsible for a reawakening of religious fervour. By the late 1740s the movement had extended into the Southern Colonies, where itinerant preachers such as Samuel Davies and George Whitefield exerted considerable influence, particularly in the backcountry.

The Great Awakening represented a reaction against the increasing secularization of society and against the corporate and materialistic nature of the principal churches of American society. By making conversion the initial step on the road to salvation and by opening up the conversion experience to all who recognized their own sinfulness, the ministers of the Great Awakening, some intentionally and others unwittingly, democratized Calvinist theology. The technique of many of the preachers of the Great Awakening was to inspire in their listeners a fear of the consequences of their sinful lives and a respect for the omnipotence of God. This sense of the ferocity of God was often tempered by the implied promise that a rejection of worldliness and a return to faith would result in a return to grace and an avoidance of the horrible punishments of an angry God. There was a certain contradictory quality about these two strains of Great Awakening theology, however. Predestination, one of the principal tenets of the Calvinist theology of most of the ministers of the Great Awakening, was ultimately incompatible with the promise that man could, by a voluntary act of faith, achieve salvation by his own efforts. Furthermore, the call for a return to complete faith and the emphasis on the omnipotence of God was the very antithesis of Enlightenment thought, which called for a greater questioning of faith and a diminishing role for God in the daily affairs of man. On the other hand, Jonathan Edwards, one of the principal figures of the Great Awakening in America, explicitly drew on the thought of men like John Locke and Isaac Newton in an attempt to make religion rational. Moreover, in attacking the leadership of the prevailing religious sects of the time, the ministers of the Great Awakening fostered a questioning of many forms of institutional authority and helped break up the oligarchic control of a few wealthy, traditionalist-minded men on organized religion in America.

AMERICA, ENGLAND, AND THE WIDER WORLD

The American Colonies, though in many ways isolated from the nations of Europe, were nevertheless continually subject to diplomatic and military pressures from abroad. In particular, Spain and France were always nearby, waiting to exploit any signs of English weakness in America to increase their commercial and territorial designs on the North American mainland. The Great War for the Empire, or the French and Indian War as the Americans termed it (see SEVEN YEARS' WAR), was but another round in a century of warfare between the major European powers. First in King William's War (1689–97), then in Queen Anne's War (1702–13), and in King George's War (1744–48; the American phase of the War of the Austrian Succession), Englishmen and Frenchmen had vied for control over the Indians, for possession of the territory lying to the north of the North American Colonies, for access to the trade in the Northwest, and for commercial superiority in the West Indies. In most of these encounters France had been aided by her ally, Spain. Because of its own holdings immediately south and west of the British colonies and in the Caribbean, Spain realized that it was in its own interest to join with the French in limiting British expansion. The culmination of these struggles came in 1754 with the Great War for the Empire. Whereas previous contests between Great Britain and France in America had been mostly provincial affairs, with American colonists doing most of the fighting for the British, the Great War for the Empire saw sizable commitments of English troops to America. The strategy of the English under William Pitt was to allow their ally, Prussia, to carry the brunt of the fighting in Europe, thus freeing the English to concentrate their troops in America.

The French, despite the fact that they were outnumbered 15 to one by the English colonial population in America, were nevertheless well-equipped to hold their own against the British. They had a larger military organization in America than did the English, their troops were better trained, and they were more successful than the British in forming military alliances with the Indians. The early engagements of the war went to the French; the surrender of George Washington to a superior French force at Ft. Necessity, the annihilation of Gen. Edward Braddock at the Monongahela River, and French victories at Oswego and Ft. William Henry all made it seem as if the war would be a short and unsuccessful one for the British. Even as these defeats took place, however, the English were able to increase their supplies of both men and material in America. By 1758, with its strength finally up to a satisfactory level, England began to implement its larger strategy, which involved sending a combined land and sea force to gain control of the St. Lawrence and a large land force aimed at Ft. Ticonderoga to eliminate French control of Lake Champlain. The first expedition against the French at Ticonderoga was a disaster, as Gen. James Abercrombie led 15,000 British and colonial troops in an attack against the French before his forces were adequately prepared. The English assault on Louisburg, the key to the St. Lawrence, was more successful. In July 1758 Lord Jeffrey Amherst led a naval attack in which his troops landed on the shores from small boats, established beachheads, and then captured the fort at Louisburg.

In 1759, after several months of sporadic fighting, the forces of James Wolfe captured Quebec from the French army led by the Marquis de Montcalm. This was probably the turning point of the war. By the fall of 1760 the British had taken Montreal, and England possessed practical control of all of the North American continent. It took another two years for England to defeat her rivals in other parts of the world, but the contest for control of North America had been settled.

The capture of Quebec

In the Treaty of Paris of 1763, England took possession of all of Canada, East and West Florida, all territory east of the Mississippi in North America, and St. Vincent, Tobago, and Dominica in the Caribbean. The British victory had not come cheaply, however. British govern-

ment expenditures, which had amounted to £6,500,000 annually before the war, rose to £14,500,000 annually during the war. The cost of winning the war, and of maintaining the spoils of war, would be very high indeed —so high, in fact, that most Englishmen thought that the American Colonies should help pay the costs. The American colonists in 1763, freed for the first time in the 18th century from the threat posed by the French and the Indians, were more reluctant than ever before to be taxed to pay for a burdensome military establishment. The British, at least in part to pay the costs of the Great War for the Empire, would institute a program reorganizing the structure of the empire and imposing taxes on the Colonies to pay for that reorganization. The American Colonies, now economically powerful, culturally distinct, and steadily becoming more independent politically, would ultimately rebel before submitting to the English plan of empire. II. The establishment of the nation

THE AMERICAN REVOLUTION AND THE FORMATIVE PERIOD, 1763–89

Effects of the French and Indian War. Although the immediate results of the war had been to secure and greatly expand Britain's empire in North America, the longer range results were to achieve just the opposite; for in winning the war, Britain had dissolved the empire's most potent material adhesives. What had held the empire together were common interests and common enemies, along with a common reverence for the "rights of Englishmen" and for an imperial constitution that all parties had scrupulously avoided defining. Subjects in the parent country and in the Colonies alike had profitted from the maintenance of a vast enclosed common market; and, when colonials had wanted or needed to trade outside the empire, lax law enforcement usually made illicit trade possible. Similarly, the presence of Spanish and French colonies to the south, west, and north of the British colonies had produced interdependence of military and political interests between England and America. Removal of the French after 1760 destroyed Anglo-American strategic interdependence and (though this was slower to become visible) thoroughly disrupted the community of economic interests. Assorted conflicts between Britain and the various colonies began to arise; and, as they arose, spokesmen for all sides arose also, demanding their "rights" and defining the imperial constitution as they understood it. For 13 years definition followed conflict and conflict followed definition until the only thing remaining clear was that the empire could no longer be held together in peace.

Even before the end of the war, two ominous developments had indicated that Americans and Englishmen were not of one mind in their understanding of the constitution. These were the celebrated Writs of Assistance case in Massachusetts (1761), protesting general search warrants, and the case of the Parson's Cause in Virginia (1763), in which James Otis and Patrick Henry successfully challenged, on "constitutional" grounds, the authority of both Parliament and royal officials. Otis argued in terms of John Locke's (see LOCKE, JOHN) concept of a higher law, and Henry in terms of Viscount Bolingbroke's (see BOLINGBROKE, HENRY ST. JOHN, 1ST VISCOUNT) concept of the king as father to his subjects; but the significance of their arguments was that they won the support of the local populace and jury and were worlds away from attitudes current in London.

Constitutional differences with Britain

But the warning implicit in these cases was lost in the wave of euphoria and myopia that swept Britain and the Colonies at the war's end. Military victory and the Peace of Paris seemed an unmixed blessing; indeed, a large part of what went wrong in the 1760s was that everyone behaved as if only his own circumstances and opportunities had been altered and failed to perceive that anything fundamental had gone wrong or even changed.

Officers of the government in London, to the extent that they concerned themselves with America at all, were interested primarily from a military point of view. They proposed to make various minor reforms in the administration of the old empire, to require the colonials to bear a share of the cost of running the expanded territory that was acquired for their own protection, to ignore as much as possible the civil administration of the former French colonies, and to devote careful attention only to the changed military situation in America.

The most important part of the latter involved relations with the Indians, who had long been taught by the French to fear and despise the English. Prudently, in the Proclamation of 1763, London ordered that Anglo-Americans remain east of the crest of the Appalachians and allowed dealings with the Indians for land or goods only through London-appointed commissioners. Rather less prudently, the British refused to pacify the Indians with either an overwhelming show of force or a systematic program of bribes, both of which the French had long found necessary to comfortable and profitable relations with the red men. The immediate consequence was that in 1763 the Indians, under the Ottawa chief Pontiac, rose in a series of "guerrilla" attacks. The professional British military men were helpless until Col. Henry Bouquet—borrowing a technique that Anglo-Americans had earlier discovered —learned to wipe out the home bases of the Indians by burning their villages and fields and killing their women and children. By 1765 the Indians were willing to acknowledge defeat, and most British officials expected relations between England and America to reach a state of harmony.

Proclamation of 1763

Local grievances. Local activities, however, sometimes in interplay with actions in London, produced turbulence instead. In the Middle Colonies—Pennsylvania, New York, New Jersey, and Delaware—there was general economic prosperity but also social and political friction and disagreement with the mother country. Production of wheat and flour boomed, bringing good times for farmers and merchants; and the output of the area's second major product, ironware, expanded steadily. But the arrival of hordes of immigrants—especially New Englanders, Ulstermen, and Highland Scots—created social tensions in each of the Middle Colonies. Each, moreover, was rent by the efforts of land speculators to gain political power so as to profit from the immigration.

In New York this took the form of rivalry between aristocratic family connections, the De Lanceys and the Livingstons, and was purely local until a new issue intruded: Parliament's Sugar Act of 1764, imposing taxes and new commercial regulations, squeezed New York's West Indies merchants and their artisan adjuncts; the De Lanceys gained popular support and power by assuming a stance as defenders of American liberties against parliamentary encroachments. (Their most important defiance of Parliament was their refusal to obey the Quartering Act, requiring colonies to support the imperial soldiers stationed in America.) In Pennsylvania a clique headed by Joseph Galloway and Benjamin Franklin made a popular issue out of efforts to secure revocation of the Penn family's proprietary charter, secretly expecting that under a royal charter they could gain for themselves the vast tracts of land they sought; their opponents, led by John Dickinson, opposed a royal charter and, by logical extension, assumed a stance comparable to that of the De Lanceys in New York.

Aristocratic factions in New York

In the lower South—the Carolinas and Georgia—the situation was somewhat similar to that in the Middle Colonies. The economy, based on the production of rice, indigo, and naval stores, was booming; but the social order was strained. Indians were strong and hostile in South Carolina and Georgia, and in the backcountry of both Carolinas the frontiersmen, mainly Scots-Irish immigrants, were demanding overhaul of local government. In the middle and late 1760s, when so-called frontier Regulators rose in armed defiance of the authority of the low-country aristocrats, they sought imperial intervention; the aristocrats for that and other reasons opposed the extension of imperial authority.

In the upper South, in the tobacco colonies of Virginia and Maryland, everything was awry. Tobacco prices were erratically downward and crop failures were common. One faction of tidewater planters, led by the speaker of

the House of Burgesses, remained afloat through fraudulent manipulations of paper currency, in violation of Parliament's Currency Act of 1764, requiring the extinction of such currency. Another pair of factions, one southwestern and the other Potomac-based, hoped to survive by land speculation that could succeed only through circumvention of the Proclamation of 1763.

Finally, there was New England, socially more or less calm and politically harmonious, except in Massachusetts, but economically depressed and afoul of the mother country and the other colonies in various ways. With rare exceptions, the complex New England economy failed to perform well after 1763. The Yankees blamed their troubles variously on the Sugar Act and other tightened commercial regulations, the Currency Act, the Proclamation of 1763, and malice in London. Meanwhile, settlers from overcrowded Connecticut, backed by the colony's government, invaded Pennsylvania; and, less officially but more numerously, colonials from Massachusetts invaded upper New York.

The Stamp Act and Townshend Duties. In sum, by the mid-1760s the colonists were sharply divided against one another, and objection to several parliamentary acts was strong though diffuse. Then, in 1765, Parliament passed the Stamp Act, designed to produce colonial revenues and thus reduce the heavy tax burden in England—which many Englishmen thought stemmed from the cost of maintaining the enlarged colonial establishment. In several American ports (notably Boston, where Samuel Adams formed and led a widely copied organization called the Sons of Liberty), opposition to collecting the Stamp Tax was violent; in Virginia legislative opposition (under Patrick Henry) was based on a radical constitutional position; and in many places colonists refused to import any British goods until the tax should be repealed. For the most part, however, the resistance, though firm, was more moderate. In October 1765, nine colonies sent delegates to New York for an extralegal congress that protested the Stamp Act mainly on the ground that it violated the ancient principle that taxes were a voluntary gift from the people to the sovereign.

The Stamp Act Congress

Much misunderstanding ensued. Parliament repealed the act, largely at the behest of London merchants suffering from the American boycott, but it saved face by pretending to bow to a distinction between acceptable "external" taxes and unacceptable "internal" taxes—a distinction suggested by Franklin, then pursuing his land schemes in London, but actually held by virtually no colonists. Colonial spokesmen cheered the repeal and failed, almost unanimously, to notice the Declaratory Act—passed along with the Stamp Act's repeal—asserting Parliament's right to legislate for the Colonies "in all cases whatsoever." Fifteen months later (June 1767) Parliament passed the Townshend Duties (Acts), imposing external taxes on lead, glass, paint, paper, and tea imported into America. Disregarding Franklin's misleading distinctions, John Dickinson penned a series of articles (*Letters from a farmer in Pennsylvania*), that galvanized a new colonial resistance. Dickinson's position was quickly adopted as the majority position in America; Parliament could tax the Colonies, but only incidentally to the power to regulate trade and other relations within the empire—and not at all for purposes of revenue.

Repeal of Townshend Duties

Though all the Townshend Duties except that on tea were shortly repealed, partly in response to a new colonial nonimportation policy and partly in response to political pressures inside England, three positions besides Dickinson's soon became manifest. Britain's position, apart from what was based on practical political considerations, was one of bewilderment; for, since the Glorious Revolution of 1688, chasing James II from the throne, the only limitation on the power of Parliament, as most Englishmen understood things, was Parliament's own self-restraint. Rather to the right of this position was that held by the Virginia Burgesses, who professed allegiance only to the crown, felt not even that, and regarded Parliament as being at best co-equal with the assembly of Virginia. Far to the left were the Yankees, especially those of Massachusetts, who regarded themselves as the heirs of 17th-century Puritanism, beyond the reach of crown and the corrupt 18th-century Parliament.

After the repeal of the Townshend Duties, however, everything cooled for awhile. A tide of credit-based prosperity, engendered by fraudulent banking activities in Scotland, swept the empire. Swollen revenues lulled royal government officials, and in New England and Virginia the more dissident elements succumbed to the lure of unexpected credit and prosperity. In Pennsylvania and in the lower South, the sudden and unexpected boom was enough to create the illusion that internal strains (from frontiersmen and Indians) were not so potent as had been imagined. In New York the De Lanceyites, given special exemption from the Currency Act and favourable treatment with regard to Indian land titles, abandoned all opposition to Parliament. In Massachusetts, Sam Adams found himself a radical leader virtually without a following.

The Tea Act and "Intolerable Acts." But late in 1772 the bubble burst. The effects of the collapse were slow to be felt, but in the spring of 1773 the most volatile groups in the Colonies felt them severely: radicals in Boston suddenly found themselves supported by the normally conservative farmers of the interior of Massachusetts, who had gotten themselves deeply into debt during the credit boom; the tobacco planters of Virginia, long trembling on the brink of insolvency, suddenly found themselves deeper in debt than farmers in New England could possibly imagine. Operators in Parliament, lately encouraged by speculative profits to ignore colonial problems, suddenly found themselves with a colonial problem in an unexpected area. The East India Company, the grandest speculation of them all, was tottering on the verge of bankruptcy. To save the company, Parliament passed (May 10, 1773) a complicated act giving it various new privileges, including a refund of import duties already paid on tea stored in London if it were reshipped to America. Consequently, high-quality English-India tea could, despite the Townshend Duties, be sold in America cheaper than inferior Dutch tea, which Americans habitually consumed because of its lower price.

The Tea Act reunited dissident elements in America. Merchants in New York, Philadelphia, and the New England outports, long accustomed to profits from illicit tea trade and now doubly squeezed by the financial collapse, financed and supported a new resistance. Propagandists, both opportunistic and idealistic, denounced the act as a dangerous "innovation" by Parliament and as an insidious plot to subvert American liberties by bribery—that is, by inducing Americans to buy taxed tea because it was cheaper. Radicals in Boston and Charleston capitalized on the furore, the former (in the Boston Tea Party) destroying and the latter confiscating cargoes of tea; tea consignments were turned back elsewhere. Virginia land speculators and planters sought any advantage they could find in the confusion.

The Boston Tea Party

Parliament, succumbing to an almost paranoid fear that the Americans were plotting independence, responded by cracking down on what most Englishmen regarded as the main source of trouble. In a series of acts passed in 1774, Parliament imposed a strangulating set of commercial restrictions on the port of Boston. Coincidentally, Parliament also passed an act, long in the making, providing for the government of the recently acquired French province of Quebec. The act provided, among other things, for retaining French law and the Roman Catholic establishment in the province and extended the province's jurisdiction to the trans-Appalachian area north of the Ohio River—thereby convincing New Englanders that the whole affair was a Catholic conspiracy aimed against Yankee Puritans along with the Boston Port Act and incidentally cutting Virginians off from the possibility of profitable land dealings in the Ohio country. Thus New England Yankees and Virginia plantation aristocrats, distrustful of one another since the Roundhead–Cavalier struggles of the English Civil War more than a century earlier, were thrust into the same radical camp in 1774.

General American response to the "Intolerable Acts"—as the restrictive parliamentary legislation was promptly

dubbed in America—resulted in the calling of a Continental Congress in October. Despite the radicalism of the Yankees and Virginians, the dominant voice in the Congress was that of John Dickinson, a thoroughgoing conservative in the sense later identified with Edmund Burke. Dickinson, steeped in British history and law but oblivious to constitutional developments since 1689, insisted that recent acts of Parliament were innovations that, if persisted in, could destroy the excellent British constitution and insisted also that colonial resistance was justified by history and tradition. He was supported by most delegates from the Middle Colonies and the lower South, where, despite inner tensions, imperial regulation had been advantageous, at least to the dominant groups.

The struggle for independence. Radical voices were distinctly in the minority, and that fact did not change much though violence was soon forthcoming. In April of 1775 British troops clashed with colonial militiamen in Lexington and Concord, Massachusetts, and at the suggestion of Congress the several colonial militias prepared themselves for more conflict. Brilliant young propagandists—notably Thomas Jefferson, John Adams, James Wilson, and Alexander Hamilton—penned persuasive tracts that essentially denied all power of Parliament over the Colonies, placed the burden of conflict upon the crown, and came perilously close to advocating independence; but still, despite everything, anger on neither side was sufficient to cause many to contemplate seriously the dismemberment of the empire. Then in December Thomas Paine wrote "Common Sense," a masterpiece of sledge-hammer logic couched in the near-poetry of the King James Bible, dissolving every claim that had been advanced for loyalty to kings.

Thomas Paine's "Common Sense"

Early in 1776 resistance hardened into war, and advocates of independence grew in numbers. Until the very end, however, congressional delegates and popular majorities in the Middle Colonies and the lower South opposed independence, for the empire had been good to them and revolution could unleash a host of troubles from Indians, slaves, and frontiersmen. New England and Virginia, less blessed by the fruits of empire and socially far more stable—and also, unlike the other colonies, having matured in the 17th century, when rebellion and even regicide were common—were willing to take the risk. On July 2, 1776, Congress voted for independence. Two days later it published the Declaration of Independence, written by Jefferson and addressed "to the opinions of mankind." (For the military history of the war, see WAR OF INDEPENDENCE, U.S.)

The Confederation and the framing of state constitutions. As the debate on independence moved toward a climax, the internal political alignments of the various colonies began to harden around that issue. In New England, minority groups were overridden, royalists fleeing for Nova Scotia or England, while Baptists and other religious minorities were vigorously suppressed; south of the Potomac, backcountry dissenters were subdued by force, though Loyalism remained endemic in the area. In the Middle Colonies, Galloway broke with Franklin and remained Loyalist as a matter of conscience; Pennsylvania's Quakers became nonmilitantly Loyalist; New York's De Lanceyites became militantly so out of fear of the social turmoil that seemed in store; the Livingston connection became reluctant rebels.

"Republicans" versus centralists

Among those who supported independence, two broad divisions soon became manifest. The reluctant rebels of the Middle Colonies and the lower South insisted, at the last minute, that if independence was to come, it should be preceded by the creation of a strong national government. The more ardent rebels of New England and Virginia became hard-shelled "republicans"—by which they meant opponents of monarchy, central government, executive authority, and all other forms of restraint upon the power of dominant local groups. The republicans prevailed from 1776 until 1780, almost preventing victory by their hostility to central authority and ensuring the adoption of the Articles of Confederation (a "league of friendship" rather than the strong national government proposed by Dickinson and supported by nationalists).

Predictably, few internal reforms were brought about by the prevalence of republicanism: all colony-states except Rhode Island and Connecticut, which had long governed themselves under colonial charters, did adopt new constitutions, but none save those of Pennsylvania and Georgia were especially radical. The latter two established unicameral legislatures virtually unchecked by executive or judicial branches and experienced considerable political turbulence. The other nine were relatively conservative and were designed to freeze political power where it was in the summer of 1776; all emasculated the executive branch and expanded legislative authority, but few broadened the franchise, only seven provided bills of rights (none of which had the force of law), and several provided elaborate checks on direct popular rule.

Problems under the Articles of Confederation. Government under the Articles of Confederation and the new state constitutions was adequate to see the United States through to independence, but only after republicanism had been discredited by corruption and incompetence in 1781, after nationalists had seized unconstitutional powers under Superintendant of Finance Robert Morris, after Gen. George Washington's army acquired military discipline and a most unrepublican spirit, and after various British generals, notoriously the commander of the southern army, Lord Cornwallis, committed blunders that bordered on the preposterous. At Yorktown, Virginia, in October of 1781, Cornwallis was forced to surrender to Washington. A year later, a definitive treaty of peace, recognizing American independence and placing the western boundary of the United States at the Mississippi, had been signed. Britain retained Canada, Spain received Florida to the Mississippi, and everything west of the river remained Spanish. France, allied with the United States after 1778, got nothing for all its troubles.

End of the war

The Americans suddenly found themselves in an unfriendly world. Britain closed its West Indies to American shipping, Spain closed its colonies entirely and also, by closing New Orleans, deterred development of the West, though frontiersmen spilled over the mountains in great numbers. Even France imposed commercial restrictions, cutting New England fish and Virginia tobacco from profitable markets. In short, the tangible gains many expected from independence were simply not forthcoming.

Domestic tensions aggravated the difficulties of the new republic. Congress, nearly impotent under the Articles of Confederation and weakened further by the resurgence of republicans after the peace, was unable to cope with either national or local problems. The most pressing of all domestic problems was the public debt, national and state, of about $60,000,000, incurred to finance the war. The vast domain of public lands might have been used to retire these debts—trans-Appalachia north of the Ohio River had come, by circuitous means, to be vested in Congress by 1784—but local and private greed, Spanish obstructionism, and efforts of nationalists to use public debts and lands as cements of a stronger union combined to thwart such action.

In default of effective national action, the several states attempted to service the public debts, with varying results. Most of the Southern states virtually repudiated their debts, alienating public creditors and straining the private economy. Even so, Georgia and North Carolina thrived for special local reasons, South Carolina might have flourished but for a freakish succession of crop failures, Virginia did well until 1786, and only Maryland was torn by internal political and financial problems. In the Middle states, New York and Pennsylvania handled their public affairs well, with the result that New York drifted away from nationalism, though internal dissension kept Pennsylvania divided. New Jersey and Delaware and two New England states, Connecticut and New Hampshire, were entirely unable to manage alone. Massachusetts, sorely depressed economically in the postimperial world and burdened by high taxes imposed to pay war debts, was torn in civil war (Shays' Rebellion) in 1786. In all of New England, only Rhode Island flourished, and it did so only through

Shays' Rebellion

the kind of brigandage that Americans had come to expect from the "otherwise-minded" colony-state.

The Constitutional Convention. In sum, by the winter of 1786–87 America was in crisis. In Massachusetts, Capt. Daniel Shays, a Revolutionary War veteran, led a band of embattled farmers against the state court to prevent foreclosures on tax delinquent farmers; and in New York the state legislature defeated an amendment to the Articles of Confederation giving Congress an independent source of revenue from import duties. In desperation, Congress and all the states except Rhode Island acceded to a call—issued by nationalists at a commercial convention in Annapolis the preceding September—for a general convention to meet in Philadelphia in May 1787 and "consider the exigencies of the Union."

The Philadelphia Convention has been described, and not without merit, as the most gifted collection of statesmen ever assembled (even though Jefferson, Sam and John Adams, Richard Henry Lee, John Hancock, Patrick Henry, and other heroes of 1776 were absent). Well-versed in political theory, the delegates were nonetheless practical men of business and public affairs who addressed themselves less to the theoretical problem of what kind of national government America should have (which, given everything, could only be answered republican and federal) than to the more basic question, whether the United States would have a national government at all. On that crucial question, the 55 delegates lined up in four general camps.

Alignment of the delegates

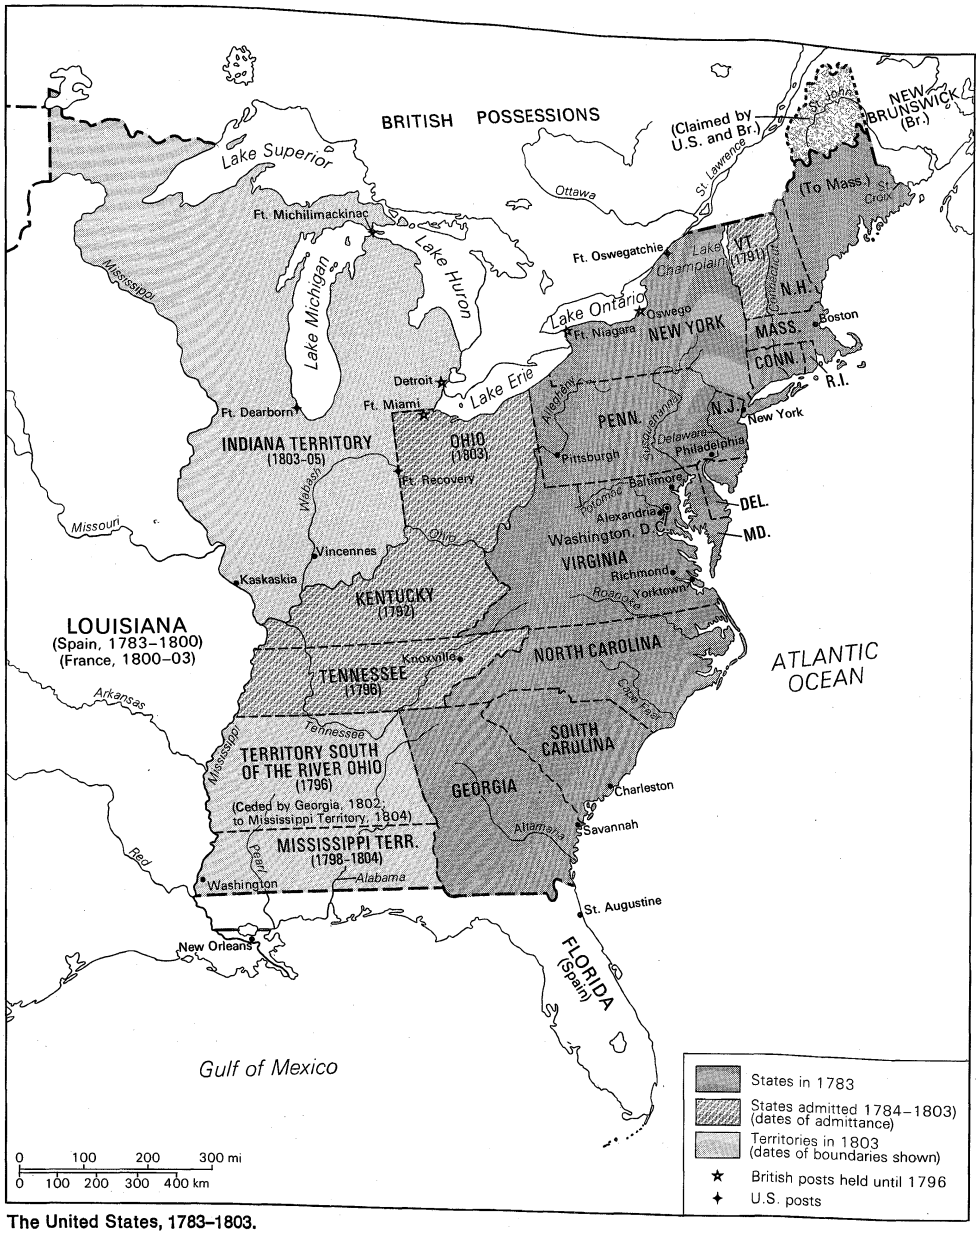
A majority of delegates were strong nationalists; an unconditional nationalist group of eight or ten, led by Washington and Franklin, who preferred a limited national authority based on a separation of powers but who would have accepted almost any form approved by the other delegates; two monarchists, Dickinson and Hamilton; six or eight aristocrats, led by Gouverneur Morris of Pennsylvania and John Rutledge of South Carolina, who would accept almost any energetic national government but preferred one as "high-toned" as possible; and seven or eight rather "democratic" nationalists, led by James Wilson of Pennsylvania and James Madison of Virginia, who wanted a strong national government founded on a broad popular base.

Next came two groups of conditional nationalists. The first of these—consisting of Elbridge Gerry of Massachusetts, George Wythe, Edmund Randolph, and George Mason of Virginia, and Luther Martin and John Francis Mercer of Maryland—were ideologues, who would support a national government only if it were founded on narrowly defined republican principles. The other group, which included most of the delegates from Maryland, New Hampshire, Connecticut, New Jersey, and Delaware, shared a more tangible concern. As representatives of states without viable claims to western lands, they insisted that the lands become the common property of all the states; but, given that condition, they were willing to support an extremely strong central authority. Finally, a few delegates, notably two of the three from New York, were flatly opposed to increased national authority.

In reconciling the ideological differences, Madison and Wilson were the most important delegates; in managing the political and economic differences, Rutledge, together with Roger Sherman and Oliver Ellsworth of Connecticut, towered over the rest.

The main business began with Washington presiding and Governor Randolph of Virginia presenting 15 resolutions, probably authored by Madison. The idea of creating a national authority was quickly approved, along with the principle that the new government should be divided into executive, legislative, and judicial branches. The most heated debate concerned the makeup of the legislative branch, the "landless" states insisting on equal representation by states and their opponents demanding that representation be apportioned according to population. A compromise was reached with a bicameral legislature, one house representing population and the other representing the states equally and the latter having control over questions of public lands. This arrangement was agreed upon by mid-July, but the constitution of the other branches was left vague and unsettled. The work of the convention was then turned over to a five-man Committee of Detail, which produced (August 6) a rough draft of a constitution, retaining the compromise legislature and making executive and judiciary subordinate to it. Early in September, however, after several weeks spent mainly in haggling over special interest features, the cumbersome electoral college was proposed (probably by Franklin), making the presidency independent of the proposed Congress. That feature made the Constitution awkward but also built into it the principle of separation of powers. Following a few more days of discussion, the convention's various resolutions were turned over to a Committee on Style, under Gouverneur Morris, which drafted the final document. Morris took several liberties with the text, introducing ambiguity at key points to make the Constitution flexible and also (without the delegates noticing) injecting various features, notably the "contract clause," which had been voted down. On September 17, 1787, the Constitution was approved by 39 of the 42 delegates remaining in the convention.

Proposal of the electoral college



Struggle for ratification. The Constitution stipulated that it should become effective when specially elected conventions in nine states ratified, despite the requirement in the Articles of Confederation that amendments be ratified by the legislatures of every state. The smallest and weakest states, most pleased with the new system, ratified quickly: Delaware, New Jersey, and Georgia all unanimously and before year's end and Connecticut early in 1788 by a majority of three to one. Meanwhile, Pennsylvania, one of the states expected to be reluctant, responded to political manipulation and high-pressure campaign techniques and ratified in December 1787 by a convention vote of 46 delegates to 23. Massachusetts, another "swing" state, ratified early in 1787 in response to clever politicking by Federalists, as proponents of the Constitution called themselves, though "Anti-Federalists" may well have been in a majority in the state.

With six states having approved and three to go, the contest came to a climax in the spring of 1788. Maryland and South Carolina (both being extremely aristocratic states that had been lukewarm toward the democratic trends implicit in independence and both being landless states that stood to gain from the pooling of the domain of public lands) ratified by sizable majorities early in the year. But New Hampshire, populated mainly by backcountrymen who were loathe to accept any change, postponed a decision; and the dominant groups in Virginia, New York, North Carolina, and Rhode Island were opposed to ratification. After considerable debate and political jockeying, however, the first three had ratified by July of 1788, despite the probable opposition of popular majorities. North Carolina finally ratified in November of 1789, several months after the new government had begun to operate, and Rhode Island ratified in May 1790.

Attitudes toward the Constitution can be accounted for on four major sets of grounds, apart from considerations already mentioned: (1) proximity to regular commerce and communication, those Americans having the broadest world view, deriving from regular contact with other places, being more favourable to national authority than those in more isolated places; (2) military vulnerability, those areas that had suffered most from the wartime fighting being the most nationalist (a striking number of the ablest pieces in favour of the Constitution, *The Federalist Papers* by Jay, Hamilton, and Madison, were concerned with the advantages for national defense that would result from ratification); (3) relative success under the Confederation, those states that had fared best as sovereign entities being least favourable toward the Constitution; and (4) ideology, the more doctrinaire republicans being cool toward the Constitution because of its ambiguity and lack of a bill of rights. Economic interests also entered the contest over ratification but won about as many enemies as friends for the new system.

NATIONAL POLITICS, 1789–1816

The first elections under the Constitution were held late in 1788. Federalists, mainly old nationalists, swept to

The United States, 1783–1803.

power: Washington received every electoral vote and became president, John Adams became vice president, and only a handful of Anti-Federalists were elected to Congress. The new government wasted some time on precedents and protocol, but by early summer of 1789 it had plunged earnestly into serious business. One such concerned an issue raised during the conflict over ratification: Anti-Federalists had demanded a second convention to add a bill of rights to the Constitution, some hoping that a second convention might undo the work of the first. Madison, fighting for his political life in predominantly Anti-Federalist Virginia, sought to please his constituents by proposing a number of amendments; he was supported, for reasons of political expediency, by some Federalists who actually opposed a bill of rights and was opposed, for similar reasons, by some Anti-Federalists who favoured such amendments. Twelve amendments were finally approved by Congress and submitted to the states for ratification. Ten, which became the Bill of Rights, were ratified in December 1791. Together the amendments restricted national authority against states and individuals and guaranteed various procedural rights, but the restrictions did not apply to state governments.

The Bill of Rights

Meanwhile, Congress was resolving two other major problems in 1789. It levied a tariff on imports, and though supplementary internal taxes were enacted from time to time, import duties would remain the major source of national revenue for more than a century. The first Congress also passed the Judiciary Act, filling a void in the Constitution by establishing a hierarchical system of appellate courts. For practical purposes this act became part of the Constitution itself.

In dealing with its remaining major tasks, Congress went only part of the way in 1789. Instead of creating new executive departments, it adopted and modified the machinery of the Confederation. The Department of Foreign Affairs became State (to head which Washington appointed Thomas Jefferson, after incumbent John Jay indicated his preference for the chief justiceship); the War Department was retained intact, including the incumbent head, Henry Knox. The Confederation's three-man Board of the Treasury was replaced by a department headed by a single secretary. Washington wanted Robert Morris, Philadelphia merchant and erstwhile "financier of the Revolution," for the post, but Morris declined and Washington appointed instead his own former aide-de-camp, the brilliant young New Yorker Alexander Hamilton. Congress promptly instructed Hamilton to produce, by the time it reconvened at year's end, a plan for retiring the public debts.

Hamilton's fiscal system. The following January, Hamilton presented his First Report on the Public Credit, a comprehensive plan modelled after the system evolved in England between the 1690s and 1730s. Instead of at-

"Funding" the debt

tempting to retire the public debt, which imposed crippling tax burdens on the nascent American economy, Hamilton proposed to "fund" it and transform it into currency. Toward that end, all obligations of the old Confederacy as well as the war debts of the states would be made exchangeable for bonds of the new national government; the new bonds would receive regular interest payments and be supported by open-market purchases by Treasury Department agents, using a "sinking fund" created for the purpose. With public bonds thus stabilized and "pegged," government obligations could form the basis of a paper currency: a national bank, quasi-public and patterned after the Bank of England, could issue notes based on the public debt.

Most Congressmen from the tobacco-growing states opposed Hamilton's plan, partly because the planters were major importers who had largely repudiated their own debts and thus stood to pay heavily for a scheme that would directly profit them little. In part, however, their antagonism arose from much deeper roots, the so-called agrarian mentality. The aristocratic republicans of the tobacco belt were by no means opposed to making profit; indeed they were so avid for profit that they were willing to enslave blacks and slaughter Indians to obtain it; but they fiercely opposed the monetization of American life, much as the Bolingbroke Tories (whom the Virginians regularly read and quoted) had opposed the monetization of England by the Walpole Whigs.

Accordingly, Hamilton's proposals met stiff resistance from the "republican interest" in Congress, led by Madison, but the plan for assuming the state debts and funding all the debts was passed in August 1790. The act creating the Bank of the United States was passed in February 1791. Washington's cabinet split on this issue, Jefferson arguing, as a "strict constructionist," that the bank was unconstitutional and Hamilton defending its constitutionality with the doctrine of implied powers. Other portions of Hamilton's program, notably his proposal for protective tariffs to promote infant American industries, were defeated.

Formation of political parties. Mainly as a result of these disputes, something resembling political parties had begun to crystallize by 1792. Republicans, led by Madison and Jefferson, founded an anti-administration newspaper, built local organizations through private clubs called Democratic-Republican societies, and tried to coordinate electioneering activities; they were strong in the upper South, on the western frontier, and among erstwhile Anti-Federalists in the Middle states. Federalists, led by Hamilton, also founded a newspaper, but for the most part their political organization consisted of Treasury Department employees. The prosperity attending Hamilton's program and the immense popularity of President Washington won Federalist supporters everywhere, though the "party" was strongest in New England, South Carolina, and the environs of New York City and Philadelphia.

Effects of the French Revolution. In 1793 a new issue arose, one that would dominate American affairs for 22 years: the wars of the French Revolution. American involvement began with the arrival of Citizen Edmond Genet as minister from France, claiming that the Franco-American Alliance of 1778 bound the United States in the current French war against England, Spain, and other European nations. Hamilton, recognizing that war with England would dry up revenues from imports (most of which came from Britain) and thus destroy the financial system that bound the nation together, insisted on neutrality. Republicans warmly favoured France, partly out of ideological kinship, partly because of opposition to Hamilton's system, partly because the alliance would justify seizure of Spanish territory on the southern and western frontiers. Washington followed Hamilton's advice and issued a neutrality proclamation, and Jefferson soon resigned as secretary of state.

The Republicans gained popular support in the winter of 1793–94, when the British Navy seized many American commercial vessels and impressed into its service a number of American seamen. To prevent a break with England, Washington sent John Jay to London. The resulting treaty ensured cordial Anglo-American relations, provided for the evacuation of British posts in the American Northwest, and (in conjunction with Orders in Council issued at the same time) afforded great opportunities for American commerce as the neutral carrier of belligerent goods. Meanwhile, when Jay was in London the so-called Whiskey Rebellion (actually only a limited opposition to the federal excise tax on liquor) was crushed in western Pennsylvania; and because the "rebels" were associated with Democratic-Republican societies, such societies were widely discredited. Even so, Republicans were able to organize a spirited opposition to Jay's Treaty; but its obvious advantages, together with the loss of enthusiasm for France during and as a result of the Reign of Terror (1793–94), were enough to secure senatorial ratification by the necessary two-thirds majority. A year later the Federalists scored another diplomatic gain with Pinckney's Treaty, whereby Spain opened the Mississippi, allowing Americans the right of deposit at Spanish New Orleans.

The Jay Treaty

On that note, and largely because the tenor of domestic politics had grown so scurrilous, Washington decided to retire at the end of his second term (March 3, 1797). Federalist vice president John Adams was elected president, but the Republican Jefferson became vice president. Adams' administration was marked throughout by strained relations with a France that was angry over Jay's Treaty and arrogant after defeating the best armies of Europe, a France that demanded bribes and tribute as a condition to recognizing American diplomats. Incensed, the United States prepared for war. What followed was complex. There was some naval fighting in 1798–99 at a time when the infant U.S. Navy consisted mainly of a new class of super-frigates designed by Joshua Humphreys. Hamilton, retired from the Treasury but still dominating the Federalist Party, demanded a large army also, partly for conquest of Spanish territory in the Southwest (Spain having become an ally of France) and partly to suppress a pro-French insurrection he feared was brewing in the South. Virginia, North Carolina, and Kentucky did contemplate insurrection and armed their militias to fight if Hamilton's "invasion" materialized. Moreover, in opposition to the Alien and Sedition Acts, restrictive measures passed as part of the war preparations, Madison and Jefferson penned the so-called Virginia and Kentucky Resolutions, defying Congress and postulating the classical states-sovereignty constitutional position. (Actually, the Alien and Sedition Acts were the mildest restrictions on civil liberties ever imposed by the United States in time of war.)

Alien and Sedition Acts

In 1799, France, suddenly jeopardized by the formation of a new coalition in Europe, signified its willingness to negotiate. Adams then sent a new minister, William Vans Murray, who agreed to the Convention of 1800, terminating the quasi-war. France continued to have designs on America; the secret Treaty of San Ildefonso, whereby Napoleon (now ruling France) obtained Spanish Louisiana, was signed on October 1, 1800, the day after Murray's convention was signed. But Adams had avoided war and gained considerable popularity in so doing. He had also split his party by his open break with Hamilton, however, and thereby prevented his re-election in 1800. Jefferson and Aaron Burr tied for the lead in the electoral college, and only after an acrimonious contest in Congress did Jefferson become president.

Jefferson's presidency. The "Revolution of 1800," as Jefferson later described his election, reflected no popular mandate—most electors were chosen by state legislatures—and did not, in fact, bring sweeping changes to the national government. To the disappointment of Republican ideologues, Jefferson neither purged the government of Federalist employees nor destroyed the Hamiltonian system, and he abandoned the principles of strict construction and a weak executive branch. Albert Gallatin, as secretary of the treasury, introduced various administrative reforms; but otherwise the Jeffersonians, in domestic affairs, concentrated mainly on trying to rid the federal courts of Federalist judges. The President and his

intimates shared a distrust of the judicial branch, were incensed by Adams' "midnight appointments" (several new judgeships created in February of 1801 and filled by Adams just before he left office in March), and were outraged when one of the late appointees, Chief Justice John Marshall, established the principle of judicial review by declaring an act of Congress unconstitutional (*Marbury* v. *Madison,* 1803). Attempts to clear the bench by impeachment reached a climax early in 1805, with the trial of Justice Samuel Chase. When Chase was acquitted, the Jeffersonians abandoned the effort.

Establishment of judicial review

Jefferson's main concern was with foreign affairs and especially with territorial expansion. The most successful action in that direction was the purchase of the vast Louisiana territory from France in 1803 for $15,000,000. Jefferson also sought diligently to obtain Spanish Florida, which was needed for a southern outlet to the sea. Toward that end he played up to Napoleon, who could have forced Spain to cede Florida to the United States—and who tantalized the President by hinting he might do so. Jefferson also flirted with the idea of secretly backing a private expedition against Spanish territory. One such expedition was that of Aaron Burr, who in 1804 had been dumped by the Jeffersonians, ran unsuccessfully for governor of New York, and killed Hamilton in a duel and who in 1805–06 was engaged in various western conspiracies. Arrested late in 1806, he was tried for treason and acquitted in 1807.

Meanwhile, the United States had again become entangled in the European wars. In 1805 Britain reversed the orders that enabled Americans to grow rich as neutral carriers to belligerents, and the next year Britain and France imposed various orders and decrees that sorely limited American trade with Europe and confiscated hundreds of American ships for violating the new rules.

Jefferson's embargo on exports

As a countermeasure, Jefferson requested and Congress authorized an embargo on all American exports. This was the darkest hour in Jefferson's presidency. In the enforcement of the embargo, civil liberties were ruthlessly suppressed; the embargo's main effect was to starve slaves in the West Indies—which the Jeffersonians expected and even welcomed because it had the incidental advantage, from their point of view as slaveowners, of punishing the blacks who had fought a successful revolution in Santo Domingo; and the effect on the European belligerents was nil. When his second term ended, Jefferson retired and never participated in public affairs again.

Louisiana Purchase.

Madison's presidency. Jefferson's secretary of state, James Madison, succeeded him as president in 1809. Madison had been skillful in politics, both as theoretician and as practical operator, but he lacked the qualities of leadership that Jefferson had brought to the presidency. Slavishly adhering to his narrow understanding of Jefferson's policies, Madison tried with a succession of commercial restrictions to force Britain and France to respect freedom of the seas. The efforts were futile, and Britain, master of the oceans since Nelson's victory over the combined French and Spanish fleets at Trafalgar in 1805, seized American ships and seamen at will and periodically insulted the small American navy. Meanwhile, the navy was considerably reduced, out of ideological opposition to standing armed forces, and the national government was drastically weakened when the charter of the national bank expired and Republicans in Congress refused to renew it.

Thus, as 1812 approached, American relations with both Britain and France degenerated, as did America's ability to wage war. But just then a popular clamour for war began to mount. In part the clamour was born of frustration and a desire to redeem the national honour. In part it was triggered by the private conquest of a portion of Spanish Florida (Spain having rejoined Britain against France), which convinced many expansionists that the rest of Florida and all of Canada would be easy prey for American militiamen. Madison himself inched toward war, seeking no conquests but determined to win freedom of the seas. These mounting forces, compounded by bungling diplomacy, resulted in a declaration of war against England on June 18, 1812. The vote was close, 79-49 in the House and 19–13 in the Senate. North and east of the Delaware River the vote was almost unanimous for peace.

THE WAR OF 1812

The American strategy in the War of 1812 was to fight for freedom of the seas by staying ashore. The navy was to be ordered to port, to defend the major cities; Canada was to be invaded at Detroit, Ft. Niagara, and Lake Champlain by a large militia force (100,000 were authorized for six months' service) and the small regular army. British strategy was to bottle the American navy in port, blockade the coast, and ignore the militia threat as so much braggadocio.

In the first year of the war, British thinking proved eminently the sounder. American militiamen under Gen. William Hull, instead of invading Canada, made a series of blunders and on August 16 surrendered Detroit to a small detachment of British. At Ft. Niagara the militiamen, first under Gen. Stephen Van Rensselaer and then under Alexander Smyth, refused to cross the frontier into Canada. At Lake Champlain the same thing happened with the largest American force, under Henry Dearborn.

Luckily for the Americans, naval captains William Bainbridge and Charles Stewart persuaded Madison, at the last moment, to allow the small U.S. Navy (12 ships fit for sea duty, versus more than 600 in the Royal Navy) to go to sea. There the Americans distinguished themselves. Capt. John Rodgers sailed with five ships on a cruise that, though disappointing in its haul of prizes, diverted the British for months. The Humphreys frigate USS "Constitution," first under Isaac Hull and then under Bainbridge, destroyed HMS "Guerrière" and "Java," two frigates of her own class; and the Humphreys frigate "United States," under Stephen Decatur, captured HMS "Macedonian." In smaller ship actions, USS "Wasp" took HMS "Frolic," and USS "Hornet" defeated HMS "Peacock." It had been years since an enemy had defeated a British naval vessel of its own class in single combat, and yet the Americans did so five times in succession during the first eight months of the war.

Early in 1813, however, the Royal Navy bottled the United States Navy in port, and it was ineffectual on the high seas thereafter. Then, having neutralized the Americans' fleet and being contemptuous of their fighting ability on land, the British in Canada were emboldened to attempt the conquest of the American Northwest, with a

combined force of regulars and Indians. Success depended on control of the Great Lakes, however, and once again the U.S. Navy performed admirably. A naval building race on Lake Ontario was more or less a stalemate. On Lake Erie, a motley fleet under Oliver Hazard Perry defeated a similar British fleet under R.H. Barclay (September 10, 1813). That victory enabled the American western commander, Gen. William Henry Harrison, to move a force of 4,500 across the lake and, at the Battle of the Thames (October 5), rout the British and their Indian allies, killing the chief Tecumseh. Efforts to follow up this victory were futile, but at least the western frontier was secure.

Perry's victory

Elsewhere, however, the United States was nearing calamity. The British, victorious over Napoleon (March–April 1814), prepared a massive blow to destroy the United States: diversionary naval raids on coastal cities, followed by invasions at Ft. Niagara, Lake Champlain, and New Orleans. Moreover, American public finances were chaotic, and popular morale was even worse. Having destroyed the Bank of the United States and alienated almost every merchant north of New York, the Republican administration had neither money nor credit. New Yorkers and New Englanders openly opposed the war, traded with the enemy, and talked of rejoining Britain (though at the Hartford Convention in December, secessionist proposals were rejected).

Yet in the actual fighting of 1814, the Americans were surprisingly successful. The only part of the British plan that worked was that for coastal raids: great destruction was wrought on the Connecticut River, Buzzard's Bay (Massachusetts), and Alexandria, Virginia; and Royal Marines took Washington and burned the public buildings there and then bombarded Baltimore (August–September). At Ft. Niagara, however, American militiamen and regulars repulsed the invasion attempt (July–September); and on Lake Champlain Capt. Thomas Macdonough, USN, assembled a fleet that, for the second time in the war, defeated a British fleet (September 11) —thus precluding invasion by that route. Finally, at the Battle of New Orleans (fought January 8, 1815, two weeks after the peace treaty had been signed), Americans under Andrew Jackson slaughtered the invading British army.

Meanwhile, the British government had heeded the sage advice of the Duke of Wellington. The hero of the Peninsular Campaign maintained that, in an unorganized frontier country like the United States, fighting could go on endlessly without either side "winning," despite the superiority of British resources. Accordingly, British negotiators at Ghent, Belgium (where talks with an American commission had been underway for several months), agreed to peace on December 24, 1814. The terms were status quo antebellum. The illusion of victory in the U.S. plus the re-establishment of peace, strengthened Madison's administration. His handpicked successor, James Monroe—former secretary of state and war—easily won the presidential election of 1816. (F.McD.)

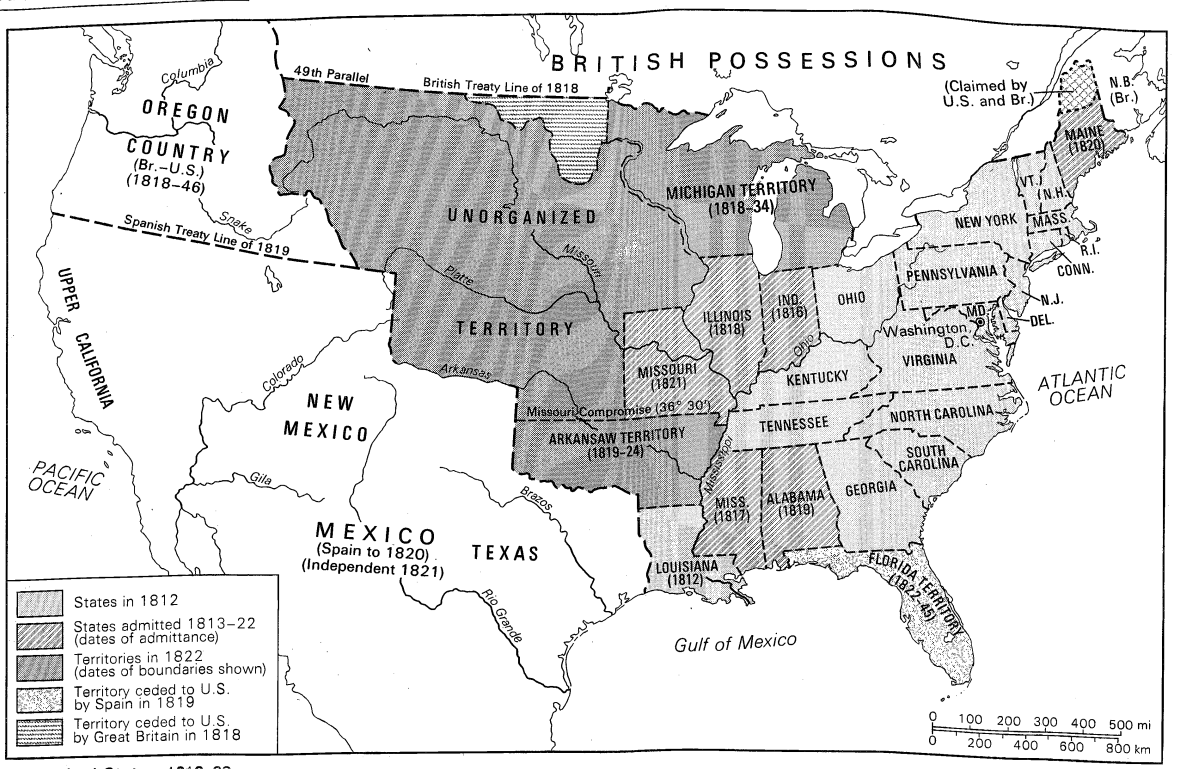
III. The United States from 1816 to 1850

THE ERA OF MIXED FEELINGS

The years between the election to the presidency of James Monroe in 1816 and of John Quincy Adams in 1824 have long been known in American history as the "Era of Good Feelings." The phrase was conceived by a Boston editor during Monroe's visit to New England early in his first term. That a representative of the heartland of Federalism could speak in such positive terms of the visit by a Southern president whose decisive election had marked not only a sweeping Republican victory but also the demise of the national Federalist Party was dramatic testimony that former foes were inclined to put aside the sectional and political differences of the past.

Effects of the War of 1812. Later scholars have questioned the strategy and tactics of the United States in the War of 1812, the war's tangible results, and even the wisdom of commencing it in the first place. To contemporary Americans, however, the striking naval victories and Andrew Jackson's victory over the British at New Orleans created a reservoir of "good feeling" on which Monroe was able to draw.

Foreign policy



Abetting the mood of nationalism was the foreign policy of the United States after the war. Florida was acquired from Spain (1819) in negotiations the success of which owed more to Andrew Jackson's indifference to such niceties as the inviolability of foreign borders and the nation's evident readiness to back him up than it did to diplomatic finesse. The Monroe Doctrine (1823) was actually a few phrases inserted in a long presidential message; its immediate effect on other nations was slight, and that on its own citizenry was impossible to gauge, yet its self-assured tone in warning off the Old World from the New reflected well the nationalist mood that swept the nation. Internally, the decisions of the Supreme Court under Chief Justice John Marshall in such cases as *McCulloch* v. *Maryland* (1819) and *Gibbons* v. *Ogden* (1824) promoted nationalism by strengthening Congress and national, or federal, power at the expense of the states. The congressional decision to charter the second Bank of the United States (1816) was explained in part by the nation's financial weaknesses, exposed by the War of 1812 and in part by the intrigues of financial interests. The readiness of Southern Jeffersonians—former strict constructionists—to support such a measure indicates, too, an amazing degree of national feeling. Perhaps the clearest sign of a new sense of national unity was the victorious Republican Party, standing in solitary splendour on the national political horizon, its long-time foes the Federalists vanished without a trace (on the national level), the Republican standard bearer elected so overwhelmingly in 1820 that it was long believed that the one electoral vote denied him had been held back only in order to preserve George Washington's record of unanimous selection.

National disunity. For all the signs of national unity and feelings of oneness, equally convincing evidence points in the opposite direction. The very Supreme Court decisions that delighted friends of strong national government infuriated its opponents, while Marshall's defense of the rights of private property was construed by critics as betraying a predilection for one kind of property over another. The growth of the West was by no means regarded as an unmixed blessing. Eastern conservatives sought to keep land prices high, speculative interests opposed a policy that would be advantageous to poor squatters, politicians feared a change in the sectional balance of power, businessmen were wary of a new section with interests unlike their own. European visitors testified that, even during the so-called Era of Good Feelings, Americans characteristically expressed scorn for their countrymen in sections other than their own.

Opponents of nationalism

The causes of the financial panic in 1819 are complex. Far clearer was the tendency of its victims to blame it on one or another hostile or malevolent interest—whether the second Bank of the United States, Eastern capitalists, selfish speculators, or perfidious politicians—each charge expressing the bad feeling that existed side by side with the good. If harmony seemed to reign on the level of national political parties, disharmony prevailed within the states. In the early-19th-century United States, local and state politics were typically waged less on behalf of great issues than for petty gain. That the goals of politics were often sordid did not mean that political contests were bland. In every section, state factions led by shrewd men waged bitter political warfare to attain or entrench themselves in power.

The most dramatic manifestation of national division was the political struggle over slavery, particularly over its spread into new territories. The Missouri Compromise of 1820 eased the threat of further disunity, at least for the time being—the sectional balance between the states was preserved; in the Louisiana Purchase, with the exception of the Territory of Missouri, slavery was to be confined to the area south of the 36°30′ line. Yet astute men knew that this compromise did not end the crisis but only postponed it. The determination by Northern and Southern senators not to be outnumbered by one

another suggests that the people continued to believe in the conflicting interests of the various great geographical sections. The weight of evidence indicates that the decade after the Battle of New Orleans was an era not of good feelings so much as it was one of mixed feelings.

THE ECONOMY

Economic growth and maturation

The American economy expanded and matured at a remarkable rate in the decades after the War of 1812. The rapid growth of the West created a great new centre for the production of grains and pork, permitting the nation's older sections to specialize in other crops. New processes of manufacture, particularly in textiles, not only accelerated an "industrial revolution" in the Northeast but, by drastically enlarging the Northern market for raw materials, helped account for a boom in Southern cotton production. If by midcentury the white South had come to regard slavery as a "positive good" rather than the "necessary evil" it had earlier held the system to be, it was due largely to the increasingly central role played by cotton in earning profits for the section; the cotton economy relied on slavery. Industrial workers organized the nation's first trade unions and even workingmen's political parties early in the period. The corporate form thrived in an era the booming capital requirements of which made older and simpler forms of attracting investment capital obsolete. Commerce became increasingly specialized, the division of labour in the disposal of goods for sale matching the increasingly sophisticated division of labour that had come to characterize production. Banks were created in unprecedented numbers, turning out quantities of paper money to meet the thriving economy's need for additional exchange. The fact that little coin or specie was actually kept in vaults to back up this paper explains both why many bank notes were discounted severely and why the state of the economy was typically unstable. A rage for speculation was widely noted by contemporaries, encouraged by an almost frighteningly rapid rise in real-estate values and in the production by state banks of large quantities of paper money on demand. Probably the most important changes occurred in the nation's system for moving people and goods. According to a number of later scholars, a "transportation revolution" was the key to almost all other economic changes in the period.

Transportation revolution. The controversial political issue of "internal improvements" focussed on a simple question: would national government finance local and state transportation projects? That some presidents hesitated, in the absence of explicit language in the Constitution urging federal support, had little effect in dampening the near-mania for such projects. More federal moneys were expended on them under Pres. Andrew Jackson (served 1829–37), who on this issue was a strict constructionist, than in the administrations of all previous presidents combined. Actually, most of the capital was raised by state governments, by private citizens, and from abroad. In their turn, turnpikes (or tollroads), canals, steamboats, and railroads inspired booms, typically featured by lack of planning, business failures, shoddy construction, profits that fell far short of expectations largely because costs exceeded anticipations, rampant corruption, and, withal, an improved transportation system that was the wonder of the world. The system did well the basic job that transportation was called on to do for a swiftly expanding region.

Waterways. Steamboats replaced rafts on the Mississippi and sharply reduced the price of Latin-American coffee in ports upstream by drastically cutting shipping time and expense. The Erie Canal, the most publicized as well as the most successful individual project constructed during the era, enabled efficient Western grain producers ultimately to undersell Eastern farmers in the distant New York City market for similar reasons. Imitators of the Erie in Pennsylvania and throughout the South and West discovered, however, that canals were poor business propositions unless cheaply and efficiently built, heavily used, and spared from drought or flooding.

Railroads. A controversy has developed among scholars over the significance of railroads in antebellum America—one interpretation regards their development as the key to the era's industrialization, while another viewpoint holds that the West would have been developed as quickly and goods moved as cheaply without them. In any case, the speed and reliability of the "iron horse" attracted investors and, at first, passengers, seeking comfort in travel, rather than freight. By midcentury, however, the advantages of the new form, for all its expense, were luring shippers of industrial and agricultural products to use the nation's thousands of miles of railroad network.

Beginnings of industrialization. Agriculture remained an important industry in all sections, although a sectional division of labour became increasingly discernible at the era's end, spurred on by transportation and mechanical developments that permitted more productive areas to undersell their competitors even in the home markets of the latter. Nevertheless, New York and Pennsylvania in the Northeast and Kentucky and Tennessee in the South remained important producers of corn, wheat, and livestock even in the 1840s. The trend, however, was in the direction of specialization. Cotton became king, not only in the South but in the nation as a whole, because its sale overseas brought in more money than the sale of all other products combined. Slavery accordingly became more entrenched, despite the sharp rise in the price of slaves that marked the era. Econometricians have used detailed statistical evidence to challenge the ideas that slavery was unprofitable and that the South's overcommitment to cash crops was ruinous to its economy in the long run. Contemporary Southerners put ever more capital into the system that promised quick profits and a "social harmony" based on the total subordination of the slaves. Slavery was a complex system, particularly in cities, marked by the hiring out of tens of thousands of skilled slave artisans and by an amazing degree of free physical movement and personal behaviour displayed by slaves in such a city as New Orleans. When most of the country referred to slavery, however, they appeared to mean the plantation system based on the labour of hundreds of field hands, though, actually, a minority of Southern whites owned slaves.

Trend toward industrial specialization

By midcentury, factories accounted for most textile production in the northeastern states, while the factory system was beginning to spread across the states of the Ohio Valley. The labour organizations that sprang up in the nation's cities were composed not of machine hands but primarily of skilled mechanics. A major purpose of this movement was to enable their membership to withstand the spread of a system associated by labour spokesmen with speedup, the devaluation of skill, low wages, child and female labour, and a general debasement of the working class. The spread of the factory system was not to be deflected, however, not even by a movement that at its height claimed a membership of 300,000 (a claim that was undocumented and undoubtedly exaggerated). The labour movement was crushed not by industrialization but rather by a depression that followed financial panics in 1837 and 1839.

These panics, like the earlier crisis in 1819, illustrate well the erratic course of the American economy during the era. Growth was not unbroken. Overspeculation, inflation, governmental inaction in some instances or chicanery in others created an atmosphere of instability that was as characteristic of the era as were its tangible achievements. Hundreds of bank and business failures, large-scale unemployment, and hard times followed in the wake of these debacles, lasting in the latter case to the middle 1840s before the economy again moved forward, more productive than ever, to resume its upward thrust.

SOCIAL DEVELOPMENTS

In the decades before the Civil War (1861–65), the civilization of the United States exerted an irresistible pull on visitors, hundreds of whom were assigned to report back to European audiences that were fascinated by the new society and insatiable for information on every facet of the "fabled republic." What appeared to intrigue the travellers above all was the uniqueness of American society. In contrast to the relatively static and well-ordered civilization of the Old World, America seemed turbulent, dynamic, and in constant flux, its people crude but vital, awesomely ambitious, optimistic, and independent. Many well-bred Europeans were evidently taken aback by the self-assurance of lightly educated American common folk. Ordinary Americans seemed unwilling to defer to anyone on the basis of rank or status.

European interest in American life

The people. American society was rapidly changing. Population grew at what to Europeans was an amazing rate—although it was the normal pace of American population growth for the antebellum decades—of between three-tenths and one-third a decade. After 1820 the rate of growth was not uniform throughout the country. New England and the Southern Atlantic states languished—the former region because it was losing settlers to the superior farmlands of the Western Reserve, the latter because its economy offered too few places to newcomers.

The special feature of the population increase of the 1830s and 1840s was the extent to which it was composed of immigrants. Whereas about 250,000 Europeans had come in the first three decades of the 19th century, ten times as many arrived between 1830 and 1850. The newcomers were overwhelmingly Irish and German. Travelling in family groups rather than as individuals, they were attracted by the dazzling opportunities of American life: abundant work, land, food, and freedom, on the one hand, and the absence of compulsory military service, on the other.

German and Irish immigrants

The German contingent did well, settling mostly on semi-improved farms and towns in the Ohio Valley, their success promoted by their relatively prosperous state on arrival and by the solid aid given newcomers by the efficient network of economic and cultural organizations founded by earlier German settlers. Irish immigrants, however, fared poorly; too poor to buy land, lacking in skills, disorganized, members of a faith considered alien and even dangerous by many native Americans, the Irish suffered various forms of ostracism and discrimination in the cities, where they tended to congregate. They provided the menial and unskilled labour needed by the expanding economy. Their low wages forced them to live in tightly packed slums, whose chief features were filth, disease, rowdyism, prostitution, drunkenness, crime, a high mortality rate, and the absence of even rudimentary toilet facilities. Adding to the woes of the first generation of Irish immigrants was the tendency of many disgruntled natives to treat the newcomers as scapegoats who allegedly threatened the future of American life and religion. In the North, only free blacks were treated worse.

Most Northern blacks possessed theoretical freedom and little else. Confined to menial occupations for the most part, they fought a losing battle against the inroads of Irish competition in northeastern cities. The struggle between the two groups erupted spasmodically into ugly street riots. The hostility shown free blacks by the general community was less violent but equally unremitting. Discrimination in politics, employment, education, housing, religion, and even in cemeteries, resulted in a cruelly oppressive system. Unlike a slave, the free Northern Negro could criticize and petition against his subjugation, but this proved fruitless in preventing the continued deterioration of his situation.

Most Americans continued to live in the country. Although improved machinery had resulted in expanded farm production and had given further impetus to the commercialization of agriculture, the way of life of independent agriculturists had changed little by midcentury. The public journals put out by some farmers insisted that their efforts were unappreciated by the larger community. Private accounts kept by farmers pointed to lives marked by unremitting toil, little cash, and little leisure. To own land was an achievement beyond the expectations of their European counterparts; but in all sections of the country, much land and agricultural wealth was concentrated in the hands of a few farmers.

Cities. Cities thrived during the era, their growth in population outstripping the spectacular growth rate of the nation as a whole. Urban expansion was not confined to New York City, Philadelphia, Charleston, or New Orleans; towns such as Syracuse, Natchez, St. Louis, Lexington, Pittsburgh, Chicago, and Cincinnati also flourished. And their importance and influence far transcended the relatively small proportions of citizens living in them. Whether on the "urban frontier" or in the older seaboard region, antebellum cities were the centres of wealth and political influence of their outlying hinterlands. New York City, with a population approaching 500,000 by midcentury, faced problems of a different

Urban expansion

order of magnitude from those confronting such cities as Poughkeepsie or Newark. Yet the pattern of change during the era was amazingly similar for eastern cities or western, old cities or new, great cities or small. The lifeblood of them all was commerce. Old ideals of economy in town government were grudgingly abandoned by the merchant, professional, and landowning elites that typically ruled. Taxes were increased in order to deal with pressing new problems and to enable the urban community of midcentury to realize new opportunities. Harbours were improved, police forces professionalized, services expanded, waste more reliably removed, streets improved, welfare activities broadened, all as the result of the statesmanship and the self-interest of property owners who were convinced that amelioration was socially beneficial.

Education and religion. Cities were also centres of educational and intellectual progress. The emergence of a relatively well-financed public educational system, free of the stigma of "pauper" or "charity" schools, and of a lively "penny press," made possible by a technological revolution, were among the most important developments. An evangelical movement that swept the Northeast and West before 1840 was largely an urban phenomenon. Cutting across Protestant denominational lines, the movement was regarded by many of its leaders as a struggle against satanic influences that thrived best in the secular atmosphere of cities. Influential merchants made generous contributions to this great "revival," which combined detailed, fiery exhortations against sin and the devil with a social message of unabashed conservatism. The urban wealthy had reason to find such a message useful.

Wealth. The brilliant French visitor Alexis de Tocqueville, in common with most contemporary observers, believed American society to be remarkably egalitarian. Most rich American men were thought to have been born poor; "self-made" was the term Henry Clay popularized for them. The society was allegedly a very fluid one, marked by the rapid rise and fall of fortunes, with room at the top accessible to all but the most humble; opportunity for success seemed freely available to all, and although material possessions were not distributed perfectly equally they were, in theory, dispersed so fairly that only a few poor and a few rich men existed at either end of the social spectrum.

Illusions about American wealth

The actuality, however, was far different. While the rich were inevitably not numerous, America by 1850 had more millionaires than all of Europe. New York, Boston, and Philadelphia had 1,000 individuals, each admitting to $100,000 or more, at a time when wealthy taxpayers kept secret from assessors the bulk of their wealth. Because an annual income of $4,000 or $5,000 enabled a man to live luxuriously, these were great fortunes indeed. Typically, the wealthiest 1 percent of urban citizens owned approximately one-half the wealth of the great cities of the Northeast, while the great bulk of their populations were worth little or nothing. In what has long been called the "Age of the Common Man," rich men were almost invariably born not into humble or poor families but into wealthy and prestigious ones. In western cities, too, class lines increasingly hardened after 1830. The common man lived in the age, but he did not dominate it. It appears that contemporaries, overimpressed with the absence of a titled aristocracy and with the democratic tone and manner of American life, failed to see the extent to which money, family, and status exerted power in the New World even as they did in the Old.

JACKSONIAN DEMOCRACY

The democratization of politics. American politics became increasingly democratic during the 1820s and 1830s. Local and state offices that had earlier been appointive became elective. The suffrage was expanded as property and other restrictions on voting were reduced or abandoned in most states. The free-hold requirement that had denied voting to all but holders of real estate was almost everywhere discarded before 1820, while the taxpaying qualification was also removed, if more slowly and gradually. In many states a printed ballot replaced the earlier system of voice voting, while the secret ballot also grew in favour. Whereas in 1800 only two states provided for the popular choice of presidential electors, by 1832 only South Carolina still left the decision to the legislature. Conventions of elected delegates increasingly replaced legislative or congressional caucuses as the agencies for making party nominations. By the latter change, a system for nominating candidates by self-appointed cliques meeting in secret was replaced by a system of open selection of candidates by democratically elected bodies.

Extension of voting rights

These democratic changes were not engineered by Andrew Jackson and his followers, as was once believed. Most of them antedated the emergence of Jackson's Democratic Party, and in New York, Mississippi, and other states some of the reforms were accomplished over the objections of the Jacksonians. There were men in all sections who feared the spread of political democracy, but by the 1830s few were willing publicly to voice such misgivings. Jacksonians effectively sought to fix the impression that they alone were champions of democracy, engaged in mortal struggle against aristocratic opponents. The accuracy of such propaganda varied according to local circumstances. The great political reforms of the early 19th century in actuality were conceived by no one faction or party. The real question about these reforms concerns the extent to which they truly represented the victory of democracy in the United States.

Small cliques or entrenched "machines" dominated democratically elected nominating conventions as earlier they had controlled caucuses. While by the 1830s the common man—of white if not of black or red skin—had come into possession of the vote in most states, the nomination process continued to be outside his control. More importantly, the policies adopted by competing factions and parties in the states owed little to ordinary voters. The legislative programs of the "regencies" and juntos that effectively ran state politics were designed primarily to reward the party faithful and to keep them in power. State parties extolled the common people in grandiloquent terms but characteristically focussed on prosaic legislation that awarded bank charters or monopoly rights to construct transportation projects to favoured insiders. That American parties would be pragmatic vote-getting coalitions, rather than organizations devoted to high political principles, was due largely to another series of reforms enacted during the era. Electoral changes that rewarded winners or plurality gatherers in small districts, in contrast to a previous system that divided a state's offices among the several leading vote getters, worked against the chances of "single issue" or "ideological" parties while strengthening parties that tried to be many things to many men.

The status of the common man

The Jacksonians. To his army of followers, Andrew Jackson was the embodiment of popular democracy. A truly self-made man of will and courage, he personified for many citizens the vast power of nature and providence, on the one hand, and the majesty of the people, on the other. His very weaknesses, such as a nearly uncontrollable temper, were political strengths. Opponents who branded him enemy to property and order only gave credence to the claim of Jackson's supporters that he stood for the poor against the rich, the plain people against the interests.

Jackson, like most of his leading antagonists, was in fact a wealthy man of conservative social beliefs. In his many volumes of correspondence he rarely referred to labour. As a lawyer and man of affairs in Tennessee prior to his accession to the presidency, he aligned himself not with have-nots but with the influential, not with the debtor but with the creditor. His reputation was created largely by astute men who propagated the belief that his party was the people's party and that the policies of his administrations were in the popular interest. Savage attacks on those policies by some wealthy critics only fortified the belief that the Jacksonian movement was radical as well as democratic.

Birth of the Democratic Party

At its birth in the middle 1820s, the Jacksonian, or Democratic Party was a loose coalition of diverse men and interests united primarily by a practical vision. They held to the twin beliefs that "Old Hickory," as Jackson was known, was a magnificent candidate and that his election to the presidency would benefit those who helped bring it about. His excellence as candidate derived in part from the fact that he appeared to have no known political principles of any sort. In this period there were no distinct parties on the national level. Jackson, Henry Clay, John C. Calhoun, John Quincy Adams, and William H. Crawford—the leading presidential aspirants—all portrayed themselves as "Republicans," followers of the party of the revered Jefferson. The National Republicans were the followers of Adams and Clay; the Whigs, who emerged in 1834, were, above all else, the party dedicated to the defeat of Jackson.

The major parties. The great parties of the era were thus created to attain victory for men rather than measures. Once in being, their leaders understandably sought to persuade the electorate of the primacy of principles. It is noteworthy, however, that former Federalists at first flocked to the new parties in largely equal numbers and that men on opposite sides of such issues as internal improvements or a national bank could unite behind Jackson. With the passage of time, the parties did come increasingly to be identified with distinctive, and opposing, political policies.

By the 1840s, Whig and Democratic congressmen voted as rival blocs. Whigs supported and Democrats opposed a weak executive, a new Bank of the United States, a high tariff, distribution of land revenues to the states, relief legislation to mitigate the effects of the depression, and federal reapportionment of House seats. Whigs voted against and Democrats approved an independent treasury, an aggressive foreign policy, and expansionism. These were important issues, capable of dividing the electorate just as they divided the major parties in Congress. Certainly it was significant that Jacksonians were more ready than their opponents to banish and use other forceful measures against the southern Indian tribes or to take punitive measures against blacks or abolitionists. But these differences do not substantiate the belief that the Democrats and Whigs were divided ideologically, with only the former somehow representing the interests of the propertyless.

Party lines earlier had been more easily broken. Jackson's firm opposition to Calhoun's policy of Nullification (*i.e.*, the right of a state to nullify a federal law) in 1828 had commanded wide support within and outside the Democratic Party. Clay's compromise solution to the crisis represented not an ideological split with Jackson but Clay's ability to conciliate and to draw political advantage from astute tactical manoeuvring.

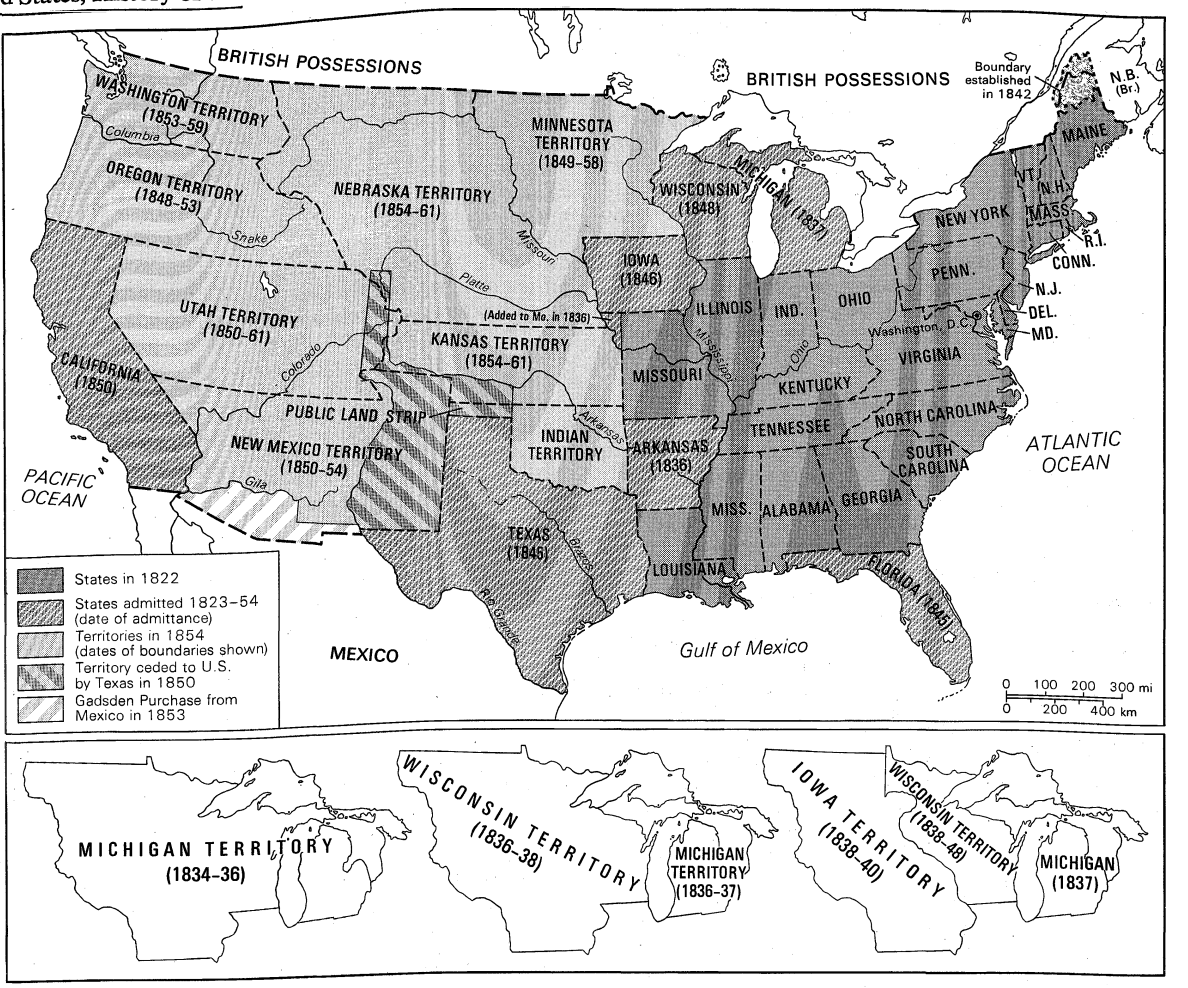
Jackson's attack on the Bank of the United States

The Jacksonians depicted their war on the second Bank of the United States as a struggle against an alleged aristocratic monster that oppressed the West, debtor farmers, and poor people generally. Jackson's decisive re-election in 1832 was once interpreted as a sign of popular agreement with the Democratic interpretation of the bank war, but recent evidence discloses that Jackson's margin was hardly unprecedented and that Democratic success may have been due to other considerations. The second bank was evidently well thought of by many Westerners, many farmers, and even by Democratic politicians who admitted to opposing it primarily not to incur the wrath of Andrew Jackson.

Jackson's reasons for detesting the bank and Nicholas Biddle, its president, were complex. Anticapitalist ideology would not explain a Jacksonian policy that replaced a quasi-national bank as repository of government funds with dozens of state and private banks, equally controlled by capitalists and even more dedicated than was Biddle to profit making. The saving virtue of these "pet banks" appeared to be the Democratic political affiliations of their directors. Perhaps the pragmatism as well as the large degree of similarity between the Democrats and Whigs is best indicated by their frank adoption of the "spoils system." The Whigs, while out of office, denounced the vile Democratic policy for turning lucrative custom-house and other posts over to supporters; but once in office they resorted to similar practices. It is of interest that the Jacksonian appointees were hardly more plebeian than were their so-called aristocratic predecessors.

Minor parties. The politics of principle was represented during the era not by the major parties but by the minor ones. The Anti-Masons aimed to stamp out an alleged aristocratic conspiracy. The Workingmen's Party called for "social justice." The Locofocos (so named after the matches they used to light up their first meeting in a hall darkened by their opponents) denounced monopolists in the Democratic Party and out. The variously named nativist parties accused the Roman Catholic Church of all manner of evil. The Liberty Party opposed the spread of slavery. All of these parties were ephemeral since they proved incapable of mounting a broad appeal that attracted masses of voters in addition to their original constituencies. The Democratic and Whig parties thrived not in spite of their opportunism but because of it, reflecting well the practical spirit that animated most American voters.

AN "AGE OF REFORM"



Historians have labelled the period 1830–50 an "age of reform." At the same time that the pursuit of the dollar was becoming so frenzied that some observers called it the nation's true religion, tens of thousands of Americans joined an array of movements dedicated to spiritual and secular uplift. There is not yet agreement as to why a rage for reform erupted in the antebellum decades. A few of the explanations cited, none of them conclusive, include an outburst of Protestant evangelicalism, a reform spirit that swept across the Anglo-American community, and a delayed reaction to the perfectionist teachings of the Enlightenment.

Variety of reform movements

What is not in question is the amazing variety of reform movements that flourished simultaneously in the northern states—women's rights, pacifism, temperance, prison reform, abolition of imprisonment for debt, an end to capital punishment, improving the conditions of the working classes, a system of universal education, the organization of communities that discarded private property, improving the condition of the insane and the congenitally enfeebled, and the regeneration of the individual were among the causes that inspired zealots during the era.

Abolitionism. There can be no doubt that antislavery, or "Abolition" as it came to be called, was the nonpareil reform. Abolition was a diverse phenomenon. At one end of its spectrum was William Lloyd Garrison, an "immediatist," who denounced not only slavery but the Constitution of the United States for tolerating the evil. His newspaper, *The Liberator,* lived up to its promise that it would not equivocate in its war against slavery. Garrison's uncompromising tone infuriated not only the South but many Northerners as well and was long treated as though it were typical of Abolitionism in general. Actually it was not. At the other end of the Abolitionist spectrum and in between stood such men and women as Theodore Weld, James Birney, Gerrit Smith, Theodore Parker, Julia Ward Howe, Lewis Tappan, Salmon P. Chase, and Lydia Maria Child, all of whom represented a variety of stances, all more conciliatory than Garrison's. James Russell Lowell, whose emotional balance has been cited by a recent biographer as proof that Abolitionists need not have been unstable, urged in contrast to Garrison that "the world must be healed by degrees."

Whether they were Garrisonians or not, Abolitionist leaders were scorned as cranks who were either working out their own personal maladjustments or as people using the slavery issue to restore a status that as an alleged New England elite they feared they were losing. The truth may be simpler. Few neurotics and few members of the northern socio-economic elite became Abolitionists. For all the movement's zeal and propagandistic successes, it was bitterly resented by many Northerners, and the masses of free whites were indifferent to its message. In the 1830s,

The United States, 1822–54.

Resentment of Abolitionists

urban mobs, typically led by "gentlemen of property and standing," stormed Abolitionist meetings, wreaking violence on the property and persons of blacks and their white sympathizers, evidently indifferent to the niceties distinguishing one Abolitionist theorist from another. It is a good question as to who betrayed greater emotional imbalance, men who attacked slavery with words or those whose hatred of such verbal attacks drove them to murder. That Abolition leaders were remarkably similar in their New England backgrounds, their Calvinist self-righteousness, their high social status, and the relative excellence of their educations are hardly evidence that their cause was either snobbish or elitist. Ordinary men were more inclined to loathe Negroes and to preoccupy themselves with personal advance within the system.

Support of reform movements. The existence of many reform movements did not mean that a vast number of Americans supported them. Abolition did poorly at the polls. Some reforms were more popular than others, but by and large none of the major movements had mass followings. The evidence indicates that few persons actually participated in these activities. Utopian communities such as Brook Farm and those in New Harmony, Indiana, and Oneida, New York, did not quite succeed in winning over many followers or in inspiring many other groups to imitate their example. The importance of these and the other movements derived neither from their size nor their achievements. Reform reflected the sensitivity of a small number of persons to imperfections in American life. In a sense, the reformers were "voices of conscience," reminding their materialistic countrymen that the American Dream was not yet a reality, pointing to the gulf between the ideal and the actuality.

Religious-inspired reform. A unique feature of antebellum reform was its religious character. Unlike European social critics of the same era, who were not only secular but often anti-religious, American perfectionists were largely inspired by religious zeal. Not that religious enthusiasm was invariably identified with social uplift; many reformers were more concerned with saving souls than with curing social ills. The merchant princes who played active roles in, and donated large sums of money to, the Sunday school unions, home missionary societies, and Bible and tract societies did so in part because the latter organizations stressed spiritual rather than social improvement while teaching the doctrine of the "contented poor." In effect, conservatives who were strongly religious found no difficulty in using religious institutions to fortify their social predilections. Radicals, on the other hand, interpreted Christianity as a call to social action, convinced that true Christian rectitude could be achieved only in struggles that infuriated the smug and the greedy. Ralph Waldo Emerson was a nice example of the American reformer's insistence on the primacy of the individual. The great goal according to him was regeneration of the human spirit rather than a mere improvement in material conditions. But Emerson and reformers like him acted on the premise that consistency was indeed a hobgoblin of small minds. For they saw no contradiction in uniting with like-minded idealists to act out or argue for a new social model. The spirit was to be revived and strengthened through forthright social action undertaken by similarly independent individuals.

EXPANSIONISM AND POLITICAL CRISIS AT MIDCENTURY

Throughout the 19th century, eastern settlers kept spilling over into the Mississippi Valley and beyond, pushing the frontier farther westward. (The American historian Frederick Jackson Turner in 1893 was to say that this ever-moving frontier was the most decisive influence on American civilization and values.) The Louisiana Purchase territory offered ample room to pioneers and

those who came after. American wanderlust, however, was not confined to that area. Throughout the era Americans in varying numbers moved into regions south, west, and north of the Louisiana Territory. Because Mexico and Great Britain held or claimed most of these outlying lands, dispute inevitably broke out between these governments and the United States.

Westward expansion. The growing nationalism of the American people was effectively engaged by Democratic presidents Jackson and James K. Polk (served 1845–49) and the expansionist Whig president John Tyler (served 1841–45) to promote their goal of enlarging the "empire for liberty." Each of these presidents performed shrewdly. Jackson waited until his last day in office to establish formal relations with the Republic of Texas, one year after his friend Sam Houston had succeeded in dissolving the ties between Mexico and the newly independent state of Texas. On the Senate's overwhelming repudiation of his proposed treaty of annexation, Tyler resorted to the use of a joint resolution so that each house could vote by a narrow margin for incorporation of Texas into the Union. In the northwest, Polk succeeded in getting the British to negotiate a treaty (1846) whereby the Oregon Country south of the 49th latitude would revert to the United States. These were precisely the terms of his earlier proposal, which had been rejected by the British. Intent on securing the Mexican territories of New Mexico and upper California and ready to resort to almost any means to do so, Polk used a border incident as a pretext for commencing a war with Mexico that the Congress did not declare and that many congressmen disliked, but appropriations for which few dared oppose.

The Mexican War

Although there is no evidence that these actions had anything like a public mandate, clearly they did not evoke widespread opposition. Nonetheless, the expansionists' assertion that Polk's election in 1844 could be construed as a popular clamour for the annexation of Texas was hardly a solid claim; Clay was narrowly defeated and would have won but for the defection from Whig ranks of small numbers of Liberty Party and nativist voters. The nationalistic idea, conceived in the 1840s by a Democratic editor, that it was the "manifest destiny" of the United States to expand westward to the Pacific undoubtedly prepared public opinion for the militant policies shortly after undertaken by Polk. It has been said that this notion represented the mood of the American people; it is safer to say that it reflected the feelings of many of the people.

Attitudes toward expansionism. Public attitudes toward expansion into Mexican territories were very much affected by the issue of slavery. Men opposed to the spread of slavery or simply not in favour of the institution joined Abolitionists in discerning a proslavery policy in the Mexican War. The great political issue of the postwar years concerned slavery in the territories. Calhoun and spokesmen for the slaveowning South argued that slavery could not be constitutionally prohibited in the Mexican cession. "Free Soilers" supported the Wilmot Proviso idea—that slavery should not be permitted in the new territory. Others supported the proposal that "squatter sovereignty" should prevail—settlers in the territories should decide the issue. Still others called for the extension westward of the 36°30′ line of demarcation for slavery that had resolved the Missouri controversy in 1820. Now, 30 years later, Henry Clay again pressed a compromise on the nation, supported dramatically by the aging Daniel Webster and by moderates in and out of the Congress. As the events in the California gold fields showed (beginning in 1849), many men had things other than political principles on their minds. The Compromise of 1850, as the separate resolutions resolving the controversy came to be known, infuriated men of high principle on both sides of the issue—Southerners resented California being admitted as a free state and the theoretical right given territories to deny existence to their "peculiar institution," while antislavery men deplored the same theoretical right of territories to permit the institution and abhorred the new, more stringent federal fugitive slave law. That Southern political leaders ceased talking secession shortly after the enactment of the compromise, indicates who truly won the political skirmish. The people probably approved the settlement—but as subsequent events were to show, the issues in controversy had not been met; they had only been deferred. (E.Pe.)

IV. Civil War, Reconstruction, and the New South, 1850–1900

PROLOGUE TO WAR, 1850–60

Before the Civil War, the United States experienced a whole generation of nearly unremitting political crisis. Underlying the problem was the fact that America in the early 19th century had been a country, not a nation. The major functions of government—those relating to education, transportation, health, and public order—were performed on the state or local level, and little more than a loose allegiance to the government in Washington, a few national institutions such as churches and political parties, and a shared memory of the Founding Fathers of the republic tied the country together. Within this loosely structured society every section, every state, every locality, every group could pretty much go its own way.

Pre-Civil War changes that linked the states more closely

Gradually, however, changes in technology and in the economy were bringing all the elements of the country into steady and close contact. Improvements in transportation—first canals, then toll roads, and especially railroads—broke down isolation and encouraged the boy from the country to wander to the city, the farmer from New Hampshire to migrate to Iowa. Improvements in the printing press, which permitted the publication of penny newspapers, and the development of the telegraph system broke through the barriers of intellectual provincialism and made everybody almost instantaneously aware of what was going on throughout the country. As the railroad network proliferated, it had to have central direction and control; and national railroad corporations—the first true "big businesses" in the United States—emerged to provide order and stability.

For many Americans the wrench from a largely rural, slow-moving, fragmented society in the early 1800s to a bustling, integrated, national social order in the midcentury was an abrupt and painful one; and they often resisted it. Sometimes resentment against change manifested itself in harsh attacks upon those who appeared to be the agents of change—especially the newly arrived immigrants, who seemed to personify the forces that were altering the older America. Vigorous nativist movements appeared in most cities during the 1840s; but not until the 1850s, when the huge numbers of Irish and German immigrants of the previous decade became eligible to vote, did the antiforeign fever reach its peak. Directed both against immigrants and against the Catholic Church, to which so many of them belonged, the so-called Know-Nothing movement emerged as a powerful political force in 1854 and increased the resistance to change.

Sectionalism and slavery. A more enduring manifestation of hostility toward the nationalizing tendencies in American life was the reassertion of strong feelings of sectional loyalty. New Englanders felt themselves threatened by the rising West, which drained off the ablest and most vigorous members of the labour force and also, once the railroad network was complete, produced grain crops that undersold the products of the poor New England hill country. The West, too, developed a strong sectional feeling, blending its sense of its own uniqueness, its feeling of being looked down on as raw and uncultured, and its feeling that it was being exploited by the businessmen of the East.

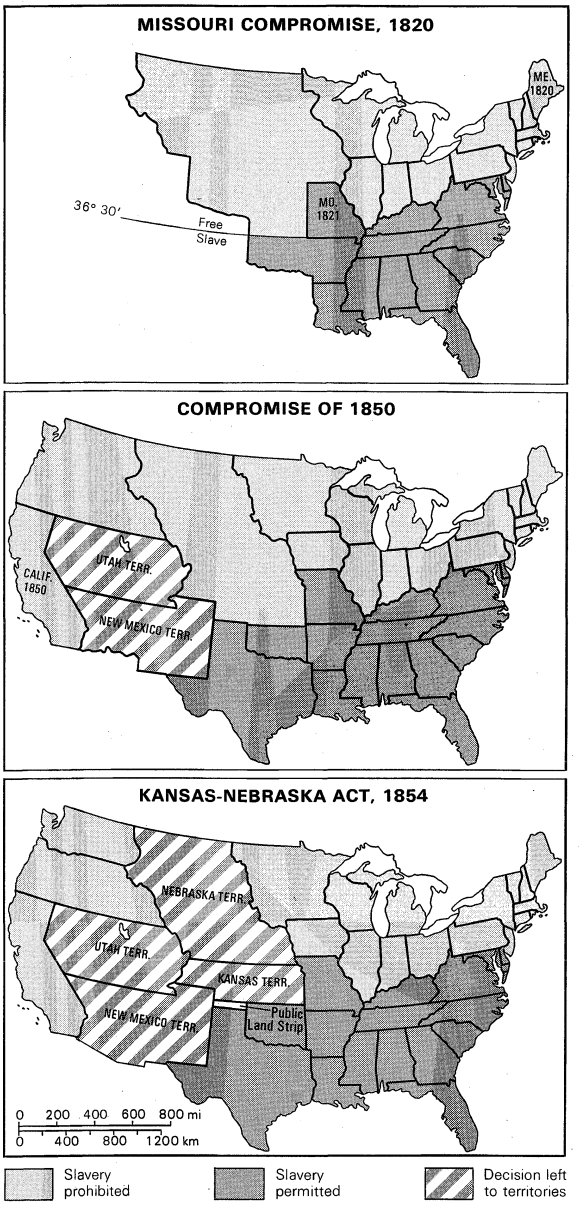
Reassertion of sectional loyalty

The most conspicuous and distinctive section, however, was the South—an area set apart by climate; by a plantation system designed for the production of such staple crops as cotton, tobacco, and sugar; and, especially, by the persistence of Negro slavery, which had been abolished or prohibited in all other parts of the United States. It should not be thought that all or even most white Southerners were directly involved in the section's "peculiar institution." Indeed, in 1850 there were only 347,525 slaveholders out of a total white population of about 6,000,000 in the slave states. Half of these owned four

slaves or less and could not be considered planters. In the entire South there were fewer than 1,800 persons who owned more than 100 slaves.

Nevertheless, slavery did give a distinctive tone to the whole pattern of Southern life. If the large planters were few, they were also wealthy, prestigious, and powerful; often they were the political as well as the economic leaders of their section; and their values pervaded every stratum of Southern society. Far from opposing slavery, small farmers thought only of the possibility that they too might, with hard work and good fortune, some day join the ranks of the planter class—to which they were closely connected by ties of blood, marriage, and friendship. Behind this virtually unanimous support of slavery lay the universal belief—shared by many whites in the North and West as well—that blacks were an innately inferior people who had risen only to a state of barbarism in their native Africa and who could live in a civilized society only if disciplined through slavery. Though by 1860 there were in fact about 250,000 free blacks in the South, most Southern whites resolutely refused to believe that the slaves, if freed, could ever coexist peacefully with their former masters. With shuddering horror they pointed to an insurrection of blacks that had occurred in Santo Domingo, to a brief slave rebellion led by the Negro Gabriel in Virginia in 1800, to a plot of Charleston, South Carolina, blacks headed by Denmark Vesey in 1822, and, especially, to a bloody and determined Virginia insurrection led by Nat Turner in 1831 as evidence that black persons had to be kept under iron control. Facing increasing opposition to slavery outside their section, Southerners developed an elaborate "proslavery argument," defending the institution on biblical, economic, and sociological grounds.

Black insurrections



A decade of political crises. In the early years of the republic, sectional differences had existed, but it had been possible to reconcile or ignore them because distances were great, communication was difficult, and the powerless national government had almost nothing to do. The revolution in transportation and communication, however, eliminated much of the isolation, and the victory of the United States in its brief war with Mexico left the national government with problems that required action.

Popular sovereignty. The Compromise of 1850 was an uneasy patchwork of concessions to all sides that began to fall apart as soon as it was enacted. Most unsatisfactory of all in the long run would be the principle of popular sovereignty, which was bound to make of each territory a battleground where the supporters of the South would contend with the defenders of the North and West.

The seriousness of those conflicts became clear in 1854, when Stephen A. Douglas introduced his Kansas–Nebraska bill in Congress. Unconcerned over the moral issue of slavery and desiring only to get on with the settling of the West and the construction of a transcontinental railroad, Douglas knew that the Southern senators would block the organization of Kansas as a free territory, as had been provided by the Missouri Compromise. Recognizing that the North and West had outstripped their section in population and hence in the House of Representatives, the Southerners clung desperately to an equality of votes in the Senate and were not disposed to welcome any new free states. Accordingly, Douglas thought that the doctrine of popular sovereignty, which had been applied to the territories gained from Mexico, might provide an escape from this impasse; and with the backing of Pres. Franklin Pierce (served 1853–57), he bullied, wheedled, and bluffed congressmen into passing his bill.

Polarization over slavery. Northern sensibilities were outraged. Disliking slavery, Northerners had made few efforts to change the South's "peculiar institution" so long as the republic was loosely articulated. (Indeed, when William Lloyd Garrison began his *Liberator* in 1831, urging the immediate and unconditional emancipation of all slaves, he had only a tiny following; and a few years later he had actually been mobbed in Boston.)

But with the sections, perforce, being drawn closely together, Northerners could no longer profess indifference to the South and its institutions. Sectional differences, centring on the issue of slavery, began to appear in every American institution. During the 1840s the major national religious denominations, such as the Methodists and the Presbyterians, split over the slavery question. The Whig Party, which had once allied the conservative businessmen of the North and West with the planters of the South, divided and virtually disappeared after the election of 1852. When Douglas' bill opened up to slavery Kansas and Nebraska—land that had long been reserved for the westward expansion of the free states—Northerners began to organize into an antislavery political party, called in some states the Anti-Nebraska Democratic Party, in others the People's Party, but in most places, the Republican Party.

Events of 1855 and 1856 further exacerbated relations between the sections and strengthened this new party. Kansas, once organized by Congress, became the field of battle between the free and the slave states in a contest in which concern over slavery was mixed with land speculation and office seeking. A virtual civil war broke out, with rival free- and slave-state legislatures both claiming legitimacy. During the turmoil, John Brown, a free-state partisan, on May 24–25, 1856, led a small party in a

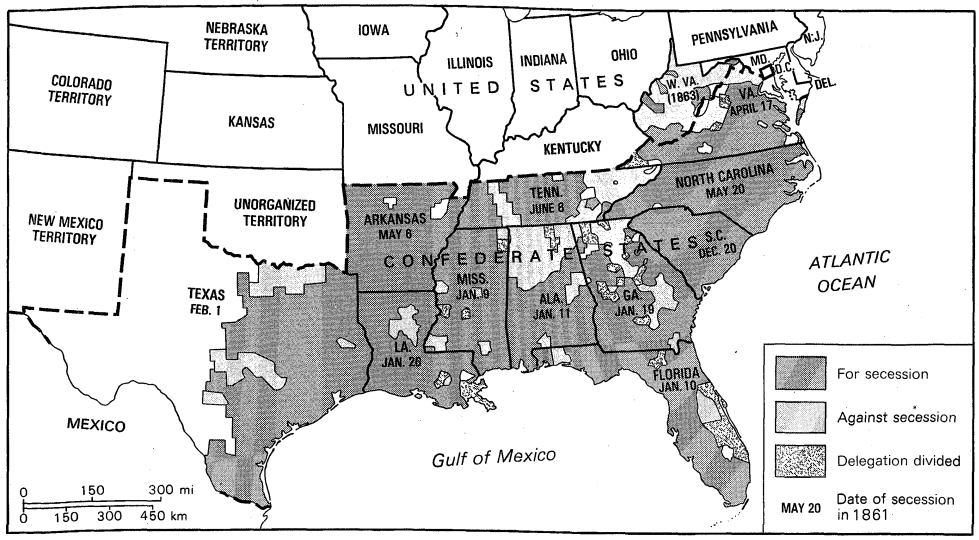
raid upon some proslavery settlers on Pottawatomie Creek, murdered five men in cold blood, and left their gashed and mutilated bodies as a warning to the slaveholders. As if to show that atrocities could be committed by both sides, almost simultaneously (May 22) a South Carolina congressman brutally attacked Sen. Charles Sumner of Massachusetts at his desk in the Senate chamber because of a speech he had given that presumably insulted the Carolinian's "honour." The 1856 presidential election made it clear that voting was becoming polarized along sectional lines. Though James Buchanan, the Democratic nominee, was elected, John C. Frémont, the Republican candidate, received a majority of the votes in the free states.

The following year the Supreme Court of the United States tried to solve the sectional conflicts that had baffled both the Congress and the President. Hearing the case of Dred Scott, a Missouri slave who claimed freedom on the ground that his master had taken him to live in free territory, the majority of the court, headed by Chief Justice Roger B. Taney, found that Negroes were not citizens of the United States and that Scott hence had no right to bring suit before the court. Taney also concluded that the U.S. laws prohibiting slavery in the territory were unconstitutional. Two Northern antislavery judges on the court bitterly attacked Taney's logic and his conclusions. Acclaimed in the South, the Dred Scott decision was condemned and repudiated throughout the North.

The Dred Scott case

By this point many Americans, North and South, had come to the conclusion that slavery and freedom could not much longer coexist in the United States. For Southerners the answer was withdrawal from a Union that no longer protected their rights and interests; they had talked of it as early as the Nashville Convention of 1850, when the compromise measures were under consideration, and now more and more Southerners favoured secession. For Northerners the remedy was to change the social institutions of the South; few advocated immediate or complete emancipation of the slaves, but many felt that the South's "peculiar institution" must be contained. In 1858 William H. Seward, the leading Republican of New York, spoke of an "irrepressible conflict" between freedom and slavery; and in Illinois a rising Republican politician, Abraham Lincoln, who unsuccessfully contested Douglas for a seat in the Senate, announced that "this government cannot endure, permanently half *slave* and half *free*."



That it was not possible to end the agitation over slavery became further apparent in 1859 when John Brown, fresh from his crimes in Kansas, on the night of October 16, staged a raid on Harpers Ferry, Virginia (now in West Virginia), designed to free the slaves and, apparently, to help them begin a guerrilla war against the Southern whites. Though Brown was promptly captured and Virginia slaves gave no heed to his appeals, Southerners feared that this was the beginning of organized Northern efforts to undermine their social system. The fact that Brown, who may have been partially insane, was an inept strategist did not lessen Northern admiration for him.

The presidential election of 1860 occurred, therefore, in an atmosphere of great tension. Southerners, determined that their rights should be guaranteed by law, insisted upon a Democratic candidate willing to protect slavery in the territories; and they rejected Stephen A. Douglas, whose popular-sovereignty doctrine left the question in doubt, in favour of John C. Breckinridge. Douglas, backed by most of the Northern and border-state Democrats, ran on a separate Democratic ticket. Elderly conservatives, who deplored all agitation of the sectional questions but advanced no solutions, offered John Bell as candidate of the Constitutional Union Party. Republicans, confident of success, passed over the claims of Seward, who had accumulated too many liabilities in his long public career, and nominated Lincoln instead. Voting in the subsequent election was along markedly sectional patterns, with Republican strength confined almost completely to the North and West. Though Lincoln received only a plurality of the popular vote, he was an easy winner in the electoral college.

Election of 1860

SECESSION AND CIVIL WAR, 1860–65

The coming of the war. In the South, Lincoln's election was taken as the signal for secession, and on December 20 South Carolina became the first state to withdraw from the Union. Promptly the other states of the lower South followed. Feeble efforts on the part of Buchanan's administration to check secession failed, and one by one most of the federal forts in the Southern states were taken over by secessionists. Meanwhile, strenuous efforts in Washington to work out another compromise failed.

(The most promising plan was John J. Crittenden's proposal to extend the Missouri Compromise line, dividing free from slave states, to the Pacific.)

Neither extreme Southerners, now intent upon secession, nor Republicans, intent upon reaping the rewards of their hard-won election victory, was really interested in compromise. On February 4, 1861—a month before Lincoln could be inaugurated in Washington—six Southern states (South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana) sent representatives to Montgomery, Alabama, to set up a new independent government. Delegates from Texas soon joined them. With Jefferson Davis of Mississippi at its head, the Confederate States of America came into being, set up its own bureaus and offices, issued its own money, raised its own taxes, and flew its own flag. Not until May 1861, after hostilities had broken out and Virginia had seceded, did the new government transfer its capital to Richmond.

Formation of the Confederacy

Faced with a *fait accompli*, Lincoln when inaugurated was prepared to conciliate the South in every way but one; he would not recognize that the Union could be divided. The test of his determination came early in his administration, when he learned that the Federal troops under Maj. Robert Anderson in Ft. Sumter, South Carolina—then one of the few military installations in the South still in Federal hands—had to be promptly supplied or withdrawn. After agonized consultation with his cabinet, Lincoln determined that supplies must be sent even if doing so provoked the Confederates into firing the first shot. On April 12, 1861, just before Federal supply ships could reach the beleagured Anderson, Confederate guns in Charleston opened fire upon Fort Sumter, and the war began.

The course of the war. For the next four years the Union and the Confederacy were locked in conflict—by far the most titanic waged in the Western Hemisphere. (The military engagements of the struggle are traced in the article CIVIL WAR, U.S.; here it is enough to suggest the general course of the war.)

Relative strengths. The Union clearly had the advantage in manpower and economic resources. It had 23 states as against 11 in the Confederacy (the states of the upper South—Virginia, Arkansas, Tennessee, North Carolina—having seceded promptly after the firing on Ft. Sumter and Lincoln's call for troops). Omitting Kentucky and Missouri, which were divided in loyalty between North and South, the Union had 20,700,000 inhabitants; the Confederacy, 9,105,000. The North in 1860 had 110,000 manufacturing establishments with 1,300,000 industrial workers, to the South's 18,000 factories with 110,000 workers. Of the 31,256 miles of railroad in the United States in 1861, only 9,283, or less than 30 percent, were in the South. Yet the Confederacy had the advantage of fighting on the defensive, with interior lines, so that it required fewer men; it began the war with high morale because it was fighting for the positive cause of its freedom, while the North usually saw itself in the negative role of subjector. Infused with a military tradition, Southern young men were accustomed to handling firearms, and Southern generals were among the finest products of West Point.

Northern and Southern policies. The policies pursued by the governments of Abraham Lincoln and Jefferson Davis were astonishingly similar. Both presidents at first relied upon volunteers to man the armies, and both administrations were poorly prepared to arm and equip the hordes of young men who flocked to the colours in the initial stages of the war. As the fighting progressed, both governments reluctantly resorted to conscription—the Confederates first, in early 1862, and the Federal government more slowly, with an ineffective measure of late 1862 followed by a more stringent law in 1863. Both governments pursued an essentially laissez-faire policy in economic matters, with little effort to control prices, wages, or profits. Only the railroads were subject to close government regulation in both regions; and the Confederacy, in constructing some of its own powder mills, made a few experiments in "state socialism." Neither Lincoln's nor Davis' administrations knew how to cope with financing the war; neither developed an effective system of taxation until late in the conflict, and both relied heavily upon borrowing. Faced with a shortage of funds, both governments were obliged to turn to the printing press and to issue fiat money; the United States government issued $432,000,000 in "greenbacks" (as this irredeemable, non-interest-bearing paper money was called), while the Confederacy printed over $1,554,000,000 in such paper currency. In consequence, both sections experienced runaway inflation, which was much more drastic in the South, where, by the end of the war, flour sold at $1,000 a barrel.

Manning and financing the armies

Even toward slavery, the root cause of the war, the policies of the two warring governments were surprisingly similar. The Confederate Constitution, which was in most other ways similar to that of the United States, expressly guaranteed the institution of Negro slavery. Despite pressure from Abolitionists, Lincoln's administration was not disposed to disturb the "peculiar institution," if only because any move toward emancipation would upset the loyalty of Delaware, Maryland, Kentucky, and Missouri—the four slave states that remained in the Union.

Moves toward emancipation. Gradually, however, under the pressure of war, both governments moved to end slavery. Lincoln came to see that emancipation of the blacks would favourably influence European opinion

toward the Northern cause, would deprive the Confederates of their productive labour force on the farms, and would add much-needed recruits to the Federal armies. In September 1862 he issued his preliminary proclamation of emancipation, promising to free all slaves in rebel territory by January 1, 1863, unless those states returned to the Union; and when the Confederates remained obdurate, he followed it with his promised final proclamation. A natural accompaniment of emancipation was the use of black troops, and by the end of the war the number of blacks who served in the Federal armies totalled 178,895. Uncertain of the constitutionality of his Emancipation Proclamation, Lincoln urged Congress to abolish slavery by constitutional amendment; but this was not done until January 31, 1865, and the actual ratification did not take place until after the war.

Lincoln's Emancipation Proclamation

Meanwhile the Confederacy, though much more slowly, was also inevitably drifting in the direction of emancipation. The South's desperate need for troops caused many military men, including Robert E. Lee, to demand the recruitment of blacks; finally, in March 1865 the Confederate congress authorized the raising of Negro regiments. Though a few blacks were recruited for the Confederate armies, none actually served in battle because surrender was at hand. In yet another way Davis' government showed its awareness of slavery's inevitable end, when, in a belated diplomatic mission to seek assistance from Europe, the Confederacy in March 1865 promised to emancipate the slaves in return for diplomatic recognition. Nothing came of the proposal, but it is further evidence that by the end of the war both North and South realized that slavery was doomed.

Sectional dissatisfaction. As war leaders, both Lincoln and Davis came under severe attack in their own sections. Both had to face problems of disloyalty. In Lincoln's case, the Irish immigrants to the Eastern cities and the Southern-born settlers of the Northwestern states were especially hostile to the Negro and, therefore, to emancipation, while many other Northerners became tired and disaffected as the war dragged on interminably. Residents of the Southern hill country, where slavery never had much of a foothold, were similarly hostile toward Davis. In order to wage war, both presidents had to strengthen the powers of central government, thus further accelerating the process of national integration that had brought on the war. Both administrations were, in consequence, vigorously attacked by state governors, who resented the encroachment upon their authority and who strongly favoured local autonomy.

Disloyalty to both presidents

The extent of Northern dissatisfaction was indicated in the congressional elections of 1862, when Lincoln and his party sustained a severe rebuff at the polls and the Republican majority in the House of Representatives was drastically reduced. Similarly in the Confederacy the congressional elections of 1863 went so strongly against the administration that Davis was able to command a majority for his measures only through the continued support of representatives and senators from the states of the upper South, which were under control of the Federal Army and consequently unable to hold new elections.

As late as August 1864, Lincoln despaired of his re-election to the presidency and fully expected that the Democratic candidate, Gen. George B. McClellan, would defeat him. Davis, at about the same time, was openly attacked by Alexander H. Stephens, the vice president of the Confederacy. But Federal military victories, especially William T. Sherman's capture of Atlanta, greatly strengthened Lincoln; and as the war came to a triumphant close for the North, he attained new heights of popularity. Davis' administration, on the other hand, lost support with each successive defeat, and in January 1865 the Confederate Congress insisted that he make Robert E. Lee the supreme commander of all Southern forces. (Some, it is clear, would have preferred to make the general dictator.)

RECONSTRUCTION, 1865–77

Reconstruction under Lincoln. The original Northern objective in the Civil War was the preservation of the Union—a war aim with which virtually everybody in the free states agreed. As the fighting progressed, the Lincoln government concluded that emancipation of the slaves was necessary in order to secure military victory; and thereafter freedom became a second war aim for the members of the Republican Party. The more radical members of that party—men like Charles Sumner and Thaddeus Stevens—believed that emancipation would prove a sham unless the government guaranteed the civil and political rights of the freedmen; and equality of all citizens before the law became a third war aim for this powerful faction. The fierce controversies of the Reconstruction era raged over which of these objectives should be insisted upon and how these goals should be secured.

Northern war aims

Lincoln's plan. Lincoln himself had a flexible and pragmatic approach to Reconstruction, insisting only that the Southerners, when defeated, pledge future loyalty to the Union and emancipate their slaves. As the Southern states were subdued, he appointed military governors to supervise their restoration. The most vigorous and effective of these appointees was Andrew Johnson, whose success in reconstituting a loyal government in Tennessee led to his nomination as vice president on the Republican ticket with Lincoln in 1864. In December 1863 Lincoln announced a general plan for the orderly reconstruction of the Southern states, promising to recognize the government of any state that pledged to support the Constitution and the Union and to emancipate the slaves if it was backed by at least 10 percent of the number of voters in the 1860 presidential election. In both Arkansas and Tennessee loyal governments were formed under Lincoln's plan; and they sought readmission to the Union with the seating of their senators and representatives in Congress.

The Radicals' plan. Radical Republicans were outraged at these procedures, which savoured of executive usurpation of Congressional powers, which required only minimal changes in the Southern social system and which left political power essentially in the hands of the same Southerners who had led their states out of the Union. The Radicals put forth their own plan of Reconstruction in the Wade–Davis bill, which Congress passed on July 2, 1864; it required not 10 percent but a majority of the white male citizens in each Southern state to participate in the reconstruction process, and it insisted upon an oath of past, not just of future, loyalty. Finding the bill too rigorous and inflexible, Lincoln pocket-vetoed it; and the Radicals bitterly denounced him. During the 1864–65 session of Congress, they in turn defeated the president's proposal to recognize the Louisiana government organized under his 10 percent plan. At the time of Lincoln's assassination, therefore, the President and the Congress were at loggerheads over Reconstruction.

Reconstruction under Johnson. At first it seemed that Andrew Johnson might be able to work more cooperatively with Congress in the process of Reconstruction. A former representative and a former senator, he understood congressmen. A loyal Unionist who had stood by his country even at the risk of his life when Tennessee seceded, he was certain not to compromise with secession; and his experience as military governor of that state showed him to be politically shrewd and tough toward the slaveholders. "Johnson, we have faith in you," Radical Benjamin F. Wade assured the new president on the day he took the oath of office. "By the gods, there will be no trouble running the government."

Johnson's policy. Such Radical trust in Johnson proved misplaced. The new president was, first of all, himself a Southerner. He was a Democrat who looked for the restoration of his old party partly as a step toward his own re-election to the presidency in 1868. And, most important of all, Johnson shared the white Southerners' attitude toward the Negro, considering black men innately inferior and unready for equal civil or political rights. On May 29, 1865, Johnson made his policy clear when he issued a general proclamation of pardon and amnesty for most Confederates and authorized the provisional governor of North Carolina to proceed with the reorganization

of that state. Shortly afterward he issued similar proclamations for the other former Confederate states. In each case a state constitutional convention was to be chosen by the voters who pledged future loyalty to the U.S. Constitution. The conventions were expected to repeal the ordinances of secession, to repudiate the Confederate debt, and to accept the Thirteenth Amendment, abolishing slavery. The President did not, however, require them to enfranchise the blacks.

"Black Codes." Given little guidance from Washington, Southern whites turned to the traditional political leaders of their section for guidance in reorganizing their governments; and the new regimes in the South were suspiciously like those of the antebellum period. To be sure, slavery was abolished; but each reconstructed Southern state government proceeded to adopt a "Black Code," regulating the rights and privileges of freedmen. Varying from state to state, these codes in general treated blacks as inferiors, relegated to a secondary and subordinate position in society. Their right to own land was restricted, they could not bear arms, and they might be bound out in servitude for vagrancy and other offenses. The conduct of white Southerners indicated that they were not prepared to guarantee even minimal protection of Negro rights. In riots in Memphis (May 1866) and New Orleans (July 1866), black persons were brutally assaulted and promiscuously killed.

Civil rights legislation. Watching these developments with forebodings, Northern Republicans during the Congressional session of 1865–66 inevitably drifted into conflict with the President. Congress attempted to protect the rights of blacks by extending the life of the Freedmen's Bureau; but Johnson vetoed the bill. An act to define and guarantee the blacks' basic civil rights met a similar fate, but Republicans succeeded in passing it over the President's veto. While the President, from the porch of the White House, denounced the leaders of the Republican Party as "traitors," Republicans in Congress tried to formulate their own plan to reconstruct the South. Their first effort was the Fourteenth Amendment, which guaranteed the basic civil rights of all citizens, regardless of colour, and which tried to persuade the Southern states to enfranchise blacks by threatening to reduce their representation in Congress.

Conflict between Republicans and Johnson

The President, the Northern Democrats, and the Southern whites spurned this Republican plan of Reconstruction. Johnson tried to organize his own political party in the National Union Convention, which met in Philadelphia in August 1866; and in August and September he visited many Northern and Western cities in order to defend his policies and to attack the Republican leaders. At the President's urging, every Southern state except Tennessee overwhelmingly rejected the Fourteenth Amendment.

Victorious in the fall elections, Congressional Republicans moved during the 1866–67 session to devise a second, more stringent program for reconstructing the South. After long and acrimonious quarrels between Radical and moderate Republicans, the party leaders finally produced a compromise plan in the First Reconstruction Act of 1867. Expanded and clarified in three supplementary Reconstruction acts, this legislation swept away the regimes the President had set up in the South, put the former Confederacy back under military control, called for the election of new constitutional conventions, and required the constitutions adopted by these bodies to include both Negro suffrage and the disqualification of former Confederate leaders from officeholding. Under this legislation, new governments were established in all the former Confederate states (except Tennessee, which had already been readmitted); and by July 1868 Congress agreed to seat senators and representatives from Alabama, Arkansas, Florida, Louisiana, North Carolina, and South Carolina. By July 1870 the remaining Southern states had been similarly reorganized and readmitted.

Suspicious of Andrew Johnson, Republicans in Congress did not trust the President to enforce the Reconstruction legislation they passed over his repeated vetoes, and they tried to deprive him of as much power as possible. Congress limited the President's control over the army by requiring that all his military orders be issued through the general of the army, Ulysses S. Grant, who was believed loyal to the Radical cause; and in the Tenure of Office Act (1867) they limited the President's right to remove appointive officers. When Johnson continued to do all he could to block the enforcement of Radical legislation in the South, the more extreme members of the Republican Party demanded his impeachment. The President's decision in February 1868 to remove the Radical secretary of war Edwin M. Stanton from the Cabinet, in apparent defiance of the Tenure of Office Act, provided a pretext for impeachment proceedings. The House of Representatives voted to impeach the President, and after a protracted trial the Senate acquitted him by the margin of only one vote.

Impeachment of Johnson

The South during Reconstruction. Contrary to conventional stereotypes, the Southern states were relatively tranquil during the Reconstruction period. Exhausted and bankrupt after four years of war, most Southern whites wanted nothing more than to return to their farms and try to make a living. Most of the former slaves also settled down to quiet lives of labour on the farms after some initial wandering about to test their freedom. Indeed, the most important developments of the Reconstruction era were not the highly publicized political contests but the slow, almost imperceptible changes that occurred in Southern society. Blacks could now legally marry, and they set up conventional and usually stable family units; they quietly seceded from the white churches and formed their own religious organizations, which became centres for the black community. Without land or money, most freedmen had to continue working for white masters; but they were now unwilling to labour in gangs or to live in the old slave quarters under the eye of the plantation owner.

Sharecropping gradually became the accepted labour system in most of the South—planters, short of capital, favoured the system because it did not require them to pay cash wages; blacks preferred it because they could live in individual cabins on the tracts they rented and because they had a degree of independence in choosing what to plant and how to cultivate. The section as a whole, however, was desperately poor throughout the Reconstruction era; and a series of disastrously bad crops in the late 1860s, followed by the general agricultural depression of the 1870s, hurt both whites and blacks.

Southern Reconstruction governments

The governments set up in the Southern states under the congressional program of Reconstruction were, contrary to traditional clichés, fairly honest and effective. Though the period has sometimes been labelled "Black Reconstruction," the Radical governments in the South were never dominated by blacks. There were no black governors, only two black senators and a handful of congressmen, and only one legislature controlled by blacks. Those blacks who did hold office appear to have been about equal in competence and honesty to the whites. It is true that these Radical governments were expensive, but large state expenditures were necessary to rebuild after the war and to establish—for the first time in most Southern states—a system of common schools. Corruption there certainly was, though nowhere on the scale of the Tweed Ring, which was simultaneously looting New York City; but it is not possible to show that Republicans were more guilty than Democrats, or blacks than whites, in the scandals that did occur.

Though some Southern whites in the mountainous regions and some planters in the rich bottomlands were willing to cooperate with the blacks and their Northern-born "carpetbagger" allies in these new governments, there were relatively few such "scalawags"; the mass of Southern whites remained fiercely opposed to Negro political, civil, and social equality. Sometimes their hostility was expressed through such terrorist organizations as the Ku Klux Klan, which sought to punish so-called uppity Negroes and to drive their white collaborators from the South. More frequently it was manifested through support of the Democratic Party, which gradually regained

its strength in the South and waited for the time when the North would tire of supporting the Radical regimes and would withdraw federal troops from the South.

The Grant administrations, 1869–77. During the two administrations of President Grant there was a gradual attrition of Republican strength. As a politician the President was passive, exhibiting none of the brilliance he had shown on the battlefield. His administration was tarnished by the dishonesty of his subordinates, whom he loyally defended. As the older Radical leaders—men like Sumner, Wade, and Stevens—died, leadership in the Republican Party fell into the hands of technicians like Roscoe Conkling and James G. Blaine, men devoid of the idealistic fervour that had marked the early Republicans.

Weakening of the Radicals

At the same time, many Northerners were growing tired of the whole Reconstruction issue and were weary of the annual outbreaks of violence in the South that required repeated use of federal force.

Efforts to shore up the Radical regimes in the South grew increasingly unsuccessful. The adoption of the Fifteenth Amendment (1870), prohibiting discrimination in voting on account of race, had little effect in the South, where terrorist organizations and economic pressure from planters kept blacks from the polls. Nor were three Force Acts passed by the Republicans (1870–71), giving the President the power to suspend the writ of habeas corpus and imposing heavy penalties upon terroristic organizations, in the long run more successful. If they succeeded in dispersing the Ku Klux Klan as an organization, they also drove its members, and their tactics, more than ever into the Democratic camp.

Growing Northern disillusionment with Radical Reconstruction and with the Grant administration became evident in the Liberal Republican movement of 1872, which resulted in the nomination of the erratic Horace Greeley for president. Though Grant was overwhelmingly reelected, the true temper of the country was demonstrated in the congressional elections of 1874, which gave the Democrats control of the House of Representatives for the first time since the outbreak of the Civil War. Despite Grant's hope for a third term in office, most Republicans recognized by 1876 that it was time to change both the candidate and his Reconstruction program, and the nomination of Rutherford B. Hayes of Ohio, a moderate Republican of high principles and of deep sympathy for the South, marked the end of the Radical domination of the Republican Party.

The circumstances surrounding the disputed election of 1876 strengthened Hayes's intention to work with the Southern whites, even if it meant abandoning the few Radical regimes that remained in the South. In an election marked by widespread fraud and many irregularities, the Democratic candidate, Samuel J. Tilden, received the majority of the popular vote; but the vote in the electoral college was long in doubt. In order to resolve the impasse, Hayes's lieutenants had to enter into agreement with Southern Democratic congressmen, promising to withdraw the remaining federal troops from the South, to share the Southern patronage with Democrats, and to favour that section's demands for federal subsidies in the building of levees and railroads.

Restoration of Southern "home rule"

Hayes's inauguration marked, for practical purposes, the restoration of "home rule" for the South—*i.e.*, that the North would no longer interfere in Southern elections to protect the blacks and that the Southern whites would again take control of their state governments.

THE NEW SOUTH, 1877–90

The era of conservative domination, 1877–90. The Republican regimes in the Southern states began to fall as early as 1870; by 1877 they had all collapsed. For the next 13 years the South was under the leadership of white Democrats whom their critics called "Bourbons" because, like the French royal family, they supposedly had learned nothing and forgotten nothing from the revolution they had experienced. For the South as a whole, the characterization is neither quite accurate nor quite fair. To be sure, Democrats in South Carolina, led by former Confederate general Wade Hampton, seemed to desire nothing so much as the restoration of the antebellum plantation way of life. But in most Southern states the new political leaders represented less the planters than the rising Southern business community, interested in railroads, cotton textiles, and urban land speculation.

Even on racial questions the new Southern political leaders were not so reactionary as the label Bourbon might suggest. Though whites were in the majority in all but two of the Southern states, the conservative regimes did not attempt to disfranchise the Negroes. Partly their restraint was caused by fear of further federal intervention; chiefly, however, it stemmed from a conviction on the part of conservative leaders that they could control the black voters.

Indeed, Negro votes were sometimes of great value to these regimes, which favoured the businessmen and planters of the South at the expense of the small white farmers. These "Redeemer" governments sharply reduced or even eliminated the programs of the state governments that benefitted poor people. The public school system was starved for money; in 1890 the per capita expenditure in the South for public education was only 97 cents, as compared with $2.24 in the country as a whole. The care of state prisoners, the insane, and the blind was also neglected; and measures to safeguard the public health were rejected. At the same time these conservative regimes were often astonishingly corrupt, and embezzlement and defalcation on the part of public officials were even greater than during the Reconstruction years.

Reduced benefits for the poor

The small white farmers resentful of planter dominance, residents of the hill country outvoted by Black Belt constituencies, and politicians excluded from the ruling cabals tried repeatedly to overthrow the conservative regimes in the South. During the 1870s they supported Independent or Greenback Labour candidates, but without notable success. In 1879 the Readjuster Party in Virginia—so named because its supporters sought to readjust the huge funded debt of that state so as to lessen the tax burden on small farmers—gained control of the legislature and secured in 1880 the election of its leader, Gen. William Mahone, to the United States Senate. Not until 1890, however, when the powerful Farmers' Alliance, hitherto devoted exclusively to the promotion of agricultural reforms, dropped its ban on politics, was there an effective challenge to conservative hegemony. In that year, with Alliance backing, Benjamin R. Tillman was chosen governor of South Carolina and James S. Hogg was elected governor of Texas; the heyday of Southern Populism was at hand.

Jim Crow legislation. Negro voting in the South was a casualty of the conflict between Redeemers and Populists. Though some Populist leaders, such as Tom Watson in Georgia, saw that poor whites and poor blacks in the South had a community of interest in the struggle against the planters and the businessmen, most small white farmers exhibited vindictive hatred toward the blacks, whose votes had so often been instrumental in upholding conservative regimes. Beginning in 1890, when Mississippi held a new constitutional convention, and continuing through 1908, when Georgia amended its constitution, every state of the former Confederacy moved to disfranchise blacks. Because the United States Constitution forbade outright racial discrimination, the Southern states excluded Negroes by requiring that potential voters be able to read or to interpret any section of the Constitution—a requirement that local registrars waived for whites but rigorously insisted upon when an audacious black wanted to vote. Louisiana, more ingenious, added the "grandfather clause" to its constitution, which exempted from this literacy test all of those who had been entitled to vote on January 1, 1867—*i.e.*, before Congress imposed Negro suffrage upon the South—together with their sons and grandsons. Other states imposed stringent property qualifications for voting or enacted complex poll taxes.

Discrimination in voting

Socially as well as politically, race relations in the South deteriorated as farmers' movements rose to challenge the conservative regimes. By 1890, with the triumph of Southern Populism, the black's place was clearly defined

by law; he was relegated to a subordinate and entirely segregated position. And while legal sanctions were being imposed upon the Negro, informal, extralegal, and often brutal steps were being taken to keep him in his "place." From 1889 to 1899 lynchings in the South averaged 187.5 per year.

Booker T. Washington and the "Atlanta Compromise." Faced with implacable and growing hostility from Southern whites, many blacks during the 1880s and 1890s felt that their only sensible course was to avoid open conflict and to work out some pattern of accommodation. The most influential black spokesman for this policy was Booker T. Washington, the head of Tuskegee Institute in Alabama, who urged his fellow Negroes to forget about politics and college education in the classical languages and to learn how to be better farmers and artisans. With thrift, industry, and abstention from politics, he thought that Negroes could gradually win the respect of their white neighbours. In 1895, in a speech at the opening of the Atlanta Cotton States and International Exposition, Washington most fully elaborated his position, which became known as the "Atlanta Compromise." Abjuring hopes of federal intervention in behalf of the Negro, Washington argued that reform in the South would have to come from within. Change could best be brought about if blacks and whites recognized that "the agitation of questions of social equality is the extremist folly"; in the social life the races in the South could be as separate as the fingers, but in economic progress as united as the hand.

Enthusiastically received by Southern whites, Washington's program also found many adherents among Southern blacks, who saw in his doctrine a way to avoid head-on, disastrous confrontations with overwhelming white force. Whether or not Washington's plan would have produced a generation of orderly, industrious, frugal blacks slowly working themselves into middle class status is not known because of the intervention of a profound economic depression throughout the South during most of the post-Reconstruction period. Neither poor white nor poor black had much opportunity to rise in a region that was desperately impoverished. By 1890 the South ranked lowest in every index that compared the sections of the United States—lowest in per capita income, lowest in public health, lowest in education. In short, by the 1890s the South, a poor and backward region, had yet to recover from the ravages of the Civil War or to reconcile itself to the readjustments required by the Reconstruction era. Economic depression in the South

V. The transformation of U.S. society, 1865–1900

NATIONAL EXPANSION

Growth of the nation. The population of the continental United States in 1880 was slightly above 50,000,000. In 1900 it was just under 76,000,000, a gain in 20 years of over 50 percent. Despite the arrival of more than 9,000,000 immigrants between 1880 and 1900, the rate of population increase was the lowest for any 20-year period of the 19th century. The rate of increase was unevenly distributed, ranging from less than 10 percent in northern New England to more than 125 percent in the 11 states and territories of the Far West. Most of the states east of the Mississippi reported gains slightly below the national average.

Immigration. The 9,000,000 immigrants who entered the United States in the last 20 years of the century were the largest number to arrive in any comparable period up to that time. From the earliest days of the republic until 1895, the majority of immigrants had always come from northern or western Europe. Beginning in 1896, however, the great majority of the immigrants were from southern or eastern Europe. Nervous Americans, already convinced that immigrants wielded too much political power or were responsible for violence and industrial strife, found new cause for alarm, fearing that the new immigrants could not easily be assimilated into U.S. society. Those fears gave added stimulus to agitation for legislation to limit the number of immigrants eligible for admission to the United States.

Westward migration. In 1880 about 22 percent of the American people lived west of the Mississippi. By 1900 that figure had increased to 27 percent. The development of the West continued to add new states to the Union. Nebraska became a state in 1867 and Colorado in 1876; they were followed by North and South Dakota, Washington, and Montana in 1889, by Wyoming and Idaho in 1890, and by Utah in 1896. In 1900 there were only three territories still awaiting statehood in the continental United States: Oklahoma, Arizona, and New Mexico.

New states 1867–96

Urban growth. In 1890 the Bureau of the Census discovered that a continuous line could no longer be drawn across the West to define the farthest advance of settlement. Despite the continuing westward movement of population, the frontier had become a symbol of the past. The movement of people from farms to cities more accurately predicted the trends of the future. In 1880 about 28 percent of the American people lived in communities designated by the Bureau of the Census as urban; by 1900 that figure had risen to 40 percent. In those statistics could be read the beginning of the decline of rural power in America and the emergence of a society built upon a burgeoning industrial complex.

The West. Abraham Lincoln once described the West as the "treasure house of the nation." In the 30 years after the discovery of gold in California, prospectors found gold or silver in every state and territory of the Far West.

The mineral empire. There were few truly rich "strikes" in the post-Civil War years. Of those few, the most important were the fabulously rich Comstock Lode of silver in western Nevada (first discovered in 1859 but developed more extensively later) and the discovery of gold in the Black Hills of South Dakota (1874) and at Cripple Creek, Colorado (1891).

Each new discovery of gold or silver produced an instant mining town to supply the needs and pleasures of the prospectors. If most of the ore was close to the surface, the prospectors would soon extract it and depart, leaving behind a ghost town—empty of people but a reminder of a romantic moment in the past. If the veins ran deep, organized groups with the capital to buy the needed machinery would move in to mine the subsoil wealth, and the mining town would gain some stability as the centre of a local industry. In a few instances, those towns gained permanent status as the commercial centres of agricultural areas that first developed to meet the needs of the miners but later expanded to produce a surplus that they exported to other parts of the West.

The open range. At the close of the Civil War, the price of beef in the Northern states was abnormally high. At the same time, millions of cattle grazed aimlessly on the plains of Texas. A few shrewd Texans concluded that there might be greater profits in cattle than in cotton, especially because it required little capital to enter the cattle business—only enough to employ a few cowboys to tend the cattle during the year and to drive them to market in the spring. No one owned the cattle, and they grazed without charge upon the public domain.

The one serious problem was the shipment of the cattle to market. The Kansas Pacific resolved that problem when it completed a rail line that ran as far west as Abilene, Kansas, in 1867. Abilene was 200 miles (300 kilometres) from the nearest point in Texas where the cattle grazed during the year, but Texas cattlemen almost immediately instituted the annual practice of driving that portion of their herds that was ready for market overland to Abilene in the spring. There they met representatives of Eastern packinghouses, to whom they sold their cattle.

The problem of cattle shipment

The open-range cattle industry prospered beyond expectations and even attracted capital from conservative investors in the British Isles. By the 1880s the industry had expanded along the plains as far north as the Dakotas. In the meantime, a new menace had appeared in the form of the advancing frontier of population; but the construction of the Santa Fe Railway through Dodge City, Kansas, to La Junta, Colorado, permitted the cattlemen to move their operations westward ahead of the frontier; Dodge City replaced Abilene as the principal centre for the annual meeting of cattlemen and buyers. Despite spo-

radic conflicts with settlers encroaching upon the high plains, the open range survived until a series of savage blizzards struck the plains with unprecedented fury in the winter of 1886–87, killing hundreds of thousands of cattle and forcing many owners into bankruptcy. Those who still had some cattle and some capital abandoned the open range, gained title to lands farther west, where they could provide shelter for their livestock, and revived a cattle industry on land that would be immune to further advances of the frontier of settlement. Their removal to these new lands had been made possible in part by the construction of other railroads connecting the region with Chicago and the Pacific Coast.

Completion of the first transcontinental railroad

The expansion of the railroads. In 1862 Congress authorized the construction of two railroads that together would provide the first railroad link between the Mississippi Valley and the Pacific coast. One was the Union Pacific, to run westward from Council Bluffs, Iowa; the other was the Central Pacific, to run eastward from Sacramento, California. To encourage the rapid completion of those roads, Congress provided generous subsidies in the form of land grants and loans. Construction was slower than Congress had anticipated, but the two lines met, with elaborate ceremonies, on May 10, 1869, at Promontory Point, Utah.

In the meantime, other railroads had begun construction westward, but the Panic of 1873 and the ensuing depression halted or delayed construction of many of those lines. With the return of prosperity after 1877, some of those railroads resumed or accelerated construction; by 1883 three more rail connections between the Mississippi Valley and the West Coast had been completed—the Northern Pacific, from St. Paul to Portland; the Santa Fe, from Chicago to Los Angeles; and the Southern Pacific, from New Orleans to Los Angeles. The Southern Pacific had also acquired, by purchase or construction, lines from Portland to San Francisco and from San Francisco to Los Angeles.

The construction of the railroads from the Middle West to the Pacific coast was the railroad builders' most spectacular achievement in the quarter century after the Civil War. No less important, in terms of the national economy, was the development in the same period of an adequate rail network in the southern states and the building of other railroads that connected virtually every important community west of the Mississippi with Chicago.

The West developed simultaneously with the building of the Western railroads, and in no part of the nation was the importance of railroads more generally recognized. The railroad gave vitality to the regions it served, but, by withholding service, it could doom a community to stagnation. The railroads appeared to be ruthless in exploiting their powerful position: they fixed prices to suit their convenience; they discriminated among their customers; they attempted to gain a monopoly of transportation wherever possible; and they interfered in state and local politics to elect favourites to office, to block unfriendly legislation, and even to influence the decisions of the courts.

Indian policy. Large tracts of land in the West were reserved by law for the exclusive use of specified Indian tribes. By 1870, however, the pressure of the frontier and the outbreak of a series of Indian wars had raised serious questions about the government's Indian policies. Many agents of the Bureau of Indian Affairs, charged with responsibility for dealing directly with the tribes, were lax, and some were corrupt in the discharge of their duties. Most Westerners and some army officers contended that the only satisfactory resolution of the Indian question was the removal of the tribes from all lands coveted by the whites.

Programs for assimilation of Indians

In the immediate postwar years, reformers advocated adoption of programs designed to prepare the Indians for ultimate assimilation into American society. In 1869 the reformers persuaded Pres. Ulysses S. Grant and Congress to establish a nonpolitical Board of Indian Commissioners to supervise the administration of relations between the government and the Indians. The board, however, encountered so much political opposition that it accomplished little. The reformers then proposed legislation to grant title for specific acreages of land to the head of each family in those tribes thought to be ready to adopt a sedentary life as farmers. Congress resisted that proposal until land-hungry Westerners discovered that, if the land were thus distributed, a surplus of land would result that could be added to the public domain. When land speculators joined the reformers in support of the proposed legislation, Congress in 1887 enacted the Dawes Act, which empowered the President to grant title to 160 acres (65 hectares) to the head of each family, with smaller allotments to single members of the tribe, in those tribes believed ready to accept a new way of life as farmers. With the grant of land, which could not be alienated by the Indians for 25 years, they were to be granted United States citizenship. Reformers rejoiced that they had finally given the Indians an opportunity to have a dignified role in U.S. society, overlooking the possibility that there might be values in Indian culture worthy of preservation. Meanwhile, the land promoters placed successive presidents under great pressure to accelerate the application of the Dawes Act in order to open more land for occupation or speculation.

INDUSTRIALIZATION OF THE U.S. ECONOMY

The growth of industry. By 1878 the United States had re-entered a period of prosperity after the long depression of the mid-1870s. In the ensuing 20 years the volume of industrial production, the number of workers employed in industry, and the number of manufacturing plants all more than doubled. A more accurate index to the scope of this industrial advance may be found in the aggregate annual value of all manufactured goods, which increased from $5,400,000,000 in 1879 to $13,000,000,000 in 1899. The expansion of the iron and steel industry, always a key factor in any industrial economy, was even more impressive; in 20 years, from 1880 to 1900, the annual production of steel in the United States went from 1,400,000 to 11,000,000 tons. Before the end of the century, the United States surpassed Great Britain in the production of iron and steel and was providing more than one-quarter of the world's supply of pig iron.

Many factors combined to produce this burst of industrial activity. The exploitation of Western resources, including mines and lumber, stimulated a demand for improved transportation, while the gold and silver mines provided new sources of capital for investment in the East. The construction of railroads, especially in the West and South, with the resulting demand for steel rails, was a major force in the expansion of the steel industry and increased the railroad mileage in the United States from less than 93,262 miles (150,151 kilometres) in 1880 to about 190,000 miles (310,000 kilometres) in 1900. Technological advances, including the utilization of the Bessemer and open-hearth processes in the manufacture of steel, resulted in improved products and lower production costs. A series of major inventions, including the telephone, typewriter, linotype, phonograph, electric light, cash register, air brake, refrigerator car, and the automobile, became the bases for new industries, while many of them facilitated the conduct of business. The use of petroleum products in industry as well as for domestic heating and lighting became the cornerstone of the most powerful of the new industries of the period, while the trolley car, the increased use of gas and electric power, and the telephone led to the establishment of important public utilities that were natural monopolies and could operate only on the basis of franchises granted by state or municipal governments. The widespread employment of the corporate form of business organization offered new opportunities for large-scale financing of business enterprise and attracted new capital, much of it furnished by European investors. Over all this industrial activity, there presided a colourful and energetic group of entrepreneurs, who gained the attention, if not always the commendation, of the public and who appeared to symbolize for the public the new class of leadership in the United States. Of this numerous group the best known were John D. Rockefeller in oil, Andrew Carnegie in

New class of leadership

steel, and such railroad builders and promoters as Cornelius Vanderbilt, Leland Stanford, Collis P. Huntington, Henry Villard, and James J. Hill.

The dispersion of industry. The period was notable also for the wide geographical distribution of industry. The Eastern seaboard from Massachusetts to Pennsylvania continued to be the most heavily industrialized section of the United States, but there was a substantial development of manufacturing in the states adjacent to the Great Lakes and in certain sections of the South.

The experience of the steel industry reflected this new pattern of diffusion. Two-thirds of the iron and steel industry was concentrated in the area of western Pennsylvania and eastern Ohio. After 1880, however, the development of iron mines in northern Minnesota (the Vermilion Range in 1884 and the Mesabi Range in 1892) and in Tennessee and northern Alabama was followed by the expansion of the iron and steel industry in the Chicago area and by the establishment of steel mills in northern Alabama and in Tennessee.

Most manufacturing in the Middle West was in enterprises closely associated with agriculture and represented expansion of industries that had first been established before 1860. Meat-packing, which in the years after 1875 became one of the major industries of the nation in terms of the value of its products, was almost a Middle Western monopoly, with a large part of the industry concentrated in Chicago. Flour milling, brewing, and the manufacture of farm machinery and lumber products were other important Middle Western industries.

The industrial invasion of the South was spearheaded by textiles. Cotton mills became the symbol of the New South, and mills and mill towns sprang up in the Piedmont region from Virginia to Georgia and into Alabama. By 1900 almost one-quarter of all the cotton spindles in the United States were in the South, and Southern mills were expanding their operations more rapidly than were their well-established competitors in New England. The development of lumbering in the South was even more impressive, though less publicized; by the end of the century the South led the nation in lumber production, contributing almost one-third of the annual supply.

Industrial combinations. The geographical dispersal of industry was part of a movement that was converting the United States into an industrial nation. It attracted less attention, however, than the trend toward the consolidation of competing firms into large units capable of dominating an entire industry. The movement toward consolidation received special attention in 1882 when John D. Rockefeller and his associates organized the Standard Oil Trust under the laws of Ohio. A trust was a new type of industrial organization, in which the voting rights of a controlling number of shares of competing firms were entrusted to a small group of men, or trustees, who thus were able to prevent competition among the companies they controlled. The stockholders presumably benefitted through the larger dividends they received. For a few years the trust was a popular vehicle for the creation of monopolies, and by 1890 there were trusts in whiskey, lead, cottonseed oil, and salt.

Trusts, mergers, and holding companies

In 1892 the courts of Ohio ruled that the trust violated that state's antimonopoly laws. Standard Oil then reincorporated as a holding company under the more hospitable laws of New Jersey. Thereafter, holding companies or outright mergers became the favourite forms for the creation of monopolies, though the term trust remained in the popular vocabulary as a common description of any monopoly. The best known mergers of the period were those leading to the formation of the American Tobacco Company (1890) and the American Sugar Refining Company (1891). The latter was especially successful in stifling competition, for it quickly gained control of most of the sugar refined in the United States.

Foreign commerce. The foreign trade of the United States, if judged by the value of exports, kept pace with the growth of domestic industry. Exclusive of gold, silver, and re-exports, the annual value of exports from the United States in 1877 was $590,000,000; by 1900 it had increased to $1,371,000,000. The value of imports also rose, though at a slower rate. When gold and silver are included, there was only one year in the entire period in which the United States had an unfavourable balance of trade; and, as the century drew to a close, the excess of exports over imports increased perceptibly.

Agriculture continued to furnish the bulk of U.S. exports. Cotton, wheat, flour, and meat products were consistently the items with the greatest annual value among exports. Of the nonagricultural products sent abroad, petroleum was the most important, though by the end of the century its position on the list of exports was being challenged by machinery.

Despite the expansion of foreign trade, the U.S. merchant marine was a major casualty of the period. While the aggregate tonnage of all shipping flying the U.S. flag remained remarkably constant, the tonnage engaged in foreign trade declined sharply. On the eve of the Civil War, the tonnage in overseas trade had exceeded 2,400,000 tons; by 1877 it had dropped to 1,571,000 tons, and, thereafter, it continued to decline until it reached a low point in 1898 of only 726,000 tons. In 1900 only about 10 percent of the exports of the United States were sent abroad in ships of U.S. registry.

Labour. The expansion of industry was accompanied by increased tensions between employers and workers and by the appearance, for the first time in the United States, of national labour unions.

Formation of unions. The first effective labour organization that was more than regional in membership and influence was the Knights of Labor, organized in 1869. The Knights believed in the unity of the interests of all producing groups and sought to enlist in their ranks not only all labourers but everyone who could be truly classified as a producer. They championed a variety of causes, many of them more political than industrial, and they hoped to gain their ends through politics and education rather than through economic coercion.

The Knights of Labor

The hardships suffered by many workers during the depression of 1873–78 and the failure of a nationwide railroad strike, which was broken when Pres. Rutherford B. Hayes sent federal troops to suppress disorders in Pittsburgh and St. Louis, caused much discontent in the ranks of the Knights. In 1879 Terence V. Powderly, a railroad worker and mayor of Scranton, Pennsylvania, was elected grand master workman of the national organization. Powderly supposedly favoured a program of aggressive action on behalf of labour. In practice, however, he hesitated to endorse strikes, and the effective control of the Knights shifted to regional leaders who were willing to initiate strikes or other forms of economic pressure to gain their objectives. The Knights reached the peak of their influence in 1885, when they claimed a national membership of nearly 700,000. In that year a much-publicized strike against the Wabash Railroad attracted substantial public sympathy and succeeded in preventing a reduction in wages. In that year also Congress took note of the apparently increasing power of labour and prohibited the entry into the United States of immigrants who had signed contracts to work for specific employers.

The year 1886 was a troubled one in labour relations. There were nearly 1,600 strikes, involving about 600,000 workers, with the eight-hour day the most prominent item in the demands of labour. About half of these strikes were called for May Day; some of them were successful, but the concerted action by workers on a nationwide basis turned public opinion against labour and deprived it of much of the sympathy it had enjoyed in the preceding year.

The Haymarket Riot. The most serious blow to the unions came from a tragic occurrence with which they were only indirectly associated. One of the strikes called for May Day in 1886 was against the McCormick Harvesting Machine Company in Chicago. Fighting broke out along the picket lines, and, when police intervened to restore order, several strikers were injured. Union leaders called a protest meeting at Haymarket Square for the evening of May 4; but, as the meeting was breaking up, a group of anarchists took over and began to make inflammatory speeches. The police quickly intervened, and a

bomb exploded, killing seven policemen and injuring many others. Eight of the anarchists were arrested, tried, and convicted of murder. Four of them were hanged, and one committed suicide. The remaining three were pardoned in 1893 by Gov. John P. Altgeld, who was persuaded that they had been convicted in such an atmosphere of prejudice that it was impossible to be certain that they were guilty.

The public tended to blame organized labour for the Haymarket tragedy, and many persons had become convinced that the activities of unions were likely to be attended by violence. The Knights never regained the ground they lost in 1886, and, until after the turn of the century, organized labour seldom gained any measure of public sympathy. Aggregate union membership did not again reach its 1885–86 figure until 1900. Unions, however, continued to be active; and in each year from 1889 through the end of the century there were more than 1,000 strikes.

The American Federation of Labor

As the power of the Knights declined, the leadership in the trade union movement passed to the American Federation of Labor (AFL). This was a loose federation of local and craft unions, organized first in 1881 and reorganized in 1886. For a few years there was some nominal cooperation between the Knights and the AFL, but the basic organization and philosophy of the two groups made cooperation difficult. The AFL appealed only to skilled workers, and its objectives were those of immediate concern to its members: hours, wages, working conditions, and the recognition of the union. It relied on economic weapons, chiefly the strike and boycott, and it eschewed political activity, except for state and local election campaigns. The central figure in the AFL was Samuel Gompers, a New York cigar maker, who was its president from 1886 to his death in 1924.

NATIONAL POLITICS

The dominant forces in U.S. life in the last quarter of the 19th century were economic and not political. This fact was reflected in the ineffectiveness of political leadership and in the absence of deeply divisive issues in politics, except perhaps for the continuing agrarian agitation for inflation. There were colourful political personalities, but they gained their following on a personal basis rather than as spokesmen for a program of political action. No president of the period was truly the leader of his party, and none apparently aspired to that status except Grover Cleveland during his second term (1893–97). Such shrewd observers of U.S. politics as Woodrow Wilson and James Bryce agreed that great men did not become presidents; and it was evident that the nominating conventions of both major parties commonly selected presidential candidates who were "available" in the sense that they had few enemies.

In the absence of leadership from the White House, public policy was largely formulated in Congress. As a result, public policy commonly represented a compromise among the views of many congressional leaders—a situation made the more essential because of the fact that in only four of the 20 years from 1877 to 1897 did the same party control the White House, the Senate, and the House.

The Republicans appeared to be the majority party in national politics. From the Civil War to the end of the century, they won every presidential election save those of 1884 and 1892, and they had a majority in the Senate in all but three Congresses during that same period. The Democrats, however, won a majority in the House in eight of the ten Congresses from 1875 to 1895. The success of the Republicans was achieved in the face of bitter intraparty schisms that plagued Republican leaders from 1870 until after 1890 and despite the fact that, in every election campaign after 1876, they were forced to concede the entire South to the opposition. The Republicans had the advantage of having been the party that had defended the Union against secession and had freed the slaves. When all other appeals failed, Republican leaders could salvage votes in the North and West by reviving memories of the war. A less tangible but equally valuable advantage was the widespread belief that the continued industrial development of the nation would be more secure under a Republican than under a Democratic administration. Except in years of economic adversity, the memory of the war and confidence in the economic program of the Republican Party were normally enough to ensure Republican success in most of the northern and western states.

Regional political differences

The administration of Rutherford B. Hayes. President Hayes (served 1877–81) willingly carried out the commitments made by his friends to reconcile Southerners to the decisions of the electoral commission that had awarded him the disputed electoral votes in three key Southern states needed for his election. He withdrew the federal troops still in the South, and he appointed former senator David M. Key of Tennessee to his Cabinet as postmaster general. Hayes hoped that these conciliatory gestures would encourage many Southern conservatives to support the Republican Party in the future. But the Southerners' primary concern was the maintenance of white supremacy; this, they believed, required a monopoly of political power in the South by the Democratic Party. As a result, the policies of Hayes led to the virtual extinction rather than the revival of the Republican Party in the South.

Hayes's efforts to woo the South irritated some Republicans, but his attitude toward the federal civil service was a more immediate challenge to his party. In June 1877 he issued an executive order prohibiting political activity by those who held federal appointments. When two friends of Sen. Roscoe Conkling defied this order, Hayes removed them from their posts in the administration of the Port of New York. Conkling and his associates showed their contempt for Hayes by bringing about the election of one of the men (Alonzo B. Cornell) as governor of New York in 1879 and nominating the other (Chester A. Arthur) as Republican candidate for the vice presidency in 1880.

One of the most serious issues facing Hayes was that of inflation. Hayes and many other Republicans were staunch supporters of a sound-money policy, but the issues were sectional rather than partisan. In general, sentiment in the agricultural South and West was favourable to inflation, while industrial and financial groups in the Northeast opposed any move to inflate the currency, holding that this would benefit debtors at the expense of creditors.

The silver controversy

In 1873 Congress had discontinued the minting of silver dollars, an action later stigmatized by friends of silver as the Crime of '73. As the depression deepened, inflationists began campaigns to persuade Congress to resume coinage of silver dollars and to repeal the act providing for the redemption of Civil War greenbacks in gold after January 1, 1879. By 1878 the sentiment for silver and inflation was so strong that Congress passed, over the President's veto, the Bland–Allison Act, which renewed the coinage of silver dollars and, more significantly, included a mandate to the Secretary of the Treasury to purchase silver bullion at the market price in amounts of not less than $2,000,000 and not more than $4,000,000 each month.

Opponents of inflation were somewhat reassured by the care with which Secretary of the Treasury John Sherman was making preparation to have an adequate gold reserve to meet any demands on the Treasury for the redemption of greenbacks. Equally reassuring were indications that the nation had at last recovered from the long period of depression. These factors re-established confidence in the financial stability of the government; and, when the date for the redemption of greenbacks arrived, there was no appreciable demand upon the Treasury to exchange them for gold.

Hayes chose not to be a candidate for re-election. Had he sought a second term, he would almost certainly have been denied renomination by the Republican leaders, with whom he had never been popular. His tolerant disposition and quiet dignity had won the respect of millions of his fellow countrymen, and he appeared to symbolize the amelioration of the economic and sectional tensions that had gripped the country in 1877. But the forces that

molded national destiny during his administration and for 20 years thereafter were economic and social rather than political.

The election of 1880. Three prominent candidates contended for the Republican presidential nomination in 1880: Grant, James G. Blaine, and John Sherman. Grant had a substantial and loyal bloc of delegates in the convention, but their number was short of a majority. Neither of the other candidates could command a majority, and on the 36th ballot the weary delegates nominated a compromise candidate, Congressman James A. Garfield of Ohio. To placate the "Stalwart," or pro-Grant, faction, the convention nominated Chester A. Arthur of New York for vice president.

The Democrats probably would have renominated Samuel J. Tilden in 1880, hoping thereby to gain votes from those who believed Tilden had lost in 1876 through fraud. But Tilden declined to become a candidate again, and the Democratic convention nominated Gen. Winfield S. Hancock. Hancock had been a Federal general during the Civil War, but he had no political record and little familiarity with questions of public policy.

The campaign failed to generate any unusual excitement and produced no novel issues. As in every national election of the period, the Republicans stressed their role as the party of the protective tariff and asserted that Democratic opposition to the tariff would impede the growth of domestic industry. Actually, the Democrats were badly divided on the tariff, and Hancock surprised political leaders of both parties by declaring that the tariff was an issue of only local interest.

Garfield won the election with an electoral margin of 214 to 155, but his plurality in the popular vote was a slim 9,644. The election revealed the existence of a new "solid South," for Hancock carried all the former Confederate states and three of the former slave states that had remained loyal to the Union.

The administrations of James A. Garfield and Chester A. Arthur. Garfield had not been closely identified with either of the two major factions within the Republican Party—the "Stalwarts" and the "Half-Breeds." Upon becoming president, he named James G. Blaine, the leader of the "Half-Breeds," as secretary of state. He gave even more serious offense to the pro-Grant "Stalwart" faction by appointing as collector of customs at New York a man who was unacceptable to the two senators from that state, Roscoe Conkling and Thomas Platt, who showed their displeasure by resigning their Senate seats, expecting to be re-elected triumphantly by the legislature of New York; but in this they were disappointed.

The assassination of Garfield

The tragic climax to this intraparty strife came on July 2, 1881, when Garfield was shot, in Washington, D.C., by a disappointed and mentally deranged office seeker. For two months the President lingered between life and death. He died on September 19 and was succeeded by Vice Pres. Chester A. Arthur.

The accession of Arthur to the presidency caused widespread concern. He had held no elective office before becoming vice president, and he had been closely associated with the Grant wing of the party. It was assumed that like others in that group he would be hostile to reform of the civil service, and his nomination for the vice presidency had been generally regarded as a deliberate rebuke to President Hayes. The members of Garfield's Cabinet immediately tendered their resignations, but Arthur asked them to continue in office for a time. By mid-April 1882, however, all but one of the Cabinet officers had been replaced. Among those replaced was Secretary of State Blaine.

Arthur soon surprised his critics and the country by demonstrating an unexpected independence of his former political friends. In his first annual message to Congress, in December 1881, he announced his qualified approval of legislation that would remove appointments to the federal civil service from partisan control. In January 1883 Congress passed and Arthur signed the Pendleton Civil Service Act, which established the Civil Service Commission and provided that appointments to certain categories of offices should be made on the basis of examinations and the appointees given an indefinite tenure in their positions.

The Chinese Exclusion Act

In May 1882 Congress enacted the Chinese Exclusion Act, prohibiting for a period of ten years the immigration of Chinese labourers into the United States. This act was both the culmination of more than ten years of agitation on the West Coast for the exclusion of the Chinese and an early sign of some modification of the traditional U.S. philosophy of welcoming virtually all immigrants. In response to pressure from California, Congress had passed an exclusion act in 1879, but it had been vetoed by Hayes on the ground that it abrogated rights guaranteed to the Chinese by the Burlingame Treaty of 1868. In 1880 these treaty provisions were revised to permit the United States to suspend the immigration of Chinese. The Chinese Exclusion Act was renewed in 1892 for another ten-year period, and in 1902 the suspension of Chinese immigration was made indefinite.

The election of 1884. President Arthur hoped to be the presidential nominee of the Republicans in 1884. His administration had won the respect of many who had viewed his accession to office with misgivings. It had not, however, gained him any powerful following among the leaders of his party. The strongest candidate for the Republican nomination was James G. Blaine. Despite opposition from those who believed he was too partisan in spirit or that he was vulnerable to charges of corrupt actions while speaker of the house many years before, Blaine was nominated on the fourth ballot.

The Democratic candidate, Gov. Grover Cleveland of New York, was in many respects the antithesis of Blaine. He was a relative newcomer to politics. He had been elected mayor of Buffalo in 1881 and governor of New York in 1882. In both positions he had earned a reputation for political independence, inflexible honesty, and an industrious and conservative administration. His record made him an attractive candidate for persons who accepted the dictum that "a public office is a public trust." This was, in 1884, a valuable asset; and it won for Cleveland the support of a few outstanding Republicans and some journals of national circulation that usually favoured Republican nominees for office.

As in 1880, the campaign was almost devoid of issues of public policy: only the perennial question of the tariff appeared to separate the two parties. Cleveland had not served in the army during the Civil War, and Republicans made an effort to use this fact, together with the power of the South in the Democratic Party, to arouse sectional prejudices against Cleveland. During the campaign it was revealed that Cleveland, a bachelor, was the father of an illegitimate son, an indiscretion that gave the Republicans a moral issue with which to counteract charges of corruption against their own candidate.

The election was very close. On the evening of the voting it was apparent that the result depended upon the vote in New York State, but not until the end of the week was it certain that Cleveland had carried New York by the narrow margin of 1,149 votes and been elected president. In the electoral college, Cleveland received 219 votes to 182 for Blaine.

Grover Cleveland's first term. Cleveland was the first Democratic president since James Buchanan a quarter of a century earlier. More than two-thirds of the electoral votes he received came from southern or border states, so that it appeared that his election marked the close of one epoch and the beginning of a new political era in which the South could again hope to have a major voice in the conduct of national affairs. Because of his brief career in politics, Cleveland had only a limited acquaintance with leaders of his own party. He accepted literally the constitutional principle of the separation of powers, and he opened his first annual message to Congress, in December 1885, with an affirmation of his devotion to "the partitions of power between our respective departments." This appeared to be a disavowal of presidential leadership, but it quickly became apparent that Cleveland intended to defend vigorously the prerogatives that he believed belonged to the executive.

Cleveland's relations with his party and politics

During his first term (1885–89) Cleveland was con-

fronted with a divided Congress—a Republican Senate and a Democratic House. This added to the complexities of administration, especially in the matter of appointments. Cleveland was a firm believer in a civil service based on merit rather than on partisan considerations, but, as the first Democratic president in a quarter of a century, he was under great pressure to replace Republicans in appointive offices with Democrats. He followed a line of compromise. In his first two years he removed the incumbents from about two-thirds of the offices subject to his control, but he scrutinized the qualifications of Democrats recommended for appointment and in a number of instances refused to abide by the recommendations of his party leaders. He thus offended both the reformers, who wished no partisan removals, and his fellow Democrats, whose nominees he rejected. Although his handling of the patronage alienated some powerful Democrats, he scored a personal triumph when he persuaded Congress to repeal the obsolete Tenure of Office Act of 1867, which Republican senators had threatened to revive in order to embarrass him.

Cleveland was a conservative on all matters relating to money, and he was inflexibly opposed to wasteful expenditure of public funds. This caused him to investigate as many as possible of the hundreds of private bills passed by Congress to compensate private individuals, usually Federal veterans, for claims against the federal government. When, as was frequently the case, he judged these claims to be ill founded, he vetoed the bill. He was the first president to use the veto power extensively to block the enactment of this type of private legislation.

Cleveland's use of veto powers

The surplus and the tariff. The flurry of private pension bills had been stimulated, in part, by a growing surplus in the Treasury. In every year since the Civil War, there had been an excess of revenue over expenditures, a circumstance that encouraged suggestions for appropriations of public funds for a variety of purposes. The surplus also focussed attention upon the tariff, which was the principal source of this excess revenue. In 1883 Congress had reviewed the tariff and made numerous changes in the rates, increasing the tariff on some items and reducing it on others, without materially decreasing the revenue received. Cleveland believed that the surplus presented a very real problem. It hoarded in the Treasury money that could have been in circulation, and it encouraged reckless spending by the government. Like many other Democrats, he disliked the high protective tariff. After waiting in vain for two years for Congress to meet this issue boldly, Cleveland adopted the extraordinary tactic of devoting his entire annual message in 1887 to a discussion of this question and to an appeal for a lowering of the tariff. The House then passed a bill generally conforming to Cleveland's views on the tariff; but the Senate rejected it, and the tariff became a leading issue in the presidential campaign of 1888.

The public domain. After 1877 hundreds of thousands of agricultural settlers went westward to the plains, where they came into competition for control of the land with the cattlemen, who hitherto had dominated the open range. The pressure of population as it moved into the plains called attention to the diminishing supply of good arable land still open to settlement, thus presaging the day when there would no longer be a vast reservoir of land in the West awaiting the farmer. It also focussed attention on the fact that millions of acres of Western land were being held for speculative purposes and that other millions of acres had been acquired by questionable means or were still in the possession of railroads that had failed to fulfill the obligations they assumed when the land was granted to them. Upon assuming office, Cleveland was confronted with evidence that some of these claims had been fraudulently obtained by railroads, speculators, cattlemen, or lumbering interests. He ordered an investigation, and for more than a year agents of the Land Office roamed over the West uncovering evidence of irregularities and neglected obligations. Cleveland acted firmly. By executive orders and court action he succeeded in restoring more than 81,000,000 acres (33,000,000 hectares) to the public domain.

Diminishing supply of land

The Interstate Commerce Act. The railroads were vital to the economy of the nation, but because in so many regions a single company enjoyed a monopoly of rail transportation, many of the railroads adopted policies that large numbers of their customers believed to be unfair and discriminatory. Before 1884 it was clear that the Granger laws of the preceding decade (state laws prohibiting various abuses by the railroads) were ineffective, and pressure groups turned to the federal government for relief. In this, Western farm organizations were joined by influential Eastern businessmen who believed that they, too, were the victims of discrimination by the railroads. This powerful political alliance persuaded both parties to include regulation of the railroads in their national platforms in 1884 and induced Congress to enact the Interstate Commerce Act in 1887.

Interstate Commerce Act

This law, designed to prevent unjust discrimination by the railroads, prohibited the pooling of traffic and profits, made it illegal for a railroad to charge more for a short haul than for a longer one, required that the roads publicize their rates, and established the Interstate Commerce Commission to supervise the enforcement of the law. The rulings of the commission were subject to review by the federal courts, the decisions of which tended to narrow the scope of the act. The commission was less effective than the sponsors of the act had hoped, but the act in itself was an indication of the growing realization that only the federal government could cope with the new economic problems of the day.

The election of 1888. Cleveland's plea for a reduction of the tariff in his annual message of 1887 made it certain that the tariff would be the central issue in the presidential campaign of 1888. The Democrats renominated Cleveland, although it was thought that he had endangered his chances of re-election by his outspoken advocacy of tariff reduction. The Republicans had their usual difficulty in selecting a candidate. Blaine refused to enter the race, and no other person in the party commanded substantial support. From among the many who were willing to accept the nomination, the Republicans selected Benjamin Harrison of Indiana, a Federal general in the Civil War and the grandson of Pres. William Henry Harrison.

Cleveland had won respect as a man of integrity and courage, but neither he nor Harrison aroused any great enthusiasm among the voters. One feature of the campaign noted by observers was the extensive use of money to influence the outcome; this was not a new phenomenon, but the spending of money to carry doubtful states and the apparent alliance between business and political bosses had never before been so open.

The results were again close. Cleveland had a plurality of 100,000 popular votes, but the Republicans carried two states, New York and Indiana, which they had lost in 1884, and in the electoral college Harrison won by a margin of 233 to 168.

The administration of Benjamin Harrison. The Republicans also gained control of both houses of the 51st Congress. Their margin in the House of Representatives, however, was so small that it seemed uncertain whether they could carry controversial legislation through it. This obstacle was overcome by the speaker of the House, Thomas B. Reed of Maine. Reed refused to recognize dilatory motions, and, contrary to precedent, he counted as present all members who were in the chamber. Using that tactic, he ruled, on occasion, that a quorum was present even though fewer than a majority had actually answered a roll call. His iron rule of the House earned him the sobriquet Czar Reed, but only through his firm control of the House could the Republicans pass three controversial bills in the summer and early autumn of 1890. One dealt with monopolies, another with silver, and the third with the tariff.

The Sherman Anti-Trust Act. The first of these major measures declared illegal all combinations that restrained trade between states or with foreign nations. This law, known as the Sherman Anti-Trust Act, was passed by Congress early in July. It was the congressional response to evidence of growing public dissatisfaction with

the development of industrial monopolies, which had been so notable a feature of the preceding decade.

More than ten years passed before the Sherman Act was used to break up any industrial monopoly. It was invoked by the federal government in 1894 to obtain an injunction against a striking railroad union accused of restraint of interstate commerce, and the use of the injunction was upheld by the Supreme Court in 1895. Indeed, it is unlikely that the Senate would have passed the bill in 1890 had not the chairman of the Senate Judiciary Committee, George F. Edmunds of Vermont, felt certain that unions were combinations in restraint of trade within the meaning of the law. To those who hoped that the Sherman Act would inhibit the growth of monopoly, the results were disappointing. The passage of the act only three years after the Interstate Commerce Act was, however, another sign that the public was turning from state capitals to Washington for effective regulation of industrial giants.

The silver issue. Less than two weeks after Congress passed the antitrust law, it enacted the Sherman Silver Purchase Act, which required the secretary of the treasury to purchase each month 4,500,000 ounces (130,000 kilograms) of silver at the market price. This superseded the Bland–Allison Act of 1878 and had the effect of increasing the government's monthly purchase of silver by more than 50 percent. The act was adopted in response to pressure from mineowners, who were alarmed by the falling price of silver, and from Western farmers, who were always favourable to inflationary measures and who, in 1890, were also suffering from the depressed prices of their products.

The McKinley Tariff. Most Republican leaders had been lukewarm to the proposal to increase the purchase of silver and had accepted it only to assure Western votes for the measure in which they were most interested—upward revision of the protective tariff. This was accomplished in the McKinley Tariff Act of October 1890, passed by Congress one month before the midterm elections of that year. The tariff was designed to appeal to the farmers because some agricultural products were added to the protected list. A few items, notably sugar, were placed on the free list, and domestic sugar planters were to be compensated by a subsidy of two cents a pound. The central feature of the act, however, was a general increase in tariff schedules, with many of these increases applying to items of general consumption.

The new tariff immediately became an issue in the congressional elections. It failed to halt the downward spiral of farm prices, but there was an almost immediate increase in the cost of many items purchased by the farmers. With discontent already rife in the agricultural regions of the West and South, the McKinley Tariff added to the agrarian resentment. The outcome of the elections was a major defeat for the Republicans, whose strength in the House of Representatives was reduced by almost half.

Farmers' resentment of the tariff

The agrarian revolt. Political disaster befell the Republicans in the trans-Mississippi West, resulting from an economic and psychological depression that enveloped the region after widespread crop failures and the collapse of inflated land prices in the summer of 1887. The Western boom had begun in the late 1870s, when the tide of migration into the unoccupied farmlands beyond the Mississippi quickly led to the settlement of hitherto unoccupied parts of Iowa and Minnesota and to the pushing of the frontier westward across the plains almost literally to the shadows of the Rocky Mountains.

Westward expansion was encouraged by the railroads that served the region. It was supported by the satisfactory price and encouraging foreign market for wheat, the money crop of the plains. For ten years, from 1877 through 1886, the farmers on the plains had the benefit of an abnormally generous rainfall, leading many to assume that climatic conditions had changed and that the rain belt had moved westward to provide adequate rainfall for the plains. Confidence was followed by unrestrained optimism that engendered wild speculation and a rise in land prices. Lured on by these illusions, the settlers went into debt to make improvements on their farms while small-town leaders dreamed of prodigious growth and authorized bond issues to construct the public improvements they felt certain would soon be needed.

The collapse of these dreams came in 1887. The year opened ominously when the plains were swept by a catastrophic blizzard in January that killed thousands of head of cattle and virtually destroyed the cattle industry of the open range. The following summer was dry and hot; crops were poor; and, to compound the woes of the farmers, the price of wheat began to slide downward. The dry summer of 1887 was the beginning of a ten-year cycle of little rainfall and searingly hot summers. By the autumn of 1887 the exodus from the plains had begun; five years later, areas of western Kansas and Nebraska that had once been thriving agricultural centres were almost depopulated. The agricultural regions east of the plains were less directly affected, though there the farmers suffered from the general decline in farm prices.

Although the disaster on the plains bred a sense of distress and frustration, the lure of good land was still strong. When the central portion of the present state of Oklahoma was opened to settlement in April 1889, an army of eager settlers, estimated to have numbered 100,000, rushed into the district to claim homesteads and build homes.

Settlement of Oklahoma

The Populists. The collapse of the boom and the falling prices of agricultural products forced many farmers to seek relief through political action. In 1888 and again in 1890 this discontent was expressed through local political groups, commonly known as Farmers' Alliances, which quickly spread through parts of the West and South. The alliances won some local victories and contributed to the discomfiture of the Republicans in 1890. They were not, however, an effective vehicle for concerted political action; and in 1891 the leaders of the alliances organized the Populist (People's) Party.

The Populists aspired to become a national party and hoped to attract support from labour and from reform groups generally. In practice they continued through their brief career to be almost wholly a party of farmers, with a platform tailored to meet the wishes of Western farmers. They demanded an increase in the circulating currency, to be achieved by the unlimited coinage of silver, a graduated income tax, government ownership of the railroads, a tariff for revenue only, the direct election of United States senators, and other measures designed to strengthen political democracy and give the farmers economic parity with business and industry. In 1892 the Populists nominated Gen. James B. Weaver of Iowa for president.

The election of 1892. The nominees of the two major parties for president in 1892 were the same as in the election of 1888. The Republicans reluctantly renominated Harrison, whose personal relations with many party leaders were distinctly cool. Before the Democratic convention there was a spirited struggle for the nomination between Cleveland and Gov. David Hill of New York, but Cleveland had far greater support among rank-and-file Democrats and was nominated on the first ballot.

The unpopularity of the McKinley Tariff gave Cleveland an advantage, as did the discontent in the West, which was directed largely against the Republican Party. From the beginning of the campaign it appeared probable that the Democrats would be successful, and Cleveland carried not only the southern states but such key northern states as New York and Illinois. His electoral vote was 277 to 145 for Harrison. Weaver carried four Western states, three of them states with important silver mines, and received 22 electoral votes.

Cleveland's second term. When Cleveland was inaugurated for his second term in March 1893, the country hovered on the brink of financial panic. Six years of depression in the trans-Mississippi West, the decline of foreign trade after the enactment of the McKinley Tariff, and an abnormally high burden of private debt were disquieting features of the situation. Most attention was centred, however, on the gold reserve in the federal Treasury. It was assumed that a minimum reserve of $100,000,000 was necessary to assure redemption of gov-

The Panic of 1893

ernment obligations in gold. When, on April 21, 1893, the reserve fell below that amount, the psychological impact was far-reaching. Investors hastened to convert their holdings into gold; banks and brokerage houses were hard pressed; and many business houses and financial institutions failed. Prices dropped, employment was curtailed, and the nation entered a period of severe economic depression that continued for more than three years.

The causes of this disaster were numerous and complex, but the attention that focussed on the gold reserve tended to concentrate concern upon a single factor—the restoration of the Treasury's supply of gold. It was widely believed that the principal cause of the drain on the Treasury was the obligation to purchase large amounts of silver. To those who held this view, the obvious remedy was the repeal of the Sherman Silver Purchase Act.

The issue was political as well as economic. It divided both major parties, but most of the leading advocates of existing silver policies were Democrats. Cleveland, however, had long been opposed to the silver purchase policy and in the crisis he resolved upon repeal as an essential step in protecting the Treasury. He therefore called Congress to meet in special session on August 7, 1893.

The new Congress had Democratic majorities in both houses, and, if it had any mandate, it was to repeal the McKinley Tariff. It had no mandate on the silver issue, and more than half of its Democratic members came from constituencies that favoured an increase in the coinage of silver. Cleveland faced a herculean task in forcing repeal through Congress, but, by the use of every power at his command, he gained his objective. The Sherman Silver Purchase Act was repealed at the end of October by a bill that made no compensating provision for the coinage of silver. Cleveland had won a personal triumph, but he had irrevocably divided his party; and in some sections of the nation he had become the most unpopular president of his generation.

Cleveland's splitting of the Democratic Party

The extent to which Cleveland had lost control of his party became apparent when Congress turned from silver to the tariff. The House passed a bill that would have revised tariff rates downward in accordance with the President's views. In the Senate, however, the bill was so altered that it bore little resemblance to the original measure, and on some items it imposed higher duties than had the McKinley Act. It was finally passed in August 1894, but Cleveland was so dissatisfied that he refused to sign it; and it became law without his signature. The act contained a provision for an income tax, but this feature was declared unconstitutional by the Supreme Court in 1895.

In the midterm elections of 1894 the Republicans recaptured control of both houses of Congress. This indicated the discontent produced by the continuing depression. It also guaranteed that, with a Democratic president and Republican Congress, there would be inaction in domestic legislation while both parties looked forward to the election of 1896.

The election of 1896. At their convention in St. Louis the Republicans selected Gov. William McKinley of Ohio as their presidential nominee. He had served in the Federal Army during the Civil War, and his record as governor of Ohio tended to offset his association with the unpopular tariff of 1890. His most effective support in winning the nomination, however, was provided by Mark Hanna, a wealthy Cleveland businessman who was McKinley's closest friend.

The Democratic convention in Chicago was unusually exciting. It was controlled by groups hostile to Cleveland's financial policies, and it took the unprecedented step of rejecting a resolution commending the administration of a president of its own party. The debate on the party platform featured an eloquent defense of agrarian interests by William Jennings Bryan, which won him not only a prolonged ovation but also his party's presidential nomination. Bryan was a former congressman from Nebraska, and at 36 he was the youngest man ever to be the nominee for president of a major party. By experience and conviction he shared the outlook of the agrarian elements that dominated the convention and whose principal spokesman he became.

Bryan conducted a vigorous campaign. For the first time a presidential candidate carried his case to the people in all parts of the country, and for a time it appeared that he might win. The worried conservatives charged that Bryan was a dangerous demagogue, and they interpreted the campaign as a conflict between defenders of a sound economic system that would produce prosperity and dishonest radicals who championed reckless innovations that would undermine the financial security of the nation. On this interpretation they succeeded in raising large campaign funds from industrialists who feared their interests were threatened. With this money, the Republicans were able to turn the tide and win a decisive victory. Outside the South, Bryan carried only the Western silver states and Kansas and Nebraska.

Economic recovery. Soon after taking office on March 4, 1897, McKinley called Congress into special session to revise the tariff once again. Congress responded by passing the Dingley Tariff Act, which eliminated many items from the free list and generally raised duties on imports to the highest level they had yet reached.

Although the preservation of the gold standard had been the chief appeal of the Republicans in 1896, it was not until March 1900 that Congress enacted the Gold Standard Act, which required the Treasury to maintain a minimum gold reserve of $150,000,000 and authorized the issuance of bonds, if necessary, to protect that minimum. In 1900 such a measure was almost anticlimactic, for an adequate gold supply had ceased to be a practical problem. Beginning in 1893, the production of gold in the United States had increased steadily; by 1899 the annual value of gold added to the American supply was double that of any year between 1881 and 1892. The chief source of the new supply of gold was the Klondike, where important deposits of gold had been discovered during the summer of 1896.

Increase in gold production

By 1898 the depression had run its course; farm prices and the volume of farm exports were again rising steadily, and Western farmers appeared to forget their recent troubles and to regain confidence in their economic prospects. In industry, the return of prosperity was marked by a resumption of the move toward more industrial combinations, despite the antitrust law; and great banking houses, such as J.P. Morgan and Company of New York, played a key role in many of the most important of these combinations by providing the necessary capital and receiving, in return, an influential voice in the management of the companies created by this capital. VI. Imperialism, the Progressive Era, and the rise to world power, 1896–1920

AMERICAN IMPERIALISM

The Spanish–American War. Militarily speaking, the Spanish–American War of 1898 was so brief and relatively bloodless as to have been a mere passing episode in the history of modern warfare. Its political and diplomatic consequences, however, were enormous: it catapulted the United States into the arena of world politics and set it, at least briefly, on the new road of imperialism. To be sure, specific events drove the United States to hostilities in 1898; but the stage had already been set by profound changes in thought about the nation's mission and its destiny.

The United States in world politics

Before the 1890s, roughly speaking, most Americans had adhered stubbornly to the belief, as old as the Revolution itself, that their country should remain aloof from European affairs and offer an example of democracy and peace to the rest of the world; but slowly in the 1880s, and more rapidly in the 1890s, new currents of thought eroded this historic conviction. The United States had become a great power by virtue of its prodigious economic growth since the Civil War; numerous publicists said that it ought to begin to act like one. Propagandists of sea power argued that future national security and greatness depended upon a large navy supported by bases throughout the world. After the disappearance of the American frontier in 1890, the conviction grew that the United States would have to find new outlets for an ever-increasing population and agricultural and industrial produc-

tion; this belief was particularly rife among farmers in dire distress in the 1890s. Social Darwinists said that the world is a jungle, with international rivalries inevitable, and that only strong nations could survive. Added to these arguments were those of idealists and religious leaders that Americans had a duty to "take up the white man's burden" and carry their assertedly superior culture and the blessings of Christianity to backward peoples of the world.

It was against this background that the events of 1898 propelled the United States along the road to war and empire. Cuban rebels had begun a violent revolution against Spanish rule in 1895, set off by a depression caused by a decline in U.S. sugar purchases from Cuba. Rebel violence led progressively to more repressive Spanish countermeasures. Cuban refugees in the United States spread exaggerated tales of Spanish atrocities, and these and numerous others were reprinted widely (particularly by William Randolph Hearst's New York *American* and Joseph Pulitzer's New York *World*, then engaged in a fierce battle for circulation). Pres. Grover Cleveland resisted the rising public demand for intervention, until by early 1898 the pressure, now on his successor, William McKinley, was too great to be defied. When an explosion —caused by a submarine mine, according to a U.S. naval court of inquiry—sank the USS "Maine" with large loss of life in Havana Harbour on February 15, 1898, events moved beyond the President's control. Though Spain was willing to make large concessions to avoid war, it adamantly resisted what had become the minimum public and official U.S. demand—complete Spanish withdrawal from Cuba and recognition of the island's independence. Hence Congress in mid-April authorized the President to use the armed forces to expel the Spanish from Cuba.

War with Spain

For Americans it was, as Theodore Roosevelt, lieutenant colonel of a volunteer regiment called the "Rough Riders," put it, "a splendid little war." An American expeditionary force, after quickly overcoming the Spaniards in Cuba, turned next against Spain's last island in the Caribbean, Puerto Rico. Meanwhile, on May 1, 1898, the American commodore George Dewey, with his Asiatic squadron, destroyed a decrepit Spanish flotilla in the Harbour of Manila in the Philippine Islands.

The fighting was over by August 12, when the United States and Spain signed a preliminary peace treaty in Washington, D.C. Negotiators met in Paris in October to draw up a definitive agreement. Spain recognized the independence of Cuba and ceded Puerto Rico to the United States, but the disposition of the Philippines was another matter. Business interests in the United States, which had been noticeably cool about a war over Cuba, demanded the acquisition of the entire Philippine Archipelago in the hope that Manila would become the base for a great Far Eastern trade; chauvinists declaimed against lowering the flag under Spanish pressure. Concluding that he had no alternative, McKinley forced the Spanish to "sell" the Philippines to the United States for $20,000,000.

But a strong reaction in the United States against acquisition of the Philippines had already set in by the time the Treaty of Paris was signed on December 10, 1898; and anti-imperialists declared that the control and governance of distant alien peoples violated all American traditions of self-determination and would even threaten the very fabric of the republic. Though there were more than enough votes in the Senate to defeat the treaty, that body gave its consent to ratification largely because William Jennings Bryan, the Democratic leader, wanted Democrats to approve the treaty and then make imperialism the chief issue of the 1900 presidential campaign.

The new American empire. McKinley easily defeated Bryan in 1900. The victory, however, was hardly a mandate for imperialism, and, as events were soon to disclose, the American people were perhaps the most reluctant imperialists in history. No sooner had they acquired an overseas empire than they set in motion the processes of its dissolution or transformation.

By the so-called Teller Amendment to the war resolution, Congress had declared that the United States would not annex Cuba. This pledge was kept, although Cuba was forced in 1903 to sign a treaty making it virtually a protectorate of the United States. The Hawaiian Islands, annexed by Congress on July 7, 1898, were made a territory in 1900 and were hence, technically, only briefly part of the American empire. Puerto Rico was given limited self-government in 1900; and the Jones Act of 1917 conferred full territorial status on the island, gave American citizenship to its inhabitants, and limited its self-government only by the veto of a governor appointed by the president of the United States. Establishing any kind of government in the Philippines was much more difficult because a large band of Filipinos resisted American rule as bravely as they had fought the Spanish. The Philippine insurrection was over by 1901, however, and the Philippine Government Act of 1902 inaugurated the beginning of partial self-government, which was transformed into almost complete home rule by the Jones Act of 1916.

The Open Door in the Far East. Although Americans were reluctant imperialists, the United States was an important Pacific power after 1898, and American businessmen had inflated ambitions to tap what they thought was the enormous Chinese market. The doors to that market were being rapidly closed in the 1890s, however, as Britain, France, Russia, and Japan carved out large so-called spheres of influence all the way from Manchuria to southern China. With Britain's support (the British stood to gain the most from equal trade opportunities), on September 6, 1899, Secretary of State John Hay addressed the first so-called Open Door note to the powers with interests in China; it asked them to accord equal trade and investment opportunities to all nationals in their spheres of interest and leased territories. With considerable bravado, Hay announced that all the powers had agreed to respect the Open Door, even though the Russians had declined to give any pledges. On July 3, 1900, after the Boxer Rebellion—an uprising in China against foreign influence—Hay circulated a second Open Door note announcing that it was American policy to preserve Chinese territorial and political integrity.

Such pronouncements had little effect because the United States was not prepared to support the Open Door Policy with force; successive administrations to the 1940s, however, considered it the cornerstone of their Far Eastern policy. Pres. Theodore Roosevelt reluctantly mediated the Russo-Japanese War in 1905 in part to protect the Open Door as well as to maintain a balance of power in the Far East. When Japan attempted in 1915 to force a virtual protectorate on China, Pres. Woodrow Wilson intervened sternly and in large measure successfully to protect Chinese independence. Victory for American policy seemed to come with the Nine-Power Treaty of Washington of 1922, when all nations with interests in China promised to respect the Open Door.

Building the Panama Canal and American domination of the Caribbean area. Strategic necessity and the desire of eastern businessmen to have easy access to Pacific markets combined in the late 1890s to convince the President, Congress, and a vast majority of Americans that an isthmian canal linking the Atlantic and Pacific oceans was vital to national security and prosperity. In the Hay–Pauncefote Treaty of 1901, the British government gave up the rights to joint construction with the United States that it had gained under the Clayton–Bulwer Treaty of 1850. A French company, which had tried unsuccessfully to dig a canal across the Isthmus of Panama, was eager to sell its right of way to the United States. Thus, the only obstacle to the project was the government of Colombia, which owned Panama. When Colombia refused to cooperate, Roosevelt, in 1903, covertly supported a Panamanian revolution engineered by officials of the French company. A treaty was quickly negotiated between the United States and the new Republic of Panama; construction began, and the canal was opened to shipping in January 1914.

Acquisition of Panama

Concern over what Americans regarded increasingly as their "lifeline" increased in proportion to progress in the construction of the canal. An early manifestation of that concern came in 1902–03, when Britain, Germany, and Italy blockaded Venezuela to force the payment of debts,

and particularly when the Germans bombarded and destroyed a Venezuelan town; so agitated was American opinion that Roosevelt used a veiled threat to force Germany to accept arbitration of the debt question by the Hague Court. When the Dominican Republic defaulted on its foreign debt to several European countries in 1904, Roosevelt quickly established an American receivership of the Dominican customs in order to collect the revenues to meet the country's debt payments. Moreover, in his annual message to Congress of 1904, the President announced a new Latin American policy, soon called the Roosevelt Corollary to the Monroe Doctrine—because the Monroe Doctrine forbade European use of force in the New World, the United States would itself take whatever action necessary to guarantee that Latin American states gave no cause for such European intervention. It was, in fact, a considerable extension of the Monroe Doctrine, not a correct historical interpretation of it; but it remained the cornerstone of American policy in the Caribbean at least until 1928.

Actually, Roosevelt was reluctant to interfere in the domestic affairs of neighbouring states; his one significant intervention after 1904—the administration of the Cuban government from 1906 to 1909—was undertaken in order to prevent civil war and at the insistence of Cuban authorities. Roosevelt's successor, however, William Howard Taft, had more ambitious plans to guarantee American hegemony in the approaches to the Panama Canal. Adopting a policy called Dollar Diplomacy, Taft hoped to persuade American private bankers to displace European creditors in the Caribbean area and thereby to increase American influence and encourage stability in countries prone to revolution. Dollar Diplomacy was a total failure; its one result was to involve the United States in a civil war in Nicaragua with the effect of perpetuating a reactionary and unpopular regime.

Dollar Diplomacy

The accession of Woodrow Wilson in 1913 seemed to augur the beginning of a new era in Latin American relations; the new president and his secretary of state, William J. Bryan, were idealists who had strongly condemned interventions and Dollar Diplomacy. But although Wilson did negotiate a treaty with Colombia to make reparation for U.S. complicity in the Panamanian revolution, it was defeated by the Senate. Moreover, Wilson tried hard to promote a Pan-American nonaggression pact; but it foundered on the opposition of certain Latin American governments.

When crises threatened the domestic stability of the Caribbean area, however, Wilson revealed that he was just as determined to protect American security as Roosevelt and Taft had been and that he was perhaps even more willing to use force. Frequent revolutions and the fear of European intervention led Wilson to impose a protectorate and a puppet government upon Haiti in 1915 and a military occupation of the Dominican Republic in 1916. He concluded a treaty with Nicaragua making that country a protectorate of the United States. Moreover, he purchased the Danish Virgin Islands in 1916 at the inflated price of $25,000,000 in order to prevent their possible transfer from Denmark to Germany.

THE PROGRESSIVE ERA

The character and variety of the Progressive movement. The inauguration of Pres. William McKinley in 1897 had seemed to mark the end of an era of domestic turmoil and the beginning of a new period of unparalleled tranquility. Prosperity was returning after the devastating Panic of 1893. The agrarian uprising led by Bryan in the election of 1896 had been turned back, and the national government was securely in the hands of friends of big business. The Dingley Tariff of 1897 greatly increased tariff rates; the Gold Standard Act of 1897 dashed the hopes of advocates of the free coinage of silver; and McKinley did nothing to stop a series of industrial combinations in defiance of the Sherman Anti-Trust Act.

Origins of Progressivism. Never were superficial signs more deceiving than during McKinley's first term. Actually, the United States already was in the first stages of what historians came to call the Progressive Movement. Generally speaking, Progressivism was the response of various groups to problems raised by the rapid industrialization and urbanization that followed the Civil War. These problems included the spread of slums and poverty; the exploitation of labour; the breakdown of democratic government in the cities and states caused by the emergence of political organizations, or machines, allied with business interests; and a rapid movement toward financial and industrial concentration. Many Americans feared that their historic traditions of responsible democratic government and free economic opportunity for all were being destroyed by gigantic combinations of economic and political power.

Problems of industrialization and urbanization

Actually there was not, either in the 1890s or later, any one Progressive movement. There were numerous movements for reform and reconstruction on the local, state, and national levels that were too diverse, and sometimes too mutually antagonistic, ever to coalesce into a national crusade. But they were generally motivated by common assumptions and goals—*e.g.*, the repudiation of individualism and laissez-faire, concern for the underprivileged and downtrodden, the restoration of government to the rank and file, and the enlargement of governmental power in order to bring industry and finance under a measure of popular control.

The origins of Progressivism were as complex and are as difficult to describe as the movement itself. In the vanguard were various agrarian crusades, such as the Grangers and the Populists and Democrats under Bryan, with their demands for stringent railroad regulation and national control of banks and the money supply. At the same time a new generation of economists, sociologists, and political scientists was undermining the philosophical foundations of the laissez-faire state and constructing a new ideology to justify democratic collectivism; and a new school of social workers was establishing settlement houses and going into the slums to discover the extent of human degradation. Allied with them was a growing body of ministers, priests, and rabbis—proponents of what was called the Social Gospel—who struggled to arouse the social concerns and consciences of their parishioners. Finally, journalists called "muckrakers" probed into all the dark corners of American life and carried their message of reform through mass-circulation newspapers and magazines.

Two specific catalytic agents set off the Progressive movement—the agrarian depression of the early 1890s and the financial and industrial depression that began in 1893. Low prices drove farmers by the hundreds of thousands into the radical People's Party of 1892. Widespread suffering in the cities beginning in 1893 caused a breakdown of many social services and dramatized for the increasing number of urban middle class Americans the wide contrast between rich and poor.

Depressions of the early 1890s

Urban reforms. A movement already begun, to wrest control of city governments from corrupt political machines, was given tremendous impetus by the Panic of 1893. The National Municipal League, organized in 1894, united various city reform groups throughout the country; corrupt local governments were overthrown in such cities as New York in 1894, Baltimore in 1895, and Chicago in 1896–97. And so it went all over the country well into the 20th century.

Despite differences among urban reformers at the beginning of their movement, by the early 1900s the vast majority of them were fighting for and winning much the same objectives—more equitable taxation of railroad and corporate property, tenement house reform, better schools, and expanded social services for the poor. Even big-city machines like Tammany Hall became increasingly sensitive to the social and economic needs of their constituents. Reformers also devised new forms of city government to replace the old mayor–city-council arrangement that had proved to be so susceptible to corrupt influences. One was the commission form, which vested all responsibility in a small group of commissioners, each responsible for a single department; another was the city-manager form, which provided administration by a professionally trained expert, responsible to a popularly

elected council (these two forms were in widespread use in small and medium-sized cities by 1916).

Reform in state governments. The reform movement spread almost at once to the state level, for it was in state capitals that important decisions affecting the cities were made. Entrenched and very professional political organizations, generously financed by officeholders and businessmen wanting special privileges, controlled most state governments in the late 1890s; everywhere, these organizations were challenged by a rising generation of young and idealistic anti-organization leaders, ambitious for power. They were most successful in the Middle West, under such leaders as Robert M. La Follette of Wisconsin; but they had counterparts all over the country—*e.g.*, Charles Evans Hughes of New York, Woodrow Wilson of New Jersey, Andrew J. Montague of Virginia, and Hiram W. Johnson of California.

Anti-organizational leaders

These young leaders revolutionized the art and practice of politics in the United States, not only by exercising strong leadership but also by effecting institutional changes such as the direct primary, direct election of senators (rather than by state legislatures), the initiative, referendum, and recall—which helped restore and revitalized political democracy. More important, perhaps, progressives to a large degree achieved their economic and social objectives—among them, strict regulation of intrastate railroads and public utilities, legislation to prevent child labour and to protect women workers, penal reform, expanded charitable services to the poor, and accident insurance systems to provide compensation to workers and their families.

Theodore Roosevelt and the Progressive movement. By 1901 the reform upheaval was too strong to be contained within state boundaries. Moreover, certain problems cried out for solution, with which only the federal government was apparently competent to deal. McKinley might have succeeded in ignoring the rising tide of public opinion, had he served out his second term. But McKinley's assassination in September 1901 brought to the presidency an entirely different kind of man—Theodore Roosevelt, at age 42 the youngest man yet to enter the White House. Roosevelt had broad democratic sympathies; moreover, thanks to his experience as police commissioner of New York City and governor of New York State, he was the first president to have an intimate knowledge of modern urban problems. Because Congress was securely controlled by a group of archconservative Republicans, the new president had to feel his way cautiously in legislative matters; but he emerged full-grown as a tribune of the people after his triumph in the presidential election of 1904. By 1906 he was the undisputed spokesman of national Progressivism and by far its best publicity agent. (The White House was, he said, "a bully pulpit.") Meanwhile, by his leadership of public opinion and by acting as a spur on Congress, he had revived the presidency and made it incomparably the most powerful force in national politics.

In 1901 Americans were perhaps most alarmed about the spread of so-called trusts, or industrial combinations, which they thought were responsible for the steady price increases that had occurred each year since 1897. Ever alert to the winds of public opinion, Roosevelt responded by activating the Sherman Anti-Trust Act of 1890, which had lain dormant because of Cleveland's and McKinley's refusal to enforce it and also because of the Supreme Court's ruling of 1895 that the measure did not apply to combinations in manufacturing. Beginning in 1902 with a suit to dissolve a northwestern railroad monopoly, Roosevelt moved next against the so-called Beef Trust, then against the oil, tobacco, and other monopolies. In every case the Supreme Court supported the administration, going so far in the oil and tobacco decisions of 1911 as to reverse its 1895 decision. In addition, in 1903 Roosevelt persuaded a reluctant Congress to establish a Bureau of Corporations with sweeping power to investigate business practices; the bureau's thoroughgoing reports were of immense assistance in antitrust cases. While establishing the supremacy of the federal government in the industrial field, Roosevelt, in 1902, also took action unprecedented in the history of the presidency by intervening on labour's behalf to force the arbitration of a strike by the United Mine Workers of America against the Pennsylvania anthracite coal operators.

The breaking of the trusts

Roosevelt moved much more aggressively after his 1904 election. Public demand for effective national regulation of interstate railroad rates had been growing since the Supreme Court had emasculated the Interstate Commerce Commission's (ICC) rate-making authority in the 1880s. Determined to bring the railroads—the country's single greatest private economic interest—under effective national control, Roosevelt waged an unrelenting battle with Congress in 1905–06. The outcome—the Hepburn Act of 1906—was his own personal triumph; it greatly enlarged the ICC's jurisdiction and forbade railroads to increase rates without its approval. By using the same tactics of aggressive leadership, Roosevelt in 1906 also obtained passage of a Meat Inspection Act and a Pure Food and Drug Act. Passage of the former was aided by the publication of Upton Sinclair's famous novel, *The Jungle* (1906), which revealed in gory detail the insanitary conditions of the Chicago stockyards and packing plants.

Meanwhile, almost from his accession to the presidency, Roosevelt had been carrying on a crusade, often independent of Congress, to conserve the nation's fast-dwindling natural resources and to make them available for exploitation under rigorous national supervision. He withdrew from the public domain some 148,000,000 acres of forest lands, 80,000,000 acres of mineral lands, and 1,500,000 acres of water-power sites. Moreover, adoption of the National Reclamation Act of 1902 made possible the beginning of an ambitious federal program of irrigation and hydroelectric development in the West.

Republican troubles under Taft. Roosevelt was so much the idol of the masses of 1908 that he could have easily gained the Republican nomination in that year. After his election in 1904, however, he had announced that he would not be a candidate four years later; adhering stubbornly to his pledge, he arranged the nomination of his secretary of war, William Howard Taft of Ohio, who easily defeated Bryan.

Taft might have made an ideal president during a time of domestic tranquility, but his tenure in the White House was far from peaceful. National progressivism was nearly at high tide; and a large group of Republican progressives, called "insurgents," sat in both houses of Congress.

The high tide of Progressivism

The Republican insurgents. These Republicans, like a majority of Americans, demanded such reforms as tariff reductions, an income tax, the direct election of senators, and even stricter railroad and corporation regulations. Taft, who had strongly supported Roosevelt's policies, thought of himself as a progressive. Actually he was temperamentally and philosophically a conservative; moreover, he lacked the qualities of a dynamic popular leader. In the circumstances, his ineptness, indecision, and failure to lead could only spell disaster for his party.

Taft's troubles began when he called Congress into special session in 1909 to take up the first item on his agenda —tariff reform. The measure that emerged from Congress actually increased rates. Republican insurgents and a majority of Americans were outraged, but Taft signed the bill and called it the best tariff law that the Republican Party had ever enacted.

By 1910 the Republican insurgents were clearly in the ascendancy in the Congress. Taking control of the President's railroad-regulation measure they added new provisions that greatly enlarged the ICC's authority. The following year they bitterly opposed Taft's measure for tariff reciprocity with Canada; it passed with Democratic support in Congress, only to go down to defeat at the hands of the Canadian electorate.

The 1912 election. Republican insurgents were determined to prevent Taft's renomination in 1912. They found their leader in Roosevelt, who had become increasingly alienated from Taft and who made a whirlwind campaign for the presidential nomination in the winter and spring of 1912. Roosevelt swept the presidential primaries, even in Taft's own state of Ohio; but

Taft and conservative Republicans controlled the powerful state organizations and the Republican National Committee and were able to nominate Taft by a narrow margin. Convinced that the bosses had stolen the nomination from him, Roosevelt led his followers out of the Republican convention. In August they organized the Progressive Party at Chicago and named Roosevelt to lead the third-party cause.

Democrats had swept the 1910 congressional and gubernatorial elections; and after the disruption of the Republican Party in the spring of 1912, it was obvious that almost any passable Democrat could win the presidency in that year. Woodrow Wilson, former president of Princeton University, who had made a brilliant progressive record as governor of New Jersey, was nominated by the Democrats on the 46th ballot.

Taft's single objective in the 1912 campaign was to defeat Roosevelt. The real contest was between Roosevelt and Wilson for control of the progressive majority. Campaigning strenuously on a platform that he called the New Nationalism, Roosevelt demanded effective control of big business through a strong federal commission, radical tax reform, and a whole series of measures to put the federal government squarely into the business of social and economic reform. By contrast Wilson seemed conservative with a program he called the New Freedom; it envisaged a concerted effort to destroy monopoly and to open the doors of economic opportunity to small businessmen through drastic tariff reduction, banking reform, and severe tightening of the antitrust laws. Roosevelt outpolled Taft in the election, but he failed to win many Democratic progressives away from Wilson, who won by a huge majority of electoral votes, though receiving only about 42 percent of the popular vote.

The New Freedom and its transformation. A trained political scientist and historian, Wilson believed that the president should be the leader of public opinion, the chief formulator of legislative policy, and virtually sovereign in the conduct of foreign relations. With the support of an aroused public opinion and a compliant Democratic majority, he was able to put his theories of leadership into effect with spectacular success.

Wilson's domestic program

The first item in Wilson's program was tariff reform, a perennial Democratic objective since the Civil War; the President's measure, the Underwood Tariff Act of 1913, reduced average rates from 40 percent to 25 percent, greatly enlarged the free list, and included a modest income tax. Next came adoption of the President's measure for banking and monetary reform, the Federal Reserve Act of 1913, which created a federal reserve system to mobilize banking reserves and issue a flexible new currency—federal reserve notes—based on gold and commercial paper; uniting and supervising the entire system was a federal reserve board of presidential appointees.

The third, and Wilson thought the last, part of the New Freedom program was antitrust reform. In his first significant movement toward Roosevelt's New Nationalism, Wilson reversed his position that merely strengthening the Sherman Anti-Trust Act would suffice to prevent monopoly. Instead, he took up and pushed through Congress the Progressive-sponsored Federal Trade Commission Act of 1914. It established an agency—the Federal Trade Commission (FTC)—with sweeping authority to prevent business practices that would lead to monopoly. Meanwhile, Wilson had abandoned his original measure, the Clayton Anti-Trust Bill passed by Congress in 1914; its severe provisions against interlocking directorates and practices tending toward monopoly had been gravely weakened by the time the President signed it. The Clayton Bill included a declaration that labour unions, as such, were not to be construed as conspiracies in restraint of trade in violation of the antitrust laws; but what organized labour wanted, and did not get, was immunity from prosecution for such measures as the sympathetic strike and the secondary boycott, which the courts had proscribed as violations of the Sherman Act.

In a public letter in November 1914, the President announced that his reform program was complete. But various groups were still demanding the advanced kind of social and economic legislation that Roosevelt had advocated in 1912; also, by early 1916 the Progressive Party had largely disintegrated, and Wilson knew that he could win re-election only with the support of a substantial minority of Roosevelt's former followers. Consequently —and also because his own political thinking had been moving toward a more advanced progressive position— Wilson struck out upon a new political course in 1916. He began by appointing Louis D. Brandeis, the leading critic of big business and finance, to the Supreme Court. Then in quick succession he obtained passage of a rural-credits measure to supply cheap long-term credit to farmers; anti-child-labour and federal workmen's-compensation legislation; the Adamson Act, establishing the eight-hour day for interstate railroad workers; and measures for federal aid to education and highway construction. With such a program behind him, Wilson was able to rally a new coalition of Democrats, former Progressives, independents, social workers, and a large minority of Socialists; and he narrowly defeated his Republican opponent, Charles Evans Hughes, in the 1916 presidential election.

THE RISE TO WORLD POWER

Wilson and the Mexican revolution. Although Wilson's consuming interest was in domestic politics, he had to deal primarily with foreign affairs while in the White House; and before the end of his presidency he had developed into a diplomatist of great skill as well as one of the commanding figures in world affairs. He was a "strong" president in the conduct of foreign policy, writing most of the important diplomatic correspondence of his government and making all important decisions himself. He usually worked well with his secretaries of state, Bryan and Robert Lansing, and often relied for advice upon his confidential counsellor, Col. Edward M. House of Texas.

Wilson's conduct of foreign affairs

Wilson served his apprenticeship by having to deal at the outset of his administration with an uprising in Mexico, set off when a military usurper, Victoriano Huerta, murdered liberal president Francisco Madero and seized the executive power in February 1913. It was difficult for the United States to remain aloof because Americans had invested heavily in Mexico and 40,000 American citizens resided there.

If Wilson had followed conventional policy and the urgings of Americans with interests in Mexico, he would have recognized Huerta (as most European governments did), who promised to respect and protect all foreign investments and concessions. But Wilson was revolted by Huerta's bloody rise to power; moreover, he believed that the revolution begun by Madero in 1910 was a glorious episode in the history of human liberty. Wilson thus not only refused to recognize Huerta but also tried to persuade the dictator to step down from office and permit the holding of free elections for a new democratic government. When Huerta refused to cooperate, Wilson gave open support to the Constitutionalists—Huerta's opponents under Madero's successor, Venustiano Carranza—and when it seemed that the Constitutionalists could not themselves drive Huerta from power, Wilson seized the port of Veracruz in April 1914 to cut off Huerta's supplies and revenues. This stratagem succeeded, and Carranza and his army occupied Mexico City in August.

The revolutionary forces then divided between Carranza's followers and those of his chief rival and most colorful general, Pancho Villa; and civil war raged for another year. Wilson refused to interfere; Carranza emerged victoriously by the summer of 1915, and Wilson accorded him de facto recognition in October. But Villa, seeking to provoke war between the United States and Mexico, raided Columbus, New Mexico, on March 9, 1916, burning the town and killing 19 inhabitants. Wilson sent a punitive expedition under Gen. John J. Pershing into Mexico in hot pursuit of Villa; but the wily bandit eluded Pershing, and the deeper the Americans penetrated into Mexican territory, the more agitated the Carranza government became. There were two serious skirmishes between regular Mexican and American troops in the spring, and full-scale war was averted only when Wilson withdrew Per-

shing's column some months later. Relations between the two governments were greatly improved when Wilson extended de jure recognition to Carranza's new constitutional regime in April 1917. Thereafter, Wilson adamantly rejected all further foreign and American suggestions for intervention in Mexico.

Outbreak of World War I

The struggle for neutrality. The outbreak of general war in Europe in August 1914 raised grave challenges to Wilson's skill and leadership in foreign affairs. In spite of the appeals of propagandists for the rival Allies and Central Powers, the great majority of Americans were doggedly neutral and determined to avoid involvement unless American rights and interests were violated. This, too, was Wilson's own feeling, and in August he issued an official proclamation of neutrality and two weeks later appealed to Americans to be "impartial in thought as well as in action."

Loans and supplies for the Allies. Difficulties arose first with the British government, which at once used its vast fleet to establish a long-range blockade of Germany. The U.S. State Department sent several strong protests to London, particularly against British suppression of American exports of food and raw materials to Germany. Anglo-American blockade controversies were not acute, however, because the British put their blockade controls into effect gradually, always paid for goods seized, argued persuasively that in a total war food and raw materials were as essential as guns and ammunition, and pointed out that they, the British, were simply following blockade precedents established by the United States itself during the Civil War. As a result of a tacit Anglo-American agreement, the United States soon became the chief external source of supply for the food, raw materials, and munitions that fed the British and French war machines. In addition, and in accordance with the strict rules of neutrality, the Wilson administration permitted the Allied governments to borrow more than $2,000,000,000 in the United States in order to finance the war trade. At the same time, the President resisted all efforts by German Americans for an arms embargo on the ground that such a measure would be grossly unneutral toward the Allies.

German submarine warfare. There was no possibility of conflict between Germany and the United States so long as the former confined its warfare to the continent of Europe; a new situation full of potential danger arose, however, when the German authorities decided to use a new weapon, the submarine, to challenge British control of the seas. The German admiralty announced in February 1915 that all Allied vessels would be torpedoed without warning in a broad area and that even neutral vessels were not safe. Wilson replied at once that he would hold Germany to "strict accountability" if submarines destroyed American ships and lives without warning. The Germans soon gave broad guarantees concerning American ships, and their safety against illegal submarine attacks was not an issue between the two countries before 1917.

The sinking of unarmed ships

An issue much more fraught with danger was the safety of Americans travelling and working on Allied ships. A German submarine sank the unarmed British liner "Lusitania" without warning on May 7, 1915, killing, among others, 128 Americans. Wilson at first appealed to the Germans on broad grounds of humanity to abandon submarine warfare, but in the subsequent negotiations he narrowed the issue to one of safety for unarmed passenger liners against violent underseas attack. Momentary resolution came when a submarine sank the unarmed British liner "Arabic" in August. Wilson warned that he would break diplomatic relations if such attacks continued, and the Germans grudgingly promised not to attack unarmed passenger ships without warning. The controversy escalated to a more dangerous level when a submarine torpedoed the packet steamer "Sussex" in the English Channel with heavy loss of life in March 1916. In an ultimatum to Berlin, Wilson threatened to break diplomatic relations if the Germans did not cease attacking liners and merchantmen without warning; once again the Germans capitulated, but they threatened to resume unrestricted submarine warfare if the United States failed to force the British to observe international law in their blockade practices.

The Allies complicated the submarine controversy in late 1915 by arming many of their liners and merchantmen sailing to American ports. Wilson tried to arrange a compromise by which the Allies would disarm their ships in return for a German promise not to sink them without warning. When the British rejected the proposal, the President gave the impression that he would hold Germany accountable for American lives lost on armed ships, setting off a rebellion in Congress and the near passage of resolutions forbidding American citizens to travel on armed ships. Actually, the President had no intention of permitting armed ships to become a serious issue; their status was never a subject of serious controversy between the United States and Germany.

Arming for war. Meanwhile, the increasingly perilous state of relations with Germany had prompted Wilson, in December 1915, to call for a considerable expansion in the nation's armed forces. A violent controversy over preparedness ensued, both in Congress and in the country at large. The army legislation of 1916 was a compromise, with Wilson obtaining only a modest increase in the army and a strengthening of the National Guard; but the Naval Appropriations Act of 1916 provided for more ships than the administration had requested.

The United States enters the war. Wilson's most passionate desire, aside from avoiding belligerency, was to bring an end to the war through his personal mediation. He sent Colonel House to Europe in early 1915 to explore the possibilities of peace and again early in 1916 to press for a plan of Anglo-American cooperation for peace. The British refused to cooperate, and the President, more than ever eager to avoid a final confrontation with Germany on the submarine issue, decided to press forward with independent mediation. He was by this time also irritated by the intensification of British blockade practices and convinced that both sides were fighting for domination and spoils. On December 18, 1916, Wilson asked the belligerents to state the terms upon which they would be willing to make peace. Soon afterward, in secret, high-level negotiations, he appealed to Britain and Germany to hold an early peace conference under his direction.

Wilson's attempts to achieve peace

Break with Germany. Chances for peace were blasted by a decision of the German leaders, made at an imperial conference on January 9, 1917, to inaugurate an all-out submarine war against all commerce, neutral as well as belligerent. The Germans knew that such a campaign would almost certainly bring the United States into the war; but they were confident that their augmented submarine fleet could starve Britain into submission before the U.S. could mobilize and participate effectively.

The announcement of the new submarine blockade in January left the President no alternative but to break diplomatic relations with Germany, which he did on February 3. At the same time, and in subsequent addresses, the President made it clear that he would accept unrestricted submarine warfare against belligerent merchantmen and would act only if American ships were sunk. In early March he put arms on American ships in the hope that this would deter submarine attacks. The Germans began to sink American ships indiscriminately in mid-March; and Wilson, on April 2, asked Congress to recognize that a state of war existed between the United States and the German empire. Congress approved the war resolution quickly, and Wilson signed it on April 6.

Mobilization. Generally speaking, the efforts at mobilization went through two stages. During the first, lasting roughly from April to December 1917, the administration relied mainly on voluntary and cooperative efforts. During the second stage, after December 1917, the government moved rapidly to establish complete control over every important phase of economic life. Railroads were nationalized; a war industries board established ironclad controls over industry; food and fuel were strictly rationed; an emergency-fleet corporation began construction of a vast merchant fleet; and a war labour board used coercive measures to prevent strikes. Opposition to

Government controls during the war

the war was sternly suppressed under the Espionage Act of 1917 and the even severer Sedition Act of 1918. By the spring of 1918, the American people and their economy had been harnessed for total war (a near miracle, considering the lack of preparedness only a year before).

America's role in the war. The American military contribution, while small compared to that of the Allies during the entire war, was in two respects decisive in the outcome. The United States Navy, fully prepared at the outset, provided the ships that helped the British overcome the submarine threat by the autumn of 1917. The United States Army, some 4,000,000 men strong, was raised mainly by conscription under the Selective Service Act of 1917; the American Expeditionary Force of more than 1,200,000 men under General Pershing reached France by September 1918, and this huge infusion of manpower tipped the balance on the western front and helped to end the war in November 1918, a year earlier than military planners had anticipated.

Wilson's vision of a new world order. In one of the most ambitious rhetorical efforts in modern history, President Wilson attempted to rally the people of the world in a movement for a peace settlement that would remove the causes of future wars and establish machinery to maintain peace. In an address to the Senate on January 22, 1917, he called for a "peace without victory" to be enforced by a league of nations that the United States would join and strongly support. He reiterated this program in his war message, adding that the United States wanted above all else to "make the world safe for democracy." And when he failed to persuade the British and French leaders to join him in issuing a common statement of war aims, he went to Congress on January 8, 1918, to make, in his Fourteen Points Address, his definitive avowal to the American people and the world.

Wilson's Fourteen Points

In his general points Wilson demanded an end to the old diplomacy that had led to wars in the past. He proposed open diplomacy instead of entangling alliances, and he called for freedom of the seas, an impartial settlement of colonial claims, general disarmament, removal of artificial trade barriers, and, most important, a league of nations to promote peace and protect the territorial integrity and independence of its members. On specific issues he demanded, among other things, the restoration of a Belgium ravaged by the Germans; sympathetic treatment of the Russians, then involved in a civil war; establishment of an independent Poland; the return of Alsace-Lorraine to France; and autonomy or self-determination for the subject peoples of the Austro-Hungarian and Ottoman empires. A breathtaking pronouncement, the Fourteen Points gave new hope to millions of liberals and moderate socialists who were fighting for a new international order based upon peace and justice.

The Paris Peace Conference and the Versailles Treaty. With their armies reeling under the weight of a combined allied and American assault, the Germans appealed to Wilson in October 1918 for an armistice based on the Fourteen Points and other presidential pronouncements. The Allies agreed to conclude peace on this basis, except that the British entered a reservation about freedom of the seas, and Wilson agreed to an Anglo-French demand that the Germans be required to make reparation for damages to civilian property.

Wilson led the American delegation and a large group of experts to the peace conference, which opened in Paris in January 1919. He fought heroically for his Fourteen Points against the Allied leaders—David Lloyd George of Britain, Georges Clemenceau of France, and Vittorio Orlando of Italy—who, under heavy pressure from their own constituencies, were determined to divide the territories of the vanquished and make Germany pay the full cost of the war. Wilson made a number of compromises that violated the spirit if not the letter of the Fourteen Points, including the imposition of a potentially astronomical reparations bill upon Germany. Moreover, the Allies had intervened in the Russian Civil War against the dominant revolutionary Socialist faction, the Bolsheviks; and Wilson had halfheartedly cooperated with the Allies by dispatching small numbers of troops to northern Russia, to protect military supplies against the advancing Germans, and to Siberia, mainly to keep an eye on the Japanese, who had sent a large force there. But Wilson won many more of his Fourteen Points than he lost; his greatest victories were to prevent the dismemberment of Germany in the west and further intervention in Russia and, most important, to obtain the incorporation of the Covenant of the League of Nations into the Versailles Treaty. He was confident that the League, under American leadership, would soon rectify the injustices of the treaty.

The League of Nations

The fight over the treaty and the election of 1920. Public opinion in the United States seemed strongly in favour of quick ratification of the Versailles Treaty when the President presented that document to the Senate in July 1919. But traditional isolationist sentiment was beginning to revive, and a group of 16 senators, irreconcilably opposed to American membership in the League, vowed to oppose the treaty to the bitter end; but they were a small minority, helpless by themselves. A crucial controversy developed between the President and a majority of the Republican senators, led by Henry Cabot Lodge of Massachusetts. Lodge insisted upon adding 14 reservations to the treaty; the second reservation declared that the United States assumed no obligations under Article X of the Covenant, which guaranteed the integrity and independence of members of the League, and moreover it said that the president could not use the armed forces to support the Covenant without the explicit consent of Congress in every instance.

Calling this reservation a nullification of the treaty, Wilson in September made a long speaking tour of the West to build up public support for unconditional ratification. He suffered a breakdown at the end of his tour and a serious stroke on October 2. The President's illness, which incapacitated him for several months, may have increased his intransigence against the Lodge reservations; with equal stubbornness, the Massachusetts senator refused to consent to any compromise. The result was failure to obtain the necessary two-thirds majority for ratification, with or without reservations, when the Senate voted on November 19, 1919, and again on March 19, 1920.

Wilson had suggested that the ensuing presidential campaign and election should be a "great and solemn referendum" on the League. The Democratic candidate, James M. Cox of Ohio, fought hard to make it the leading issue; but the Republican candidate, Warren G. Harding of Ohio, was evasive on the subject, and a group of 31 leading Republican internationalists assured the country that Harding's election would be the best guarantee of American membership in the League of Nations. Harding swamped Cox, and his victory ended all hopes for American membership. In his inaugural Harding announced that the United States would not be entangled in European affairs; he emphasized this determination by concluding a separate peace with Germany in 1921. (A.S.L.)

VII. The United States from 1920 to 1945

THE CHARACTER OF THE POSTWAR REPUBLICAN ADMINISTRATIONS

Politics and economics. Harding assumed the presidency pledged to return to normalcy a nation suffering postwar dislocation and depression. He and his Republican administration put into effect his campaign slogan, "Less government in business and more business in government." They reversed the progressive and wartime trend toward business regulation but tried through a number of measures to foster business both large and small.

Harding's administration

Harding's cabinet, together with Republican congressional leaders, helped establish probusiness policies. Harding wanted to put the best qualified men in the cabinet and was partly successful. The distinguished secretary of state, Charles Evans Hughes, was a well-known New York lawyer who fostered American economic interests overseas. The secretary of the treasury Andrew W. Mellon, one of the nation's wealthiest men, tried to stimulate business expansion by persuading Congress to cut drastically the taxes of those with large incomes; Mellon also

promoted economy within the government and sharply reduced the national debt. The secretary of commerce Herbert Hoover, the defender of small enterprise, promoted foreign trade and, through the National Bureau of Standards, improved business efficiency; Hoover also encouraged the formation of trade associations. The secretary of agriculture Henry C. Wallace obtained for Midwest farmers (with progressive Republican support) legislation regulating commodity exchanges and stockyards, providing credit for distressed farmers, and encouraging farm cooperatives. The secretary of the interior Albert B. Fall was one of the most outspoken opponents of conservationist interference with western development. The attorney general Harry M. Daugherty aided railroads and mining companies by obtaining injunctions against strikes.

Capping this program to aid businessmen and farmers was a tariff act in 1922, which, although it placed a 42¢ a bushel duty on wheat, gave farmers little protection. By raising duties to cover the differential between the cost of production within the United States and that abroad, it helped manufacturers. Its effect upon other countries was to stimulate them to raise their own tariffs.

The government itself became more businesslike. The Budget and Accounting Act of 1921 established the Bureau of the Budget, which prepared a single unified budget, and also the General Accounting Office, an auditing agency.

Legislation restricting immigration reversed traditional American policy and stemmed the flow from Europe. In 1920, the year before enactment of emergency legislation, 800,000 immigrants had arrived. Added to the protests of organized labour were the objections of business leaders and patriotic organizations, who feared that some of the immigrants might be radicals. Legislation in 1924 set small quotas totalling 164,000 people yearly; it favoured immigrants from northwestern Europe and outraged the Japanese by banning all immigration from east Asia. Immigration from within the Western Hemisphere continued—900,000 Canadians (mostly French-speaking) and 500,000 Mexicans entered the United States during the 1920s.

The return of prosperity

By 1923, with the return of prosperity, Harding was enjoying widespread popularity but was heartsick over evidence of scandal within his administration. He died of a heart attack in the summer of 1923, and in subsequent months the public learned of the corruption. The most publicized was the illegal leasing of naval oil reserves at Teapot Dome, Wyoming, which led to the conviction of Secretary Fall for accepting a bribe.

Calvin Coolidge and the progress of business. Calvin Coolidge, Harding's successor, was so impeccably honest and frugal that his administration suffered none of the stigma of the Harding scandals. "Keep cool with Coolidge," was the campaign slogan when he ran in 1924 against the conservative Democrat John W. Davis. The Republicans directed more of their campaign oratory against the third-party Progressive candidate, Sen. Robert La Follette. Coolidge received more popular votes than his opponents combined.

Through essentially negative policies, the President presided over what came to be known as the years of "Coolidge prosperity." He was considerably more conservative than Harding, and through exercise of the veto and appointment power he prevented restrictions upon business. Like his predecessor, he appointed judges and members of regulatory commissions whom he felt would not interfere with the nation's economic life, and regulation did slacken (he did not always succeed, however; Harlan F. Stone, whom he appointed to the Supreme Court, became one of its most liberal members). Toward the end of his administration, Coolidge refused to use his influence to tighten credit or to make stock market speculation more difficult. In 1927 he vetoed a bill that would have raised prices of basic farm commodities because he considered it contrary to laissez-faire; the same day he authorized a 50 percent increase in the tariff on pig iron. In 1928 he pocket-vetoed Sen. George W. Norris' bill for the development of the federally owned dam at Muscle Shoals on the Tennessee River. On the other hand, Norris led the senators in blocking Coolidge's recommendation to sell Muscle Shoals to the industrialist Henry Ford.

Overall, the national economy was booming during the 1920s. Improvements in machinery and management brought an increase of 50 percent in industrial productivity, while labour costs dropped 9.5 percent. Production of automobiles and consumer durable goods rose dramatically; although the wealthy benefitted most, living standards of middle class and working people rose. Between 1922 and 1929 salaries increased 42%; wages, 33%; and consumer purchases, 23%. Corporate net profits rose 76%; dividends to stockholders, 108%. On the other hand, agriculture and several industries, such as textiles and bituminous coal mining, were seriously depressed, and after 1926 construction declined; thus the prosperity was not solidly based.

New social trends and the growth of organized crime. For millions of Americans, the sober-minded Coolidge was a more appropriate symbol for the era than the journalistic term "jazz age." Although there was stock market speculation and a real estate boom in Florida, and though there were emancipated young women with short skirts and bobbed hair—the "flappers"—dancing the Charleston to the music of jazz orchestras, playing in speakeasies, where liquor was sold illegally, most people shared in the excitement only vicariously, through several innovations of these years—through tabloid newspapers or radio or through silent motion pictures, which drew an audience of 50,000,000 a week (all these were novel, as was the automobile, in which the family went out on freshly paved highways for a Sunday outing or to spend an afternoon at the country club). They also read the novels of Sinclair Lewis, which satirized the age, and those of F. Scott Fitzgerald, which made it glamourous.

The "jazz age"

Many of the nation's writers and intellectuals were sharply critical of the mass culture of the period. Nevertheless the 1920s brought improved communications, erasing differences between urban and country life; the building of highways, parkways, and parks; and spectacular improvement in education, from kindergarten through universities.

On the darker side, the 1920s were years of mass lawbreaking and the rise of organized crime. The Volstead Act, providing for the federal enforcement of the Prohibition (Eighteenth) Amendment (which prohibited the manufacture, sale, or transportation of intoxicating liquors), went into effect in January 1920. But enforcement machinery was so slight that gangsters were soon engaged in large-scale smuggling, manufacture, and sale of alcoholic beverages. Millions of otherwise law-abiding citizens drank the prohibited liquor. On the other hand, millions of mostly Protestant churchgoers hailed prohibition as a moral advance, and the liquor consumption of working people seemed to have dropped.

The presidential campaign of 1928 between the Republican nominee, Herbert Hoover, and the Democrat, Gov. Alfred E. Smith of New York, involved the twin issues of prohibition and religion. Smith was an opponent of prohibition and a Roman Catholic. His candidacy brought enthusiasm and a heavy Democratic vote in the large cities and a landslide against him in the dry and Protestant hinterlands. Some of the opposition to Smith was marshalled by the Ku Klux Klan, anti-Catholic as well as anti-Negro, which had flourished in the early 1920s. A national law enforcement commission, formed to study the flouting of prohibition and the activities of gangsters, was to report in 1931 that prohibition was virtually unenforceable; and with the coming of the Great Depression, prohibition ceased to be a key political issue. In 1933 the Twenty-first Amendment brought its repeal.

Herbert Hoover and the Great Depression. Hoover won an overwhelming victory in 1928, in part because his opponent was a "wet" Catholic but in larger part because Hoover, as the "Great Engineer," seemed best qualified to continue the prosperity of the 1920s. Yet within a few months of his inauguration in 1929, the stock market crashed and the Great Depression began; ironically Hoover had to devote his administration to trying to regain a vanished prosperity.

The stock market crash of 1929

In the stock market crash of October 1929, stocks in a few weeks lost 40 percent of their value; the market continued an intermittent downward course through 1932. The crash had come in response to declines in industrial production, construction, and retail sales. It helped trigger a deflationary spiral that became difficult to stop as businessmen were gradually forced to curtail their activities.

Anti-Depression measures. In trying to end the Depression, Hoover went further than any of his predecessors in utilizing government powers in a positive, although limited way; his administration created many of the precedents for later measures. At first he tried to restore public confidence by obtaining the voluntary cooperation of business and labour leaders, who pledged to maintain production, employment, and existing pay scales. Hoover also tried to stem deflation by liberalizing Federal Reserve credit, cutting taxes, and obtaining from Congress an unprecedented increase of $423,000,000 in the public works appropriation. Before the crash, he had already signed the Agricultural Marketing Act of 1929, creating the Federal Farm Board to bolster farm prices by purchasing surpluses. In 1930 he signed the Hawley–Smoot Tariff Bill, which raised the average ad valorem duty from 26 to 50 percent and brought retaliation from other countries.

Into 1931 these mild expedients seemed sufficient, and the Depression appeared no worse than that of 1921. Then, the threatened financial collapse of western Europe brought a new wave of deflation to the United States. In order to save the financial system of Germany, whose collapse might well take under that of other nations, Hoover agreed in June 1931 to a one-year moratorium on reparations and war debt payments. This was of relatively little help. The financial systems of England and other western European nations survived, but by September most of them had gone off the gold standard and had devalued their currency. European gold was withdrawn from the United States, and European-held securities were dumped on the U.S. stock markets. Devaluation of currency further cut the already declining foreign trade. These disasters, heightening difficulties at home, caused the Depression to become steadily worse from May 1931 to July 1932.

Democratic control of Congress. Worsening conditions forced Hoover to propose more drastic expedients to bring recovery; but as much as possible, he still wished the recovery program to be voluntary. In the 1930 elections the Democrats had won control of the House by a narrow margin and had almost won the Senate. Through a coalition with 12 Republican progressive senators, the Democrats were able to muster a majority of votes against administration measures when the 72nd Congress assembled in December 1931. Congress thus attacked many of Hoover's proposals and called for still more drastic action.

The Reconstruction Finance Corporation

Nevertheless Congress did, as Hoover requested, in January 1932 establish a federal loan agency—the Reconstruction Finance Corporation (RFC)—with a capitalization of $2,000,000,000, empowered to make loans to banks, insurance companies, agricultural associations, railroads, and other industries. The RFC loaned $1,500,000,000 to banks and businesses during its first year. In July 1932 Hoover signed a measure allowing it to lend an additional $1,500,000,000 for self-liquidating public works and $300,000,000 for relief purposes. The RFC did much to keep the Depression from becoming even worse than it eventually became.

Despite the efforts of President Hoover and Congress, the Depression continued to deepen. By 1932 banks had failed by the hundreds; mills and factories were shut down or operating only part-time. Estimates of the unemployed ranged as high as 13,000,000 (one worker in four); many of those employed received only subsistence wages. A quarter of the farmers had lost their farms. In the 1932 election, voters by a wide margin rejected Hoover and voted for the Democratic candidate, Gov. Franklin D. Roosevelt of New York, who promised them a New Deal.

THE NEW DEAL

The first New Deal. The nation was in a state of acute banking crisis when Roosevelt took office. Beginning in Michigan in mid-February 1933, runs on banks had forced state after state to close or limit the activities of its banks. This was the setting in which the new President delivered his inaugural address on March 4. Above all he tried to dispel the fright in peoples' minds; he emphatically stated, "the only thing we have to fear is fear itself."

Roosevelt's first 100 days. In the next several days Roosevelt acted quickly, and rather conservatively, to restore business confidence. In March he submitted to Congress the Emergency Banking Bill, empowering the administration to strengthen and reopen sound banks; Congress enacted the bill in four hours. Within three days three-fourths of the banks within the Federal Reserve system had reopened. There followed an economy act reducing federal salaries and veterans' pensions and legislation legalizing the sale of beer of 3.2 percent alcoholic content. The stock market went up 15 percent.

Roosevelt's recovery program

With the country enthusiastically behind him, Roosevelt kept Congress in special session and piece by piece sent it recommendations that formed the basic recovery program of his first 100 days in office. He expected later to submit to Congress proposals for long-range reform legislation to eliminate maladjustments responsible for the Depression and likely to cause future depressions. Between March 16 and May 17, 1933, he sent messages and draft bills to Congress proposing an agricultural recovery program, unemployment relief, federal supervision of investment securities, creation of a Tennessee Valley Authority, prevention of mortgage foreclosures on homes, railroad recovery legislation, and an industrial recovery program. From March 9 to mid-June 1933, Congress enacted all of Roosevelt's proposals—an unprecedented legislative achievement.

Farm recovery. The passage of the Agricultural Adjustment Act in May 1933 marked the beginning of an era in which the American farmer received aid from the Federal government to improve his economic status. It was an omnibus farm-relief bill embodying the schemes of the major farm organizations to limit crops and of agrarian radicals to inflate the currency. The Agricultural Adjustment Administration (AAA) established by the act put into effect a "domestic allotment" plan to make benefit payments to producers of seven basic commodities, including wheat, cotton, and corn, in return for cutting their output. At first a processing tax upon the commodities provided funds for the benefit payments; but after an adverse Supreme Court decision in 1936, Congress appropriated funds for crop reduction coupled with soil conservation. The AAA program was of only limited help to farmers. Drought in 1933–36 did more than production quotas to cut farm surpluses and increase commodity prices, but most farmers nonetheless favoured the early program. The cash income of farmers nearly doubled between 1932 and 1936 but did not again reach the 1929 level until 1941.

Business recovery. The New Deal sought to bring business recovery through the omnibus National Industrial Recovery Act (NIRA) of June 1933. This act, administered by the National Recovery Administration (NRA), granted businessmen government backing for agreements to stabilize production and prevent price slashing. Labour was to receive wages-and-hours protection and the right to bargain collectively. A large-scale public-works appropriation, administered through the Public Works Administration (PWA), was intended to pour sufficient money into the economy to increase consumer buying power while prices and wages went up.

Failure of the NRA

In practice, the NRA program went awry. While codes were being negotiated, in the summer of 1933, manufacturers increased production in anticipation of higher prices and greater demand. Buying power did not keep pace, and in the fall of 1933 the boomlet collapsed. The NRA then became too complicated; by February 1934 it had negotiated far too many codes with even minor industries, covering vast intricacies of regulations—a total

of 557 basic codes and 208 supplementary ones. Such a mass of detail proved almost unenforceable. Workingmen felt they obtained little from the codes, although in a few industries, like textiles, child labour was ended and working conditions were improved. The collective bargaining provision in the act led to a strong unionization movement and to numerous strikes against nonunion employers. The National Labor Board in 1933 and its successor, the National Labor Relations Board, dealt with labour disputes but had little power.

The NRA was a failure, despite some achievements in improving wages and hours and in bringing order to chaotic large industries. It was too complicated to be enforceable, it tended to create monopoly conditions, and because public works expenditures were too slow it raised prices without a comparable increase in consumer buying power. When the Supreme Court invalidated the NRA code system in 1935, Congress enacted new laws salvaging parts of it, but the experiment was basically over.

Relief. Relief programs were urgent in the New Deal to provide aid to millions of hungry people for whom states and cities were able to provide only a pittance. The Federal Emergency Relief Administration provided grants to state relief agencies; in return the state agencies had to meet federal standards. The Civilian Conservation Corps (CCC), which employed young men from families on relief in reforestation and similar projects, became one of the most popular New Deal agencies. Several laws aided farmers and homeowners threatened by mortgage foreclosures. The Farm Credit Administration (FCA) was a consolidation of several earlier federal agencies; in 1933–34 it refinanced one-fifth of all farm mortgages. A farm bankruptcy act of June 1934 enabled farmers who had lost their farms to regain them. For homeowners, the Home Owners Loan Corporation refinanced about one-sixth of the mortgages on homes. In 1934 the Federal Housing Administration (FHA), more a recovery than a relief agency, began to insure mortgages upon new construction and home repairs. The Reconstruction Finance Corporation continued to make large recovery loans.

The economic downturn in the fall of 1933 led to new relief and recovery devices. During the winter of 1933–34, the Civil Works Administration (CWA) employed 4,000,000 people on emergency projects. Roosevelt also experimented with mild currency inflation, devaluating the gold content of the dollar to 59.06 percent of what it had been formerly and beginning in 1934 a silver purchase program (these were the beginnings of America's government management of the currency).

Reform. Early in the New Deal there was some reform legislation. The Glass–Steagall Act of 1933 created the Federal Deposit Insurance Corporation (FDIC), guaranteeing small bank deposits. Later, the Banking Act of 1935 altered and strengthened the Federal Reserve System. Two measures regulated stock exchange: the Truth-in-Securities Act of 1933, requiring corporations to file data on new securities, and the Securities Exchange Act of 1934, establishing a commission to check new securities and to police the stock markets. The most spectacular piece of conservation legislation was the establishment in 1933 of the Tennessee Valley Authority (TVA), which took over the dam at Muscle Shoals and four other existing dams; it also built 20 new dams in the next two decades, regulating floods in an area previously devastated by them, generating cheap electricity, and undertaking the general rehabilitation of a poverty-stricken area. Other power development and irrigation projects were built in the West. The Taylor Grazing Act of 1934 regulated public rangeland; the Indian Reorganization Act of 1934 protected the Indians and their lands.

The second New Deal and the Supreme Court. In reaction to pressures from the left and hostility from the right, the New Deal shifted more toward reform in 1935–36. Popular leaders, promising more than Roosevelt, threatened to pull sufficient votes from him in the 1936 election to bring Republican victory. Sen. Huey P. Long of Louisiana was building a national following with a "Share the Wealth" program. The poor in northern cities were attracted to the Roman Catholic priest the Rev. Charles E. Coughlin, who later switched from a program of nationalization and currency inflation to an antidemocratic, anti-Semitic emphasis. Many older people supported Dr. Francis E. Townsend's plan to provide $200 per month for everyone over age 60. At the same time, conservatives, including such groups as the American Liberty League, founded in 1934, attacked the New Deal as a threat to states' rights, free enterprise, and the open shop.

The shift toward reform

Roosevelt's response in 1935 was to propose greater aid to the underprivileged and extensive reforms. Congress created the Works Progress Administration (WPA), which replaced direct relief with work relief; between 1935 and 1941 an annual average of 2,100,000 workers were carried on WPA rolls. For younger people there was the National Youth Administration (NYA). Of long-range significance was the Social Security Act of 1935, which provided federal aid for the aged, retirement annuities, unemployment insurance, aid for persons who were blind or crippled, and aid to dependent children; the original act suffered from various inadequacies, but it was the beginning of a permanent, expanding national program. A tax reform law, labelled by newspapers as the "soak the rich tax," fell heavily upon corporations and well-to-do people. The National Labor Relations Act, or Wagner Act, reluctantly accepted by Roosevelt, gave organized labour federal protection in collective bargaining; it prohibited a number of "unfair practices" on the part of employers and created the strong National Labor Relations Board (NLRB) to enforce the law.

While the New Deal was moving toward reform in 1935, the Supreme Court was invalidating several of its earlier key measures. In *Schechter Poultry Corp.* v. *U.S.* the Court invalidated the NIRA, creating a national sensation; Roosevelt charged the justices with taking a "horse-and-buggy age view" of federal regulatory power. In 1936 Roosevelt, aided by his reform program, defeated the Republican nominee for president, Gov. Alfred ("Alf") M. Landon of Kansas, receiving over 60 percent of the popular vote and the electoral votes of every state except Maine and Vermont.

Viewing his decisive victory as an electoral mandate for continued reform, Roosevelt sought to remove the impediment the Supreme Court seemed to be placing in his way. He felt that the powers involved in such reform legislation as the Wagner Act and Social Security Act, both being challenged before the Supreme Court, were to be found in the Constitution and that the court had been interpreting it too narrowly. In February 1937 he proposed to Congress a reorganization of the court system, which would have included giving him the power to appoint one new justice for each justice who was 70 years of age or older, but not exceeding six new justices in all. Roosevelt's proposal created a furor, especially because he did not state frankly the obvious fact that he wished the court to interpret the Constitution more broadly. Some Democrats and a few liberal Republicans in Congress supported the proposal, but a strong coalition of Republicans and conservative Democrats, backed by much public support, fought the so-called court-packing plan.

Roosevelt's court-packing plan

Meanwhile the court itself in a new series of decisions began upholding as constitutional measures involving both state and federal economic regulation. In April 1937 it approved the National Labor Relations Act. These decisions, which began an extensive revision of constitutional law concerning governmental regulation, made the reorganization plan unnecessary; the Senate defeated it in July 1937 by a vote of 70 to 22. Roosevelt had suffered a stinging political defeat, even though he no longer had to fear the court. Turnover on the court was rapid as older members retired or died; by 1942 all but two of the justices were Roosevelt appointees.

The culmination of the New Deal. Roosevelt lost further prestige in the summer of 1937, when the nation plunged into a sharp recession. Economists had feared an inflationary boom as industrial production moved up to within 7.5 percent of 1929. Other indices were high except for a lag in capital investment and continued heavy

unemployment. Roosevelt, fearing a boom and eager to balance the budget, cut government spending, which most economists felt had brought the recovery. Between August 1937 and May 1938 the index of production fell from 117 to 76 (on a 1929 base of 100) and unemployment increased by 4,000,000 persons. Congress voted an emergency appropriation of $5,000,000,000 for work relief and public works, and by June 1938 recovery once more was under way.

Considerable legislation augmenting and consolidating earlier New Deal measures was passed during the second Roosevelt administration. There was further legislation to reduce farm production and raise crop prices and to alleviate rural poverty. For workers the Fair Labor Standards Act of 1938 established a minimum wage and maximum work week (in later years the minimum wage was repeatedly raised and coverage was broadened). Substantial construction of public housing began with establishment of the U.S. Housing Authority in 1937. Altogether this was a considerable array of legislation; but it had been vigorously opposed by many conservative Democrats in Congress, allied with the Republicans. During the congressional campaign of 1938, Roosevelt intervened in primaries, mostly in the South, trying to defeat conservative Democratic congressional leaders. For the most part he failed; throughout the country the tide of support for the New Deal was ebbing, and the Republicans gained 80 seats in the House and seven in the Senate. Nevertheless, the Democrats still controlled each house by a heavy margin.

Decline of New Deal support

Spectacular violence accompanying union organization drives was another factor in the New Deal's waning popularity among middle class Americans. Aided by the Wagner Act, unions had begun organizing vigorously early in the New Deal. A few months after the passage of the Wagner Act, John L. Lewis, president of the United Mine Workers of America, led in forming the Committee for Industrial Organization (CIO) to organize the great mass-production industries, which for the most part had never been unionized. The CIO came into conflict with the American Federation of Labor (AFL), which mounted its own unionization drives. The result was struggle between organizers and industrialists and at times between rival organizers. In bitter fights with the automobile companies the CIO used the sit-down strike, in which the strikers entrenched themselves in the factories and refused to work or to let others in to work; in February 1947 General Motors Corporation recognized the United Automobile Workers, and gradually other manufacturers did the same. The United States Steel Corporation signed union contracts in the spring of 1937 rather than risk strikes, but three "little steel" companies resisted vigorously before finally signing contracts with the CIO. Roosevelt, declining to take sides during the struggle, called down "a plague on both your houses." The organizing drives continued to make headway; union membership, which had been about 3,000,000 in 1932, was 9,500,000 by 1941.

An assessment of the New Deal. The New Deal established federal responsibility for the welfare of the economy and the American people. At the time, conservative critics, among whom the most notable was former President Hoover, charged it was bringing statism or even socialism. Left-wing critics of a later generation have charged just the reverse—that it bolstered the old order and prevented significant reform. Others have suggested that the New Deal was no more than the extension and culmination of Progressivism.

In its early stages, the New Deal did begin where Progressivism left off and built upon the Hoover program for fighting the Depression. But Roosevelt soon took the New Deal well beyond Hoover and Progressivism, programs came to have more of an element of compulsion in them and were larger in scale. For the first time the federal government assumed responsibility for the social security of the nation's citizens. The Wagner Act fostered unionism, and organized labour became a vital part of the Democratic coalition, contributing both votes and campaign dollars.

Growth of federal responsibility

New Deal efforts to stimulate prosperity resulted in a trial-and-error approach to economic regulation. National planning failed in the NRA yet continued for decades as a means of reducing production of major farm crops. Management of currency and credit, beginning in 1933, slowly became more sophisticated and came to be a key means by which the government could control inflation or prevent deflation. Government spending, undertaken at first as a means primarily of relief, became the prime device for stimulating the economy. Social Security through automatically providing benefits in time of unemployment became another countercyclical economic stabilizer.

Roosevelt himself, though he adopted some of his proposals, never became a disciple of J.M. Keynes, the contemporary British economic theorist, who advocated spending during reunion; but many of the young New Deal economists were Keynesians by the late 1930s. The New Deal did not achieve complete economic recovery before war intervened, but it had taken the nation well in that direction. (It was also evolving economic devices which after 1945 further developed in both Democratic and Republican administrations as the means of preventing runaway inflation and depression.)

THE IMPACT OF WORLD WAR II

Isolation, neutrality, and the U.S. entry into the war. During the New Deal years the American response to threats of war in other parts of the world was to seek security through isolation. Congress, with the approval of Roosevelt and Secretary of State Cordell Hull, enacted a series of neutrality laws; in order to keep the nation out of a new conflict, these legislated against the factors that supposedly had taken the United States into World War I. As Italy prepared to invade Ethiopia, Congress passed the Neutrality Act of 1935, embargoing shipment of arms to either aggressor or victim. Stronger legislation followed the outbreak of the Spanish Civil War in 1936, even relinquishing the traditional American claim to freedom of seas in wartime.

Threats to American security. The gravest threat seemed to come from Japan. Roosevelt followed the doctrine of nonrecognition of Japan's conquests on the Asiatic mainland, and in 1934, began rebuilding the navy toward treaty strength. When Japan in 1937 began a large-scale drive into north China, Roosevelt did not proclaim neutrality; thus munitions could be sold to both sides. But in October, when Roosevelt suggested that war, like disease, was a contagion that peace-loving nations should quarantine, he created a furor and had to retreat. In December, when Japanese aviators sank the U.S. gunboat "Panay" in the Yangtze River, the United States accepted Japanese apologies and indemnities.

As war continued in Asia and threatened to break out in Europe as a result of German aggressions, Roosevelt tried to develop a policy of collective security. He encountered little opposition as long as he confined himself to working agreements for mutual defense among the nations of the Western Hemisphere—at Buenos Aires in 1936, at Lima in 1938, and with Canada in 1938.

The policy of collective security

When Germany's invasion of Poland in 1939 touched off World War II, Roosevelt called Congress into special session to revise the Neutrality Act to allow belligerents (in reality only Great Britain and France both on the Allied side) to purchase munitions on a "cash-and-carry" basis. With the fall of France to Germany in 1940, Roosevelt, with heavy public support, threw the resources of the United States behind the British, including the spectacular exchange of 50 overage U.S. destroyers in return for 99-year leases on bases stretching from Newfoundland to British Guiana. In the fall of 1940 Roosevelt also conducted a political campaign for a tradition-breaking third term, running against the Republican Wendell L. Willkie, and was re-elected with over 54 percent of the popular vote.

From the fall of France until the Japanese bombing of the American naval base at Pearl Harbor, Hawaii (December 1941), a great debate stirred the nation as isolationists, especially through a group called the America First Committee, charged that Roosevelt was taking the

nation into war, and interventionists complained that he was not moving rapidly enough. While the debate went on, the United States built its defenses and sent supplies to the British. The Burke–Wadsworth Act of 1940 established the first peacetime selective service, or conscription, act in the nation's history. The Lend-Lease Act of 1941, passed after vehement debate, provided the British and their allies with munitions, which could be repaid after the crisis was over. In August 1941 Roosevelt met with British prime minister Winston Churchill off the coast of Newfoundland and then announced a set of war aims known as the Atlantic Charter. It called for national self-determination, larger economic opportunities, freedom from fear and want, freedom of the seas, and disarmament.

American military involvement. In September a German submarine attacked an American destroyer, and Roosevelt issued orders to "shoot on sight." In October another destroyer was sunk, and the United States embarked on an undeclared naval war against Germany.

For a decade the relations of the United States with Japan had grown less friendly. In January 1940 the United States abrogated its commercial treaty of 1911 with Japan, yet Americans continued to sell Japan materials used in its war against China. When Japanese armies invaded French Indochina in September 1940 with the apparent purpose of establishing bases for an attack on the East Indies, the United States placed an embargo on scrap iron and steel. Japan retaliated by signing a triple alliance agreement with Germany and Italy (September 1940). Japan was close to war with the United States, but it entered into negotiations in the spring of 1941, which continued into December. The United States, to try to thwart an expected Japanese thrust into the East Indies, placed tight economic sanctions upon Japan in July. The Japanese reaction was to prepare for war in case negotiations failed. Neither nation would make serious concessions over China, and by the end of November the United States (through intercepted Japanese messages) knew that a military attack was likely. Roosevelt and his military advisers, expecting it to be against the East Indies and possibly the Philippines, were caught by surprise when Japanese planes struck at Pearl Harbor on December 7, 1941. They destroyed or damaged 15 ships and 188 airplanes and inflicted 3,435 casualties.

Declaration of war

On December 8, 1941, Congress with only one dissenting vote declared war against Japan. Three days later Germany and Italy declared war against the United States; and Congress, voting unanimously, reciprocated. As a result of the attack on Pearl Harbor, the previously divided nation entered into the global struggle with virtual unanimity.

The conduct of the war and its domestic effects. Within the United States during World War II, the American people had to produce the enormous quantities of every sort of material of war, clothing, and food with which to defeat the enemies. The war also meant great dislocations as 15,000,000 men and women went into uniform and many additional millions moved to jobs in war plants. The war brought an enormous increase in productivity and a higher living standard than ever before; it also brought continued debates among the American people over the way in which the war was to be conducted and what national policies should be afterward.

Congressional controls. Congress moved to the right during the war. In the 1942 election Republicans gained 47 seats in the House and 10 in the Senate. Democrats still controlled Congress, but conservatives of both parties were able to force dismantling of several New Deal agencies. Congress used its investigatory power to keep a check on war agencies and military expenditures, especially through the Senate War Investigating Committee, headed by Harry S. Truman of Missouri. Congress also became committed to the policy of postwar American cooperation with other nations to preserve the peace.

War production. As the government tried to control war production, government agencies were organized and reorganized repeatedly. In January 1942 the War Production Board replaced an earlier agency, and in 1943 it became subsidiary to the Office of War Mobilization. Agencies established priorities to channel scarce raw materials into the most essential types of production, controlled prices (through the Office of Price Administration), and allocated war supplies to the various branches of the armed forces and to the Allies. After initial snarls and never-ending disputes, by the beginning of 1944 production was reaching astronomical totals—double those of all the enemy countries combined. The output of American factories almost doubled between 1939 and 1945. (By the end of the war the United States had produced, for example, 6,500 naval vessels, 296,400 airplanes, and 86,330 tanks.)

Much of the production was in new types of weapons, as U.S. engineers and scientists matched their ingenuity against the Germans. The Office of Scientific Research and Development directed scientists in the development of superior radar and sonar, radio-directed proximity fuses, and countless other devices. The most dramatic race was the secret one to try to build an atomic bomb more quickly than the enemy. Through the Manhattan Project, $2,000,000,000 was expended upon plants and laboratories; and on July 6, 1945, the first workable atomic bomb was tested.

Development of the atomic bomb

The use of manpower. The War put manpower suddenly at a premium after years of heavy unemployment. Selective Service draft boards registered 31,000,000 men; including volunteers, more than 15,000,000 men and women served in the armed forces during the war. At the same time, the working force at home increased from 46,500,000 to 53,000,000, and 6,600,000 persons moved from rural poverty to cities. Some 2,000,000 blacks obtained work in war industries, protected by the Fair Employment Practices Committee (FEPC), established in 1941. Although 2,000,000 families still suffered from substandard incomes, most families benefitted economically from the war; gross weekly wages increased from $25.20 to $43.39. Most workers were better off, although the cost-of-living index (1935–39 = 100) went up to 128.4 by 1945, and most workers for the first time had to pay a federal income tax. Personal incomes were a third greater than available goods and services; much of the excess buying power was drained off into purchases of war bonds and stamps.

Financing the war. Through taxes the government raised 41 percent of the cost of the war (compared with 33 percent in World War I). The Revenue Act of 1942 levied 94 percent on the largest incomes; a withholding-tax measure passed in 1943 provided for deducting tax payments from workers' pay as it was earned. The total cost of the war to the Federal government between 1941 and 1945 was $321,000,000,000 (ten times as much as World War I), and the national debt mounted from $49,000,000,000 in 1941 to $259,000,000,000 in 1945.

Labour. Unions agreed not to strike during the war and submitted disputes to the strong National War Labor Board. Nevertheless, there were 15,000 work stoppages during the war, which created much resentment among the public and in Congress (they accounted for only one-ninth of 1 percent of total hours worked). Congress in 1943 passed over the President's veto the Smith–Connally, or War Labor Disputes, Act, requiring unions to wait 30 days before striking and giving the president the right to seize a struck war plant.

Farmers. Congress was relatively generous with farmers, granting them less than they wanted but nevertheless setting price ceilings at 100 percent of parity. Produce prices more than doubled. In good-crop years during the war, agricultural production set new records, increasing from an index figure of 108 to 123.

Japanese Americans. During the war most Americans were undisturbed in the exercise of their civil liberties. But Japanese Americans felt the brunt of public anger. In February 1942 Roosevelt authorized the removal of 117,000 of them, two thirds of whom were United States citizens, from the Pacific Coast to ten interior relocation centres. Some 17,600 Japanese Americans fought in the armed forces; some of their units established notable records for bravery.

The 1944 election. In 1944 the United States underwent the first wartime presidential election since the Civil War. Roosevelt was nominated for a fourth term; the vice presidential nominee was Sen. Harry S. Truman. The Republican party nominated the governor of New York, Thomas E. Dewey. Roosevelt was again elected.

The end of isolation and the new U.S. role in world affairs. The United States entry into World War II brought an end to isolation. The United States as a result of conferences between President Roosevelt and Prime Minister Churchill in December 1941 formed a grand wartime alliance, the United Nations, which 46 nations ultimately joined.

International conferences

In 1943 six major conferences took place. At Casablanca, Morocco, in January the Allies decided to invade Italy and declared the need for "unconditional surrender." In May, in Washington, D.C., they decided to increase the bombing of Germany. From Quebec in August came the decision to invade German-occupied France in a "second front." In October Secretary Hull in Moscow reached agreements on establishment of a United Nations organization after the war. At Cairo in November Roosevelt and Churchill, meeting with Pres. Chiang Kai-shek of the Republic of China, affirmed a postwar settlement for east Asia. Later that month at Teheran, Iran, Roosevelt, Prime Minister Joseph Stalin of the Soviet Union, and Churchill agreed upon plans for launching a second front in Europe.

In June 1944 a cross-channel Allied landing took place on the coast of German-occupied Normandy. By the end of August, Allied forces occupied most of France. In August, at Dumbarton Oaks in Washington, D.C., representatives of the United States, Great Britain, the Soviet Union, and China met and agreed upon a charter for a permanent international organization. In mid-September in Quebec, Roosevelt again met with Churchill, and they tentatively agreed upon plans for dealing with Germany after the war.

The year 1945 brought an end to the war. Roosevelt, in February, met with Stalin and Churchill at Yalta in the Crimea. There policies were agreed upon to enforce the unconditional surrender of Germany, to divide it into zones for occupation and policing by the respective Allied forces, and to provide democratic regimes in eastern European nations. A series of secret agreements were also made at Yalta; chief among these was the Soviet pledge to enter the war against Japan after the German surrender, in return for concessions in east Asia.

Roosevelt died on April 12 and was succeeded by Truman. In the following months, the German armed forces collapsed; and on May 7, all German forces surrendered. In the Pacific, the invasions of Iwo Jima and Okinawa in early 1945 brought Japan under a state of siege. In the summer, before an invasion could take place, the United States dropped atomic bombs on Hiroshima and Nagasaki. On September 2 the surrender of Japan was signed in Tokyo Harbour on the battleship "Missouri." (F.Fr.)

VIII. The United States since 1945

THE PEAK COLD WAR YEARS, 1945–60

The death of Roosevelt

The Truman administration. Upon the sudden death of President Roosevelt on April 12, 1945, Harry S. Truman became president of the United States. Truman was aware of the nation's problems only in a general way, for he had not had close association with the administration. The conference to establish the United Nations took place as planned, opening on April 25 in San Francisco. In May the German forces surrendered, and in July Truman conferred at Potsdam, Germany, with Stalin and Churchill (later succeeded by Clement Richard Attlee) to discuss future operations against Japan and a peace settlement for Europe. The Soviets had been ignoring many of their Yalta pledges concerning eastern Europe; at Potsdam they refused to make satisfactory arrangements with Truman. These difficulties did not seem serious, because the United States held a monopoly of atomic secrets and it was thought that the Soviet Union would need U.S. help to reconstruct its vast devastated areas.

In September the war with Japan ended and extensive demobilization of United States forces began. By the end of 1946 the army was down to 1,500,000 men and the navy to 700,000; by the spring of 1950 the army numbered 500,000 men, and the United States was relying mainly on air power and atomic weapons.

In June 1946 the United States proposed a plan for international control of atomic energy through the United Nations, but the Soviet Union would not agree to such control, insisting that the United States unilaterally destroy its atomic arsenal. Meanwhile, Soviet scientists were engaged in nuclear research; in 1949 they exploded their first atomic bomb. The U.S. continued research and development in atomic energy under the control of a five-man Atomic Energy Commission (AEC), created in 1946. The U.S. armed forces were reorganized and brought under a secretary of defense by the National Security Act of 1947, which created the U.S. Air Force as an independent service. In 1949 a Department of Defense was established, and greater unification of the services took place.

The Cold War and containment. In 1946 and early 1947 the Soviet Union supported Communist guerrillas in Greece and brought pressure upon Turkey in a way that seemed to foreshadow Soviet expansion to the Mediterranean. In March 1947, after the British government declared that it could no longer afford to continue its aid to Greece and Turkey, Truman asked Congress to appropriate funds for military aid to help these two countries resist Communist aggression. "It must be the policy of the United States," he declared, "to support free peoples who are resisting attempted subjugation by armed minorities or by outside pressures." This policy came to be known as the Truman Doctrine. Congress appropriated $400,000,000, and by 1949 the Communist threat had diminished.

The Truman Doctrine

In June 1947 Secretary of State George C. Marshall proposed a plan for economic rehabilitation of Europe to meet the growing Communist threat. Despite Communist harassment, 16 nations (plus western Germany) participated, and in the next three years the United States spent $12,000,000,000 through the Economic Cooperation Administration. The Marshall Plan (or European Recovery Program) revitalized the economy of western Europe and cut the strength of western European Communist parties. In his inaugural address in 1949, following re-election, Truman proposed extending the same sort of aid to underdeveloped nations throughout the world. The fourth of his proposals called for giving technical assistance to underdeveloped countries and came to be known as the Point Four Program.

The U.S. and Great Britain set out to rebuild western Germany as an economically strong area with sovereignty over its domestic affairs. When the U.S.S.R. retaliated in June 1948 by blockading the land and waterway routes leading from eastern Germany into the western-occupied sectors of Berlin, Truman ordered military planes to fly food and supplies into the city. In the spring of 1949 the Soviet Union ended the blockade.

In June 1948 the U.S. Senate passed the Vandenburg Resolution, authorizing negotiations that led to the signing of the North Atlantic Treaty of April 1949 by 12 nations (and later also by Greece and Turkey). The treaty created a new defense force to resist Soviet aggression, the North Atlantic Treaty Organization (NATO). Its first supreme commander was Gen. Dwight D. Eisenhower.

On the other side of the world, Truman had sent General Marshall to China as early as December 1945 to prevent warfare between Nationalist and Communist forces and to form a coalition government. In the summer of 1947, after the Communists had made rapid advances, the President sent Gen. A.C. Wedemeyer to study the situation; Wedemeyer recommended sending military personnel and large quantities of supplies. The President, who was concentrating upon containment in Europe, asked for only $570,000,000 to aid Chiang Kai-shek; Congress in April 1948 voted $400,000,000, of which only $125,000,000 could be spent for military supplies. By the end of 1949 the Nationalist government had

fallen and had retreated to Taiwan. The response of the United States was to inaugurate a policy of strengthening occupied Japan.

The Fair Deal. In September 1945 Truman sent a message to Congress outlining a 21-point domestic program, which later came to be known as the Fair Deal. It called for expanded social security, new wages-and-hours and public-housing legislation, and a permanent Fair Employment Practices Act to prevent racial or religious discrimination in hiring. Congress and the country were so preoccupied with problems of reconversion and the threat of inflation, however, that Truman was unable to get his proposals enacted; one significant exception was the Employment Act of 1946, which clearly stated the government's responsibility for maintaining full employment and established a three-man Council of Economic Advisers to advise the President and issue an annual economic report.

Truman's 21-point domestic program

Reconversion went smoothly and rapidly: war contracts were cancelled and settled; war agencies were curtailed; and surplus factories and property were sold. The Serviceman's Readjustment Act of 1944 (the G.I. Bill of Rights) provided aid to former members of the armed forces. Consumer buying power, including almost unlimited credit, was far greater than the output of consumer goods and put pressure on prices to rise. In addition, labour unions, no longer bound by their wartime no-strike pledge, began to strike for higher wages. Settlement of a steel strike early in 1946 allowed a large wage increase and a resulting rise in steel prices. This "bulge in the line," justified on the basis that living costs had gone up by more than 30 percent since 1941, led to a spiral of increased wages and prices throughout industry. Farmers and businessmen tried to end price controls entirely, but Congress in June 1946 passed a bill preserving limited controls; Truman vetoed the bill because it did not go far enough. Controls expired, the prices of 28 basic commodities jumped 25 percent in the first 16 days of July, and Congress passed a new price-control bill, which Truman signed. Because of price increases, real earnings dropped 12 percent below what they had been in July 1945. In 1946 Republicans won control of both houses of Congress. Truman, regarding the election as a mandate against controls, dropped most of them. Retail prices rose at the rate of 3 percent a month, leading to a second round of strikes and higher wages and prices.

The 80th Congress, dominated by conservative Republicans, ignored the Fair Deal program. It authorized a commission on the reorganization of executive departments, and Truman appointed former president Herbert Hoover as chairman. It also enacted a new basic labour law, the Taft-Hartley Labor Management Relations Act of 1947, over Truman's veto, which removed some restrictions on management and added several on labour unions.

In the 1948 campaign the Republican presidential candidate, Gov. Thomas E. Dewey of New York, seemed almost certain of victory over Truman. A third party, the Progressive Party, calling for a more conciliatory policy toward the Soviet Union, nominated former vice president Henry A. Wallace; a fourth party, the States' Rights Democrats (Dixiecrats), protesting civil-rights provisions in the Democratic platform, nominated Gov. Strom Thurmond of South Carolina. Truman embarked upon a vigorous campaign directed against the conservative congressional Republicans. Mustering the support of labour, discontented farmers, and Northern Negroes, Truman defeated Dewey by a popular vote of 24,106,000 to 21,970,000 and an electoral vote of 303 to 189. Thurmond received 1,169,000 votes and 39 electoral votes; Wallace, 1,157,000 votes. The Democrats recaptured the House (263 to 171) and the Senate (54 to 42).

In his inaugural address on January 20, 1949, Truman called for a vigorous advancement of his Fair Deal program to aid the underprivileged. Except for the Social Security Act of 1950, which added almost 10,000,000 persons to the beneficiaries of old-age insurance, only a small part of the Fair Deal was enacted into law.

During the postwar years public attention focussed more and more on charges that the federal government was infiltrated with Communists. In 1946 a Soviet spy ring was uncovered in Canada, and Truman set up a Temporary Commission on Employee Loyalty, which recommended the establishment of loyalty review boards. By 1951 these boards had dismissed 212 government employees, and more than 2,000 others had resigned; 3,000,000 had been cleared. Over the President's veto, Congress in 1950 passed the McCarran Internal Security Act, which placed numerous restrictions upon Communists throughout the nation. In 1949, under the Smith Act of 1940, which prohibited conspiring to teach the violent overthrow of the government, 11 Communist leaders were convicted and sentenced to prison. In 1951 two Communist agents, Julius and Ethel Rosenberg, were convicted of transmitting atomic secrets to the U.S.S.R.; they were executed in 1953. In 1950 Alger Hiss, formerly an employee of the Department of State, was convicted of perjury. Capitalizing upon the resulting furor, Sen. Joseph R. McCarthy of Wisconsin charged in February 1950 that he had a list of 57 (some listeners said 205) men loyal to Communism still in the State Department. A subcommittee of the Senate Foreign Relations Committee could not find even one, but McCarthy, going on rapidly to other sensational charges, built a national following. (F.Fr.)

Charges of Communists in government

With the victory of the Communists in China in 1949 and the announcement that September of a Soviet atomic explosion, fear of Communist expansion and a determination to contain it became the dominant theme in U.S. foreign policy. Truman's Point Four program was motivated in large part by a desire to persuade impoverished nations to cast their lot with the United States rather than with the Soviet Union. It was matched by the announcement in January 1950 that the President had directed the U.S. Atomic Energy Commission to proceed with work on a hydrogen bomb that would be vastly more powerful than the atomic bombs used in World War II.

The Korean War. On June 25, 1950, armed forces of the Democratic People's Republic of Korea (North Korea), supported by the Soviet Union, advanced south of the 38th parallel separating the northern Communist state from the Republic of Korea (South Korea). The U.S. government immediately presented the matter to the UN Security Council, urging that military forces under UN auspices be sent to Korea to resist Communist aggression. The Security Council, acting during a Soviet boycott, adopted a resolution calling upon UN members to resist the North Korean invasion.

Under the command of Gen. Douglas MacArthur, UN forces drove the North Koreans north of the 38th parallel. As the year ended, however, the UN troops were forced into a costly and precarious retreat by overwhelming numbers of Chinese Communists, whose entrance into the struggle had been foreseen as a possibility but was not expected. The situation for the United States, as the leader against Communist aggression, now became critical, and Congress supported the President in a gigantic program for defense. On December 16, 1950, Truman declared a national emergency and outlined plans for placing the nation on a war basis.

Truman's defense program

MacArthur, whose view of the conduct of the war contrasted with the policy of the administration, was recalled by Truman on April 11, 1951, and was succeeded by Gen. Matthew B. Ridgway. Armistice talks began on July 10, 1951, but not until July 27, 1953, was an armistice signed. After further negotiations, an exchange of prisoners was completed by September 6, 1953. Efforts to negotiate the unification of Korea ended in failure at Geneva in June 1954.

Peace treaties. The United States had meanwhile taken the lead in concluding a peace treaty with Japan; the treaty was signed in San Francisco on September 8, 1951, by 49 nations. Japan and the U.S. also agreed upon a bilateral security treaty, which provided that U.S. troops could be stationed in Japan for an indefinite period; the U.S. signed separate defense pacts with the Philippines, Australia, and New Zealand.

On July 1, 1952, the Senate approved a peace agreement

between western Germany and the western Allies. The U.S.S.R. retained control of all territory it occupied at the end of World War II and drew an "iron curtain" between eastern and western Europe.

The election of 1952. In 1952 General Eisenhower's name was entered in Republican state presidential primaries, a number of which he won. After he retired from his military post, Eisenhower's supporters campaigned actively for his nomination, and the Republican convention nominated him on the first ballot. Sen. Richard M. Nixon of California was named Republican vice presidential candidate. The Democratic national convention nominated Gov. Adlai E. Stevenson of Illinois as its presidential candidate.

Eisenhower charged the Truman administration with responsibility for events leading to the Korean War and promised that, if elected, he would visit Korea before his inauguration. Republican campaigners continued to make accusations of Communist infiltration in government offices. Truman supported Stevenson.

In November the popular vote of more than 61,000,000 was the largest in the nation's history. Eisenhower carried 39 states (442 electoral votes); Stevenson carried 9 (89 electoral votes). Republicans gained control of the House and won a narrow 48-to-47 margin in the Senate, not including one independent Republican. Gubernatorial contests in 30 states resulted in 20 Republican victories.

Eisenhower's landslide victory

The Eisenhower administration. The new president had run far ahead of his party ticket, attracting portions of the labour vote that had been consistently Democratic for 20 years, as well as a substantial Negro city vote and a widespread Middle Western farm vote.

Domestic policies. Eisenhower's middle-of-the-road policy in domestic affairs weakened the influence of labour elements in the Democratic Party and strengthened liberal elements in the Republican Party. Among his appointments were those of Gov. Earl Warren of California as Supreme Court chief justice and John Foster Dulles as secretary of state. Eisenhower was not supported by the united action of his party members in House and Senate. His differences with the right-wing elements were most marked. The President won important victories in legislation only because of Democratic support.

The Eisenhower administration was plagued throughout its first two years by the activities of the Senate subcommittee charged with investigation under the loyalty-security program. Eisenhower took the position that loyalty and security maintenance were the responsibility of the executive branch of the government; yet he did not interfere with the activities of the subcommittee, the chairman of which, Senator McCarthy, was later condemned by the Senate for conduct "contrary to Senate traditions."

The years 1953–56 were characterized by general prosperity. Confidence on the part of investment capital contributed to business development, but the Federal Reserve Board checked expansion of bank credit by adopting a tight-money policy intended to prevent inflation. The national budget was balanced, despite huge expenditures for national defense, because taxes were maintained at the necessary level and employment and earnings were moderately high.

The Supreme Court decision on racial segregation

On May 17, 1954, the Supreme Court unanimously ruled, in effect, that racial segregation in elementary and secondary public schools was unconstitutional. This decision resulted in a division of sentiment in both political parties, especially the Democratic Party. Some immediate progress toward integration of schools was made in the North and in the border states, but in the South change was less immediate.

Foreign policy. Eisenhower's attempts to improve international relations were seconded by John Foster Dulles, who travelled widely on diplomatic missions; but the administration suffered a series of defeats in promoting U.S. objectives. Following the prolonged Korean armistice discussions, a stalemate ensued in the Far East and Communist strength in that area continued to grow.

Eisenhower's Atoms for Peace plan, proposed in 1953, was a step toward using nuclear science for the welfare of the world. His proposals for international control of atomic armaments and his suggestion for open-sky inspection of military installations were not adopted, but they conferred an important initiative on the democracies in the controversy with the Soviet Union over arms limitation. The leaders of the Big Four powers met in Geneva in 1955 in the hope of lessening Cold War tensions, but the results were inconclusive.

Eisenhower's illness and re-election. The President's personal role in government was basically altered in the months following a heart attack on September 24, 1955. Although he gradually resumed the responsibilities of the presidency, the temporary disability raised concern over the increasing burden placed upon a president of the United States and the calibre of men nominated for the vice presidency. The President's gradual return to health was interrupted by a severe attack of ileitis and a surgical operation on June 9, 1956. He resumed his duties and, well in advance of the Republican convention, let it be known that he would accept the nomination for re-election. He and Vice President Nixon were nominated unanimously. Adlai E. Stevenson was again nominated by the Democrats.

World crises in 1956

The outcome of the election was largely determined by external events. Late in October eastern Europe and the Middle East burst into flames. Protest against Soviet Communist Party domination raged in Poland and brought the Soviet army into Hungary. An invasion of Egyptian territory by Israel, claiming self-defense against border depredations, and the swift attack of Great Britain and France upon Egypt to regain control of the Suez Canal, which Egypt had seized in July, dominated the final days of the presidential campaign. The electorate voted overwhelmingly for the President, who carried all but seven states. It was more a personal than a party victory, however, for the Democrats won control of both houses of Congress.

The Democratic majority in House and Senate was divided, especially on civil rights, and there was also a wide division among the Republican minority. Eisenhower's vetoes defeated Democratic plans on public housing, enlarged social security, and deficit spending.

In the midterm elections an economic recession in 1957–58 and a continuing increase in unemployment were determinning influences. The Democrats won a widespread national victory, including 32 governorships. Alaska was formally admitted to the Union on January 3, 1959. The resolution admitting Hawaii as the 50th state was signed by the President on March 18.

Racial and labour problems increased in intensity; public-school integration was contested by Southern states, and peaceful sit-in demonstrations by blacks seeking service at "white" lunch counters led to police action. In July 1959 some 500,000 steelworkers went on strike. The strike lasted 116 days before the government obtained an injunction forcing the workers back while efforts were made for government arbitration. No decision completely satisfactory to either side was reached, but work was resumed. Investigation of union leadership by committees of Congress led to passage in 1959 of the Landrum–Griffin Act, aimed at fighting corruption in labour unions and at the establishment of procedures to maintain democratic elections within unions.

The United States in world affairs. On October 4, 1957, the Soviet Union launched the first artificial Earth satellite. This achievement seemed to shift the world balance of power to the Soviet Union until, on January 31, 1958, the U.S. Army launched an Earth satellite. Within the United States the space age brought increased attention to the long-range program of education necessary for scientists and the increased costs of experimental programs.

Beginning of the space race

Several crises in 1958 brought the U.S. to the brink of war. In July Eisenhower ordered U.S. troops to Lebanon to prevent the overthrow of the Lebanese government by elements unfriendly to the Western powers. In August, the bombardment, by Communist China, of the offshore islands of Quemoy and Matsu brought the administration face to face with its treaty commitment to Nationalist China. In November, the Soviet Union again threatened

to isolate Berlin. On December 31 rebels led by Fidel Castro seized control of the government of Cuba.

The illness of Secretary of State Dulles in March 1959 led the President to increase his own activity in foreign affairs. On April 15 Eisenhower announced Dulles' resignation, and on April 18 he named Undersecretary of State Christian Herter to replace him. Dulles died on May 24.

Eisenhower's personal diplomacy. Eisenhower accepted personal diplomacy by heads of states as desirable in the Cold War. The President on August 26, 1959, flew to Europe, where he conferred with British prime minister Harold Macmillan, French president Charles de Gaulle, and West German chancellor Konrad Adenauer. On September 15 Soviet premier Nikita Khrushchev, at Eisenhower's invitation, began a tour of the United States. In December Eisenhower travelled 22,000 miles (35,000 kilometres) in 19 days, visiting 11 countries; early in 1960 he visited five countries in Latin America.

Khrushchev proposed that a summit conference be held in May 1960 at Paris to discuss a relaxation of world tensions. But, when the heads of state met in Paris, the conference was broken up by Khrushchev, who angrily announced that a high-altitude U.S. reconnaissance plane (U-2) had been shot down over Soviet territory on May 1. Eisenhower still pursued his plan to visit the Far East that summer. He visited Alaska, Hawaii, the Philippines, Okinawa, Taiwan, and Korea. Violent anti-American outbursts in Japan brought about cancellation of a visit to Tokyo. On his return, he restated his belief in the efficacy of personal diplomacy.

Anti-American outbursts in Japan

Growth and prosperity. The decade 1950–60 was marked by a steady increase in population, which passed 179,000,000 in 1960. The shift of population from east to west continued, with a new emphasis upon movement from urban to suburban areas. Widespread prosperity, increased productivity, and higher incomes gave impetus to construction activities of all kinds. Recessions in 1953–54 and 1957–58 did not alter the generally prosperous character of the period, although agricultural income continued to lag and unemployment persisted. (E.E.R.)

The election of 1960. The two major U.S. political parties nominated comparatively young presidential candidates at their 1960 national conventions. The Republican nominee, Vice Pres. Richard M. Nixon of California, was 47; the Democrat, Sen. John F. Kennedy of Massachusetts, was 43. A dramatic feature of the campaign was a series of television appearances (publicized as debates), during which the two candidates stated their positions and answered questions from newsmen. Kennedy defeated Nixon in the most closely contested election of the century; Kennedy won 303 electoral votes to Nixon's 219, but, in the popular vote of more than 68,000,000, Kennedy's margin was only 118,000. The Democrats retained control of both houses of Congress but with a somewhat smaller majority than before.

The Kennedy-Nixon debates

THE 1960S AND 1970S

The Kennedy administration. The population growth and westward movement continued into the 1960s, with the total U.S. population passing the 200,000,000 mark and California replacing New York as the most populous state. The nation's economy was fairly stable and buoyant, as production, employment, and corporate profits reached new high levels. U.S. scientists and engineers made remarkable progress in space exploration in the 1960s. But numerous problems remained. In domestic affairs, racial tensions mounted, urban problems multiplied, poverty remained widespread, and air and water pollution reached alarming proportions. The predicted long-term effects of automation on employment posed fundamental questions as to the future of the nation's economy and of its educational system. In Southeast Asia a controversial war in Vietnam continued year after year with increasing U.S. involvement. In Europe, NATO, a key element in U.S. military strategy of the 1950s, suffered a severe setback in 1966 when France declared its intention of withdrawing its forces and requested the removal of all NATO installations from French soil. The proliferation of nuclear weapons, with both France and China setting off nuclear explosions during the decade, greatly complicated the prospects for disarmament and world peace.

Kennedy was inaugurated as the 35th president of the United States on January 20, 1961, the first Roman Catholic and the youngest man ever to be elected to that office. His vice president was Lyndon B. Johnson of Texas, who had been majority leader of the Senate during the Eisenhower administration. The new President set the tone of his administration in an eloquent inaugural address that called for national dedication to a worldwide struggle against tyranny, poverty, disease, and war. His Cabinet included Dean Rusk as secretary of state, Robert F. Kennedy, the President's brother, as attorney general, and Robert S. McNamara as secretary of defense.

Foreign affairs. President Kennedy's first year in office saw an abortive invasion of Cuba, aimed at overthrowing the Castro regime by forces that had been secretly trained and supplied by the United States, a personal meeting of the President with Soviet premier Khrushchev in Vienna, and a continuation of Cold War tensions. In October 1962 the Cuban problem reached a critical point, when U.S. intelligence agencies learned that the Soviet Union had installed in Cuba ballistic missiles capable of attacking the United States. The President ordered a naval quarantine of Cuba to prevent Soviet ships from delivering additional missiles to the island. After five tense days during which the U.S. and the U.S.S.R. seemed on the verge of war, the U.S.S.R. agreed to dismantle its missile bases and to withdraw its troops.

The Cuban missile crisis

On August 5, 1963, diplomats representing the U.S., the U.S.S.R., and the U.K. signed a nuclear test-ban treaty in Moscow. The signatories agreed to stop all testing of nuclear weapons in the atmosphere, in outer space, and under water, thus permitting only underground tests, which did not contaminate the atmosphere. Within a few months, more than 100 other nations signed the treaty. France, the only other nation then possessing a nuclear capability, did not sign, nor did China, which was soon to detonate its first nuclear device and become the world's fifth nuclear power.

Domestic affairs. President Kennedy appealed to Congress for legislation to stimulate international trade, reduce unemployment, provide medical care for the aged under social security, reduce federal income taxes, and protect the civil rights of blacks. The latter issue, which had aroused national concern in 1962 when federal troops were employed to assure the admission of a Negro at the University of Mississippi, caused further concern in 1963, when similar action was taken at the University of Alabama. Although the Democrats controlled both houses of Congress, the administration's proposals encountered strong opposition from a coalition of Republicans and Southern Democrats. Enactment of the Trade Expansion Act and a tax-reform law were the only important administration victories in 1962. The two most important bills before Congress in 1963 called for reduction of income taxes and the strengthening of civil-rights legislation.

On November 22 President Kennedy was assassinated in Dallas, Texas. Lyndon Johnson took the oath of office as 36th president of the United States at the Dallas airport and flew to Washington. Hours after the assassination, the Dallas police arrested 24-year-old Lee Harvey Oswald. While the Dallas police were transferring the suspected assassin from one jail to another on November 24, Jack Ruby, owner of a Dallas nightclub, shot and killed Oswald in full view of millions of persons watching the events on television.

Kennedy's assassination

The Johnson administration. During his first days in office, Johnson conferred with scores of leaders from other countries, who were in Washington for the funeral of President Kennedy, and assured them that there would be no basic change in U.S. foreign policy. He also appointed a commission, headed by Chief Justice Earl Warren, to investigate the events surrounding the assassination.

Domestic affairs. On November 27, before a joint session of Congress, Johnson paid tribute to his predecessor

and called for prompt enactment of measures Kennedy had proposed. Johnson's skill as a parliamentary strategist helped push the tax-reduction bill through Congress, but the civil-rights bill encountered opposition from Southern Democrats in the Senate, finally passing in June 1964.

Johnson's Great Society

In his state-of-the-union message of 1964, Johnson declared "an unconditional war on poverty," and in 1965 he outlined a program for a "Great Society." Many of his proposals were enacted by Congress, among them the antipoverty bill; Medicare, providing hospital and nursing-home care for persons over 65 under the Social Security Act; a strong right-to-vote bill that abolished literacy tests and other voting restrictions; two new executive departments, of housing and urban development and of transportation; and a measure to aid cities to rebuild their blighted areas.

In 1964 Johnson won a landslide victory over his Republican opponent, Sen. Barry Goldwater of Arizona, losing only six states. The Democrats also strengthened their majority in Congress; in 1966, while retaining a comfortable majority, they lost 47 seats in the House and three in the Senate.

Shortly after the 1966 election, Johnson underwent surgery—the second time in 13 months—focussing attention on the proposed 25th Amendment to the Constitution that provided procedures by which the vice president could become acting president and for filling the office of vice president if it became vacant. The amendment became a part of the Constitution in February 1967.

Riots in the Negro slums of many large cities during the mid-1960s caused extensive property damage. After the riots of 1967 President Johnson appointed a commission to investigate the causes and to recommend a course of action. The commission's report in February 1968 placed most of the blame on "white racism" and recommended action by all levels of government to provide employment, better housing, improved education, and more adequate police protection for black ghetto residents.

In April the nation was shocked by the assassination in Memphis of the black civil-rights leader Martin Luther King, Jr. Congress passed a civil-rights bill forbidding discrimination in the sale or rental of houses and apartments because of race, religion, or national origin.

Foreign affairs. President Johnson soon gave American foreign policy his own emphasis. It was directed chiefly toward Southeast Asia, where the U.S. had for several years been helping South Vietnam defend itself against the Viet Cong, who were being aided by North Vietnam. During 1964 U.S. aid, initially military supplies and advisers, rapidly increased. When U.S. warships patrolling the Gulf of Tonkin were allegedly attacked by torpedo boats, Johnson ordered retaliatory air strikes against North Vietnamese torpedo-boat bases. Congress approved a resolution authorizing "all necessary measures to repel any armed attack" against U.S. forces and "to prevent further aggression." Beginning in 1965 the President sent more and more troops to Vietnam, the total reaching more than 500,000 by 1968. He also ordered the bombing of North Vietnamese military targets, while repeatedly announcing a willingness to negotiate peace.

Expansion of the war in Vietnam

Opposition to the Vietnam War rose sharply in the winter of 1967–68 as casualties mounted and victory for either side seemed impossible. In March 1968 Johnson declared that he would not seek or accept the Democratic nomination for another term. He restricted the U.S. bombing of North Vietnam and again called upon Hanoi to negotiate. A discussion between the U.S. and North Vietnam began at Paris in May 1968. On November 1 all bombing of North Vietnam ceased.

The election of 1968. The Vietnam War was the major issue in 1968. The chief contenders for the Democratic presidential nomination were Sen. Eugene J. McCarthy of Minnesota, a champion of the antiwar faction; Sen. Robert F. Kennedy of New York; and Vice Pres. Hubert H. Humphrey. On June 5 Kennedy was shot by an assassin; he died the following day. Humphrey was nominated at Chicago in August, with Sen. Edmund S. Muskie of Maine as his running mate. Violent disorders, arising from opposition to the war as well as to party positions and procedures, marred the convention. Earlier in August, the Republicans had nominated former Vice President Nixon for president and Gov. Spiro T. Agnew of Maryland for vice president. In the election the popular vote was close, but Nixon won most of the electoral votes, 301 to 191 for Humphrey and 46 for the former governor of Alabama, George Wallace, who led a third party. The Democrats, however, retained substantial majorities in both houses of Congress.

The Nixon administration. *Foreign affairs.* Nixon in 1969 enunciated what some observers called the "Nixon Doctrine," to the effect that the United States would maintain a presence in the Far East but that Asian nations would have to carry the main burden of their own defense. Strategic Arms Limitation Talks (SALT) between the U.S. and the Soviet Union were initiated in Helsinki in November 1969; on November 24 the Treaty on the Nonproliferation of Nuclear Weapons was signed.

The Vietnam War

The pace of the Vietnam War slackened in 1969, but in April 1970 the fighting spread to Cambodia. Nixon continued his policy of "Vietnamization" and reduced U.S. ground forces to fewer than 70,000 by early 1972; air power, however, remained heavily employed. The long-stalled peace negotiations in Paris concluded a cease-fire agreement in January 1973, providing for the exchange of prisoners of war and for U.S. withdrawal from South Vietnam. Thus ended 12 years of U.S. military effort that had taken nearly 46,000 American lives.

In March 1972 Nixon completely reversed U.S. policy by accepting an invitation from the People's Republic of China and visiting Peking. Long-term tensions between the two nations were markedly lessened by the journey, which included several days of discussion with the Chinese leaders Mao Tse-tung and Chou En-lai. Similarly Nixon travelled to Moscow in May for discussions with Soviet leaders; several accords were signed, including agreements aimed at limiting the production of strategic armaments. In July Nixon announced an agreement for the sale of large quantities of grain to the Soviet Union over a period of three years.

In June 1973 a visit to the U.S. by Leonid I. Brezhnev, general secretary of the Soviet Communist Party, appeared to strengthen the détente of the previous year, but the Arab–Israeli war that broke out in October brought some strain to the relationship. Secretary of State Henry A. Kissinger was active in negotiations that brought about a cease-fire between Israel and Egypt in November and between Israel and Syria in mid-1974.

Domestic affairs. Nixon's domestic policies made slow progress, partly because of opposition from the Democratic Congress. On May 21, 1969, the President nominated Warren E. Burger to succeed Earl Warren as chief justice of the United States, and the nomination was quickly approved. He also nominated, successively, two Southern judges for associate justice, but both were rejected by the Senate. The President's third nominee was confirmed in May 1970.

Supreme Court appointments

As a political issue the Vietnam War had subsided until the announcement in April 1970 of the U.S. military involvement in Cambodia. This aroused strong protest, especially on university and college campuses. Student demonstrations at Kent State University in Ohio led (May 4) to a confrontation with troops of the Ohio National Guard, who fired on the students, killing four and wounding several others.

The fight for minority rights continued as a major domestic issue, and the 12 black members of the U.S. House of Representatives charged the administration with reneging on past promises and with refusing to listen to minority groups. In 1972 Congress, with the support of the President, adopted (49 years after it was first introduced) a proposed constitutional amendment guaranteeing equal rights for women and submitted it to the states for ratification.

Nixon gave high priority to the control of inflation and the reduction of military expenditures. But the cost of living continued to rise, until by June 1970 it was 30 percent above the level of 1960; industrial production declined, as did the stock market. By mid-1971 unemployment had

reached a 10-year peak of 6 percent, and inflation continued. Wage and price controls were instituted in various phases, the dollar was devalued twice, and the limitation on the national debt was raised three times in 1972 alone. The U.S. trade deficit improved, but inflation continued.

The 1972 election and the Watergate scandal. Sen. George McGovern of South Dakota, an early and earnest opponent of the Vietnam War who called for drastic reforms in welfare programs and cuts in military spending, won the Democratic nomination for president in 1972. The primary campaign had been marred by an assassination attempt on George Wallace that left him disabled. Sen. Thomas Eagleton of Missouri was the vice-presidential candidate but was soon replaced by R. Sargent Shriver after unfavourable publicity about the Senator's earlier psychiatric treatment. Nixon and Agnew, who were renominated by the Republicans, won a landslide victory in November, capturing every state except Massachusetts and the District of Columbia. The Democrats retained majorities in both the Senate and the House.

Watergate

The scandal that was to haunt Nixon's second term, and lead to its premature end, first surfaced in June 1972, when five men were arrested for breaking into the Democratic national headquarters at the Watergate office–apartment building in Washington. It was revealed that the men were in the hire of the Committee for the Re-election of the President (CRP). The director of security and a counsel of CRP were discharged and later convicted on charges of burglary and wiretapping; John N. Mitchell, former U.S. attorney general and the campaign director of CRP, resigned.

The events had no effect on the election and roused no national attention until 1973, when it was revealed that an attempt to suppress knowledge of the connection between the Watergate affair and CRP involved highly placed members of the White House staff. In response, a Senate select committee was formed and opened hearings on May 17, 1973; Nixon appointed a special prosecutor on May 25 to investigate the scandal.

The Watergate affair itself was further complicated by the revelation of other irregularities. It became known that a security unit in the White House had engaged in illegal activities under the cloak of national security. Nixon's personal finances were questioned, and Vice President Agnew resigned after pleading no contest to charges of income-tax evasion. On December 6, 1973, Nixon's nominee, Congressman Gerald R. Ford of Michigan, was approved by Congress as the new vice president.

The resignation. By late 1973, both Democratic and Republican leaders were beginning to talk of Nixon's resignation or impeachment. His popularity in the country, as indicated by public-opinion polls, declined steadily. On July 24, 1974, the Supreme Court ruled unanimously that Nixon must provide potential evidence (including, in this case, tapes of recorded conversations) for the criminal trial of his former subordinates, rejecting flatly his contention that he had authority to withhold such material. The Judiciary Committee of the House of Representatives, which since May 9 had been hearing evidence relating to a possible impeachment proceeding, voted on July 27–30 to recommend that Nixon be impeached on three charges. When, on August 5, Nixon released transcripts of three of the tape recordings previously sought by the Supreme Court, he admitted to having taken steps to direct the FBI away from the White House during its Watergate inquiries.

The admission created a storm, and Nixon's support in Congress vanished. On the evening of August 8, in a television address, Nixon announced his resignation, effective the next day. He was the first man to resign the presidency. At noon on August 9, Vice President Ford was sworn in as his successor, the first president not elected to the office or to the vice presidency.

The Ford administration. *Domestic affairs.* Ford saw as his first duty the binding of the nation's wounds and the restoration of confidence in the presidency. His nomination on August 20 of Nelson A. Rockefeller to be vice president was widely acclaimed, although extensive congressional hearings delayed confirmation until December 19. But Ford's pardon of Nixon on September 8 undermined his base of support so seriously that he volunteered to appear before a subcommittee of the House of Representatives to explain his action. Watergate reappeared in the headlines in October at the beginning of the trial of five of Nixon's aides on charges of obstructing justice (four were subsequently convicted). Ford took an active part in the autumn election campaigns, but the Democrats gained 43 seats in the House, three in the Senate, and the governorships of four states. The new Congress took action that reduced the powers of its firmly entrenched seniority system.

Ford presented an anti-inflation program to Congress on October 8. His "Whip Inflation Now" (WIN) proposals contained little mandatory action and were received coolly. As unemployment overtook inflation as a serious problem, a recession began, and the WIN program quietly disappeared. The pace of inflation rose to 10.2 percent for 1974 but declined to a "manageable" 5 to 6 percent in 1976; the unemployment rate reached a peak of 8.9 percent in April 1975 and remained high. The administration was criticized for inaction, but it was generally agreed that the economy was improving by the end of 1975. In the post-Watergate mood of assertiveness, the Congress passed a bill that established procedures for greater involvement of Congress in the budget-making process, and in September 1976 an extensive revision of the tax structure was enacted.

Inflation and unemployment

The growing financial plight of U.S. cities reached crisis proportions in 1975. In New York City expenses had exceeded tax revenues over the previous 10 years, and the city was unable to pay its maturing debt obligations. In June 1975 the state legislature created the Municipal Assistance Corporation (MAC), which virtually took control of the city's fiscal affairs. President Ford repeatedly refused federal help, but he changed his position after the state approved still more aid and the city showed signs of making major economies. Congress authorized restricted loans and a revision of municipal bankruptcy laws.

Allegations made during the Watergate scandal led separate subcommittees of the Senate and House in 1975–76 to scrutinize the Central Intelligence Agency (CIA) and the Federal Bureau of Investigation (FBI), as well as the Internal Revenue Service and the army intelligence staff. The inquiries revealed numerous illegal activities, both at home and overseas, that dated back through several administrations. Tighter controls were urged; actions included the dismissal of the CIA director and the FBI associate director, issuance of an executive order outlining a new command structure and restricting activities, and selection of a Senate committee to oversee all intelligence gathering.

Additional scandal emerged in 1976, when it was revealed that the Lockheed Aircraft Corporation had paid $24,400,000 in bribes to members of foreign governments to facilitate sales of its planes. Repercussions were felt in Japan, The Netherlands, and Italy.

Foreign affairs. Soon after assuming the presidency, Ford began a series of trips that included two visits to the Orient and three to Europe by the end of 1975.

End of the Vietnam War

The Vietnam War came to an end in April 1975. Just a few weeks earlier the President had requested nearly $1,000,000,000 in military and humanitarian aid for South Vietnam but had been rebuffed by Congress. Only hours before the end he ordered an airlift of refugees from Indochina, and Congress later authorized expenditure of $455,000,000 for assistance to refugees. In May Ford sent the Marines to rescue a cargo ship from illegal seizure by Cambodia.

The policy of détente continued as the basis of relations between the U.S. and the Soviet Union, but not without incidents of strain. A five-year trade agreement was signed in October 1975, under which the U.S. would supply grain to the Soviet Union in return for petroleum; this was followed two months later by a six-year shipping agreement. The Soviet government had cancelled (January 1975) a trade agreement made in 1972, claiming internal interference in Congress' stipulation that Moscow must permit freer emigration of Jews. A treaty limiting

underground nuclear explosions for peaceful purposes, signed in May 1976, complemented a treaty of July 1974. The Strategic Arms Limitation Talks (SALT) continued, but produced only limited agreements.

Henry A. Kissinger was retained as secretary of state from the Nixon Cabinet (one of only three holdovers remaining by the end of 1975), and he dominated foreign policy in the Ford administration even more thoroughly than he had under Nixon. He accompanied Ford on his travels and undertook many missions of his own, continuing his "shuttle diplomacy" in the Middle East and in 1976 adding Africa to his areas of activity. He was responsible for a five-year treaty of friendship and cooperation (January 1976) between Spain and the U.S. and for Iran's plans (August 1976) to purchase U.S. arms worth $10,000,000,000.

Bicentennial celebration. July 4, 1976, marked the 200th anniversary of the Declaration of Independence, the birth of the nation. A celebration began in July 1975 and continued to the end of 1976 with projects, exhibits, and activities in almost every institution and community of the country. The bicentennial inspired many varieties of commemoration, including restoration and conservation projects, such as refurbishing and restoring parts of Independence Historical National Park in Philadelphia, the site of the original event; and the British Parliament's loan of one of the four first copies of Magna Carta, escorted from London by 25 members of Congress and displayed in the rotunda of the Capitol in Washington. In perhaps the most spectacular observance of all, more than 225 high-masted sailing ships under 31 flags entered New York Harbor on the historic day, followed by 53 warships from 22 nations and an estimated 30,000 small craft.

The election of 1976. The election of 1976 was the first to be held under provisions of a law regulating the financing of political campaigns, passed in 1974 and amended in 1976. Ford announced his candidacy for the Republican nomination in July 1975 and in November said that he would enter all of the 30 primaries. Though he was seriously challenged by Ronald Reagan, the former governor of California, Ford had secured slightly more votes by the beginning of the nominating convention in August 1976. The President retained his lead and won the nomination, choosing Sen. Robert J. Dole of Kansas as his running mate (Vice President Rockefeller had removed himself from consideration in November 1975).

Reagan challenge of Ford nomination

In the Democratic contest there were, at the beginning, 10 major contenders. By June 1976, however, more than a month before the Democratic National Convention, Jimmy Carter, a former governor of Georgia, had won enough delegates to be assured of the nomination. He chose Walter F. Mondale, senator from Minnesota, as his running mate.

The most notable feature of the autumn campaign was a series of debates on television (the first in 16 years) between the two major presidential candidates and one between the vice-presidential opponents. Both Ford and Carter seemed to stand solidly in the traditions of their respective parties. Though stumbling badly in the first weeks of the campaign, Carter maintained his early lead and was elected president in November.

The Carter administration. *Foreign affairs.* During his first year in office, Carter introduced his policy of tying the guarantee of human rights to the conduct of foreign affairs. This policy was echoed by Andrew Young, the U.S. ambassador to the United Nations, despite protests by the Soviet Union. To protest racial policies, the U.S. voted for a UN embargo of arms sales to South Africa and ended the importation of chromium from Rhodesia. In May restrictions on arms sales to all nations not linked to the U.S. in defense treaties were announced.

In February 1977 the U.S. extended its control of fishing rights to 200 miles offshore, giving priority to U.S. fishermen, placing restrictions on the kinds of fish caught, and limiting foreign fishing permits. This action led to the first direct formal negotiations in 16 years with Cuba, which lies only 90 miles off the U.S. coast.

On September 7, 1977, the U.S. and Panama signed two treaties giving control of the Panama Canal to Panama at the end of 1999 and guaranteeing the neutrality of the waterway thereafter. Ratification of the treaties by the U.S. Senate, however, was resisted.

A change in U.S. policy in the Middle East was indicated by a joint U.S.–Soviet communiqué issued on October 1 and calling for a guarantee of "the legitimate rights of the Palestinian people," the "withdrawal of Israeli armed forces from territories occupied in the October 1967 conflict," and the presence of Palestinians at the Geneva Conference. This was balanced, however, by U.S. support for the negotiations between Egypt and Israel begun by Pres. Anwar as-Sadat and Prime Minister Menahem Begin in November 1977. On December 29, Carter began a foreign tour to Poland, Iran, India, Saudi Arabia, France, and Belgium.

Domestic affairs. The day after his inauguration on January 20, 1977, Carter granted a pardon to those who evaded the armed services draft between August 1964 and March 1973; *i.e.,* during the period of the war in Indochina. He also ordered a review of the cases of deserters and of those who received qualified discharges during the same period. This swift fulfillment of a campaign promise was followed by three months of intense activity that produced numerous proposals for reform. Congress was presented with programs including reform of the government bureaucracy and of the electoral, federal welfare, and Social Security systems.

Carter stressed his energy program, which met with great resistance in Congress. Aimed at reducing domestic consumption of energy and promoting the search for alternatives to foreign petroleum products, the program included a gasoline tax, taxes on domestic oil, and tax incentives for the purchase of automobiles of low gasoline consumption and for the discovery of new domestic natural gas deposits. Although the House passed all but the gasoline tax, the Senate blocked or greatly modified the entire program.

Energy program

U.S. economic growth was slower than expected in 1977 and continued to be obstructed by the large deficit in foreign trade caused by petroleum imports. Inflation continued at an annual rate of 6 percent, and unemployment hovered at just under 7 percent of the work force. The adverse effects of a second successive severe winter were exacerbated by a nation-wide coal strike that began in December and led to Carter's implementation of the Taft–Hartley Labor Relations Act in March 1978.

In August 1977 Tongsun Park, a Korean businessman living in Washington, D.C., was indicted on charges of attempting to bribe government officials on behalf of the South Korean government. The action further cooled U.S. relations with South Korea, which had been strained in February by the U.S. decision to withdraw its troops from Korea over a five-year period. (Ed.)

(*America, England, and the wider world*): LAWRENCE H. GIPSON (*op. cit.*); FRANCIS PARKMAN, *A Half-Century of Conflict*, 5th ed., 2 vol. (1893, reprinted 1965); HOWARD PECKHAM, *The Colonial Wars, 1689–1762* (1964), an excellent overview of the balance of power struggles in America; MAX SAVELLE, "The American Balance of Power and European Diplomacy, 1713–78," in RICHARD B. MORRIS (ed.), *The Era of the American Revolution* (1939), an important interpretation of the place of the American continent in the balance of power struggles of Europe.

From 1763–1815: The classical work on the coming of the Revolution is LAWRENCE H. GIPSON (*op. cit.*); Gipson's one-volume summary, *The Coming of the Revolution, 1763–1775* (1954), is less valuable. Far better is MERRILL JENSEN, *The Founding of a Nation* (1968); for a good brief treatment see EDMUND S. MORGAN, *The Birth of the Republic, 1763–1789* (1956). A provocative and controversial view is CHARLES H. MCILWAINE, *The American Revolution: A Constitutional Interpretation* (1923, reprinted 1958). American arguments are set forth in RANDOLPH G. ADAMS, *The Political Ideas of the American Revolution*, 3rd ed. (1958). An excellent account of the development of American ideology, suffering only by inattention to the importance of Bolingbroke and his circle in shaping thinking of American radicals, is BERNARD BAILYN, *Ideological Origins of the American Revolution* (1967). On British politics during the period, the indispensable work is LOUIS NAMIER, *England in the Age of the American Revolution*, 2nd ed. (1961). CARL BECKER, *The Declaration of Independence* (1922, reprinted 1942), is a masterpiece of historical literature, though it and Becker's other works on the Revolution are no longer highly regarded. On the Confederation and Constitution, Jensen's *Articles of Confederation* (1940) is extremely valuable, his *New Nation . . . 1781–1789* (1950) is less so. E. JAMES FERGUSON, *The Power of the Purse* (1961), is excellent on the crucial matter of public finance in the wartime and postwar years. ALLAN NEVINS, *The American States During and After the Revolution, 1775–1789* (1924), is a standard work but contains many inaccuracies and other shortcomings. CHARLES A. BEARD, *An Economic Interpretation of the Constitution of the United States* (1913), was for decades the most influential work on the making of the Constitution, but the consensus of historians is that his work was effectively disproved by ROBERT E. BROWN, *Charles Beard and the Constitution* (1956); and FORREST MCDONALD, *We the People* (1958). McDonald's own interpretation of the event, followed in the present account, is *E Pluribus Unum: The Formation of the American Republic, 1776–1790* (1965). On the 1790s the best one-volume narrative is JOHN C. MILLER, *The Federalist Era, 1789–1801* (1960). For a provocative essay from the Republican point of view, see JOSEPH CHARLES, *Origins of the American Party System* (1956). Adams' presidency is covered—adequately, if one discounts the bias against both Hamilton and Jefferson—by STEPHEN KURTZ, *The Presidency of John Adams* (1957); and MANNING J. DAUER, *The Adams Federalists* (1953). More useful than either, perhaps, is CHARLES PAGE SMITH, *John Adams*, 2 vol. (1962). On politics in general, see WILLIAM N. CHAMBERS, *Political Parties in a New Nation: The American Experience, 1776–1809* (1963). On the years after 1800 the classical work, still towering over everything written since, is HENRY ADAMS, *The History of the United States of America During the Presidencies of Thomas Jefferson and James Madison, 1801–1817*, 9 vol. (1889–91). Also useful are JULIUS PRATT, *The Expansionists of 1812* (1925); and ROGER H. BROWN, *The Republic in Peril: 1812* (1964).

From 1816 to 1850: (*The era of mixed feelings*): GEORGE DANGERFIELD's two books, *The Era of Good Feelings* (1952) and *The Awakening of American Nationalism, 1815–1828* (1965), are highly readable and comprehensive works, particularly useful on foreign affairs. SHAW LIVERMORE, JR., *The Twilight of Federalism: The Disintegration of the Federalist Party, 1815–1830* (1962), is a detailed study of what became of the Federalist Party after the War of 1812.

Books, the topics of which are clearly stated by their titles, are MURRAY N. ROTHBARD, *The Panic of 1819* (1962); DEXTER PERKINS, *The Monroe Doctrine, 1823–1826* (1927, reprinted 1966); F. LEE BENNS, *The American Struggle for the British West Indies Carrying Trade, 1815–1830* (1923); GLOVER MOORE, *The Missouri Controversy, 1819–1821* (1953); and BRAY HAMMOND, *Banks and Politics in America: From the Revolution to the Civil War* (1957). (*The transportation revolution and the beginnings of industrialism*): GEORGE R. TAYLOR, *The Transportation Revolution, 1815–1860* (1951), is a survey of other than agricultural economic developments during the entire period. Also useful as surveys are DOUGLASS C. NORTH, *The Economic Growth of the United States, 1790–1860* (1961); and STUART BRUCHEY, *The Roots of Economic Growth, 1607–1861* (1965). An example of the "new economic history," with its stress on econometric interpretations of quantitative data is PETER TEMIN, *The Jacksonian Economy* (1969). (*Social developments*): Many European visitors wrote accounts of America. Among the most valuable are ALEXIS DE TOCQUEVILLE, *De la démocratie en Amérique*, 3rd ed., 2 vol. (1838; Eng. trans., *Democracy in America*, 2 vol., 1898, reprinted 1964); FRANCIS TROLLOPE, *Domestic Manners of the Americans*, 2 vol. (1832, reprinted 1969); HARRIET MARTINEAU, *Society in America*, 3 vol. (1837); and MICHEL CHEVALIER, *Lettres sur l'Amérique du Nord*, 3rd ed., 2 vol. (1838; Eng. trans., *Society, Manners, and Politics in the United States*, 1839, reprinted 1969). Useful scholarly studies are FREDERICK JACKSON TURNER, *The Frontier in American History* (1920, reprinted 1962); CARL R. FISH, *The Rise of the Common Man, 1830–1850* (1937); ROBERT RIEGEL, *Young America, 1830–1840* (1949); and EDWARD PESSEN, *Jacksonian America: Society, Personality, and Politics* (1969). For discussions of immigration and immigrant life during the era, see OSCAR HANDLIN, *Boston's Immigrants, 1790–1865* (1941); MARCUS LEE HANSEN, *The Atlantic Migration, 1607–1860* (1940); and ROBERT ERNST, *Immigrant Life in New York City, 1825–1863* (1949). LEON LITWACK, *North of Slavery, The Negro in the Free States, 1790–1860* (1961), is comprehensive. Modern studies of urban developments are RICHARD C. WADE, *The Urban Frontier: The Rise of Western Cities, 1790–1830* (1959); D. CLAYTON JAMES, *Antebellum Natchez* (1968); ROBERT A. DAHL, *Who Governs? Democracy and Power in an American City* (1961); and JEFFREY G. WILLIAMSON and JOSEPH A. SWANSON, "The Growth of Cities in the American Northeast, 1820–1870," *Explorations in Entrepreneurial History*, 2nd Series, vol. 4, pp. 3–101 (1966). EDWARD PESSEN, "The Tocqueville Myth and the American Social Reality: Wealth, Mobility, and Equality in the 'Age of Egalitarianism,' " a paper read before the American Historical Association (December 1970), is a detailed, factual refutation of the thesis that antebellum America was egalitarian. Making a similar point are DOUGLAS T. MILLER, *Jacksonian Aristocracy: Class and Democracy in New York, 1830–1860* (1967); and GARY B. NASH, "The Philadelphia Bench and Bar, 1800–1861," *Comparative Studies in Society*

and History, 7:203–220 (1965). (*Jacksonian democracy*): Comprehensive studies whose interpretations are diametrically opposed are ARTHUR M. SCHLESINGER, JR., *The Age of Jackson* (1945), which sees the Jacksonian movement as radical and dedicated to the interests of have-nots; and EDWARD PESSEN (*op. cit.*), which disagrees. GLYNDON G. VAN DEUSEN, *The Jacksonian Era, 1828–1848* (1959), is a brief survey of national politics. JOHN W. WARD, *Andrew Jackson, Symbol for an Age* (1955), is an interpretation of Jackson's popular appeal; and MARVIN MEYERS, *The Jacksonian Persuasion* (1957), discerns tensions and ambivalence in the movement's political beliefs. For the "new politics" of the era, see RICHARD P. MCCORMICK, *The Second American Party System: Party Formation in the Jacksonian Era* (1966); CHILTON WILLIAMSON, *American Suffrage: From Property to Democracy, 1760–1860* (1960); ROBERT V. REMINI, *Martin Van Buren and the Making of the Democratic Party* (1959) and *The Election of Andrew Jackson* (1963); SIDNEY H. ARONSON, *Status and Kinship in the Higher Civil Service* (1964); and LEONARD D. WHITE, *The Jacksonians: A Study in Administrative History, 1829–1861* (1954). For national issues see ROBERT V. REMINI, *Andrew Jackson and the Bank War* (1967); JOEL H. SILBEY, *The Shrine of Party: Congressional Voting Behavior, 1841–1852* (1967); and an old but still important study, ARTHUR C. COLE, *The Whig Party in the South* (1914, reprinted 1962). A useful collection of newer viewpoints is EDWARD PESSEN, *New Perspectives on Jacksonian Parties and Politics* (1969). ALFRED A. CAVE, *Jacksonian Democracy and the Historians* (1964), contains summaries of the various interpretations of Jacksonian Democracy. (*An age of reform*): The most comprehensive single treatment of reforms is ALICE FELT TYLER, *Freedom's Ferment: Phases of American Social History to 1860* (1944), a book more descriptive than analytical. LOUIS FILLER, *The Crusade Against Slavery, 1830–1860* (1960), covers its subject thoroughly. Useful collections are edited by MARTIN DUBERMAN, *The Antislavery Vanguard: New Essays on the Abolitionists* (1965); RICHARD O. CURRY, *The Abolitionists: Reformers or Fanatics?* (1965); GEORGE F. WHICHER, *The Transcendentalist Revolt Against Materialism* (1949; rev. by GAIL KENNEDY, *The Transcendentalist Revolt*, 1968); and DAVID BRION DAVIS, *Ante-Bellum Reform* (1967). Studies that explore the connection between religious enthusiasm and reform are WHITNEY R. CROSS, *The Burned-Over District: The Social and Intellectual History of Enthusiastic Religion in Western New York, 1800–1850* (1950); DAVID M. LUDLUM, *Social Ferment in Vermont, 1791–1850* (1939); JOHN HUMPHREY NOYES, *A History of American Socialisms* (1870, reprinted 1961); HENRY STEELE COMMAGER, *Theodore Parker* (1936, reprinted 1960); CLIFFORD S. GRIFFIN, *Their Brothers' Keepers: Moral Stewardship in the United States, 1800–1865* (1960); and TIMOTHY L. SMITH, *Revivalism and Social Reform in Mid-Nineteenth-Century America* (1957). (*Expansionism and political crisis at midcentury*): Valuable discussions of the ideology of expansionism are conducted by ALBERT K. WEINBERG, *Manifest Destiny: A Study of Nationalist Expansionism in American History* (1935, reprinted 1958); FREDERICK MERK, *Manifest Destiny and Mission in American History* (1963); and NORMAN A. GRAEBNER, *Empire in the Pacific: A Study in American Continental Expansion* (1955). Useful studies of the process of expansionism include RAY A. BILLINGTON, *The Far Western Frontier, 1830–1860* (1956); FRANCIS PARKMAN'S classic, *The California and Oregon Trail* (1849, reprinted 1964); BERNARD DEVOTO, *Across the Wide Missouri* (1947) and *The Year of Decision, 1846* (1943); FREDERICK MERK, *The Oregon Question: Essays in Anglo-American Diplomacy and Politics* (1967); WILLIAM C. BINKLEY, *The Texas Revolution* (1952); ALLAN NEVINS, *Fremont, Pathmaker of the West*, new ed. (1955); A.H. BILL, *Rehearsal for Conflict: The War with Mexico, 1846–1848* (1947); and OTIS A. SINGLETARY, *The Mexican War* (1960). For the political conflicts stemming from expansionism and the war with Mexico, informed coverage is provided by HOLMAN HAMILTON, *Prologue to Conflict: The Crisis and Compromise of 1850* (1964); and ERIC FONER, *Free Soil, Free Labor, Free Men: The Ideology of the Republican Party Before the Civil War* (1970).

From 1850 to 1877: The best general synthesis of modern scholarship, covering the entire era, is J.G. RANDALL and DAVID DONALD, *The Civil War and Reconstruction*, 2nd ed. rev. (1969), which contains an extensive annotated bibliography. Though outdated at many points, JAMES FORD RHODES, *History of the United States from the Compromise of 1850 . . . to 1877*, 8 vol. (1893–1906; abridged ed., 1966), gives sweeping coverage. More recent scholarly interpretations are incorporated in ALLAN NEVIN, *Ordeal of the Union*, 2 vol. (1947); *The Emergence of Lincoln*, 2 vol. (1950); and *The War for the Union*, 4 vol. (1959–71), which cover the period from 1848 to 1865. CLEMENT EATON, *A History of the Old South*, 2nd ed. (1966), is the best general history of the region. ULRICH B. PHILLIPS, *American Negro Slavery* (1918, reprinted 1966), depicts the peculiar institution as essentially kindly, while KENNETH M. STAMPP, *The Peculiar Institution* (1956), sharply criticizes it from an abolitionist point of view. AVERY CRAVEN, *The Coming of the Civil War*, 2nd ed. (1957), is a provocative work, which stresses the possibility that the war could have been averted. The most perceptive account of the political conflicts of the late 1850s is ROY F. NICHOLS, *The Disruption of American Democracy* (1948). THOMAS J. PRESSLY, *Americans Interpret Their Civil War* (1954), offers a thorough review of the literature on the causes of the conflict. BRUCE CATTON, *The Centennial History of the Civil War*, 3 vol. (1961–65), is an eloquent and moving treatment, which stresses military developments. The best accounts of Lincoln's presidency are CARL SANDBURG, *Abraham Lincoln: The War Years*, 4 vol. (1939); and J.G. RANDALL and RICHARD N. CURRENT, *Lincoln the President*, 4 vol. (1945–55). Two comprehensive general histories of the South at war are CLEMENT EATON, *A History of the Southern Confederacy* (1954); and CHARLES P. ROLAND, *The Confederacy* (1960). HUDSON STRODE, *Jefferson Davis*, 3 vol. (1955–64), is the most ambitious account of the Confederate President. Three excellent syntheses of recent scholarship on the Reconstruction period are REMBERT W. PATRICK, *The Reconstruction of the Nation* (1967); JOHN HOPE FRANKLIN, *Reconstruction: After the Civil War* (1961); and KENNETH M. STAMPP, *The Era of Reconstruction, 1865–1877* (1965). Though old, W.E.B. DU BOIS, *Black Reconstruction* (1935, reprinted 1956), remains an invaluable account of the part played by blacks. The best account of Grant as President is WILLIAM BEST HESSELTINE, *Ulysses S. Grant, Politician* (1935, reprinted 1957), which, however, should be supplemented with ALLAN NEVINS, *Hamilton Fish: The Inner History of the Grant Administration*, rev. ed., 2 vol. (1957). DAVID DONALD, *Charles Sumner and the Rights of Man* (1970), offers a full account of one of Grant's principal critics. PAUL L. HAWORTH, *The Hayes-Tilden Disputed Presidential Election of 1876*, new ed. (1927, reprinted 1966), is the standard account of the political compromises that ended Reconstruction, but C. VANN WOODWARD, *Reunion and Reaction* (1951), tells more about behind-the-scenes political and economic negotiations. The definitive account of the South in the post-Reconstruction era is C. VANN WOODWARD, *Origins of the New South, 1877–1913* (1951).

The late-19th century: (*The West*): The one comprehensive study of the several "frontiers" of the period is HAROLD E. BRIGGS, *Frontiers of the Northwest* (1940). WALTER PRESCOTT WEBB, *The Great Plains* (1931, reprinted 1957), is a scholarly classic by a man who knew and loved the Plains. Important works dealing with special aspects of the post-Civil War West include RODMAN W. PAUL, *Mining Frontiers of the Far West 1848–1880* (1963); E.S. OSGOOD, *The Day of the Cattleman* (1929); J.B. FRANTZ and J.E. CHOATE, *The American Cowboy: The Myth and Reality* (1955); and ROBERT E. RIEGEL, *The Story of the Western Railroads* (1926). HENRY E. FRITZ in *The Movement for Indian Assimilation 1860–1890* (1963), traces the development of Indian policy after the Civil War. Two excellent studies of the occupation of the Plains by the farmers are FRED A. SHANNON, *The Farmer's Last Frontier: Agriculture 1860–1897* (1945, reprinted 1968); and GILBERT C. FITE, *The Farmers' Frontier, 1865–1900* (1966). EVERETT DICK presents a scholarly and interesting treatment of phases of frontier life unique to the Plains in *The Sod-House Frontier, 1854–1890* (1937, reprinted 1954). (*Industrial development*): Among many accounts of the development of industry after the Civil War, see EDWARD C. KIRKLAND, *Industry Comes of Age: Business, Labor, and Public Policy, 1860–1897* (1961). SAMUEL P. HAYS in *The Response to Industrialism, 1885–1914* (1957), offers a perceptive appraisal of the impact of industry upon many aspects of American life. Among many biographies of individual industrialists, two are noteworthy: ALLAN NEVINS, *John D. Rockefeller*, 2 vol. (1940, reprinted 1969), which is generally sympathetic with its subject; and JOSEPH WALL, *Andrew Carnegie* (1970), which is scholarly and unusually well balanced. The best brief summary of the role of the trade unions during the period is NORMAN J. WARE, *The Labor Movement in the United States, 1860–1895* (1929, reprinted 1964). (*Politics*): The literature dealing with the politics of the period is extensive, both in monographs and biographies. One contemporary study that is still invaluable for an understanding of the politics of the time is JAMES BRYCE, *The American Commonwealth*, 2 vol. (1888; new rev. ed., 1931–33), by a distinguished British scholar and public servant. LEONARD D. WHITE, *The Republican Era, 1869–1901* (1958), presents

a careful and useful analysis of political and administrative policies of the period. Two valuable books that cover all or part of the period are H. WAYNE MORGAN, *From Hayes to McKinley* (1969); and HAROLD U. FAULKNER, *Politics, Reform and Expansion, 1890–1900* (1959). Books dealing with major parties include H.S. MERRILL, *Bourbon Democracy of the Middle West, 1865–1896* (1953); and ROBERT D. MARCUS, *Grand Old Party: Political Structure in the Gilded Age, 1880–1896* (1971). The standard study of Populism, regarded by some as too sympathetic with the Populists, is JOHN D. HICKS, *The Populist Revolt* (1931, reprinted 1961). Two works dealing with major political issues of the period are GABRIEL KOLKO, *Railroads and Regulation, 1877–1916* (1965), which attributes much of the support for regulation to railroad management rather than to reform groups; and H.B. THORELLI, *Federal Antitrust Policy* (1954). Among the numerous biographies of political leaders of the time, a few of the most important are HARRY BARNARD, *Rutherford B. Hayes, and His America* (1954); ALLAN NEVINS, *Grover Cleveland: A Study in Courage* (1932); H.J. SIEVERS, *Benjamin Harrison: Hoosier Statesman* (1959); LOUIS W. KOENIG, *Bryan: A Political Biography of William Jennings Bryan* (1971); MARGARET LEECH, *In the Days of McKinley* (1959); and HERBERT CROLY, *Marcus Alonzo Hanna: His Life and Work* (1912, reprinted 1965), which is still the only satisfactory biography of the man who was the chief architect of Republican policy at the end of the century.

Imperialism, Progressivism, and America's rise to power in the world, 1869–1920: ERNEST R. MAY, *Imperial Democracy* (1961) and *American Imperialism* (1968); WALTER LAFEBER, *The New Empire: An Interpretation of American Expansion, 1860–1898* (1963); WILLIAM APPLEMAN WILLIAMS, *The Roots of the Modern American Empire* (1969); and JULIUS W. PRATT, *Expansionists of 1898* (1936, reprinted 1964), present varying interpretations of imperialism. FRANK FREIDEL, *The Splendid Little War* (1958), is the best account of the Spanish-American War, while JULIUS W. PRATT, *America's Colonial Experiment* (1950), is nearly definitive on the administration of the American overseas empire. A. WHITNEY GRISWOLD, *The Far Eastern Policy of the United States* (1938, reprinted 1962), remains the standard work on this subject, but for the Open Door policy and relations with China, see also TYLER DENNETT, *John Hay* (1933) and *Roosevelt and the Russo-Japanese War* (1925); and CHARLES VEVIER, *The United States and China, 1906–1913* (1955). The story of American penetration and domination of the Caribbean is well recounted in SAMUEL F. BEMIS, *The Latin American Policy of the United States* (1943, reprinted 1967); DEXTER PERKINS, *The Monroe Doctrine, 1867–1907* (1937, reprinted 1966); and, most authoritatively, DANA G. MUNRO, *Intervention and Dollar Diplomacy in the Caribbean, 1900–1921* (1964). The best introduction to the United States during the progressive era is ROBERT H. WIEBE, *The Search for Order, 1877–1920* (1967). Still the standard work on Populism and its continuing contributions is JOHN D. HICKS, *The Populist Revolt* (1931). For the contributions of intellectuals to progressivism, see HENRY S. COMMAGER, *The American Mind* (1950); for the muckrakers, LOUIS FILLER, *Crusaders for American Liberalism*, new ed. (1964); for the social workers, ROBERT H. BREMNER, *From the Depths: The Discovery of Poverty in the United States* (1956); and ALLEN F. DAVIS, *Spearheads for Reform* (1967); and for the Social Gospel, CHARLES H. HOPKINS, *The Rise of the Social Gospel in American Protestantism, 1865–1915* (1940); HENRY F. MAY, *Protestant Churches and Industrial America* (1949); and AARON I. ABELL, *American Catholicism and Social Action* (1960). Excellent examples of the growing literature on urban and state progressivism are JAMES B. CROOKS, *Politics and Progress: The Rise of Urban Progressivism in Baltimore, 1895 to 1911* (1968); ZANE L. MILLER, *Boss Cox's Cincinnati* (1968); HOYT L. WARNER, *Progressivism in Ohio, 1897–1917* (1964); and SPENCER C. OLIN, JR., *California's Prodigal Sons: Hiram Johnson and the Progressives, 1911–1917* (1968). The best surveys of American national politics from Roosevelt through Wilson are GEORGE E. MOWRY, *The Era of Theodore Roosevelt, 1900–1912* (1958); and ARTHUR S. LINK, *Woodrow Wilson and the Progressive Era, 1910–1917* (1954). Biographical studies are particularly important for this period. Some of the best are WILLIAM H. HARBAUGH, *Power and Responsibility: The Life and Times of Theodore Roosevelt* (1961); HOWARD K. BEALE, *Theodore Roosevelt and the Rise of America to World Power* (1962); HENRY F. PRINGLE, *The Life and Times of William Howard Taft*, 2 vol. (1939, reprinted 1964); and ARTHUR S. LINK, *Wilson*, 5 vol. (1947–65), which concentrates on Wilson's public career from 1910 to 1917 and gives as much attention to foreign affairs as to domestic politics. The last three volumes of Link's *Wilson* contain the most definitive account of the struggle for neutrality and American entrance into World War I, but see also ERNEST R. MAY, *The World War and American Isolation, 1914–1917* (1959); and CHARLES SEYMOUR (ed.), *The Intimate Papers of Colonel House*, 4 vol. (1926–28, reprinted 1971). American mobilization is well covered by BERNARD M. BARUCH, *American Industry in the War* (1941); and DANIEL R. BEAVER, *Newton D. Baker and the American War Effort, 1917–1919* (1966). For special aspects, see SEWARD W. LIVERMORE, *Politics Is Adjourned: Woodrow Wilson and the War Congress, 1916–1918* (1966); ZECHARIAH CHAFEE, JR., *Free Speech in the United States* (1941); and HORACE C. PETERSON and GILBERT C. FITE, *Opponents of War, 1917–1918* (1957). On Wilson and the Russian Revolution, see GEORGE F. KENNAN'S magisterial *Russia Leaves the War* (1956) and *The Decision to Intervene* (1958), published together as *Soviet-American Relations, 1917–1920* (1967); and the more compact monograph, BETTY M. UNTERBERGER, *America's Siberian Expedition, 1918–20* (1956). ARNO J. MAYER, *Political Origins of the New Diplomacy, 1917–1918* (1959), is a brilliant account of the development of Wilson's peace program in its worldwide context. Still the best studies on Wilsonian and American participation in the Paris Peace Conference are PAUL BIRDSALL, *Versailles Twenty Years After* (1941); and RAY STANNARD BAKER, *Woodrow Wilson and World Settlement*, 3 vol. (1922); but see also THOMAS A. BAILEY, *Woodrow Wilson and the Lost Peace* (1944); ARNO J. MAYER, *The Politics and Diplomacy of Peacemaking* (1967); and N. GORDON LEVIN, JR., *Woodrow Wilson and World Politics: America's Response to War and Revolution* (1968). The fight over the treaty is amply covered by THOMAS A. BAILEY, *Woodrow Wilson and the Great Betrayal* (1945); DENNA F. FLEMING, *The United States and the League of Nations, 1918–1920* (1932); JOHN A. GARRATY, *Henry Cabot Lodge* (1953); and RALPH STONE, *The Irreconcilables: The Fight Against the League of Nations* (1970). Nearly definitive is WESLEY M. BAGBY, *The Road to Normalcy: The Presidential Campaign and Election of 1920* (1962).

From 1920 to 1945: FRANK FREIDEL, *America in the Twentieth Century*, 3rd ed. (1970), a textbook, provides a good survey of the period. A comprehensive political review of the twenties is JOHN D. HICKS, *Republican Ascendancy, 1921–1933* (1960); while WILLIAM E. LEUCHTENBURG, *The Perils of Prosperity, 1914–32* (1958), is a lively and enterprising short account. A second volume by Leuchtenburg provides a balanced examination of the New Deal: *Franklin D. Roosevelt and the New Deal, 1932–1940* (1963). Three vividly written and richly detailed volumes by ARTHUR M. SCHLESINGER, JR., *The Age of Roosevelt* (1957–60), cover the New Deal through the 1936 election. See also FRANK FREIDEL, *Franklin D. Roosevelt*, 3 vol. (1952–56), covering down to the 1932 election. Companion volumes providing the standard economic view for this period are GEORGE H. SOULE, *Prosperity Decade: From War to Depression, 1917–1929* (1947); and BROADUS MITCHELL, *Depression Decade: From New Era Through New Deal, 1929–1941* (1947). FREDERICK L. ALLEN'S two engaging contemporary studies of the social history of this era are *Only Yesterday: An Informal History of the Nineteen-twenties* (1931, reprinted 1957) and *Since Yesterday* (1940); while ARTHUR A. EKIRCH, *Ideologies and Utopias: The Impact of the New Deal on American Thought* (1969), offers a fine study of the intellectual milieu. Two solid summaries of diplomatic developments are FOSTER R. DULLES, *America's Rise to World Power, 1848–1954* (1955); and SELIG ADLER, *The Uncertain Giant, 1921–1941: American Foreign Policy Between the Wars* (1965). Roosevelt's wartime years are accurately portrayed in JAMES MACGREGOR BURNS, *Roosevelt: The Soldier of Freedom, 1940–1945* (1970); while A. RUSSELL BUCHANAN emphasizes military and administrative matters in *The United States and World War II*, 2 vol. (1964).

From 1945 to the present: The diplomatic history of the period after 1945 has attracted broad attention and interpretation. Among these, especially valuable are surveys of American foreign policy by WALTER LAFEBER, *America, Russia, and the Cold War, 1945–1966* (1967); and JOHN SPANIER, *American Foreign Policy Since World War II*, 2nd rev. ed. (1965). The difficulty of adjustment to world responsibility in foreign affairs is emphasized by HERBERT AGAR in *The Price of Power: America Since 1945* (1957); and by JOYCE and GABRIEL KOLKO in their *The Limits of Power: The World and United States Foreign Policy, 1945–1954* (1972). Important insights on presidential elections in the sixties can be gained from THEODORE H. WHITE, *The Making of the President*, 3 vol. (1960–68). Among the valuable works on individual presidents are CABELL PHILLIPS, *The Truman Presidency* (1966); BARTON J. BERNSTEIN and A.J. MATUSOW

(eds.), *The Truman Administration* (1966); and ROBERT J. DONAVAN, *Eisenhower: The Inside Story* (1956). Two authors close to the Kennedy administration produced court studies of his presidential years that are important because of their inside knowledge of events. ARTHUR M. SCHLESINGER, JR., *A Thousand Days: John F. Kennedy in the White House* (1965); and THEODORE C. SORENSEN, *Kennedy* (1965). The Johnson years are examined in detail in ERIC F. GOLDMAN, *The Tragedy of Lyndon Johnson* (1969). Several studies of American society deserve mention. ERIC F. GOLDMAN, *The Crucial Decade* (1959), catches the tone of the immediate postwar years, 1945–55; while JOHN KENNETH GALBRAITH, *The Affluent Society*, 2nd ed. rev. (1969), emphasized the wealth and complacency of America in the 50s. WILLIAM O'NEILL, *Coming Apart: An Informal History of America in the 1960's* (1971), is a lively study of the quality of American life under the impact of changing social values. RONALD BERMAN writes of *America in the Sixties: An Intellectual History* (1968). WALT W. ROSTOW, *Politics and the Stages of Growth* (1971), offers an insightful commentary on national and international economic forces.

United States Outlying Territories

The so-called United States Outlying Territories consist of about 2,360 islands, islets, atolls, and cays (small low islands), plus the Canal Zone. They reach almost halfway around the world from east to west, and are spread over nearly half the distance between the north and south poles. Their total area (excluding disputed islands in the Pacific Ocean) amounts to 5,142 square miles (13,318 square kilometres), or a little less than two thirds the size of Massachusetts. In 1970 their population totalled approximately 3,000,000.

Scattered through the Caribbean Sea and the Pacific Ocean, the outlying territories consist of areas that have United States sovereignty or are otherwise under U.S. jurisdiction or administration. These far-flung locations are most extensive in the Pacific where they penetrate the Eastern Hemisphere and extend south of the Equator into the Southern Hemisphere.

The term United States may be interpreted in two ways. In a narrow sense it identifies the 50 states and the District of Columbia. The U.S. Board on Geographic Names approves this usage and further defines continental United States as comprising the 49 states and the District of Columbia located on the North American Continent. A third approved term, conterminous United States, refers to 48 states and the District of Columbia and excludes both Hawaii and Alaska. In a broad sense the term United States can encompass territory beyond that of these definitions. In most instances the inhabitants of the outlying areas are United States citizens or nationals, thus giving some validity to the broader concept of national territory.

The various outlying territories conveniently break down into two major regional categories, those associated with the Caribbean and those lying in the Pacific. The groupings for the two regions may be listed as follows: (1) Caribbean: Canal Zone; Commonwealth of Puerto Rico; Navassa Island; Quita Sueño Bank, Roncador Cay, and Serrana Bank; Swan Islands; Serranilla Bank; and Virgin Islands of the United States; (2) Pacific: American Samoa; Disputed Islands in the Pacific; Guam; Howland, Baker, and Jarvis Islands; Islands under U.S. administration; Johnston and Sand Islands; Kingman Reef; Midway Islands; Palmyra Island; Trust Territory of the Pacific; and Wake Island. Both Colombia and Honduras claim Quita Sueño Bank and Roncador Cay. In addition, Colombia has claimed Serrana Bank.

The relatively small land surface of the territories is equal to only 0.14 percent of that within the 50 states. Likewise, any comparison of population statistics is highly disproportionate. In 1970 the 3,000,000 inhabitants of the territories represented only 1.48 percent of the population of 203,000,000 in the 50 states. For coverage of individual outlying territories, see PANAMA; PANAMA CANAL; PUERTO RICO; SAMOA (AMERICAN AND WESTERN); PACIFIC ISLANDS, TRUST TERRITORY OF THE; and VIRGIN ISLANDS. For historical aspects, see OCEANIA, HISTORY OF. For coverage of associated physical features, see CARIBBEAN SEA; PACIFIC ISLANDS; and PACIFIC OCEAN.

The status of the territories. The statuses of the various outlying territories are by no means uniform. Those in which the United States has residual sovereignty include the Commonwealth of Puerto Rico and the organized unincorporated territories of the Virgin Islands of the United States, America Samoa, and Guam. Before they became states in 1959, Alaska and Hawaii each had the status of incorporated territories—that is, areas that the U.S. Congress had "incorporated" into the United States by making the Constitution applicable to them. In addition, a number of smaller islands, including the Swan Islands, Navassa Island, Midway Islands, and Wake Island, are unincorporated territories. In all cases these small islands are uninhabited or have only a few residents, thus making an organized governmental structure impractical. Beyond these fragments of sovereign territory belonging to the United States, several others are included as outlying territories by virtue of other types of jurisdiction or for purposes of administrative control. The Canal Zone is under U.S. jurisdiction according to the provisions of a treaty with Panama and enjoys full sovereign rights granted in perpetuity. The Trust Territory of the Pacific Islands, consisting of the Caroline, Mariana (except Guam), and Marshall islands, in 1947 was placed under the international trusteeship system established by the Charter of the United Nations. The Bonin, Volcano, and Daito island groups and Marcus Island were formerly under U.S. administration. These islands, located some hundreds of miles south and southeast of Tokyo, were returned to Japan in 1968; the southern Ryukyu Islands, also formerly under United States administration, were returned to Japanese jurisdiction in 1972.

Variations in status

In the western Caribbean, several low-lying islands and banks have special jurisdictional association with the United States. The United States maintains control under an arrangement whereby the claims of these countries are not prejudiced.

The outlying territories of the United States are no longer considered to be colonies, nor are those with significant populations generally referred to as possessions. The decline of colonialism throughout the world has brought about this change in terminology. In each instance the status accorded America's populated outlying territories permits a degree of autonomy commensurate with the capacity of the inhabitants to assume responsibilities of self-government. Puerto Rico, its rank as a commonwealth interpreted as a "free associated state," is in some ways similar to an independent country. It is sometimes considered "semi-independent" or "quasi-independent," being free to govern itself but conforming to U.S. policies in matters of postage, currency, customs, and in international relations and defense. Organized unincorporated territories have limited self-government, though within their borders the Constitution has not been expressly and fully extended.

Degrees of autonomy

The Pacific territories. In the Pacific area the United States claims 25 islands that are in dispute, 18 of them also being claimed by the United Kingdom, and seven by New Zealand. In the case of two, Canton and Enderbury Islands, the United States and the United Kingdom have by agreement established joint control. In all instances the disputes entail no ill feelings or tensions, for populations are small and no strategic significance is attached to their locations.

The Caribbean territories. In the Caribbean area the outlying territories are extended in a 1,500-mile (2,400-kilometre) arc, extending from the Canal Zone through the western segment of the Caribbean to Puerto Rico, and to the Virgin Islands at the eastern extremity of the Greater Antilles. By far the largest, and most important, unit is Puerto Rico, making up well over half of the total area of all U.S. outlying territories and accounting for nearly 90 percent of the total population. In striking contrast, Quita Sueño Bank, Roncador Cay, and Serrana Bank must be measured in acres rather than square miles and are uninhabited. They represent formations that are

largely underwater, with only a few small surfaces emerging above the high water level to form true islands.

Locations and sizes. In the Pacific the outlying territories are far more scattered, though they tend to be concentrated in the Southwest Pacific region. The area of all the islands totals 1,604 square miles (2,580 square kilometres); the area of those directly under undisputed U.S. sovereignty amounts to only 293 square miles (470 square kilometres). Among the latter Guam is the largest with an area of 209 square miles (341 square kilometres) followed by American Samoa with 76 square miles (122 square kilometres). Population of the Pacific islands is unimpressive in size, totalling only about 200,000; about half of these live in the Trust Territory of the Pacific Islands. The Trust Territory of the Pacific Islands is widely scattered, encompassing 2,141 islands of which 96 have residents. Though occupying only 687 square miles (1,100 square kilometres) of land surface, the islands extend over an oceanic area of 3,000,000 square miles (4,800,000 square kilometres), nearly as large as the 48 conterminous states.

2,141 Pacific islands

In both the Caribbean and Pacific, many of the United States outlying territories lie near or among territories of other countries and in some instances within actual sight of them. Seventeen national flags fly over lands in the Caribbean region, including those of the United Kingdom, France, and The Netherlands. The Virgin Islands of the United States make up only the western part of an archipelagic cluster, the remainder forming the British Virgin Islands. In the Pacific the United Kingdom, France, New Zealand, and Australia also have widely scattered island realms, while Japan's offshore islands extend as far as 1,500 miles (2,400 kilometres) east of continental Asia.

Administration. Each of the United States outlying territories has a civil government closely associated with, or under the direct control of, some federal agency in Washington. An exception is Puerto Rico, but even in this instance the Commonwealth maintains an office in the U.S. capital. The remainder of the islands stand in relationship to one or another of the U.S. executive departments, and thus have U.S. cabinet members as chief officials. The U.S. Departments of the Interior and of the Navy have the greatest responsibilities, while the U.S. Department of State is responsible for all affairs pertaining to islands in dispute. The Canal Zone has two administering agencies, one responsible for various civil services, and the other responsible for the operation of the canal. Four of the outlying territories have governors and legislatures. In Puerto Rico elections are held for the governorship and for the Senate and House of Representatives. American Samoa, Guam, and the Virgin Islands have appointed governors, but the local inhabitants are endeavouring to effect legislation for elected governorships. The inhabitants of the Trust Territory of the Pacific Islands are striving to increase the degree of self-government, although the U.S. Department of the Interior currently has administrative control.

History of their acquisition. All of the United States outlying territories were officially acquired or claimed between 1856 and the end of World War II. Each acquisition was made in conjunction with some advantage thought to accrue to the country, whether economic, political, or strategic. The first insular possessions came under the American flag through an Act of Congress (Guano Act of 1856) in order to secure rich deposits of natural fertilizer made up of bird droppings that had accumulated. As a result of the Treaty of Paris of 1898 that ended the Spanish–American War, Puerto Rico and Guam became U.S. possessions, as also did the Philippines, which remained as a U.S. Commonwealth until 1946 when it became independent. In 1917 the United States purchased the Virgin Islands from Denmark as a measure of protection against German submarines. From a strategic viewpoint, the Canal Zone is a centre of U.S. interest in the Caribbean, with Puerto Rico and the Virgin Islands serving as sentinels to guard its approaches. Following World War II it proved expedient to maintain control over the Caroline, Mariana, and Marshall is-

U.S. OUTLYING TERRITORIES IN THE PACIFIC OCEAN

lands, which make up the Trust Territory of the Pacific. The island of Guam, though geographically a part of the Marianas, is excluded from the Trusteeship. The southern Ryukyu Islands, including Okinawa, are under Japanese sovereignty but following World War II were placed under U.S. administration.

Throughout the western Pacific the various outlying areas—outposts over America's western horizon—have served as stepping stones in the development of transportation patterns across the world's widest ocean. Midway and Wake, for example, made air transportation history as stops along Pan American's early transpacific routes. Others—such as Kwajalein, Saipan, and Eniwetok—were battlegrounds during World War II. After the war nuclear tests were conducted on Bikini and Eniwetok.

Geographic relief. The United States outlying territories are all insular except the Canal Zone. The islands, regardless of size, tend either to be volcanic and to have a rough topography, or to be formed of coral and to be low-lying. Cerro de Punta Mountain in Puerto Rico, rising to an elevation of 4,389 feet (1,338 metres), represents one extreme of altitude, while many atolls lie only feet, if not inches, above the sea. Despite some rugged relief on the volcanic islands, some of the islands have coastal plains, streams, valleys, and rolling hill lands that permit extensive agricultural development.

Climate. Only the Midway Islands lie outside the tropics, but even these are subtropical. Throughout the entire area the climate is consistently warm but seldom excessively hot because of the moderating influence of the sea. Rainfall, however, varies enormously from place to place. Exposed windward slopes may receive great amounts while leeward slopes or flat areas may obtain relatively little. Climatic hazards usually take the form of hurricanes in the Caribbean and typhoons in the Pacific. Puerto Rico has had three destructive hurricanes in the last three quarters of a century, and every year storm warnings constitute reminders of the potential danger. In the Pacific there is the added menace of tidal waves, which from time to time may sweep over an entire island and leave destruction in their wake.

Hurricanes and typhoons

Vegetation. Vegetative growth closely follows the climatic pattern, being primarily dependent upon rainfall. In Puerto Rico a mountain known as El Yunque stands in an equatorial rainforest with dripping, luxuriant foliage, while at the other extreme some of the low-lying islands have desert-like characteristics. Because a high sun means high evaporation, 30–40 inches (750–1000 millimetres) of rainfall produces less growth than it would in a cooler climate.

The territorial economies. The United States must necessarily spend large sums to sustain the economies of these territorial entities in order to support their growing populations. Such assistance is provided by preferential legislation, subsidy, or direct aid. Natural resources that permit vigorous economic development are lacking. None of the islands has substantial mineral deposits, while commercial agriculture is limited to a few crops, particularly sugarcane and coconuts, which in general do not yield revenue commensurate with the number of people employed in their production. A principle source of income for local inhabitants is often provided by tourism, or by the servicing of government offices and installations, military and civilian. More than a million tourists visit Puerto Rico each year and in the Virgin Islands the tourist industry constitutes the primary economic activity. Steps were taken in the 1960s to popularize tourism in the Pacific, but so far facilities catering to tourists are limited. Transportation is well developed in all the populated islands and in the Canal Zone.

Peoples and population. Populations in the major outlying territories have been growing at comparable or more rapid rates than on the U.S. mainland. From 1960 to 1970 the increase in Puerto Rico was more than a third of a million inhabitants, or 14.5 percent. On the three organized unincorporated territories of Guam, Samoa, and the Virgin Islands, population growth was strikingly greater, being 29.7 percent, 38.5 percent, and 96.9 percent respectively. The Canal Zone, however, had a modest population increase of only 6 percent. The small islands, including those in the Caroline, Mariana, and Marshall groups, generally do not have the economic advantages associated with major installations, nor are their economies substantially developed; their populations consequently inch upward in defiance of the limitations imposed by the local means of subsistence.

Ethnic groupings. The racial characteristics throughout the outlying territories vary with location. Puerto Ricans are frequently of Spanish ancestry, while in the Virgin Islands the majority of local inhabitants are descended from African slaves who worked on the Danish sugar plantations. Most of the residents of the Canal Zone are U.S. citizens, but there are also Panamanians and other Caribbeans living there who either directly or indirectly contribute to the operation of the Canal. Pacific islanders stem from the peoples associated with specific island groups before the coming of the Europeans. The Chamorros of Guam and the Polynesians of American Samoa in many ways live as they did before American rule. With only a few exceptions the inhabitants of the Trust Territory of the Pacific are Micronesians, though within this broad category they belong to different ethnic groups. On all islands U.S. citizens from the mainland are present as administrators or as technical personnel. Others represent U.S. organizations or are members of the armed forces.

Linguistic patterns. To a marked degree linguistic patterns follow ethnic lines, although the English language has made great inroads on other tongues. Spanish is in wide local use in Puerto Rico and also penetrates the Canal Zone from nearby Panama. The English spoken by Negroes in the Virgin Islands is of a dialect peculiar to the eastern West Indies, which Americans often find difficult to understand. On the Pacific islands each ethnic group continues to use its own language or dialect. In the Trust Territory of the Pacific Islands, for example, nine major languages are in use, though Japanese is widely spoken and English is official. In all instances English holds an important position in the educational system.

Religious affiliations. Traditional religious practices have largely disappeared. Catholicism, traceable to early Spanish influence, prevails in Puerto Rico, the Canal Zone, and Guam. In the Virgin Islands churches represent Catholic, Protestant, and Jewish faiths. Missionary groups throughout the Pacific have succeeded in converting the majority of the islanders to Christianity.

Prospects for the future. Through various agencies and by numerous devices, the U.S. government is striving to improve living conditions in its outlying territories. Good transportation and communication facilities have been assured. Educational systems are said to rank with many on the mainland. Representatives of the U.S. Peace Corps have recently begun work to help the inhabitants of the Trust Territory of the Pacific Islands. Industry has been fostered in Puerto Rico. On a broader scale, the people of the outlying territories enjoy considerable freedom in running their own local affairs. Appointment of officials is increasingly giving way to elections. Local movements toward independence have in some instances been formed, and some of the outlying territories may in the future become independent states. In the meantime the widely scattered peoples of the territories are, in as far as their location and traditions permit, living as Americans.

Universe, Origin and Evolution of

Man's present knowledge of the origin and evolution of planets, stars, stellar systems, galactic systems, and the universe as a whole is pitifully small, and the French scientist Henri Poincaré's words (*Leçons sur les Hypothéses Cosmogoniques*) are as appropriate today as in 1913:

> It is impossible to contemplate the spectacle of the starry universe without wondering how it was formed: perhaps we ought to wait to look for a solution until we have patiently assembled the elements, . . . but if we were so reasonable, if we were curious without impatience, it is probable we would never have created Science and that we would always have been content with a trivial existence. Thus the mind has imperiously laid claim to this solution long before it was ripe, even while perceived in only faint glimmers—allowing us to guess a solution rather than wait for it.

Early views

In ancient Greece, the Milesian school of pre-Socratic thinkers, including Thales, Anaximander, and Anaximenes of the 6th century BC, developed the view that the formation of the world occurred as a natural, rather than supernatural, sequence of events. This view was elaborated by the Pythagorean school of that era, which stressed the concept of an ordered cosmos governed by mathematical relations, and which culminated in the work of Leucippus and Democritus of the Atomist school. The Atomist view is expressed by the Roman poet Lucretius in *De rerum natura*. He describes a boundless universe in which the interplay of atoms creates endless worlds in various stages of development and decay. These early pictures of the physical world were supplanted by the geocentric, finite cosmologies of Plato, Aristotle, and Ptolemy, which later were embodied in medieval theology. From the 16th century, the Copernican theory that the Sun is the centre of the universe, the meticulous celestial measurements of Tycho Brahe, the mathematical discoveries of Kepler, the observations and arguments of Galileo, and the theories of Newton, in a period of about 200 years, opened minds to the possibility of an apparently infinite universe whose centre has no specific location. The realization that stars may be arranged into a system of "island universes," now known as galaxies, emerged in the middle of the 18th century as a result of suggestions by the Swedish scientist and philosopher Emanuel Swedenborg, the British scientist Thomas Wright, the German philosopher Immanuel Kant, and the German scientist Johann Heinrich Lambert. Such conjectures were supported by the observations of the English astronomer William Herschel. Herschel's studies of the "structure of the heavens" were extended by his son, the astronomer John Herschel, and many others, who developed the view that the Milky Way is a single galaxy. Not, however, until after considerable dispute among astronomers was it finally established, in 1924 by the U.S. astronomer Edwin Hubble, that the majority of observed "nebulae" are at great distances outside the Galaxy and that most likely they, too, are galaxies. Hubble's discovery, in 1929, that the distant galaxies are apparently receding at speeds increasing with distance and Albert Einstein's theory of general relativity together established modern cosmology. Cosmology is the study of the universe as a unified whole, cosmogony is the study of the origin and evolution of the principal constituents of the universe. It is not always easy to strike a balance between the two, and nowadays it is recognized that cosmogony overlaps the separate sciences of cosmology and astrophysics. Thus subjects such as galaxy formation belong naturally to cosmology, whereas other subjects such as star formation and evolution are well-established areas of research in astrophysics. This article is concerned with the large-scale evolutionary processes operating in the universe, particularly the origin, evolution, and age of planets, stars, stellar systems (astrophysics), and galactic systems and the universe as a whole (cosmology), which together established modern cosmology.

EVOLUTION OF THE UNIVERSE

Alternative theories of evolution. The recession of distant galaxies implies that the universe is expanding. The expansion is isotropic—that is, the same in all directions—and, for objects not too distant, obeys Hubble's law, which states that the velocity of expansion equals distance over T (V = distance/T) where $1/T$ is called Hubble's constant. According to present estimates, the value of T lies between 10^{10} and 2×10^{10} years. Observations support the belief that, on a large scale, the universe is homogeneous; that is, it appears similar at all locations in space. This is the famous "cosmological postulate" whose origins can be traced back to Nicholas of Cusa (1401–64) and even earlier. The large-scale isotropy and homogeneity of the universe is independent of the small-scale irregularities due to galaxies and clusters of galaxies.

Models of the universe

Because of the complexity of the universe, the usual procedure in cosmological studies is to construct simple representations known as cosmological models. In these models everything in the universe is smoothed out into a uniform fluid whose density is somewhere between 10^{-29} and 10^{-31} gram per cubic centimetre (g/cm^3). Most cosmological models have these same kinematic properties: they are isotropic, homogeneous, and are expanding.

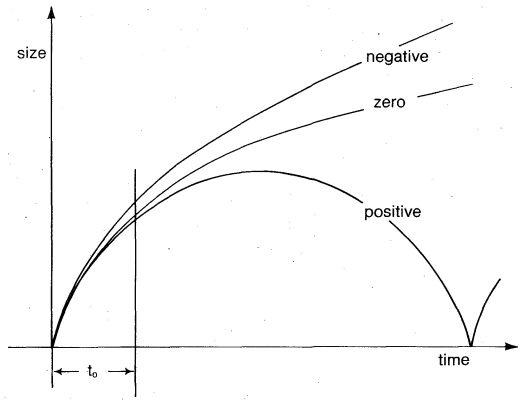

Figure 1: *Changes in the universe according to the Friedmann big-bang models.*
The present age of the universe is t_o. The negative and zero curvature models always expand; the positive curvature model, however, stops expanding at some time in the future and then collapses.

In the majority of models, it is assumed that gravity or some modification of gravity determines dynamic behaviour. Einstein's first model (1917), prior to Hubble's great discovery of the expanding universe, was static and of infinite age (T = infinity). It was assumed that a repulsive force exists, represented by a "cosmological term," that exactly balances the large-scale gravitational attraction. The more realistic evolutionary models of the Soviet mathematician Alexander Friedmann (1922, 1924) and later Einstein and the Dutch astronomer Willem de Sitter (1932) are of the big-bang kind (the universe began at high density, and it is still expanding; see below), and the

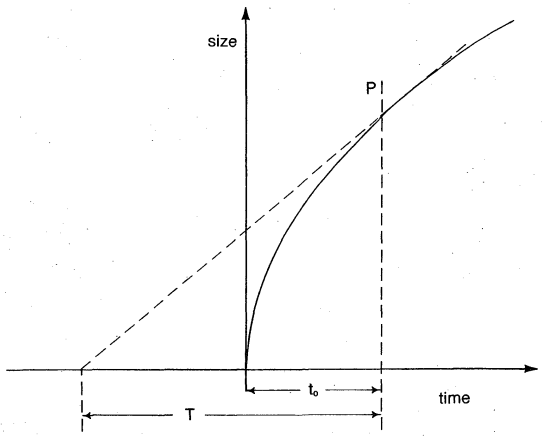

Figure 2: The relation of t_o, the age of the universe according to the Friedmann model, to time, T, with a measured value of between 10,000,000,000 and 20,000,000,000 years.

behaviour of these models is shown in Figure 1. The relation of T and the age t_o of the universe is illustrated in Figure 2 for a model of this type. It is seen that with the Friedmann models the age t_o is always less than T.

It was thought for many years that T had a value of only 2×10^9 years and, in the 1930s and 1940s, cosmologists were greatly concerned with the problem of reconciling this value with, for example, an age of the Earth of 5×10^9 years. One solution was the model proposed by the Belgian astronomer Georges Lemaître, about 1930, in which it is supposed that the cosmological term is even greater than in the Einstein static model. It is then possible for the age t_o of the universe to be greater than T, as shown in Figure 3. A second solution was the steady-state model of the English astronomers Hermann Bondi, Thomas Gold, and Fred Hoyle, which is based on the theory that matter is continuously created at a rate sufficient to maintain a constant mean density in an expanding universe. According to this theory, the universe is of infinite age and obeys a "perfect cosmological postulate" such that it appears the same at all instants of time as well as at all locations in space. The revision upward of extragalactic distance estimates in the late 1950s drastically altered the value assigned Hubble's constant and increased T, and consequently the desperate need for models in which t_o exceeds T has now vanished.

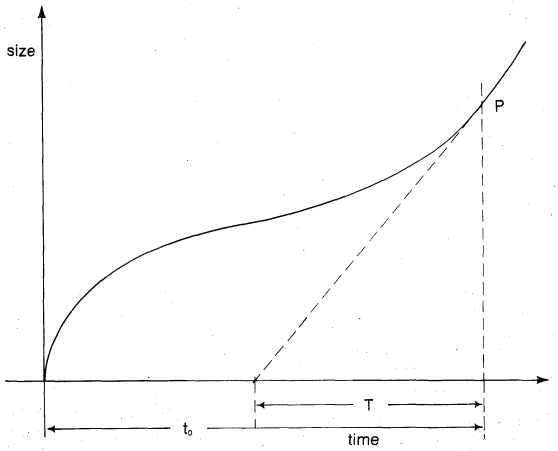

Figure 3: *Lemaître model of a universe containing a repulsive force.*
In this great model the age of the universe is at the present moment, *P*, greater than *T*.

The background radiation

Arguments in favour of the steady-state model were further weakened by the momentous discovery of the background blackbody radiation. This radiation, discovered by the U.S. physicists Arno A. Penzias and Robert W. Wilson in 1965, and identified by Robert Dicke and his colleagues, is distributed throughout the universe and has a temperature of 3° K. It is generally regarded as evidence supporting a big-bang origin of the universe. In the 1940s, the U.S. physicists George Gamow, Ralph A. Alpher, and Robert C. Herman had argued that in the big-bang models the early universe is not only dense but also hot and had proposed that low-temperature radiation still survives as a vestige of the big bang. This prediction apparently is confirmed by the detection of the 3° K radiation.

The early universe. An observer travelling back in time would find the universe becoming hotter and denser than it is at present according to the big-bang cosmologies. When the universe is about 100,000 years old, the background radiation has a temperature of 10,000° K. At this epoch the densities of matter and radiation are equal, at a value of about 10^{-20} g/cm^3. Going back even earlier, the universe is flooded with intense brilliant light, denser than matter; this is the radiation era of the early universe, or of the primordial fireball. Further back still, when the universe is one second old, the radiation era terminates, at a temperature 5×10^9 degrees; at this stage the universe is filled with electrons, positrons, and neutrinos, formed from the energetic photons of the high-temperature radiation. At a time earlier than $\frac{1}{10,000}$ second when the temperature is thousands of times higher still, the universe consists mainly of strongly interacting particles (the hadrons) and antiparticles. The difference in the amounts of matter and antimatter can be calculated and is about one part in 10^9.

As the universe expands and cools, equal amounts of primordial matter and antimatter annihilate each other, leaving a slight residue of ordinary matter. The energy released by this annihilation is eventually transformed into the radiation of the radiation era, which survives and ultimately becomes the 3° K background radiation detected in 1965. The small amount of residual matter is not destroyed, and it therefore survives to become the present matter that occupies the universe. Thus the very early and present universes exhibit contrary properties: the small residual difference of matter and antimatter ultimately becomes the predominant constituent; whereas the 3° K radiation, which is now a minor ingredient, was once the immense energy of the big bang. It is possible, but by no means certain, that in some regions of the universe antimatter was originally in slight excess compared with matter. These regions would now consist entirely of antimatter. As yet there are no means of determining whether or not distant "antigalaxies" exist (see MATTER AND ANTIMATTER). At the beginning of the radiation era, the universe consists of photons, neutrinos, and relatively few protons, neutrons and electrons. The protons and neutrons continuously combine to form deuterium, which is then immediately dissociated by the energetic photons. But because of the expansion of the universe, the temperature is dropping, and the deuterium forms more rapidly than it is dissociated. The deuterium is now free to interact to form helium. The production of deuterium, and then helium, however, is possible for only a short period of time, principally because neutrons decay into protons and electrons. Calculations show that approximately 25 percent of the mass in the universe is converted to helium, so that the primordial matter from which the galaxies and earliest stars were formed consisted of 25 percent helium and 75 percent hydrogen by mass, with a negligible amount of other elements. There is uncertainty concerning this important result. Some blue stars in the halo of the Galaxy have apparently little or no helium in their atmospheres. One possibility is that the helium exists in these stars but so far has not been detected. Another possibility is that the helium abundance varies from place to place in the Galaxy owing to variations in the density of matter during the radiation era. Yet a third possibility depends on modifying the general theory of relativity to alter the expansion rate of the big-bang models in the manner proposed by Robert Dicke. Early work on element building was based on the hope that nuclear reactions in the primordial universe could account for the cosmic abundances of most elements that exist today. There is, however, a serious difficulty in building up elements beyond helium because of the absence of stable nuclei of atomic weights five and eight. One method is to combine three helium nuclei to form C^{12}, as in stellar nucleosynthesis. But the rate at which carbon is formed under the conditions prevailing is far too slow, and it is now thought that elements with atoms heavier than those of helium are produced only in stars (see CHEMICAL ELEMENTS, ORIGIN OF; STAR).

Production of the chemical elements

GALAXIES

Origin of galaxies. One of the chief problems in cosmology is to explain why in an expanding universe matter becomes aggregated into galaxies. Since the time of Isaac Newton, most theories have invoked gravity as the basic cause. Newton himself stated, in some correspondence with the English classics scholar Richard Bentley: "But if the matter were evenly distributed throughout an infinite space some of it would convene into one mass and some into another, so as to make an infinite number of great masses, scattered great distances from one another throughout all that infinite space. And thus might the Sun and fixed stars be formed. . . ." And so began a long history of astrophysical investigation, of which the early pio-

neers were Wright, Kant, and P. de Laplace. In *Astronomy and Cosmogony*, 1928, the English physicist and astronomer Sir James H. Jeans wrote: "We have found that, as Newton first conjectured, a chaotic mass of gas of approximately uniform density and of very great extent would be dynamically unstable: nuclei would tend to form in it, around which the whole of matter would ultimately condense." On the basis of this theory he proposed that all celestial objects originate by a process of fragmentation: "of nebulae out of chaos, of stars out of nebulae, of planets out of stars and of satellites out of planets." The results of Jeans's mathematical analysis of a uniform and initially stationary gas cloud can be expressed rather simply as follows. A spherical region is considered in a uniform distribution of gas. If the escape velocity (the speed necessary for a particle to escape the gravitational attraction of the cloud), estimated from the mass within this region, is greater than the velocity of sound in the gas, then the region is unstable, and it commences to collapse. Thus there is a critical radius of the spherical region, known as the Jeans length, such that regions of greater radius are unstable, and those of lesser radius are stable and do not collapse. The gas cloud therefore breaks up into collapsing fragments, and the smallest fragments have a radius close to the Jeans length. But as these fragments collapse it is possible, as shown by Hoyle, for the Jeans length to contract even faster than the radius. Hence the fragments themselves divide into smaller fragments, which in turn subdivide, and so on.

Stability of gas clouds

In the formation of stars and even planets, it is possible that Jeans's basic idea is still largely true. But in the case of galaxies, the initial state probably consists of an expanding universe of gas and not the stationary distribution as conceived by Newton and Jeans. A spherical region that is part of an expanding gas cloud will become unstable when the expansion velocity at its surface is greater than the velocity of sound. When the region becomes unstable, its density increases as compared to the mean density. But the rate of this increase is extremely slow. An expanding universe in fact is not dramatically unstable; and this has led to an impasse in the study of galaxy formation. An initial state having density variations large enough to develop into galaxies in roughly 10^9 years will hopefully also explain why most galaxies are grouped in clusters.

Protogalaxies. According to the model of the U.S. astronomers R. Bruce Partridge and Phillip J.E. Peebles (1967) protogalaxies emerge from the radiation era with a density 1 percent greater than the average density in the universe. They continue to expand, but more slowly than the universe, and reach a maximum size a few times their present radius. Thereafter they collapse and attain their present size in a few hundred million years. During this early stage, gas clouds within the protogalaxy become gravitationally bound and evolve into globular clusters of stars (see STAR CLUSTERS AND STELLAR ASSOCIATIONS). Also there is widespread formation of the first generation of Population II stars (see STAR). The surviving gas, heated by stars and contaminated with elements produced in the rapidly evolving stars, settles slowly to the central region in the case of elliptical galaxies or to the equatorial plane (because of rotation) in the case of spiral galaxies. Formation of Population I stars (such as the Sun) in the disk of a spiral galaxy is delayed to a later stage because of turbulence, rotation, and the magnetic fields of the interstellar medium. Consistent with this model is the idea that galaxies acquire their rotation rather rapidly by the interplay of tidal forces. (In a somewhat analogous way, the rate at which the Earth rotates about its axis changes because of the tides produced by the Moon.) The tidal theory of the origin of galactic rotation is not yet entirely convincing, and an alternative view is that the initial fluctuations already possess rotation before they develop into galaxies, as in the vortex cosmogonies (particularly that of the German scientist Carl F. von Weizsäcker, 1951). If this is indeed true, then current ideas of galaxy formation must suffer drastic modification. Furthermore, the present model does not explain the origin of galactic magnetic fields and leaves astronomers in the unhappy state of of having to suppose that the magnetic field in the Galaxy is a fossil remnant of a primordial field created with the universe. One of the attractions of the model is its simplicity; but perhaps it is too simple, for it gives no clue concerning the obscure nature of galactic nuclei, the large-scale energetic phenomena of exploding galaxies and radio galaxies, and the extraordinary quasi-stellar objects.

Evolution of galaxies. Hubble's classification of galaxies led to the belief that elliptical galaxies gradually flatten and evolve ultimately into spiral galaxies. It has also been suggested that irregularly shaped galaxies might evolve into spirals, and when the dust and gas has completely condensed into stars, they in turn become ellipticals. But nowadays it seems less certain that the different morphological types are linked by an evolutionary sequence. The oldest stars in the various galaxies of the Local Group are all of similar age. This suggests that most if not all galaxies formed at about the same time. Also, spirals rotate more rapidly than ellipticals, and it is difficult to see how massive systems like galaxies can change their rate of rotation. At present, rapid progress is being made in the study of galactic structure and evolution, although a glance at the *Atlas of Peculiar Galaxies* (1966) by the U.S. astronomer Halton Arp reveals an amazing assortment of complex structures for which so far there is no explanation whatever.

STARS

Formation and evolution of stars. The evolution of a given star cannot be directly observed. Stars such as the Sun evolve extremely slowly and their properties change significantly in a characteristic time of several times 10^9 years. Even stars that are much more massive have a characteristic time of several times 10^6 years. Stellar evolution tends therefore to be a theoretical subject, and the results are checked with the observed properties of stars thought to be at different stages in their evolution. The main-sequence stage, which occupies a long period of time during which the star converts hydrogen to helium, is well understood. But even these main-sequence studies are limited to the simplest configurations and exclude stars that rotate rapidly, that have strong magnetic fields, or are members of close binary systems. The protostellar or pre-main-sequence stages are by no means well understood, and the post-main-sequence evolution has been followed in detail only to the helium- and carbon-burning stages.

At present there is no general agreement concerning the formative stages of stars. The Soviet astronomer Viktor Amazaspovich Ambartsumian proposed (1955) that stars formed from prestellar matter at high density in the early universe. But the more common theory is that stars form from the low-density interstellar medium. Available information strongly suggests that stars have been forming for several times 10^9 years and are still being born. For example, stars in groups often recede from each other with speeds indicating that the groups were formed only a few times 10^6 years ago. Also, very luminous stars evolve so rapidly that ages of only millions of years are possible. Stars apparently form in those regions where the interstellar medium is rich in gas and dust, and the presence of stars in these regions indicates that they are still young and have not had time to leave their birthplaces.

Stages of star formation

The various stages in the formation of a star are possibly as follows: (1) A cloud or region of enhanced density in the interstellar medium becomes unstable and starts contracting under the influence of its gravitational field. The cloud has a radius of roughly a Jeans length and a mass of hundreds or thousands of times that of the Sun. (2) As the density increases, the gravitational attraction becomes stronger, and the cloud commences to collapse. But because it is transparent and radiation escapes, the cloud remains cool. The Jeans length therefore gets progressively smaller than the cloud radius and the cloud breaks up into separate collapsing fragments. Eventually, radiation fails to escape, and the temperature begins to rise. Fragmentation now ceases and the cloud has become a

cluster of protostars. (3) The pressure inside the protostars is now sufficient to halt collapse and a period of relatively slow contraction commences. The internal temperature slowly rises during the contraction and eventually reaches 2,000°–3,000° Kelvin. (4) At this stage energy is required to dissociate and ionize hydrogen. To supply this energy, the protostar enters a second phase of rapid collapse, and again fragmentation can occur. When the hydrogen and helium are ionized, and the protostar has a radius roughly equal to that of the Earth's orbit, collapse ceases and slow contraction recommences. (5) In the last stage the contracting protostar approaches the main sequence and reaches it when its central temperature has risen to several million degrees Kelvin and nuclear energy becomes available by the conversion of hydrogen into helium. For a star such as the Sun, the five stages (1) to (5) take a total time of approximately 10^7 years. If the mass of the star is less than 9 percent that of the Sun, the internal temperature is never high enough to convert hydrogen to helium. These stars continue to contract until the electron pressure is sufficient to stop contraction; they then cool down and become "black dwarfs."

Advanced stages of evolution. In stars of low mass (less than that of the Sun), the hydrogen in the central regions is converted into helium, which in turn is consumed and transformed into carbon. But the temperature is never sufficient to convert carbon into heavier elements. At the end of their active life, these stars contract and become white dwarfs with a radius of about 0.01 that of the Sun.

Collapse of massive stars

The fate of massive stars is apparently far more spectacular. As these stars approach the end of their life, their interiors consist largely of iron and other elements of similar atomic weight. Their nuclear fuel is almost exhausted, and yet the loss of energy by radiation and neutrino emission is thousands of times greater than the energy radiated by the Sun. There is only one solution: such a star must collapse; and as a result the temperature rises and the heavy elements are dissociated into helium and neutrons. Confronted with this ruinous situation, the star goes bankrupt and embarks on a career of catastrophic collapse. But the worst has yet to come: the helium begins to dissociate, and the star must pay back in seconds all the energy it has radiated in its main-sequence lifetime. At the same time, the rise of temperature in the outer layers causes the unconsumed nuclear fuel there to explode. The neutrino flux streaming outward from the central region has increased and become an intense blast that expels the exploding envelope.

This ejected mass then becomes a supernova remnant such as the Crab Nebula. Only one slender chance can save the imploding core. If its mass is less than the Chandrasekhar limit of approximately 1.4 solar masses, it may survive as a neutron star. But if its mass is greater than this critical value, it continues to collapse, and its ultimate fate is a challenge to the imagination. A massive supernova has momentarily a luminosity comparable with that of all the stars in the Galaxy taken together.

Neutron stars are extremely dense and have radii of only a few miles. The discovery of pulsars has awakened renewed interest in such objects, and one possibility suggested by the British astronomer Thomas Gold is that pulsars are rotating neutron stars emitting intense searchlight beams of radio waves.

THE SOLAR SYSTEM

The origin of the planetary system is the oldest problem in cosmogony and is still unsolved. A satisfactory theory must explain at least the following facts: (1) All planetary orbits are almost circular and in the same plane. The planets move around the Sun in the same direction as the Sun itself rotates. (2) The satellites move about the planets in almost circular orbits, mostly in the same plane; they have a mass roughly one-thousandth of the planets, whereas the planets have a mass approximately one-thousandth of the Sun. (3) The terrestrial planets (Mercury, Venus, Earth, Mars) are small, dense, and near the Sun, but the giant planets (Jupiter, Saturn, Uranus, Neptune) are large, of low density, and are further from the Sun. (4) The planetary distances from the Sun are in approximate agreement with the Titius-Bode law. This states that, in terms of the Earth's distance, the planetary distances are given by adding 0.4 to each term of the series 0, 0.3, 0.6, 1.2, 2.4, 4.8. . . . The asteroids, or minor planets, together are counted as one planet. (5) The Sun rotates slowly and its angular momentum is only ½ percent that of the planetary system (see SOLAR SYSTEM).

Elements essential to a theory of origin

The various theories proposed to explain these and other facts can be characterized as either dualist or monistic.

Theories of origin through a chance encounter of stars. According to the dualistic theories, planetary systems are relatively rare and are created by the chance encounter of stars. The first known theory of this kind is due to Georges-Louis Leclerc, Comte de Buffon, who proposed in 1745 that the impact of a massive "comet" tore material from the Sun, which dispersed and condensed into planets. More than a century later, the English astronomer Alexander William Bickerton modified this idea into an encounter of the Sun with a second star, and in the early decades of the 20th century the idea was developed by the U.S. geologist Thomas Chrowder Chamberlin, the U.S. astronomer Forest Ray Moulton, the Swedish chemist Svante August Arrhenius, and others. In the work of the English astronomer Harold Jeffreys and Jeans the tidal effect of a close encounter produces a gaseous filament extending from the Sun, which then breaks up into planetary fragments. The U.S. astronomer Lyman Spitzer, Jr., has shown, however, that in all these theories the gas is dispersed long before it cools sufficiently to form condensations. More recently Hoyle has suggested that the Sun was once a member of a binary system, and the companion star evolved into a supernova. It is proposed that some of the material from the supernova outburst formed a gas cloud about the Sun and then condensed into planets. This theory is subject to objections of the kind raised by Spitzer.

Theories of origin from a single star. In these monistic-type theories a planetary system forms within a gas cloud that is part of the original star. The formation of planetary systems is thus an integral part of the subject of star formation, and it is therefore possible that large numbers of stars have planetary systems. In the nebular hypothesis of Kant (1755), developed by Laplace (1796), a rotating gas cloud contracts; the outer region of the cloud develops into a cool gaseous disk in which the planets condense, while the inner region contracts to form the Sun. According to this theory, the Sun should rotate much more rapidly than is observed. The Swedish astrophysicist Hannes Alfvèn and Hoyle have shown it is possible that the Sun transferred its original angular momentum to the planetary disk with the aid of magnetic fields. The U.S. astronomer Gerard P. Kuiper has suggested that the protoplanets were much more massive than the present planets and had a composition similar to that of the Sun. The inner planets, heated by the Sun, subsequently lost their volatile elements. The problem of how protoplanets condense in a Laplacean disk of gas and dust is still not understood. All theories so far are of a qualitative nature, and there is no generally accepted doctrine.

Analysis of Moon rocks

The Earth–Moon system is at present under intensive study stimulated by the scientific data from the space programs. In relation to its primary, the Moon is an unusually large satellite. Initial analyses of Moon rocks are disclosing differences in chemical abundances that suggest the Moon did not originate from the Earth, as proposed in the tidal resonance theories. It is generally agreed that the lunar craters and maria—some of which resemble in certain respects the surface features of Mars —were formed by a combination of volcanism and the explosive impact of incident bodies of all sizes. In its earlier stages, the solar system apparently contained a widespread distribution of aggregated material such as meteoroids and minor planets that were the remnants of the birth processes of the planets. Some of this material still survives, notably the minor planets, meteoroids, comets, and the finely divided dust in the ecliptic plane responsible for the zodiacal light—a diffuse glow seen in the

West after twilight and in the East before dawn. The minor planets, of which the majority have diameters less than a few tens of miles, are either fragments of a disrupted planet or are material aggregations that failed to coalesce into a single planet.

TIME-SCALE OF THE UNIVERSE

In most cosmologies, events are arranged in the following order: beginning of the universe; creation of hydrogen atoms; formation of the first galaxies; formation of the oldest stars in the Galaxy; origin of the heavy elements; formation of the solar system; and formation of the Earth's crust. Some adjacent steps in the sequence may have occurred simultaneously.

The age of the Earth's oldest surface rocks is estimated from the decay processes of the radioactive elements they contain. Uranium and thorium decay slowly at a known rate and produce other elements such as radium and lead. From the measured abundance of the radioactive elements and their decay products, it is possible to determine the age of the rocks. From the results of various investigations, it is found that the oldest surface rocks have an age of 3.5×10^9 years. From the abundances of lead isotopes, it is estimated that meteorites, the Moon, and the Earth itself have an age of 4.7×10^9 years. The age of the solar system, from the time it first began to form from the interstellar medium, is no more than about 5×10^9 years.

From the chemical composition of stars of various ages, it is known that the heavy elements were produced mainly during the early history of the Galaxy, 7 to 8×10^9 years ago. The production of heavy elements in stars since that period has not greatly affected their abundance. The determination of the age of the elements from the cosmic abundances depends on the theory of nucleogenesis (see above *The early universe*) in highly evolved stars and supernovae. The best estimates at the present time give an age of 6.2 to 7.7×10^9 years. The stars in globular clusters are among the oldest in the Galaxy. For a given cluster the stars have the same age and similar original composition. Initially, all the stars in the cluster belong to the main sequence. The massive stars evolve rapidly and are therefore the first to leave the main sequence; in the course of time stars of lesser mass also begin to evolve away from the main sequence. Thus by knowing the mass of the stars that are leaving the main sequence (the "turn-off point" in the Hertzsprung-Russell Diagram in which stellar brightness in magnitudes is plotted against the stellar temperatures), it is possible to calculate the age of the stars in the cluster. For the globular clusters a U.S. astronomer, Allan R. Sandage, finds (1968) an age of 10^{10} years, with a maximum uncertainty of 5×10^9 years.

Evolution of stars in clusters

According to current theories, the first galaxies were born after the radiation era at a time when the universe was a few hundred times 10^6 years old. The reciprocal of the Hubble constant is close to 10^{10} years, and for the simplest big-bang models the age of the universe is slightly less than this value. Although the various dating procedures mentioned above are still inexact, it is remarkable that the errors involved are generally not greater than a factor of 2. The results are consistent with a rational cosmology in which structure originates and evolves as an ordered sequence of events.

POSSIBLE FATE OF THE UNIVERSE

The remote future may be considered in the same spirit of speculation as the early universe. In some 10^{10} years, the Sun will have evolved into a luminous red giant and have a radius much greater than at present, perhaps reaching the orbit of Mercury. The oceans will have disappeared and the Earth lost much of its present atmosphere, and life as it is now known will have become impossible if only because of the intense heat. The gas and dust in the Galaxy must slowly disappear as it forms into new stars, and in 10^{10} years most stars will be old and only a very few will be young. Inevitably, in the course of time, the Milky Way will become faint and dark and the Galaxy a graveyard of stars that have reached the end point of stellar evolution, and similarly with other galaxies. Man, if he has survived, in a form beyond the wildest dreams of the 20th century, will have embarked on his last and perhaps greatest adventure.

According to the steady-state theory, dying systems are forever superseded by new-born systems, and the general appearance of the universe will remain unchanged. But in the evolutionary cosmologies, the present dark and relatively empty universe is doomed to greater darkness and emptiness. If the cosmos must forever expand, the glory of the early universe has departed forever, and an eternal future lies gripped in a frozen state of meaningless death. But if expansion is followed eventually by collapse, the future is obscured by an eschatological shroud; in some tens of times 10^9 years the recession of neighbouring galactic systems will cease, and the process will start to reverse. Distant systems will still appear to recede because the observer will see them as they were in the past when the universe was still expanding. But as time passes more and more galaxies will be seen to be approaching, and eventually, either dying or dead, they will be back where they are now, but in a universe that is catastrophically collapsing. As the end approaches, first the galaxies, and then the stars, are crushed into each other in an overwhelming cataclysmic inferno, in which ultimately the collapsing cosmos reverts to the primeval chaos of the big bang. Whether the universe rises again phoenix-like is not known, and it depends perhaps on whether it can preserve identifying qualities as it passes through an inchoate quantum cosmological state of a nearly infinite density.

The Abbé Lemaître, in *The Primeval Atom* (1931), has written: "Standing on a cooled cinder, we see the slow fading of the suns, and we try to recall the vanished brilliance of the origin of the worlds." The brilliance has gone; the suns are doomed; but the vanished brilliance, and with it new worlds, may once again return.

Universe, Structure and Properties of

The physical universe as a whole is the universe that concerns astronomers, but only a part of that universe can be observed directly. The observed universe is composed basically of galaxies, vast star systems comparable to the Galaxy (see Table 1) of which Earth's solar system is a vanishingly small component.

of a large telescope are stars and interstellar clouds that comprise the Milky Way Galaxy. Exceptions are the Andromeda Nebula in the northern sky and the Magellanic Clouds in the south, systems outside the Galaxy but generally similar to it; were the Andromeda Nebula and the Galaxy viewed from the same distance, they would probably look nearly like twin objects. With a large telescope an astronomer can observe millions of such systems, and it is evident that they are scattered through the depths of space. Whereas they differ much in size, shape, structure, and physical activity (see GALAXIES, EXTERNAL), the astronomer seems justified in regarding them all as members of a single class, the galaxies. A crucial problem for astronomy is to determine whether there is also sufficient intergalactic matter to form a significant constituent of the universe. Many astrophysicists believe that the most energetic cosmic-ray protons (see COSMIC RAYS) reach the Earth from remote galaxies. If so, they are the only known radiation, other than electromagnetic radiation, to reach Earth from these sources. At present there is no direct check because cosmic rays, being charged particles traversing magnetic fields, travel along paths that are not straight, so there is no simple way of knowing where they come from. If they do come from other galaxies, intergalactic space must be permeated by them, but their contribution to the total mass in any large region would be negligible.

Cosmology

Cosmology, in the broadest sense, is the branch of learning that treats of the universe as an ordered system. The name is derived from two Greek words, *kosmos* ("order," "harmony," "the world") and *logos* ("word," "discourse"). Almost all of the astronomical observations upon which modern cosmology depends depend in turn upon electromagnetic radiation sent out by the object observed. This includes visible light, but during the second half of the 20th century the astronomer has also become able to detect, as transmissions from celestial objects, radio radiation of wavelengths from metres down to millimetres and infrared radiation from the submillimetre range down to the red end of the optical spectrum; at the other end, using instruments in rockets and satellites, he can detect far ultraviolet radiation, X-radiation, and gamma radiation.

Every type of discrete source of any such radiation appears to be associated with some galaxy. Classification, however, is in relative terms rather than absolute distinctions. For example, whereas normal optical galaxies (those known chiefly by their emission of visible light) are relatively weak radio sources, galaxies that are strong radio sources are identified with optical galaxies in some disturbed state. The main sources of radio emission in such objects are often detached from the optical part.

While intergalactic space is traversed by electromagnetic radiations from the galaxies, these produce only a minute energy-density at a typical point in it—an astronomer there would have a darker sky than ever he has on Earth. Radio astronomers, however, have detected a microwave background radiation that, they infer, an observer anywhere in intergalactic space would also observe. The flux of this radiation—*i.e.*, the amount of it arriving anywhere in unit time—is extremely feeble; nevertheless, at a typical point it is about 100 times the estimated flux from all the galaxies. Thus, intergalactic space apparently contains a significant measure of radiations that have not come from observed sources.

Background radiation

Space scientists have discovered also an unexpected background of X-rays, but its energy contribution is relatively small. The energy contribution of intergalactic cosmic-ray particles is probably also small. There might be intergalactic magnetic fields, of intensity not exceeding perhaps 10^{-8} gauss (the strength of Earth's magnetic field at the surface is a little less than one gauss), pervading intergalactic space generally; but there is as yet no direct evidence of such fields. Another possibility is that space may be continually traversed by gravitational waves that may originate in matter collapsing into "black holes," the postulated terminal states of certain stars, too massive to allow the escape of light.

The astronomical universe consists then of all of the matter and radiation and gravitational fields that form the galaxies or that occupy the space around them. Table 2 gives some properties of that universe. The study of the universe as a whole is concerned with processes within any galaxy only to the extent to which they affect phenomena outside that particular galaxy; it leaves to astrophysics the study of such processes for their own sakes.

HISTORY OF MAN'S IDEAS ABOUT THE UNIVERSE

In ancient times and through the Middle Ages, people regarded everything outside the solar system as an unchanging background of "fixed stars." In the view of a few enlightened individuals, the Earth rotated about its axis relative to this background; but almost everybody held that the Sun, Moon, and the five known planets revolved around the Earth past the background of unchanging stars, and that the Earth was the centre of the universe. There were occasional new or guest stars, as the novae and supernovae (stars that suddenly brighten enormously) were then called, and sometimes comets moved swiftly through the system. Otherwise the heavens appeared to be eternally the same.

Astronomers inevitably took the Earth, from which they made their observations, as the origin of their system of reference; they described the apparent position of any other member of the solar system by its projection onto the celestial sphere of the fixed stars. With refinements, this is what observers still do. The earliest observers inferred that the Sun and the Moon move relative to the Earth

approximately in circles centred on the Earth and described with uniform speed. More refined observations showed that the account could be improved by using epicyclic motion, complex systems of perfect circles, instead of simple circular motion, and that this method could be applied also to the motions of the planets. This scheme was elaborated between the 2nd century BC and the 2nd century AD, culminating in the work of Ptolemy about AD 140. It provided a kinematic model—*i.e.*, a model dealing with motion without consideration of mass or force—corresponding to the observations. Its most lasting concept was that the physical universe is not capricious but behaves with regularity in a fashion that man can discover and utilize to predict future experience.

The Ptolemaic universe

The scheme became the victim of its own success. Thus, since all motions in it were compounded of uniform circular motions, such motion came to be regarded as having unique significance. It was then only a short and unfortunate step to treating this as the perfect motion from which the motion of all heavenly bodies must be derived. The apparent success of the notion that the "fixed" stars are in fact fixed in some sort of celestial sphere was even more unfortunate. For, so long as it served its purpose, it implied a special status for the Earth—*i.e.*, that it is permanently at the centre of the universe. What had begun as a descriptive convenience thus became a matter of singular significance. There was no further scope for cosmology in the model, which continued to be taught and used almost everywhere until the 17th century.

Aristarchus of Samos in the 3rd century BC had indeed taught that pride of place should be given to the Sun, not to the Earth. While the idea had had little lasting direct effect on ancient and medieval thought, it appears that in certain quarters the heliocentric hypothesis did come to be debated again during the century or so before Copernicus completed his own version in the early 16th century. Actually, there seems to have been no official or dogmatic view until after the disputes almost a century later, in which Galileo was concerned. About the time of Copernicus, the implicit attitude seems to have been the following: in principle, perhaps it does not matter what is used as a standard of rest, but in practice no one knows whether it is feasible to work out a scheme based on a standard other than the Earth or, if so, whether anything would be gained by doing this.

Significance of Copernicus

The significance of the work of Copernicus, finally published in 1543, was that he did work out and exhibit a system different from that of Ptolemy that was as good as, and even better than, the Ptolemaic system that had endured with little change for some 13 centuries. Although Copernicus took the Sun as providing the standard of rest, it played no particular physical role in his system. But he prepared the way for Johannes Kepler, who assigned to the Sun a physically unique position when, early in the 17th century, he formulated his simple rules of planetary motion. Isaac Newton, later in the same century, derived these rules, and much else, from far more powerful general laws of motion and gravitation. Conceptually, the great advance in all this was to remove the Earth from the centre of the cosmos to a rank as one of a half-dozen planets in modest attendance upon the Sun. It was not long before astronomers gave up the requirement for any preferred centre of the universe.

The change of outlook became complete in Newton's lifetime, largely as a result of his work. The idea that the fixed stars are bodies generally similar to the Sun, with its implication that the stars are at very great and diverse distances, came to be accepted. But the measurement of even a few of the shortest of these distances had to wait until the middle of the 19th century. Since then astronomers have patiently proceeded step by step to the measurement of greater and greater distances until, as will be seen, the concept of distance itself has had to be revised.

The greatest contribution made by Newton to cosmology was the concept of the universality of the laws of physics. Newton postulated that the behaviour of material systems may be inferred mathematically from certain simple general laws, and that these laws hold good at all times and at all places in the universe. While such laws have been modified and extended since the time of Newton, there has scarcely been any serious doubt that they could be formulated in such a way as to have the same validity throughout the universe. All progress has depended upon assuming this, and it has never led to any inconsistency.

Universality of the laws of physics and of the composition of the universe

Another great advance was the discovery of the universality of the composition of the universe. From the development of spectrum analysis in the 19th century, through all the applications of atomic physics and nuclear physics, to the latest work on quasi-stellar objects, all the evidence is that matter is everywhere made of the same particles and that the universal constants of physics are indeed universal. It is hoped that cosmology will sometime account for this situation in terms of some more fundamental concepts.

To return to the development of astronomy, in the late 18th and early 19th centuries the astronomer William Herschel, in England, followed by his son John Herschel and some contemporaries, inaugurated the study of stellar astronomy. This was partly the cause, and partly the result, of William Herschel's making better reflecting telescopes than had ever been made before. In far greater numbers than previously, stars could be resolved and apparent brightnesses assigned to them. On the principle that faintness is a statistical measure of distance, it was then possible to infer how the stars are distributed with respect to relative distance, in various directions in space. A qualitative picture of the Galaxy as a flattened system of stars and nebulae, isolated in space, emerged about 1785. But it was not until about 1918 that the United States astronomer Harlow Shapley and his contemporaries could assign reliable dimensions to the system and estimate the location of the Sun (some 30,000 light-years from the centre). In 1927 the Netherlands astronomer Jan Oort accounted for the motions of the stars as orbital motions in the gravitational field of the Galaxy. This led to the most direct way of estimating the mass of the Galaxy (about 100,000 million solar masses).

The conclusion that the observed stellar system is an island in boundless space suggested to William Herschel and his successors that there might be other such "island universes" beyond its boundaries, and that certain nebulae might in fact be such systems. Later in the 19th century astronomers discovered the spiral structure of some of these and the first observational indication that they are composed of stellar aggregates. Only about 1924 did astronomers derive reliable estimates of their distances and thence establish that they are indeed systems comparable with the Galaxy. The distance scale has ever since been under review, and even now the best that astronomers can claim is to know the distances of the nearer galaxies and clusters of galaxies within a factor of about two.

From 1925 astronomers had the quantitative knowledge necessary to embark upon large-scale observational exploration of the universe; it is now possible to survey the outcome of nearly half a century of observational and theoretical study.

BASIC PROPERTIES OF THE UNIVERSE

Structure of the universe. Galaxies are distributed through space in a patchy fashion; the Milky Way belongs to a Local Group of 20-odd members; there are single galaxies, galaxy pairs, large galaxies attended by a few satellite galaxies; there are clusters of galaxies of anything up to 1,000 members or more. Some of the nearer groupings seem to belong to a supercluster, and it seems possible to recognize other such systems; but evidence for a general hierarchical arrangement is not convincing.

The astronomer sees no significant difference in the general appearance of the universe looked at in different directions. Looking at his overall picture, he sees no reason to suppose that another astronomer anywhere else in the whole system would have a significantly different overall picture. So he tentatively infers that the universe in the large is homogeneous and isotropic.

Behaviour of the universe. Perhaps the most exciting observation about the universe in the large is that, seemingly, it is expanding. In 1929, following earlier fragmentary evidence, the U.S. astronomer Edwin Hubble published his finding that the lines in the spectra of remote galaxies show a red shift that, statistically, is systematically greater, the fainter the galaxy. The red shift is a change to longer wavelengths of recognizable lines in the spectrum and could be caused by a movement of the emitting object away from the observer. This is an instance of the Doppler effect that may be noticed, in the case of sound waves, in the change in pitch of a train whistle or automobile horn as the vehicle approaches or moves away, resulting in higher or lower pitch. Hubble interpreted his measurements as showing that every other galaxy is receding from the Milky Way with speed proportional to its distance; *i.e.*, recession speed equals distance divided by a quantity τ the same for all galaxies. This is called Hubble's law, and τ, which has the dimension of time, is the "Hubble time." The latest estimate is that it is about 1.9×10^{10} years. If the law applies to the galaxies as seen from one of them, it clearly applies to them as seen from any other. Had each galaxy always possessed the same speed, taken literally the law would mean that all galaxies were in the same place τ years ago.

The red shift, usually denoted by z, is such that $1 + z$ is the ratio of the wavelength of a line in the observed spectrum to the laboratory wavelength of the same line, which is assumed to be the wavelength that would be seen in a spectrum taken at the source. Hubble's law is derived from observing galaxies showing red shifts with z values up to about 0.2; *i.e.*, receding with speeds up to one-fifth that of light. Cases of much larger red shifts and the question of alternative interpretations are mentioned below. But the Hubble red shift is generally interpreted as a Doppler effect denoting the general recession of the galaxies; this is called the cosmological red shift.

Age of the universe. The Sun and the other stars are continually emitting energy into surrounding space and so, presumably, they have not been shining forever. On the other hand, astronomical and geophysical evidence demands certain minimum ages. Modern astrophysical theory has provided progressively more reliable inferences about physical conditions throughout a star, and physics has shown what nuclear reactions must proceed under these conditions to supply the star's energy output. Such work shows the oldest stars in the Galaxy to be about 10^{10} years old. Apparently, existing stars are survivors belonging to two or three generations. Astrophysicists commonly believe that the matter that forms the Galaxy was brought together in some diffuse state into about the volume now occupied by the Galaxy, and it was not long, astronomically speaking, before the matter formed itself into stars. The first-generation stars might have been on the average 10 to 100 times more massive than present typical stars. The time since their formation is calculated to be between 10^{10} and 2×10^{10} years—the so-called age of the Galaxy. During that time, it seems that it cannot have been appreciably influenced by any other material system. Accumulating evidence tends to show that all the galaxies in any cluster are of approximately the same age. But how the raw material of the galaxies was originally gathered together in appropriate quantities is a major unsolved problem.

Formation of stars

Hubble's law implies some sort of a start to the expansion of the universe at a time of the order 10^{10} years ago. On totally different evidence, the estimated age of the Galaxy is also of this order. Even without the cosmological theories discussed below, a picture is thus formed of an evolving universe in which, somewhat over 10^{10} years ago, matter had a much higher average density than at present and was not yet resolved into galaxies and stars.

If an astronomer observes part of the universe a thousand million (10^9) light-years away, say, he sees it as it was 10^9 years ago when the light set out. If the whole universe is evolving, he sees that part as it was when 10^9 years younger than his own part. In particular, if there were no galaxies, say, 2×10^{10} years ago, the astronomer could see no galaxy more than 2×10^{10} light-years distant. Thus he does not see a background of galaxies that extends indefinitely into the distance (as "distance" is here understood). Estimates are that the background light from all other galaxies is only about 1 percent of the background light at the Earth from the Milky Way (excluding sunlight)—the cosmic sky is black indeed.

Structure of galaxies. Cosmology is bound to be somewhat concerned about the constitution of galaxies because: (1) a description of the universe should include that of its stock of galaxies; (2) recognition of the type of a galaxy aids in estimating its distance; (3) knowledge of the structure and evolution of galaxies aids in the interpretation of large-scale surveys—*e.g.*, counts of radio sources; (4) galaxies are the only sources of radiation that are observed (if, as mentioned above, the quasi-stellar sources are included) and it is necessary to take account of every kind of radiation transmitted by them. Although galaxies are described in greater detail elsewhere (see GALAXIES, EXTERNAL), brief descriptions of the main types are needed here and are given in the next few paragraphs.

An elliptical galaxy appears to contain very little interstellar gas or dust and to be composed almost entirely of stars distributed in a very regular fashion. In spiral galaxies, most of the stars occupy a lens-shaped volume; spirals also contain large amounts of gas and dust mostly concentrated, along with the brightest stars, into a structure of spiral arms or bars or both, which may exhibit remarkable regularity or much irregularity of form. Most galaxies have a marked concentration of material in their central regions; many possess a well-defined nucleus characterized by a sharp peak in the number-density of stars, there being between 10^7 and 10^9 stars in a volume probably no more than a few tens of light-years across. In 1 or 2 percent of spirals the nucleus is the dominant feature, making the rest of the object difficult to observe (the so-called Seyfert galaxies). In recent times, astronomers have been surprised to find that apparently every nucleus is to a greater or lesser extent the scene of some sort of activity revealed by the outflow of material and/or the variability of some component of its radiation. A galactic nucleus evidently may also experience a violent event, when material of millions of stellar masses is ejected to distances comparable to the whole extent of the galaxy concerned. Such an event may indeed denote a stage in the original formation of the nucleus and is possibly concerned in the genesis of spiral arms. Also, it has generally been considered that such an event may have something to do with a galaxy becoming a radio galaxy. More recently, however, astronomers have begun to question whether the material of the radio-source part of a radio galaxy has necessarily been ejected from the optical part; a galaxy as a whole may well be a more complex and extended object than hitherto envisaged.

The centres, or nuclei, of galaxies

The mass of a particular galaxy may be inferred from the motions of stars and gas contained in it and, to some extent, from its surface brightness; but the methods are such as to leave the integrated mass uncertain by a factor of perhaps two. Giant ellipticals and great spirals have masses up to almost one million million (10^{12}) solar masses, while some dwarf galaxies are estimated to have less than 1,000,000 solar masses.

Clusters of galaxies. Clusters differ greatly in the number of galaxies in them and in the space-density of these galaxies. Any sizable cluster includes members in a wide range of shapes and sizes. The study of clusters at known relative distances has led some astronomers to conclude that the brightest galaxy in a cluster is a rather standard object. If valid, this provides astronomers with "standard candles" that have, for instance, facilitated an apparently improved investigation of Hubble's law. It seems nearer the truth, however, to say that the luminosity distribution of galaxies has a rather abrupt cutoff on the high-luminosity side so in any sample, such as a cluster, the brightest member is apt to be fairly near this cutoff. Consequently, even the most recent determinations of Hubble's constant are less secure than had been hoped.

The study of the dynamics of groupings of apparently physically associated galaxies usually leads to masses 10

The problem of "missing mass"

to 100 times the value obtained by totalling the estimated masses of the member galaxies. This produces the notorious problem of the "missing mass." Almost certainly, the explanation is that the groupings concerned may not be treated as independent permanent gravitating systems. The problem is mentioned here because it emphasizes the great difficulty in determining how much matter there is in even a relatively small tract of the universe. At the same time, the expansion of the universe should be described in terms of the mutual recession of clusters rather than of individual galaxies.

Counts of galaxies. Were all galaxies of the same intrinsic brightness, the radiation flux S from a galaxy would be inversely proportional to the square of its distance. Were all galaxies at rest and distributed uniformly through ordinary space, the number n within any distance would be proportional to the cube of the distance. Thus the number n of galaxies producing flux not less than S would be inversely proportional to the power 3/2 of S. The rule is not affected even if the galaxies are not all of the same intrinsic brightness, provided the other assumptions hold good. In principle, it is, then, a simple matter to take some particular part of the sky and, for various values of S, to count the number N of actual galaxies giving a flux S or more. Comparing the observed values of N with the values of n calculated from the rule tells something about how the actual galaxies are distributed in depth; doing this for different parts of the sky shows how they are distributed in different directions in space.

In practice, this task is prohibitively difficult for optical astronomy. It is different for radio astronomy. This is because radio galaxies are much fewer than optical galaxies; using existing instruments, radio galaxies can apparently be detected out to considerably greater distances than optical galaxies; there is less difficulty with foreground objects; the radio records may be analyzed by statistical methods not applicable to optical observations.

Radio astronomers in Cambridge, England, have done the most extensive work in this field; some surveys have been made in a few other observatories and, taking account of the character of the radio spectrum when comparing observations at different wavelengths, the various counts are in satisfactory agreement. Radio observers claim that there cannot be any significant source category overlooked by the counts; for these counts, along with a plausible extrapolation allowing for unresolved sources, account for all the measured resultant flux at the wavelengths concerned—a test of completeness not available to optical astronomers. If N and n (as defined above) agree for the strongest sources, the counts show that N increases more steeply than n with decreasing radiation-flux S, until N reaches a value about 100 times the corresponding value of n: going to still smaller S, N increases less rapidly, ultimately reaching values below the corresponding n-values. The results for different parts of the sky are similar, thus confirming that what are being studied are genuine cosmical properties.

All objects that show a particular cosmological red shift z being at the same distance from the observer, they are seen as they were at a particular past cosmic epoch—"epoch z." While optical identifications and red shift measurements are not available for most of the sources concerned, a long chain of extrapolation from cases of known red shifts shows a possible interpretation of the counts to be that at about epoch $z = 3$ the ratio of radio sources to ordinary galaxies was about 100 times its present value, while before about $z = 4$ there were almost no sources.

Infrequency of radio sources beyond $z = 4$

This result is a major discovery about the structure and evolution of the universe. It confirms that the universe is evolving and is certainly not in a steady state on the scale concerned here. The result has frustrating implications, too, for it shows that evolutionary effects have a predominant influence on the counts, which are thus of little help in discriminating between different cosmological models.

Space-time. A 20th-century man describing the flight of a golf ball or a space vehicle employs the same notions of space and time as did Newton and all his followers. Obviously, these notions serve such purposes with great accuracy. But Newton and his followers assumed that space and time have an existence unaffected by anything else. Actually, however, times and distances are just the names given to the results of certain operations performed with pieces of material equipment. Ideally, therefore, matter and space and time ought to be treated as aspects of one entity, or "field," that cannot strictly be separated into independent parts. The realization of such a treatment was the great achievement of Einstein in his theory of general relativity. Einstein described everything within the scope of the theory by a single field; certain aspects of the field specify the density, momentum, and stress of the material present; certain other aspects describe the temporal and spatial interrelationships of the material; and still other aspects represent its gravitational interactions.

General relativity, as distinct from special relativity, is not important for laboratory physics, but it is essential for cosmology because: (1) it provides the best treatment of gravitation known, and gravitation appears to be the only interaction of matter that affects the behaviour of the universe in the large; (2) it shows (apparently correctly) that the field affects what is usually called the geometry of space-time in ways that are all-important for the structure of the universe in the large; (3) precisely because it treats space-time and matter as interdependent, it can treat the universe as a whole, which all previous theories had failed to do; (4) it makes predictions only in terms of quantities that are observable by means admitted by the theory; *i.e.*, the theoretical results are directly testable by the astronomer's observations.

COSMOLOGICAL MODELS

Procedures for model construction. The aim of cosmological theory is to construct a theoretical model universe, in strict accordance with well-formulated physical theory, that adequately reproduces the broad features of the actual universe. In particular, the model universe is supposed to be filled with some continuous fluid, which is intended to represent a smoothed-out version of the contents of the actual universe.

Fundamental observers

In the model, an observer who moves along with the "fluid" where he happens to be is called a fundamental observer; he represents any typical observer in the actual universe. It is postulated that (1) each fundamental observer sees the (model) universe as isotropic (*i.e.*, with its properties having the same values in all directions) about himself, and (2) the history of the universe seen by one fundamental observer is identical with that seen by any other. The time kept by a fundamental observer is called cosmic time t: it may be calibrated so that any two fundamental observers record the same t when they see the same cosmic state; *i.e.*, fundamental observers may treat the universe as its own cosmic clock. The postulate that the model must admit these properties is called the cosmological principle. It is found to cause the model to depend essentially on only one unknown function of t, the expansion factor, symbolized as $R(t)$, say. General relativity then expresses the density and pressure of the material present in terms of $R(t)$. The nature of this material is specified by the appropriate relation between its density and pressure. This yields a single differential equation for $R(t)$. The Russian meteorologist Alexander Friedmann (1922) and the Belgian mathematician Georges Lemaître (1927), independently, were the first to formulate this mathematics; it is customary to speak of the Friedmann–Lemaître equation leading to the F–L model universes.

If a fundamental observer sees his universe to be expanding, he may estimate that every part has sufficient energy to escape from the gravitational pull of the rest so that the model will go on expanding forever; or he may estimate that no part has sufficient energy to escape from the gravitational pull of the rest so that the model must ultimately fall back upon itself. Clearly one parameter is needed to cover these possibilities. Further, in ordinary mechanics an arbitrary constant may be added to the pressure and energy without changing the equations of motion. If all fundamental observers are to be treated

alike, it is found that just one constant arises in this way. It is the analogue of Einstein's "cosmical constant" in the relativistic treatment. Thus two parameters are needed to determine a model universe of the sort under discussion, including, of course, its expansion factor $R(t)$. The mathematical treatment would be needed, naturally, in order to give a full explanation. In order to compare the predicted observations of a fundamental observer with observations of the actual universe, the cosmic time at which he observes must be assigned additionally.

It is a major advance upon classical theory to obtain any self-consistent model of an entire universe. The mathematics shows that there is no stable static model; *i.e.*, the model has to be expanding (or contracting). Using the observational estimate of the Hubble time, almost all models predict a present mean density of the order 10^{-29} gram per cubic centimetre. So if the actual universe behaves in accordance with the theory, it must be expanding (or contracting); and the density is almost certainly about 10^{-29} gram per cubic centimetre. Now astronomers do find that the actual universe is apparently expanding and that the density of luminous matter in it is nearly 10^{-30} gram per cubic centimetre. Since there must be some other matter, the situation is entirely plausible. Consequently, most astronomers believe that the interpretation of the red shift in terms of the expansion of the universe is valid, and that the motion proceeds under the gravitational interaction of its parts and none other. Were any other interaction concerned, then some different universal constant would enter, and the calculations would presumably lead to some altogether different (and implausible) value of the density. This position was reached as early as 1930, and it is encouraging so far as it goes. Ever since, astronomers have tried strenuously to find whether some particular Friedmann–Lemaître model can be selected to give satisfactory overall agreement with all the relevant observations. The work has led to many discoveries about galaxies. Unfortunately, however, the main problem remains unsolved. Attempts to derive higher approximations to the Hubble magnitude-red shift relation are largely frustrated by the scatter in the intrinsic properties of the galaxies and by selection effects; attempts to use source-counts are defeated by evolutionary effects; attempts to set bounds to the amount of intergalactic matter would have to be about ten times more accurate than hitherto in order to be significant; hopes of using other properties—*e.g.*, some measure of the angular size of galaxies or of clusters—have not yet been fulfilled.

Cosmologists may claim that, were the search for a model basically misdirected, then 40 years of trying would have produced some absurdity. But such has not been the outcome, although it has sometimes seemed as if it might be. For instance, the early measures of the Hubble time led to an age of the universe that was less than the accepted age of the Earth. But in 1952 a well-known German-American astronomer, Walter Baade, showed how the intrinsic brightness of the stars known as Cepheid variables had been underestimated. This is a key quantity in constructing the scale of distances: so these stars and everything more remote must be farther away than had been supposed, whence the Hubble time and the inferred age of the universe are greater. The revisions due to Baade and his successors have greatly reduced the age difficulty, although, because of the uncertainty in the determination of all the quantities involved, it cannot yet be said to have been finally resolved.

The true brightness of distance indicators

The steady-state model. In its original form, the age difficulty played a crucial part in a dramatic phase of the subject—the emergence in 1948 of a steady-state cosmology.

The models thus far considered are derived on the hypothesis that there is nothing special about any particular place in the universe. It was argued by some, however, that scientists should also contemplate the possibility that there is nothing special about any particular epoch in the universe. The problem then became one of constructing a model of the expanding universe that is everywhere and always the same; and it was urged that if such could be done, this steady-state universe might be regarded as the simplest possible universe and, if only for this reason, its model ought to be the first one studied. Crudely stated, this was the starting point in 1948 of Hermann Bondi and Thomas Gold, and of Fred Hoyle, all working in Cambridge (England).

Such a model calls for no new concept of space-time, and so the relativistic outlook is accepted. But not unnaturally, it is found that there is a unique geometry of space-time that can admit a steady-state behaviour. The matter in the model has to be always dispersing (so as to depict the expansion of the universe), but always of the same density (so as to preserve a steady state). Clearly, this requires that new matter be continually created at a fixed rate throughout the universe; this is a new concept of the behaviour of matter. It means that in any large region there is matter of all ages, and calculation gives the mean age of the matter as $\frac{1}{3}\tau$; there are galaxies of all ages, and the mean age of the galaxies is $\frac{1}{3}\tau$, and so on, where τ is again the Hubble time defined above (see above *Behaviour of the universe*). A consequence is that most of the material in any region must be renewed in a time of the order of τ.

The concept of the continuous creation of matter

If this is applied to the actual universe, the rate of creation would be utterly beyond the possibility of direct detection. The simplest interpretation would be that in any large region of space new matter is created at a statistically uniform rate in time and space, and that this material is continually condensing into new galaxies that replace those leaving the region by virtue of the continual recession of the galaxies. It can be estimated that it would require something of the order of the Hubble time for diffuse matter to condense into a galaxy, and that consequently, in any region at any time, there is between 10 and 100 times as much intergalactic matter as luminous matter in the form of galaxies. Further, the age difficulty is resolved because, even if it is found that the age of the Galaxy is greater than, for instance, the Hubble time itself, this means simply that the Galaxy happens to be older than the average. All such features are plausible and, to some minds, aesthetically satisfying.

As was pointed out above, however, an observer who looks into the distance looks into the past. But in a steady-state universe the past is the same as the present. In such a universe, therefore, no intrinsic feature can depend upon distance from the observer. In the actual universe, on the other hand, the occurrence of radio galaxies is evidently very different at different distances. This is a direct contradiction of the steady-state. It seems certain that simple steady-state cosmology cannot be accepted—in spite of its undoubtedly attractive features.

Differences between the actual universe and the steady-state universe

HISTORY OF THE UNIVERSE

It is necessary to return to models without continual creation, technically models in which the baryon number is conserved in accordance with standard physics (a baryon being an actual or potential proton). For simplicity, the cosmical constant (see above *Procedures for model construction*) is ignored here. All relevant F–L universes start explosively with a "big bang" at what may be called the zero of cosmic time t. They all give qualitatively about the same history of the universe, but they differ in the cosmic dating of developments.

The expansion factor for a model gives the rate of expansion at any epoch. Because of the homogeneity and isotropy of the model, the material in the vincinity of any fundamental observer behaves as though it were enclosed within an enclosure that expands with the expansion of the universe and whose bounding surface is perfectly reflecting for all forms of radiation present. So the behaviour can be inferred from ordinary physical theory.

As the universe expands, the density and temperature of the contents will diminish. The process starts explosively with the big bang. Up to some early epoch t_0, the density and temperature are so great that interactions between atomic nuclei are fast enough, compared with the rate of expansion, for the nuclear composition of the material to be determined by instantaneous conditions only, independently of what the composition was at any pre-

Table 3: Big-Bang Cosmology: History of the Universe

vious instant. Thus there is no significance in an "initial chemical composition" of the universe. Following epoch t_0, there is a short interval t_0 to t_1 during which nuclear interactions continue to operate, but at a decreasing rate, so that they have effectively ceased at epoch t_1. Consequently, at t_1 a certain nuclear composition is "frozen into" the material. Until some subsequent epoch t_2, the energy in the form of radiation (photons) is large compared with that in the form of matter, while from soon after t_2 the reverse is the case. Up to some further epoch t_3 the radiation and matter are in thermal balance; but this circumstance has little effect upon the radiation field because, during this phase, the amount of energy that could be emitted or absorbed by the matter is small compared with the total energy that already resides in the radiation. After t_3 the radiation and the matter become "de-coupled"; *i.e.*, the material becomes highly transparent to the radiation. There is then a phase during which the temperature of the matter decreases more steeply than that of the radiation; the subsequent career of the matter is discussed below.

The "frozen in" chemical composition can be calculated only by following all the nuclear reactions through the interval t_0 to t_1 using a computer. Workers who did this in 1967 found that, for any plausible model, from t_1 onward the material consists effectively of hydrogen, helium, and small fractions of "heavy" hydrogen and lithium. For a wide range of models, helium constitutes between 25 and 35 percent of the mass, the rest being nearly all hydrogen.

Source of the background radiation

On the picture here described, most of the photons in the universe at large have not interacted with matter since before t_3, at which time the universe was radiation-dominated anyhow. Thus most of the photons that compose cosmic background radiation have not come out of stars and galaxies. They are left from stages of the universe long before such sources existed; hence the term remanent radiation, which is sometimes used. Since a typical photon has travelled uninterruptedly through the universe from a very early stage, it has come a very long way and undergone an enormous red shift. This is why the radiation is so feeble at the present epoch. But if scientists can measure the present energy-density of this radiation and the present smoothed-out density of matter, it ought to be possible to work backward in time to construct a quantitative history of the actual universe—assuming that it behaves like a model of the present sort.

This program is usually illustrated by the case: Hubble time, 10^{10} years; present density of smoothed-out matter, 2×10^{-29} gram per cubic centimetre; present temperature of background radiation, 3° Kelvin (some few degrees above absolute zero). Table 3 shows some of the main results; these are not particularly sensitive to the choice of model.

As was remarked, after epoch t_3 the temperature of the matter begins to fall steeply. In the example, it could reach about 1° K at cosmic epoch t_4 between 10^8 and 10^9 years, the density being then of order one-tenth the overall mean density of the Galaxy; if astronomers could see back to that stage it would correspond to a red shift z of about 20. Given that galaxies did form with the masses and sizes they are known to possess (although it is not yet known what determines these quantities), the conditions would be favourable to the formation of such condensations. It is usually reckoned that the formation of a condensation, or of the resulting galaxy, would occupy some few times 10^8 years, so that galaxies could not have formed before about t_4. On the other hand, source-counts are interpreted as implying the existence of radio galaxies, at any rate as far back as z about 4. Thus the stage in the history of the universe when conditions were suitable for the occurrence of condensations lies within the bounds set by these further considerations. After galaxies were formed, the various radiations from them would heat up the remaining intergalactic matter; its present temperature is estimated as between 10^5 and 10^6 degrees Kelvin (180,000°–1,800,000° F). The rising temperature and falling density make conditions unfavourable for the formation of further condensations; in this picture, all galaxies would have been formed at about the same stage in the evolution of the universe. These conditions would also make intergalactic matter difficult to detect; *e.g.*, it could not interact appreciably with cosmic background radiation.

Composition of stars in newly formed galaxies

The first stars in the newly formed galaxies would be composed of the raw material already mentioned, consisting chiefly of hydrogen and helium. Heavier elements —which still compose only 1 or 2 percent of the mass of a galaxy—would be formed by nucleosynthesis in this and succeeding generations of stars. Calculations concerning this synthesis are based on accurate laboratory investigations of the properties of the relevant nuclei, and by about 1960 astrophysicists seemed to have reached substantial agreement about the course that events had taken. By 1970 the situation had changed. Evidence was being found that many of the first-generation stars were in the mass range of about 10 to 50 solar masses, and that these had ended their careers in explosions in which much of the production of heavy elements occurred.

Before the possible importance of explosive nucleosynthesis was appreciated, astrophysicists had shown that helium synthesized in ordinary stars would be no more than about 2 percent of the mass of a galaxy like the Milky Way, whereas helium evidently forms 25 to 30 percent of the mass. The discrepancy presented the so-called helium problem. It is now seen that almost any hot big bang must ensure that the raw material of the galaxies contained over 25 percent helium. Whether a much larger fraction of the helium now in a galaxy could have been formed in explosions than the 2 percent or so formed in nonviolent evolution is not yet known.

Thus it apparently may be claimed that big-bang cos-

mology has correctly predicted the background radiation, solved the helium problem, and provided an overall history of the universe that accommodates various evolutionary developments in a plausible manner. Such positive claims have caused the hot big bang ("universal fireball") to be given serious scientific attention as possibly accounting for the main physical features of the cosmic environment (see Table 3).

QUASI-STELLAR OBJECTS

A few hundred quasi-stellar objects, or quasars, have been observed individually; it is estimated that about a million are accessible to the largest telescopes. The quasars have starlike optical images and characteristic optical spectra showing emission lines and sometimes absorption lines. Sometimes they are radio sources, and possibly they contribute largely to source-counts. Sometimes they emit strongly in the infrared, sometimes also in X-rays. The emission lines of a quasar show a unique red shift z, regarded as the red shift of the object; the status of absorption red shifts is complex. Whereas optical galaxies show red shifts up to about $z = 0.2$, and one or two radio galaxies have z values near 0.5, quasar red shifts range up to about $z = 2.9$.

If the red shifts are cosmological, a quasar is typically about 100 times brighter intrinsically than a bright optical galaxy. Quasars should thus enable astronomers to explore a volume of the universe about 1,000 times greater than they can by observing ordinary galaxies. Unfortunately, observations of quasars have hitherto made little contribution to cosmology. Apparently this is because the spread of intrinsic properties is so great that it obscures all other statistical properties. Some astronomers have doubted the cosmological interpretation of the red shifts, but have not succeeded in proposing an acceptable alternative. An understanding of the physics of quasi-stellar objects must precede progress in other directions.

PRESENT PROBLEMS OF COSMOLOGY

Originally, Friedmann–Lemaître models were intentionally the simplest ones possible that would illustrate the essentials of nonstatic relativistic cosmology. After nearly 50 years, it appears that little would be gained by using more general models; some of the most significant recent progress has been in discovering why this should be so. Relativists have shown that, under very general conditions, theory demands at least one happening that would be interpreted as a big bang. If, in fact, there has been just one—so that everything was once much closer together and has been dispersing ever since—to a first approximation the dispersal is bound to obey Hubble's law. If the universe is homogeneous, the discovery of neutrino viscosity shows it must have been isotropic from a very early stage, almost independently of what it was like before that. As already mentioned, study of the hot big bang shows that the broad features of the chemical composition of the universe could scarcely be other than as observed and that there must be background radiation like that which seems to be observed. Thus, it may be claimed that all the resources of physical theory are tending to show that the actual universe is the only universe permitted by the theory. If so, this is a discovery about physics just as much as about the universe.

In an evolving universe, the astronomer looks into the past by looking into the distance. But the further back he looks, the less precise the information he gets, and he certainly cannot see the actual beginning. He ought not to expect theory to tell him more than he can check by observation; this, too, seems to be how the subject is unfolding. On the observational side, there are foreseeable needs for more extensive work in all departments, and much is expected of observations made from space vehicles. But there are bound to be unforeseen developments like the discoveries about quasars in the 1960s. On the theoretical side, a proper understanding of these objects should lead to many advances. The central problem is perhaps that of the formation of galaxies. This is the study of the origin and evolution of inhomogeneities on a cosmically small scale. But there are also problems for observation and theory about the large-scale homogeneity. As ever larger tracts of the universe are considered, it is not yet known whether it should be treated as more nearly homogeneous, or whether the notion of homogeneity becomes ever less meaningful.

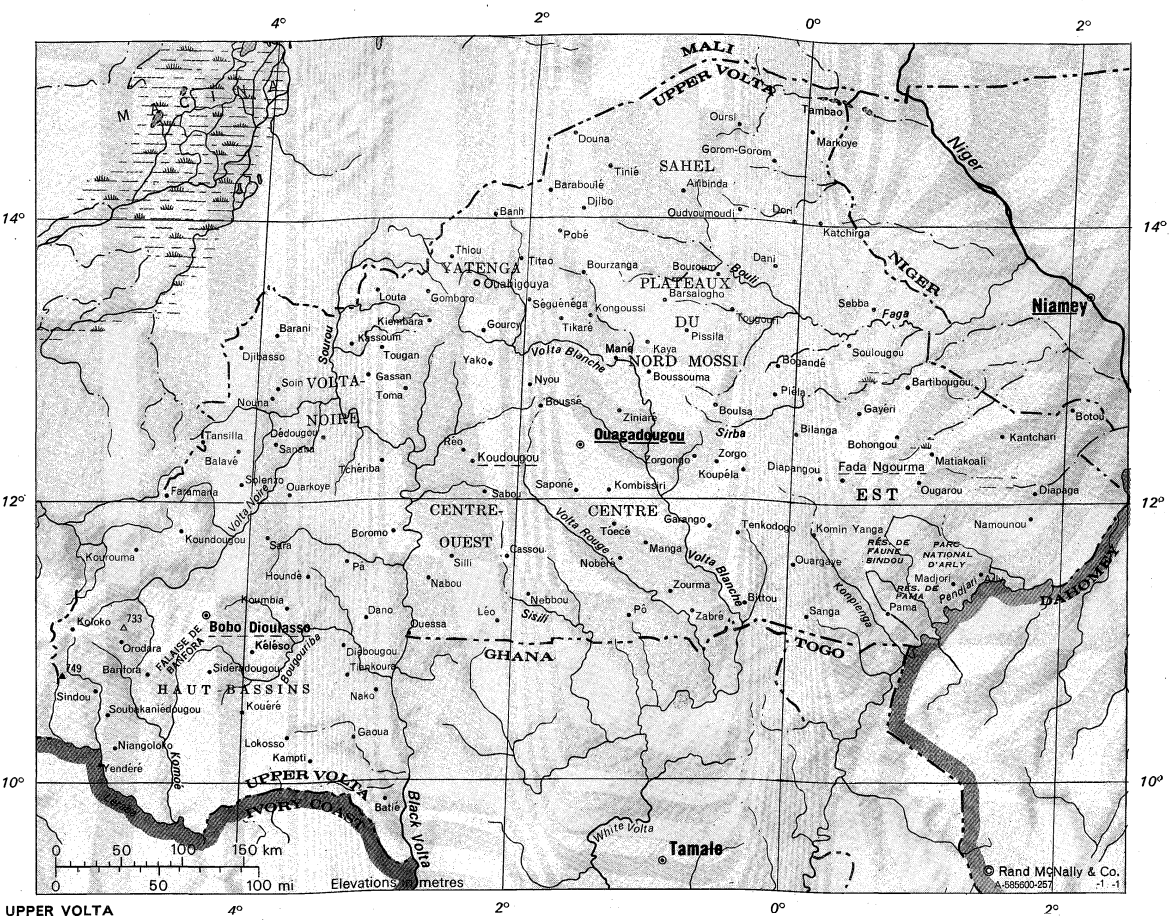
Upper Volta

The Republic of Upper Volta (République de Haute-Volta) is a landlocked West African state, with an area of 105,792 square miles (274,000 square kilometres). A former French colony, it gained independence in 1960. It is bounded to the north and west by Mali, to the south by the Ivory Coast, Ghana, and Togo, and to the east by Dahomey and Niger. The population numbers nearly 6,000,000. The capital, Ouagadougou, is about 500 miles by road from the sea.

Upper Volta's economy is based primarily on agriculture and livestock raising. About half the population belong to the Mossi tribe, and the former Mossi Empire is included within the borders of the present state. After a military coup in 1966, led by Gen. Sangoulé Lamizana, who was to become president, a new constitution was approved by referendum in 1970. (For an associated physical feature, see VOLTA RIVER; for historical aspects, see WEST AFRICA, HISTORY OF.)



The landscape. *Physiography.* Upper Volta consists of an extensive plateau, slightly inclined toward the south. The lateritic (red, leached, iron-bearing) layer of rock that covers the underlying crystalline rocks is cut into by the three principal rivers—the Volta Noire, Volta Rouge, and Volta Blanche—all of which converge in Ghanaian territory to the south to form the Volta River. The Oti, another tributary of the Volta, rises in southeastern Upper Volta. In the southwest there are sandstone plateaus, bordered by the Falaise de Banfora (Banfora Cliffs), which is about 500 feet high and faces southeast. The country is generally dry and infertile. Great seasonal variation occurs in the flow of the rivers.

The river system

Climate. The climate is generally sunny, hot, and dry. In the north it is of the Sahelian type (Arabic *sāḥil*, "shore"; in this instance it refers to the region bordering the Sahara [*q.v.*]), characterized by three to five months of rainfall, which is often erratic. To the south it becomes increasingly of the tropical savanna (grassy parkland) type, sometimes called Sudanic, characterized by greater variability of temperature and rainfall.

Four seasons may be distinguished: a dry and cool season from mid-November to mid-February, with temperatures dropping to about 50° F (10° C); a hot season from mid-February to June, when maximum temperatures rise to about 104° F (40° C) in the shade; a rainy season, which lasts from June to September; and an intermediate season, which lasts until mid-November.

Vegetation and animal life. The northern part of the country consists of savanna, with prickly shrubs and stunted trees that come to life during the rainy season. In the south the prickly shrubs give way to scattered forests, which become more dense along the banks of the perennial rivers. While tree growth in the north is dis-

UPPER VOLTA

couraged by the climate, farmers in the south often permit only useful trees, such as the karite (shea tree) or the baobab, to survive.

Animal life in the eastern region includes buffalo, antelope, lions, hippopotamuses, elephants, and crocodiles. Elephants, buffalo, and antelope are also found in the southeast and on the banks of the Black Volta, while herds of hippopotamuses are to be seen some 40 miles from the city of Bobo Dioulasso. Animal life also includes monkeys. Bird and insect life is rich and varied, and there are many fish in the rivers.

The landscape under human settlement. Most of the population lives in villages, which tend to be grouped toward the centre of the country. For several miles on either side of the Volta rivers the land is uninhabited because of flooding and the prevalence of the deadly tsetse fly, carrier of sleeping sickness.

Ouagadougou, the administrative capital and the seat of government, is a modern town, in which several commercial companies have their headquarters. It is also the residence of the Moro Naba, emperor of the Mossi. The suburbs have shade trees and artificial lakes.

Bobo Dioulasso, in the west, was the economic and business capital of the country when it formed the terminus of the railroad running to Abidjan, Ivory Coast, on the coast; since 1955, however, when the railroad was extended to Ouagadougou, it has lost some of its former importance, although it remains a commercial centre.

The people. *Ethnic, linguistic, and religious groups.* The two major ethnic groupings

Two principal ethnic groupings may be distinguished. The first of these is the Voltaic grouping, which may be subdivided into four groups—the Mossi, who numbered about 3,700,000 in the early 1970s including the Gurma and the Yarse; the Grunshis (Crurunsi) (310,000); the Bobo (300,000); and the Lobi (130,000). The second grouping is the Mande family, which is divided into five subgroups; the Samo (100,000), the Marka (80,000), the Busansi (50,000), the Senufo (50,000), and the Dyula (Diouala) (30,000). In addition, there are Hausa (Haoussa) traders, about 300,000 Fulani herdsmen, and the Tuareg, or rather their settled servants, the Bella, who number 250,000.

Each of the ethnic groups possesses its own language, although Moré, the language of the Mossi, is spoken by a great majority of the population, and Diula is the language of commerce. French, the official language, is used for all communication with other countries. About three-quarters of the population is animist in religion, attaching great importance to ancestor worship. Islām exerts an increasing influence upon customs; about 1,200,000 people, or 20 percent of the population, were Muslims in 1970; in the same period, Catholicism was the religion of about 5 percent, or 220,000 people. The seat of the Catholic archbishopric is Ouagadougou, and there are eight bishoprics. There are few Protestants.

Demography. Compared to most of the neighbouring countries, Upper Volta, with nearly 6,000,000 inhabitants in 1971, is populous, with an average population density of 55 persons per square mile. The total population figure does not include approximately 500,000 people from Upper Volta who live in the Ivory Coast, Ghana, or Mali. According to a survey conducted in 1968, the rate of population increase is about 2 percent a year and the birth rate about 5 percent a year. An alien population of about 20,000 persons is mostly composed of Yorubas from Nigeria and of citizens of Mali and other neighbouring countries. The European colony numbers about 4,000, most of whom are French.

The population as a whole is unequally distributed among the different regions. The Mossi country is densely settled, with an average population density of between 91 and 130 persons per square mile. Situated in the eastern and central regions, it contains about two-thirds of the total population. In the remaining regions the population is scattered, with an average density of between 13 and 39 persons per square mile.

About 95 percent of the population is rural, living in about 7,000 villages. Apart from Ouagadougou, the capital, which had a 1970 population of over 110,000, the principal towns are Bobo Dioulasso, with a population of The principal towns

77,000; Koudougou (25,000); Ouahigouya (13,000); and the towns of Kaya, Fada Ngourma, and Banfora, each with a population of about 10,000.

The national economy. About 95 percent of the population is engaged in agriculture or stock raising. This sector of the population produces peanuts (groundnuts), cotton, livestock, and sesame seeds for export. There is, however, considerable unemployment in rural districts, and every year about 150,000 people leave their villages to seek work in such neighbouring states as the Ivory Coast or Ghana. The development of industry is hampered by the small size of the market economy and by the absence of a direct outlet to the sea. The gross national product averages 14,000 francs CFA (CFA Fr. 277.71 = $1 U.S.; CFA Fr. 666.50 = £1 sterling on December 1, 1970) a head.

Agriculture. Agricultural production consists of foodstuffs, which are primarily grown for subsistence, with the surplus being sold as cash crops. Thus, in 1969 to 1970 about 7,000 tons of peanuts, 2,700 tons of sesame seeds, 15,000 tons (1968–69) of shea butter (oil), and 8,300 tons of cottonseed were grown for export, while 550,000 tons of sorghum, 120,000 tons of corn (maize), 93,000 tons of peanuts, and 40,000 tons of rice were grown for local consumption. Fonio (a crabgrass with seeds that are used as cereal), yams, sweet potatoes, and beans are also grown. Stock raising is one of the principal sources of revenue. Livestock is estimated to amount to 2,800,000 cattle, 4,500,000 sheep and goats, 139,000 pigs, 180,000 donkeys, 71,000 horses, and 6,000 camels. Chickens, ducks, and guinea fowl are also raised.

Industry. Industry is limited to a number of plants mainly in rural areas producing processed rice, vegetable oil, and hides, and manufactured soap and textiles.

Trade, aid, and development. External commerce, both in imports and in exports, is primarily with the franc zone in general and with neighbouring African countries in particular. Many cattle are exported to the Ivory Coast as well as to Ghana. There is a deficit in the balance of payments, largely due to the relatively small amounts of exports, which are not of sufficient value to equal the value of imported materials required for promoting further development.

Aid from abroad

Foreign aid is extended primarily by France, which finances a number of economic and social projects. Further financial aid and technical assistance is also supplied by the Federal Republic of Germany, the United States, the Republic of China, and Israel. United Nations assistance is supplied through the International Development Association and other United Nations agencies.

Developmental policy, outlined in the Second Five-Year Plan (1972–76), aims at increasing agricultural output. While mineral resources are little developed, copper, marble, bauxite, and manganese (the most significant) deposits have been located.

Transportation. In addition to the rail line, which links Ouagadougou to the port of Abidjan in the Ivory Coast, the capital is also linked by road to the principal administrative centres in the country and to the capitals of neighbouring countries. The railroad to Abidjan is 712 miles long, of which 341 miles run through Upper Volta. Running from east to west before crossing the border, the line serves Koudougou, Bobo Dioulasso, and Banfora. A proposed 220-mile extension to the manganese, chrome, and nickel deposits of Tambao in the northeast is being studied.

Upper Volta has the most extensive road network in proportion to its size of any of the French-speaking African states. Out of about 9,000 miles of roads, about 2,750 are usable year round. The remainder consist of rural roads. Three recently completed road-building projects were financed by the European Development Fund. The first of these roads runs from Bobo Dioulasso to Faramana to the Mali frontier. The second runs from Ouagadougou to Pô to the Ghanaian frontier. The third runs from Ouagadougou to Koupéla. Road transport is supplied by the Compagnie Transafricaine, as well as by individual enterprises.

International airports are located at Ouagadougou and Bobo Dioulasso. Internal air service, linking almost 50 smaller airstrips, is supplied by the national airline.

Administration and social conditions. *Administration.* Although the constitution adopted by referendum in 1970 provides that the people shall exercise sovereignty through regularly elected political representatives, the role of the army is nevertheless preponderant in political life. The constitution provided that, during a four-year transitional period, the presidency was entrusted to the highest ranking military officer with the longest term of service and that one-third of the members of the government were to be military men. The president of the republic is elected for five years by direct universal suffrage and may be re-elected only once. The prime minister establishes and conducts national policy, presiding over a council of ministers and directing the work of the government. A national assembly, elected for five years by universal suffrage, drafts legislation and regulates governmental initiatives.

Local government

Upper Volta is divided into eight *départements*, headed by prefects. These, together with their administrative centres, are the Centre (Ouagadougou), Volta-Noire (Dédougou), Hauts-Bassins (Bobo Dioulasso), the Est (Fada Ngourma), Yatenga (Ouahigouya), Centre-Ouest (Koudougou), Sahel (Doni), and Plateaux du Nord-Mossi (Kaya). The *départements* are grouped into 44 administrative areas called *cercles*, which in turn are divided into 39 subdivisions and 54 administrative posts. In addition there are six *communes* administered by mayors and elected municipal councillors.

Labour conditions. Labour conditions are governed by a labour code, adopted in 1962. Unemployment is endemic, however, and the industrial sector weak. The economically active population, numbering about 3,000,000, is for the most part intermittently employed in agriculture. There are about 27,000 wage earners, of whom about 15,000 are in public service. There are three trade unions.

Health. There are five hospitals—at Ouagadougou, Bobo Dioulasso, Ouahigouya, Pô, and Fada Ngourma—as well as 30 medical centres, about 250 dispensaries, and about 70 maternity centres. There are about 68 doctors—about one for every 74,000 people.

Education. School enrollment is one of the lowest in Africa. In 1960, at the time of independence, it amounted to only 8 percent of the school age population, and by 1970 it had risen to only 10 percent, even though the government devotes a quarter of the national budget to education. There are about 600 primary schools, with a total enrollment of about 100,000 pupils, as well as about 40 secondary schools, with an attendance of about 9,000 pupils. A program to promote education in rural areas is being financed by the European Development Fund. Students seeking higher education usually attend universities in France; in Dakar, Senegal; or in Abidjan, Ivory Coast. There is a teacher-training school at Ouagadougou, as well as a school of national administration.

Cultural life. Folklore is rich, reflecting the country's ethnic diversity. On national occasions, each region is represented in the capital by its own folkloric group.

Houses of Youth and Culture, where young people play cards, read, or watch films or theatrical performances, are located in the main administrative centres.

Press, radio, and television

Press and information services are provided by government agencies under the supervision of the Ministry of Information. Daily bulletins disseminate news and business information, and there are weekly and bimonthly newspapers, as well as an official journal, a monthly statistical bulletin, and a national press agency, the Agence de Press Voltaïque.

There are radio transmitters at Ouagadougou and at Bobo Dioulasso. A television transmitter provides two programs a week to the Ouagadougou area, where television receivers are available for public viewing.

Prospects for the future. Upper Volta, with an average annual per capita income of CFA Fr. 12,000, is one of the poorest countries in Africa. During the colonial period, development took place primarily in coastal countries endowed with rich natural resources; relatively little attention was paid to Upper Volta, where difficulty of access was added to a difficult climate. After independence, therefore, in addition to the problems faced by other newly independent states, Upper Volta was confronted with the necessity of constructing the infrastructure of a modern state—the necessary public buildings, a developed road network and communications system, and other services. It is symbolic of the change of direction that Ouagadougou, which for long was known as a "swish capital" (swish is a hard mud, made from West Africa's red iron-bearing laterite soil), today has a more modern aspect, characterized by a varied architecture, gardens, and paved streets.

Since the previous government, whose scale of expenditure had provoked public discontent, was overthrown in 1966 by the army and the trade unions, strict economic measures have been enforced, which have resulted in the reduction of the long-standing burden of debt. While there is still a foreign-trade deficit, this is also being reduced. With the return in 1970 to a type of civilian rule —in which the military will continue to play a transitional role for a further four years—there is hope that the progress already achieved will be consolidated and further progress made.

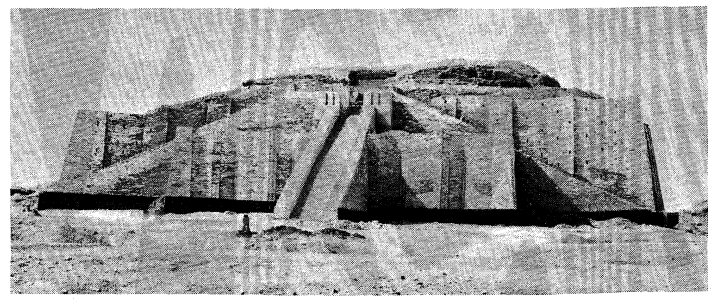
Ur

Ur (biblical Ur of the Chaldees) was an important city of ancient southern Mesopotamia (Sumer), reputed to have been the early home of Abraham. The site (now called Tall al-Muqayyar) lies about 140 miles (225 kilometres) southeast of the site of Babylon and about 10 miles (16 kilometres) west of the present bed of the Euphrates River, a mile and a half from the modern Ur Maḥaṭṭah (Junction) of the Iraqi Republican Railway in southern Iraq. In antiquity the river ran much closer to the city; the change in its course has left the ruins in a desert that once was irrigated and fertile land. The first serious excavations there were made after World War I by H.R. Hall of the British Museum, and as a result a joint expedition was formed by the British Museum and the University of Pennsylvania that carried on the excavations under Leonard Woolley's directorship from 1922 until 1934. Almost every period of the city's lifetime has been illustrated by discoveries made, and knowledge of Mesopotamian history has been greatly enlarged.

Foundation of the city. At some time in the 4th millennium BC, the city was founded by settlers thought to have been from northern Mesopotamia, farmers still in the Chalcolithic phase of culture. There is evidence that their occupation was ended by a flood, formerly thought to be the one described in Genesis. From the succeeding "Jamdat Nasr" (Late Protoliterate) phase a large cemetery produced valuable remains allied to more sensational discoveries made at Erech.



Ur in the early dynastic period, 29th–24th centuries BC. In the next (Early Dynastic) period Ur became the capital of the whole of southern Mesopotamia under the Sumerian kings of the 1st dynasty of Ur (25th century BC). Excavation of a vast cemetery from the period preceding that dynasty (26th century) produced royal tombs containing almost incredible treasures in gold, silver, bronze, and semiprecious stones, showing not only the wealth of the people of Ur but also their highly developed civilization and art. Not the least remarkable discovery was that of the custom whereby kings were buried along with a whole retinue of their court officials, servants, and women, privileged to continue their service in the next world. Musical instruments from the royal tombs, golden weapons, engraved shell plaques and mosaic pictures, statuary and carved cylinder seals, all are a collection of unique importance, illustrating a civilization previously unknown to the historian. A further development of it, or perhaps a different aspect, was shown by the excavation at al-ʿUbaid, a suburb of Ur, of a small temple also of a type previously unsuspected, richly decorated with statuary, mosaics, and metal reliefs and having columns sheathed with coloured mosaic or polished copper. The inscribed foundation tablet of the temple, stating that it was the work of a king of the 1st dynasty of Ur, dated the building and proved the historical character of a dynasty that had been mentioned by ancient Sumerian historians but that modern scholars had previously dismissed as fictitious.

A few personal inscriptions confirmed the real existence of the almost legendary ruler Sargon I, king of Akkad, who reigned in the 24th century BC, and a cemetery illustrated the material culture of his time.

Third dynasty of Ur, 22nd–21st centuries BC. To the next period, that of the 3rd dynasty of Ur, when Ur was again the capital of an empire, belong some of the most important architectural monuments preserved on the site. Foremost among these is the ziggurat, a three-storied structure of burnt bricks set in bitumen, rather like a stepped pyramid, a solid mass of brickwork on the summit of which was a small shrine, the bedchamber of the moon god Nanna (Sin), the patron deity and divine king of Ur. The lowest stage measures at its foot some 210 by 150 feet (64 by 46 metres), and its height was about 40 feet (12 metres). On three sides the walls, relieved by shallow buttresses, rose sheer. On the northeast face were three great staircases, each of 100 steps, one pro-

jecting at right angles from the centre of the building, two leaning against its wall, and all three converging in a gateway between the first and the second terrace. From this a single flight of steps led upward to the top terrace and to the door of the god's little shrine. The lower part of the ziggurat, built by Ur-Nammu, the founder of the dynasty, was astonishingly well preserved; enough of the upper part survived to make the restoration certain.

The excavations showed that by the 3rd millennium BC Sumerian architects were acquainted with the column, the arch, the vault, and the dome—*i.e.*, with all the basic forms of architecture. The ziggurat exhibited its refinements. The walls all sloped inward, and their angle, together with the carefully calculated heights of the successive stages, leads the eye inward and upward; the sharper slope of the stairways accentuates that effect and fixes attention on the shrine, the religious focus of the whole huge structure. Surprisingly, there is not a single straight line in the structure. Each wall, from base to top and horizontally from corner to corner, is a convex curve, a curve so slight as not to be apparent but giving to the eye of the observer an illusion of strength where a straight line might have seemed to sag under the weight of the superstructure. The architect thus employed the principle of entasis, which was to be rediscovered by the builders of the Parthenon at Athens.

Succeeding dynasties, 21st–6th centuries BC. The great brick mausoleums of the 3rd-dynasty kings and the temples they built were sacked and destroyed by the Elamites, but the temples at least were restored by the kings of the succeeding dynasties of Isin and Larsa; and Ur, though it ceased to be the capital, retained its religious and its commercial importance. Having access by river and canal to the Persian Gulf, it was the natural headquarters of foreign trade. As early as the reign of Sargon of Akkad it had been in touch with India, at least indirectly. Personal seals of the Indus Valley type from the 3rd dynasty and the Larsa period have been found at Ur, while many hundreds of clay tablets show how the foreign trade was organized. The "sea kings" of Ur carried goods for export to the entrepôt at Dilmun (Bahrain) and there picked up the copper and ivory that came from the east.

Eastern trade

The clay tablets were found in the residential quarter of the city, of which a considerable area was excavated. The houses of private citizens in the Larsa period and under Hammurabi of Babylon (*c.* 18th century BC, in which period Abraham is supposed to have lived at Ur) were comfortable and well built two-story houses with ample accommodation for the family, for servants, and for guests, of a type that ensured privacy and was suited to the climate. In some houses was a kind of chapel in which the family god was worshipped and under the pavement of which the members of the family were buried. Many large state temples were excavated as were also some small wayside shrines dedicated by private persons to minor deities, the latter throwing a new light upon Babylonian religious practices; but the domestic chapels with their provision for the worship of the nameless family gods are yet more interesting and have a possible relation to the religion of the Hebrew patriarchs.

After a long period of relative neglect, Ur experienced a revival in the Neo-Babylonian period, under Nebuchadrezzar II (604–562 BC), who practically rebuilt the city. Scarcely less active was Nabonidus, the last king of Babylon (556–539 BC), whose great work was the remodelling of the ziggurat, increasing its height to seven stages.

The Neo-Babylonian city

The last phase, 6th–4th centuries BC. The last king to build at Ur was the Achaemenian Cyrus the Great, the inscription on whose bricks is similar to the "edict" quoted by the scribe Ezra regarding the restoration of the Temple at Jerusalem. The conqueror was clearly anxious to placate his new subjects by honouring their gods, whatever those gods might be. But Ur was now thoroughly decadent; it survived into the reign of Artaxerxes II, but only a single tablet (of Philip Arrhidaeus, 317 BC) carries on the story. It was perhaps at this time that the Euphrates changed its course; and with the breakdown of the whole irrigation system, Ur, its fields reduced to desert, was finally abandoned.

Discoveries made on other sites have supplemented the unusually full record obtained from the Ur excavations. Knowledge of the city's history and of the manner of life of its inhabitants, of their business, and of their art is now fairly complete and remarkably detailed (see also MESOPOTAMIA AND IRAQ, HISTORY OF).

Uralic Languages

The Uralic language family consists of two related groups of languages, the Finno-Ugric and the Samoyedic, both of which are thought to have developed from a common ancestor, called Proto-Uralic, that was spoken 7,000 to 10,000 years ago in the general area of the northern Ural Mountain Range. Over the millennia, both Finno-Ugric and Samoyedic have given rise to more or less divergent subgroups of languages, which nonetheless have retained certain traits from their common source. For example, the degree of similarity between two of the least closely related members of the Finno-Ugric group, Hungarian and Finnish, is comparable to that between English and Russian (which belong to the Indo-European family of languages). The difference between any Finno-Ugric language and any Samoyedic tongue would be even greater. On the other hand, more closely related members of Finno-Ugric, such as Finnish and Estonian, differ in much the same manner as greatly diverse dialects of the same language.

Finno-Ugric languages

The Finno-Ugric languages are represented today by some 15 languages scattered over an immense Eurasian territory. In the west they include the European national languages—Hungarian, Finnish, and Estonian—as well as Lapp, the westernmost member of the group, spoken by numerous separate groups across the northern Scandinavian Peninsula from central Norway to the White Sea. The remaining Finno-Ugric languages are located within the Soviet Union, with one major concentration—including Estonian, Livonian, Votic, Karelian, and Veps—along a broad zone extending from the Gulf of Riga to the Kola Peninsula. The Mordvin and Mari (or Cheremis) languages are found in the region of the central Volga; from there extending northward along the river courses west of the Urals are the Permic languages—Udmurt (Votyak) and Komi (Zyryan). East of the Urals, along the Ob River and its tributaries are the easternmost representatives of the Finno-Ugric group—Mansi (Vogul) and Khanty (Ostyak).

The largely nomadic Samoyeds are sparsely distributed over an enormous area extending inward from the Arctic shores of the Soviet Union from the White Sea in the west to Khatangsky (Khatanga) Bay in central Siberia in the east. Nenets (Yurak), the westernmost of these languages, reaches eastward to the mouth of the Yenisey River and includes a small insular group on Novaya Zemlya. Speakers of Enets (Yenisey) are located in the region of the upper Yenisey. The lower half of the Taymyr Peninsula is the habitat of the Nganasan (Tavgi), the easternmost of the Uralic groups. The fourth language, Selkup, lies to the south in a region between the central Ob and central Yenisey; its major representation is located between Turukhansk and the Taz River. A fifth Samoyedic language, Kamas (Sayan), originally spoken in the vicinity of the Sayan Mountains, was spoken in the

Distribution of the Uralic languages.

early 1970s by one elderly speaker, then residing in Estonia.

Numbers of speakers

In general, the westernmost members of the Uralic family are spoken by the greatest numbers of speakers. The largest groups are Hungarian, with some 14,000,000 speakers; Finnish, with 5,000,000; and Estonian, with approximately 1,000,000. Among the lesser known Uralic languages of the Soviet Union, several have rather substantial representation: Mordvin, nearly 1,000,000 speakers; Mari, over 500,000; Udmurt, close to 500,000; Komi, almost 400,000; and Karelian, with just under 100,000 (estimates based on the 1970 Soviet census). The approximately 35,000 Lapps are distributed over four countries: Norway, 20,000; Sweden, 10,000; Finland, 3,000; and the Soviet Union, 1,500. Other Finno-Ugric languages with more than 1,000 speakers are Khanty (about 15,000), Veps (about 8,000) and Mansi (about 4,000). In the mid-20th century, Votic and Livonian were still maintained by small communities of speakers, but they appeared to be facing extinction in future generations. The entire Samoyedic group consists of only 25,000 to 30,000 speakers. Of these, Nenets claims over 24,000 speakers; Selkup, roughly 3,000; Nganasan, fewer than 1,000; and Enets, about 300.

The political history of the various Uralic groups largely has been one of resisting encroachment from adjacent European (especially Germanic and Slavic) and Turkic groups and from other Uralic neighbours. Only three groups have succeeded in achieving political independence—Hungary, Finland, and Estonia (the latter is now, however, one of the 15 republics of the U.S.S.R.). Five of the minority groups in the Soviet Union have the status of autonomous republics: Mordovskaya (Mordvin) A.S.S.R., Mari A.S.S.R., Udmurt A.S.S.R., Komi A.S.S.R., and the Karelian A.S.S.R. (formerly a republic of the U.S.S.R.). Four more groups are recognized at the level of local administration under their own *natsionalny okruga* (national areas): Khanty and Mansi (under one area), the Permyak dialect of Komi, and Nenets (under three *okruga*).

The earliest known manuscript in a Uralic language is a Hungarian funeral oration (*Halotti Beszéd*), a short, free translation from Latin, which stems from the turn of the 13th century AD. A 12-word Karelian fragment also dates from the 13th century. Old Permic, the earliest attested form of Komi, received its own alphabet (based on the Greek and Old Slavic symbols) in the 14th century through the missionary efforts of St. Stephen, bishop of Perm. The first Finnish and Estonian texts date from the 16th century, and are in printed form. Lapp was first written in the 17th century. Since then, nearly all the more populous Uralic languages have some kind of written form, but at present there is a native literature only for the above-mentioned languages and for those groups in the Soviet Union that have their own administrative regions. Currently, the Uralic languages within the Rus-

Alphabets used for the Uralic languages

sian Soviet Federated Socialist Republic use a modification of the Cyrillic alphabet; the others employ the Latin alphabet, adapted to the peculiar demands of their own sound systems. For example, the important distinction between long and short vowels in Finnish is indicated by doubling the letters for long vowels (*a* versus *aa*), whereas in Hungarian the long vowel is marked by an acute accent (*a* versus *á*).

Racially, the Uralic peoples present an unhomogeneous picture. In general, they may be considered a blend of European and Mongoloid types, with the more western groups (especially the Hungarian, Baltic-Finnic, and Erza-Mordvin groups) being strongly European and those east of the Urals primarily Mongoloid. Although scholars do not agree as to what features, if any, constitute the most archaic Uralic type, recent study indicates that it is possible to speak of a Uralic racial type, an intermediate stage between the European and the Mongoloid, the basic features of which are medium-dark to dark hair and eye colour, relatively small stature, and often a concave bridge of the nose. According to this view, the more archaic Uralic type is best preserved among the Lapp, Mari, and Permic groups.

Attempts to trace the genealogy of the Uralic languages to periods earlier than Proto-Uralic have been hampered by the great changes in the attested languages, which preserve relatively few features upon which to base meaningful claims for a more distant relationship. Most commonly mentioned in this respect is a putative connection with the Altaic language family (including Turkic and Mongolian). This hypothetical language group, called Ural-Altaic, is not considered by most scholars to be soundly based. Although the Uralic and Indo-European languages are not generally thought to be related, more speculative studies have suggested such a connection. Of the various attempts to find outside relationships, only those linking Uralic with Yukaghir, a Paleosiberian tongue, appear to have serious support.

Because the names designating many of the Uralic peoples have never been standardized, a wide range of appellations is encountered in references to these groups. Earlier designations, especially in the case of the groups in Russia, tended to be taken from derogatory names used by neighbouring peoples; *e.g.*, Cheremis—now Mari. Table 1 indicates the names in use. Standard usage is in the left column, and earlier, Russian-based forms are in the right column. Several names are identical to the word for man in these languages. (Finnish *mies* "man" has also been etymologically related to the names Magyar and Mansi.) It is important that Ostyak (Khanty) not be confused with Ostyak Samoyed (Selkup) nor with Yenisey Ostyak (Ket, a non-Uralic, Paleosiberian tongue), which should also not be confused with Yenisey (Enets).

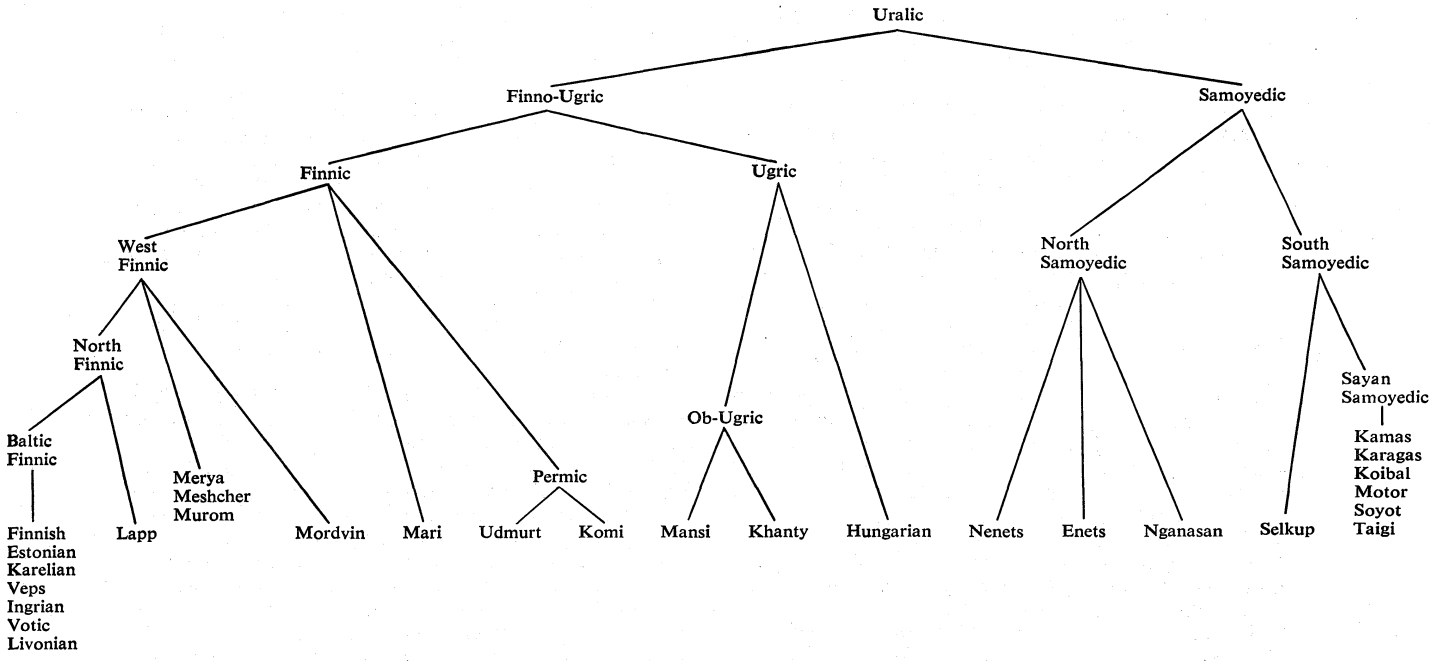
LANGUAGES OF THE URALIC FAMILY

Divisions within Finno-Ugric

The two major branches of Uralic are themselves composed of numerous subgroupings of member languages on the basis of closeness of linguistic relationship. Finno-Ugric can first be divided into the most distantly related Ugric and Finnic (sometimes called Volga-Finnic) groups, which may have separated as long ago as five millennia. Within these, three relatively closely related groups of languages are found: the Baltic-Finnic, the Permic, and the Ob-Ugric. The largest of these, the Baltic-Finnic group, is composed of Finnish, Estonian, Livonian, Votic, Ingrian, Karelian, and Veps. The Permic group consists of Komi and Udmurt; the Ob-Ugric group includes Mansi and Khanty.

The Ugric group comprises the geographically most distant members of the family—the Hungarian and Ob-Ugric languages. Finnic contains the remaining languages: the Baltic-Finnic languages, Lapp, Mordvin, Mari, and the Permic tongues. There is little accord on the further subclassification of the Finnic languages, although the fairly close relationship between Baltic-Finnic and Lapp is generally recognized (and is called North Finnic); the degree of separation between the two may be compared to that between English and German. Mordvin has most frequently been linked with Mari (a putative Volga group), but comparative evidence also suggests a bond with Baltic-Finnic and Lapp (that is, West Finnic). The extinct Merya, Murom, and Meshcher groups, known only from Old Russian chronicles, are assumed to have been Finnic peoples and from their geographical location northwest of Mordvin must have belonged to West Finnic. One hypothesis for the internal relationships of the Uralic family as a whole is given in the accompanying diagram (see below).



The precursor of the modern Samoyedic languages is thought to have divided near the turn of the Christian Era into a northern and a southern group. North Samoyedic consists of Nenets, Enets, and Nganasan. South Samoyedic contains but a single living language, Selkup, but is known to have been represented by numerous other dialects, now extinct: Kamas, Motor, Koibal, Tofalar (Karagasy), Soyot, and Taigi.

Hungarian. Hungarian, the official language of Hungary, remains the primary language of the fertile Carpathian Basin. Bounded by the Carpathian Mountains to the north, east, and southwest, the Hungarian area is represented by over 2,000,000 speakers outside the boundaries of Hungary—in Czechoslovakia, the Ukranian S.S.R., and Romanian Transylvania (some 1,600,000). To the south, a substantial Hungarian population (over 500,000) extends into central Yugoslavia. Hungarian emigrant communities are found in many parts of the world, especially in North America and Australia.

The ancestors of the Hungarians, following their separation from the other Ugric tribes, moved south into the steppe region below the Urals. As mounted nomads, in contact with and often in alliance with Turkic tribes, they moved westward, reaching and conquering the sparsely settled Carpathian Basin in the period 895–896. The Hungarians came under the influence of Rome through their first Christian king, Stephen (István), in 1001, and the use of Latin for official purposes continued into the 19th century. Following a Hungarian defeat at the Battle of Mohács in 1526, Hungary was occupied by Turkish forces, who were replaced by German Habsburg domination in the late 17th century. Concern for a common literary medium, closely tied with Hungarian nationalism, began in the late 18th century. More recent foreign influences on the language were suppressed and replaced by native words and constructions. The literary form received a broad dialect base, facilitating its use as a national language.

Dialects of Hungarian

Modern Hungarian has eight major dialects, which permit a high degree of mutual intelligibility. Budapest, the nation's capital, is located near the junction of three dia-

Family tree diagram of the Uralic languages (see text).

lect areas: the South, Transdanubian, and Palóc (Northwestern). As a result of unfavourable treaties following both world wars, especially the Treaty of Trianon, two dialects (Central Transylvanian and Székely) lie almost entirely within Romania, and the remaining six dialects radiate outward into neighbouring countries.

The Hungarians' own name for themselves is *magyar*. Other Western appelations, such as the French *hongrois*, German *Ungar*, and Russian *vengr*, all stem from the name of an early Turkic tribal confederation, the *on-ogur* (meaning "ten tribes"), which the Hungarians joined in their wanderings toward the west, and does not indicate relationship with the ancient Huns, a Turkic tribe. One of the earliest recorded references to the Hungarians, a Byzantine geographical survey of Constantine Porphyrogenitus (died 959) entitled *De administrando imperio*, lists the *megyer* as one of the Hungarian tribes, but, as was typical in early reports, the Hungarians were not distinguished from their Turkish allies.

Ob-Ugric: Khanty and Mansi. The Ob-Ugric peoples, the Khanty and the Mansi, are among the smallest Finno-Ugric groups. Although their numbers have declined over recent centuries, Khanty is still maintained by almost 15,000 speakers, and, according to the 1970 Soviet census, 52 percent of the 7,700 Mansi still claim it as their mother tongue. To a large extent they have been assimilated by their Russian and Tatar neighbours. These two peoples are widely dispersed along the Ob River and its tributaries, for the most part within the Khanty-Mansiysky *natsionalny okrug*, which has its administrative centre in Khanty-Mansiysk at the junction of the Ob and the Irtysh. The Mansi are found along the western tributaries primarily north of the Irtysh and just east of the Urals; a few speakers are also found in the Arctic lands west of the Urals. The Khanty live along both the Ob itself and its tributaries.

Khanty and Mansi dialects

Because of the great distances between the various groups, the dialects of both languages show considerable divergence. They are usually designated by the name of the river on which they are spoken. Mansi has four main dialect groups, of which one (Tavda) is practically extinct and another (Konda) is no longer spoken by the youth of the area. The largest dialect group (Northern) is centred on the Sosva and serves as the basis for the literary language. Khanty is divided into three main dialects: a northern dialect in the general area of the mouth of the Ob, an eastern dialect extending from east of the Irtysh to the Vakh and Vasyugan tributaries, and a southern dialect lying between the other two. Literary Khanty has been based primarily on the northern group, but standardization remains weak, and in recent decades other dialects have also been used.

After the division of the Proto-Ugric language into separate languages, it is likely that the precursors of the Ob-Ugric tribes were still centred west of the Urals well within historic times. The Old Russian Chronicles of Nestor, which assigned them the common name *jugra*, places them in the vicinity of the Pechora River in 1092; they did not shift to the Ob waterways until several centuries later. Both of the Ob-Ugric languages first appeared in printed form in 1868 as a result of gospel translations published in London, but it was not until after the formation of their *natsionalny okrug* in 1930 that any sort of literary form of Khanty and Mansi really existed. Until 1937 numerous books were published using a modified Latin (roman) alphabet; since then Cyrillic has been used. To a certain extent, elementary education is conducted in the native languages within the *natsionalny okrug*.

Finnish. Finnish, together with Swedish (an unrelated North Germanic language), serves as the official language of Finland. It is now spoken by over 5,000,000 people, including 92.4 percent of the inhabitants of Finland plus nearly 1,000,000 Finns in North America, Sweden, and the Soviet Union. It is also recognized as an official language in the Karelian A.S.S.R., alongside Russian.

Finnish as the common language of the Finns is not the direct descendant of one of the original Baltic-Finnic dialects; rather, it arose through the interaction of several separate groups in the territory of modern Finland. These included the Häme; the southwestern Finns (originally called Suomi), who appear to be close relatives to the Estonians, because they arrived directly from across the Gulf of Finland; and the Karelians, perhaps themselves a blend of Veps and more western Finnic groups. Early Russian chronicles refer to these as *jemj*, *sumj*, and *korela*. The intermixture of the three groups is still reflected in the distribution of the five main modern dialects, which form a western and an eastern area. The western area contains the southwest dialect (near Turku), Häme (south central), and a northern dialect subgroup (largely a mixture of the other two plus eastern traits). The eastern area consists of the Savo dialect (perhaps a blend of the original Karelian and Häme dialects) and a southeastern dialect, which strongly resembles Karelian. The Finnish word for their land and their language is *suomi*, the original meaning of which is uncertain. The first use of the term Finn (*fenni*) is found in the 1st century AD

Modern Finnish dialects

in Tacitus' *Germania*, but this usage is generally considered to refer to the ancestors of the Lapps, who have also been labelled Finns at various times. (The province of Norwegian Lappland is called Finnmark.)

The first book in Finnish was an ABC book from 1543 by Mikael Agricola, founder of the Finnish literary language; five years later it was followed by Agricola's translation of the New Testament. Finnish was accorded official status in 1809, when Finland entered the Russian Empire after six centuries of Swedish domination. The publication of the national folk epic, the *Kalevala*, created from folk songs collected among the eastern dialects by folklorist and philologist Elias Lönnrot (first edition in 1835; substantially expanded in 1849), gave increased impetus to the movement to develop a common national language encompassing all dialect areas.

Estonian. Estonian serves as the official language of the Estonian S.S.R., located immediately south of Finland across the Gulf of Finland. There are slightly over 1,000,000 speakers, most of them living within the Estonian S.S.R. but also elsewhere in the Soviet Union and abroad, especially in North America and Sweden. Modern Estonian is the descendant of one or possibly two of the original Baltic-Finnic dialects. The modern language has two major dialects, a northern one, which is spoken in most of the country, and a southern one, which extends from Tartu to the south. The northernmost dialects share many features with the southwestern Finnish dialect. The Estonians' own name *eesti* came into general use only in the 19th century. The name *aestii* is first encountered in Tacitus, but it is likely that it referred to neighbouring Baltic-Finnic peoples.

The first connected texts in Estonian are religious translations from 1524; the *Wanradt-Koell Catechism*, the first book, was printed in Wittenberg in 1535. Two centres of culture developed—Tallinn (formerly Reval) in the north and Tartu (Dorpat) in the south; in the 17th century they gave rise to two literary languages. Influenced by the Finnish *Kalevala*, the Estonian author Friedrich Reinhold Kreutzwald fashioned a national epic, the *Kalevipoeg* ("Son of Kalevi"), which appeared in 20 songs between 1857 and 1861. As with the *Kalevala*, this was instrumental in kindling renewed interest in a common national literary form in the late 19th century.

Karelian, Veps, Ingrian, Votic, Livonian

Smaller Baltic-Finnic groups. The five less numerous Baltic-Finnic groups—Karelian, Veps, Ingrian, Votic, and Livonian—lie within the territory of the Soviet Union, largely in the general vicinity of the Gulf of Finland. The Karelians, Veps, and Livonians were among the original Baltic-Finnic tribes; Votic is considered to be an offshoot of Estonian, and Ingrian, a remote branch of Karelian. None of these languages currently has a literary form, although unsuccessful initial attempts to establish one have been made for all but Votic (for Livonian as early as the 19th century, for the others during the 1930s). Since the beginning of the 20th century the numbers of these Baltic-Finnic speakers have been drastically reduced, and, with the exception of Karelian and Veps, their extinction within several generations seems certain. Votic and Livonian, both with fewer than 1,000 speakers, were not included in the 1959 census, and of the 1,100 Ingrians recorded at that time only 34 percent still considered themselves native Ingrian speakers.

Karelian, the largest of these groups, with nearly 120,000 speakers—not counting those Karelians who emigrated into Finland following World War II—lies along a broad zone just east of the Finnish border from just north of Leningrad to the White Sea. A separate group of Karelians is found far to the south near Kalinin (formerly Tver) on the upper Volga. Karelian has two major dialects, Karelian proper and Olonets (*aunus* in Finnish), which is spoken northeast of Lake Ladoga. One of the first historical mentions of the Karelians is found in a report of the Viking Ohthere to King Alfred of England at the end of the 9th century; this indicates that they were already on the southern Kola Peninsula as neighbours of the Lapps and gives their name as *beorma*.

The language of one of the original Baltic-Finnic tribes, Veps, is spoken southeast on a line connecting lower Lake Ladoga with central Lake Onega. Fewer than half of the 16,000 Veps still consider the language their native tongue—a sharp decline from the 26,172 speakers reported in the mid 1800s. A small Baltic-Finnic group, the Ludic dialects, is found between Veps and Karelian and is generally considered as a blend of the two major groups, rather than a separate language; the dialects are more closely akin to Karelian. The Ingrians and the Votes live on the southern Gulf of Finland in the border area between Estonia and Soviet Russia, where they have survived because the border area has been closed to outsiders, even within the Soviet Union. Livonian, maintained in a dozen villages on the northernmost tip of Latvia, on the Courland Peninsula, has nearly 500 speakers, but the language is not used among the younger generation.

Lapp. The Lapps are widely distributed, from central Norway northward and eastward across northern Sweden and Finland to the Kola Peninsula. The number of Lapps has increased over the past century to somewhat over 30,000, but the number of Lapp speakers has declined rapidly in recent decades as the language has given way to the various official national languages. Lapp is generally divided into three main dialect groups, each with various subtypes. These dialects are virtually mutually unintelligible, so that when speakers of different Lapp groups meet, they generally converse in Finnish, Swedish, or Norwegian. To speak of a single Lapp language is thus misleading. Lapp represents a group of at least four or five languages at least as diverse as the separate Baltic-Finnic languages. The largest group, North Lapp (with roughly two-thirds of all speakers), is centred in northern Norway, Sweden, and Finland. East Lapp consists of two small groups in eastern Finland—Inari and Skolt—plus Kola Lapp in the Soviet Union. South Lapp is still represented by a few speakers scattered from central Norway to north central Sweden.

Dialect groups of Lapp

North Lapp has had a literary tradition that began with the 17th-century Swedish Lapp Bible and other religious translations; in the mid-20th century elementary schools that used Lapp as the language of instruction were found in many larger North Lapp communities. Two basic variants of the literary language are in use. One, in Norway and Sweden, employs a special Lapp orthographic system devised to accommodate a wide range of dialectal variation; a second, in Finland, is based on a more narrow adaptation of Finnish orthography. Each of the two types has numerous local variants, and progress toward a common Lapp orthography has been slow.

A wide range of theories has been posited to reconcile the apparent conflict between the different racial features of the Lapps and the Baltic-Finnic peoples and their strong linguistic similarities. The Lapps have been said to represent a non-Uralic people (the so-called Proto-Lapps) or perhaps a Samoyed tribe that abandoned its own language for a late stage of Finnic, perhaps early Baltic-Finnic. Another view is that the Lapps are one of the original Finnic tribes and not linguistically more closely related to Baltic-Finnic. In the absence of any compelling evidence, no conclusive answer can be provided. On the other hand, the fact that the non-Uralic origin of the Baltic Finns is rarely considered, despite recent evidence suggesting that the Lapps best represent the racial characteristics of the Finno-Ugric peoples, leads to the possibility of a certain degree of chauvinism in the earlier hypotheses suggesting outside origins for the Lapps. In any case, it is clear that the Lapps were already present north of the Gulf of Finland prior to the arrival of the first Baltic-Finnic tribes, and from there they may have extended over much of the Scandinavian Peninsula. They have been mentioned as the northern neighbours of the north Germanic tribes in numerous historical sources of the 1st millennium of the Christian Era. The Lapps were taxed by the Norwegians in the 9th century and by the Karelians in the 13th century and since that time have continually retreated northward under pressure from their southern neighbours. The Lapps' own name for themselves, *sabme*, is etymologically related to the Finnish dialect name, *häme*.

Other Finnic languages. Mordvin, Mari, and the Permic languages—Udmurt and Komi—are each recognized by autonomous republics within the Russian Soviet Federated Socialist Republic, where they share official status with Russian. Mordvin, Mari, and Udmurt are centred on the middle Volga River, in roughly the area considered to have been the original home of Proto-Finno-Ugric. Because of their location, the history of these groups over the past millennium has been closely tied to that of the Turkic Bulgars, the Tatars (until 1552), and then the Russians. The Komi, having moved far to the north, eventually reaching into the Arctic tundra, did not come under Bulgar or Tatar influence. A written form of early Komi, Old Permic, was used in religious manuscripts in the 14th century, and a native Komi literary tradition stems from the 19th century. Grammars of Mari and Udmurt prepared by Russian linguists appeared in 1775, but native literary development in these languages, as well as in Mordvin, is of recent origin. Although these groups currently enjoy the status of large minorities, even in their respective autonomous areas, their numbers have increased over the past century, and they have maintained ethnic consciousness.

Mordvin, Mari, and the Permic languages

Mordvin. Mordvin, with nearly 1,000,000 speakers (78 percent of the 1,263,000 Mordvinians reported in 1970), is the third-largest Uralic group. The Mordvinians are widely scattered over an area between the Oka and Volga rivers, some 200 miles southwest of Moscow. Less than half of their number live within the Mordovskaya Autonomous Soviet Socialist Republic. Mordvin has two main dialects, Moksha and Erza, which are sometimes considered separate languages. Both have literary status. Although the Mordvinians do not have a common designation for themselves beyond the two dialect names, the name *mordens* appears in the 6th-century *Getica* of Jordanes and is no doubt related to the Permic word for "man," *murt/mort*.

Mari. Mari is currently maintained by over 500,000 speakers (91 percent of 599,000 in 1970), primarily in an area north of the Volga between Kazan and Gorki, northeast of the Mordvin area, especially within the Mariyskaya A.S.S.R. Mari's three main dialects are: the Meadow dialect, used by the largest group north of the Volga and the basic dialect of the Mariyskaya A.S.S.R.; Eastern Mari, used by a small group near Ufa, originally speakers of the Meadow dialect who emigrated in the late 18th century; and the Mountain dialect, to the west and on the south bank of the Volga. The Mountain and Meadow dialects both serve as literary languages and differ from each other only in minor details.

Udmurt and Komi

The Permic languages. Speakers of the two closely related Permic languages number close to 1,000,000—roughly 581,500 Udmurts and 397,500 Komi. Udmurt is concentrated largely in the vicinity of the lower Kama River just east of the Mariyskaya A.S.S.R., in the Udmurtskaya A.S.S.R. Only very minor dialectal differences are found within Udmurt. The Komi language area extends into the Nenetskaya *natsionalny okrug* far to the north. Lesser groups of Komi are found as far west as the Kola Peninsula and east of the Urals. Three major dialects are recognized, although the differences are not great: Komi Zyryan, the largest group, which serves as the literary basis within the Komi A.S.S.R.; Komi-Permyak, the dialect of the Komi-Permyatsky *natsionalny okrug*, where it has literary status; and Komi-Yazva, spoken by some 4,000 Komi to the east of the Komi-Permyatsky *okrug* and south of the Komi A.S.S.R.

The Samoyed languages. Nenets, with the largest number of speakers of all the Samoyed languages, has added a substantial increase in the number of its speakers over the past century, from 9,245 in 1897 to over 24,000 in the mid-1900s. Two distinct groups of Nenets differ in dialect as well as in cultural traditions: the Forest Nenets, a smaller, more concentrated group in the wooded area north of the central Ob; and the Tundra Nenets, a group whose territory stretches roughly 1,000 miles eastward from the White Sea. These are the "Samoyadj" of Nestor's chronicles, but little is known of the history of any of the Samoyed peoples until recent centuries. Nenets alone among the Samoyed languages can claim a native literature, although both it and Selkup have been in written form since the 1930s. Evidence of the cultural prestige of certain Nenets tribes is seen in the adoption of a Samoyed language by Khanty speakers on the Yamal Peninsula. Enets is spoken by a dwindling group of several hundred Samoyeds near the mouth of the Yenisey, just east of the Nenets. Nganasan, spoken by the northernmost Eurasian people, is found north and east of the Enets-speaking group, centring on the Taymir Peninsula. The number of Nganasans has remained fairly constant, and they seem to have a high degree of ethnic identity (93.4 percent of 1,000 Nganasans still claimed Nganasan as their mother tongue in 1970).

Selkup, the last of the southern Samoyed languages, is represented by scattered groups of speakers who live on the central West Siberian Plain between the Ob and the Yenisey. Only half of the 4,300 Selkup speakers counted in 1970 still consider the language their mother tongue.

EARLY HISTORY OF THE URALIC LANGUAGES

Determining the geographical location, material culture, and linguistic characteristics of the earliest stages of Uralic at a period thousands of years prior to any historical records is a problem beset with enormous difficulties; consensus among Uralic scholars is limited to a handful of general hypotheses.

Hypotheses concerning early Uralic cultures and languages

The original homeland of Proto-Uralic is considered to have been in the vicinity of the central Urals, possibly centred west of the mountains. Following the dissolution of Uralic, the precursors of the Samoyeds gradually moved northward and eastward into Siberia. The Finno-Ugrians moved to the south and west, to an area close to the junction of the Kama and Volga rivers.

Knowledge of the location of these early groups is based on several kinds of indirect evidence. One approach attempts to reconstruct their natural environment on the basis of shared cognate words for plants, animals, and minerals and on the distribution of these words in the modern languages. For example, cognates (related words) designating certain types of spruce are found in all the Uralic languages except Hungarian (Finnish *kuusi*, Lapp *guossâ*, Mordvin *kuz*, Komi *koz*, Khanty *kol*, Nenets *xādy*, Selkup *kūt*). Because the range of this type of fir tree is restricted to more northern climates, it is generally assumed that the widespread consistent association of the name and the tree suggests a period in which Proto-Uralic was spoken within that zone. Several other terms for plants (*e.g.*, Finnish *muurain* "cloudberry" [*Rubus arcticus*]), a term for metal (Estonian *vask* "copper," Hungarian *vas* "iron," Nganasan *basa* "iron"), and a word for "reindeer" (Lapp *boazo*) are also consistent with a northern Ural location. Great caution is necessary in such matters, because the association of words and objects can also result from borrowing, perhaps long after the period of Uralic unity; especially such culturally mobile items as "metal" and "reindeer" cannot with certainty be traced to a Proto-Uralic community. The central Volga location of Proto-Finno-Ugric is rather strongly supported by an abundance of shared terminology dealing with beekeeping, which forms an important part of the culture of this region.

A second approach to determining the location of Proto-Uralic is based on contacts with other, unrelated languages as evidenced by loanwords from one group to the other. Early Finno-Ugric borrowed numerous terms from very early dialects of Indo-European. Though these words are entirely lacking from the Samoyed languages, within the Finno-Ugric division they are shared by the most remotely related members and show the same phonetic relationships as the native Finno-Ugric vocabulary. Examples include agricultural and bee-culture terminology (*e.g.*, "honey": Finnish *mete*, Komi *ma*, Hungarian *méz* [compare Indo-European **medhu*-]; "pig": Finnish *porsas*, Komi *porś*); several numerals ("hundred": Finnish *sata*, Hungarian *száz*); mineral words ("salt": Finnish *suola*, Komi *sol*); and the word for orphan (Finnish *orpo*, Hungarian *árva*). The nature of these borrowings, together with the linguist's relatively richer knowledge of

early Indo-European, supports a southward movement of Proto-Finno-Ugric and also provides some insight into the culture of the Finno-Ugrians.

The central Volga location is also supported by the geographical distribution of the daughter languages. Except for Hungarian, which moved westward across the steppe, the Finno-Ugric languages form two chains distributed along major waterways, with the junction of the Kama and Volga at their centre. One chain extends northward along the Kama, across the northern tip of the Urals into the Ob watershed, then south along the Ob and its tributaries. The second extends northeast along the Volga to the Gulf of Finland. The extinct Merya, Murom, and Meshcher languages were once links in this chain. Finally, assumptions about the more distant relationships of Uralic have influenced views concerning its original location. Earlier, proponents of the Ural-Altaic hypothesis tended to place the Uralic homeland in south central Siberia, near the sources of the Ob and Yenisey, but there is no support for this view.

LINGUISTIC CHARACTERISTICS OF THE URALIC LANGUAGES

The linguistic structure of Proto-Uralic has been partially reconstructed by a comparison of the similarities and differences among the known Uralic tongues. Not all existing similarities can be attributed to a common Uralic origin; some may also reflect universal pressures and limitations on language structure (*e.g.*, the tendency to weaken stopped consonants between vowels, the modifying of a sound to become more similar to a preceding or following sound) or the influence of neighbouring, even genetically unrelated language structures (*e.g.*, the various types of vowel harmony [see below] in Finno-Ugric probably reflect such areal pressure).

Finnish and Hungarian sound correspondences

Phonological characteristics. The correspondences of sounds in cognate Uralic words are illustrated in Table 2. Thus, a *p* in the beginning of a Finnish word corresponds to *f* in Hungarian (*puu* : *fa*); a Finnish *k* is matched by Hungarian *h* before a back vowel (*a, o*), otherwise by *k*; within the word, Finnish *t* is matched by Hungarian *z* and *nt* by *d*; Finnish initial *s* sometimes corresponds to Hungarian *s* (spelled *sz*) and sometimes to no consonant at all (*syli* : *öl*). In most of these instances, Finnish has retained the consonants of the Proto-Uralic consonant system. One exception is *nt*, which was originally **mt*; the *m* has become *n*, matching the position of articulation of the adjacent *t*. (An asterisk marks a form that is not found in any document or living dialect but is reconstructed as having once existed in an earlier stage of a language.) A second Finnish innovation is the loss of the distinction between the two original *s* sounds, **s* and palatalized **ś*. (Palatalization is the modification of a sound by simultaneous raising of the tongue to or toward the hard palate.) Hungarian maintains a distinction, but the original **s* words have lost this sound. By careful examination of such systematic relationships it is possible to sketch out much of the phonological structure of early Uralic. The reconstructions of Table 2 (last column) are based on the view that the vowel system of Baltic-Finnic is relatively more conservative, whereas the consonant contrasts have been best preserved in Lapp.

Consonants. The following consonant sounds are generally posited for the early stages of Uralic: **p*, **t*, **č*, **k*, **s*, **š*, **δ*, **l*, **r*, **m*, **n*, **ŋ*, **j*, **v* (*č* is pronounced as the *ch* in "chip," *š* as the *sh* in "ship," *δ* as the *th* in "then," *ŋ* as the *ng* in "sing," *j* as the *y* in "yet"), and the palatalized alveolar sounds **t'*, *ś*, *δ'*, *l'*, *ń*, plus a few others less well established. Modern Finnish has a much smaller inventory of consonants, having lost the palatalized alveolar sounds and **č*, **š*, **δ*, and **ŋ*. Hungarian, on the other hand, has a larger number of consonants by virtue of a newly introduced distinction between sounds made with and without vibration of the vocal cords (voicing), such as voiceless *p, t, s* as opposed to voiced *b, d, z*; *e.g.*, *dél* "noon" : *tél* "winter." Other Uralic languages, such as Komi, have also acquired a voicing contrast (*e.g.*, *doj* "pain" : *toj* "louse"), but the geographical distribution of those languages in which the voicing contrast plays an active role leaves little doubt as to its areal (regional) origin under the influence of Indo-European and Turkic languages.

Proto-Uralic vowels

Vowels. Essentially nothing is known of the Proto-Uralic vowels, and there is little agreement about the nature of the Proto-Finno-Ugric vowel system. It is clear, however, that, in contrast to a relatively limited number of consonants, Finno-Ugric must have had a fairly large number of vowels (nine to 11 are usually posited). One hypothesis is that the original vowel system was essentially like that of Finnish, which has eight vowel sounds: *i, ü, u, e, ö, o, ä, a* (*ü*—spelled *y* in the standard orthography —and *ö* are front rounded vowels, as in German; *ä* is a low front vowel, as *a* in "cat"). Hungarian has a similar system, although not all dialects have a separate *ä* sound, which is not distinguished from *e* in the orthography. A second approach posits a Proto-Uralic vowel structure closely resembling that of Khanty, with seven full vowels and three reduced vowels.

The early Finno-Ugric system of vowels most likely possessed quantitative vowel contrasts (long versus short, or full versus reduced). Such contrasts are present in Baltic-Finnic, Lapp, and Ugric and within Samoyedic; *e.g.*, Finnish *tulen* "of fire" and *tuulen* "of wind," *tuleen* "into fire," and *tuuleen* "into wind"; Hungarian *szel* "slice" and *szél* "wind," *szelet* "wind" (accusative case),

and *szelét* "its wind" (accusative). The possibility of influence by neighbouring languages cannot be ruled out in the case of vowel length, because western Finno-Ugric languages have been in close contact with Slavic and Germanic languages with similar vowel contrasts, and the eastern languages form an areal group among themselves. The remaining languages lack vowel quantity and are in intimate contact with Russian, which has lost the original contrastive vowel quantity of Indo-European. The Izhma dialect of Komi, adjacent to Nenets, has superficial contrasts such as *pi* "son" versus *pī* "cloud," but this vowel length is the result of a change of an *l* at the end of the syllable to a vowel.

Stress. In numerous Uralic languages—including Finnish, Estonian, Hungarian, and Komi—stress is automatically on the first syllable of the word; it is likely that Proto-Uralic also had word-initial stress. Closely related to this initial stress is the apparent severe limitation on early Finno-Ugric noninitial vowels; the full range of contrasts was permitted only in the first syllable. In certain languages, such as Eastern Mari and the Yazva Komi dialect, stress is not bound to a given syllable, and determining the place of stress requires information concerning vowel quality as well; *e.g.*, Yazva *śibdinə* "to bind," *liććinə* "to descend," *l'išina* "wood" (the two stressed *i*'s are phonologically tense; *ś, ć, l'* are palatalized consonants). Stress at the end of a word is also found; *e.g.*, in Eastern Mari and Udmurt. Nganasan has a mora-counting stress, falling on the third unit of vowel length from the end of the word (where short vowels count as one unit, long vowels as two).

Vowel harmony. Vowel harmony is among the more familiar traits of the modern Uralic languages. Although most Uralic scholars trace this feature back to Proto-Uralic, there is good reason to question this view.

Conditions for vowel harmony

Vowel harmony is said to exist when certain vowels cannot occur with other specific vowels within some wider domain, generally within a word. For example, of the eight vowels of Finnish, within a simple word, any member of the set *ü, ö, ä* prohibits the use of any member of the set *u, o, a*, but *i* and *e* may occur with either set. That is, within a word, vowels that are either rounded, such as *ü, ö, u, o*, or low, such as *ä, a*, must agree with each other in frontness or backness. (The distinction is marked phonetically by putting two dots over the front vowels.) The unrounded front vowels, *i* and *e*, may occur with any of the other vowels. Thus, from *talo* "house" one may form *talossa* "in (the) house," but for *kynä* "pen" the comparable form is *kynässä* "in (the) pen"; similarly, *talossansa* "in his house" contrasts with *kynässänsä* "in his pen" and *talossansako* "in his house?" with *kynässänsäkö* "in his pen?", whereas *taloni* "my house" and *kynäni* "my pen" have the same ending because *i* can occur with either of the two sets of vowel classes. Hungarian has essentially the same system, differing only in certain minor details (short *e* is the front vowel counterpart of *a*); *e.g., asztal* "table," *asztalok* "tables," *asztalokban* "in the tables," but *föld* "land," *földök* "lands," *földökben* "in the lands." Similar though less general front–back vowel-harmony systems are found in given dialects of Mordvin, Mari, Mansi, Khanty, and Kamas.

Frequently confused with the true harmony situations above are partial and total assimilations of vowels in adjacent syllables. These assimilations illustrate a universal tendency of vowel interaction and are of relatively recent origin; they are best held apart from the question of vowel harmony. Examples of vowel assimilations abound. In Finnish an unstressed *e* in the illative case ("place into") is totally assimilated to a preceding vowel, even across an intervening *h*: *talo* + *hen* becomes *taloon* "into the house," *talo* + *i* + *hen* yields *taloihin* "into the houses," *työ* + *hen* becomes *työhön* "into the work." The Hungarian allative case ("place to or toward which") shows an assimilation of the phonetic feature of lip rounding with front vowels in addition to the standard vowel harmony; thus, *ház-hoz* "to the house," *kéz-hez* "to the hand," *betu-höz* "to the letter." Apart from such nonharmony alternations, no support for rounding harmony is found in Uralic.

Considered from an areal viewpoint, two aspects of Uralic vowel harmony must be considered. First, those languages that show productive or active vowel harmony, with the exception of Baltic-Finnic, have had recent Turkic neighbours whose languages exhibited vowel harmony. For languages such as Mansi and Khanty, dialects with vowel harmony are located closer to Tatar groups. Second, the original homeland of Uralic lies in the centre of an enormous hypothetical areal grouping, labelled by some as the "Eurasian language union." The languages of this "union" are said to be characterized by two features: (1) the absence of a tonal accent (changes in pitch that change meaning, as is found in Chinese, Swedish, or Serbian) and (2) the contrast of plain and palatalized consonants (as in Russian). The phonetic basis for the consonantal contrast between nonpalatalized and palatalized is acoustically the same as the contrast of front and back vowels (*i.e.*, it involves the timbre of the second formant). Indeed, in Erza-Mordvin, vowel harmony and palatalization appear to be conditioned by essentially the same rules. Instead of seeking a genetic explanation of vowel harmony in Uralic, a somewhat more recent areal origin—in part under Turkic influence—must be considered. Of significance is the further consideration that, among the northwestern languages far from Turkic influence, it is precisely Lapp and the Baltic-Finnic Estonian and Livonian that do not have vowel harmony and that have developed special syllable-accent systems (thus, they lack both traits of the Eurasian union).

Possible influence of Turkic and other languages

Consonant gradation. The alternation of consonants known as consonant gradation (or lenition) is sometimes thought to be of Uralic origin. In Baltic-Finnic, excluding Veps and Livonian, earlier single stops were typically replaced by voiced and fricative consonantal variants, and geminate (double) stops were weakened following a stressed vowel when the next syllable was closed; that is, **p* alternated with **v* and **b*; **t*, with **ð* and **d*; **k*, with **ɣ* and **g*; **pp* with **p*; and so on. Finnish thus shows pairs such as *mato* "worm" and *madon* "of the worm," *matto* "rug" and *maton* "of the rug," *poika* "boy" and *pojan* "of the boy," *lintu* "bird" and *linnun* "of the bird," *selkä* "back" and *selän* "of the back." Estonian shows the same type of alternations, with considerable difference in detail; *e.g., sada* "hundred" and *saja* "of a hundred," *madu* "snake" and *mao* "of the snake," *lind* "bird" and *linnu* "of the bird," and *selg* "back" and *selja* "of the back." Most of the Lapp languages exhibit similar alternations, but the process applies to all consonants and, moreover, works in reverse—single consonants are doubled in open syllables; *e.g., čuotte* "hundred" and *čuoðe* "of a hundred," *borra* "eats" and *borâm* "I eat." The change of *t* to ð, however, is not a part of Lapp gradation but rather a general process that voices and weakens all single stops between voiced sounds (in this case, vowels).

Despite their essential differences, the Baltic-Finnic and Lapp gradations appear to be areally related. The Baltic-Finnic type, which represents a more plausible phonetic change, indicates that early Lapp may have acquired its gradation under Baltic-Finnic influence. The evidence within Baltic-Finnic points to a relatively late, post-Proto-Baltic-Finnic origin. The existence of analogous consonant weakening in various Samoyedic languages (Nganasan, Selkup) is the result of independent innovation.

Syllable-accent structures. Closely related to the gradation phenomena is the development of syllable-accent structures in Estonian, Livonian, and Lapp. Estonian is known for its unique quantity alternations of three contrastive vowel and consonant lengths—thus, *vara* "early" versus *vaara* "of the hillock" (*aa* = long *ā*) versus *vaara* "hillock (partitive)" (here *aa* = extra-long *â*); *lina* "linen" versus *linna* "of the city" (*nn* is pronounced as two short *n*'s) versus *linna* "into the city" (here *nn* is pronounced as long *n̄* plus short *n*; the contrast with the previous *nn* is not shown in the standard orthography). The extra-quantity contrast is in fact found with all stressed syllable types containing at least one vowel or consonant following its first vowel; thus, *taevas* "sky" (with short *e*) versus *taevas* "in the sky" (with long *ē*);

Length variations in Estonian sounds

osta "buy!" (with short *s*) versus *osta* "to buy" (with long *s̄*), whereas a two-syllable form such as *osa* "part" (*o/sa*) with only a single vowel in the first syllable is incapable of such a quantity contrast. A multitude of analyses of Estonian quantity have been proposed, although not all have recognized the phenomenon as a function of whole syllables bound to stress—in other words, that it is an accent phenomenon. One orthographic dictionary (by E. Muuk), for example, utilizes this principle, placing a grave accent mark before syllables with extra quantity. Otherwise, Estonian orthography marks the three degrees of duration only for stops: *b, d, g* indicate single short (voiceless lenis) stops (*tuba* "room"); *p, t, k* are plain geminates, or double consonants (*tupe* "of the sheath"); and *pp, tt, kk* mark extra-long geminates (*tuppa* "into the room," *tuppe* "into the sheath"). Because the extra quantity is in part tied to an original open next syllable, it frequently operates together with gradation alternations; *e.g., linnu* "of the bird" versus *lindu* "bird (partitive)," with extra quantity.

The syllable quantity accent in Lapp superficially resembles that in Estonian and, like the former, occurs only under stress and is in part conditioned by the openness of the next syllable. In North Lapp (Utsjoki), alternations in paradigms involve three grades of quantity shaping: *mânâm* "I go" (*â* is a Lapp letter for a somewhat rounded *a*) versus *mânna* "he goes" versus *mân'ne* "goer"; *dieδam* "I know" versus *dietta* "he knows" versus *diet'te* "knower"; *juol'ge* "leg" versus *juolge* "of the leg." This series of contrasts shows a three-stage decrease in initial-vowel duration and a three-stage increase in the duration of the first consonant after the first vowel or vowels. The other northern and eastern Lapp languages display similar alterations, but there is considerable diversity in the phonetic details.

Grammatical characteristics. The grammatical structures of the various Uralic languages, despite numerous superficial differences, generally indicate a basic Proto-Uralic sentence structure of (subject) + (object) + main verb + (auxiliary verb)—the parenthesized elements are optional, and the last element is the finite (inflected) verb, which is suffixed to agree with the subject in person and number. This pattern has been best preserved in the more eastern languages, especially Samoyed and Ob-Ugric; *e.g.*, Nenets *ŧiky pevśumd'o-m saravna t'eńe-va*ʔ "we well remember that evening" (literally, "that evening-[accusative] well remember-we"); Mari *joltaš-em-blak lum tol-mə-m buč-aš tüŋal-ət* "my friends begin to wait for the coming of snow" (literally, "friend-my-[plural] snow coming-[accusative] wait-to begin-they"). This order is common but optional in the languages of central Russia. Lapp, Baltic-Finnic, and Hungarian now show the typical European subject–verb–object order; *e.g.*, Finnish *isä osti talo-n* "father bought a house (-genitive)," Hungarian *János keres egy ház-at* "John seeks a house (-accusative)." Although these more western languages have relatively "free" word order, the object precedes the verb only for special emphasis; *e.g.*, Hungarian *János egy házat keres* "John is looking for a *house* (and not something else)," Estonian *ma ta-lle nuia ei anna* "I won't give *him* a *club*" (literally, "I him-to club not give"). Estonian sentence structure somewhat resembles that of German, with its tendency to place the finite verb in second position while the rest of the verb complex remains at the end of the sentence; *e.g., mehe-d ol-i-d ammu koju jõud-nud* "the men had got home long ago" (literally, "man-[plural] be-[past]-they long-ago home get-[past participle]").

Proto-Uralic sentence structure

In place of a verb "have," the Uralic languages use the verb "be," expressing the agent in an adverbial (locative or dative) case; *e.g.*, Finnish *isä-llä on talo* "father has a house" (literally, "father-at is house"), Hungarian *János-nak van egy ház-a* "John has a house" (literally, "John-to is one house-his"). In Proto-Uralic the copula verb "be" was lacking in simple predicate adjective or noun sentences, although the predicate was probably marked to agree with the subject. The following Hungarian sentences reflect this situation: *a ház fehér* "the house [is] white," *a ház-ak fehér-ek* "the houses [are] white." In Nenets and Mordvin such nonverbal predicates are conjugated for subject agreement and tense in the manner of intransitive verbs; *e.g.*, Nenets *mań xańenadm*ʔ "I am a hunter," *pydańi*ʔ *xańenadi*ʔ "you two are hunters," *mań xańenadamź* "I was a hunter," *pydara*ʔ *xańenadać* "You (plural) were hunters." Otherwise, a wide range of grammatical usage is found. In Baltic-Finnic and Lapp the use of a copula verb is obligatory, in Permic it is optional, and in Hungarian the copula is absent only in the 3rd person ("he, she") in a nonpast tense.

Negative sentences in Proto-Uralic were indicated by means of a marker known as an auxiliary of negation, which preceded the main verb and was marked with suffixes that agreed with the subject, and perhaps tense. This is best reflected in the Finnic and Samoyedic languages; *e.g.*, Finnish *mene-n* "I go," *e-n mene* "I don't go," *mene-t* "you go," *e-t mene* "you don't go." Ugric employs undeclined negative particles (*e.g.*, Hungarian *nem*), and in Estonian only negative imperative forms are still conjugated, although colloquial Estonian has initiated a tense distinction; *e.g., ma/sa ei tule* "I/you don't come" and *ma/sa e-s tule* "I/you didn't come."

Use of negative sentences

In Proto-Uralic questions were formed with interrogative pronouns, beginning with **k-* and **m-*, illustrated by Finnish *kuka* "who," *mikä* "what" and Hungarian *ki* "who," *mi* "what." Yes–no questions were formed by attaching an interrogative particle to the verb, as in Finnish *mene-n-kö* "am I going?", *e-n-kö minä mene* "am *I* not going?" (in Finnish, the verb also shifts to initial position). The use of intonation (changes in pitch) in interrogative sentences is currently widespread. In Hungarian it is the only way to form direct yes–no questions, although in indirect questions a particle *-e* is used; *e.g., a házak fehérek?* (with sharply rising intonation of the next to the last syllable, dropping again on the final syllable) "are the houses white?", *nem tudom, fehérek-e a házak* "I don't know whether the houses are white."

Conjunction, the connecting of clauses, phrases, or words, was formerly without the aid of specialized conjunctions. In the modern languages the conjunctions are largely borrowings from Germanic (Finnish *ja* "and") and Russian (Mari *da* "and; in order to," *a* "but," *ńi . . . ni* "neither . . . nor," *jesle* "if"). Both coordination and subordination in sentences are marked by a wide range of constructions, especially by means of infinitive verbs, participles, and gerunds; e.g., Mari *keče peš purgəžan poranan ulmaš* "the weather was very stormy and snowy" (literally, "weather very stormy snowy was"), *ača-ž aba-št* "their father and mother" (literally, "father-his mother-their"), *nuno batə-ž-den* "he and his wife" (literally, "they wife-his with"); Finnish *kirja-n lue-ttu-a-ni* "when I had read the book, . . ." (literally, "book-[genitive] read-[past passive participle-partitive case]-my"), *luke-akse-ni kirja-n* "in order for me to read the book" (literally, "read-to-[translative case] my book-[genitive]").

Case suffixes and postpositions were and are used to show the function of words in a sentence. Prefixes and prepositions were unknown in Proto-Uralic. Adjectives, demonstrative pronouns, and numerals originally did not show agreement in case and number with the noun, as is still the case in Hungarian; *e.g., a négy nagy ház-ban* "in the four large houses." Finnish, however, has initiated a case–number agreement system much like that in neighbouring Indo-European languages; *e.g., neljä-ssä iso-ssa talo-ssa* "in the four large houses." The case system of the Proto-Uralic language contained an unmarked nominative case, an accusative, a case of separation (ablative), a locative (essive) case, and a case of direction (lative), plus possibly several others. The modern languages show a range of from three cases in Khanty, six in Lapp, 14 in Finnish, up to 16 to 21 for Hungarian (the case status of several suffixes is debatable). The average number of cases is around 12. For the most part, these cases are the same for all nouns (nouns are not classified for gender; and 3rd person pronouns generally do not distinguish between "he, she"), singular and plural, and many are similar in function to English prepositions.

Cases in the modern Uralic languages

The distinction between a case and a preposition is often based on arbitrary and superficial criteria. Postposi-

Table 3: Case Endings in Several Uralic Languages

Finnish	Komi	Hungarian	Nenets	English translation
talo-ssa	*kerka-yn*	*ház-ban*	*xarda-xa-na*	"in (the) house"
talo-i-ssa	*kerka-jas-yn*	*ház-ak-ban*	*xarda-xa-ʔ-na*	"in (the) houses"
talo-sta	*kerka-yś*	*ház-ból*	*xarda-xa-d*	"from (the) house"
talo-i-sta	*kerka-jas-yś*	*ház-ak-ból*	*xarda-xa-t* (from *xa-ʔ-d*)	"from (the) houses"

tions, preposition-like elements placed at the end of words, are generally more independent, and also function as adverbs. They often resemble inflected nouns (*e.g.*, Finnish *takana* "behind": *talo-n takana* "[at] behind the house [-genitive]," *talo-n taka-a* "from behind the house," *taka-osa* "back part").

The original case relationships of essive–lative–ablative form a three-way set of contrasts that has been extended into several parallel series of cases in the modern languages—perhaps under areal influence. For example, Finnish uses essentially the original three in relatively abstract functions (essive, a state of being, *-na*; translative, a change of state, *-ksi;* partitive, a case of separation, [*-t*]*a*), and also adds an *-s-* element to indicate internal relationship (*-ssa* from **s* + *na* "in"; *-hen*, or a vowel + *n*, etc. from **s* + *ń* "into"; *-sta* "out of"), and an *-l-* element to indicate external relationship (*-lla* from **l* + *na* "on, at," *-lle* from **l* + *k* "onto, to," *-lta* "off of, from"). Hungarian has nine cases similarly organized into three series of three, the internal set of which (*-ben* "in," *-be* "into," *-ből* "out of") has recently developed from a noun with the meaning "intestines" (*bél*). In Finnish the personal pronouns are declined throughout on a pronoun stem; *e.g.*, *minä* "I," *minu-ssa* "in me," *minu-n* "me (genitive)," and so on. In Hungarian, however, only the nominative and accusative forms are formed this way, and the remaining cases are formed by adding the possessive suffixes to a form of the case marker (sometimes expanded); *e.g.*, *te* "you (singular)," *teged-et* "you (accusative)," *benn-ed* "in you," *belé-d* "into you," *belő l-ed* "out of you."

Number in Uralic nouns

The inflection of nouns for number (singular and plural) in the Uralic languages is much looser than in the Indo-European languages. Suffixes for the plural in the various Uralic languages are so diverse as to suggest that early stages of Uralic did not possess a specialized number marker; *e.g.*, Finnish *-t* and *-i-*, Mari *-blak*, Komi *-jas*. A dual-plural distinction ("two" as opposed to "more than two") is found in Lapp, Ob-Ugric, and Samoyedic, but here again the specific elements cannot be traced to a common source. If Proto-Uralic had plural and dual suffixes, they were probably used only with the personal pronouns. In the modern languages personal pronouns often take a plural marker different from that of the nouns, and in Lapp the dual formation is restricted to pronouns and personal affixes.

The category of definiteness (like English "the") is marked in numerous ways in the modern languages and originally appears to have been tied to the manner of number marking in Uralic (plural being reflected by indefiniteness). Hungarian alone has a definite article, *a(z)*, a demonstrative in origin; Mordvin has three sets of inflectional endings: indefinite, definite singular, and definite plural (*kudo-so* "in a house," *kudo-so-ńt'* "in the house," *kudo-t'ńe-sə* "in the houses"). Nearly all the more eastern members have a definite marker that is identical with the 3rd or 2nd person possessive suffix (Komi *kerka-ys/yd* "the house" or "his/your house").

In possessive constructions the possessor noun precedes the possessed noun, or in the case of a personal pronoun possessor, possessive suffixes are used; *e.g.*, Finnish *isä-n talo* "father's house" (*-n* = genitive, *talo-ni/si* "my/your house"; Hungarian *János ház-a* "John's house" (*-a* = possessive construction marker), *ház-am/ad* "my/your house." Although in earlier stages the possessive suffixes followed the case suffixes, more recent case formations (especially from original postpositions) have led to restructuring of this order; *e.g.*, Finnish *talo-i-ssa-ni* "in my houses," but Hungarian *ház-a-i-m-ban* "in my houses" (*-i-* = plural); Komi *kerka-yd-ly* "for your house" (*-yd-* = "your"), *kerka-ś-yd* "from your house," where two fixed orders coexist. The Proto-Uralic comparative construction was similar to the Finnish *talo-a iso-mpi* "house-from larg-er" (= "larger than a house"); *cf.* Hungarian *egy ház-nál nagy-obb* "house-by larg-er" (in dialects also *ház-tól* "house-from"); Komi *kerka dor-yś yǐyd-ǰyk* "house by-from larg-er." Parallel "than" type conjunctions are now common in the more western languages; *e.g.*, "larger than a house" in Finnish can also be expressed as *isompi kuin talo* (*kuin* = "than"), and in Hungarian *nagyobb mint egy ház* (*mint* = "than").

Compounding and derivation in word formation

The formation of nouns in Proto-Uralic included compounding (adding two or more words together) as well as derivation by the use of suffixes (word endings). In noun + noun constructions, including titles of address, the qualifying noun came first; *cf.* Hungarian *házhely* "house site," *Szabó János úr* "Mr. John Szabó"; Finnish *taloryhmä* "group of houses," *Sirpa täti* "Aunt Sirpa." The rich system of derived words in Uralic together with the various inflectional suffixes led to relatively long words; *cf.* Finnish *talo-ttom-uude-ssa-ni-kin* "even in my houselessness" (literally, "house-less-ness-in-my-even"), Hungarian *ház-atlan-ság-om-ban* "in my houselessness."

The Proto-Uralic verb was inflected for tense-aspect (**-pa* indicated "nonpast," **-ka* indicated "perfect nonpast; imperative," **-ja* indicated "past") and mood (**-ne* indicated "conditional-potential"). The use of auxiliary verbs to indicate tenses was unknown, although Lapp, Baltic-Finnic, and Hungarian now have essentially a Germanic-type tense system, with perfect formations based on the "be" verb; *e.g.*, Finnish *mene-n* "I go," *ole-n men-nyt* "I have gone" ("be-I go-[past participle]"), *men-i-n* "I went," *ol-i-n men-nyt* "I had gone," *men-isi-n* "I would go," *ol-isi-n men-nyt* "I would have gone." Under Germanic and Slavic influence both Estonian and Hungarian have developed separable verbal prefixes with adverbial and aspectual meanings; *e.g.*, Estonian *ära söö-* "eat (perfective)" and *ta sõ-i kala ära* "he ate the fish" versus *ta sõi kala* "he was eating fish," *ta hakkas kala ära söö-ma* "he began to eat (up) the fish"; Hungarian *meg-tanul* "learn" (perfective) and *János megtanul-t magyar-ul* "John learned Hungarian" versus *János tanult magyarul* "John was learning Hungarian," *János tanult meg angolul* "*John* learned English," *János nemetül tanult meg* "John learned *German*" (with special emphasis as indicated).

Proto-Uralic did not have specialized voice markers, such as the Indo-European passive; rather, the function of voice was interwoven with topicalization (a way of indicating the main subject of a sentence), emphasis, and definiteness of the subject and object as well as with verbal aspect. An indefinite subject of an intransitive verb or an indefinite object were marked with the ablative case (**-ta*), but a definite object took the accusative marker (**-m*) and other subject situations were unmarked (nominative). This system is best preserved in Finnish: *vesi* (-nominative) *juoksee* "the water is running" versus *vettä juoksee* "there is water running," *juon vede-n* "I will drink the water" (*-n* is from older **-m*) versus *juon vettä* "I drink water," (Note that aspect as well as tense is affected by these case distinctions.)

Subjective and objective conjugations

The widespread use of separate subjective and objective conjugations among the Uralic languages (as in Mordvin, Ugric, and Samoyedic) are the result of an original system for singling out the subject or object for emphasis (focus), and not simply a device for object–verb agreement (similar to subject agreement). For example, Nenets *tymʔ xada-v* "*I* killed a deer (focus on the agent)" versus *tymʔ xada-dmʔ* "I killed a *deer* (focus on the object)," in which *-v* signifies "I . . . it" (the objective conjugation) and *-dmʔ* signifies "I" (the subjective conjugation). Note also the objective forms *xada-n* "I killed [them]," *xada-r* "you (singular) killed [it]," *xada-d* "you (singular) killed [them]," and so on for nine possible subjects (three persons times singular, dual, plural) times two object numbers (singular and nonsingular [not actually distinguished with 3rd-person subjects]); and the subjective forms *xad-n* "you (singular) killed" and so on, for nine subject agreements. Hungarian similarly opposes definite and indefinite conjugations: two

different sets of personal endings are used—one with transitive verbs with definite objects and the other elsewhere; *e.g.*, *olvas-om/od a level-et* "I/you read the letter" versus *olvas-ok/ol egy level-et* "I/you read a letter." Along with its subjective and objective conjugations Khanty has added a so-called passive conjugation (*cf. kitta-j-m* "I am being sent," *-j-* = "passive") as an extension of the earlier focus-topicalization system. Mari and Komi have two past tense formations with related function. Again, the westernmost languages have passive constructions similar to those in Slavic and Germanic.

Verbal derivation was richly developed already in Proto-Uralic with a wide variety of verbal nouns, infinitives, and participles. Each of the three tense-aspect markers was apparently used as a participial formative (*cf.* Finnish *lähde* from **läkte-k* "source," *lähtijä* "one who leaves," *lähte-vä* from **-pa* "leaving"). Several of the modern languages have made extensive use of their native derivational processes to eliminate foreign loanwords; *e.g.*, for "telephone" Finnish has *puhelin*, which is derived from *puhel-* "talk," just as *soitin* "musical instrument" comes from *soitta-* "to play." The Uralic finite verb originally may have been based on participial constructions parallel to the noun plus predicate adjective sentences (like Hungarian *a ház fehér* "the house [is] white"). Thus, one may reconstruct sentences like **ema tumte-pa* "mother [is] knowing," **ema tumte-pa-ta* "mothers [are] knowing" (with subject number expressed only in the predicate [agreement]) to explain the close similarity of participial and finite verb constructions such as Estonian *tundev ema* "knowing mother," *tundvad emad* "knowing mothers," *ema tunneb* "mother knows," *emad tunnevad* "mothers know."

Ural Mountains

The major part of the traditional boundary between Europe and Asia, the Ural Mountains are a rugged spine running more than 1,250 miles (2,000 kilometres) from the fringe of the Arctic in the north to the Ural River Valley, at the same latitude as Paris, in the south. The low, severely eroded Pay-Khoy Ridge forms a fingerlike extension to the northern tip of the Urals proper, with the long curve of Novaya Zemlya forming an insular extension separating the Barents and Kara seas. The Mugodzhar Hills form a broad, arrowhead-shaped southerly extension beyond the Ural Valley. The Urals are the first mountains to be reached by the traveller journeying eastward across the huge expanses of the eastern European plain, a factor that adds to their significance, for the maximum elevation at Mt. Narodnaya is but 6,214 feet (1,894 metres), a relatively low figure for great mountain ranges. The north–south course of the Urals cuts across the vast latitudinal landscape regions of the Eurasian landmass, from Arctic waste to semidesert; the Urals also separate the developed and populous western portion of the Soviet Union from the developing, mineral-rich Siberian region and are themselves the home of peoples with roots reaching deep into history. (For related information, see SOVIET UNION; and RUSSIAN SOVIET FEDERATED SOCIALIST REPUBLIC.)

The natural environment. *Physical features.* The Urals divide into five sections. The northernmost Polar Urals, extending 240 miles from northeast to southeast, are typically Alpine. Their highest peak is Mt. Pay-Er, 4,918 feet (1,499 metres). The next stretch, the Nether-Polar Urals, is on a larger scale, boasting, in addition to Mt. Narodnaya itself, Mt. Karpinsk, at 6,161 feet (1,878 metres) the second highest peak of the whole range. These first two sections are strewn with glaciers and heavily marked by permafrost (a permanently frozen layer of soil). Farther south come the Northern Urals, with most mountains topping 3,300 feet, the highest, Mt. Telpos-Iz, rising to 5,305 feet (1,617 metres). Many of the summits are flattened, the remnants of ancient peneplains (eroded surfaces of large area and slight relief) uplifted by recent tectonic (relating to deformation of the Earth's crust) movements. In the north, intensive weathering results in vast "seas of stone" on mountain slopes and summits. The lower Central Urals rarely exceed 1,600 feet, though the highest peak, Mt. Kachkanar, rises to almost twice the average. The summits are smooth, with isolated residual outcrops. The last portion, the Southern Urals, follows a north-northeast to south-southwest direction and consists of several parallel ridges rising to 3,900 feet, culminating in Mt. Yamantau, 5,374 feet (1,638 metres).

The Urals' five sections

The rock composition helps shape the topography: the high ranges and low, broad-topped ridges consist of quartzites (compact rock composed of quartz), schists (crystalline rocks separable into thin plates), and gabbro (another type of rock), all weather-resistant. Buttes (isolated hills with steep sides) are frequent, and there are north–south troughs of limestone, nearly all containing river valleys.

Geological structure and mineral resources. The Urals date from the structural upheavals of the Hercynian orogeny (about 250,000,000 years ago). In the Upper Carboniferous and Permian periods (280,000,000 years ago) arose a high mountainous region, which, at the end of the Paleozoic and during the Mesozoic eras (about 200,000,000 years ago), was eroded to a peneplain. Alpine folding resulted in new mountains, the most marked upheaval being that of the Nether-Polar Urals. This slow uplifting still continues. In the watershed region lies the Ural-Tau Anticlinorium (a rock formation of arches and troughs, itself forming an arch), the largest in the Urals, and in the Southern Urals, west of it, is the Bashkir Anticlinorium. Both are composed of layers (sometimes four miles thick) of metamorphic (heat-altered) Precambrian and Lower Paleozoic rocks (from 570,000,000 to 395,000,000 years old), gneisses (metamorphic rocks separable into thin plates), quartzites, and schists.

The western slope of the Urals is composed of Middle Paleozoic (about 340,000,000 years ago) sedimentary rocks (sandstones and limestones). In many places it descends in terraces to the Cis-Ural region (west of the Urals), to which much of the eroded matter was carried during the Upper Paleozoic Era (about 300,000,000 years ago). Here there are widespread karst (a starkly eroded limestone region) and gypsum, with large caverns and subterranean streams. On the eastern slope, volcanic layers alternate with sedimentary strata, all dating from Middle Paleozoic times (roughly 350,000,000 years ago). These rocks compose the Tagil-Magnitogorsk Synclinorium (a group of rock arches and troughs, itself forming a trough), the largest in the Urals. In the Central and Southern Urals, the eastern slope blends into broad peneplained foothills, where there are frequent outcrops of granite and often fantastically shaped buttes. To the north the peneplain is buried under the loose, easily pulverized deposits of the West Siberian Plain.

Sedimentary rocks of western slopes

The Urals are extremely rich in mineral resources, with variations on the eastern and western slopes according to

geological structure. Ore deposits, for example, notably magnetite, predominate on the eastern slope, where contact (the surface where two different rock types join) deposits are found, as at Magnitogorsk, Vysokogorsk, and Mt. Blagodat, as well as magmatic deposits (formed from liquid rock), as at Kachkanar. Sedimentary deposits are of less importance. Some ores contain alloying metals —vanadium, a gray-white, resistant element, and titanium—as impurities. The largest copper-ore deposits are at Gay, Gumeshki, and Turinsk, and nickel ores are known in the regions of Orsk, Ufaley, and Rezh. There are also large deposits of bauxite, chromite, gold, and platinum. Among the nonmetallic mineral resources of the eastern slope are asbestos, talc, fireclay, and abrasives. Gems and semiprecious stones have been known for a long time: they include amethyst, topaz, and emerald. Among the western deposits are beds of potassium salts on the upper Kama River and petroleum and natural-gas deposits in the Ishimbay and Krasnokamsk areas. Bituminous coal and lignite are mined on both slopes. The largest deposit is the Pechora bituminous coalfield, located far to the north, where transport connections with the industries of the Urals are lacking.

Climate. The climate is of the continental type, marked by temperature extremes whose presence becomes increasingly evident both from north to south and from west to east. The Pay-Khoy Range and the Polar Urals enjoy the moderating influence of the Arctic and the North Atlantic oceans, particularly in winter. In the Mugodzhar Hills and the Southern Urals, there are summer breaths of hot, dry air from Central Asia. Winds are for the most part westerly and bring precipitation from the Atlantic Ocean. In spite of their low elevation, the mountains exert a considerable influence on the moisture distribution, and the western slope receives more moisture than the eastern. Precipitation is particularly heavy on the western slope of the Nether-Polar and Northern Urals, as high as 40 inches. Northward and southward precipitation diminishes to about 14 inches. On the eastern slope there is less moisture (about ten inches) and snow: the depth on the western slope averages 30 inches and, on the eastern, 18 inches. Maximum precipitation occurs in the summer, for the cold, dry air of the Siberian anticyclone is powerful in winter. The eastern slope is particularly chilled, and winter lasts longer than summer throughout the Urals. In January the average temperature in the north is −5.8° F (−21° C), and in the south the average is 5° F (−15° C). Average temperatures in July vary more, between 50° F (10° C) in the north and 72° F (22° C) in the south.

Precipitation

Drainage. The rivers flowing down from the Urals drain into the Barents, Kara (two gulfs of the Arctic Ocean), and Caspian seas. The Pechora River, which drains the western slope of the Polar, Nether-Polar, and part of the Central Urals, empties into the Barents Sea. Its largest tributaries are the Ilych, Shugor, and Usa. Almost all the rivers of the eastern slope belong to the Ob River system (*q.v.*), emptying into the Kara Sea. The largest are the Tobol, the Iset, the Tura, the Tavda, the Severnaya Sosva (Northern Sosva), and the Lyapin. The Kama (a tributary of the Volga) and the Ural rivers belong to the drainage basin of the Caspian Sea. The Kama collects water from a large area of the western slope: the Vishera, Chusovaya, and Belaya all empty into it. The Ural River, with its tributary the Sakmara, flows along the Southern Urals.

The location and character of the Urals' rivers and lakes are closely connected with the topography and climate. In their upper reaches many rivers flow slowly through the mountains in wide, longitudinal troughs. Later they change to a latitudinal direction, cut through the ridges in narrow valleys, and descend to the plains, particularly in the Northern and Southern Urals. The main watershed does not correspond with the highest ridges everywhere. The Chusovaya and Ufa rivers of the Central and Southern Urals, which later join the Volga drainage basin, have their sources on the eastern slope.

The rivers on the western slope carry more water than those of the east, particularly in the Northern and Nether-Polar Urals; the slowest rate of flow is on the eastern slope of the Southern Urals, reflecting intense evaporation as well as low precipitation. In winter the rivers freeze for five months in the south and for seven months in the north.

There are many lakes, especially on the eastern slope of the Southern and Central Urals. The largest ones are Uvildy, Itkul, Turgoyak, and Tavatuy. On the western slope are many small karst lakes. In the far north, lakes occur in glacial valleys, the deepest of them being Lake Bolshoye Shchuchye, at 446 feet deep. Medicinal muds are common in a number of the lakes, such as Moltayevo, and spas and sanatoriums have been established.

Vegetation. The Urals pass through several vegetation zones, with the northern tundra giving way to vast mixed forests, while still farther south is the steppe, culminating in semidesert around the Mugodzhar Hills. Small nooks of mountain tundra still occur in the Southern Urals, where the foothills merge with steppe, especially in the east. Feather grass and meadows predominate on the chernozems (black earth) and dark-chestnut soils (a characteristic steppe soil). Other characteristic growths are clover, feather grass, fescue (a pasture grass), and timothy (a grass grown for hay). South of the Ural River the steppes give way to wormwood and semidesert growths on light-chestnut soils (again typical steppe soil), highly saline in places. Many steppe regions of the Southern Urals have been plowed up and converted to arable lands, and large areas grow wheat, buckwheat, millet, potatoes, and vegetables.

Forests appear about 100 feet up in the Southern Urals. Lindens, oaks, maples, birches, and pines grow on the western slope, and undergrowth consists of reed grass, ferns, and other plants. The predominant soils are of the gray mountain-forest type, loamy and clayey. The broadleaf forests extend to 2,100 feet, above which conifers appear. On the eastern slope there are no broadleaf trees except the linden, and magnificent pine forests with some larches are widespread.

Farther northward forests of spruce, fir, pine, and larch grow on mountain-taiga (a vast, swampy, coniferous region of Siberia), podsolic (type of soil developing in temperate or cold, moist climate) soils. In the more northerly regions, dark coniferous species are common, and, in the Northern Urals, the Siberian cedar is widespread. Here, forests climb to 2,800 feet or so, above which is a narrow belt of thin larch and birch, trailing off to mountain tundra. In the Nether-Polar and Polar Urals, the forest yields to mountain tundra as low as 1,400 feet up. North of the Arctic Circle there is only brushwood and moss-lichen tundra on the Pay-Khoy Ridge. The forests of the Urals are of great economic importance: they yield valuable wood, regulate the flow of the rivers, and shelter many valuable animals.

Economic importance of the Ural forests

Animal life. There are no specifically mountain animals, primarily because of the low elevations and easy accessibility, and fauna differs little from that of eastern Europe and Western Siberia. In the last few centuries, valuable animals such as the Arctic fox, sable, and beaver have become scarcer, but the Soviet period has witnessed conservation measures, especially in the Ilmen and Bashkir national preserves in the Southern Urals and the Pechoro-Ilych National Preserve in the Northern Urals. New species have been introduced, for example, the spotted deer and muskrat. The most valuable animal of the tundra is the Arctic fox, and trade in its fur is flourishing. The lemming, the tundra partridge, and the reindeer are other inhabitants, though the latter are few. Many wild ducks, geese, and swans breed there in summer. But the richest and most varied fauna in the Urals, such as the brown bear, lynx, wolverine, and elk, are found in the forested zones. Some have valuable furs: the sable, ermine, fox, Siberian weasel, and squirrel. In the taiga forests there are such birds as the wood grouse and the hazel hen (a woodland grouse). Down in the mixed, broadleaf forests of the Southern Urals' western slopes live roe deer, badgers, and polecats, as well as many birds typical of the European part of the Soviet Union, such as the nightingale and oriole. The commonest animals of the steppes

and semideserts are rodents, including susliks (a type of ground squirrel), jerboas (a social, nocturnal, jumping rodent), and other agricultural pests. Predators include the Siberian polecat and Afghan fox. The rivers and lakes of the Northern Urals abound in fish, the most valuable being the nelma (related to the whitefish), common salmon, grayling, and sea trout. Farther south, in the densely populated and industrial regions, animal life is less abundant.

The human imprint. *Population.* Human habitation of the Urals dates from the distant past. The Nentsy (Samoyeds—a Finno-Ugrian people) are natives of the Pay-Khoy region, and their language belongs to the Samoyedic group of languages, which is widespread throughout Northern Siberia. Farther south live the Komi, Mansi (Voguls), and Khants (Ostyaks), who speak a tongue belonging to the Ugric group of the Finno-Ugric languages (a family of languages spoken in Hungary, Finland, and parts of Russia). Another group, the Bashkirs, long settled in the Southern Urals, speak a tongue related to the Turkic group. Most of these formerly nomadic peoples are now settled. The majority of the population centres are concentrated in river valleys and on the lower slopes. The Nentsy, Komi, Mansi, and Khants are virtually the only inhabitants in the highest parts of the Urals, especially in the north, where they have preserved their traditional ways of life, raising reindeer, hunting, and fishing. The Bashkirs are excellent horse breeders. These people are nevertheless being drawn increasingly both to industries and to agriculture, part of a vigorous economic development of the Urals that has attracted large numbers of people (mostly Russians) from other parts of the country. The total population of the entire Ural region approached 20,000,000 in the early 1970s, while that of the Ural Economic Region, an administrative unit, exceeded 15,000,000. The Russian population is concentrated primarily in the Central and Southern Urals, and most people live in cities (notably Sverdlovsk, Chelyabinsk, Perm, and Ufa) and work in industries. The population of the central and southern Cis-Ural and Trans-Ural regions is primarily agricultural, where conditions are very favourable for wheat, potatoes, and other crops.

History, discovery, and exploration. The existence of the Riphean and Hyperborean mountains at the eastern fringe of Europe in antiquity was regarded as being more mythical than real. Not until the 10th century AD does the first mention of the Urals occur, in Arabic sources. At the end of the 11th century, the Russians discovered the northernmost part of the Urals, but they did not complete the discovery of the entire range until the beginning of the 17th century, when the mineral wealth of the Urals was discovered. Systematic extraction of iron and copper ore began early in the 18th century, and the Urals rapidly became one of the largest industrial regions of Russia. The first serious scientific study of the Urals was made in 1770–71. Scholars studying the Urals during the 19th century included several Russian geologists and also such prominent foreign scholars as the German naturalist Alexander von Humboldt. Much work has been done in the Soviet period on geological structure and associated mineral resources, while topographical research has discovered recent glaciation in the Polar and Circumpolar Urals.

Scientific studies of the Urals

Future prospects. With their rich natural resources, the Urals have become one of the foremost Soviet industrial regions. Mineral reserves are sufficient to allow increasing production of various metals. With the continuing eastward shift of the Soviet population, the whole region is likely to continue to be of major importance, though traces of traditional ways of life will doubtless remain.

Uranium Products and Production

Uranium—a dense, hard, radioactive nickel-white metal with the heaviest atomic weight of any naturally occurring element—was known for 150 years before any serious application could be found for it. The discovery in 1938 that the uranium nucleus could be made to fission, or split, when bombarded with neutrons suddenly opened the dramatic possibility that the uranium atom could be made to give up its energy in a sustained chain reaction. One pound of uranium—in size, about 1 cubic inch—can, in such a reaction, yield as much energy as 3,000,000 pounds of coal. As a consequence, intense study of the element was launched together with extensive exploration for its ores. The first nonlaboratory application of the 1938 discovery was military, in the form of the original atomic bomb dropped on Hiroshima in 1945. After World War II, exploitation of atomic energy as a power source and for other peaceful purposes was developed in the United States, Great Britain, the U.S.S.R., France, and other countries. By the 1970s uranium had become a metal of vast economic significance.

History. The discovery of uranium is usually attributed to Martin Heinrich Klaproth, a Berlin apothecary and an outstanding analytical chemist, who described it in a lecture to the Royal Prussian Academy of Science in 1789. Mineralogists had tended to classify the mineral pitchblende, found in Joachimsthal (now Jáchymov, Czechoslovakia) and in the Erzgebirge (Germany), as an ore of zinc. Klaproth processed the mineral to produce specks of a black substance, which he termed uranit, a new metal, but which in fact must still have been an oxide or mixture of oxides of uranium. A year later Klaproth changed the name from uranit to uranium, after the planet Uranus, which had been discovered in 1781. He continued to work with this substance and by the end of the 18th century had prepared nitrate, sulfate, formate, and acetate compounds of uranium.

A French chemist, Eugène-Melchior Peligot, was the first man to succeed in extracting the metal (1841). He passed chlorine over heated "uranium," studied the products of the reaction, and found that the "uranium" he used was an oxide. Peligot then tried to reduce uranium tetrachloride with potassium in a heated platinum crucible. The potassium chloride dissolved away, leaving a black powder that was truly the element uranium.

First extraction

This new metal had an atomic weight of 120 ascribed to it, but Dmitry Ivanovich Mendeleyev, who developed the periodic table of the elements, found that that value did not accord with the properties expected on the basis of his table; he suggested that the correct value was 240. This hypothesis was subsequently confirmed, and the exact weight of 238.03 assigned. Scientific interest in the metal and its compounds was temporarily stimulated by French physicist Henri Becquerel's discovery of the radioactivity of uranium salts in 1896. In spite of this interest, however, in the early 20th century uranium found only very minor practical applications (as an occasional substitute for tungsten or as a colouring agent in glasses and glazes). But with the demonstration of uranium fission in the late 1930s and the harnessing of nuclear energy in the 1940s, scientific and technological study of uranium and its compounds was accelerated. It culminated in a massive release of information at the First International Conference on the Peaceful Uses of Atomic Energy (Geneva, 1955).

Occurrence. Uranium is estimated to be present in the earth's crust to the extent of about four parts per 1,000,000. It is thus considerably more abundant than gold and silver, ranking closer to tungsten and tantalum. Its presence in seawater amounts to 0.000001 to 0.000002 gram per litre. It is highly reactive and forms many compounds, some of which are water soluble.

Compounds of uranium are present in rocks of varying composition and origin. The actual concentration of uranium in most of these ores is low, however, and ore bodies suitable for economic mining are rare. Local concentrations of suitable ores may have occurred when uranium-rich compounds were exuded into rock faults after the molten uranium silicates in the earth's crust had crys-

tallized. Later the rock weathered, leaving deposits of the more chemically unreactive uranium minerals; other uranium minerals may have been taken into aqueous solution, transported, and subsequently precipitated as oxides after reacting with other materials.

Major ore locations

Uranium ore is found in Africa, in Zaire, and in the Witwatersrand region of South Africa; in France and Czechoslovakia; in Australia; in South America; in Canada, in the Great Bear Lake area and the province of Ontario; and in the western U.S. The U.S.S.R. and China are also believed to hold substantial deposits.

Primary, relatively unoxidized uranium minerals of particular importance are uraninite (a crystalline uranium form that is 45 to 85 percent uranium) and its black friable or massive variety, pitchblende; coffinite (hydrated uranium silicate; black, friable; 60 percent uranium); brannerite (uranium, thorium, calcium titanate; black; 30 to 40 percent uranium); davidite (rare earth, uranium, iron titanate; black; 7 to 10 percent uranium). Important secondary, oxidized uranium minerals are carnotite, autunite, and torbernite. Carnotite is a complex compound of uranium, potassium, vanadium, and oxygen; autunite is a calcium uranyl phosphate; and torbernite is a copper uranyl phosphate.

Mining. Ore deposits may be deep or shallow, regular or irregular, and may be found in association with a variety of other minerals. Most of the customary metal mining techniques are used, many quite technically advanced because of the relatively recent commercial interest in uranium.

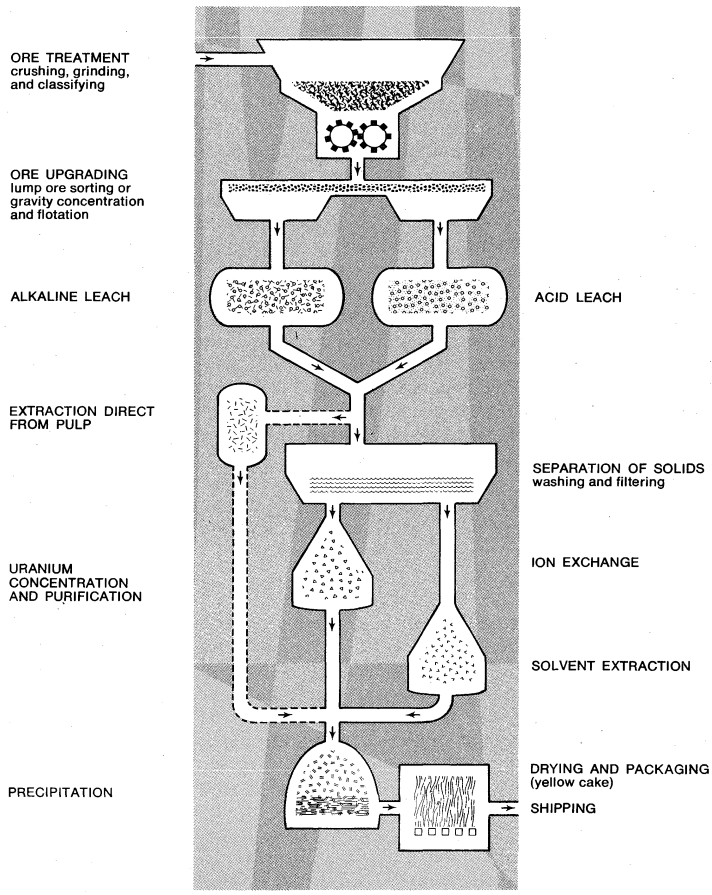
For the period 1955–70, the United States was the largest producer of uranium in the Western world, followed in order by Canada and the Republic of South Africa.

Surface mining. The methods of mining uranium at the surface are similar to those for mining other minerals and coal. The Lucky Mc Mine in Wyoming produces ore at the rate of 400,000 dry tons per year and in the process must remove at least 13,500,000 cubic yards of waste. Earth-removing vehicles with capacities of 1.5–2.5 cubic yards follow the narrow, winding lodes, mining out 2-foot-thick slices of ore, while scrapers remove the surrounding waste. Pit design is dictated largely by the stability of the rock; at the Lucky Mc, the slopes of the pit walls average 50 to 57 degrees with bench heights (the distance from one horizontal surface to another) of 70 to 90 feet and widths of 20 to 40 feet. Keeping the wall angle as steep as possible reduces the total volume of waste material, or overburden, that must be removed.

To set up a surface-mining program, engineers must determine the pit limits and ore reserves, as well as uranium content of the ore. Radiometric surveys to determine the extent and amount of the ore's radioactivity both prior to and during working may provide the first two sets of data; rapid spectrographic analysis measures content. This information must then be coupled with other relevant data in scheduling production. Computer systems are widely used in this process.

Underground mining. Techniques of underground mining vary somewhat with the nature of the ore body. Deposits that lie at depths of 1,000 to 4,000 feet, in thicknesses of up to 100 feet, and in strata sloping at angles of up to 45 degrees are extracted by the usual underground mining methods.

Basically, the ore is released from the main body of rock by blasting and then transported to collection points for transmission to the surface through vertical shafts. For a more detailed description of these and other mining techniques, see MINING AND QUARRYING; COAL MINING.



Control of ore grade quality is important and, again, radiometric assessment methods are widely used underground. Ventilation is of particular importance in underground uranium mining because of the presence of radon gas, one of the products of the radioactive disintegration of uranium. Radon also is radioactive and must be kept at a strictly regulated low level, to protect miners from overexposure to radiation.

Problems of underground operations

In South Africa, where uranium is a by-product of gold-ore processing, mining practice is determined by gold-mining requirements.

Refining and recovery. The chemical inertness of uranium minerals makes recovery difficult, but because of their relatively high density and hardness, mechanical enrichment of the ore is possible (see illustration). Such enrichment, or concentration, is necessary, since the bulk of uranium in most regions comes from ores that contain fewer than six pounds of uranium per ton of ore; the uranium mineral is finely distributed throughout a quartz-containing matrix.

Drawing by D. Meighan

Steps involved in the recovery of uranium.

Mechanical separation. The mined ore is first coarse-crushed, sometimes separated on the basis of its radioactivity, and then fine-ground and mixed with water to produce a slurry. The fine grinding exposes the uranium mineral for subsequent chemical attack. Mechanical concentration of the ore slurry is accomplished in a series of steps. First, the water is drained off; then the use of thickeners or filters, or both, creates a product suitable for leaching (dissolving out the uranium). Either acid or alkali agents are used in such leaching processes.

Leaching and purifying. In the most common leaching process dilute sulfuric acid is added to the pulverized ore in a pachuca, a vessel in which the mixture is agitated with compressed air. Mechanical stirring may also be used, along with high pressures and temperatures. Such leaching produces a rather crude solution of uranyl sulfate. Some ores, particularly those rich in carbonates and alkaline earths that would be expensive to acid-leach, can be alkali-leached by sodium carbonate, yielding sodium uranyl carbonate. The alkali-leach solution is generally more concentrated than that for the acid process, but, because the chemical reaction is specific in nature, finer initial grinding is necessary to ensure efficient breakdown of the uranium mineral in the alkali method.

After leaching, the crude solution is separated from the ore pulp by filtration or settling, with the raw mineral solution gradually concentrated as it moves along the processing line; the solution is then purified by various chemical techniques. Precipitation from the purified solu-

tion, separation, and drying constitute the final stages of the extraction of uranium concentrates. The solution is neutralized with caustic soda, ammonia, or magnesia. By controlling the acidity, the iron is precipitated out first and then the uranium, as a uranate, usually sodium diuranate, the principal component of yellow cake. After thickening, the uranium precipitate passes through automatic filter presses or vacuum filter drums and is allowed to dry. This crude uranium compound concentrate is in the form of a bright, claylike material. It contains about 60 percent by weight of uranium together with a variety of impurities.

Preparation for nuclear uses. The nuclear uses of uranium demand high purity in general, particularly a high degree of freedom from certain rare-earth metals, as well as from cadmium and boron, all of which have the ability to absorb neutrons. For the final purification stage uranyl nitrate solution is extracted in a process employing a concentrated solution of tributyl phosphate in kerosene or hexane. First the crude concentrate is dissolved in nitric acid, using either batch or continuous processes, yielding a solution of uranyl nitrate and silicic acid, which is separated out. The remaining uranyl nitrate solution containing about 200 grams of uranium per litre is purified by solvent extraction. The solvent is further purified to recover the uranium as an aqueous solution of uranyl nitrate of a purity suitable for nuclear purposes.

Final purification

Production of uranium and its compounds. Preparation of the oxides of uranium from the pure uranyl nitrate solution constitutes the next important processing stage. As these oxides are used in solid form to produce other uranium compounds, their physical state (particularly the size and distribution of particles) is of major importance and must be closely controlled.

Extraction processes. Extraction of the uranium oxide from the uranyl nitrate solution is accomplished by heating the nitrate in air. When heated below 300° C (570° F), the solution is converted to uranium trioxide; above 430° C (810° F), the oxide of uranium U_3O_8 is formed. Or uranium may be precipitated from the solution as bright yellow ammonium diuranate using ammonia or urea, or as hydrated uranium peroxide using hydrogen peroxide. These compounds are then thermally decomposed to give uranium trioxide, which is reduced to the dioxide by using hydrogen or cracked ammonia at 600° C (1,100° F), and above.

Uranium tetrafluoride, important in making uranium metal, is produced by reaction of uranium dioxide with anhydrous hydrofluoric acid at 450°–600° C (840°–1,100° F). The higher the temperature the more rapid the reaction rate, but a practical upper limit is imposed by the availability of structural materials and equipment able to withstand attack by hydrofluoric acid and the ability to control the reaction, which produces considerable heat. In all these refining methods the trend has been away from batch to continuous processes, which generally result in a more uniform product.

Preparation of uranium metal. Of the many processes for the preparation of uranium metal, the one in almost universal use employs uranium tetrafluoride with magnesium as the reducing agent. The compound is mixed with magnesium chips, compacted, loaded into a refractory container, and placed inside an electric resistance furnace in an argon atmosphere. The mixture is then heated; the reaction generates sufficient heat to melt both the resulting uranium and the magnesium fluoride. Because of the large differences in their specific gravities, the molten magnesium fluoride forms a slag on the uranium surface. Uranium ingots weighing about 3,000 pounds (1,360 kilograms) have been produced by this method.

Uranium oxides can also be reduced to a metal using calcium and magnesium in a similar manner, but of the reaction products only uranium is melted by the heat of reaction and is thus produced as a powder in a lime or magnesia matrix.

Uranium hexafluoride used in the gaseous diffusion enrichment process (see below) can be prepared by fluorinating the metal, an oxide, uranium tetrafluoride, or other compounds with fluorine, hydrogen fluoride, or halogen fluorides. The least amount of fluorine is needed for the fluorination of uranium tetrafluoride. This reaction, the basis of methods for industrial preparation of uranium hexafluoride, occurs at high temperatures (above 400° C, 750° F). Fluorination of the tetrafluoride with chlorine trifluoride, which requires lower temperatures (50°–150° C, 120°–300° F), is also used to produce uranium hexafluoride on an industrial scale. The hexafluoride may be handled as gas, solid, or liquid. Because this process, like much of the industrial chemistry of uranium compounds, entails major usage of highly corrosive fluorine and fluorine compounds, highly sophisticated chemical engineering techniques, standards, and equipment are required.

Applications of uranium and its compounds. *Fuelling nuclear reactors.* Uranium in elemental or compound form fuels nuclear reactors, principally for the generation of electricity. In practice, when the uranium is used in reactors, it is alloyed with minor amounts of aluminum and iron, which serve to minimize dimensional changes resulting from fission. Uranium alloyed with molybdenum also is used as fuel in some reactors.

Many different compounds of uranium have been explored as nuclear fuels. Uranium dioxide has so far proved the most economically attractive fuel for reactors in the production of electricity. Its use was being built into the systems of the majority of nuclear power stations being installed in the early 1970s. The fuel consists of pellets of uranium dioxide of about 95 percent theoretical density packed into a can of stainless steel or zirconium alloy. The dioxide has a low thermal conductivity and tends to fragment in the can under the thermal stresses imposed in service. The can protects the fissionable material from contamination from coolants, and prevents contamination of the coolant and hence the remainder of the reactor by fission products from the uranium.

Reactor fuel for power production

Uranium monocarbide, in contrast with uranium dioxide, is more metallic in nature, more chemically reactive, has a much higher thermal conductivity, and is better able to withstand thermal stresses. Its behaviour in a nuclear reactor is acceptable, but since its chemical reactivity is more akin to that of uranium metal, the choice of coolants for use with it is limited largely to molten sodium. Uranium carbide, therefore, is likely to find major application in sodium-cooled fast reactors.

Natural uranium contains only 0.7 percent of the fissionable isotope, uranium-235. In many reactor applications, this percentage must be increased, a process called enrichment. This is accomplished by a gaseous diffusion technique in which the lighter isotope uranium-235 diffuses through a membrane more rapidly than the heavier uranium-238. With a sufficient number of diffusion stages, enrichment can be carried out to any desired degree. Uranium hexafluoride, being gaseous at moderate temperatures and pressures, is the main feed material for this process. The by-product from such enrichment is uranium with most of its uranium-235 removed (primarily the isotope uranium-238), called depleted uranium.

Other uses. Efforts to find outlets for uranium outside nuclear technology have met with little success. Because it is more dense than lead, it has replaced that metal for some X-ray and gamma-ray shielding in which there is a need to minimize the volume of material, as in apparatus for medical therapy or as screening for remote-handling of radioactive material. As an oxide it can be used for catalytic purposes but has proved beneficial only in minor applications.

Economic importance. The needs of the nuclear power industry will probably determine the economic importance of uranium during the remainder of the century. By 1970 capacity for nuclear electrical generation exceeded 5,000,000 kilowatts in Britain, 3,000,000 kilowatts in the United States, and smaller but substantial amounts in France, Germany, Italy, Japan, the Soviet Union, and in some of the developing countries. Worldwide installations on order in 1970 totalled nearly 100,000,000 kilowatts, with capacities near 200,000,000 kilowatts projected for 1980.

Nuclear electrical generation

Within national power programs the balance among the

various methods of power generation is determined by social and political pressures as well as by economics. Within the industry, technological advances in reactor design are aimed at increasingly efficient use of uranium. These advances will culminate in the introduction of a new class of reactors called fast-breeder reactors, which produce more fissionable material than they use. In such reactors, uranium-235 will be supplanted by plutonium-239 as the important fissile material, thereby greatly reducing uranium demand.

It has been estimated that by the end of the century world demand for the basic raw material, the uranium oxide U_3O_8, will reach 165,000 tons per year, against a 1970 production of 23,707 tons and a peak of about 44,000 tons in 1959. Known mineral reserves recoverable within reasonable cost limits stood at a little less than 1,000,000 tons in 1970 and estimated reserves at an equivalent amount. If the demand reaches the expected level, a further reserve of 1,000,000 tons will be required by the year 2000. New ore discoveries are being reported continuously. A number of discoveries of the magnitude of the Queensland, Australia, ore body discovered in 1970, would help to remove any concern over supply. Other possible sources are low-grade deposits, expensive to mine, but economically feasible at a higher price; and the oceans, which have been estimated to contain 1,000,000,000 tons of uranium.

Uranus

Seventh in order of distance from the Sun, Uranus is the third largest of the planets of the solar system. Less than half the size of Jupiter, it has a diameter still four times that of the Earth. Although faintly visible to the naked eye, Uranus has been known as a planet for less than 200 years. It has five known satellites, a number exceeded only by the 12 of Jupiter and the ten of Saturn. Physically, Uranus is almost a twin of Neptune. These two, with Jupiter and Saturn, constitute the family of Jovian planets characterized by large size, low density, and compositions consisting primarily of the very light chemical elements. Hence, they are radically different from the terrestrial planets.

Discovery, naming, and early observations. The planets out through Saturn have been known since antiquity; Uranus was the first major solar-system body to be discovered after the invention of the telescope. The outstanding astronomer of the 18th century, William Herschel of England, undertook a survey of all stars down to the eighth magnitude—*i.e.*, those about ten times fainter than are visible to the naked eye—using a six-inch telescope of his own manufacture at his private observatory in Bath. On March 13, 1781, he found "a curious either nebulous star or perhaps a comet," distinguished from the stars by its clearly visible disk. Its lack of any trace of tail and its slow motion led almost immediately to the suggestion that the observations were consistent with a planet moving in a nearly circular orbit. Within a year, independent studies established that the orbit was planetary, with a radius exceeding 18 astronomical units (one astronomical unit is the mean Earth–Sun distance, 149,700,000 kilometres [93,000,000 miles]). The object was thus twice as far from the Sun as Saturn, and its discovery at once doubled the size of the known solar system.

Proposed names for the new planet

Three names were seriously considered for the new planet. Herschel proposed first to call his discovery Georgium Sidus (in English, Georgian Planet) after his sovereign patron, King George III of England. The name Georgian appeared intermittently in England for more than 50 years, especially in the *Nautical Almanac*. In France the name Herschel was also used occasionally until the middle of the 19th century. But already in the year of discovery the German astronomer Johann Elert Bode had suggested Uranus, as the father of Saturn in Roman mythology, who was, in turn, the father of Jupiter; and this name was eventually universally accepted.

Progressive improvements in knowledge of the motion made possible the projection of the orbit farther into the past, in a search for prediscovery observations for which accurate coordinates had been noted by observers who assumed the planet to be a star. The earliest of 22 such prediscovery observations proved to have been made in 1690, nearly a century before Herschel's discovery.

The orbit. The orbit of Uranus departs only slightly from a circle, the deviation corresponding to an elliptical orbit with eccentricity of 0.047. The mean distance from the Sun is 19.18 astronomical units; the eccentricity brings Uranus to a perihelion (or point nearest the Sun) of 18.3 astronomical units and an aphelion (point farthest from the Sun) of 20.1 astronomical units, corresponding to an extreme difference of about 10 percent. The orbit is very slightly inclined, by 0.73°, to the ecliptic plane (the Earth's orbit).

Uranus completes one revolution about the Sun in 84.01 years. In the nearly 300-year span over which at least some observations exist, the planet has thus completed about three and one-half revolutions. This is sufficient to test rigorously any proposed orbit of Uranus, including a careful accounting for the perturbations (gravitational influences) exerted by the other known planets of the solar system. But determinations of precise orbits for Uranus proved vexing from the beginning. By 1830 the observed motion departed from a best-fitting ellipse by an intolerable 15″ of arc. Several astronomers suggested that perturbations by a hitherto unknown planet, lying outside the orbit of Uranus, might explain the anomalies. Computations, first in 1845 by an English mathematician and astronomer, John Couch Adams, and in 1846 by a French astronomer, Urbain-Jean-Joseph Le Verrier, led to precise predictions of the position of the hypothetical planet. The resulting discovery of Neptune in 1846 provided a stunning vindication of gravitational theory.

Appearance and spectrum. Under good conditions, Uranus shows a perceptible blue-green disk, through even a four-inch telescope. The astronomically unusual colour is caused by absorption of red light in its atmosphere.

Reports of faint markings

Experienced visual observers report faint markings on the disk, in particular, grayish belts; but such features are far less conspicuous than the latitudinal cloud belts on Jupiter. Elusive faint spots plus darkening of the disk toward the limbs, or edges, of the planet are also reported. Such observations are difficult, since the disk of the planet subtends an angle less than 4″ of arc in the sky; and atmospheric conditions on Earth seldom permit features smaller than about 0.5″ of arc to be resolved. A fine series of pictures taken in 1971, resolving 0.1″ of arc, showed pronounced limb darkening but no clearly discernible surface markings with contrast as great as 5 percent.

On the visual stellar-magnitude scale, Uranus over the past century had an average brightness at mean opposition (that is, when closest to the Earth) of about 5.8 magnitudes (the faintest stars visible to the naked eye on a very clear, totally dark night are about 6.5). The observed brightness can change by half a magnitude from the mean, depending on the Earth–Uranus and Uranus–Sun distances and also possibly on real change of reflectivity. Recent accurate photoelectric measures give a mean-opposition (photoelectric–visual) magnitude of about 5.5.

Possible brightness changes. Some 3,000 visual observations made during 1916 showed a regular 15 percent variation of brightness with a period of 10 hours 49.4 minutes. This was taken to be the rotation period, but the large diffuse spots or areas presumably responsible for hemispheric differences in brightness apparently change with time, since observations of 1917–18 were not consistent with those of 1916. Other visual and photographic observers have found transient intervals in which a period very close to the 1916 value appears to be present in their data. But more accurate photoelectric observations, beginning in 1927 and including half a dozen series up through the 1950s, showed no detectable (1 to 2 percent) change in brightness with rotation. If the visual observations of variations are correct, either the spottedness is rare and transient, or the variation may be present only in red light, to which the eye is somewhat sensitive but which was generally excluded in the photoelectric observations so far reported.

In 1933 a summary of most of the observations for the previous 50 years contained evidence for two additional variations, each of about 30 percent, in the brightness of Uranus, with eight-year and 42-year periods, respectively. The longer interval coincides with half the orbital period of Uranus. If real, it probably arises from effects connected with the alternate presentation of equatorial and polar hemispheres to the Earth and Sun as a consequence of the planet's rotational axis lying nearly in its orbital plane; Uranus appears brightest when seen pole-on. A careful series of photoelectric observations in blue light at the Lowell Observatory beginning in 1949 failed to detect any eight-year variation exceeding the 1 percent level.

Effect of rapid rotation

The rapid rotation of Uranus on its axis leads to an appreciable reduction in the effective force of gravity at the equator, hence to a substantial oblateness (equatorial bulging). Direct micrometer measures give an equatorial diameter about 6 to 8 percent greater than the polar diameter, consistent with the amount of flattening expected theoretically.

For a rotating planet, spectral lines from the approaching limb are shifted to shorter wavelengths and from the receding limb to longer wavelengths (according to the phenomenon known as the Doppler effect) in a uniform progression across the planet. The tilt of the resulting spectral lines allows direct determination of the rotational velocity of the planet. Measures of this type made in the decades 1910–30 give for Uranus a rotation period about 10.75 hours, consistent with the photometric value.

Uranus' atmosphere. Since the 1860s the spectrum of Uranus has been known to contain deep absorption bands toward the red. In 1932 these were shown theoretically to be almost certainly due to methane (CH_4). Laboratory and high-resolution spectroscopic studies confirmed this. The photographic spectrum of Uranus is dominated by methane, corresponding to about 3.5 kilometre atmospheres of the gas. Like those of Jupiter and Saturn, the atmosphere must, nevertheless, consist primarily of hydrogen and helium; but, because both these gases are nearly invisible spectroscopically at low temperatures, the methane dominates. Weak hydrogen quadrupole lines are found in the spectrum of Uranus, in amounts consistent with some 480 kilometre atmospheres of this gas in the visible part of the atmosphere. Other common gases, such as water and ammonia, would be frozen out of the upper atmosphere and be present only at depths to which the line of sight from Earth cannot penetrate.

The temperature of a planet can be determined either by direct measurement of the infrared and radio radiation that it emits or by detailed spectroscopic studies of relative strengths of temperature-sensitive spectral features. Both techniques indicate that temperatures in the visible outer atmosphere of Uranus are in the range −150° to −200° C (−250° to −350° F).

Mass, radius, density, and composition. The orbital period and orbital radius of any satellite suffice to establish the mass of its primary, a result first derived by Newton. Determinations in 1950, using all five satellites, give Uranus a mass that is $\frac{1}{22,934}$ times that of the Sun, or about 14.5 times that of the Earth. The mass has also been determined from perturbations by Uranus on the orbit of Saturn, and in 1970 this method gave $\frac{1}{22,692}$.

The actual size of any object may be calculated from its distance and apparent angular size. For Uranus the best results for equatorial diameter are probably those made in 1902, 56,100 kilometres (34,900 miles), and 1949, 47,400 kilometres (29,500 miles). Several indirect arguments suggest adoption of the intermediate value 52,700 kilometres (32,800 miles), uncertain by 5 percent; this corresponds to 4.1 times the diameter of the Earth.

With the mass and diameter of Uranus given above, the average density is about 1.15 times the density of water; for comparison, that of Saturn is 0.71 and that of the Earth is 5.52. So low a mean density requires Uranus to be composed of materials far lighter than those that make up the Earth; otherwise, its greater mass would lead to compression producing greater central pressures and densities than the Earth's. By the same reasoning, its average composition must be somewhat heavier than that of Saturn. Theoretical models of Jupiter and Saturn are consistent with a total composition similar to the basic solar chemical abundance (roughly 70 percent hydrogen, most of the remainder helium). But in Uranus these two lightest elements must be accompanied by appreciable amounts of the next heavier common elements, especially carbon, nitrogen, and oxygen. Since comets are rich in these elements, preferential accretion of comet-like bodies in cool outer regions of the early solar nebula may have contributed greatly to the formation of Uranus.

The satellites. In 1787 William Herschel found two faint Uranus satellites, later called Oberon and Titania. The next two satellites, Ariel and Umbriel, were discovered in 1851 at Liverpool. The names for these first four satellites were apparently proposed by the English scientist and astronomer Sir John Herschel, the son of William Herschel. The last known satellite, Miranda, less than 10″ of arc from the planet, was first photographed in 1948 at the McDonald Observatory in Texas. There are probably no other satellites of Uranus brighter than 20th magnitude within a radius of 0.5° from Uranus.

Uranus's satellite system is compact and closely coplanar with the planet's equator. But, whereas the equators and satellite orbits of all the other planets of the solar system have only modest inclinations to the plane of the ecliptic, in the case of Uranus these are all curiously tilted, by an extreme 98°. Thus, the rotation of the planet and revolution of its satellites are essentially perpendicular to the orbital revolution of Uranus about the Sun. Further satellite data are shown in the Table.

Satellites of Uranus

Urartu and Armenia, History of

Urartu and Armenia are the names given to two ancient countries of southwest Asia centred in the mountainous region southeast of the Black Sea and southwest of the Caspian. Urartu, mentioned in Assyrian sources from the early 13th century BC, enjoyed considerable political power in the Near East in the 9th and 8th centuries BC. The Urartians were succeeded in the area in the 6th century BC by the Armenians, who, by the late 1st century AD had built a state that briefly contested the hegemony of the Roman Empire in the East. Thereafter the region was dominated by powerful neighbouring empires, but its people retained a fiercely independent spirit. Armenian nationalism nettled international diplomacy even in the late 19th century. The geographical boundaries of both kingdoms varied greatly with their political vicissitudes, and today the region is divided among eastern Turkey, northwest Iran, and the Armenian Soviet Socialist Republic of the U.S.S.R.

URARTU

Urartian territory, c. 1275–840 BC. Shalmaneser I, king of Assyria, marched through the country of "Uruatri" as early as 1275 BC. It then denoted a region close to Arina (Ardini) in the land of Musri (Muşaşir) in the upper valley of the Great Zab River. By 860 BC the Assyrians came to use the name Urartu specifically for the kingdom that had newly arisen around Lake Van, Turkey, and the Urartian kingdom is sometimes called the Kingdom of Van. The Urartians themselves called their country Biainili and their capital, located at modern Van, Tushpa (Turushpa). Most Urartian settlements are found between the four lakes Çildir and Van in Turkey, Urmia in Iran, and Sevan in Soviet Armenia, with a sparser extension toward the Euphrates.

Hurrian background

The Urartians had a number of traits in common with the Hurrians, an earlier Near Eastern people. Both nations spoke closely related languages and must have sprung from a common ancestor nation (perhaps 3000 BC or earlier). Both people worshipped certain gods in common, which they may have inherited from the ancestor nation: the principal Hurrian god, Teshub ("the Destroyer"), corresponds to the second-ranking Urartian god, Teisheba, while the Hurrian sun god Shimegi corresponds to the Urartian Shiwini (Shiuini). Common features in Hurrian and Urartian religious imagery, such as the animals that served as mounts for the gods and the minor deities that were depicted holding up the sky, must have been derived from a common ethnic background, or the Urartians may have borrowed wholesale from the Hurrians, who surrounded Urartu on the west, south, and east. In Hittite sources of the 2nd millennium BC, Hurrian geographical and personal names are widely attested in the Euphrates Valley near the Taurus Mountains, to the west of Lake Van. In Assyrian sources of the 1st millennium BC, Hurrian names, among others, also appear in the south, on the Upper Tigris and its tributaries.

The Assyrians used the term Nairi for the area later to become the territory of the Urartian state. In a general sense, it denoted the headwaters of the Tigris and Euphrates, together with lakes Van and Urmia. In a narrower sense, King Shalmaneser III of Assyria used the term as an equivalent of Urartu, with its capital at Arzashku, somewhere north of Lake Van. (Arzashku may possibly have been located at Mollakent, near Liz, the site of a large Urartian town.) Early in his reign Shalmaneser III (858–824 BC) fought and overcame an Urartian king named Arramu, or Arame, who resided at Arzashku.

Rise of the Urartian kingdom. It was probably the complete destruction of this capital by Shalmaneser in 856 and the destruction of additional Urartian settlements in 844 that made possible the rise to power of a new and more formidable dynasty founded by Sarduri I (*c.* 840–830) that was to rule Urartu for two and a half centuries. Sarduri I's descendants were usually designated ruler of Tushpa as part of their title, and it is natural to assume that the city was in Urartu's domain before Sarduri I extended his power over most of Nairi. The link between the country of Nairi and the kings of Urartu at Van is established by an inscription of Sarduri I on the building blocks of a fortress at the foot of the citadel of Van. There he styled himself "great king, mighty king, king of the universe, king of (the country of) Nairi." This title was obviously copied after those of the Assyrian kings, and the inscription is in Assyrian, unlike those of his descendants, which are in Urartian, transcribed in 9th-century Assyrian script.

The inscription suggests that Sarduri I had founded his kingdom on the Assyrian pattern. There is good reason to believe that his family came from the bilingual buffer zone of Muşaşir, and the chief god of the Urartian state was to be Haldi (Khaldi, god of the heavens and war), whose holy city Ardini (Muşaşir) was the capital of that zone.

Assyrian influences

If the Urartians owed much of their cultural heritage to the Hurrians, they were to a much greater degree indebted to the Assyrians, from whom they borrowed script and literary forms, military and diplomatic practices, and artistic motifs and styles.

The Assyrian influence was manifested in two phases: first, from *c.* 1275 BC to 840, when the Assyrians campaigned in Urartian territory and met only scattered resistance; second, from 840–612, during the heyday of the Urartian kingdom. In the first phase Assyrian influence was felt directly, and the local inhabitants were helplessly exposed to ruthless depredation at the hands of the Assyrians. But they seem also to have eagerly absorbed or imitated the amenities of Assyria's higher civilization. In the second phase, Urartu produced its own distinctive counterparts to all Assyrian achievements.

The first century of the new kingdom seems to have emphasized military operations in imitation of Assyria, and Urartu waged relentless warfare on its neighbours to the east, west, and north.

For the reign of Sarduri I there remain only the inscriptions at Van mentioned above. But for the reigns of his son Ishpuini (*c.* 830–810) and especially of Ishpuini's son Meinua (*c.* 810–781) Urartian conquests can be measured indirectly from widespread inscriptions ranging from the lower Murat basin (around Elâzığ) in the west, to the Aras (Araks, Araxes River; from Erzurum to Mount Ararat) in the north, and to the south shore of Lake Urmia in the southeast. Ardini, or Muşaşir, once conquered by Tiglath-pileser I of Assyria *c.* 1100, now became part of the Urartian sphere of influence, although technically neutral under its own dynasty of priest-rulers. The temple of Haldi at Ardini was richly endowed by the Urartian kings, but was open to Assyrian worshippers.

A number of Urartian inscriptions dealing with religious subjects date to the end of Ishpuini's reign, when Meinua acted as co-regent. It seems that the state religion received its established form under these kings, and the hierarchy of the many gods in the Urartian pantheon is expressed by a list of sacrifices due them.

The first evidence of engineering projects, designed to increase the productivity of the home country by irrigation, dates to the reign of Meinua. This is the "Canal of Meinua," which led and still leads fresh water over a distance of about 46 miles from an abundant spring to the southern edge of Van.

From the reigns of Meinua's son Argishti I (*c.* 780–756) and grandson Sarduri II (*c.* 755–735) there is, in addition to inscriptions, a direct historical source in the form of annals carved into the rock of Van and into stelae that were displaced in later times to other locations in the vicinity. Under these kings Urartu thrust out westward to the great bend of the Euphrates and intermittently beyond, toward Melitene (modern Malatya) and the ancient Syrian district of Commagene, thus cutting off one of the main supply roads by which Assyria obtained essential iron from the western Taurus Mountains. Argishti I subdued the Melitene Hilaruada (*c.* 777), as did Sarduri II in the 750s. King Kushtashpi of Commagene was subjected by Sarduri II around 745. Part of the domain of King Tuate of Tabal in the Taurus had also fallen to Argishti I about 777. For a short time Urartu thus had a bridgehead west of the Euphrates from Malatya to Halfeti (ancient Halpa) in Commagene, and its empire reached to within 20 miles of Aleppo in northern Syria.

Agricultural organization

Argishti and Sarduri also embarked on what was in the end to prove the most fruitful of all Urartian ventures: the conquest and subsequent agricultural exploitation of the regions across the Aras: under Argishti I, Diauehi ("the Land of the Sons of Diau"; Assyrian Daiaeni) was finally defeated, and the upper and middle Aras Valley became a major centre of building, irrigation, and agricultural activity. Sarduri added lakes Çildir and Sevan. Further advance to the northwest was checked by a new adversary, the kingdom of Qulha (Greek Colchis). The tens of thousands of prisoners taken on the yearly military campaigns (in one year as many as 39,000) provided the manpower for intensive cultivation of the royal estates and processing of their crops.

Armenian legend attributed much of the surviving Urartian construction to Queen Semiramis. The historical queen Sammu-ramat, however, Babylonia-born regent of Assyria from 810 to 806, did not intervene at all in the affairs of Urartu. On the contrary, the reigns of her husband, son, and elder grandsons (823–745) marked a period of Assyrian military decline, during which the Urartians extended their frontiers.

Several times the Urartian kings of this period claimed, probably with justification, to have defeated Assyrian armies: Argishti reported victories over the Assyrians in his sixth and seventh regnal years, when he operated in the Zab and Lake Urmia areas; and Sarduri II defeated the Assyrian king Ashur-nirari V in the upper basin of the Tigris *c.* 753.

Destruction of the Urartian kingdom. The period *c.* 744–715 saw the renewal of Assyrian expansion. In spite of the support of a number of south Anatolian and north Syrian vassals, Sarduri II lost ground steadily, and in 743 Tiglath-pileser III of Assyria (744–727) defeated him and his allies in Commagene near Halfeti. When Tiglath-pileser in 735 advanced all the way to the gates of Tushpa, a palace revolt may have placed Sarduri's son Rusas I (*c.* 735–713) at the head of the state.

Tiglath-pileser's son, king Sargon II of Assyria (721–705) completed the elimination of Urartu as a rival for hegemony in the Near East. Urartu's hopes of help from the north Syrian principalities were dashed by their swift subjection, ending with the incorporation of Carchemish into the Assyrian Empire in 717. In the metal-rich Taurus Mountains, the kingdom of Tabal remained a potential ally of Rusas I, as well as of the Phrygian king Midas of the legendary golden touch. After the latter's defeat, Tabal was annihilated and annexed to Assyria.

In the same year Sargon began to close in on Urartu from the east. For two years operations were mostly limited to western Iran. There Assyria championed the interests of the kingdom of Manna, while Urartu aided and abetted Iranian tribes encroaching upon Manna from east and north. But behind the Urartian lines Assyrian intelligence officers were collecting information with a view to a much more ambitious military undertaking against Urartu.

Cimmerian invasion

What finally tipped the scales in favour of Assyria was the opening up of a second front: the Cimmerians, a nomadic people from the Caucasus, invaded Urartu shortly before 714. Perhaps Rusas I (*c.* 735–713) himself provoked the onslaught by unwisely destroying several buffer states to the north. In any case, Rusas soon found the Cimmerians at his borders. Undaunted, he proceeded to the attack but suffered a major disaster: the Assyrian crown prince Sennacherib, sent north by King Sargon II (721–705) to gather intelligence about Urartian affairs, reported to his father that Rusas' whole army had been defeated in Cimmerian territory and that Rusas himself had fled back to Urartu, having lost contact with his commanders. This encouraged Sargon to undertake the ambitious campaign of 714 that put an end to the aspirations of the Urartian kings outside of their mountain homeland. After unsuccessfully heading a coalition of his allies against Assyria, Rusas hastened back to Tuspha, which Sargon wisely did not try to besiege. Sargon avoided a clash with the Cimmerians and instead plundered the main sanctuary of the Urartians at Ardini and carried off the statue of Haldi. Hearing of this third calamity, Rusas committed suicide.

The military setbacks of Rusas I ended Urartu's political power. Nevertheless, his son Argishti II (*c.* 712–685) and successors continued the royal tradition of developing the country's natural resources, and Urartian culture not only survived but continued to flourish, despite its political impotence. Inscriptions of Argishti II have been found near Erzincan, 100 miles from the Black Sea, and on the way from Tabriz to Ardabīl, 60 miles from the Caspian Sea.

Under Rusas II (*c.* 685–645) Urartu witnessed a renaissance, based on a further shift away from military exploits and toward economic and administrative activity.

It was probably Rusas II (not Rusas I, as earlier scholars believed) who created the artificial "Lake of Rusas" about 25 miles to the east of Van and the "Canal of Rusas" that carries fresh water to the vineyards, forests, and barley fields at the foot of Toprakkale (ancient Rusahinili), which must have been founded at the same time. This huge irrigation project still waters this garden area that has become the new city of Van.

Raids on neighbouring countries are mentioned by Rusas II, but these were conducted only as a means to populate newly built cities: women were forcibly imported from Kurdistan and men from the Anatolian districts Halitu (Pontus), Mushki (Phrygia), and Hate (Cappadocia). Possibly Rusas II allowed the Cimmerians to raid these neighbouring countries from a base in Urartu. By 672 he had also come to an understanding with the Assyrians under Esarhaddon, who in turn was negotiating with the Scythians and certain Median chieftains. Ashurbanipal re-established Assyrian sovereignty over Manna in 660 or 659. In or shortly after 654 Rusas II sent a diplomatic mission to the court of Ashurbanipal, presumably still on the basis of an equal. In Rusas II's later years his son Sarduri III served as co-regent. After *c.* 650 Urartu and Assyria felt the pressure of a new and more formidable power in the east: the Medes. In 644, probably at the beginning of his sole kingship, Sarduri III (*c.* 644–640) sent an embassy to Ashurbanipal acknowledging the latter as sovereign. Three more kings reigned Urartu between 640 and 609: Sarduri IV, son of Sarduri; Erimena, son of Ar . . . (Argishti?); and Rusas III, son of Erimena.

In the last days of the Assyrian Empire, Urartu allied with Manna and Assyria against Media and Babylonia, but to no avail, as the latter put an end to the Assyrian empire, between 612 and 609. A change of allegiance by the Scythians is said to have tipped the scales in favor of Media and Babylonia.

Scythian attack

Similarly, the cast-bronze arrowheads found both in and outside the citadel of Teishebaini (Karmirblur, near Yerevan, Soviet Armenia) indicate the presence of Scythians among both defenders and attackers of this Urartian stronghold. According to the Babylonian chronicle, the

Scythians in 609 marched "as far as the district of the city of Urartu," stayed there for some time and plundered it. This would seem to indicate the conquest and sack of Van itself and surroundings, especially as the Babylonians then proceeeded to annex the mountainous parts of Urartu south of the Taurus range in 608–607. In an alternate view, based on Jeremiah 51:27, Urartu (biblical Ararat) existed as an independent country as late as 593 BC.

Influence of the Urartian state. Gold scabbards found in the Kelermes and Melgunov barrows in southern Russia clearly show that goldsmiths steeped in the traditions of the Urartian court worked for Scythian chieftains in the time shortly after 600 BC. After a new war (590–585), in which the western Anatolian kingdom of Lydia unsuccessfully championed the cause of the Scythians, eastern Anatolia, up to the river Halys (Kizil Irmak), was incorporated into the Median empire.

There are indications that some Urartian sites, such as the citadel of Erebuni (Arin-berd above Yerevan, Soviet Armenia), were not destroyed but continued through the Median and into the Persian period. This would explain how certain characteristics of Urartian statecraft, literature, architecture, and artistic representation were inherited by the Persian Empire. Urartian settlements are distingushed from those of the Assyrians by vast irrigated and drained royal estates, worked largely by resettled captives. At their centre stood well-watered hilltop fortresses, where the agricultural produce was processed and stored, where a garrison was stationed, and where the king could reside and worship. From the material remains Urartu appears largely as the creation of one single-minded dynasty imposing a uniform life-style over a wide area. In this respect it resembled, and probably served as a prototype for, the Median and Persian empires.

In addition to the speakers of the Urartian language (written in cuneiform script) there was in the kingdom of Urartu a second ethnic group that wrote in hieroglyphs. It is not known if this was the language later called Armenian. In the enumeration of countries subjected by the Persian king Darius I (520), Armina is given as the Old Persian name for Urartu. (M.N.v.L.)

ARMENIA

The Armenians, an Indo-European people, first appear in history shortly after the collapse of Urartu toward the end of the 7th century BC. Driving some of the ancient population to the east of Mount Ararat, where they were known to the Greeks as Alarodioi ("Araratians"; *i.e.*, Urartians), the invaders imposed their leadership over regions which, although suffering much from Scythian and Cimmerian depredations, must still have retained elements of a high degree of civilization (*e.g.*, walled towns, irrigation works, arable fields, and vineyards) upon which the more primitive newcomers might build. The Hayk, as the Armenians name themselves (the term Armenian is probably due to an Iranian or Greek confusion of them with the Aramaeans), were not able to achieve the power and independence of their predecessors and were rapidly incorporated first by Cyaxares into the Median Empire and then annexed with Media by Cyrus II the Great to form part of the Achamenian Empire of Persia (*c.* 550). The country is mentioned as Armina and Armaniya in the Bīsitūn inscription of Darius I the Great and, according to the 5th-century Greek historian Herodotus, formed part of the 13th satrapy (province) of Persia, the Alarodians forming part of the 18th. Xenophon's *Anabasis*, recounting the adventures of Greek mercenaries in Persia, shows the local government *c.* 400 BC to have been in the hands of village headmen, part of whose tribute to the Persian king consisted of horses. Armenia continued to be governed by Persian or native satraps until its absorption into the Macedonian empire of Alexander the Great (331) and its successor, the Seleucid Empire (301).

The Artaxiads. After the defeat of the Seleucid king Antiochus the Great by Rome at the Battle of Magnesia (winter 190–189), his two Armenian satraps, Artashes (Artaxias) and Zareh (Zariadres), established themselves, with Roman consent, as kings of Greater Armenia and Sophene, respectively, thus becoming the creators of an independent Armenia. Artashes built his capital Artashat (Artaxata) on the Aras River near modern Yerevan. The Greek geographer Strabo names the capital of Sophene as Carcathiocerta. An attempt to end the division of Armenia into an eastern and a western part was made about 165 BC when the Artaxiad ruler sought to suppress his rival, but it was left to his descendant Tigran II the Great (*c.* 94-*c.* 56 BC) to establish, by his conquest of Sophene, a unity that was to last almost 500 years. Under Tigran, Armenia ascended to a pinnacle of power unique in its history and became, albeit briefly, the strongest state in the Roman east. Extensive territories were taken from the kingdom of Parthia in Iran, which was compelled to sign a treaty of alliance. Iberia (Georgia), Albania, and Atropatene had already accepted Tigran's suzerainty when the Syrians, tired of anarchy, offered him their crown (83 BC). Tigran penetrated as far south as Ptolemais (Acre). Deeming Artaxata too far north to serve as the capital of his new empire, he founded a new one, Tigranakert (Tell Armen/Kızıl Tepe? or Silvan?), nearer the centre. Although Armenian culture at the time of Tigran was Iranian, as it had been and as it was fundamentally to remain for many centuries, Hellenic scholars and actors found a welcome at the Armenian court. The Armenian Empire lasted until Tigran became involved in the struggle between his father-in-law, Mithradates VI of Pontus, and Rome. The Roman general Lucullus, capturing Tigranakert in 69 BC, failed to reach Artashat, but in 66 the legions of Pompey, aided by one of Tigran's sons, succeeded, compelling the King to renounce Syria and other conquests in the south and to become an ally of Rome. It has been the fate of Armenia throughout a long and turbulent history to be a small state struggling to preserve its independence between two poweful neighbours; it now became a buffer state, and often a battlefield, between Rome and Parthia. Their natural self-interest gave the Armenians a reputation for deviousness; the Roman historian Tacitus called them an *ambigua gens*.

Strongest state in the east under Tigran II

The Arsacids. Both Rome and Parthia strove to establish their own candidates on the Armenian throne until a lasting measure of equilibrium was secured by the treaty of Rhandeia, concluded in AD 63 between the Roman general Corbulo and Tiridates (Trdat), whereby an Arsacid occupied the throne of Armenia, but as a Roman vassal. A dispute with Parthia led to the country's annexation by the emperor Trajan in 114, but his successor, Hadrian, withdrew the frontier of the Roman Empire to the Euphrates. A similar dispute resulted in the destruction of Artashat by Marcus Aurelius' general Priscus in 163 and in the building of a new capital, Kainepolis (Vagharshapat, modern Echmiadzin). After Caracalla's capture of King Vagharshak and his attempt to annex the country in 216, his successor, Macrinus, recognized Vagharshak's son Tiridates II (Khosrow the Great in Armenian sources) as king of Armenia (217). Tiridates II's resistance to the Sāsānids after the fall of the Arsacid dynasty in Persia (224) ended in his assassination by their agent Anak the Parthian (*c.* 238) and in the conquest of Armenia by Shāpūr I, who placed his vassal Artavazd on the throne (252). Under Diocletian, the Persians were forced to relinquish Armenia, and Tiridates III, the son of Tiridates II, was restored to the throne under Roman protection (*c.* 287). The reign of Tiridates III determined the course of much of Armenia's subsequent history. His ultimate conversion by St. Gregory the Illuminator and the adoption of Christianity as the state religion (*c.* 300) created a permanent gulf between Armenia and Persia, and the Armenian patriarchate became one of the surest stays of the Arsacid monarchy while it lasted and the guardian of national unity after its fall. The Mamikonian family, which played a similar role, came to the fore in his reign. Tiridates' assassination by his own chamberlain in league with the *nakharars* (clan chiefs, barons; Parthian *n.ḥwd.r*, "Nohodares") of Siuniq underlines the disloyalty of many of the local nobles, whose revolts and jealous quarrels fill the pages of Armenian historians.

Christianity's adoption as the state religion

Historical divisions of Armenia.

The dissatisfaction of the *nakharar*s with Arshak II led to the division of Armenia into two sections, Byzantine Armenia and Persarmenia (*c.* 390). The former, comprising about one-fifth of Armenia, was rapidly absorbed into the Byzantine state, to which the Armenians came to contribute many emperors and generals. The latter continued to be ruled by an Arsacid in Dvin, the capital after the reign of Khosrow II (330–339), until the deposition of Artashes IV and his replacement by a Persian *marzpan* (governor) at the request of the *nakharar*s (428). Although the Armenian nobles had thus destroyed their country's sovereignty, the cause of national unity was furthered by the development of a national Christian literature; culturally, if not politically, the 5th century was a golden age.

The marzpans. The Persians were not as successful as the Byzantines in their efforts to assimilate the strongly individualistic Armenian people. The misjudged attempt of Yazdegerd II to impose the Zoroastrian religion upon his Armenian subjects did much to reunite them as a nation. In the war of 451, which resulted from this policy, the Armenian commander St. Vardan Mamikonian and his companions were slain at the Battle of Avarayr (June 2?, 451), but the Persians renounced their plans to convert Armenia by force and deposed their *marzpan* Vasak of Siuniq, the archtraitor of Armenian history. The revolt of 481–484 led by Vahan Mamikonian secured religious and political freedom for Armenia in return for military aid to Persia, and with the appointment of Vahan as *marzpan* the Armenians were again largely the arbiters of their own affairs. Their independence was further asserted in 554, when the second Council of Dvin rejected the dyophysite formula of the Council of Chalcedon (451), a decisive step that cut them off from the West as surely as they were already ideologically severed from the East.

Byzantine Armenia

In 536 Justinian I reorganized Byzantine Armenia into four provinces, and, by the suppression of the power of the Armenian nobles and by transfers of population, he completed the work of hellenizing the country. In 591 its territory was extended eastward by the emperor Maurice as the price of re-establishing Khosrow II on the throne of Persia. After transporting many Armenians to Thrace, Maurice (according to the Armenian historian Sebeos) advised the Persian King to follow his example and to send "this perverse and unruly nation, which stirs up trouble between us" to fight on his eastern front. During the war between the emperor Phocas and Khosrow, the Persians occupied Byzantine Armenia and appointed a series of *marzpan*s, only to be ousted by the emperor Heraclius in 623. In 628, after the fall of Khosrow, the Persians appointed an Armenian noble, Varaztirotz Bagratuni, as governor. He quickly brought Armenia under Byzantine rule but was exiled for plotting against Heraclius (635).

The Mamikonians and Bagratids. The first, unsuccessful, Arab raid into Armenia in 640 found the defense of the country in the hands of the Byzantine general Procopius and the *nakharar* Theodor Rshtuni. Unable to prevent the pillage of Dvin in 642, Theodor in 643 gained a victory over another Arab army and was named commander in chief of the Armenian army by Constans II. In 653, after the truce with Mu'āwiyah, then governor of Syria, Constans voluntarily surrendered Armenia to the Arabs, who granted it virtual autonomy and appointed Theodor as governor (*ostikan*).

Theodor's successor, Hamazasp Mamikonian, sided with Byzantium, but after 661 Arab suzerainty was re-established, although Byzantine-Arab rivalry, Armenian nationalism, and reluctance to pay the tribute made the region a difficult one to govern. An unsuccessful revolt led by Mushegh Mamikonian (771–772) resulted in the virtual extinction of the Mamikonians as a political force in Armenia and in the emergence of the Bagratunis and Artsrunis as the leading noble families. The Arabs' choice in 806 of Ashot Bagratuni the Carnivorous to be prince of Armenia marked the establishment of his family as the chief power in the land. The governor Smbat Ablabas Bagratuni remained loyal to the caliph al-Mutawakkil when he sent his general Bugha al-Kabir to bring the rebellious *nakharar*s to submission, although he too was dispatched in 855 with the rest of the captive nobles to Samarra. The election by the nobles of Smbat's son Ashot I the Great, who had been accepted as "prince of princes" by the Arabs in 862, to be king of Armenia in 885 was recognized by both Caliph and Emperor. Throughout the 10th century art and literature flourished. Ashot III the Merciful (952–977) transferred his capital to Ani and began to make it into one of the architectural gems of the Middle Ages.

The Bagratids of Ani, who bore the title of *shāhanshāh* ("king of kings"), first conferred upon Ashot II the Iron by the Caliph in 922, were not the sole rulers of Armenia. In 908 the Artsruni principate of Vaspurakan became a kingdom recognized by the Caliph; in 961 Mushegh, the brother of Ashot III, founded the Bagratid kingdom of Kars; and in 970 the Prince of East Siuniq declared himself a king.

Byzantine conquest

By the time of the Seljuq invasions in the 11th century the Armenian kingdoms had already been destroyed from the west. The province of Taron had been annexed to the Byzantine Empire in 968, and the expansionist policy of Basil II finally extinguished Armenian independence. The possessions of David of Tayq were annexed in 1000 and the kingdom of Vaspurakan in 1022. In the latter year, the Bagratid king of Ani, Yovhannes-Smbat, was compelled to make the Emperor heir to his estates, and in 1045, despite the resistance of Gagik II, Ani was seized by Constantine IX Monomachus. The Byzantine conquest was short-lived: in 1048 Togrul led the first Seljuq raid into Armenia, in 1064 Ani and Kars fell to Alp-Arslan, and after the Battle of Manzikert (1071) most of the country was in Turkish hands. In 1072 the Kurdish Shāddādids received Ani as a fief. A few native Armenian rulers survived for a time in the Kiurikian kingdom of Lori, the Siunian kingdom of Baghq or Kapan, and the principates of Khachen (Artzakh) and Sasun. In the 12th century

many former Armenian regions became part of Georgia, and between 1236 and 1242 the whole of Armenia and Georgia fell into the hands of the Mongols. Armenian life and learning, centred around the church, continued as best it could.

Little Armenia. On the collapse of Greater Armenia many Armenians emigrated to Georgia, Poland, and Galicia, while others crossed into Cilicia, where some colonies had already settled at the end of the 10th century. One of Gagik II's lieutenants, a certain Ruben, established himself about 1080 at Bardzrberd in the Taurus, and another noble named Oshin at Lambron: the former became the founder of Rubenid dynasty of barons and kings who ruled Cilicia until 1226, and the latter was the ancestor of the Hethumid dynasty, which succeeded them and ruled until 1342. The barons Constantine I (1092–1100), Thoros I (1100–29), and Leo I (1129–39) enlarged their domains at the expense of the Byzantines, and by 1132 Vahka, Sis, Anazarbus, Mamistra, Adana, and Tarsus were under Rubenid rule. Although the Byzantine emperor John II Comnenus succeeded in annexing the whole of Cilicia during 1137–38, Thoros II (1145–68) and Mleh (1170–75) restored Armenian rule, with some Turkish aid. Leo II (I) the Great (1187–1219), an ally of the German emperor Frederick I Barbarossa, received the royal crown from the latter's son Henry VI and Pope Celestine III and was crowned king of Armenia in Tarsus in 1199 by the cardinal Conrad von Wittelsbach. The Byzantine Emperor lost no time in sending a crown also, but Little Armenia was now firmly allied to the West.

Influence of the crusaders

Intermarriage with Frankish crusading families from the West was common, and Frankish religious, political, and cultural influence, though resisted by the more nationalistic barons, was strong. Leo reformed his court and kingdom on Western models, and many French terms entered the language. Little Armenia played an important role in the trade of the Venetians and Genoese with the East, and the port of Lajazzo (on the Gulf of Iskenderun) rivalled Alexandria. Leo II left no son, and the throne passed to his daughter Zabel. Her first husband, Philip of Antioch, who refused to accept the Armenian faith—Leo II's lip service to Rome as the price of his coronation being largely ignored—was deposed by the barons, and the regent Constantine, baron of Lambron, a descendant of Oshin, arranged the marriage of Zabel to his son Hethum (Hayton) I (1226–69), the first of the Hethumid dynasty. Hethum conceived the idea of employing the Mongols against the growing menace of the Mamlūks of Egypt and was present with the Mongol army that entered the Syrian cities of Aleppo and Damascus in 1260. His successors followed the same policy, but the Mongols weakened and, after their defeat in 1303 near Damascus, were unable to protect Cilicia.

On the death, without heir, of Leo V, the crown passed to Guy de Lusignan, the eldest son of Hethum II's sister Zabel and her husband Amaury de Lusignan (Amalric of Cyprus). He was assassinated by the barons in 1344 for doctrinal reasons, and the next two kings, Constantine IV and V, were elected from their own ranks. On the assassination of Constantine V, the crown passed again to a Lusignan, to Guy's nephew Leo VI (V) (1374–75). By this time, as a result of the Mamlūk advance, little remained of Armenia except Sis and Anazarbus; Lajazzo had finally fallen in 1347, followed by Adana, Tarsus, and the Cilician plain in 1359. In 1375 the capital of Sis fell to the Mamlūks, and the last king of Armenia was captured; ransomed in 1382, he died in Paris in 1393. The title "king of Armenia" passed to the kings of Cyprus, thence to the Venetians, and was later claimed by the house of Savoy, but from the end of the 14th century the history of Armenia as a separate state is replaced by the history of Armenians under foreign domination.

The Turkish conquest. After the capture of Constantinople by the Ottoman Turks, the Armenian bishop of Bursa, transferred in 1461 to the capital, was appointed leader of the Armenian *millet* in the Ottoman Empire. Although as non-Muslims they were greatly disadvantaged, the Armenians of Turkey retained, as *zimmî*s (Arabic, *dhimmī*) or "people of the Book," the management of their own affairs. Their numbers were increased at the beginning of the 16th century by the conquest of Cilicia and Greater Armenia.

On the death of Timur in 1405, the eastern Armenian regions had passed into the hands of the Turkmen rival confederacies, the Black Sheep and the White Sheep, until the defeat of the latter by the Persian Shāh Esma'īl I in 1502. Armenia again became the battlefield between two powerful neighbours, and in 1514–16 the Ottomans wrested it from Persian rule. During the war that broke out in 1602, Shah 'Abbās I strove to regain the lost territories, and in 1604–05, with the aim of stimulating trade in his dominions, he forcibly transferred thousands of Armenians from Julfa to Isfahan, where those who survived the march settled in the quarter named New Julfa. At the peace of 1620, while the greater part of Armenia remained in Ottoman hands, Persia regained the regions of Yerevan, Nakhichevan, and Karabagh. In the mountainous region of Karabagh a group of five Armenian *malik*s (princes) succeeded in conserving their autonomy and maintained a short period of independence (1722–30) during the struggle between Persia and Turkey at the beginning of the 18th century; despite the heroic resistance of David Beg, the Turks occupied the region but were driven out by the Persians under Nāder Qolī (the future Nāder Shāh) in 1735. In New Julfa the Armenian merchants served as links between Europe (including England, Spain, and Russia) and the East, exporting Persian silk and importing glass, clocks, spectacles, paintings, etc. In the course of the 17th century they amassed great wealth and built many magnificent churches and mansions, thereby attracting Persian envy, and from the beginning of the 18th century, when Nāder Shāh (1736–47) penalized them with excessive taxation, they began the gradual decline that continues at the present day.

Armenian settlement in New Julfa

Armenia and Europe. At the beginning of the 19th century the Russians advanced into the Caucasus. In 1813 the Persians were obliged to acknowledge Russia's authority over Georgia, northern Azerbaijan, and Karabagh, and in 1828 they ceded Yerevan and Nakhichevan. Contact with liberal thought in Russia and western Europe was a factor in the Armenian cultural renaissance of the 19th century. In Turkey, the Armenians benefitted with the rest of the population from what measures of reform there were, and in 1863 a special Armenian constitution was recognized by the Ottoman government. But social progress in Turkey was slow and the Armenians in Anatolia were subject to many abuses. After the Russo-Turkish War of 1877–78, in which Russian Armenians had taken part, Russia insisted in the Treaty of San Stefano that reforms be carried out among the Sultan's Armenian subjects and that their protection against the Kurds be guaranteed. This demand was reiterated at the Congress of Berlin, and the "Armenian question" became a factor in international politics in which Great Britain took a special interest.

The socialist Hënchak ("Handbell") party was founded in 1887 and the nationalist Dashnaktzutiun ("Confederacy") party, commonly called Dashnaks, in 1890, and in the face of increasing Armenian demands for much needed reforms both the Turkish and Russian governments grew more repressive. In 1895, after Abdülhamid II had felt compelled to promise Britain, France, and Russia to carry out reforms, large-scale systematic massacres took place in the provinces. In 1896, following the desperate occupation of the Ottoman Bank by 26 young Dashnaks, more massacres broke out in the capital. In 1897 Nicholas II closed hundreds of Armenian schools, libraries, and newspaper offices, and in 1903 he confiscated the property of the Armenian Church. The greatest single disaster in the history of the Armenians came with the outbreak of World War I. In 1915 the Young Turk government, regarding the Turkish Armenians, despite pledges of loyalty, as a dangerous foreign element with friends among the enemies who had launched the Dardanelles campaign and with cousins in the Russian army on their eastern front, resolved to deport the whole Armenian population of about 1,750,000 to Syria and Mesopotamia.

Russian and Turkish atrocities

The chances of survival in these ill-prepared desert re-

gions were slight: it was a death sentence, a "final solution" that Adolf Hitler was to emulate consciously in Germany. It is estimated that about 600,000 Armenians died or were massacred en route. Many of those who survived or escaped settled in Syria or emigrated to France and the United States.

The Republic of Armenia. In 1916 the Turkish Armenian regions fell to the Russian army, but in March 1918 Russia was forced by the Treaty of Brest-Litovsk to cede all Turkish Armenia and part of Russian Armenia to Turkey, though some Armenians continued to hold out against the advancing Turks. On April 22, 1918, Armenia, Georgia, and Azerbaijan formed the Transcaucasian Federal Republic, but their basic diversity caused them to split into separate republics on May 26, 1918. Though short-lived, this Armenian republic was the first independent Armenian state since the Middle Ages. On June 4, 1918, Armenia was forced to sign the Treaty of Batum with Turkey, acknowledging the pre-1878 Russo-Turkish frontier along the Arpa and Aras rivers as its boundary, but after the Allied victory the Armenians reoccupied Alexandropol (Leninakan) and Kars. A short war with Georgia ensued for the possession of Borchalu and Akhalkalaki, and with Azerbaijan for the Karabagh region; despite temporary military success, these regions were destined to remain outside Armenia. On January 15, 1920, the Allies recognized the de facto existence of the three Transcaucasian republics. Pres. Woodrow Wilson hoped to persuade the U.S. to accept a mandate for an independent Armenia, but the Senate refused the responsibility (June 1, 1920). On August 10, 1920, Armenia, now recognized de jure, signed the Treaty of Sèvres by which Turkey recognized Armenia as a free and independent state. On November 22, 1920, Wilson, as instructed, announced projected boundaries that ceded to Armenia most of the vilayets of Erzurum, Trabzon, Van, and Bitlis. Already in the summer of 1919, however, the Turkish government of Ankara, under Mustafa Kemal, had repudiated Constantinople's treaties with Armenia. In September 1920 the Turks attacked, seizing Kars and Alexandropol by November 7; at the treaty of Alexandropol on Dec. 2, 1920 Armenia renounced all pre-1914 Turkish territories and Kars and Ardahan, recognized that there were no Armenian minorities in Turkey, and accepted that the region of Nakhichevan should form an autonomous Turkish state. The next day a new Armenian government at Yerevan, a coalition of Communists and Dashnaks (nationalists), proclaimed Armenia a Soviet republic; the Dashnaks were quickly eliminated, provoking an abortive revolt in February 1921. In March 1922 Armenia joined Georgia and Azerbaijan to form the Transcaucasian Soviet Federated Socialist Republic, which became part of the U.S.S.R. on December 30, 1922. The Nakhichevan enclave was awarded to Azerbaijan, sandwiching the southern part of Armenia between Turks and remaining a constant cause of friction between Armenia and Azerbaijan. Irrigation and hydroelectrical work began immediately, and though industry developed slowly at first, by 1935 the value of the gross industrial product was six times that of 1928. Yerevan State University was founded in January 1921. Under the new Soviet constitution (December 5, 1936) Armenia, Georgia, and Azerbaijan became separate constituent republics of the Soviet Union (see ARMENIAN SOVIET SOCIALIST REPUBLIC).

Urban II, Pope

Urban II, as pope during the last years of the 11th century—an epoch of profound historical change in the medieval world and an age of crisis and reform in the church, especially in its relations with temporal political powers—continued the ecclesiastical reform begun by his predecessors, particularly Gregory VII, one of the great reformers of the church in the Middle Ages. Urban defined the reform ideas of papacy, church, and Christian society more precisely, developed them further, and won recognition for them in large areas of Europe. Many of Urban's legal decisions were adopted in the church's legal code of the Middle Ages, the *Decretum* of Gratian, which was completed about 1140. Urban demonstrated the pope's leading position in Christendom by launching the Crusade movement, which greatly enhanced papal prestige and influence.

Early life and career

Urban, whose name was Odo, was born of noble parents about 1035 in Châtillon-sur-Marne or Lagery in the Champagne region of France. After studies in Soissons and Reims, he took the position of archdeacon in the diocese of Reims, at that time the most important metropolis in France. An archdeacon was an ordained cleric appointed by the bishop to assist him in administration; in the Middle Ages it was an office of considerable power. Odo held the position probably from 1055 to 1067. Subsequently he became a monk and then (*c.* 1070–74) prior superior at Cluny, the most important centre of reform monasticism in Europe in the 11th century. At Reims and Cluny, Odo gained experience in ecclesiastical policy and administration and made contacts with two important reform groups of his time: the canons regular—clergymen dedicated to the active service of the church, who live a strict life in community—and the monks of Cluny. In 1079 he went to Rome on a mission for his abbot, Hugh of Cluny. While in Rome he was created cardinal and bishop of Ostia (the seaport for Rome) by Gregory VII. In 1084 Gregory VII sent him as papal legate to Germany.

During the crisis of Gregory VII's struggle with Henry IV, the Holy Roman emperor, Odo remained loyal to the legitimate papacy. After Gregory VII's death in 1085, he also served his successor, Victor III, who died in September 1087. After a long delay during which the reform cardinals tried unsuccessfully to regain control of Rome from Guibert of Ravenna, who had been named Pope Clement III by Henry IV in 1080, Odo was elected pope in Terracina, south of Rome, on March 12, 1088.

Elected pope

As pope, Urban II found active support for his policies and reforms among several groups: the nobility, whose mentality and interests he knew; the monks; the canons regular, for whom he became patron and legislator; and also, increasingly, the bishops.

Urban felt that his most urgent immediate task was to secure his position against the antipope Clement III and to establish his authority as legitimate pope throughout Christendom. He attempted, with moderation and tolerance, to reconcile the church–state traditions of his age with ecclesiastical notions of reform. In practice he pushed the question of lay investiture—the act whereby a temporal ruler granted title and possession to a church office—more into the background while at the same time retaining reform legislation. He thus softened the conflict and permitted a more peaceful discussion of the problems at issue. At the Council of Clermont, France, in 1095, during which he eloquently called the First Crusade, Urban attempted, however, to prevent a further and complete feudalization of church–state relationships by prohibiting the clergy from taking an oath of fealty to the laymen.

Despite Urban's attempts at reconciliation, it did not prove possible to come to terms with Henry IV or with a large part of the church within the empire. England also remained closed to papal policies of reform and centralization, although Urban had been recognized there since 1095; a conflict between Anselm, the theologian who was named archbishop of Canterbury, and King William II particularly strained the relations between Urban and the King. On the other hand, despite a long standing conflict between Philip I of France and Urban (brought about by the King's scandalous marriage), France began under this French pope to become the most important support of the medieval papacy. Urban obtained special support in southern Europe: his particularly faithful allies were the Normans of southern Italy and Sicily. In Spain, Urban supported the Christian reconquest of the country from the Moors and carried out the ecclesiastical reorganization of the country. In southern Italy, southern France, and Spain, kings and princes became vassals of the Roman See and concluded treaties and concordats in feudal form with the pope: by this the temporal rulers sought to secure their independence from more powerful lords, and the pope for his part was able to carry out his reform aims in these territories.

From 1095 Urban was at the height of his success. From this time several important church councils took place: in 1095 at Piacenza, Italy, at which reform legislation was enacted; also in 1095 at Clermont, where Urban preached the First Crusade; in 1098 at Bari, Italy, where he worked for a reunion between Greek Christians and Rome; and in 1099 at Rome, where again reform legislation was passed. Urban's idea for a crusade and his attempt to reconcile the Latin and Greek churches sprang from his idea of the unity of all Christendom and from his experiences with the struggles against the Muslims in Spain and Sicily. He was, for a while, able to attract the Byzantine emperor Alexius I to his plans but never the Greek Church. Whereas the First Crusade led to military success with the conquest of Jerusalem in 1099, the project for union failed. Urban's pontificate not only led to a further centralization of the Roman Church but also to the expansion of papal administration; it contributed to the development of the Roman Curia, the administrative body of the papacy, and to the gradual formation of the College of Cardinals. The term Curia Romana first appeared in a bull written by Urban in 1089.

Urban died in Rome on July 29, 1099. Despite many problems that were still unsolved, the victory of medieval reform papacy was secured. Urban was beatified in 1881 by Pope Leo XIII, and his feast day is celebrated on July 29.

Urban Climates

The climates of most large urban areas differ from those of their rural surroundings and, appropriately, are designated urban climates. High concentrations of such pollutants as sulfur oxides, nitrogen oxides, hydrocarbons, particulate matter, carbon monoxide, and oxidants are becoming more and more characteristic of the atmosphere over large cities throughout the world. Differences of air temperature, atmospheric humidity, wind speed and direction, precipitation, and visibility also distinguish urban climates from surrounding rural climates.

Man has changed his immediate climate from that of the natural state by the activity of industry and the populace, alterations in the physical features of the city terrain, and the introduction of foreign materials into the atmosphere. The heat generated by combustion for energy production, for example, is largely responsible for warmer urban temperatures. The presence of tall buildings, paved streets, and parking lots affects the wind flow and energy balance of a city, as well as precipitation runoff. Although they constitute only a fraction of the total land area of the earth, metropolitan areas nevertheless emit the bulk of all the air pollutants, and these pollutants can and do influence temperature, visibility, and precipitation, as well as other climatic elements.

Of increasing concern is the extent to which the urban atmosphere influences both the life within it and the larger scale climate with which it interacts. The warmer city temperatures can cause greater death rates for urban residents during summer heat waves; air pollution frequently causes eye irritation and respiratory illness, and other problems are known or suspected. Certain plants are susceptible to damage from ozone, a photochemically produced pollutant, for example, and such materials as house paint and fabrics are often damaged by air pollutants. The pollutants emitted into the atmosphere can also affect the environment on a global scale. Most prominent in this regard is the background concentration of carbon dioxide in the atmosphere; it directly influences world climate and has been increasing steadily during the past century as a result of the burning of fossil fuels.

This article treats the elements of urban climate and describes the various air pollutants. A discussion of possible ways in which man's activities may be affecting climate on a global scale also is presented. For an overview of climate and its meteorological basis in general, see CLIMATE; WINDS AND STORMS; see also MICROCLIMATES, which covers the climate near the ground, and the separate articles on climate elements (*e.g.*, HUMIDITY, ATMOSPHERIC; PRECIPITATION).

ELEMENTS OF URBAN CLIMATE

Air temperature. Of all the urban–rural meteorological differences, those of air temperature are probably the most documented. That the centre of a city is warmer than its environs, forming a "heat island," has been known for more than a hundred years; two main processes are involved in its formation, both of which depend on the season. In summer, the buildings, pavement, and con-

Formation of heat islands

crete of the city absorb and store larger amounts of solar radiation than do the vegetation and soil typical of rural areas. In addition, less of this energy is used for evaporation in the city than in the country because of the large amount of precipitation runoff from streets and buildings. During the night, both the city and countryside cool by radiative losses, but the urban construction material gradually gives off the additional heat accumulated during the day, keeping urban air warmer than that of the outlying areas.

In winter a different process dominates. Because the sun angle at midlatitudes is low, and lesser amounts of solar radiation reach the earth, man-made energy significantly augments the solar energy naturally received. This artificially produced heat results from such sources as combustion for home heating, power generation, industry, transportation, and human and animal metabolism. This energy reaches and warms the urban atmosphere directly, or indirectly by passing through imperfectly insulated homes and buildings.

Besides these primary seasonal causes of heat islands, another factor is important throughout the year. The "blanket" of pollutants over a city, including particles, water vapour, and carbon dioxide, absorbs a portion of the upward-directed thermal radiation emitted by the earth's surface. Part of this radiation is re-emitted by the pollutants; another part warms the ambient (surrounding) air, a process that tends to increase the low-level atmospheric stability over the city, enhancing the probability of higher pollutant concentrations. Thus, airborne pollutants not only can cause a more intense heat island but can alter the vertical temperature structure in a way that hinders their own dispersion.

Urban-rural temperature differences

Daily minimum temperatures at related rural and urban sites often show the urban site to be 6° C (10° F) warmer than the rural site, and occasionally this difference is as great as 11° C (20° F). These nighttime temperatures are dependent on the topography of the site and its surroundings, however, and some significant fraction of these differences can often be ascribed to terrain features.

The greatest mean-temperature differences occur in summer or early autumn, but the greatest extreme city–country difference usually occurs in winter. For large, relatively flat cities, such as London or Washington, D.C., the mean annual minimum temperature is about 2° C (about 3° to 4° F) warmer than that of the surrounding rural areas. This difference is less for smaller cities.

Diurnal and seasonal heat-island variations are illustrated by the hour by hour monthly average of temperatures at an urban and a suburban site in Vienna (Figure 1). The city's nighttime temperature is higher during both February and July, with the greatest urban–rural difference in July. In the daytime, however, the city–suburban temperature differences are small during July and consistently small and positive during winter.

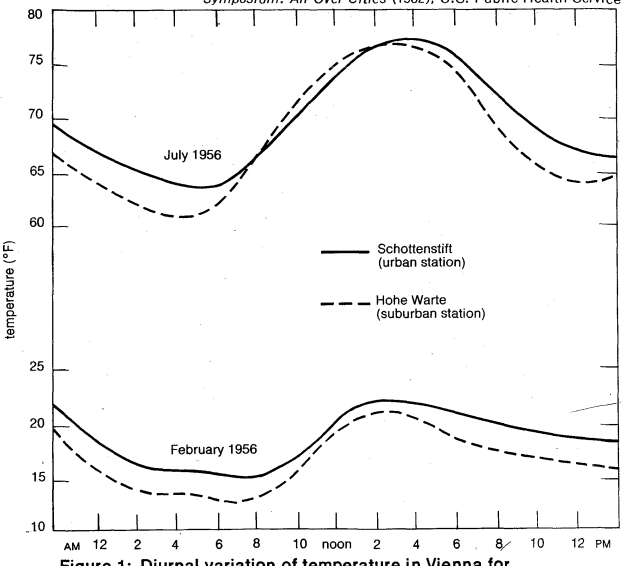

Figure 1: Diurnal variation of temperature in Vienna for February and July, for an urban and suburban station.

The heat island of a city can be detected during the day but much less readily than during the evening. The slight daytime temperature differences observed are often difficult to distinguish from those due to topographic differences. In some instances, daytime city temperatures may even be lower than those of the suburbs. City and airport observations at Lincoln, Nebraska, which is essentially free from complicating terrain factors, showed little difference between the cold-season daily maximum temperatures at the two sites. During the warm season, however, the airport was frequently warmer than the downtown site. Such results are not the rule, and data from such diverse cities as London, Toronto; San Jose, California; Dallas, Texas; Minneapolis, Minnesota; and Winnipeg, Manitoba, have shown that the city's warmest sector, near the downtown or central area, averages about 0.5° C (about 1° F) warmer than its environs.

A city's warmest temperatures at ground level often do not occur in the central section of tall buildings, but rather just outside the central area, near that part of downtown that frequently consists of parking lots and densely packed three- to five-story buildings. A map of daily maximum temperatures over a city frequently resembles a doughnut, with cooler temperatures in the hole and outside the doughnut.

Effects of city size and population

As a general rule, the larger the city, the greater is the average difference between its temperature and that of the surrounding countryside. The annual urban–rural temperature difference for large cities such as Washington, D.C., Paris, Moscow, Berlin, and New York averages about 1° C (about 1.5° to 2.0° F). The relation between city size and urban–rural temperature difference is not linear, however; sizable nocturnal-temperature contrasts have been measured even in such relatively small cities as Palo Alto, California (population 33,000 at the time of survey), Corvallis, Oregon (population 21,000), and Ina, Japan (population 12,000). On the other hand, during daytime hours the magnitude of the heat island is small in such small communities.

General relationships have been developed between heat-island magnitude and some parameter representing city size, such as area, population, or building density. The heat-island magnitude at a given location often depends strongly on the local microclimatic conditions, however. Data from several English towns have shown that the strength of the local heat island strongly depends upon the density of urban development very near the observation point, sometimes within a radius of 500 metres (1,650 feet).

Vertical temperature distribution

Rural nighttime temperatures, through the lowest several hundred feet of the atmosphere, are frequently coldest at the ground and warmest at the top of this layer, a "temperature inversion." When such an inversion occurs, this part of the atmosphere becomes very stable, and the dispersion of pollutants is inhibited. In large cities, however, the heat released by man's activities warms the air and retards the formation of surface-based inversions. In contrast to rural areas, air temperature usually decreases with height through the lowest few hundred feet over large cities.

The magnitude of an urban heat island depends on various meteorological parameters in addition to city size. The urban–rural nighttime-temperature contrasts, for example, are greatest when wind speeds are low and skies clear. The meteorological parameter most significantly related to heat-island magnitude, however, is the nearby rural, low-level, temperature lapse rate (vertical gradient). Heat islands tend to be greatest when pronounced ground-based inversions exist and least when air temperature decreases rapidly with height. This relationship results because the heat added to the atmosphere by the city serves to warm the atmosphere near the ground and, by convection, to warm higher layers of the atmosphere. For a given amount of heat added by the city, the greatest surface-temperature increase occurs when this added heat is distributed through a small layer of the atmo-

sphere (when a strong temperature inversion is present); the least urban-temperature increase occurs when air temperature decreases rapidly with height, so added heat is distributed through a large atmospheric layer.

Humidity. The average relative humidity in towns is usually several percent lower than that of nearby rural areas, whereas the average absolute humidity is only slightly lower in built-up regions. The main reason to expect differences in the humidity of urban and rural areas is that markedly different surfaces lead to a lower evaporation rate in a city than in the country. The countryside is covered with vegetation, which retains rainfall, whereas the floor of a city is coated with concrete, asphalt, and other impervious materials that cause rapid runoff of precipitation. Although the city's low evaporation rates result from the shortage of available water and the lack of vegetation for evapotranspiration, some moisture is added to urban atmospheres by the many combustion sources. Usually the addition is through chimneys at a height somewhat above ground level.

Variations of relative humidity within metropolitan areas resemble those of temperature because the temperature changes of a city are significantly greater than changes in vapour pressure. Thus, because of the heat island, relative humidities in a city are lower than in suburbs and outlying districts. The humidity differences are greatest at night and in summer, corresponding to the time of greatest heat-island intensity. Data from several cities, including Tokyo and London, have shown that a relative-humidity difference of about 5 percent is common between downtown and rural sites.

Turbulence over urban areas

Wind. The flow of wind over a city differs in several aspects from that over the open countryside. Two features that represent deviations from the regional wind-flow patterns are the differences in wind speeds in city and country and the convergence of low-level wind over a city. These differences occur because the surface of a built-up city is much rougher than that of rural terrain—causing increased frictional drag on air flowing over it—and because the heat island of a city causes horizontal thermal gradients, especially near the city periphery. The excess heat and friction also produce more turbulence over the urban area. The annual mean surface wind speed over a city has been estimated to be 20 to 30 percent lower than that over the nearby countryside, the speed of extreme gusts to be 10 to 20 percent lower, and the calms to be 5 to 20 percent more frequent.

A difficulty in estimating urban–rural wind differences is selecting representative sites within the city from which to take measurements. Most observations of urban wind flow have been made either from the roofs of downtown buildings, usually several stories high, or from parks or open spaces. Very few data have been obtained at street level in the city centre, the place where most human activity occurs. These measurements are generally representative, however, and can be useful for urban–rural comparisons.

The conventional measurements do not provide data on the fine-scale wind-flow patterns that are often important in the diffusion of pollutants very near their source. Even an isolated building increases turbulence in the atmosphere both in its lee and immediately upwind. The wind-flow direction near the ground for some distance in the lee of the building is actually opposite of that away from the building. Furthermore, wind direction in the "canyons" of the downtown section of most major cities usually parallels the street orientation, regardless of the direction of the natural wind flow. This channelling of the wind is also frequently observed naturally within straight, narrow valleys.

Past research on the direction of wind flow over urban areas has been primarily concerned with detecting and measuring a surface flow in toward the urban complex. It has been surmised that, if a city is warmer than its environs, the warm city air should rise and be displaced by cooler rural air. This inflow is weak, however, and occurs only in conjunction with well-developed heat islands, which in turn are dependent on certain meteorological conditions. Direct measurements of the inflow require a coordinated set of accurate observations, and few such investigations have been made. One such study was made at Frankfurt am Main, Germany, where during clear, calm nights an inflow toward the city centre was detected. When the large-scale surface wind speed reached three to four metres (ten to 13 feet) per second, however, a local city-circulation was prevented.

Two indirect techniques have been used to investigate the low-level convergence of wind flow over a city: the observation of smoke plumes from household chimneys and measurement of rime ice, which forms on the windward side of tree trunks. The thickness of the rime ice has been found to be proportional to wind speed around the periphery of Asahikawa, Japan (Figure 2). Local

wind-flow patterns can therefore be deduced; when the large-scale wind flow is weak, a convergence occurred.

Reduction of sunshine in cities

Solar radiation. The blanket of particulates in the atmosphere over most large cities causes the solar energy that reaches urban areas to be significantly less than that observed in rural areas. The particles are most effective as attenuators of radiation when the sun angle is low because the path length of the radiation passing through the particulate material is dependent on sun elevation. Thus, for a given amount of particles, solar radiation will be reduced by the largest fraction at high-latitude cities and during winter. On the average, the largest cities annually receive 15 to 20 percent less total solar radiation than nearby rural areas. Measurements taken in and around Rotterdam, The Netherlands, show that the city centre received 3 to 6 percent less radiation than the urban fringe and 13 to 17 percent less than the country. Until recently, central London annually received about 270 hours less of bright sunshine than did the surrounding countryside because of the high concentration of atmospheric particles. Other examples of the pollution effect on solar radiation have been obtained by comparing records of radiation received on weekdays with those of Sundays, when man's activities are at a minimum.

The introduction of smoke controls in London during the mid-1950s has afforded an opportunity to study the relationship between solar radiation and atmospheric particles. In general, the income of solar radiation and the frequency of bright sunshine in London have increased markedly in recent years, since implementation of the air-pollution laws. During the period 1958 to 1967, the average number of hours of bright sunshine from November through January was 50 percent greater than that observed from 1931 to 1960.

Visibility. Increased concentrations of particles usually characterize the atmosphere of metropolitan areas; consequently, visibilities are lower within a city than beyond its limits. These particles attenuate visible solar

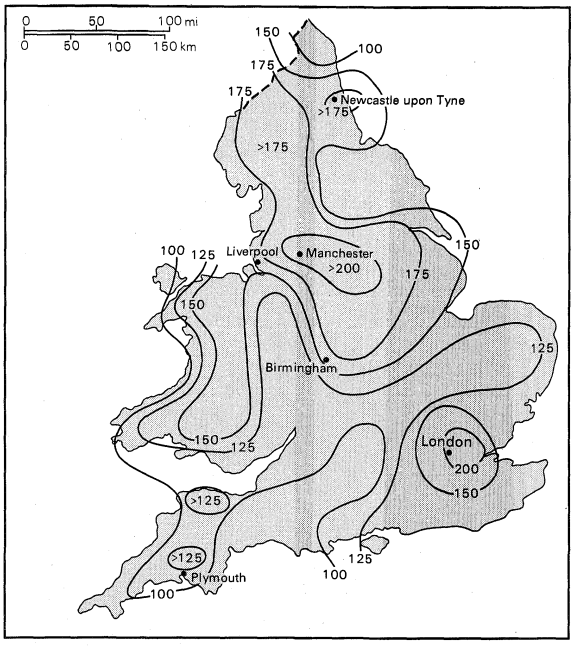

Figure 3: Average number of days per year with afternoon visibilities less than 6¼ miles in England and Wales.

energy in two ways, by scattering and by absorption—both of which serve to limit visibility. The importance of these two physical processes is determined by several factors, including particle size, shape, and chemical composition. Moreover, some pollution particles are hygroscopic; that is, water vapour readily condenses on them to form small water droplets, the ingredients of fog. By this process, a small dust particle becomes a much larger water droplet, which, because of its size, is a much more effective attenuator of solar energy. Water vapour condenses on some hygroscopic pollution particles at relative humidities as low as 70 percent; it condenses on many such particles at 90 percent relative humidity. Thus, urban visibilities are often less than those of nearby rural areas because of higher concentrations of dust particles and greater frequencies of fog. Industrial areas, such as those near London and in Manchester, Lancashire, report about twice as many days with low visibilities as occur in rural areas (Figure 3).

Increase of fog frequency

Fog generally occurs more frequently within metropolitan areas than the nearby countryside; this is not true for very dense fog, however. Apparently the extra warmth of a city often reduces the relative humidity and prevents the thickest fogs from reaching the densities reported in outlying districts. Table 1 shows the number of hours per year of the various-density fogs occurring in the vicinity of London.

Visibility in some communities has actually improved during the last two decades in response to local efforts at air-pollution abatement and the substitution of cleaner burning oil and gas for soft coal. London is notable in that respect, and several cities in the United States have shown similar improvement.

Precipitation. A city also influences the occurrence and amount of precipitation in its vicinity. An urban complex might be expected to increase precipitation because combustion sources add to the amount of water vapour in the atmosphere, higher temperatures intensify thermal convection, greater surface roughness increases mechanical turbulence, and the urban atmosphere contains greater concentrations of particles effective as ice nuclei. On the other hand, the higher concentrations of cloud condensation nuclei and very high concentrations of ice nuclei in a city's atmosphere may cause less precipitation. The relative significance of these parameters is not easy to establish because the few studies of urban precipitation have not included their continuous, quantitative measurement. Data from Europe and North America suggest, however, that the amount of precipitation over many large cities is about 5 to 10 percent greater than that over nearby country areas, with the greatest increases occurring downwind of the city centre.

An example of the distribution of precipitation around a Midwestern American city that is free of complicating topography is shown in Figure 4. The mean summer

Factors that complicate analysis of urban rainfall

Several difficulties have limited the number of detailed studies of the distribution of precipitation around metropolitan areas, such as that for St. Louis. Few rural areas remain undisturbed from their natural state, and many cities are associated with bodies of water or hilly terrain that affect the patterns of precipitation. Moreover, there are few urban areas that have many rain gauges with long-term records and uniform exposure throughout the period of record. Finally, the natural variability of rainfall, particularly the summer showers of mid-America, further complicates the analysis of urban–rural precipitation differences. The record from Central Park, New York City, illustrates the general difficulty of rainfall analysis. A statistically significant decreasing trend of precipitation of 0.3 inch per year was observed for this area from 1927 to 1965. Data from other nearby sites did not substantiate this trend, and, in fact, at Battery Place (the nearest measurement station) a small rainfall increase was observed during the same period.

Urban areas produce large amounts of heat that cause a warming of the atmosphere near the earth's surface and in turn may lead to increased vertical motions within the atmosphere. The buildings in a city, both large and small, present obstacles to a smooth flow of wind. This greater "surface roughness" causes greater turbulence of the urban wind flow and increases the likelihood of vertical atmospheric motions. The greater tendency for rising air over a city because of the added heat and roughness, together with the added possibility of atmospheric water vapour from combustion sources, increases the likelihood of precipitation in a metropolitan region.

Urban areas are a prolific source of cloud condensation nuclei, and these, theoretically, can lead to a decrease in rainfall. The concentration of continental condensation nuclei in the lower atmosphere is naturally only a few hundred per cubic centimetre of air. Consequently, when water vapour condenses within the atmosphere to form a cloud, the available water is shared by relatively few nuclei, and large waterdrops result. Downwind of and within urban areas, however, where cloud condensation nuclei concentrations often exceed 1,000 per cubic centimetre, the same amount of available water forms many small droplets. This inhibits the coalescence mechanism of rainfall development, which depends upon the presence of some large drops within a cloud. The large drops will fall by gravity, collect other drops as they do fall, and thereby grow large enough to fall to the ground.

Ice nuclei produced by automobile exhaust

Ice nuclei also are an important factor in cloud and precipitation development. If these nuclei are present at the right time and place within clouds that contain supercooled water droplets, they can augment the growth of the clouds and their ability to produce precipitation. Too great a concentration of these nuclei can result in too many ice crystals within a cloud, however, and, as in the case of condensation nuclei, inhibit the formation of raindrops large enough to fall from the cloud. Certain human activities produce ice nuclei; a particularly good source is steel mills. The lead particles in automobile exhaust also are effective ice nuclei when combined with atmospheric iodine to form lead iodide. Although the amount of iodine in the atmosphere is apparently quite small, this mechanism represents a great potential for the modification of metropolitan ice-nucleus counts and the corresponding precipitation patterns because of the large amount of automobile traffic.

POLLUTION

The most common air pollutants of urban atmospheres are such substances as carbon dioxide, carbon monoxide, sulfur dioxide, hydrocarbons, nitrogen oxides, ozone, and particles that originate from such sources as automobile exhaust, industrial processes, fuel combustion for electrical-power generation, burning of wastes, and photochemical reactions. Nearly every urban area can attribute a significant monetary loss to the adverse effect of these pollutants on human health, vegetation, such materials as rubber and house paint, and visibility.

Two important factors that determine the concentration of a pollutant within an urban area are the magnitude of the local emission sources of that pollutant and prevailing meteorological conditions. The meteorological parameters that specify the "ventilation" of an area are the height of the atmospheric layer through which pollutants are being mixed and the average wind speed through that layer. These parameters are usually least favourable for pollutant dispersion from sunset, throughout the evening, until just after sunrise. The observed urban concentrations of pollutants the major source of which is automobile exhaust frequently have two maxima each 24 hours, during the early-morning and late-afternoon peak-traffic periods. In general, the morning concentrations are greater than those of the afternoon because of less favourable atmospheric dispersion at that time. At infrequent intervals, meteorological conditions conducive to the accumu-

Concentration of pollutants and fatal episodes

lation of pollutants will persist over an area for several days. These episodes are usually characterized by temperature inversions (temperature increases with height), which strongly inhibit atmospheric mixing. Three of the worst such past episodes, resulting in loss of life, occurred at the Meuse Valley, Belgium (1930), Donora, Pennsylvania (1948), and London (1952). During the Donora incident, 43 percent of the local population reported illness; at London, about 4,000 people died as a result of several days of high pollutant concentrations.

Carbon dioxide. Carbon dioxide (CO_2) is an important constituent of the atmosphere because of its influence on global climate. The background concentration of this substance has been increasing for more than a century, mainly as a result of the burning of fossil fuels. It is now slightly over 320 parts per million (ppm) by volume. Concentrations are higher over urban areas, and they show a strong diurnal and seasonal dependence. During summer, green plants convert carbon dioxide to oxygen by photosynthesis during daytime, whereas decomposition and respiration of organic matter produces carbon dioxide continuously. During winter, plant growth and organic decomposition are minimal, and little diurnal variation occurs in near-surface atmospheric carbon dioxide concentrations.

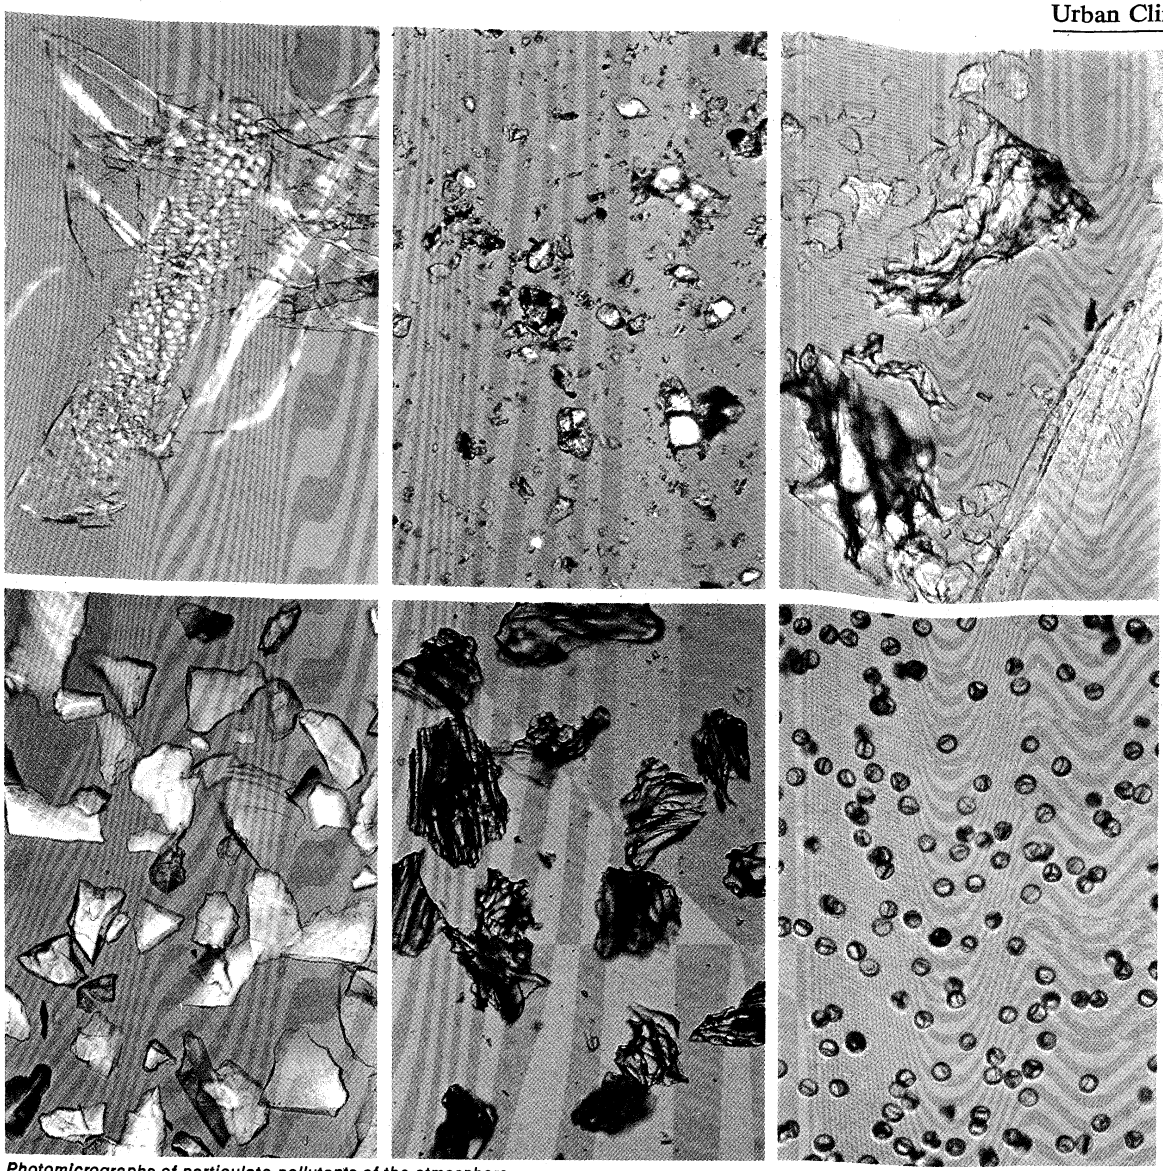
Carbon monoxide. Carbon monoxide (CO) is a highly toxic, but nonirritating (colourless, odourless, tasteless) gas with a natural background concentration of about 0.1 part per million. A major source of pollutant carbon monoxide is the emissions from internal-combustion engines. In fact, vehicle exhaust accounts for about 60 percent of all the pollutant carbon monoxide released in the United States, and in many cities the mass of carbon monoxide annually emitted exceeds that of any other pollutant. The highest urban concentrations are usually found where automobile traffic is heaviest, and the daily concentration variations over most cities show a bimodal distribution, reflecting usual weekday traffic patterns. Typical urban concentrations for large cities range from five to ten parts per million; the maximum observed concentrations are about ten times as great. Although even the highest concentrations of carbon monoxide observed today appear to have no effect on vegetation or materials, this substance has a notably detrimental effect on human health. Large dosages of carbon monoxide can cause death, but even exposure to concentrations as small as ten to 15 parts per million for eight hours have been shown to affect time-interval discrimination in nonsmoking adults.

Relation to automobile traffic

Sulfur dioxide. Sulfur dioxide (SO_2) is a common gaseous pollutant in nearly all cities. More than 75 percent of all the pollutant sulfur dioxide in the United States is caused by the combustion of coal and petroleum products; about 40 percent results from electrical-power generation alone. Sulfur dioxide is a relatively short-lived atmospheric pollutant because it is readily oxidized to sulfur trioxide (SO_3) and finally to sulfuric acid mist and sulfate particles. This characteristic oxidation, coupled with a very low natural background concentration and variable meteorological conditions, causes a wide range of sulfur dioxide concentrations to be observed over urban areas. Typical concentrations for large cities range from 0.01 to 0.1 part per million; only occasionally do observed concentrations exceed one part per million. High concentrations of sulfur dioxide can affect human health, visibility, materials, and vegetation. A mean concentration of 0.04 part per million for a year or 0.11 part per million for three to four days can be detrimental to human health; an annual mean concentration of 0.03 part per million can damage vegetation. As these adverse effects of sulfur dioxide have become documented and air-pollution regulations have been tightened many electric utility companies and other industries have begun using fuel with low sulfur content to reduce sulfur dioxide emissions. Reliable, economical techniques to control emissions of sulfur dioxide from smokestacks have not been available generally.

Need for low-sulfur coal

Hydrocarbons. A class of pollutants known as hydrocarbons is composed of hundreds of individual organic compounds made up of atoms of hydrogen and carbon. Methane is the most common hydrocarbon and usually represents more than 50 percent of the total. Other common constituents are such compounds as ethane, propane, acetylene, butane, and ethylene. Motor vehicles are the source of roughly one-half of all the hydrocarbon emissions, and consequently the diurnal variation of observed concentrations exhibits a morning and late-afternoon peak. Typical urban concentrations are a few parts per million. Hydrocarbons themselves apparently have no adverse effect on human health, but the nonmethane fraction is important in photochemical reactions. In the presence of sunlight, hydrocarbons will combine with oxides of nitrogen to produce photochemical oxidants, including ozone, which are harmful to human health.



Nitrogen oxides. Within the oxides of the nitrogen group of air pollutants, nitric oxide (NO) and nitrogen dioxide (NO_2) occur most frequently. Nitric oxide is commonly formed during high temperature combustion. In nearly every city, the source of at least 50 percent of all the nitric oxide emissions is automobile exhaust. Nitrogen dioxide is formed both by combustion and within the atmosphere when nitric oxide combines with oxygen. At low nitric oxide concentrations this atmospheric reaction proceeds slowly, but in the presence of sunlight and hydrocarbons nitrogen dioxide is formed rapidly. In the Los Angeles area, characterized by heavy automobile traffic and much sunlight, nitrogen dioxide is primarily responsible for the brownish colour of the local smog. Both nitric oxide and nitrogen dioxide are short-lived pollutants without any global accumulation because of their ability to participate in atmospheric reactions. In Los Angeles, concentrations of nitrogen dioxide occasionally have exceeded one part per million, but concentrations of 0.1 part per million to 0.3 part per million are more typical. Observed concentrations of nitric oxide apparently have no direct adverse effects, but concentrations of nitrogen dioxide greater than one part per million can affect both human health and sensitive plants. Furthermore, these pollutants play a vital role in the formation of photochemical oxidants.

Role of sunlight in creation of smog

Oxidants. The group of pollutants called photochemical oxidants is defined as that class of substances that will oxidize certain substances not readily oxidized by oxygen. Ozone (O_3) is the main constituent of the group, which also includes peroxyacetyl nitrate (PAN), and in terms of vegetation damage is the most harmful of all pollutants. Photochemical oxidants are the products of atmospheric reactions involving hydrocarbons, oxides of nitrogen, and sunlight. Because sunlight is necessary for these reactions, maximum oxidant concentrations usually occur around noon, whereas during nighttime, concentrations are quite low. In the Los Angeles area, the highest concentrations occur in late summer and fall; one-hour average values may then exceed 0.5 part per million during episodes of high air pollution. Average hourly concentrations exceeding 0.07 part per million have been shown to impair the performance of student athletes; instantaneous oxidant concentrations of about 0.1 part per million have been associated with eye irritation. Sensitive vegetation has been adversely affected by exposure to concentrations of 0.05 part per million for four hours.

Particles. In addition to the gaseous pollutants, large quantities of solid material, generally referred to as particulate matter, or particles, are emitted into the atmosphere over urban complexes. These man-made emissions are superimposed on a natural continental background concentration of about 20×10^{-6} gram of particles per cubic metre of air (one cubic metre equals 35.05 cubic feet). Natural particles are composed of such materials as sea salt, windblown dust from the earth's surface, and volcanic ejecta. The sources of atmospheric particulate matter resulting from man's activities include both particles directly emitted into the atmosphere and those formed within the atmosphere from conversion of gaseous pollutants to particles, including sulfur dioxide, oxides of nitrogen, and hydrocarbons. The main sources of directly emitted particles are internal-combustion engines (automobiles), industrial processes, refuse incineration,

and fuel combustion for electrical-energy production and heat. Typical concentrations of particulate matter in the centre of large cities are about 200 × 10^{-6} gram per cubic metre; higher concentrations are often found near heavy industrial areas. Particles collected over urban areas have a widely varied chemistry; nitrates, sulfates, organic material, and many elements, including iron, lead, zinc, manganese, copper, nickel, and carbon, have all been commonly identified. Both the natural and man-made particles are removed from the atmosphere primarily by sedimentation (large particles fall to the earth by gravitational attraction) and washout by rain and snow. The smaller ones may be carried many miles by the prevailing wind patterns, however. Natural dust blown from the surface of the Sahara during the summer, for example, is transported westward by the trade winds and can frequently be detected in the West Indies, several thousand miles away.

Both natural and man-made atmospheric particles near the earth's surface vary greatly in size. Particles will coexist with radii between about 10^{-7} to 10^{-2} centimetre (one inch equals 2.5 centimetres). Very few of the larger particles are present in the atmosphere, but the number increases rapidly at progressively smaller sizes. Most particles are usually about 10^{-6} to 10^{-5} centimetre in size. The smallest particles (10^{-6} centimetre and smaller) can affect human health because this size will remain in the respiratory tract once it enters. Those with sizes between about 10^{-5} and 10^{-4} centimetre attenuate visible solar radiation most effectively and thus have a significant effect on visibility. The larger particles may act as cloud condensation nuclei and thereby influence fog formation.

Table 2 summarizes the principal atmospheric pollutants in terms of the characteristics of London and Los Angeles types of smog. London pollution features particulate matter, the presence of sulfur compounds from combustion of coal and petroleum, and very low visibilities. The major source of the Los Angeles type of pollution is automobile exhaust; through photochemical reactions, the exhaust products are transformed into oxidants, particularly ozone, which can cause eye irritation and damage to vegetation.

EFFECTS OF MAN'S ACTIVITIES ON GLOBAL CLIMATE

Man's ability to alter his environment is a recognized aspect of the modern world. Some of the local effects of atmospheric pollution, which have been previously discussed, are obvious to the inhabitants of urban areas. A more subtle aspect of air pollution may be the long-term modification of climate, particularly on a global scale, brought about by a worldwide buildup of pollutants. This section will indicate some of the ways in which man

Ways in which man may affect climate

may inadvertently be modifying his climate on a large scale as a result of his activities, most of which are centred in urban areas. These include: (1) the effects of carbon dioxide and atmospheric particles on the earth's energy balance, modifying the distribution and quality of radiant energy; (2) the effect of particles in the form of condensation and ice nuclei on the precipitation mechanisms; and (3) the effect of the heat produced by man's activities on the global energy balance.

No study has yet shown that the large-scale global climate has been significantly affected by man's activities. The climate within an urban area has been demonstrated to be different from that which would have existed naturally, but man's role in altering continental or larger scale climate has not been proved. This inconclusiveness results because the specific cause or causes of climatic change have not yet been determined. Although many theories have been presented, no one can definitively account, for example, for the origin of the glaciers that covered much of North America 10,000 to 15,000 years ago. Similarly, a cooling of the mean surface temperature of the earth by a fraction of a degree has been observed since World War II, but scientists cannot determine whether the cause of this climate change was natural or man-induced or what specific factor produced this change (see further CLIMATIC CHANGE).

Nonetheless, several mechanisms have been proposed to relate man-made pollution to climate. As yet, these theories are not detailed, and such items as the magnitude and specific nature of the change in climate resulting from a given amount of a pollutant remain to be determined. Several of these theories are mentioned below.

Increase of carbon dioxide. The global concentration of carbon dioxide (CO_2) has been steadily increasing since the mid-1800s, mainly as a result of the burning of such fossil fuels as coal and oil. At that time, the concentration of carbon dioxide in the atmosphere was about 290 ppm by volume, whereas in the early 1970s it averages slightly over 320 ppm. Through the mechanism known as the greenhouse effect, carbon dioxide in the atmosphere absorbs thermal infrared radiation emitted by the surface of the earth and re-radiates a portion of it back toward the earth. Thus, as the amount of atmospheric carbon dioxide increases, the average temperature of the earth's surface also increases. This fact—that changes in the amount of carbon dioxide can cause changes in climate—was first suggested in about 1900. Since then, a number of theoretical attempts have been made to relate quantitatively carbon dioxide concentration and the mean temperature of the earth. The conclusion drawn from one theoretical model is that a doubling of carbon dioxide would result in a 2° C (4° F) rise in mean surface temperature. Despite this model's sophistication, it is based on radiative processes alone and does not include the interactions between carbon dioxide and such factors as evaporation and condensation, cloudiness, and the oceans. Consequently, it cannot provide a definitive analysis of the relationship between carbon dioxide and climate. If these results are accepted as indicative of the true effect of carbon dioxide, then the 10 percent carbon dioxide increase since the end of the 19th century has resulted in an increase of mean, worldwide temperature by only a fraction of a degree centigrade.

The greenhouse effect and temperature

Beginning with the International Geophysical Year in 1957, accurate and systematic measurements of carbon dioxide have been made at several widely separated locations. The most frequent and continuous are those at the Hawaiian Volcano Observatory, at 11,150 feet elevation. These observations have shown that since 1958 the carbon dioxide concentration has been steadily increasing at an average rate of about 0.7 ppm (0.2 percent) per year. During this time the total amount of carbon dioxide produced from fossil-fuel consumption has been roughly double the amount that stayed in the atmosphere. The fraction not in the atmosphere has gone into the hydrosphere (the waters of the earth) and the biosphere (the mass of organic matter and living things in all earth environments), the largest component of which is the forests.

These nonatmospheric reservoirs are important in attempts to forecast future carbon dioxide concentrations because changes in the mass of the biosphere or the circulation and mean temperature of the oceans could affect the fraction of carbon dioxide remaining in the atmosphere. If, however, it is assumed that the annual growth rate in the global consumption of fossil fuel is 4 percent and that 50 percent of the released carbon dioxide remains in the atmosphere, a concentration of about 380 ppm can be forecast for the year 2000. This would be an increase of nearly 20 percent from the 1970 concentration. This carbon dioxide increase theoretically corresponds to an increase in mean air temperature of roughly 0.5° C.

Atmospheric particles and recent cooling. From the late 1800s until World War II the mean surface air temperature of the earth increased by about 0.5° C (about 1° F). Many scientists attributed this warming to the gradual increase in carbon dioxide. Since then, however, much of this temperature increase has been offset by a cooling trend. This reversal of the global temperature trend, coincident with increased industrial activity throughout the world, has led to suggestions that the recent cooling trend is a result of the attenuation of solar radiation by atmospheric aerosols. From measurements in large cities it is apparent that particle-laden air can cause a depletion in the amount of total solar radiation received at the city surface. Some of the greatest observed reductions of solar energy, as previously noted, occurred over London and other British cities about 1955, before any significant pollution-abatement actions were undertaken. At that time, attenuation of total solar radiation of 50 percent over the major cities during winter was not uncommon.

The theory that particulate matter in the atmosphere is responsible for the recent global cooling is supported by evidence that the background concentration of atmospheric particles has increased during this century. Measurements of direct solar radiation, which indirectly yield a measure of the atmospheric particle concentration, have shown a trend of decreasing solar intensity and atmospheric transparency at sites throughout the United States, Europe, and the Soviet Union. An upward trend in fine-particle pollution over the north Atlantic Ocean has been inferred from measurements of atmospheric electrical conductivity. These data have been confirmed by direct particle measurements at remote sites throughout the United States during the last decade. Whereas particle concentrations have been rising at remote United States locations, similar observations in urban areas have shown a slight decreasing trend, presumably the result of air-pollution-abatement activity.

Atmospheric particles are not uniform in composition or physical characteristics, and the absorptive and scattering properties of many of them are unknown. Consequently, scientists cannot determine whether the aggregate of particles being emitted into the atmosphere is causing a warming or cooling of the atmosphere. The solution to this problem requires more detailed knowledge of the characteristics of atmospheric particles and a sophisticated mathematical computer model that can

accurately simulate the effect of particulate matter on global climate.

Another aspect of weather and climate that possibly can be modified on a large-space scale by man's activities is the distribution and amount of precipitation.

Modification of precipitation

An example of inadvertent precipitation modification was reported in which the smoke particles from the burning of sugarcane fields in Australia were found to be effective condensation nuclei. A subsequent analysis of local climatological records showed that, as the production of cane increased over the years, a 20 percent decrease in precipitation had occurred downwind of the cane-producing areas during the three months of the harvesting season. It was concluded that the local clouds had been stabilized by these smoke particles—the many condensation nuclei present inhibited the formation of large droplets that could fall as rain.

Perhaps the particles in automobile exhaust, particularly the lead particles, have the greatest potential for inadvertent modification of precipitation on a large scale. It has been suggested that, when these lead particles combine with iodine in the atmosphere, the resulting product, lead iodide, is very effective as an ice nucleus. Because of the proliferation of automobiles, this mechanism may be an important influence on both local and large-scale weather when sufficient quantities of iodine are present in the atmosphere.

Thermal energy. Man can also affect world climates when the artificial heat produced by his activities becomes a significant fraction of that received naturally from the sun. Unfortunately, present knowledge of the dynamic interactions between this thermal-energy release and climate is not sufficient to predict accurately just when and how climate will be significantly affected. Man-made heat is known to cause urban heat islands, however, and during winter, when the solar intensity is relatively small, energy produced by man's activities in large metropolitan areas can actually be greater than that naturally received from the sun. On a global scale, the artificially produced energy is an insignificant fraction of that received naturally. If the amount of worldwide waste thermal energy continues to increase at the current rate (about 5.5 to 6 percent per year), it will still not be of global climatic significance in the year 2000. But, if this growth in energy consumption continues indefinitely into the future, it undoubtedly will affect global climate eventually. Using a crude model and tenuous projections of future energy consumption, it has been concluded that climate could be significantly altered within several hundred years.

Effects of other activities of man. A number of man's other activities have been suggested as being responsible for or capable of causing global climatic change. First, man may be altering climate on a large scale by changing the surface characteristics of the land and oceans. Converting forests and prairies to agricultural fields, building cities, damming rivers to create lakes, and spilling oil at sea all affect the surface absorption of solar radiation and evaporation of water (see further PHYSIOGRAPHIC EFFECTS OF MAN). These activities can influence climate on a small scale, such as the city heat island, but apparently have a minor effect on global climate. Second, because the amount, type, and distribution of clouds are extremely important factors in regulating worldwide climate, when man significantly alters natural cloudiness, climate will probably also be altered. He can affect cloudiness by such processes as the emissions of cloud and ice nuclei, moisture, heat, and the condensation trails formed by high-flying jet aircraft. Third, the development of supersonic transport (SST) aircraft has been accompanied by controversy concerning the effect that the exhaust products may have on climate. These aircraft emit water vapour, soot particles, and other combustion products in the stratosphere at a height of about 20 kilometres (12 miles), where the diffusion of these substances will be slower—and their lifetime longer—than at lower altitudes. In sufficient quantity the water vapour could increase cloudiness and, through the greenhouse effect, change atmospheric temperatures. The particulate matter also could affect climate by attenuation of solar radiation.

Urban Design

Design is the imaginative creation of possible form intended to achieve some human purpose: social, economic, aesthetic, or technical. One can design a garden, the layout of a book, a fireworks display, a drainage channel. Urban design deals with the form of possible urban environments. Urban designers work on three different kinds of task: (1) Project design, which is concerned with the form of a definite geographic area in which there is a definite client, a concrete program, a foreseeable time of completion, and effective control over the significant aspects of the form; housing projects, shopping centres, and parks are examples. (2) System design, which considers the form of a functionally connected set of objects. These may be distributed over extensive areas, are built or managed by one agency, but do not make a complete environment. A highway network, a lighting system, and a set of standardized signs provide examples. (3) City or regional design, in which there are multiple clients, indeterminate programs, partial control, and constant change. Regional land-use policies, the formation of new towns, and the rehabilitation of older urban districts are examples of this kind of design. In emphasizing the direct human impact of the environment, it must be noted that design is not solely concerned with any single influence of form.

FAILURES OF URBAN DESIGN

Many examples of magnificent buildings, gardens, or bridges may be cited. It is far harder to find cases of fine complete environments, particularly in the modern world. There are a few residential areas of moderate scale that are comfortable, workable, and handsome. There is an equally small number of well-designed urban centres.

Large planned settlements of distinguished form are quite rare; Tapiola in Finland and Vällingby in Sweden are among the few. But planned, ugly and inhuman places, formless suburbs, gray city districts, and industrial wastelands are endless.

Toni Schneiders

Pedestrian centre, Vällingby, Sweden.

Distinguished historical, unplanned areas are much easier to find. Most texts on landscape or urban design are illustrated with views of historic cities, old farming regions, or primitive or wilderness areas. The apparently unplanned squatter settlement, or the old urban district, can have more visual warmth and interest than the newest designed suburb or apartment project.

Explanations of design failures

There are a number of possible explanations. One is that a fine landscape will only develop in time, as historical meaning accumulates, and form and culture come to a close rubbed fit. If so, the best that can be done is to conserve the past, while producing technically workable settings today in the hope that they will acquire character for later generations. If true, it is discouraging for a generation committed to building more urban environment than already exists.

The difficulty may be one of scale and control: that good environments are the direct products of their users, or of professionals who have an exact knowledge of user requirements and values. Superb houses are designed, but not superb housing projects, which are designed for people en masse. Or the true reason may be more profound—that environments reflect the state of society. The crisis of environmental quality arose with the Industrial Revolution, which looked on space and people as resources to be used. That crisis can only be surmounted by a radical change in society, and technical innovations will be of small account.

A possible solution may be the resolve to spend greater resources on quality, but while it is true that such efforts are often starved for funds, some very expensive projects are equally inhuman. And many areas of the world are too hard pressed to be able to allocate economic resources specifically to fine environment.

A final explanation for failure is the technical one: that large-scale environmental design is simply very new, and that urban designers have yet to learn their trade. Good environments were made piecemeal, because that was the only way in which they could be produced in the past. Good ones are not made now, because no one has mastered the new scale of intervention. There have been some successes in planned environments and there may be some hope in increased technical skill. But it will not be effective on any substantial scale unless it is linked to changes in values and in society.

Urban design is effected by many kinds of professionals and decision makers, sometimes consciously, often inadvertently. Those who call themselves urban designers are most likely to be men with architectural or landscape backgrounds, working as parts of much larger teams. For the most part they do project design: shopping centres, housing projects, parks, expositions, universities, medical or government centres, urban renewal sites, and large suburbs. Their employers are large investors and real estate developers, or public development authorities.

Urban designers tend to be found in one of three kinds of organizations. One is the large architectural planning and consulting firm which develops complete projects for their clients from market studies, through programming, financial and legal planning, physical design and engineering, to working drawings and field supervision. They are also employed within public or private agencies that are actually building and managing a piece of the environment. Finally, urban designers may be found in area governments, particularly at the city level, where they regulate the design of public and private projects.

The professional urban designer is distant from the ultimate user, and often at odds with the other actors in the decision-making process. The designer may only implement decisions already made, or may wield substantial power, because of his personal prestige and his ability to frame the terms of debate about spatial alternatives. But his concerns are usually seen as skills to be applied after a basic program is fixed and are thus rarely well meshed into the web of decision. Many other professionals and decision-makers shape the city environment, with far more aggregate effect, most often without conscious consideration for environmental quality. Engineers design roads, bridges, and other major features. Real estate developers create substantial districts. Economic planners set resource allocations. Lawyers and administrators frame tax regulations and municipal codes, or set the standards of eligibility for grants. Architects and builders erect single buildings; industrial designers create store fronts, signs, light fixtures, and street furniture. Government departments build and maintain the public ways and put up public buildings. Surveyors lay out subdivisions; utility companies design and install their systems. The manufacturers of standard products, such as light standards or wall panels, have a pervasive effect. Even in Socialist countries, the responsibility for developing and maintaining the city environment is widely fragmented. The man who ultimately suffers or enjoys the product is heard with difficulty.

Fragmentation of urban design

ELEMENTS AND MATERIALS OF URBAN DESIGN

The raw materials from which the urban designer creates his effects are numerous, but the more salient ones may be categorized as follows:

Space. The voids in a landscape are of primary importance, since man is a mobile animal. The urban designer deals with the spaces accessible to the public, both external (streets, parks, squares) and also internal (lobbies, arcades, tunnels, concourses), with their location, scale, and form, as well as the linkages between them. Large spaces, outdoor ones in particular, are often loose in form, and subject to many optical illusions of distance, visual masking, level change, and geometry. Spaces may be enclosed by opaque barriers, or by intermittent walls, or even by visual suggestions: colonnades, bollards, changes in group pattern, breaks in grade, and imaginary extensions. Buildings have been the traditional enclosures of urban space, but outdoor places are rarely completely enclosed, and contemporary spaces are increasingly open and complex.

Spatial character is affected by proportion, or the size of parts relative to each other, and also by scale, or the size in relation to surrounding objects and to the observer. Spaces vary in effect by the way one moves through them, and by the spaces that precede or follow them. Appearance is modified by activity, by the colour and texture of walls and floor, and by the objects with which they are furnished. A deserted square is quite different from a

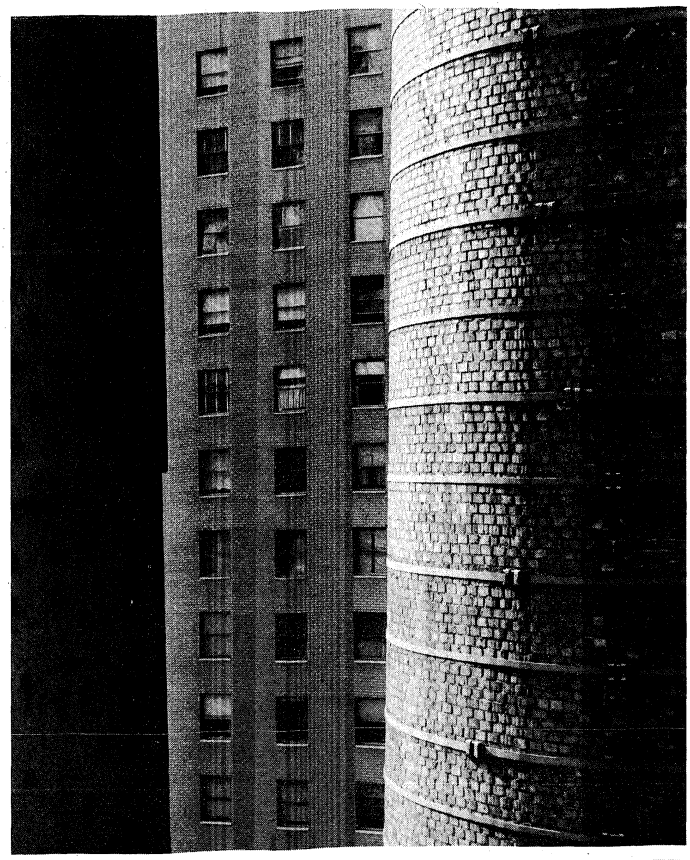
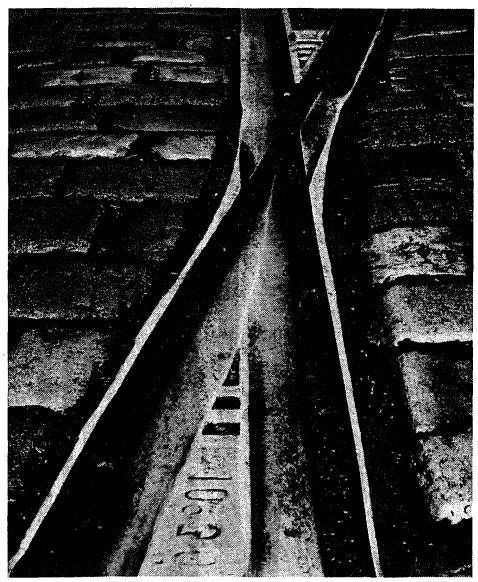
busy one. Light can be used effectively to emphasize texture, conceal or reveal a feature, contract or expand spatial dimensions.

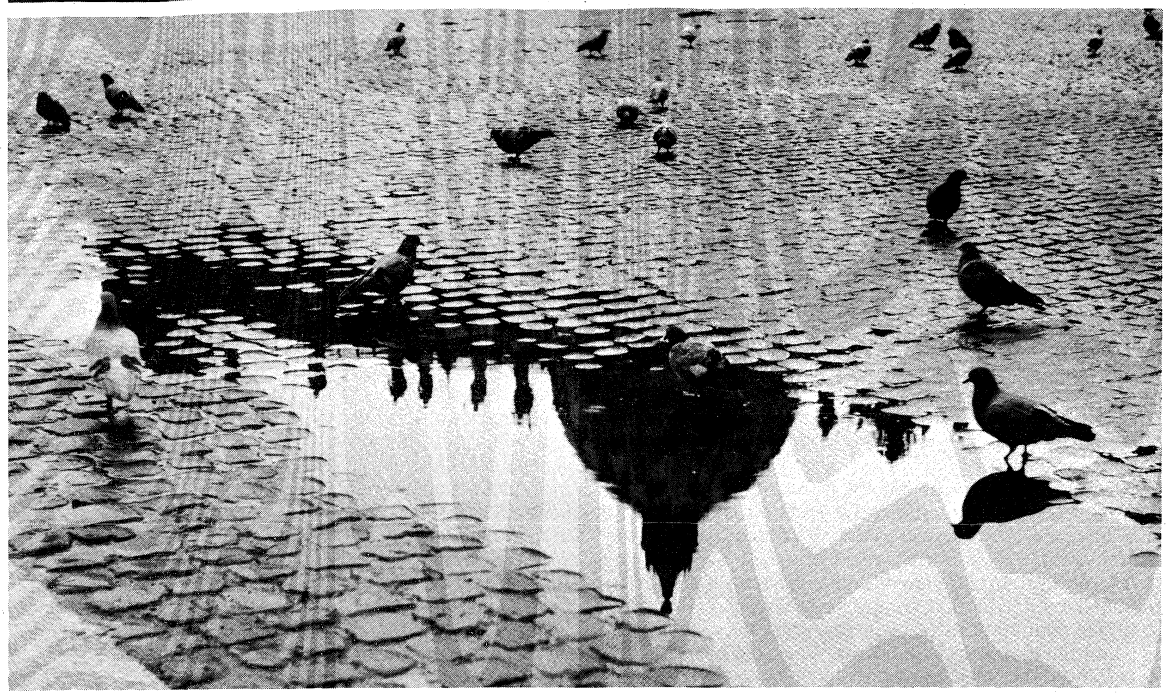


Other senses than vision convey the shape of a space, hearing most notably, since echo location is an accurate cue. The smell of a place is part of its identity, and so is its microclimate: it will be remembered as cool and moist, or hot, bright, and windy. All of these can be modified by the design of a place. Spatial forms have symbolic connotations as well: the awesomeness of great size and the interest of diminutive scale; the protection of the cave and the freedom of the prairie.



There is a rich vocabulary of spatial types: the vista, the court, the slot, the maze, the tunnel, the avenue, the canopy, the glade, the meander, the park, the bowl, the crest, the valley, and many others. At a less abstract level, there are complex urban spatial types: the English residential square, the Italian piazza, the formal French place, the parkway, the avenue, the arcade, the waterfront promenade. New social requirements and the creative efforts of designers are evolving new types as well: freeway, subway station, shopping mall, superblock interior, and industrial estate.

Visible activity. While designers traditionally focus on visible space, it is not as prominent to most observers as is the sight and sound of other human beings. Seeing and being seen—observing who is there, what they are doing, and what they intend are permanent attractions. The designer can make activity visible; provide places for meetings, promenades, and celebrations; and can reinforce the conduct and mood of action. Light and distance determine whether faces can be read; sound levels make conversation easy or difficult. The movement of ships and trains, the workings of giant machinery, are as fascinating as fire and water.



Sequences. A landscape is also a network of sequences along the streets, walkways, and transit lines. Any single view is less important than the cumulative effect of a series of views. Coming out of a narrow slot into a broad expanse, for example, is a sure-fire effect. Questions of orientation become significant: the apparent direction toward a goal, the marking of the distance traversed, the clarity of entrance and exit. Each event should prepare for the next. Great cities are known for their walks—a pleasure now often denied. A basic step in urban design is to analyze the consequences of a setting seen, not flatwise or instantaneously, but as a form through which one moves.

Communications. A landscape communicates meanings to its users, whether by explicit symbols or by the observer's knowledge of the meaning of visible shapes and motions. These meanings are frequently embodied in

City patterns and textures.

Shapes and motions, signs and symbols

intentional symbols: words, icons, or conventional referents like the barber pole or the marquee. These signs are necessary and interesting, a flow of information to be clarified and enhanced. They can be used, not simply to sell or command, but to speak of history, ecology, the presence of people, the flow of traffic, weather, time, events to come, and basic values.

Surfaces. The texture of walls, roofs, and floors is a very noticeable characteristic of the urban scene. The city floor is most important: one touches it as well as sees it. Its cleanliness is an emotional symbol; changes of level force one's attention to it. Textural patterns guide and express action patterns: curbs, runnels, footpaths, tanbark, sand. Textures neutralize or dramatize form. Asphalt is a metaphor for urbanization, but the range of possible surfacing is much wider: cultivated and stabilized earth, low shrubs and ground covers, tall weeds and grass, thickets, tanbark, macadam, sand, gravel, concrete with jointing or surface aggregates, wood blocks and decking, terrazzos, mosaics, blocks, bricks, tiles, cobbles, setts, and slabs. Short-run cost and mechanical maintenance lead to the use of concrete or grass, but variety of use should lead to variety of material.

Rock, earth, and water. Under the surface finish, the environmental base is rock and earth. Cuts and fills, pits and outcrops, cliffs, caves, and hills give one an intuition

of the planet whose surface one inhabits. Underlying rock is hidden, and bare earth seems indecent, yet they are expressive, and often welcome, materials.

Water is also elemental—simple in its nature but extremely varied in effect. The range of common terms is an index of its potential—ocean, pool, sheet, jet, torrent, rill, drop, spray, cascade, film—as are the kinds of liquid motion—trickle, splash, foam, flood, pour, spout, surge, ripple, run. This range of form and motion, this changeableness in unity, the play of light and sound, the intimate connection with life, all make water a superb outdoor material. Moving water gives a sense of life, still water unity and rest. Water plays with light, reflecting the changing sky or sunlit objects nearby. Water is technically troublesome, but hypnotically attractive.

Plants. Many great landscapes are treeless; there are handsome squares that do not include a visible plant of any description. Yet plants are one of the fundamental landscape materials, and the most widely enjoyed. But planting is the "extra" in development, the first item to be cut when the budget pinches.

Reasons for the choice of plants

Plant species are chosen for their hardiness, given the microclimate, soil condition, expected traffic, and level of maintenance. Texture and the general habit of growth are more predictable than individual shape, and more telling. Initial appearance, maturity, and decay must all be considered, since this is a living landscape. The aim is to so manage the landscape that it becomes a stable, self-replacing system as rapidly as possible.

Detail. A developed site includes many man-made details: fences, seats, signal boxes, poles, meters, trash cans, fireplugs, manholes, wires, lights, mailboxes, steps, curbs, and telephones. It is curious that most of this list evokes a sense of disharmony. This is the as yet unassimilated equipment of urban civilization whose presence cannot be banished. Alarms must be found; trash cans must be moved; tired people want to sit; fences mark off personal territory. Designers have often been concerned about site detail, but usually in order to hide it, or to "organize" it, or to give it stylish form. Less attention has been given to its actual use and the form appropriate to that use.

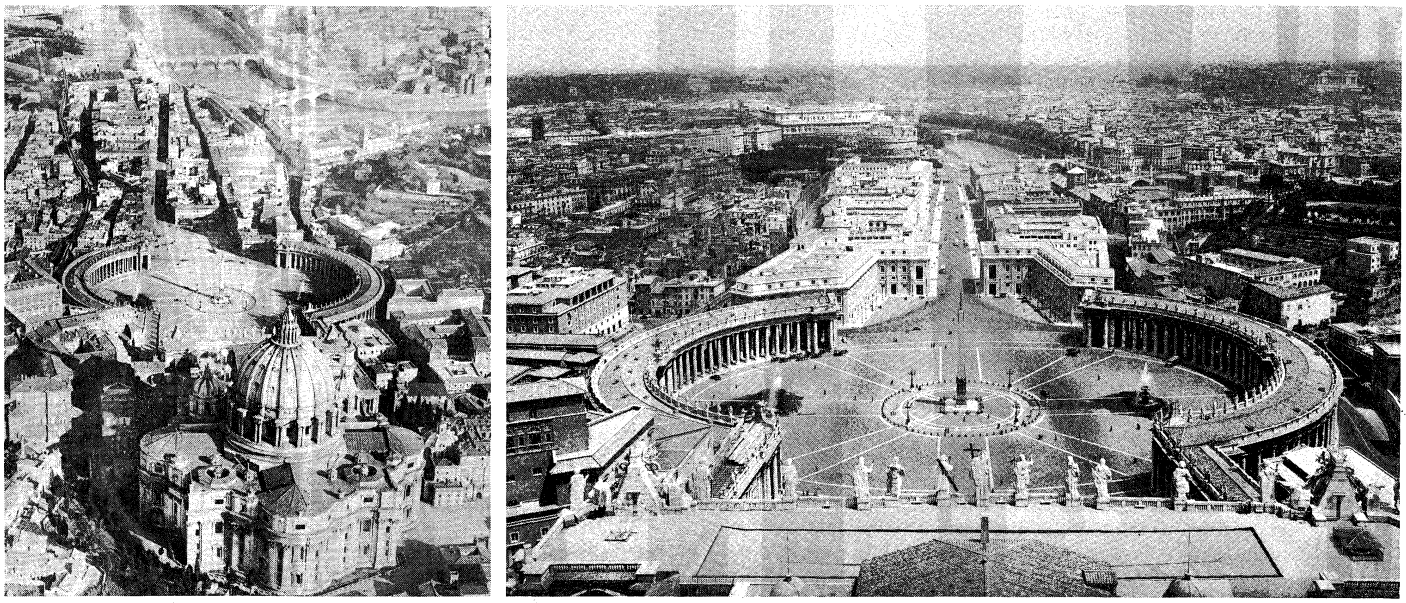
CRITERIA

Environmental stress. A place may be too hot, too noisy, too bright, too loaded with information, too odorous, too windy, too dirty or polluted, even too clean, too empty, or too silent. The physiological and perceptual stresses imposed by the physical environment are a common complaint of city life. Climate, noise, pollution, and the level of visual input are the factors most often referred to. Usually there is an acceptable range, with a threshold of tolerance at either end. The range has a biological basis, but it is affected by what is culturally acceptable, by the temperament of the person, and by the activity he is engaged in. For particular groups, engaged in similar behaviour, one can usually find substantial agreement about what is unpleasant or intolerable. Thus there is a commonly accepted Western standard for the maximum noise level in a sleeping area, while the standards for comfortable domestic indoor temperatures shift by as much as ten degrees from one European country to another.

Relation of environmental stress to health

Somewhat more objective than the sense of comfort is the relation of environmental stress to health and efficiency. There is information that links air pollution to lung disease, and noise to work output or to the health of pregnant mothers, for example. But the human organism is notoriously adaptable, and survives, sometimes without conscious difficulty, under conditions of loud noise or heavy pollution. The key issue is whether these adaptations may not be exacting a severe but hidden price. In any event, the complaints about city noise, city pollution, and city climate are widespread. There are known ways of ameliorating those effects, and no place should be designed without thought for the microclimate it will produce, how clean its air or water will be, and whether it will be well shielded from intrusive noise.

Behavioral support. It may seem obvious that a place should support the actions that people want to undertake in it, but this is normally disregarded. Doors cannot easily be opened, packages must be carried up steep stairs, paths are slippery or do not lead where people want to go, there is no place to sit or to talk in comfort, public toilets are lacking, there is no place to wash the car, or to dig, or to leave the baby. Outdoor spaces are conceived of as volumes having a visual or formal character, rather than as settings for people doing things. If behaviour is considered, it is usually of the most formal and stereotyped kind: playing baseball, admiring a view, or parking a car. The actions intended are reduced to a single class, to which the place is completely dedicated. Or the setting is used as a determinant to compel people to act in a certain way—an effort that normally and happily fails. No thought is given to the actual diversity and richness of human behaviour, nor to how different groups and actions often overlap with each other. This can in part be overcome by a specific program; *i.e.,* a careful and detailed statement of the human behaviour that is expected and desired, an account of how the environment should facilitate it, and to what extent it should be open to variant behaviour. This is quite different from the standard program, which is a simple list of spaces to be provided. The behavioral program must consider timing as well as location, so that conflicts and joint use can be provided for. Places can also be analyzed to see if they provide for the actions that men are always engaged in: the ability to move about easily, without confusion, and safely; the ability to use one's senses; the opportunity to communicate with others; the chance for privacy and security. A place should increase a user's competence in doing what he proposes to do and even more, make it possible for him to act in new ways. Thus the designer must consider the management of a place, as well as its initial form.



Identity. Particular places should have a clear perceptual identity: recognizable, memorable, vivid, engaging of attention, and differentiated from other locations. This is the objective basis for perception. It is a support for the sense of belonging to some place-attached group, as well as a way of marking a behavioral territory.

The test for site identity is not the novelty of its graphic presentation, but the degree to which it is vividly remembered and identified by its people. Thus an understanding of how a user looks at the world is critical to achieving identity. Since it is a function of the observer's mental image, identity can also be increased by educating the observer, and by training him to see significant differences that he never noticed before. If users are allowed to adapt a site to their particular purposes, and if these adaptations are allowed to accumulate over time, the identity of the site can be expected to increase.

Diversity. One of the commonly recognized delights of great cities is their diversity of people and places. A corresponding criticism of small towns, or suburbs, or central ghettoes, is the lack of access to varied opportunities. Diversity is an obvious prerequisite for choice, and corresponds to a widely felt pleasure in variety and change. Some variety of stimulus is an important condition for cognitive development, and indeed for the very maintenance of the human perceptual system, as experiments have demonstrated.

It is more difficult to determine what should be diversified, and the relative diversity between two different proposals is also difficult to measure. All objects are to some extent different from each other, and most differences are trivial. Equally puzzling is the measurement of "adequate" diversity. A range of choice exhilarating to one person may be threatening to another. One person may want choice of places in which to buy clothes, and another a choice of views.

An urban designer must therefore inquire into the diversity that people consider important. Much of the apparent variety in the environment—of commercial products, for example—is simply trivial and confusing. Some of the diversity that is desired will refer to the sensuous environment—to having choices between places that are calm or stimulating, lonely or crowded, artificial or natural, as well as some choice of behaviour settings. There

Legibility.
The legibility of the Piazza of St. Peter's (1656-67), Gian Lorenzo Bernini's memorable Baroque enclosure in Rome, was destroyed in the 20th century by the addition of a desolate and monumental approach from the Tiber River. View from St. Peter's basilica, (left) before and (right) after opening an avenue to the Tiber.
Alinari

is a common fantasy, for example, of living in a secluded garden, from which one may pass onto a lively street.

Perceived diversity is a function of actual variety, but also of how accessible that variety is, and of how capable or interested the residents are in being aware of that objective variety. Perceived diversity can therefore be changed by increasing objective diversity, but also by improving the access to it, or by educating the person to be interested in it. Building on present choices, a good environment also opens up new ones.

Legibility. There is a common, and more debatable, argument that the elements of an environment should be so arranged that the normal observer can understand their pattern in time and space. Under this rule, a city whose layout can be understood, or whose history is visible, is better than one that is chaotic or has destroyed its past.

Importance of "legibility" of structure

Legible structure in the outside world has an obvious value in facilitating the practical tasks of way-finding and cognition. It improves access, and therefore opportunity. It can be a source of emotional security, and a basis for a sense of self in relation to society. It can support civic cohesion, and be a means of extending one's knowledge of the world. It also confers the aesthetic pleasure of perceiving the relatedness of a complex thing. There is a common pleasure in seeing a city from some high place. On the other hand, the structural chaos of the great urban regions is notorious.

Legibility must work for the anxious tourist, the knowledgeable inhabitant intent on his practical task, and the casual stroller. Different people look for different kinds of clues, yet most refer to certain basic elements, such as main circulation, basic functional areas, principal centres, the natural site, the big open spaces, perhaps the best-known "historic" points. Temporal legibility is as important as spatial legibility. The landscape can orient its inhabitants to the past, to the cyclical rhythms of the present and even to the hopes and dangers of the future.

Meaning. The environment is an enormous communications device. People read it constantly—they seek practical information, they are curious, they are moved by what they see.

The symbolic role of landscape

The symbolic role of landscape is interesting, but it is unfortunately little understood. Significance differs widely between various groups. Dominant values may be clearly expressed by the size of buildings devoted to large corporations and insurance companies, or by the multiplicity of signs that urge one to buy things. But these symbols are not correspondent to the values of the submerged groups, or to values newly rising into prominence.

Regardless of this divergence, the identity and legibility of places provide a common visible base to which all people can give their own interpretations. A cluster of skyscrapers may signify exhilarating power to one and cruel oppression to the other, but both have a visible object for their feelings. Visible structure should be congruent with functional and social structure. Visual units, for example, should correspond with social units, such as the family. Landmarks should correspond to actual foci of activity or of social significance. Physically defined territories fitted to behavioral territories is another example of congruence between the visible and the social world.

City signs are often damned on aesthetic grounds, but they perform an important function. The flow of information must be regulated, so that priority signs (public control messages, for example) cannot be missed. At the same time, the observer must be able to tune out, which argues against various obtrusive devices: public broadcasts, flashing lights, or the pre-emption of key locations in vistas or at decision points. Signs may be used to expand what a man can learn of his city. Public information centres could become highly attractive.

The "transparency" of the city landscape

It may also be desirable to increase the "transparency" of the city landscape, for economic and social processes are today increasingly hidden from sight. Indeed, construction sites are so interesting because they are one of the few industrial processes still left open to view. It might be public policy to encourage visual exposure, partly directly, and partly by remote sensing. Cities might regain, without impairment of function, some of the vitality and immediacy of the pre-industrial city, with its open workshops and markets. On the other hand, there is also the risk of invading privacy. A policy of visual exposure is intriguing but sensitive.

As one goes deeper into the subject, numerous difficulties are encountered: diversity of values, the efforts of special interests to capture and to falsify the communications system, and even the embarrassments of revealing some features of society as they really are. And yet places and buildings evoke strong feelings in their observers, and these feelings should be an important concern for the designer; the seeming aloofness and impenetrability of a city hall, for example, the awesome frigidity of an office lobby, or the calm invitingness of a public park.

Development. Particularly in childhood, but to some extent in later years, environment plays its part in the intellectual, emotional, and physical growth of the indi-

vidual. The negative effects of highly impoverished settings have been demonstrated. The role of rich sense perceptions in human maturation has some basis in laboratory experiment, but for the most part it remains speculative, although highly probable.

An educative environment would be full of available information, visibly encouraging attention and exploration, particularly when the observer is not task-oriented —as when he is at play, travelling, or just waiting. A learning environment alternates moments of high stimulus and quiet privacy. It would include opportunities to manipulate the world directly. The use of a city as a teaching device is a fascinating subject. Its connection to city design criteria is suggestive but uncertain.

Perceptual engagement. Beyond all these, there is the sheer delight of sensing the world: the play of light, the feel and smell of the wind, touches, sounds, colours, forms. It is difficult to impose such things, but the designer can prevent the blotting-out of sensation (as by featureless noise, or a bland facade). He can keep the environment open to the sky or the presence of people. Dynamic elements never fail to catch attention: moving water, living creatures, clouds, light and fire, moving machinery, or pennants, which make visible the currents of air.

Constraints. The power and purposes of clients and users will always be the key determinant in the urban design process. There are numerous other conditions, however, that also influence the outcome. One is the basic nature of the site itself: its topography, vegetative cover, climate, ecology. Seacoast and riverine sites, plains and mountains, marshes and deserts, each impose typical limitations and offer typical possibilities. Local accidents of ground, as well as basic site character, are also influential: a small rise of ground may determine a view, the orientation of a building, or the course of a street. The variations in the microclimate can be particularly important.

Influence of the nature of the site itself

Natural site conditions are perhaps less determining than in the past, because of the power of modern technology to change them: to fill in the sea, cut off a hill, or air condition large interior spaces. But as this power is exercised, it is often found that the secondary consequences are surprising: the buried river floods, heat islands build up over the cities, tidal water becomes stagnant, and the land slips and erodes.

The power to override the particularities of natural site has had still another effect. Cities begin to look like one another all over the world. Airports, as an extreme case, are almost indistinguishable, but so are many central areas, suburbs, or apartment districts. Closer attention to site conditions would help to prevent this. But close support and expression of cultural differences would do even more.

Urban designers must cope not only with natural, but with previous man-made conditions. There are existing structures, and an existing system of circulation. There is a network of utilities and of public services. Only occasionally can a society afford to sweep away all its previous environmental capital, and even then the unanticipated social and psychological costs are likely to be severe. Urban designs are most often complex remodellings, successive sets of changes that retain much of the previous pattern of development. An analysis of what previous elements must be retained and which can be cleared away is a typical early step.

Persistence of circulation patterns

Circulation patterns are particularly persistent, since they are reinforced by other patterns such as ownership lines and utility systems. The pattern of streets will last for centuries, while buildings come and go, and even the street itself is many times rebuilt. The invisible lot lines and buried utilities are extremely conservative in effect. There will be other legal or social rights, inclusive of mutually agreed-upon "territories" felt to be the proper domain of some special group. There will be persistent behaviour settings: places where people are accustomed to doing certain things, and which resist disruption. There are sacred places, old market locations, and meeting grounds; and any plan that displaces them will meet resistance. Therefore, account must be taken of the images that people have about their environment: the territories they divide it into, how they link it up, what meanings they attach to it, what activities they are accustomed to carry out where. Like the ecological system, or the inherited physical setting, this existing social image must be understood before changes can be made. If not, the consequences may be unexpected: vandalism, bitterness, the failure of a new commercial facility, disorientation, or political opposition.

In planning, as in spatial economics, the environment is considered to be a set of activity locations and their linkages. Each activity has preferences for its site and for its connection to other activities. A plan seeks an optimum pattern of locations and linkages, considering the relative importance of each activity (which may be measured in social value, political power, or the ability to pay). This planned pattern, which includes a transportation network, can then become the framework of an urban design. How those activities were classified, linked, and weighted was critical in setting the pattern. Therefore, those assumptions cannot be accepted without demur. Circulation requirements, in particular, are a chief technical constraint in urban design. Requirements for moving and storing automobiles loom very large in most urban schemes: the demands of access, alignment, and sheer volume of space are substantial. That these demands are not iron laws, but rather the reflection of social decisions about the mode and speed of travel, is sometimes forgotten. But a high level of circulation and communication, whatever the mode, is likely to be a persistent feature of any new urban development, and so the techniques of arranging highways, vehicle storage, transit lines, airports, waterways, railways, and pedestrian paths turn out to be the most frequently used urban design skill. Utilities and communication nets are equally important features of the urban infrastructure, but their technical demands are less often determining in the spatial arrangement of a place.

Among other technical requirements, the demands of safety usually rank high; *i.e.*, safety from fire or earthquake, and individual safety from moving traffic or personal assault. Traffic fatalities are numerous, and the incidence of theft and assault is rising. Thus there will be much attention given to the safety of intersection designs, the spacing of buildings for fire retardation, or the ability of an area to be surveyed and controlled by police or local neighbours. Elsewhere, the dominant fear may be the likelihood of organized assault: aerial bombardment, ground attack, or organized sabotage. Historically, one of the chief technical skills of a city designer was his knowledge of defense fortifications.

Health requirements are another set of technical constraints. The greatest successes of 19th-century city planning were their improvements in local sanitation, improvements generally well assimilated into the urban design principles of today. The worst problems are now the large-scale pollution of ground, air, and water and its long-term consequences for human health. Preventing such pollution puts some special constraints on environmental design, of which planners are only now becoming aware. Of the effects of environmental form on mental health, however, there is still great ignorance.

Costs of design decisions

Cost is a powerful constraint, as in any kind of capital investment, and urban designers must know how to make estimates of construction and maintenance costs. These costings are not only less detailed than typical architectural or engineering estimates, but are quite incomplete in other ways. The social and psychological costs of a change are often disregarded, a feature sadly so familiar in most economic decisions. But even the direct money costs of a proposal are incompletely analyzed due to the multiplicity of clients, the long time spans, and the way in which decisions are made. Political costs may dominate the outcome. Only the money costs to the initiating developer or agency may be computed, while the resulting costs to other actors—a transit agency, for example, or a dislocated business—are simply ignored. The effects of inflation over the long period of construction,

or the costs of maintenance, are as often neglected. Urban developments thus typically cost substantially more to carry out than originally estimated. Since benefits are calculated even more carelessly, it sometimes happens that real benefits may inflate as rapidly as costs. Rational cost–benefit accounting of urban designs is just beginning and necessarily remains incomplete, since many costs and benefits are not to be translated into money units. More rational cost–benefit studies may, in fact, tend to submerge factors not easily quantifiable.

THE SOCIAL SETTING OF URBAN DESIGN

The visible form of a city reflects the social and economic setting in which it was created and maintained. This is quite apparent during the normal design process. When the designer enters that process, the solution has long been evolving. A problem has been recognized, a client organized, the economic resources to be allotted to the task are usually determined, and the political and administrative rules are set. Even the act of turning to an urban designer implies that a new spatial pattern should be a part of the solution. More often than not, a complete schedule of space requirements has been prepared.

Even within these limits, the designer has some room in which to manoeuvre. He can raise questions about elements of the program. He can communicate with others who have a stake in the outcome, or even help them to manoeuvre into a client position. He can propose other values and criteria, such as those outlined above, and suggest possibilities that resolve old conflicts or that create new values to be exploited. He may also sway decisions by his personal prestige, or by the way he formulates the complicated alternatives for decision, alternatives that are difficult for the nondesigner to pick apart and reformulate. Finally, he is often able to make decisions about form in areas independent of his client's major concerns, which may focus on profit, on a favourable political reaction, or on completion on time and within the budget. In this case, the client may be glad to leave to the designer features that do not compromise those central aims.

Decision-making in the design process

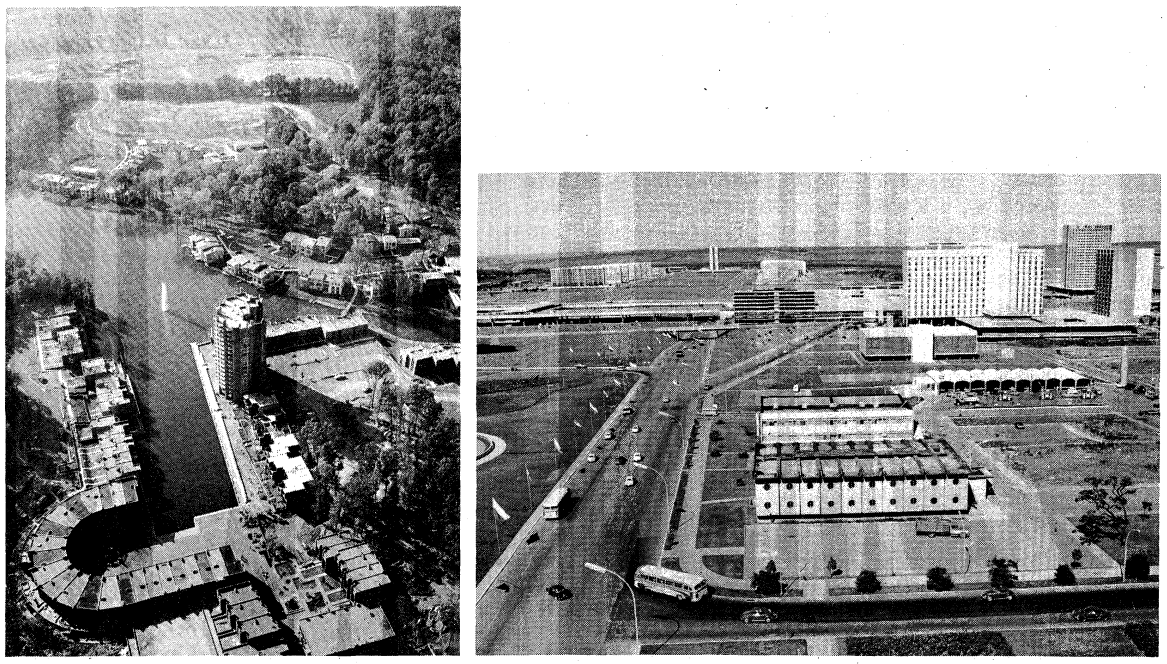
A number of groups are usually involved in any decision, and the designer is often motivated to bring in still more, so that ultimate users can also participate in the decision making. This implies complex and sometimes cumbersome communications, and causes frequent recycling of design. Usually it is necessary to impose arbitrary limits on the participating clients, if the decision process is to work at all. Deciding on the key clients—those with the greatest stake in the outcome or with the greatest real power to carry it out—and determining the balance between those clients is difficult. Enforcing it takes substantial political energy. The designer does not usually make such decisions, but he plays some role in the decision making, and is ethically implicated.

Since there are many decision makers, conflicts are to be expected. Progress is made by negotiation, and the negotiators who have a single functional goal in mind or are focussed on a small area and can therefore be flexible on all other issues, are those most likely to succeed. The private developer will accept all sorts of public rules that do not threaten his rate of profit. The transit agency is happy as long as it gets its routes and terminals. Quality, however, usually depends on the effect of a whole system. At the points of hard bargaining and over a long succession of decisions, quality gives ground to the thrust of quantifiable, bounded, functional goals or of narrow territorial interests.

On occasion, this typical situation is modified. Sometimes the designer is part of a constructing agency that has effective powers of decision and implementation—a new town authority, for example. The designer does not make the decisions, but he is linked directly to those who make and carry out decisions; and he is therefore in a much better position to help set up the problem and participate in its realization and management. In return, the decision makers and implementers penetrate more deeply into his own design process.

At other times, designers attach themselves directly to some client group, helping the group organize to influence the definition of the problem. Rather than creating some definite solution, the designer gathers technical information and sketches possibilities so that his group can influence a larger decision process. He is an advocate, whose loyalty is to his client group—which may be a comfortable position, or may entail sacrifices if the client is weak and poor.

The designer may become a champion rather than an advocate, attaching himself to some solution and pressing to assemble the client and the power to carry it through. This is uphill work, only rarely successful in the individual case, but often having a slow cumulative effect, as the possibilities of some new kind of design solution begin to enter the world of alternatives perceived by the decision makers. Thus new towns, parkways, adventure playgrounds, urban renewal, city parks, or downtown plazas have been successfully championed and picked up by other groups to carry through. In some cases, however, the motives of the implementing group may differ from those of the champion, and thus the nature of the solution will be distorted.



Controlling environmental form

The form of the environment can be influenced in a number of ways. The most obvious, to a designer trained in architecture, is simply to specify the environment in a set of drawings. This is rarely possible. It may be possible, however, to design the key localities in detail (major squares, main avenues) or some special elements or systems (bikeways, lighting, prototype housing, highways). The design of repeatable systems is an opportunity often neglected in urban design. One may choose to design some demonstration project as a stimulus to other actors.

Most urban designs are diagrammatic. They refer, not so much to the exact form of things, as to the character or spatial effect intended, the clusters of behaviour expected in the spaces provided, the image structure, the basic circulation and activity location, and the types of management of control. They may specify selected detail: lighting, signs, textures, sounds. A diagrammatic model, a control document, a series of slides, or a film, may be better than a plan, section, or elevation. Showing how a place will develop over time is more effective than drawing what its final form will be. Illustrative sketches, showing one possible outcome according to the principles proposed, are frequently used in place of definitive plans. The "hard-line" drawings of engineering and architecture are too frequently used in circumstances in which there is no certainty, finality, or detailed control.

Without making specific designs, one may control the design process of others. This can be done by legal rules, or by specifying characteristics of the design process (imposing competitions or user consultation, for example), by design review, or by indirect economic controls (subsidies, tax rules). In the complexities of large-scale development, such indirect controls must be relied upon. Design review has often been successful, especially where it has been introduced early in the design process. Economic controls are a powerful means in an economy dependent upon private enterprise. Design controls, such as those that specify the character of facades or the shape of built volume, have had very uneven success, and are laborious to administer. All too often, they are a signal that urban designers are playing at designing a city as if it were a building.

Performance standards of environmental quality might be a more efficient and flexible means of control, although they are not often employed. They could be founded on a sensuous program that would specify desired visibility, spatial character, visible activity, texture, apparent motion, sign content, light, noise, or climate. Thus such a program might propose, at some particular junction, that there be a landmark identifiable day or night from a mile away, visibly displaying its internal activity, whose form distinguishes the various turns and approaches one from another. Such a program could be satisfied by many particular shapes, according to the motives of that structure's developer. In another case, the desired microclimate, noise level, sign content, and provision of seating and shelter along a public street might be the characteristics specified, just as one is as accustomed to specify lane width for

traffic, or the allowable inflammability of building materials.

The principal aim of urban design is to improve the quality of the human spatial environment, and, by so doing, to improve the quality of human life. It does not directly attack underlying social problems, such as poverty, war, inequality, or alienation, nor is it usually a very efficient way of doing so. But since it deals with the setting of social life, it is necessarily influenced by those underlying problems, and in turn influences them. War can destroy a fine landscape, poverty can make it unbearable, and alienation can render it meaningless. The effect of a place cannot be judged without reference to social conditions; neither can the quality of life be deduced solely from social conditions without reference to the spatial setting. Environment can have specific effects of its own: its territorial division may serve to reinforce segregation; it may open up new opportunities to people; its form influences the personal growth of children. The process of building the environment may support self-reliance and new institutions among disadvantaged people. Environmental modification is always a possible element in any general strategy of social change. Most revolutionary societies devote some of their effort to the reorganization of their living space, even though purely perceptual effects may not have a high priority.

TYPICAL PROBLEMS IN URBAN DESIGN

A better understanding of urban design comes from looking at some of the typical situations in which it is involved, or might be involved.

Area policy. Only rarely has environmental quality been considered at the scale of the whole city or region, at which level recommendations have traditionally dealt with land use and open space patterns, housing supply, public facilities, and the technical systems of transport and utilities. Regional quality is the framework for local quality, however. Analyses of the visual form of a region or a city have been accomplished recently: as in the cities of Minneapolis, San Francisco, and Los Angeles in the United States. Large landscape elements have also been surveyed, such as the lower Thames and its banks in England, and part of the valley of the Ticino, in Italy.

Examples of plans for regions

Regional plans have been made that incorporated visual criteria with ecological considerations, such as a plan for the Green Spring and Worthington valleys near Baltimore. The new agricultural greenbelt around Havana, the so-called Cordon, is a conscious attempt to create a new visual scene, as well as to remold the economy of the city and the ideology of its citizens. Existing areas of strong character have plans for their preservation, as in the vicinity of Florence. Studies of the ability of small areas to absorb new development without visual damage are being used as one input for regional growth policy, notably around Helsinki. But the technical and political effort that will be required to control regional landscape quality and to think of humane conditions of existence at that reach of size, has still to be made.

New settlements. Where new settlements are being built by conscious plan, there is greater acceptance of the necessity for dealing with sensuous form, although the results have not been spectacular. The best work has been done in residential suburbs of moderate size, usually built for the well-to-do. Roland Park, Riverside, Chatham Village, and Radburn in the United States, and the earlier Bedford Park and Hampstead Garden Suburb in Great Britain, may be cited. Good suburbs are still being built, and the most recent phenomenon is the designed community of vacation homes, as at New Seabury, on Cape Cod. These are pleasant places, relying on a careful fit to the ground, ample space and greenery, good design of spatial form along the street, and close control of signs, lights, fences, street furniture, and other detail.

Designs for new towns have been more ambitious, and in general the earlier examples, such as England's Welwyn, seem to be the more successful ones. Reston, Virginia has a handsome, if rather unreal, central area and lake; and the recent Tapiola in Finland is outstanding for its landscaping and the variety and finesse of its detailed site planning. Most of the new towns, however, have been no better than moderately pleasant suburbs, at least in visual terms, and many are quite monotonous or raw. Thamesmead, upriver of London, displays a sophisticated use of industrialized components and a fine use of river bottom land, but the housing is expensive, and some of its formal brilliance is of doubtful use. Cumbernauld (Scotland), Chandīgarh (India), and Brasília (Brazil) are now widely criticized for their imposition of an alien form on a living community.

Problems of new town design

The difficulties in dealing with the form of new towns are quite similar to those in evolving areawide policies: the large scale, the complexity, the distance between designer and user, the inability to control or diversify rapid mass development. Thus the plans for one of the newest and technically most advanced of the British new towns —Milton Keynes—passes over questions of visual form

very lightly, except for policies on the retention of natural features. To these difficulties must be added the peculiar nature of the new towns—their rapid growth, their lack of a past, the dissociation of the planning from the future inhabitants. The visual richness deriving from a visible history, or from the diverse ways in which different people fit their environment to a local situation, are necessarily missing. Any successes have primarily depended on skillful local site planning. The vast mass of new urbanization throughout the world is monotonous and barren. Nor is this simply a matter of poverty, since some of the most interesting new places are the intricate self-help settlements of the underdeveloped nations.

The record in the denser housing project is equally poor, although the task is closer to the normal architectural one, and the techniques are better developed. It is quite possible to cite moderate- or high-density residential projects of good quality, but they are lost in a great wilderness of inhuman slabs and grim barracks. In Great Britain and Scandinavia, however, there are many more frequent examples of livable, pleasant housing projects.

Rehabilitation, redevelopment, conservation. Urban design received its strongest official impetus in the United States from the federally sponsored urban renewal program, in which moderately large sites were cleared for complex housing and commercial projects in the centre of the cities. Since this was a highly visible program under political attack and was backed by groups for whom visual quality was important, a substantial stress was put on good urban design. Opportunities for laying out complex projects were frequent, whereas previously they had been rare. Schools and firms specializing in this work appeared. The results were uneven. While some handsome projects resulted, mostly in central business districts, most work suffered from designer megalomania and administrative confusion. Operating agencies and large developers made the key decisions, while the future user (much less the existing one) was rarely consulted.

Isolated designs and lack of true renewal

Even though these projects were concerned with city-centre areas, they were usually treated as isolated designs. True renewal (*i.e.*, a restoration of the existing fabric for the use of existing occupants) was not accomplished. Urban design has little skill in enhancing existing social and built values, as one might enhance a natural landscape. Improvements have occurred in older areas attractive to higher income owners, but these improvements usually conceal social costs. In only a very few instances have public agencies been successful in helping local inhabitants to improve the appearance of their own local region, as in Wooster Square in New Haven. The key action has been the rendering of design services to the inhabitants, rather than designing for them. Rehabilitation and renewal remain among the most critical social tasks to be undertaken in urban design.

When the problem is not rehabilitation, but the preservation of quality already achieved, the technical task is relatively simple and familiar: to analyze the existing visual quality of the place, and to draw up guidelines for any remodelling or new construction. These guidelines may require strict replacement or copying, especially of exterior facades, or may only entail careful attention to mass, scale, spacing, fenestration, and materials. There are numerous successful and admired examples of this type of action: Boston's Beacon Hill, New Orleans' Vieux Carré, or the heart of Charleston, South Carolina spring to mind. At times, preservation of this kind may have a high political priority, and may absorb significant capital in a hard-pressed nation, as did the Stare Miasto in Warsaw. Preserving existing values is easier than creating new ones, yet preservation can play no more than a minor role in the general task of urban design.

Lines of movement. One perceives the city while walking or riding through it. Since roads, paths, and transit systems are normally built and maintained by public agencies, the design of these channels is an important branch of urban design. The design criteria focus on the functioning of the transportation line, the pleasure and information to be had while travelling along it, and the impact of the channel on the observer who is outside of it. The latter concern introduces goals partially in conflict with the former ones.

Main avenues have been designed in the past, principally in terms of their cross section, and sometimes as slow monumental approaches. Designs that deal with sequence and dynamic experience are relatively new and scarce.

Successes of freeway design

A number of rural freeways in the United States are among the best examples of large-scale environmental design in the world today. The fit to ground, the use of landscaping, the variations of space and motion, are superb. On the other hand, although there are interesting urban highways whose form arose by exterior circumstance (the Schuylkill River Parkway in Philadelphia, for example), there are no examples of successful deliberate design, although there have been illustrative proposals.

While some thought has been given to highway visual design, almost no consideration has been given to mass transit design. Riding a bus or train is quite different in visibility and role from driving a car, and expectations are low. The view from the bus enters into no current designer calculations. The design of pedestrian ways in parks or tourist grounds is a more traditional concern, but the pedestrian on the ordinary city street is usually ignored. Bicycle paths are carefully designed in many European countries and are appearing in the United States, but again with little thought for the moving view. In Great Britain, some of the old industrial canals have been retained and refurbished for recreational voyages. The view from the airplane seems a ridiculous question and yet in the future may merit attention. Roads are often only one element of an entire linear environment. The highway commercial strip is notoriously ugly and confusing, but it has a strong functional justification. In order to create a handsome landscape, it might be feasible to combine a highway with linear uses in one integrated structure. The idea has been proposed intermittently, but never carried through, except in a few rather trivial uses of "air rights" by office or apartment buildings.

Commercial centres and central districts. Some of the most sophisticated work in urban design has occurred in commercial centres. This is hardly surprising, considering the large investments in those centres, the effective control of form that is possible, and the importance of attractive form for increasing profits. The urban renewal work most often admired for its quality has almost all occurred within central business districts. The projects are typically a mix of shops, offices, public buildings, and some luxury apartments. They are complex in form, using separate levels and specialized buildings to deal with use and traffic mixtures at high densities. Normally, they include a public plaza. Arcades, escalators, raised pedestrian decks and walkways, and underground parking are common features. They are expensive, handsome in detail, and often rather cold and inhuman in general effect because of the design focus on pure form and of economic pressures toward a narrow spectrum of high-paying uses. The complex sequences of interior public space set new problems for design. Artificial light and climate replace their natural counterparts. The public ways are the corridors and tunnels.

The regional shopping centre is now a successful and much imitated model, more closely based on behavioral knowledge than any other type of environmental design. Now rather artificial, specialized, and physically isolated, they could, nonetheless, be integrated with other functions to become true social centres.

Special areas. Urban design has had some success in the layout of large institutions, where centralized control of form has also been possible. Large urban hospitals have usually been an exercise in complex technical form at high intensity. Campus planning for universities and colleges has provided frequent opportunities to establish an integrated landscape. Not only are the existing schools growing, but new campuses are being set out. Many of them are barren affairs, but it is quite possible to produce a pleasant environment. Some of the outstanding successes provide complete living environments, usually with

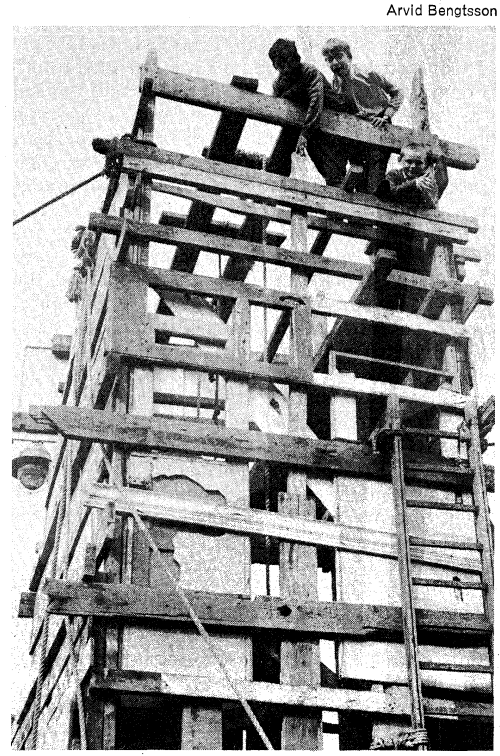
enough space to allow for fine landscaping. Planning for rapid growth is a typical difficulty, as is maintaining a handsome landscape in the face of demands for parking and access. The traditional organization of higher education often results in some rather stereotyped buildings and unit organizations. The nature of an environment for learning has not yet been considered in any profound way. Yet university campuses are often, because of their visible life and landscaped setting, very attractive parts of cities. Too often, they are islands of culture, as shopping centres are islands of consumption.

Another special area that has received some design attention is the industrial park or estate. Extensive areas under single control are set aside for industry, often with accompanying services such as banks, restaurants, or maintenance and distribution facilities. Most often, the form of these estates has been determined by rail and road access, or by internal layout requirements. More recently, the visible aspect of these estates has come to be considered. Such estates or parks are regulated to keep factories simple in form, of good materials, and well set back and landscaped. At best, an innocuous green landscape of low buildings is the result. Little attention is given to making the work that goes on in these areas significant or pleasant, or to connect it with other life functions. Similarly, no advantage is taken of the potential drama of industry: there is no immediate vision of what goes on inside.

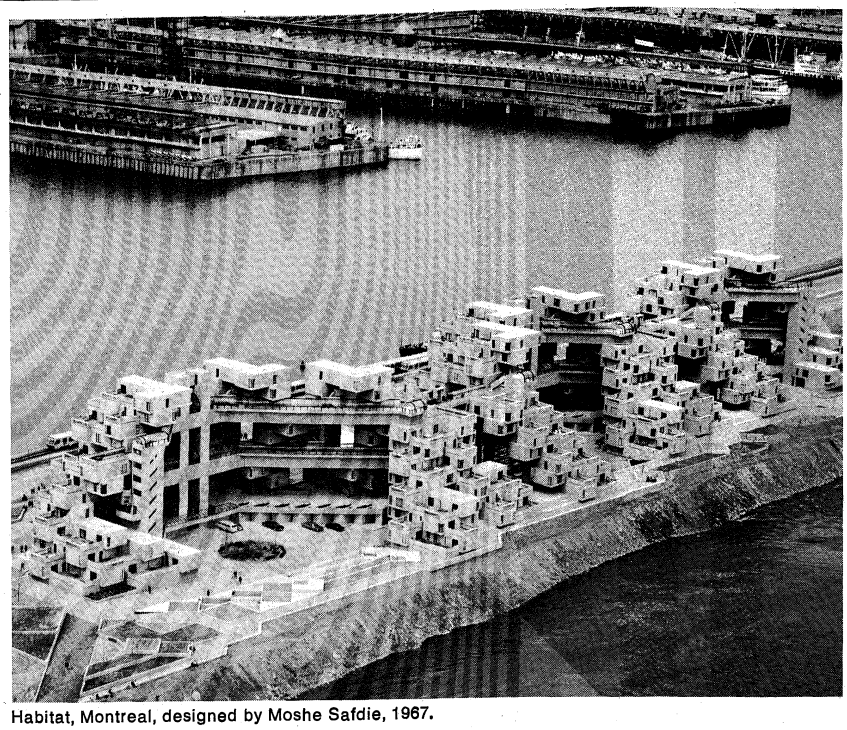
The great expositions are excellent occasions for innovation, and indeed many of the earlier ones were outstanding: the World's Columbian Exposition of 1893 in Chicago, the Paris Exposition of 1889, and the London Exposition of 1851. Recent fairs have produced little that is new amid much visual confusion. There have been innovations in structures, such as Montreal's Habitat, but not in the organization of the general environment. The modern fair is highly competitive, and the scattered developers, who are under extreme time pressure, are difficult to coordinate.

Large natural and man-made features. The design of large state and national parks has become a well-developed environmental specialty, closely related to landscape architecture and forestry. Handling big crowds, preventing ecological damage, preserving the appearance of a natural landscape, supplying a whole range of recreation for varied tastes without mutual interference—all of these are the central problems, and they are often competently handled. Details are simple, and maintenance is stressed. The landscape is used to teach the visitor about the structure of nature.



The smaller urban park was the problem on which landscape architecture cut its teeth, and some of the older city parks provide fine examples of environmental design. Recent city park design has been less successful, and suffers from a certain standardization and emptiness of appearance and function. New work in children's playgrounds has been more impressive: complex and challenging landscapes have been created, built of simple materials, and fitted to the actual behaviour and interests of the child. The "adventure playgrounds" in which children use space and raw materials to build their own surroundings and equipment, have been particularly interesting. Hopefully, this will lead into the design of true "learning environments."

Recent work with children's playgrounds



The enhancement of large natural features was an important aspect of earlier work in what was then called civic design. Seafronts, lakefronts, streams, and ponds were improved as promenades, or for boating, swimming, and picnicking. Waterfronts and river banks have been magnificently developed in many European cities. They have been generally neglected in the United States, although there are a few fine examples: the Chicago lakefront, the basin of the Charles River in Boston, the Golden Gate Park in San Francisco, and the river walk in San Antonio. But with the economic decline of the city waterfront as a port and industrial region, many cities in the United States are now slowly moving to reclaim those water edges: Boston, New York, Philadelphia, and St. Louis are but a few among the best-known American examples.

Mountains and great hills, less frequent within urban limits, are rarely used for their landscape qualities, although they may have a small park or panoramic view near their summit. A number of great cities have exceptional opportunities in the contrast of mountain and city: Caracas, San Salvador, Buenos Aires, and Los An-

geles, to name a few. The great bridges are dramatic city elements, but few are designed as landscape to be walked over, climbed, passed under, and played upon. Dams and reservoirs are strong landscape elements, but the enormous spoil heaps of industry are classed as ugly and therefore ignored or camouflaged.

Special systems. Some work has been done on particular environmental systems: sets of things that are extended over large areas but do not make complete landscapes in themselves. In a time when urbanized areas will expand at unprecedented rates, using industrialized components in designing systems may be an excellent lever for the extensive improvement of quality. Planting plans are the most familiar example of environmental system design. Typical arrangements and species are prescribed for avenues, minor streets, walkways, paths, and front gardens. The designs are intended to ensure minimum quality and to fit tree types to typical demands and scales. They may also be used to give an identifiable character to particular districts or streets, or to mark out the main structure of the region. Although trees are not usually thought of as industrial products, in fact they are grown in quantity, on demand, by factory methods. Many fine urban areas are notable primarily for the way in which they are planted.

Signs have been given some attention. Most of the emphasis has been on immediate visual appearance, and very little on information content, which is a sign's reason for being. Public lighting has also been discussed, since many designers see the tremendous potentialities of artificial light. But lighting studies frequently come down to the form of the light pole, which is the least important aspect of the subject. Other products are rarely designed for their direct human impact. Various pieces of street furniture are obvious examples, as are the ubiquitous paving materials: asphalt, concrete, and the concrete curb.

System design might also be applied to larger chunks of the environment. One promising possibility is the design of mobile housing units and their immediate settings. While the houses themselves are meticulously designed as industrial products, the trailer settlements are not far from the quality of the original lots where they were first parked. Systematic design of typical units and their arrangement in housing neighbourhoods would be a strategic way of affecting the quality of a large sector of the moderate cost housing supply. The temporary settlements of the Tennessee Valley Authority were pioneer successes whose results have been forgotten.

VISIONS

Most urban designers take no time to create new visions, in contrast to their reputations as imaginative men. Their visions are the historic plazas of Europe or the romantic site planning of Sir Raymond Unwin and Frederick Law Olmstead, or that combination of high density and high technology that is found in Le Corbusier's designs.

Perhaps the most famous recent demonstration of new environmental possibilities has been the Habitat of Expo 67, the Montreal World's Fair of 1967, in which residential units were piled one above the other in an irregular hill-like structure. The roofs of units below provided the open spaces for units above, and all parts were interconnected by pedestrian links at every level, as if the apartment building had become a three-dimensional village. Construction costs were high, but visitors were enchanted.

Recent visionary projects for large environments take up the theme of three-dimensional complexity and usually marry it with a very advanced technology of movement and climate control, coupled with an emphasis on rapid change, high density, and a display of startling, machine-made yet organic-looking forms. These ideas arise just at a time when most people in the world are hoping for lower densities and when there is a revulsion against high technology and centralized control. The visions seem to point where no one wants to go and ignore much of what has been learned about the impact of environment on behaviour.

Concern for ecological balance

Another strong idealistic current has as yet had less direct effect on urban design, although the current comes from deep historical sources, and most urban designers have a sympathy for it. This is the theme of ecological balance, which links up with the old ideas of a "return to nature," and to some extent with the Marxist ideal of the merging of city and country. The romantic, low-density suburb and the widespread American "second home in the country" have been a realistic working out of the same ideas. But while suburbs and vacation houses allow many people to enjoy a more pleasant and humane setting, they have also been one further step in the urbanization of the countryside. They make no true integration to rural pursuits.

In the United States the new "communes" are another expression of the longing for a rural return, as were many

attempts at subsistence farming during the Great Depression. The communes combine radical social change with the old dream of agricultural simplicity and with a preference for handmade artifacts and environment. As yet all these currents have had little direct influence on the practice of urban design, except for the new use of ecological surveys to help determine the future use of undeveloped land. It is remarkable that no visions (with the exception of the "paradigms," which appeared in the 1940s in the Goodmans' "Communitas") deal with new social possibilities or with what we are learning about the interaction between man and environment.

The urban design field is in upheaval and conflict. Throughout the world, the architect is losing his unquestioned position of primacy and is becoming one member of a complex design team. Some attempts are being made to train men as designers able to analyze and deal with areawide spatial form, or with the coordinated management and design of environment, rather than as architects with an added knowledge of city problems. Research on the interaction of environment and behaviour is developing, and its findings are challenging many cherished ideas about civic form. New methods for large-scale design are evolving, relying on the computer in particular. Urban design is under attack for its preoccupation with visual form, and is accused of remoteness from basic social issues. Designers themselves are bewildered by the complicated politics and economics of large-scale decisions. Clients are no longer passive and mute, but demand a part in the design process.

Urban design as a separate profession arose in response to certain gaps between the older arts of environment, disturbing gaps which appeared, for example, when it became necessary to design large building complexes for multiple clients. The new profession aspired to the design of entire cities, under the misapprehension that they might be detailed in the same way that buildings are, as if constructed rapidly for a single client. It tended to stress the psychological and sensuous aspects of form, because these factors were generally disregarded at the scale of the community, region, or large engineering work. It blossomed in the wake of the city planning field, which is moving from purely physical concerns to a focus on economic and social policy, and is probably on the verge of breaking into various subdisciplines. It is instructive to note the areas of environmental success: the affluent suburb, the shopping centre, the historic district, the rural freeway, the campus, the large country park. It is even more instructive to see the areas of failure, or at least of nonperformance: the quality of large regions, the new towns and extensive new residential areas, localities in need of rehabilitation and renewal, the city streets, the working landscape of industry and agriculture, the mobile home park.

Where this turmoil may lead is hard to see. Hopefully, it would result in a profession competent to deal with community spatial form in all its social, political, economic, and psychological dimensions. This implies that the profession would focus its attention on those qualities in the environment that allow people to develop to their fullest potential. It would mean looking on the landscape as a changing, living system of which man is an integral part. Therefore, it would draw eagerly on knowledge from ecology, environmental psychology, and sociology. It would develop the design process into a recycling process of forethought, invention, experiment, and management, in which the ultimate user has an intimate role, so that the acts of planning and building and maintaining become joyful social arts. Its attention would turn to neglected areas: regions, rehabilitation, new settlements, environmental systems, and the small ordinary everyday places where people live and work and pass their lives. Necessarily, its course would parallel, and reinforce, changes in the organization of society. (K.L./Ed.)

II. Historical review

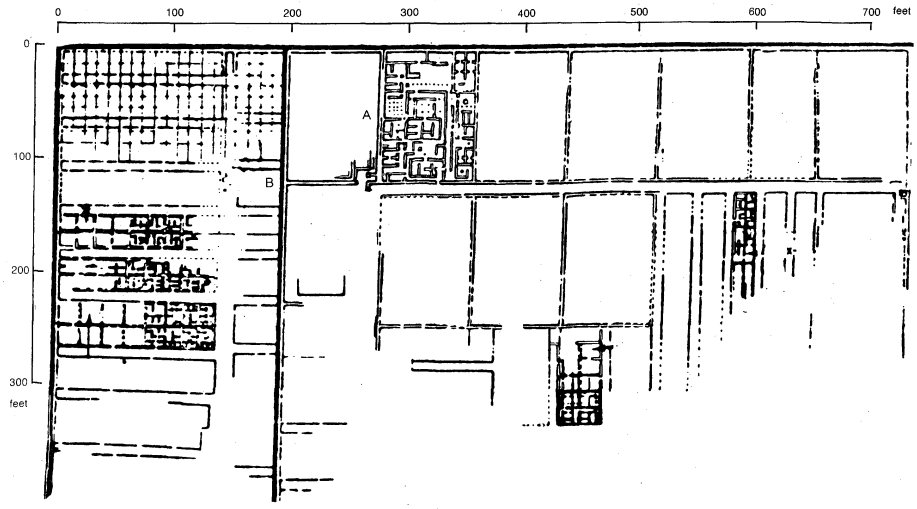
ORIGINS

For eons men lived as roaming hunters, now sheltering in caves or earth pits, in trees or in primitive tents, now moving on with the horde, following wandering herds of game. What the hunting range was to the hunter, the fishing range was to the fisherman. The latter, though, tended to keep to a "good ground." Fishermen were indeed the first to found settlements. These first settlements at the water's edge present three features: (1) a certain order in the relative positions of huts or tents, or in their subordination to external influences such as temperature, the sun's path, tides, and winds; (2) a tentative order of precedence of buildings; and (3) magical symbols, deterrent or propitiating, to avert harm or induce good. Frightened by the phenomena of disease and death, men sought the protection of supernatural powers and propitious signs.

A new era dawned when men learned to tame and domesticate animals; this led to livestock breeding and pasturing. Yet it still compelled man to keep moving, following good grazing and the seasons. Thence arose an extensive trade by which animal products were bartered for wares from far places. New symbols appear in textiles and in graves; winter quarters and summer pastures became fixed poles, as did good watering places. But still the need for mobility ruled out any fixed abodes for the summer. Nomadic life meant living in tents.

A third era began with crop growing. There appear increasing signs of integration of the human habitation into its environment (shelter from sun, cold, and wind), and observation of the cardinal points of the compass and their pleasant and unpleasant implications.

Earliest village settlements



It is today hardly possible to locate the areas of the earliest village settlements. The only certain fact is that they arose in crop-growing areas, chief among which were the alluvial plains of the rivers Nile, Tigris, Euphrates, Indus, Yangtze, and Huang Ho. In Egypt, Palestine, Syria, Mesopotamia, and Iran settlements assumed village form about 5000 BC. And so mankind split for the second time. It had done so first when the livestock breeders dissociated from the hunters and fishermen, and it did so again when the cultivators dissociated from the breeders. This development seems to have been brought about by a brown-skinned race, perhaps related to the aboriginal population of South Arabia and the Dravidians of India, perhaps to the Hamites of North Africa. In Egypt, villages developed in the Badarian period (to about 4000 BC). In the Gerzean period (to about 3100 BC) there were already very small towns on the substratum of a rural culture. Villages, proto-urban settlements, and the first primitive towns appeared in Mesopotamia and Syria during the same period.

WESTERN ANTIQUITY

Urban culture began in antiquity in the regions of Egypt, Mesopotamia, Syria, Iran, and Asia Minor. These developments may be considered independent. Rarely are any influences recognizable between countries, even less so between regions. The natural conditions in each land largely determined the patterns of development—first of all, in the orientation of the towns. Thus, in ancient Egypt, the towns are largely oriented in a north–south axis, with the exception of Thebes and Tell el-Amarna, which followed the local course of the Nile. In Mesopotamia (Sumer, Babylonia, Assyria), however, the towns are oriented along the course of the rivers Euphrates and Tigris and at the same time on the preferred wind direction, so that their main axes run from northwest to southeast. In Palestine, Syria, and Anatolia the towns are variously oriented, depending on their situations on the coast, in valleys, or on hills. Rules also emerge from the plan of the town: in Egypt it is mostly square or rectangular, in Sumer oval, in Assyria rectangular. Yet all the town layouts follow geomantic (geographic divining) or religious notions.

Ancient Egypt. Among the most remarkable of the Early Dynastic sites is the town founded by King Djoser (3rd dynasty). He, with his adviser and architect Imhotep, built the town of Memphis and his own tomb at Ṣaqqārah. Town and tomb correspond in layout as the dwelling of the living king and that of the dead king. Djoser's necropolis covered an area of about 3,900 by

1,740 yards (3,600 by 1,600 metres), or about the same area as that occupied by the inner city of Memphis. Both town and necropolis were strictly oriented north and south. Imhotep obtained the town's presumed area of 4.1 by 8.2 miles (6.6 by 13.2 kilometres) by diverting the Nile into a new bed farther east and upstream of the site. The town, favoured by the 3rd to 6th dynasties, grew to megalopolitan proportions until 2263 BC when it was destroyed in a revolution.

The same planning skill is observable in the remains of the town of Kahun, founded about 2000 BC under the 12th dynasty. In layout it reveals divisions between the workmen's district in the west, with very small houses; the notables' district in the north, with big houses of several hundred rooms, courts, and corridors; the market in the east; and what is thought to be the temple area in the centre. The big houses of the notables face the pleasant north wind, while those of the workmen in the west are exposed to the hot desert wind. The remains of Thebes, located in Upper Egypt, are scattered in and around Luxor, Karnak, Birket Habu, and the area of mortuary temples on the west bank of the present Nile. Thebes became the country's capital under the 11th dynasty and, favoured by the succeeding dynasties, grew into the greatest and most monumental city of antiquity. It was destroyed first by the Assyrians in 661 BC, then by the Persian king Cambyses in 525 BC, and again by the Romans in 24 BC. Always encroached upon by the Nile, its original layout can only be tentatively traced out today. The terrain would permit a town to cover an area of 6 by 4 miles (9 by 6 kilometres) or, including Birket Habu, one of 8 by 4 miles (13 by 7 kilometres), with the long axis running southwest and northeast.

The capital at Amarna

The capital founded at Amarna by Amenophis IV (Ikhnaton) (1379–1362 BC), who seems to have been under the influence of his queen, Nefertiti, probably a foreigner, arose from an attempt to break with all the old traditions and to introduce an enlightened way of life. The cult of the sun, or light; a realistic art; equal rights for women; and naturalness of manner characterize the reign of that revolutionary monarch. Those traits also marked the layout of the new town, which extended in a narrow ribbon, slightly curved, along the Nile. It was more than 2.3 miles (3.7 kilometres) long and 0.9 mile (1.4 kilometres) wide. A street system flexibly adapted to the Nile's course connected the palace and temple district in the north with the dwelling quarters in the south. In these were courtyard houses for the lords' dwellings, surrounded by courts and outbuildings of all kinds, including farm buildings, servants' dwellings, cattle sheds, store houses, and gardens. The town seems to have been far removed from anything magical, mystical, dark, and sombre. The big houses of the residential quarters are interspersed with smaller houses, revealing that even social attitudes changed under Amenophis and his queen. It may be that the influence of Nefertiti was responsible for this short-lived bright Amarna period; it remained a refreshing oasis in the history of ancient Egypt. Then, cursed by the priests of Amon in Thebes, abandoned by all its people after the king's death, the sun city sank back into the sand and dust.

Iran. Only gradually did the Indo-European Medes who invaded Iran develop fixed dwellings with primitive markets from the existing settlements of peasants and cattle breeders. Rarely were there any suggestions of a town in connection with a feudal stronghold before whose walls an urban population of craftsmen and traders settled. Yet the very first Medo-Iranian capital, Ecbatana, had a citadel modelled on the universe. According to Herodotus, that citadel was girdled with seven walls in the colours of the planets. The innermost ring was golden (sun, Sunday), the second one silver (moon, Monday), the third scarlet (Mars, Tuesday), the fourth blue (Mercury, Wednesday), the fifth amber (Jupiter, Thursday), the sixth black (Venus, Friday), and the seventh ring white (Saturn, Saturday). This pattern points to the significance of the number seven, the star cult of the Medes, and the connection of the microcosm (citadel town) with the macrocosm of the universe.

Of Pasargadae, the early Persian capital, still less remains than of Ecbatana. More has been preserved of Persepolis, built by Darius in 520–515 BC. Its remains do not represent a town, however, but rather a magnificent palace complex. Sited on a terrace, Persepolis is essentially oriented toward the plain before it, parallel to the Zagros range. Nothing suggests any geomantic or magical notions, although the inscriptions set by Darius speak of the great supreme god Ahura-Mazdā, who bade Darius build the town and whom Darius requests to protect the land.

Influence of Zoroastrianism on Parthian towns

The spiritual successors of the Persians, the Parthians, or Arsacids, whose empire lasted from 247 BC to AD 224, were much influenced in their design of towns by Zoroastrianism. Of special interest is the old Parthian town of Phraaspa, allegedly Zoroaster's place of birth, which lay southeast of Lake Urmia. It was oval-elliptical in plan. From the south, along the northward main axis, lay an artificial lake, the fire temple, and a tower. It is possible to recognize in the ruins two parallel north–south main streets defining the central sacred area on the sides. It is also possible to visualize a quarter with small buildings in the northeast and the remains of a big complex of buildings in the west. In any case, Phraaspa is yet another example of a town designed to an overruling idea. Other Parthian towns, such as in Dārābgerd, a Parthian metropolis, are laid out in a perfectly concentric form, with circular outer and inner walls, eight main streets, eight gates, and a hill in the centre, the Meru.

It was the symbol of light and fire that the successors of the Parthians, the Sāsānids (AD 226–651), adopted as the basic idea for their towns. The first Sāsānid king, Ardashīr I, built his new capital of Gūr (Fīrūzābād) around that symbol—the disk of the sun. Gūr was laid out as a circular town with three ring walls. The innermost area comprised the palace and the government quarter, temples, fire tower, and priestly dwellings. The innermost wall had four gates, as did the outermost wall. The impression made by the town on its plain reveals successive ring streets and radial streets, forming two pairs of crossed axes. The whole town had the form of a shallow dish, surrounding the fire tower in its middle. The pattern seemed designed to symbolize the disk of the sun. It was also oriented on the cardinal points. The circles and rays symbolized the penetration of all earthly life, with its dark and evil aspects, by the light and the good.

Greece. Although Europe has a rich record of town developments, it is poor in models and rules of urban design. Pre-Hellenic and early Greek towns were laid out around strongholds or palaces on hills or terraces—as in Crete at Gourniá, Mallia, Phaestus, and Knossos, or in the Peloponnese at Mycenae and Tiryns. They were all laid out to serve practical and military needs, without a hint of a basic, symbolic idea of urban design, except that of building a stronghold protected against enemy attack. The plans of early towns of the Aegean are clearly influenced by Phoenicia in the layout of their harbours, both naval and commercial, and beyond that show the influence of the early Greek dwelling in the form of the megaron (a large, central hall). The houses face south, as does the town, but no geomantic notions are detectable.

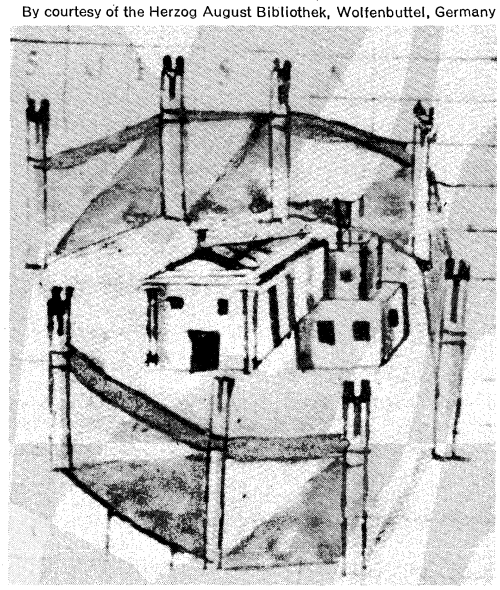
Mythological associations of Greek towns

The later development of the town in the Aegean islands, in Greece, and in western Asia Minor had a rich mythological accompaniment. Each town was linked with a city deity, yet without giving rise to any rules on layout. The Greeks were, in fact, for a long time reluctant to adopt rules for the layout of a town as a whole. The rebuilding of Miletus in 479 BC, after its destruction by the Persians, seems to mark the birth of a new style. It consisted in laying out a regular system of streets crossing at right angles within an arbitrary town plan determined by the local topography. The public and private buildings were then set within the squares of the grid. Priene—the third town of that name (350 BC), the two earlier ones having perished in the alluvial mud of the Meander—shows, within a plan freely adapted to the topography, a street system strictly oriented on the cardinal points, with all the buildings ordered into the grid. A similar pattern had already been adopted in 408 BC in the planning of Selinus on the south coast of Sicily, and at many other places. Generally, the new style preferred southward-sloping sites and south orientation.

The orientation of the Hellenistic town was freer. Doura-Europos (end of 4th century BC) follows the northwest–southeast orientation usual in Mesopotamia from olden times. In Laodicea, the position of the ruined buildings suggests a street system diagonal to the cardinal points; and the same applies to Pamukkale, ancient Hierapolis. The new style assumed a regularity that made it a classic model for later times. And so geomantic notions and mystical connections gave way to rational criteria.

The Roman town. Rome was bound by ideas of foundation ritual as well as formal town layout. In the foundation of a Roman town, Pierre Lavedan, a 20th-century French historian of architecture, distinguishes four phases: *inauguratio* (siting), *limitatio* (demarcation of area and subdivision thereof), *orientatio* (orientation of streets), and *consecratio* (consecration of the town). There were planning experts, the *gromatici*, and sacred formulas comparable to those of the geomancers of China and India. These formulas met the Roman bent for codification and deep religious sentiment, for the codified rule was both right and law.

The German Werner Müller gives a detailed description of the Roman *limitatio* and *orientatio*, which arose from Roman surveying practice and also harked back to very ancient notions. In the *limitatio*, the surveyors saw the earthly reflection of a heavenly model.



Not only does the cardo (baseline) represent the world axis, but the quartering of the ground mirrors the cosmological model: the quartered terra in the Roman idea of the world.

Even in Roman antiquity, a whole literature, including textbooks and polemic treatises, arose on the subject. The origins of the *limitatio* go back to the Etruscans, but whether that Etruscan root really represents the earliest origin of the Roman idea of the world, the *mundus*, is an open question.

In their ideas on construction, however, the Romans followed Greek and Hellenistic models. Rome thus relied for urban design on a tradition that the Etruscans had brought from Asia, and for architecture on the concepts of the Greek feeling for nature. Even the form of the *castrum* (fortress) presumably has an Alexandrian origin, the Romans having followed the model of the camp of Pyrrhus, which they had captured in 275 BC. The application of the ancient rules to the *castrum* made this the prototype of Roman urban design. The model consisted of a square plan, oriented on the cardinal points, with central crossroads leading to the four gates of the square on the north, south, east, and west. Even so, remains of *castra* show that the directions were not always and everywhere strictly adhered to. Instead of taking sights on the true cardinal points, the *gromatici* might work out some relation between the point of sunrise and the emperor's birthday or the day of foundation. And so the *orientatio* varied, for it seems that the *gromatici* followed fashions or practical needs and might on one occasion simply set the *porta praetoria* (main gate) opposite the enemy. Whether the lore of the *gromatici* came from Old Babylonia via Etruria, or, as some claim, from the north via the neighbouring Celts or Teutons, is still a matter for research.

Fortress towns as prototypes of Roman urban design

EARLY ASIA

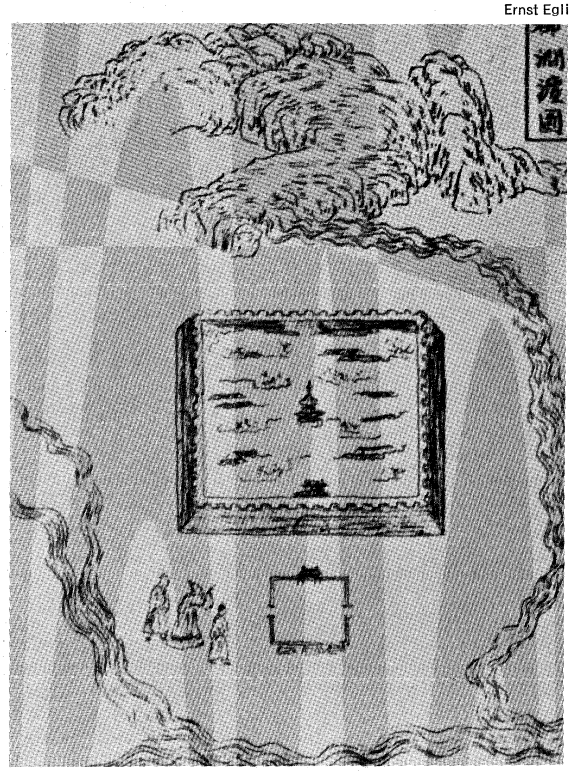
Indian region. The layout of the early towns of the Indus civilization (2600–1500 BC) has become known mainly through the excavations at Mohenjo-daro and Harappā. Mohenjo-daro, on the lower reach of the Indus River, now a field of ruins measuring about 1,100 by 1,100 yards (1,000 by 1,000 metres), was square in plan, probably with three north–south streets crossed by two east–west streets; thus, the town was oriented on the cardinal points. In the middle third of its western strip stood a citadel containing a *stupa* (cylindrical mound or tower), baths, assembly hall, and storehouses, while the other areas were occupied by dwellings (courtyard houses) of various size. It seems that part of the town was washed

away by the Indus breaking its banks. Harappā, of about the same size and layout, also had its citadel in the middle of the west side, with storehouses and workmen's quarters to the north. It may thus be that locating the civic centre on the town's middle west side corresponded to the rules and concepts of urban design at the time. Streets and drainage systems as well as the house layouts reveal that the art of construction had reached a very high level and that nothing was left to chance.

Soon after the arrival of the Aryans in India, a new culture was founded. Beginning on a rural base, it gradually matured into an urban culture. Settlements with forts as power bases and for the protection of the peasantry were built. About 1000 BC certain settlements began to be fortified with girdling walls and rules started to be formulated for the layout of house and town. Those rules are laid down in the *Śilpa-sāstra* (compendium of science in 64 books), notably in the *Mānasāra* book of 58 chapters, containing rules on architecture and sculpture, and also in another book called *Bṛhat-Saṃhitā*. The first prerequisites of "good luck" in house and town were strict orientation on the cardinal points and certain divisions and endowments of area in the inner town. All measures, forms, and proportions were fixed. Every town had a long street running from east to west called *rāja-patha* (king's way), and a short street running north and south, called *mahāk-āla* (broad way), as well as a ring street within the walls, called *mangalavithi*, for religious processions. The centre of the town was to be occupied by a hill, later in tower form (the *stupa*).

Ancient towns of India

The struggle between the invading Aryans in India and the aboriginal population was reflected in the ancient Vedic traditions as the struggle of the Pandu sons with the Kuru sons. Named as their chief towns are Indraprastha (Pandu) and Hastinapura (Kuru), towns that the epic work of that time, the *Mahābhārata*, describes as splendid, glamorous cities. Nothing remains of them or of any contemporary cities of the Vedic or immediate post-Vedic periods, but they are described as having been modelled on the heavenly city. How is modern man to imagine them?



In Sanskrit literature, the identity of microcosm (town) and macrocosm (world) is taken for granted. In Indian religion (both Hindu and Buddhist), the world spreads out toward the four cardinal points from its centre, the world mountain, which is called Hinawat or Meru and commands the concentric bands of the world and the oceans. The town layout reflects the plan of the universe. Such a pattern is shown in particular by the towns of Indochina, such as Angkor Thom, the capital of the Khmer kingdom (modern Cambodia). Jayavarman II (*c.* 802–850) founded the first Angkor as one of his residences, and Jayavarman VII (1181–*c.* 1215, possibly as late as 1219) built the second Angkor Thom in 1201. In the centre of the earlier town of Angkor Thom stood the temple complex of Phnom Bakheng. In the southeast quadrant rose the huge structure of the Angkor Wat temple. Town and temple were quartered by crossroads, with the step pyramid (Bayon) in the centre. In the Bayon, the Buddhists set up an image of Bodhisattva Avalokiteśvara, the Lord of the World, while the Hindu kings set up the *liṅga*, the phallic symbol of Śiva, the supreme god. Angkor was thus the perfect uranopolis (heavenly city). Later, when rebuilt, Angkor Thom was considerably reduced in size. Phnom Bakheng remained outside the new town, south of the new south gate, and so did Angkor Wat, but yet farther to the south. The model becomes clear from the designation of the town walls as world mountain, the town moats as world ocean, the step temples as gold (sun) mountains, and the centre as the gods' abode. And so the notion of the heavenly city provided the model for the earthly city. Some cosmological layouts were followed in many early cities of Southeast Asia.

Early Chinese towns

China. In China, as in India, a feudal form of society developed early, with protectors and clients, rulers and subjects. An urban system arose that was shaped partly by the need to ward off the continual raids of the nomads of the steppes on the settled population. The towns were thus laid out as refuges. The priests, augurs, and geomancers, on the other hand, wanted the towns laid out in keeping with the divine and natural laws. It was only by the time of the Chou dynasty (*c.* 1122–221 BC), however, that this deeper sense of law and regularity was felt. Later, the towns at the time of the barbarian raids were laid out square, usually with twin girdling walls, but with sufficient space between the two for crop-growing to sustain the population during a siege. The philosopher Mencius (*c.* 371–289 BC) describes such a town, and the chronicle *Shu-li* calls its general arrangement a rational and organic system. Soon, however, those towns seem to have been taken over by temples and the military, and the peasants, traders, and craftsmen told to settle outside the gates.

The geomantic rules on the construction of house, palace, temple, and town employed in later periods also probably arose during the Chou dynasty. The principles of town layout are laid down in the *Feng-shui* doctrine, which treats of the integration of human works into the pattern of the universe (*feng*—wind, floods of heaven; *shui*—water, floods of the earth). On *feng* and *shui* depends man's luck. It was the task of the geomancer to fix a propitious site for every structure (house, bridge, town, and so on). He used a compass disk divided into rings and sectors that indicated the site's relation both to the five elements (water, fire, metal, wood, and earth) and to the four cardinal points. The general rule governing the town is called *pei-shan-mien-shui* ("mountains to the north, water to the south"). Rules governing the design

of houses were concerned with spirits and forces within the house that could be controlled by arrangements relating to air, light, and shelter from the wind and cold.

Japan. The Japanese house and the Japanese town are primarily models of the integration of building into nature. It appears that the early Japanese did not regard the town as a desirable ideal. Towns in the real sense only arose after the adoption of Buddhism (about AD 550). They were founded by the emperors and laid out on Chinese models. Thus were founded Hesho Kio (south of Kyōto) after AD 710, Nagaoka after 784, and Kyōto ("the big city") after 792. They are laid out in a regular chessboard pattern. Kyōto measured 3.3 by 3.0 miles (5.3 by 4.8 kilometres) and was oriented on the cardinal

points. The emperor's palace stood in the middle of the north side. It is likely that geomancers also had a hand in laying out other towns, as in China. From 1200 on, however, the Chinese model was discarded in favour of a picturesque, spatial composition. The Japanese were more given to a mystical feeling for nature that included both the remoter scenery and the close vicinity of the site. Streams, groves, bridges, rocks, pebble tracts, stones—all had their symbolic meaning. Thus, to the Japanese, all nature was pervaded with spiritual symbols, and to bring these into their right mutual relations was a great art—an art that consisted in a symbolic spiritualization of the details, yet without any geometry or axes.

ANCIENT AMERICA

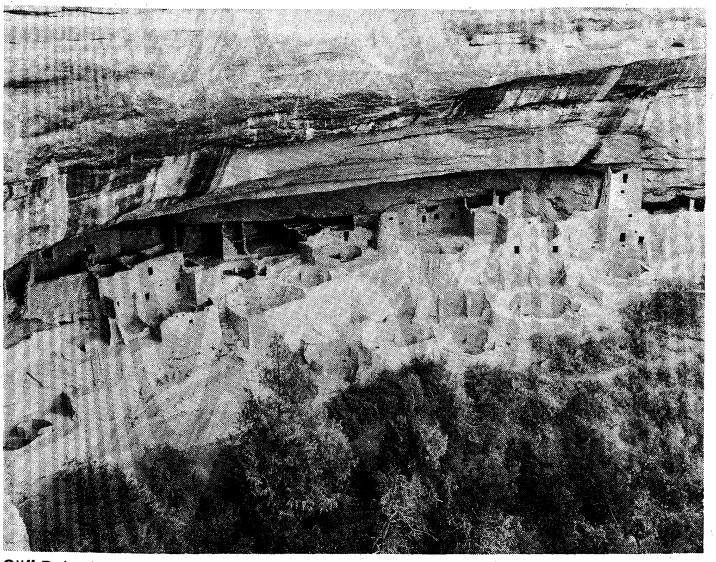
Singularity of the towns of ancient America

When referring to towns in ancient America, it must be remembered that one cannot say whether they really were towns in the normal sense. Few remains of a complete town have been found that include all the usual sections: a commercial and industrial district and market, an administrative area with castle or palace, a religious compound with temples and places of worship, and an agricultural complex with storehouses. The existing remains are mostly confined to a monumental nucleus, the religious or ruling centre of a town. It is not known whether any dwelling quarters were associated with such centres. Sometimes the ruins comprise dwellings without any trace of a temple or sacrificial site or of a commercial section. This applies particularly to the pueblo settlements of the southwestern United States. As far as the apparently purely ceremonial centres are concerned, it is most unlikely that they did not employ numbers of servants, officials, and craftsmen. Their dwellings, however, apparently were not built of stone.

The choice of site seems to have been determined less by good communications than by the proximity of fertile land, suitable building material, water, and possibly by the geomantic aspects of the place. An important factor seems to have been the possibility of laying out terraces. In plan, the towns do not always follow geomantic notions, and in the mountains are often adapted to the terrain for defense.

Pueblo cultures. The chief sites are Betatakin (Arizona), Mesa Verde (Colorado), Aztec (New Mexico), Canyon de Chelly (Arizona), Pueblo Bonito, and Frijoles Canyon (both New Mexico). The population of the region between the Rio Grande and the Colorado River built cliff settlements either as clusters of cells in natural caves or as compact, uniform settlements in open country. Which form is the earlier is arguable. The pueblo form might be regarded as being based on an old cave settlement removed into a valley and subsequently transferred back again to a cave under the pressure of external enemies. Pueblos follow a comprehensive form, with structures curving or set at angles surrounding a court area.

The site at Aztec (New Mexico) obviously represents a later development, as it is regulated by a strict order. Both forms, however, are based on an ancient symbol, the mother's enclosing of a valuable fruit. The spaces enclosed by the pueblos are either rectangular rooms, which may have served as dwelling and store rooms, or circular ceremonial chambers called kivas, from 10 to 33 feet (3 to 10 metres) in diameter.



The cave form of pueblo structure is found at Mesa Verde, in Colorado. Carbon dating of the timber remains assigns it to the 12th century AD.

For an earlier example, reference might be made to Pueblo Bonito, one of the twelve pueblo ruins in the Chaco Canyon. The plan reveals an earlier building subsequently greatly extended. The ring of the structure rises rearward to form a high back surface, from which the approaching person descends toward the inner court. A second early example, at Aztec, has a rectangular plan of U-shape; the house encloses the rectangular court, with the main kiva in the centre. Smaller kivas inside the building were regularly distributed.

Middle America. The capital of the Toltecs, Teotihuacán, was a large-scale layout 28 kilometres northeast of Mexico City. The ruins comprise a straight, monumental avenue running north and south, about two kilometres long; abutting it in the north is the Pyramid of the Moon and further groups of buildings. On its east side is the great Sun Pyramid, 200 feet (60 metres) high, and further groups of buildings on both sides of the avenue. To the south is found the so-called Citadel, and perhaps (though this is merely conjecture) the secular town, possibly with the ruler's seat. Around Teotihuacán, at a distance of a few miles, were big communal dwellings of 50 to 60 rooms. So the town may have been a combination of a monumental temple city serving priests and king, and rural communal villages.

Lake Texcoco, much larger at the time, flourished after AD 1400. Canals were its main thoroughfares. Three main streets running south, north, and west from the central square gave access to the hinterland. The town was peopled by 20 different tribes, each of which had its own tribal house and which all jointly owned the big central square. Facing the square from the east was the great pyramid with the main temple on its top platform; beside it stood the palace of Montezuma; farther south rose a second pyramid. According to a contemporary account there was also a great market square surrounded by colonnades.

Similar in layout to Tenochtitlán was the town of Tlatelolco, which had a large and remarkable market place with shops arranged behind colonnades. Of special interest is Monte Albán, the town of the Zapotecs and later of the Mixtecs. To judge by its ruins, it measured about 19 square miles (50 square kilometres) and was exactly oriented on the cardinal points. The town centre was a big square, measuring 330 by 215 yards (300 by 195 metres), with a remarkable flight of steps, 121 feet (37 metres) wide and 39 feet (12 metres) high. A ball court with rows of stone seats at the sides occupied a corner of the square. Again, nowhere in this large-scale layout of well-planned proportions and classic style can any traces of ordinary dwelling districts be found.

Other towns of the period include Texcoco, Culhuacán, Tenayuca, Xochicalco, Malinalco, Calixtahuaca, Tajín, Cholula, and La Venta, which is assigned to the Olmecs. The remains of La Venta's religious quarter reveal an architecturally important cultural centre, oriented on the cardinal points, with pyramids, squares, cisterns, tombs and sarcophagi, altars, columns, and stelae, all overgrown by jungle.

Accomplishment of Mayan design—Copán and Tikal

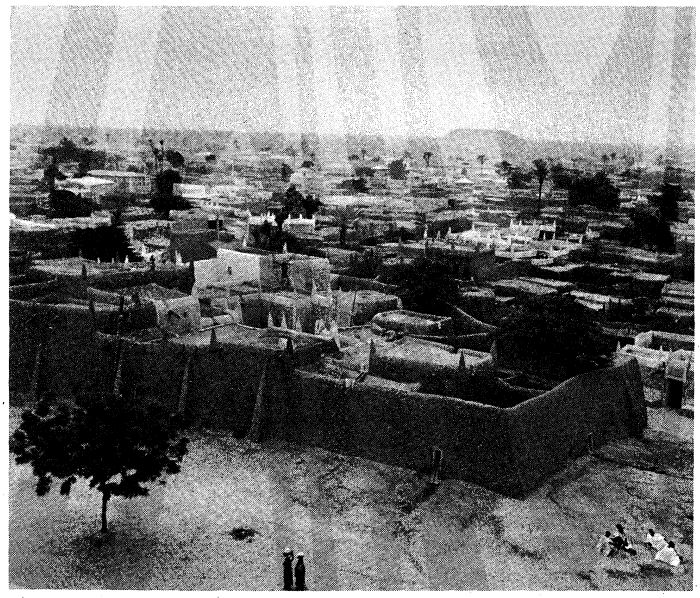
The Maya towns, dating from an earlier period, are noted for their masterly grouping of temples, squares, pyramids, courts, and colonnades, interspersed with individual buildings. Outstanding examples are Copán (in present-day Honduras) and Tikal (in Guatemala); they are models of accomplished layout. The remains of the monumental centre of Tikal cover an area of 900 by 1,300 yards (800 by 1,200 metres); in Copán, part of the centre was washed away by the Copán River, but the remainder still measures more than 1,100 yards (1,000 metres) in length. The later Maya period saw the construction of the towns of Chichén-Itzá (not later than AD 450), Uxmal, Labná, Tula, Mayapán, Cobá, and others. They reveal a free, picturesque attitude in their layout and architectural detail and thus almost exactly correspond to the development that Chinese urban design took between Ch'ang-an or Ho-Yang and the later town of Tsien-fu. Typical of this second Maya period is the development of Chichén-Itzá, where three periods are discernible: the first from 534 to 987, the second from 987 to the arrival of the Spaniards in the 16th century, and the third marking the decline of the town. The town centre belongs to the first period; it comprises the so-called Nunnery, the Red House, and the House of the Three Lintels (about 889). Under the Toltecs, further typical units were added: squares, temples, courts, and also baths.

The Andes. In the Andes region, the towns on the coastal plain are quite different in character from those built in the Andes themselves. The towns on the plateau of the Andes are no doubt the earlier. Of special importance was Tiahuanaco, southeast of Lake Titicaca at an altitude of 12,546 feet (3,825 metres). The remains antedating AD 1000 comprise the Acapana, an artificial earth mound set broad on an area 690 by 690 feet (210 by 210 metres), presumably a kind of acropolis; the Calasasaya, a temple area of 425 by 440 feet (130 by 135 metres) surrounded by huge walls, which also served as a celestial observatory; and the Puma-Puncu (Lion Gate), the Tunka-Puncu (Gate of Ten), and the Umu-Puncu (Water Gate), surrounded by many pieces of architecture. The gates undoubtedly had symbolic value, but the riddles posed by the town have so far been neither solved nor plausibly interpreted.

In the coastal area of the Andes, various political entities from prehistoric times can be identified. The Chimú area was of paramount importance. Pacatnamú in the north was a large town of regular layout containing about 70 pyramids, the biggest measuring 65 by 65 yards (60 by 60 metres), as well as steps, terraces, and a palace. Huanca de Chira, seat of a Chimú ruler, had a three-stepped pyramid measuring 100 by 130 yards (90 by 120 metres) at the base. Chan Chan, probably the most important layout in the whole south, has a ruined area measuring 11 square miles (28 square kilometres). Sited between the sea and a river in the south, with mountains on the north and east, Chan Chan had a harbour before its west wall, with docks that could be closed by gates. It also had residential districts with gardens. Inside the town walls were the clan quarters, separated from each other by walls. Each was rectangular in plan, interspersed with pyramids, tumuli (grave mounds), and temples. Two special complexes attract attention: the so-called Great Palace, about 450 by 550 yards (400 by 500 metres), and the small, second palace. The former comprised courts, quadrangles, countless buildings with many rooms, and a large poundlike water reservoir. All the elements of the Great Palace are ruled by a rigorous order. This applies similarly to the small palace, comprising a large number of buildings similar to courtyard houses, large quadrangles, a pyramid, corridors, and courts. All sections of this admirably laid-out town are oriented strictly on the cardinal points, with the south–north direction dominating. Without a doubt, Chan Chan presented a splendid sight with its regular pattern, its wall alignments, its parks along the canals, its painted scenes, and the stucco ornamentation of the walls. It may be compared to Peking, the residence of Kublai Khan, and it is fair to ask whether the roots of those two towns had not at some time grown on common ground.

Layout of Chan Chan

Chavín de Huántar is the second most important town in the Andes region south of the Chimú realm. It was a centre of religion and power, as evidenced by the ruins of temples and a palace. To the south are further complexes, palaces, forts, temple areas, pyramids, irrigation systems, water reservoirs, terraces, and remains of dwellings with scattered centres not concentrated within the framework of a comprehensive town. It is a town scattered within the confines of a valley community. Farther south lay Pachacamac, a large town within the realm of the Cuismancú rulers, with a large temple complex, which in the 9th century became the main centre of pilgrimage on the coast. The temple, measuring 133 by 60 yards (122 by 55 metres), formed the centre of a sacred enclosure and rose in five steps. Adjacent to the temple lay the old town, itself girdled by a wall. It was divided into four quarters by crossroads.



Pacatnamú, Chan Chan, and Pachacamac were all complete towns, places of both temporal and spiritual rule, with dwellings for the ordinary people. All three were the result of a social system that submitted to supernatural powers and infused its life with symbols. A glance at the layouts and the monumental ruins is sufficient to suggest how strongly those people felt committed to their ideas of order within the community. It was therefore easy for the urban designers of the time to embody that spiritual order in an artistic order.

EARLY AFRICA

There are various accounts of the feudal system prevailing in early African times, mainly by the Arabs al-Bakri (11th century), Yāqūt (12th century), Ibn Baṭṭūṭah and Ibn Khaldūn (both 14th century), and others.

According to one authority the population was divided into five classes: the knights (*horro*), the bards (*korrongo* or *djulli*), the serfs (also weavers), the smiths and other craftsmen (*numu*), and the domestic servants and captives (*ulussu*). The *horro* were the town founders. The disinherited sons of knights, they set out with bards and smiths to found a town. The site chosen was by a river, and was marked out as a circle or a rectangle in keeping with geomantic rites. Four gates were set up to the cardinal points, and a bull was ritually sacrificed. After three months, another bull was sacrificed together

with a virgin; only then was the town permitted to hold market. Then the *horro* set out on raiding expeditions, after which the newly built houses were occupied and life took its normal course.

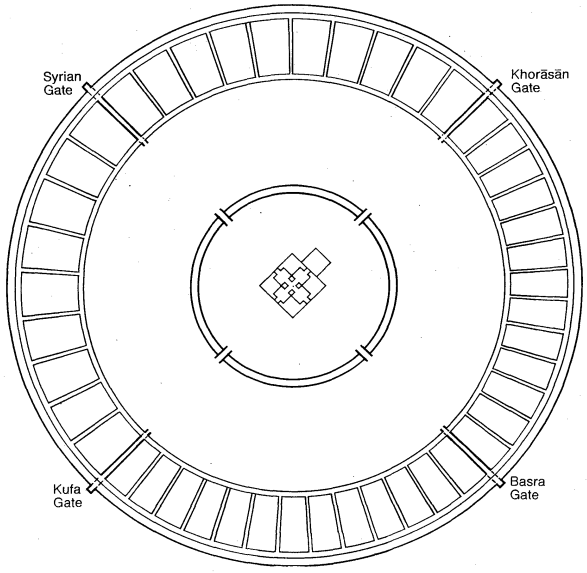
The shape of the towns may be deduced from present-day Kano (Nigeria), Timbuktu (Republic of Mali), Benin (Nigeria), and Loandjili (Congo [Brazzaville]). In Kano there are compounds with cubic components set against the enclosure wall, and with huts of clay standing clear in the court. The huts are cylindrical, and not too high. The streets are mainly winding and often with dead ends. In Loandjili, the houses are quite different: they are built as a group around a free central space, which they face. These groups seem to be laid out as districts forming clan dwellings. Both Kano and Loandjili are complete with temple, palace, market place, and commercial section.

The towns of early Africa were oriented on the cardinal points; were related to the country, to water and rivers, certainly allowing for the influence of the environment on settlements; and followed geomantic rules governing layout. They varied in plan, being circular or rectangular or often compact, with the clan compound as the basic unit. They obviously formed neighbourhoods, and were built on hillsides, hilltops, and on plains.

MEDIEVAL ISLAM

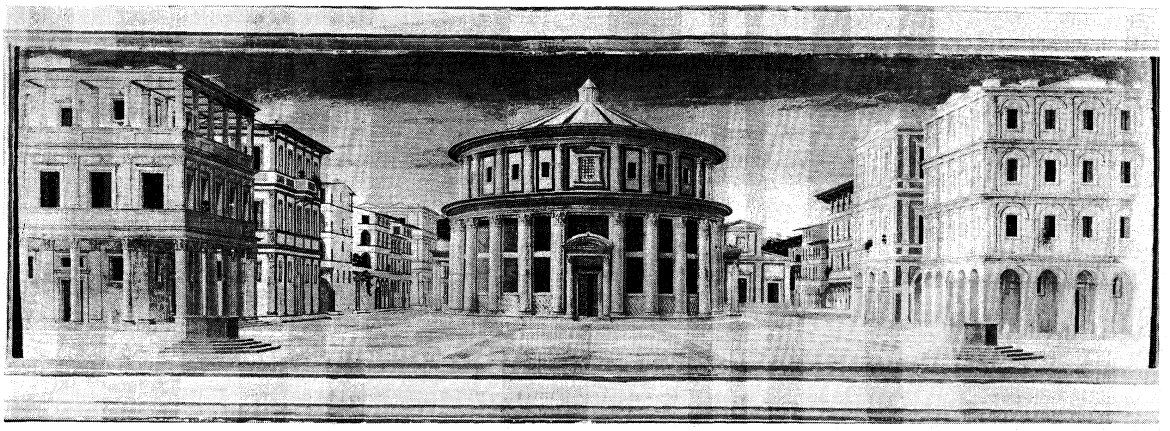
Islām refashioned the urban concepts that had developed earlier in the Near and Middle East areas. The new urban concept was deeply rooted in Islām itself, which had arisen in the world of the nomads, in Arabia's steppes and deserts, and thence spread out over the Near and Middle East, North Africa, and neighbouring areas. And it was that world that conditioned the Muslim way of thinking and feeling. The people living in that dry, bare, and hazardous environment carried in them a dream image of paradise; in the Qur'ān it is described in terms of gardens and springs, shade-giving trees, and abundance of food and drink. But while that dream image inspired various Islāmic palace layouts, it never determined an Islāmic town layout. For the actual initiators of Islām, the Arabians, were nomads and as such were hostile to urban life. To them, and to most Muslims, the town was not essential; it was simply accepted as incidental. Nevertheless, the Muslims founded towns, partly for military necessity, partly from the wish of the Muslims to camp in quarters of their own, partly from the wish of their rulers to build protected palaces, and, above all, because of the worldwide trade of the Muslim empire and the tradition of peoples who had lived in urbanized areas before the rise of Islām.

Muslims as town founders



Istanbul, seat of the caliph, the Prophet's successor, was not called the holy city or the Prophet's city, but rather the seat of felicity, with a clear allusion to the idea of paradise. Islām knew practically no generally applicable rules for the layout of towns. The town consisted simply of so many quarters, without any plan ordering the whole. It was the Muslim quarter, the *mahalle*, the neighbourhood associated with a particular mosque, that constituted the real unit in the social life of the Islāmic town. Such a quarter, in its advanced phase, comprised the mosque, a library, baths, a hospital, a school, a religious college, and well-houses. In setting out his environment, the Muslim wavered between sheer neglect of the worldly city and lavish attention to the world of the hereafter, to the divine and the eternal.

And so the Islāmic town is conditioned by outlook, but also by climatic factors, being built as an enclosed town of the arid zone, with enclosed quarters and enclosed courtyard houses. Politically, it may be divided into two sections: the palace of the rulers and, surrounding it, the quarters of the faithful. It is further characterized by its peculiar street system. This comprises two types of street: winding streets, which turn in one direction and then another, as if searching for the way; and blind streets, which simply provide access to the interior of a quarter or dwelling group and come to an abrupt end. Thus, a district is usually skirted with winding streets, from which radiate the blind streets into the interior.



The early period of Islām saw the growth of cities from military camps, called *ḫīrah*. Kufa and Basra, founded in 638, provided examples. In 642 the Muslims founded Fusṭāṭ on the Nile; it developed rapidly from a military camp into a large town surrounding the 'Amr Mosque, on the site of present-day Cairo. Kairouan (modern al-Qayrawān) in Tunisia was founded as a military camp in the 7th century. None of these towns reveals any specific design, let alone a common one. Neither do Mecca, the city of pilgrimage, or Medina, originally a trading post, show any deliberate design or any development toward such. In Syria and Palestine, urban layouts had mostly been established before the rise of Islām—as in Damascus, Jerusalem, Jericho, Amman, Haifa, and other important centres.

In Mesopotamia, however, Islām founded new towns, such as Baghdad and Sāmarrā' on the Tigris. Baghdad in particular is of interest in terms of design. It was founded in 762 by the Abbāsid caliph Mansūr and was completed in 766. Mansūr, advised by a former Persian magus, Halit, undoubtedly followed the model of the Sāsānian town of Gūr, which was laid out in a circle as a symbol of the sun. The diameter of Baghdad was 3,100 yards (2,800 metres), so that the town covered 1,500 acres (600 hectares). It had four gates, the Syrian Gate in the north-

west, the Khorāsān Gate in the northeast, the Basra Gate in the southeast, and the Kufa Gate in the southwest. The town's main axes were thus diagonal to the square of the cardinal points, as had been the practice in earlier times. Sāmarrā,' however, took the form of a ribbon town along the left bank of the Tigris, mainly because the caliphs at various times built their residences at that spot, with all their retainers, troops, craftsmen, and merchants settling around them.

Islāmic towns of Persia

The Persian towns of Tabrīz, Tūs, Isfahan, Mashad, Shīrāz, Hamadan, Kandehar, Neyshābūr, and Kermān are typical Islāmic towns. Isfahan, rebuilt in 903 on a circular plan, had four gates and a hundred towers on the Zoroastrian model. It reached its zenith with the buildings erected by ʿAbbās (1587–1629). These included the palace and monumental avenues and bridges, all governed by geometrical regularity. But frequent dynastic changes and earthquakes make it difficult to trace the development of the town. Like Isfahan, Shīrāz seems to have originally been circular in plan, while Hamadan was laid out square. Besides the influences of Islāmic architecture and Sāsānian tradition, it is possible to detect a Turanian influence from Central Asia. These influences are mostly superimposed on one another.

In central Asia, the Turkish element is dominant. The layout of the Turkish town consisted of a casual grouping devoid of axes. The Turkish contribution to urban design consists in the picturesque arrangement of domes and pavilions. Thoroughfares stretching from gate to gate formed the trading and religious centres, while the buildings themselves, influenced by Persian architecture, presented geometrical crystalline perspectives of exceptional charm and imagination. The centres of the bigger towns thus became jewels of Islāmic layout and district construction and at the same time exemplified Turkish patterns. Such patterns spread under the Turkish Mughal dynasty as far as India, where the layout of Fatehpur Sikri represents a great contrast to a layout such as that of Delhi, stamped with the axis-mindedness of the Indo-European Aryans.

In the Maghrib, towns were at their height in the 10th to 13th centuries. The sharp contrast between the exalted feudal lords and the anonymous mass of the faithful was clearly reflected in the layout—a gulf separating the dream world and luxury of the palace as the image of paradise from the humble utility of the ordinary man's dwelling. The latter, however, often contained a secluded, shaded, and cool court with a bubbling fountain.

MEDIEVAL EUROPE AND THE RENAISSANCE

In the Middle Ages, European towns arose as the seats of bishops and kings, around the strongholds of feudal lords, around markets, as spontaneously settled places granted charters, and as revivals of old Roman sites. German charters granted the right to a town wall, the right to a market, the right to a law court, and to self-administration. In no case is there any mention of a supernatural order, of the town as the mirror image of a heavenly city or of a universal order. Layouts were diverse, with parallel, radial, grid, triangular, and square plans. The main determinant of layout was topography.

Diverse layouts of medieval towns

A medieval town was hallowed not for having a cross in its plan, but for its associations with a saint; cathedrals were hallowed not because of their plan, but because they enshrined a holy relic. And this superseded the geomancy of the ancients and filled the people's need for mysticism.

The Renaissance introduced the rational element in the form of geometry, mathematics, and practical considerations as the factors determining urban design. The square, the octagon, polygons, and the circle are proposed as the plan, with the streets visualized as laid in regular chessboard patterns or radiating from a centre. Thus, a great many ideal towns were set out, on paper, but most of them were never built. The real towns were already there, creations of the Middle Ages, and with them all the institutions, laws, and patterns. Since adoption of the new trend would have required wholesale demolition, only in special cases was it possible to apply new concepts. All Renaissance theorists searched for new models for urban design. Vitruvius, the ancient Roman architect, provided the basis for Leon Battista Alberti (1404–72), who starts with the environment of the town, its topography, climate, and soil, and discusses the rational choice of site and the best form for a town and its streets from the military angle. His are the views of a thinker and architect who sees the town in the light of practical needs and who attempts to subordinate these needs to a rational order. The same applies to Antonio di Pietro Averlino Filarete, who intended to create a rational town with a planned place for each of its parts. Following him come several designers of ideal towns, such as Francesco di Giorgio, Francesco de Marchi, Pietro Cataneo, and others. They all visualize their towns set in fortifications. Alberti mentions two basic elements of design: *commoditas*, corresponding to the modern idea of functionality, and *voluptas*, or the pleasure taken in styling. In this context he speaks of beauty, which to him is the effect of rational design, geometrical relations, and numerical laws. His approach spread from Italy to France, Germany, Spain, and to the rest of Europe, including Russia. In all those countries arose theorists of urban design, and models passed from one hand to another, from one country to another.

The Baroque style in architecture

Soon, however, there was a change of attitude, leading in the 16th century to the Baroque style. As it was impossible in practice to build a town as a whole, the urban designers lost out to the detail designer, the architect. And his thought proceeded not from the whole to the detail, but rather from his work to its surroundings, and his object was to make his work radiate into the surroundings. Urban design thus abandoned the comprehensive view and became the architecture of the individual building complex. As a consequence, the concerns of the ordinary citizens were neglected in favour of those of the princely builders of the period. Such was the background to Michelangelo's design for the Capitol in Rome, the

rebuilding of Rome by Sixtus V, and the construction of St. Peter's in Rome. Everywhere in Europe the supremacy of perspective began. Axes of vision became axes of architecture. The influence of Baroque design extended even outside Europe, to Latin America. (E.A.E.)

Urbanization

The term urbanization refers to the process by which a population becomes concentrated in cities or "urban places." The process may proceed in either of two distinct ways: (1) through an increase in the number of urban places or (2) through an increase in the size of the population resident in each urban place. Although the term is sometimes also used to refer to the consequences of living in urban places, scholars prefer, for that purpose, to use the word urbanism, as in "urbanism as a way of life."

Conventional terminology

An *urban place* or city may be defined in as many ways as there are ways of regarding it—architecturally, geographically, economically, politically, and so on. As a matter of convenience and in the interest of comparability, an urban place or city is generally defined in demographic terms—on the basis of some minimum number of inhabitants. The United Nations, for purposes of international comparability, has recommended that all nations in tabulating their censuses and other official statistics, regard all concentrated places of 20,000 or more inhabitants as urban. Currently and in the past, various countries have defined different cutting-off points ranging from under 1,000 to over 20,000 (the U.S. uses the figure 2,500), and some countries use no criterion of size at all.

The *place* element in "urban place" also poses problems of definition, for a city's boundaries may be subject to change through annexation or disannexation or may be ill defined or nonexistent. Prior to 1950 in the United States, for example, an urban place included only *incorporated* places of 2,500 persons or more, but beginning in 1950 *unincorporated* places of 2,500 or more were also included as "urban"—a practice that required census geographers to impose arbitrary boundaries around concentrations of population, usually around larger cities. The problem is compounded by the fact that in many countries (including the U.S.) incorporated urban boundaries may embrace open country or "rural" populations.

With continued urbanization, population agglomerations have often spilled over established city boundary lines, thus inspiring new areal concepts in an effort to capture the actual, as contrasted with the political, population unit. The U.S. census report for Chicago, for instance, has information on the City of Chicago (the area incorporated in a charter granted by the state of Illinois), the Urbanized Area of Chicago (the city plus all adjoining densely populated areas), the Standard Metropolitan Statistical Area (the central city together with the adjoining counties—six of them—that are socially and economically related to the central city), and the Chicago-Northwestern Indiana Standard Consolidated Area (consisting of two adjoining Standard Metropolitan Statistical Areas, the Chicago area and the Gary-Hammond-East Chicago area). Besides such official designations, another term that has appeared with increasing frequency is megalopolis, referring to metropolitan areas that coalesce to become one continuous clumping of peoples and economic activities. One such area in the United States stretches from metropolitan Boston to metropolitan Washington, D.C. The English use the term conurbation to refer to essentially the same thing around such areas as London and Manchester-Liverpool.

CHARACTERISTICS OF URBANIZATION

Urban population growth. In view of the complexities of definition and the absence of widespread census taking prior to 1800, one can readily understand the impossibility of tracing world urbanization with any precision prior to the beginning of the 19th century. But since 1800 the proportion of the world's population resident in cities of 20,000 or more (and 100,000 or more) has been reasonably summarized. In the accompanying table it can be seen that the proportion of the world's population that was urban increased between 1800 and 1950, from 2.4 percent to 20.9 percent. By 1970, according to the United Nations, about 28 percent of the world's population was resident in urban places (of 20,000 or more population).

The United States can be taken as an illustration of the process of urbanization. In 1790, when the first decennial census of the United States was taken, there were only 24 urban places (with 2,500 persons or more). By the 19th

decennial census in 1970, the number had increased to 7,062. However, not only did the number of urban places increase but so did the average number of inhabitants in each place: in 1790 the average number of persons in an urban place was 8,400; by 1970 the average number had risen to 21,145. In consequence of both these increases, the urban proportion of the population rose from five percent in 1790 to 73.5 percent in 1970.

Population distribution. Man, in building his culture over his 2,000,000-to-4,000,000-year occupation of this planet, has precipitated three developments that have culminated in urbanization and urbanism as a way of life. The *population explosion* describes the remarkable acceleration in the rate of world population growth, especially during the past three centuries of the modern era. This phenomenon is highlighted by pointing out that it required almost all of the time man has been on the earth to produce a world population of 1,000,000,000, a number not attained until about 1830. It required but one additional century to produce a second billion persons, achieved in 1930. The third billion required only 30 years and was reached in 1960. By the century's end present patterns of fertility and continued mortality decline could result in a population of 7,500,000,000. Even with allowances for fertility declines, the population of the world is almost certain, short of castastrophe, to exceed 7,000,000,000 by the year 2000.

The *population implosion* refers to the increased concentration of the world's peoples into relatively small portions of the earth's surface. This also is a relatively recent phenomenon. Fixed human settlement was not possible until as recently as the Neolithic Period, some 10,000 years ago. Human settlements in excess of 100,000 persons were as recent as Greco-Roman civilization, and the proliferation of cities of 1,000,000 or more was as recent as the beginning of the 19th century.

Population differentiation refers to the increasing heterogeneity of peoples sharing the same geographic locale and the same economic and political activities. Heterogeneity refers to diversity of population by culture, language, religion, value systems, ethnicity, and race. This, too, is a relatively recent phenomenon achieved on a global basis only with the shrinking of the world by means of modern communication and transportation. It is probably correct to say that the world has shrunk more during the course of this century, as measured by the interaction of diverse peoples, than in all previous human history.

Initial requirements for urban development. *The ecological base.* It was no accident that the earliest of man's fixed settlements are found in the rich subtropical valleys of the Nile, the Tigris, the Euphrates, the Indus, and the Yellow rivers or in such well-watered islands as Crete. Such areas provided favourable environmental factors making town living relatively easy: climate and soil favourable to plant and animal life, an adequate water supply, ready materials for providing shelter, and easy access to other peoples. Although man with ingenuity has been able to utilize almost any environment for town living, environments favourable to the production of food and shelter and ease and comfort of living clearly possessed advantages for the beginnings of urban life.

Psychological influences. A distinguished historian, Ralph E. Turner, has suggested that various preurban developments made possible the technology and organization permitting city life. These included psychological elements such as recognition of "in-group" versus "out-group" interests; the notion of a universe, even if mysterious, that could be controlled; and belief in the existence of a soul. The in-group and out-group differentiation provided a basis for respect for the rights of others and for life, property, and family values. The notion that man could control the world in which he lived was of great importance, even if the methods of control were primitively based on magic and religion. The belief in a soul helped make life on earth more acceptable, even if hard, for life was just an incident in a long journey.

Sociological influences. Preurban developments that paved the way for urban life also included such factors as traditionalism, a power structure, and a form of economic as well as social organization. Traditionalism lay in the acceptance and transmission of what had worked in the life of the group and was therefore "right" and to be retained. Some form of power structure involving subordination was necessary, for leadership was a vital element in urban living in that it was essential to the performance of such vital functions as sustenance, religious practices, social life, and defense. Also prerequisite to group life were new economic and social institutions and groupings such as property, work, the family, a system for distribution of commodities and services, record keeping, police for internal security, and armed forces for defense.

New value orientations and ideologies may also have affected the course of urbanization, though their importance is still highly conjectural. There are those who have felt that urbanization depended on a new outlook; it meant that people had become more rationalistic (and less mystical); it meant that, for purposes of building, they were more willing and able to defer immediate for more desirable later gratification; it meant more emphasis on achievement and success as distinguished from status and prestige; it meant a cosmopolitan as distinguished from a parochial outlook; and it meant that relations between people were more ordered, impersonal, and utilitarian, rather than only personal and sentimental.

PATTERNS OF URBANIZATION BEFORE THE MODERN ERA

Ancient world. *Technological developments.* About 10,000 years ago in the Neolithic Period, man achieved relatively fixed settlement, but for perhaps 5,000 years such living was confined to the semipermanent peasant village—semipermanent because, when the soil had been exhausted by the relatively primitive methods of cultivation, the entire village was usually compelled to pick up and move elsewhere. Even when the village prospered in one place and the population grew relatively large, the village usually had to split in two, so that all cultivators would have ready access to the soil.

The evolution of the Neolithic village into a city took at least 1,500 years—in the Old World from 5000 to 3500 BC. The technological developments making it possible for man to live in urban places were, at first, mainly advances in agriculture. Neolithic man's domestication of plants and animals eventually led to improved methods of cultivation and stock breeding and the proliferation of the crafts, which in turn eventually produced a surplus and freed some of the population to work as artisans, craftsmen, and service workers.

Transportation development

As human settlements increased in size, by reason of the technological advances in irrigation and cultivation, the need for improving the circulation of goods and people became ever more acute. Pre-Neolithic man leading a nomadic existence in his never-ending search for food moved largely by foot and carried his essential goods with the help of his wife and children. Neolithic man, upon achieving the domestication of animals, used them for transportation as well as for food and hides. Then came the use of draft animals in combination with a sledge equipped with runners for carrying heavier loads. The major technological achievement in the early history of transportation, however, was obviously the invention of the wheel, used first in the Tigris-Euphrates Valley about

3500 BC and constructed first with solid materials and only later with hubs, spokes, and rims. Wheels, to be used efficiently, required roads, and thus came road building, an art most highly developed in ancient times by the Romans. Parallel improvements were made in water transport—with rafts, dugouts, the Egyptian reed float, eventually wooden boats, and of course canals used for both navigation and irrigation.

Architectural developments

Fixed human settlement also led to great improvements in the material and the permanence of human shelters. Lewis Mumford, an architect and historian of cities, has visualized the development of the city plant as consisting of the construction of more and more complex "containers." In the Neolithic Period, the containers varied from a "hole dug out of the soil sun-dried to brick hardness," as found in Mesopotamia, to mud and other types of huts. Other Neolithic containers included stone and pottery utensils, structures such as barns and granaries, and also "collective containers" such as irrigation ditches and the villages themselves.

The increase in population size converting the village to the town and then to the city was accompanied by a great increase in the built-up area and the number of structures. Archaeologists have discovered that Megiddo in Israel covered some 3½ acres, Gurnia in Crete about 6½ acres. These were among some of the larger early cities. Much later the walled area at Mycenae contained 12 acres, and at about the same time Carchemish in Syria was built on 240 acres. Menevia in about 600 BC covered perhaps as much as 1,800 acres.

The density of structures and people within such cities was very great—partly because distances could be no greater than a person could walk, partly because the water supply had to be within carrying distance of each home, and partly because technology was too primitive for man to build many sophisticated, spacious structures far from one another. Indeed, small row houses, rather than detached houses, remained prevalent from ancient times well into the modern era. Some of the archaeological finds suggest that the population densities in ancient cities about 2000 BC ranged as high as from 76,000 to 128,000 persons per square mile. This compares with present-day densities in New York City, with 26,300 persons per square mile; San Francisco with 10,900; Frankfurt with 8,900; Tokyo with 39,700. A city like Paris, however, does have a rather high density—63,650 persons per square mile. Ancient cities, moreover, were usually walled to provide protection against enemies, and city walls, in fact, remained important structural elements down to the 18th century. Mankind did not achieve a level of technological and social organizational development to achieve cities of 100,000 or more persons until during the Greco-Roman civilization. The Greek city-state had its origin in and owed its relatively large size to the ability to acquire and dominate a hinterland by force of arms. Superior military prowess enabled the Greeks to build fortress city-states that developed economic relations with a rural service area that was physically subordinated and subjected to tribute. The same can be said of Rome and other prominent cities of antiquity. Ancient wars can in large measure be interpreted as wars between cities seeking rural hinterlands.

The example of Rome

Rome may be taken as an example of the developments achieved in the building of urban plants in the later days of antiquity. At its greatest size, in the 3rd century AD, Rome covered an area of about four square miles within its walls, with a population minimally estimated at about 800,000 persons. The original settlement of Rome was on the hills nearest the Tiber River, but as the settlement increased in size, population spread into the adjoining valleys and eventually well away from the river by means of such technological developments as aqueducts and improved roads. Moreover, at the level of the river itself, drainage and embankments permitted the use of low-lying land as well.

To provide water for the population, the Romans built aqueducts as early as 312 BC. Later aqueducts brought water from as far away as the Sabine Hills, 44 miles distant. To get the water to higher ground, the aqueducts were carried on high arches, and thence the water was distributed to individual structures by a complex system of conduits and lead pipes, which were not equalled until the present century.

In the earliest of Roman settlements, building materials consisted of wickerwork plastered with clay on a timber framework. Later developments led to timber and mud brick and, eventually, to more durable materials including stone, marble, and concrete, which went into the now famous monuments of antiquity, such as the Forum, the great public works of the Capitoline Hill, the Colosseum, the Circus Maximus, and the Pantheon. Finally, Rome serves as a good example of the walled city—its town walls serving to defend it not only during the period of its glory but also throughout the Middle Ages.

Social developments. Because usually no one village can support full-time craftsmen and other nonagricultural functionaries, such specialists normally have to wander from village to village to make their living. This must have been the case in the Neolithic Period.

The ancient city, on the other hand, required and developed more sophisticated methods of pooling and distributing surpluses of food, crafts, and other products. Forms of exchange, including money, had to be developed, which in turn required systems of recording and, therefore, the invention of writing and of numbers. The city was also characterized by large public structures, including temples for worship, granaries for sorting grain, magazines for armaments, and workshops. The rise of new administrative, security, religious, and economic functions led to more complex social organization, including upper and lower classes, with rulers, priests, military leaders, craftsmen, and peasants. Finally, the city engaged in exchange with other cities and in foreign trade in an effort to obtain new forms of products.

Ecologically, the elite—the higher clergy, government officials, aristocrats, and, in due course, the wealthier tradesmen—resided at the centre of the city near its forum or temple. Away from the centre were distributed the lower classes toward, and sometimes beyond, the safety of the city walls. Within the city separate quarters generally arose by ethnic origin or by occupational grouping. Such distinguishable quarters were often separated by lesser walls, moats, or ditches and often constituted separate, isolated worlds. This type of ecological patterning describes not only the ancient city but much of urban organization prior to the Industrial Revolution.

The extended family was the primary unit of social organization and the key to the person's social and economic position, for, with limited social mobility, kinship was a major factor in determining social and economic status. The elite household contained the members of the extended family together with domestics and workers (including slaves) related to the household's economic activity. Male dominance and age-grading tended to be the rule, with elders in the dominant power position.

Economic organization centred on specialization in product rather than specialization in process, thus guilds or their precursors were organized largely in terms of a product. Market procedures were complicated by the absence of standardization in products, weights and measures, currencies, and prices, and by extensive adulteration of products.

Technological developments. Roman technology survived the collapse of Rome, and expanded trade carried the relatively advanced technology of India and China to the West, including gunpowder, iron casting, paper and printing, silk-working machinery, and more sophisticated rigging for sailing ships. Moreover, the "barbarians" who inherited the old Roman Empire added inventions of their own, including soap, barrels and tubs, heated houses, the horseshoe, and new agricultural techniques.

Perhaps most significant in accelerating urbanization were the use of gunpowder, nonhuman sources of power, the mechanical clock, and printing.

Gunpowder helped destroy a medieval feudal order that had already been undermined by the rise of towns, the growth of trade, the toll of internecine wars, and the effects of such epidemics as the Black Death. The initial

use of gunpowder was in siege artillery, which quickly reduced feudal walls and castles; the eventual addition of hand guns rendered all armoured feudal armies antiquated, and older forms of warfare and defense collapsed. The increasing use of nonhuman sources of energy—at first animal power and then water and wind—greatly increased productivity. Agriculture benefitted from improved harnesses, wheeled plows, teams of animals, and new systems of cultivation. The mill, powered by wind or water and involving such transmission mechanisms as gearing, was used mainly for grinding grain but also for moving bellows and powering hammers in the process of crushing ore and forging wrought iron. Although the sun dial, the sand glass, and the water clock can be traced to antiquity, the mechanical clock was not invented until the 14th century and proved to be a great boon to the increasingly interdependent economic and social order that required time synchronization for effective operation. Finally, the printing press greatly increased the ability of man to communicate both between and within generations and did as much to advance science and technology as it did to facilitate communication of ideas in the expanding urban world.

The physical form of medieval and Renaissance towns and cities followed the pattern of the village, spreading along a street, a crossroad, in circular patterns or in irregular shapes—though rectangular patterns tended to characterize some of the newer towns. Most streets were little more than footpaths—more a medium for communication than for transportation—and even in major cities paving was not introduced until 1184 in Paris, 1235 in Florence, and 1300 in Lübeck. As the population of the city grew, walls were often expanded, but few cities at the time exceeded a mile in length. Sometimes sites were changed as in Lübeck, and many new cities emerged with increasing population—frequently about one day's walk apart. Towns ranged in population from several hundred to perhaps 40,000 (London in the 14th century). Paris and Venice were exceptions, reaching 100,000.

Housing varied from elaborate merchant houses to crude huts and stone enclosures. Dwellings were usually two to three stories high, aligned in rows, and often with rear gardens or inner courts formed by solid blocks. Windows were small apertures with shutters, at first, and later covered with oiled cloth, paper, and glass. Heating improved from the open hearth to the fireplace and chimney. Rooms varied from the single room for the poor to differentiated rooms for specialized use by the wealthy. Space generally was at a premium. Privacy was rare and sanitation primitive.

Social developments. An increase in the size of a city often carried with it increased diversity of people. Although such heterogeneity could have resulted in conflicts between peoples of different origin, culture, ethnicity, or religion, the actual result was that the division of the city into quarters made for self-sufficiency, each quarter tending to have its own church, provision market, water supply, and social institutions. The city was, therefore, really a collection of separate quarters or neighbourhoods in which people with like interests and needs could live peacefully together.

Family and kinship

Medieval and Renaissance life was characterized by households that included not only the extended family of three or more generations and other relatives but also domestics and workers associated with the family's economic activities. Young men of the upper classes, for example, often served as waiting men in noble families, and apprentices and even journeymen lived with the master craftman's family. Household members would work together, eat together, and often sleep in the same common room arranged into dormitories.

Marriage was generally arranged by family heads, and child marriages were not infrequent in China, India, Japan, the Near East, and parts of Europe, although in child marriages the partners did not live together until adulthood. Families tended to be patriarchial; that is, the wife was subordinated to the husband, and her life was largely restricted to household duties, with few opportunities to play a role in the larger world. Children were reared to respect and obey their elders, sons often remaining under the authority of the father even after they were married. Such schooling as was available was generally limited to the upper classes and to boys.

MODERN PATTERNS OF URBANIZATION

Industrial Revolution and modernization. Just as in ancient times the growth and improvement of agriculture had produced food surpluses and thus made cities possible, so did the growth and improvement of cities in modern times produce greater division of labour and more specialization and thus make mass production in factories possible. As Adam Smith noted, the larger the size of a population, the greater the possibility of division of labour. Greater division of labour led to increased specialization. Increased specialization operated to increase productivity both because the specialist could concentrate on one relatively simple activity and because the specialized function could more easily be mechanized and accomplished through the use of nonhuman energy. It is true that this Industrial Revolution at the outset perhaps made the life of the average worker and urbanite more hundrum and impoverished, but in the long run it has led to greatly improved levels of living for the mass populations in those countries that have become industrialized.

Urban growth

Not only did cities facilitate industrialization but also, conversely, industrialization had a striking effect on the growth of cities. In the pioneer country of industrialization, England and Wales, for example, there were in 1801 only 106 cities or urban places containing 5,000 inhabitants or more—representing no more than 26 percent of the country's total population (some estimates placing the figure even lower at 10 percent). A half century later, in 1851, there were 265 urban places, constituting 45 percent of the total population. By 1891 the growth had reached 622 places, representing 68 percent of the population. By the turn of the century most of Europe had joined or was joining the processes of industrialization and urbanization. By 1920 the population of Europe (excepting the U.S.S.R.) was 32 percent urban; by 1970 it was 64 percent, with the heaviest densities in such industrial areas as the Rhineland and the English Midlands. Most significantly, whereas Europe's total population between 1920 and 1970 increased by 42 percent (from 325,000,000 to 462,000,000) its urban population jumped by 182 percent (from 104,000,000 to 293,000,000). Parallel developments of course took place in the United States: in 1800 only 6.1 percent of the population lived in urban places (defined as places of 2,500 or more); in 1970 the figure was about 73.5 percent.

Such figures contrast with the figures for countries and regions that have not yet industrialized or are only now beginnning the processes of modernization. Although the overall population densities in the underdeveloped world are generally far greater, their urban percentages are smaller. In 1970 East Asia was 30 percent urban, south Asia (from the Middle East to Southeast Asia) was 21 percent, Latin America was 56 percent, and Africa was 22 percent. The industrial nation of Japan, in comparison, was about 72 percent urban.

Communication and transportation. Urbanization and industrialization (or the factory system) thus had mutual influences. They each caused the other to spiral upward. This mutual cause-and-effect relation also applies to urbanization when twinned with other fields of development. Increased division of labour and specialization necessarily required more intercommunication of peoples in the production and distribution of goods and services. This led to great improvements in communication and transportation, which in turn permitted a larger and ever more complex order.

The developments in audiovisual communication throughout the globe have been accompanied by great improvements in interpersonal communication. Mail delivery systems made it possible for people to communicate at great distances under conditions of privacy, even though considerable time was required. Then the invention and development of the telegraph made interpersonal communication even more efficient and rapid. The inven-

tion of the telephone made interpersonal communication instantaneous, and continued improvements have made long-distance telephone communication possible not only within nations but between all parts of the world. Another important part of the story of improved communication is the accumulation of knowledge and its transmission from generation to generation—by means of the printed word, the desk calculator, and, ultimately, the modern computer. Such improvements in communication, in short, have made possible ever larger clumps of people and economic activities and therefore ever larger cities.

19th-century transportation and urban patterns

Nineteenth-century cities, when the means of transportation were relatively poor, drew dense populations tightly around the factory—within walking distance. With the advent of the horse-drawn vehicle on rails, the railroad, and the trolley car, population could spread away from the factory and the city grow ever larger. Such population dispersion as occurred, however, was relatively limited in the late 19th and early 20th centuries and extended in star-shaped fashion along the major lanes of transport—usually the commuting railroad. With the widespread use of the automobile and improvement of roads including expressways and freeways, much greater dispersion ensued. Moreover, with the introduction of expressways encircling the city, population flowed into the interstices of the earlier star-shaped urban agglomerations to fill all available residential areas with ready access to the city.

Beyond the city proper, however, the most important advances in transportation during the 19th century were first the canals and then the railroads. The development of railroads, in particular, paved the way for the great expansion and scattering of urban places and for the industrial development that accompanied it. The railroad became and remains the major means of transporting goods across land surfaces, and it was also a major means for transporting people until the automobile became popular after the 1920s and the airplane after the 1940s. On the international front, great improvements in ocean transport stimulated not only foreign trade but also international migration—mostly to cities.

In short, improvements in transportation led directly to much greater sizes of population clumps and contributed to increased productivity by improving the speed and efficiency with which supplies and people could be carried. As in the case of communication, a circular reaction was involved. Improved transportation made larger cities possible, and larger cities required better means of transportation for the circulation of people and goods.

19th-century centripetal patterns

The developing structure of urban areas: 19th century. In England, France, the United States, and other nations that experienced the Industrial Revolution relatively early, 19th-century urbanization was closely linked with industrialization. The physical structures of the cities inherited from preindustrial centuries were subjected to great modification required by the rapid growth of the factory system and the accompanying mass production. The combination of the steam engine, the belt, and the pulley set centripetal forces in motion that generated high population densities near places of work. This was especially true of the heavy industries—iron, smelting, metal products, machine building, and glass manufacture. The two most prominent features of the 19th-century industrial city were the factory and the slum.

The industrial city was characterized in physical form by rectangular blocks, generally of uniform size separated by a pattern of streets and thoroughfares, usually of uniform width. Subject to local topography, the rectangular pattern—which Mumford refers to as the nonplan—permitted, the indefinite extension of the city in all directions. As the city expanded, open lands were absorbed with little regard for areas needed for public use, including recreation. The rectangular block pattern was a boon to engineers, architects, and realty brokers, but it also created many physical problems. The streets of uniform width provided thoroughfares too broad for many residential areas and too narrow for major traffic arteries. Moreover, it was too rigid a form to adapt easily to various topographical features such as hills, valleys, rivers, lakes, and canals.

The factory introduced into the urban area unprecedented forms of pollution, fouling the atmosphere with heavy smoke containing chemical agents hazardous to both human health and surrounding agriculture. Plants were usually located on sites near water upon which they depended for steam, processing, transport, and sewerage; in consequence, rivers, lakes, and canals became open sewers with water not only unfit for human consumption or bathing but dangerous as well to fish, plants, and animals. The factory created new levels of environmental pollution, unaesthetic and hazardous to all forms of life.

The industrial cities, especially in the early part of the 19th century, contained miserable residences for the workers and their families. Housing was poorly constructed and crowded closely together—typically as tall tenements or row housing, often with little or no provision for water and sanitation. In one part of Manchester in 1843–44, for example, surveys reported only one toilet per 212 persons. Cellars—dark, dank, and unsanitary—often served as dwelling places. Provision for garbage and rubbish removal was inadequate. Windows were small and narrow and lighting inadequate. Limited space was available for gardens or children's play.

The filth and congestion bred insects and vermin that afflicted large proportions of the population. Rats, bugs, flies, and lice were the source of disease, including bubonic plague brought by rats and typhus by lice. Inadequate plumbing made typhoid widespread. In consequence, mortality, especially infant and child mortality, was inordinately high. Studies showed that city death rates greatly exceeded those in rural areas and that within cities the areas with highest densities had the highest morbidity and mortality.

Toward the end of the 19th century, however, the miserable conditions led to various forms of legislation to alleviate the condition of the working classes. Gradually the amenities of urban existence available at first only to the elite (who could not, however, escape from disease and environmental pollution) spread to the poor and persons of modest means. By the end of the 19th century the lower classes began to get the benefits of mass production reflected in their rising levels of living. Housing improved and increasingly contained piped water, sewerage, lighting, and easy access to transportation.

20th-century centrifugal patterns

The developing structure of urban areas: 20th century. With improvements in transportation and communication, 20th-century technology began to set centrifugal forces in motion that operated to disperse population and economic activities across city boundaries and into the adjoining countryside. This expanding urban agglomeration transcended political units and boundaries, causing new areal concepts to be developed for describing the emerging new urban reality, as distinguished from the historical urban units. The "metropolitan area," under various national designations, came to stand for the central city together with its outlying "ring." The "urbanized area" came to be the designation for solidly built-up areas with, in general, population densities requiring residence in city block patterns—the urban concentration as seen from an airplane in which all political boundaries are obscured. "Consolidated areas" came to be used in the United States to describe contiguous metropolitan areas. Finally "megalopolis" emerged as the designation of a number of coalescing metropolitan areas.

Continued advances in transportation and communication led not only to the dispersal of population but increasingly, also, to the decentralization of economic activities—trade, services, and production. The decentralized shopping centre diminished the dominance of the central business district for purveying many types of goods and services, and the decentralized factory, gaining the advantages of more and better space for mass production and space for automotive and truck parking, competed favourably with many inner-city industries. The central business district, nevertheless, continued to be the economic centre of the metropolitan area and dominated the metropolis with its concentration of professional and white-collar activities.

In most cases the urban physical plant—residential, in-

dustrial, commercial, and governmental—was constructed hurriedly in response to rapid urbanization. Land-use patterns and infrastructure development were largely the product of market forces, which produced a remarkable physical plant but which also permitted rapid obsolescence and decay as evidenced by large proportions of "substandard housing" and areas of slum. In affluent countries the automobile, which has been a major factor in the development of the 20th-century metropolis, is now threatening it with congestion, and new attention is being focussed on problems of circulation within the city. Finally, problems of air and water pollution are also becoming critical in many areas.

Urban decay

In the developing regions of the world—in Asia, Latin America, and Africa—the most visible consequence of rapid urbanization is the decadence of the urban environment. The city is characterized by a large proportion of shanty towns and tenement slums; inadequate urban services, including poor housing, water supply, sewerage, utilities, and transport; uncontrolled land use; excessive population densities; deficient education and recreational facilities; and inefficient commercial and marketing services. Rapid urbanization in the underdeveloped areas is accompanied not only by a defective but also a deteriorating urban environment. It is estimated that, in Latin America alone, some 4,000,000 or 5,000,000 families live in urban shanty towns and slums.

With increased productivity and a growing middle class and despite evidence of deterioration, modern housing has been characterized overall by great advances in convenience and in safety and comfort. Since the 19th century, space per person has greatly increased; piped water, private bathrooms and sanitary facilities, electric lighting, central heating, and increased air conditioning have become standard in the more affluent nations.

Urban planning

During the 20th century, in response to physical and other problems, governments have increasingly intervened to protect health, life, and safety. Nations in which centralized governments exerted great control over municipal areas were quicker to respond to urban evils—nations such as England and the Scandinavian countries. Nations with federal systems, in which state and local governments had more autonomy, as in the United States, were slower to respond to the need for eliminating the evils that accompanied urban living: air and water pollution, substandard housing, slums, traffic congestion, the "commuters' crisis," and inadequate parks and public recreational and cultural facilities. By mid-20th century, however, programs of public housing, urban renewal, and city planning had become almost universal among the economically advanced nations.

The underdeveloped nations are of course aware of the need for city and regional, as well as national, planning. But the city planner in the underdeveloped country is confronted with insuperable difficulties. These stem largely from low income levels; from rapid population growth, including hordes of in-migrants from rural areas who are ill adapted to urban living; from inadequate development services and government urban development—all in all, from a bewildering array of needs, each of which seems to have first priority. Although urban agglomerations of the size of Western cities are to be found, the physical amenities associated with such in the West have not yet developed—at least, not for the mass population. The amenities of urban existence are available only to very small fractions of the total urban population. It is in the impact on the already inadequate urban physical plant that the rapid rate of urbanization produces some of its more serious consequences.

Social developments. The combination of technological and demographic developments led in the 19th century to the proliferation of cities of 1,000,000 or more inhabitants. Prior to the 19th century, although there may have been an occasional city in ancient China or in Japan (Edo, the precursor of Tokyo) that reached a population of 1,000,000, there certainly were no great number of cities of this size. By the onset of the 19th century, however, technological and social organizational developments together with the population explosion and implosion that accompanied them had reached levels that led to the generation of a number of such great cities. According to one estimate, by 1900 there were 10 cities of 1,000,000 or more inhabitants in the world; by 1950 there were 49 such cities.

That the city makes a difference in man's way of life was perceived by the ancients, but especially during the 19th and early 20th centuries a number of scholars began discussing the difference it makes and clarifying the factors involved. Twentieth-century scholars have shed further light on the impact of the city.

The effects of increasing population densities on social life (and on individual attitudes and behaviours) can be partly explained by reference to a hypothetical circle with a 10-mile radius (altogether, 314 square miles). At a density of one person per square mile there are only 314 persons on the fixed land area; at a density of 25,000 (approximately the density of New York City) the size of the population will increase to almost 8,000,000. The significance of these figures is that they indicate the magnitude of potential human interaction—that is, the maximum number of persons with whom any one person could potentially make contact. With a density of one the maximum number of other human beings any one person could meet is 313 (314 minus one); with a density of 25,000 the maximum number of other human beings increases to almost 8,000,000. It is to the increase in the number of contacts that the effects of urbanization may be traced, because the increase in contacts results in qualitative as well as quantitative changes in human interaction.

In the community of small size and low density (the "little community," to use Robert Redfield's terminology) people live in "primary groups" and experience "primary contacts"—that is, human interaction is "face to face" and encompasses virtually all spheres of activity. In the little community interpersonal relations are intimate and often are based on sentiment and emotion. In contrast, in the society characterized by great size and high population densities (the "mass society," to use Karl Mannheim's language) people characteristically live in "secondary groups" and have "secondary contacts"—that is, contacts tend to be segmental—in that people interact only at that point where their life paths intersect. It is the contact typified by the relation between physician and patient, lawyer and client, grocer and customer, teacher and student, or tax collector and taxpayer. In this situation human relations seldom are based on sentiment and emotion but rather on utility.

Moreover, in the mass society, behavioral heterogeneity increases not only because of size but also because of the intermingling of persons of diverse background—diverse by culture, language, religion, ethnicity, or race. The combination of heterogeneous and secondary contacts greatly modifies human behaviour. Thought and action tend to depend less and less on the traditional; the influence of the folkways and mores diminishes. In ever-larger spheres of thought and action, behaviour seems less determined by the norms of the group. The sphere of personal decision making is greatly extended in areas such as the kind and degree of education, occupation or profession, residential location, choice of mate, size of family, political affiliation, and religion.

It follows, then, that increased size and density of population, especially if accompanied by heterogeneity, diminishes the power of informal social controls. Informal social controls, effected largely through the play of folkways and the mores, gives way to increased formal control—the control of law, police, courts, jails, regulations, and orders. The breakdown in informal social controls is in large measure responsible for increased personal disorganization as manifest in juvenile delinquency, crime, prostitution, alcoholism, drug addiction, suicide, mental disease, social unrest, and political instability. Formal controls have by no means proved as efficacious as the informal in regulating human behaviour.

The effect of the city on the way of life may be observed in the adjustment problems of the newcomers. The city as a recipient of migrants has played and continues to play a

prominent role in the modification of thought and behaviour, in subjecting people with traditional and rural backgrounds to the conditions of urban living. Most of the severe physical, social, and economic problems of the city are disproportionately manifest among newcomers and are symptomatic of the difficulties of adjustment to urban life.

It may be that, to the extent that size, density, and heterogeneity of population have changed behaviour in urban places, they represent necessary, rather than sufficient, conditions for such a transformation. For certainly much behaviour in urban places, especially in the economically underdeveloped countries, is still traditional rather than rational and, in other respects, resembles folk rather than urban characteristics. The explanation for this may lie in the difference between *potential* human interaction in the city and that actually achieved; that is, in large population clumps of high density, which are essentially an agglutination of separate and distinct noninteracting communities, human behaviour may still be largely the product of the primary group.

As a microcosm of the social whole, the family is a convenient unit through which to trace many of the influences of the city on social institutions. The family is in most societies regarded as the primary social unit: it has been a basic and largely self-sufficient economic unit, it has had primary responsibility for the socialization and education of the young, it has been a focal point for religious training and practices, it has provided for the security and protection of its members, and it has been the centre for affectional and recreational life. The family in modernized urban societies, however, has certainly been transformed: the urban family today is smaller; it is more often childless and has fewer children, if fertile; it is more mobile; it possesses comparatively little economic or social unity; it is more frequently broken by separation or divorce; and it has long since lost or shared many of its various historic functions with new, specialized urban institutions, such as the clothing store, the grocery, the restaurant, the school, the library, and systems of social security.

Social stratification

The development of the city also altered—and produced new forms of—social stratification. The rise of the commercial city greatly increased the importance of the merchants, who became an ever more powerful group. With the increasing size and power of the city, merchants displaced landlords not only in the power structure of the cities but increasingly in the power structure of larger entities, including nations as a whole. With the ascendancy of the industrial city, the industrialist, the financier, and the manager achieved positions of power arising from wealth and strategic location in the economy. The development of intellectual traditions, bolstered by the scientific revolution, provided high status to persons in intellectual and professional pursuits. To these various sources of status would be added older residual sources of social stratification based on status; that is, birth or "social" honour as well as on economic power. Contemporary urban society tends, therefore, to be stratified on three axes: power as achieved through wealth, status as achieved through birth, and prestige as achieved largely through intellectual and professional pursuits.

THE FUTURE OF URBANIZATION

Megalopolitanization. Megalopolis, as earlier suggested, is a term used to designate the coalescence of multiple metropolitan areas into a single huge clumping of people and economic activities. The term was introduced in this sense by the French geographer Jean Gottmann, who referred to the urbanized northeastern seaboard of the United States as perhaps "the cradle of a new order in the organization of inhabited space." Although maybe a new type of agglomeration, megalopolis is nevertheless undoubtedly the result of the same processes that produced urbanization; it is the logical culmination of urbanization as cities and their suburban areas continually expand, grow contiguous, and become integral parts of a continuous built-up area. Gottman's megalopolis extending from Boston to Washington, D.C., contained about 37,000,000 persons in 1960 in a land area comprising 53,500 square miles, about 600 miles long and 30 to 100 miles wide.

This megalopolis in the United States, and other emergent megalopolises in the world, owe their origin to (1) the economic opportunities they offered that made them areas of immigration and (2) the functions they were able to perform first in their local and regional hinterlands and later on the national and world scene. This northeastern seaboard area had the advantage of being located on the sea, thus serving as a link between Europe (and, more generally, the outside world) and inland United States: it early became the major centre for world trade between Europe and American continents; it was strategically located to be influenced by industrializing England and Europe during the 19th century and thus to become itself a locus for the industrialization of the United States; and it served as the major port of entry for immigration to the United States. Such a megalopolis also represents a "revolution in land use," in which urbanization generates an urban region, as distinct from an agricultural region (such as the Great Plains in the United States). Within megalopolis land becomes increasingly specialized for use in residence, industry, trade, and services, as well as in agricultural functions encapsulated in the area.

Other megalopolises are emergent within the United States and throughout the world: in the United States, around such areas as metropolitan Los Angeles and San Francisco, around metropolitan Dallas and Houston, around metropolitan Chicago, Milwaukee, and South Bend and other Great Lakes metro areas that could eventually consolidate the entire Great Lakes region into a major megalopolis, and in Europe in the region around London and in the Midlands, in the Greater Paris area of France, in the Ruhr industrial basin in Germany, and in The Netherlands and central Belgium. In Asia a major megalopolis is emergent in the Tokyo-Osaka complex, and in the longer run, megalopolises may well develop in China and India with their huge populations and rapidly growing governmental, commercial, and industrial cities. On the other hand, it is doubtful that European or other American areas will reach the size of the urbanized agglomeration on the northeastern seaboard of the United States—the reasons being restricted national boundaries in Europe and relatively restricted opportunity for comparable world roles in the other areas of the United States. Moreover, the complex problems of metropolitan living, which became greatly exacerbated in megalopolis —physical, personal, social, economic, and governmental problems—may conceivably lead planners to retard or prevent megalopolitan development. Should the future nevertheless bring great megalopolitan agglomerations containing 100,000,000 or more inhabitants, the northeastern seaboard in the United States will likely be the first to achieve such gargantuan size.

Suburbanization. The growth of suburbs—politically separate residential communities surrounding large cities and economically dependent upon the cities—can be traced back at least to the 19th century, when city populations were already beginning to decentralize. The 20th century has confirmed this 19th-century tendency: the "ring" outside the central city has become an increasingly larger proportion of the metropolital demographic and economic complex.

The growth of suburbia has often been attributed to a "flight" from the city. Yet this explanation is but a half-truth, for although it is true that suburban growth in North America and parts of Europe has been mainly the product of movements out of central cities, it is also true that these central cities have until relatively recently been repopulated by in-migrants from rural and other urban areas. Furthermore, until relatively recently, newcomers to the central city have outnumbered those moving out to suburbia (only since the 1930s have some central cities begun losing populations slightly, as suburbs accelerated their growth). It is more accurate, therefore, to regard the suburb not so much as the product of a flight from the city as the result of the city ever growing and overflowing its boundaries into adjacent territory. Generally speaking,

In-migrants

the only places that populations and economic activities can expand are in the metropolitan ring. Indeed, in some European and many Latin American and Asian cities there is little "flight" involved at all. Those who settle on the outskirts of cities—often in very high densities—are generally migrants attracted to the city but unable to find feasible inexpensive housing within it; thus they cluster around the city, usually in shanty towns and other makeshift settlements. Whereas in older American cities migrants are often drawn to the inner city containing flats and tenements abandoned by newly affluent workers and middle classes, movement in other areas of the world is generally to the urban periphery. In fact, everywhere, at least in newer cities, the tendency for in-migrants to live in the centres of cities seems to be waning.

Suburbs are thus by no means homogeneous in population type or function, and they can vary as much in socioeconomic status as do neighbourhoods within the city. Moreover, although suburbs are generally thought of as dormitory cities for persons commuting to their employment in the central city, the metropolitan ring is increasingly embracing satellite areas that are predominantly industrial or commercial.

Suburbs vary widely in the extent to which they are well planned or constitute "urban sprawl" in the economic level of their inhabitants, in their tax rates, in the quality of their educational facilities and cultural life, and in the character of their local government and public services. With increasing decentralization it can be anticipated that they will become more rather than less heterogeneous, more similar to than different from the central city, and more aware of the common needs and interests of all elements of the metropolitan area.

Regional integration. The city has always been dependent on a hinterland for its origin, its function, and its expansion. It has performed a variety of services for its surrounding area and, in turn, has been dependent upon it for sustenance. The various types of cities in this sense have thus always involved regional integration—whether they were central places performing service functions or transport cities performing services along transport routes or specialized cities (industrial, mining, commercial, political, educational, recreational, or otherwise) or relatively great cities combining some or all of these functions.

The American sociologist Otis Dudley Duncan and his colleagues have made an intensive analysis of the interrelations of metropolitan areas and regions for the United States (*Metropolis and Region*, 1960); and the English geographer Robert E. Dickerson earlier did the same for a number of countries (*City and Region: A Geographical Interpretation*, 1964). Duncan and his colleagues, for example have developed a classification of metropolitan areas in the United States that in effect, constitutes an analysis of different levels of regional integration. The classification distinguishes (1) "national metropolises," (2) urban places with "diversified manufacturing" and "metropolitan functions," (3) "regional metropolises," (4) "regional capitals," (5) urban places with "diversified manufacturing" and "few metropolitan functions," (6) "urban places with specialized manufacturing," and (7) "special cases." Although this classification has elements of hierarchy, it actually constitutes a multidimensional approach to the study of regional integration. It is probably correct to say that the potential size of individual cities or metropolitan areas depends on the size and integration of the region of which they were a part.

As the world grows increasingly interdependent and continues to shrink with rapid technological advances in communication and transportation, the integration of economic and cultural activities should become characteristic of even larger regions both within and across national boundaries. In consequence urban agglomerations will continue to increase in size toward megalopolitan dimensions.

The role of advancing technology. Continued advances in communication and transport facilities will undoubtedly permit further decentralization of population and economic activities but, undoubtedly, still within the metropolitan complex or at least within its influence. Instantaneous communication from anywhere to anywhere, for instance, possesses the potential for profound increases in the integrative activities of metropolitan areas on a regional, national, continental, and global basis.

Automation and computerization

Similarly, continued advances in automation and the computer can also operate to accelerate decentralization of activities within the metropolitan area and to greatly extend the dominance and influence of urban concentrations. Computer programs coupled with electronic automation will permit greater separation between central offices and production plants, since direct supervision and control can then be achieved from a distant central office, which can thus largely eliminate *intermediate* management and supervisory personnel.

The development of automation and the computer could greatly transform many present urban institutions and processes. The retail shopping facility, for example, could virtually disappear as the shopper acquires direct three-dimensional television and audio contact with warehouses containing automated distribution facilities, which could fill and package orders for home delivery. Such advances would profoundly alter not only present retail practices but also warehousing, wholesaling, jobbing, and broker practices. They could also affect the patterns and means of intracity as well as intercity transport. In theory at any rate, the possibilities for change are limited only by the imagination.

The role of population control and urban planning. Even with the most realistic success in population control, the population of this planet by the year 2000 is likely to approximate 7,000,000,000, and almost half that population (48.3 percent) is likely to be urban (residing in places of 20,000 or more). The accommodation of such an urban increase would require the construction of about 5,000 new cities of 500,000 inhabitants each.

Even with much greater success with population control than the above figures assume, it is clear that urban population will increase tremendously until the century's end. Even the economically advanced nations will be hard pressed to provide new urban amenities for the burgeoning urban population while trying to eliminate current and ongoing urban problems. In the developing nations of Asia, Latin America, and Africa, the prospect is even grimmer, for the combination of migration from rural to urban areas and high natural increase will put ever greater pressure on pathetically limited urban facilities. With what lies ahead, it is almost certain that urban planning will become increasingly necessary in both the economically advanced and the developing areas—planning that will necessarily involve not only cities but also metropolitan and regional areas and that will include not only physical layouts but also social, economic, and administrative considerations. In the decades lying ahead it is clear that urban problems will require much more attention than has been given to date.

Urban Planning and Redevelopment

Urban planning and redevelopment is aimed at fulfilling social and economic objectives that go beyond the physical form and arrangement of buildings, streets, parks, utilities, and other parts of the urban environment. Urban planning takes effect largely through the operations of government and requires the application of specialized techniques of survey, analysis, forecasting, and design. It may thus be described as a social movement, as a governmental function, or as a technical profession. Each aspect has its own concepts, history, and theories. Together they fuse into the effort of modern society to shape and improve the environment within which increasing proportions of humanity spend their lives: the city.

In many countries, urban planning has been broadened to cover larger areas as the need for orderly development of the entire physical environment has been recognized. In some small countries where usable land is scarce, such planning may extend to the whole country. In Great Britain this broader approach is termed "town and country planning"; in the United States the usual term is "city and regional planning" (see also URBAN DESIGN).

URBAN PLANNING AS A SOCIAL MOVEMENT

Early history. There are examples from the earliest times of efforts to plan city development. Evidence of planning appears repeatedly in the ruins of cities in China, India, Egypt, Asia Minor, the Mediterranean world, and South and Central America. There are many signs: orderly street systems that are rectangular and sometimes radial; divisions of a city into specialized functional quarters; development of commanding central sites for palaces, temples, and what would now be called civic buildings; and advanced systems of fortifications, water supply, and drainage. Most of the evidence is in smaller cities, built in comparatively short periods as colonies. Often the central cities of ancient states grew to substantial size before they achieved governments capable of imposing controls. In Rome, for example, the evidence points to no planning prior to late applications of remedial measures.

For several centuries during the Middle Ages, there was little building of cities in Europe. There is conflicting opinion on the quality of the towns that grew up as centres of church or feudal authority, of marketing or trade. They were generally irregular in layout, with low standards of sanitation. Initially, they were probably uncongested, providing ready access to the countryside and having house gardens and open spaces used for markets and fairs or grazing livestock. But as the urban population grew, the constriction caused by walls and fortifications led to overcrowding and to the building of houses wherever they could be fitted in. It was customary to allocate certain quarters of the cities to different nationalities, classes, or trades, as in cities of the Far East in the present day. As these groups expanded, congestion was intensified.

Urban design in the Renaissance

During the Renaissance there were conscious attempts to plan features, such as logistically practical circulation patterns and encircling fortifications, which forced overbuilding as population grew. As late as the 1860s, the radial boulevards in Paris had military as well as aesthetic purposes. The grand plan, however, probably had as its prime objective the glorification of a ruler or a state. From the 16th to the end of the 18th century, many small cities and parts of large cities were laid out and built with monumental splendour. The result may have pleased and inspired the citizens, but it rarely contributed to the health or comfort of their homes or to the efficiency of manufacturing, distribution, or marketing.

The planning concepts of the European Renaissance were transplanted to the New World; examples are Williamsburg, Virginia, and Washington, D.C. In particular, Pierre l'Enfant's plan for Washington (1791) illustrated the strength and weakness of these concepts; it was a plan ably designed to achieve monumentality and grandeur in the siting of public buildings but was in no way concerned with the efficiency of residential, commercial, or industrial development. More prophetic of the layout of U.S. cities was the rigid, gridiron plan of Philadelphia, designed by William Penn (1682), with a layout of streets and lots (plots) adaptable to rapid changes in land use but wasteful of land and inefficient for traffic. The gridiron plan travelled westward with the pioneers, since it was the simplest method of dividing surveyed territory. Its special advantage was that a new city could be planned in the eastern offices of land companies and lots sold without buyer or seller ever seeing the site.

The New England town also influenced later settlement patterns in the United States. The central common, initially a cattle pasture safe from marauding Indians, provided a focus of community life and a site for meetinghouse, tavern, smithy, and shops. It became the central square in county seats from the Alleghenies to the Pacific and remained the focus of urban activity. Also from the New England town came the tradition of the freestanding, single-family house. Set well back from the street and shaded by trees, it had an ornamental front yard and a working backyard and became the norm of American residential development. This was in contrast to the European town house, with its party wall and tiny fenced backyard.

19th century. In both Europe and the United States, the surge of industry during the 19th century was accompanied by rapid population growth, unfettered individual enterprise, great speculative profits, and remarkable lapses of community responsibility. During this era, sprawling, giant metropolitan cities developed, offering wealth and adventure, variety and change. Their slums, congestion, disorder, and ugliness provoked the beginnings of the modern housing and city-planning movements. Reacting against the slums of 19th-century industrial cities, housing reform was the first demand. Industrial slums in European and American cities were unbelievably congested, overbuilt, unsanitary, and unpleasant. The early regulatory laws enacted against these conditions set standards that improved upon the slums of the time but seemed a century later to be impossibly low. Progress was very slow, for the rent-paying ability of slum dwellers did not make it profitable to invest in better housing for them. Housing improvement as an objective, however, recurred continually. Early significant improvements in public health resulted from engineering improvements in water supply and sewerage, which were essential to the later growth of urban populations.

Toward the end of the 19th century, another effort to

improve urban environment emerged from the recognition of the need for recreation. Parks were developed to provide visual relief and places for healthful play or relaxation. Later, playgrounds were carved out in congested areas, and facilities for games and sports were established not only for children but also for adults, whose workdays gradually shortened.

Concern for the appearance of the city had long been manifest in Europe, in the imperial tradition of court and palace and in the central plazas and great buildings of church and state. The resurgence of this tradition had a counterpart in the "city beautiful" movement in the United States following Chicago's World Columbian Exposition of 1893. This movement expressed itself widely in civic centres and boulevards, contrasting with and in protest against the surrounding disorder and ugliness.

In the course of the 19th century, a number of utopian and religious groups contributed ideas for more satisfactory urban forms, though their experimental communities met with indifferent success. The garden-city movement in England developed from the writings of the reformer Ebenezer Howard in the 1890s and was a great and continuing influence on efforts to improve the urban environment.

20th century. Early in the 20th century, during the sprawling growth of industrial cities, factories invaded residential areas, tenements crowded in among small houses, and the first skyscrapers overshadowed other buildings. To preserve property values and achieve economy and efficiency in the structure and arrangement of the city, the need was felt to sort out incompatible activities, to set some limits upon height and density, and to protect established areas from despoilment. Zoning (see below) was the result.

Consequences of developments in transportation

As transportation evolved from foot and horse to street railway, underground railway or subway, elevated railroad, and automobile, the new vehicles made possible tremendous territorial urban expansion. Workers were able to live far from their jobs, and tremendously complex systems of communications developed. The new vehicles also rapidly congested the streets in the older parts of cities. By threatening strangulation, they dramatized the need to establish orderly circulation systems of new kinds.

Metropolitan growth so intensified these and other difficulties that the people living in cities—who for the first time outnumbered the rural population in many countries—began to demand an attack upon all of these problems. In response, city planning by midcentury aimed not at any single problem or reform but at the improvement of all aspects of the urban physical environment. An important concept was that all these problems were related and could not be attacked successfully in isolation. It became apparent that the planning of the urban environment could not be separated from the planning of the whole metropolitan area. This introduced issues of national planning and in many countries brought city planning into the field of planning the nation's economic and social resources as a whole.

Also at midcentury, when a coherent and unified approach to physical-development planning had finally evolved, a new urban crisis emerged with which physical planning alone could not cope. U.S. cities—especially those in the North—took in millions of black migrants, pushed off the land by changes in agricultural technology, attracted initially by wartime job opportunities. Many of them were even less equipped for urban life than the earlier European immigrants. Illiterate objects of prejudice and discrimination, they suffered severely from the reduction in low-skilled jobs caused by automation. The black ghetto in the 1960s, physically a slum, was healthier than the 19th-century slums but, in contrast to the living conditions of the middle class white majority, relatively far worse. The ghetto was the focus of unemployment, poor education, family disorganization, crime, and delinquency.

As it developed, city planning laid stress on those aspects of the urban environment that in the common interest should be improved and that required protection and promotion through government action. Countries varied in the relative importance that they attached to these aims—some stressing the government function in promoting planning, some the role of individual enterprise, with government playing a subsidiary role as the protector of the public from the adverse effects of the actions of others.

Goals of modern urban planning. The ultimate goals had always been social, even during the period when city plans themselves related only to physical change. They had been and continued to be deeply involved with intermediate economic objectives. The expression of the goals was, of course, coloured by the culture of the society seeking them. In the United States and countries following western European traditions, the ideal urban environment would reconcile the maximum opportunity for individual choice with protection for the individual from the adverse effects of the actions of others. Of increasing weight was the goal of equality of opportunity and the redress of the grievances of disadvantaged minorities. Within this value system the physically oriented urban planning of the first half of the 20th century had evolved a set of environmental objectives that continued to be valid: (1) the orderly arrangement of parts of the city—residential, business, industrial—so that each part could perform its functions with minimum cost and conflict; (2) an efficient system of circulation within the city and to the outside world, using to the maximum advantage all modes of transportation; (3) the development of each part of the city to optimum standards, in terms of lot size, sunlight, and green space in residential areas, and parking and building spacing in business areas; (4) the provision of safe, sanitary, and comfortable housing in a variety of dwelling types to meet the needs of all families; (5) the provision of recreation, schools, and other community services of a high standard of size, location, and quality; (6) the provision of adequate and economical water supply, sewerage, utilities, and public services.

Six objectives of urban planning

Even these superficially clear objectives, however, were not fully operational. They involve such terms as "adequate" and "high standard," which are relative rather than absolute, and change with new insights from experience or research (medical, psychological, social) and with new technological achievements. Inherent in the concept of city planning was the recognition that an ideal is not a fixed objective but will itself change, that the ideal city can be striven toward but never achieved. This turned the focus of planning away from the "master plan" and toward a stress upon the process and the directions of change.

By the late 1960s, hardly any major cities in the Western world had made more than token progress toward this new kind of "comprehensive" planning, involving coordination of a set of interrelated programs for directed change in physical, social, and economic conditions. Even the undertaking of this kind of planning was as yet an unfulfilled objective.

PLANNING AND GOVERNMENT

As a normal and identifiable function of government, city planning for the physical environment has been recognized in Europe and the United States since the early years of the 20th century. The year 1909 was a milestone. It saw the passage of Britain's first town planning act and, in the United States, the first national conference on city planning, the publication of Daniel Burnham's plan for Chicago, and the appointment of Chicago's Plan Commission (the first official planning agency in the U.S. was in Hartford, Connecticut, in 1907). Germany, Sweden, and other European countries also developed planning administration and law at this time.

City planning as a government function involves the coordination of all governmental activities that bear upon community growth and change, especially those that influence private development, so that they all work toward comprehensive objectives. In its early form, emphasis was on preparation of a single and authoritative plan. In time, as noted above, it was realized that the future was not precisely predictable and that the plan

must be flexible. It was also realized that governmental influence on private activities must be primarily negative and that many of the decisions that resulted in significant growth and change in cities were made by private agencies, such as industries, banks, or land developers, especially in the parts of the world that permitted private economic activity. Accordingly, planning was broadened to include the measures needed to foster a realization by business and civic leaders of their stake in city development and of their opportunities to capitalize on it. In European countries, the planning powers of central as well as local government were strengthened in order that the community, through government, might take more positive action to accomplish planning objectives.

Varying approaches to the administration of planning

The place of the city-planning function in the structure of urban government has developed in different ways in different countries. On the continent of Europe, where municipal administration was strongly centralized, city planning became the sphere of an executive department with substantial authority. In Great Britain, the local planning authority was a local legislative body (the county or county borough in England and Wales, the county or burgh in Scotland), advised by a planning committee of local councillors and with a planning department to act in an executive and advisory capacity. In the United States, with its tradition of tripartite government, it was recognized that decisions of importance to community development were made both by the executive branch (mayor) and the legislative (council). Rather than impinge on the authority of either, planning was allotted to a separate commission, advisory to both, with no authority beyond the right to be consulted before any action affecting the plan was taken.

After the late 1930s there was a trend toward making city planning a staff arm of the executive, in line with a general trend toward the strengthening of executive powers. There was also, as municipal government became more complicated, a trend toward formalizing the planning of administrative operations, budgeting, and other executive functions, which led to some confusion between this kind of planning and city planning as covered in this article.

Zoning and subdivision controls. Zoning, the regulation of the use of land and buildings, the density of population, and the height, bulk, and spacing of structures, was the principal means of putting into effect a comprehensive scheme for land use. It is generally dated from the adoption of New York City's first comprehensive ordinance in 1916. Though zoning was used in Great Britain and other European countries, it was developed furthest in the United States. The first ordinances were simple regulations, intended primarily to protect existing property values and preserve light and air. As planning itself broadened its objectives and evolved its techniques during the 1930s, zoning developed into a more precise and sensitive tool. Zoning was employed more and more to give legal effect to planning policies for land use.

Parallel to the evolution of zoning in the United States was the development of subdivision controls—subjecting the initial laying out of vacant land to public regulation. It was realized, after bitter experience with suburban land speculations in the 1920s, that the interest of the owner and developer of raw land is sometimes temporary and purely financial, while the urban community must live with the results for generations afterward. Subdivision regulations in many United States cities specified that new streets conform to the overall city plan and that new lots be properly laid out for building sites. Some required the developer to give the land needed for streets, playgrounds, and school sites and to pay all or most of the cost of development of these facilities.

Zoning and subdivision control offered adequate controls over the growth of new parts of cities, where they were used by enlightened legislative bodies. It was realized, however, that they were insufficient to correct past mistakes and especially to bring about the rebuilding of the obsolete parts of cities.

Large-scale planning. In order to clear slums and to provide decent housing for slum dwellers unable to afford private housing, publicly owned and subsidized housing was developed. It was used first in Europe, especially in the 1920s, and was supplemented by cooperatives and other forms of limited-profit or publicly aided housing, particularly in Scandinavia. Public housing with federal aid became government policy in the United States in the 1930s. Most states authorized their cities to condemn and clear slums and to build public housing. In Great Britain and Europe in the 1920s and 1930s, public housing was also built in vacant suburban areas, in some cases on such a scale as to almost constitute new towns. This was a result of the recognition that all slum dwellers could not be rehoused in the same areas without repeating the slum congestion. Though such action was legal in the United States after the 1930s, it was rarely employed.

Experimental new towns of the early 20th century

All over the Western world, in the first half of the 20th century, new towns were built, constituting a very small part of the total or urban growth but serving as experiments and as examples of what could be done. This was largely the product of England's garden-city movement, which proposed preplanned new cities, on land held by the community and limited to 30,000 population, complete with business services and employment centres and surrounded by permanent greenbelts of rural land. The initial experimental cities were undertaken in England by private initiative, motivated by a spirit of reform; Letchworth was started in the early 1900s and Welwyn Garden City in the 1920s.

The concept had substantial influence in the United States. Kingsport, Tennessee, was a new city built by industrial interests. Some of the design ideas were used in suburban real-estate developments, outstanding being that of Radburn, New Jersey, which pioneered the super-block scheme as the "town for the motor age." U.S. examples, however, omitted the community-ownership feature, and almost all omitted employment centres, balanced income groups, and effective greenbelts. The federal government undertook a few large-scale housing developments for immigrant industrial workers during World Wars I and II, as make-work projects during the depression of the 1930s, and as examples of sound urban design. During the 1960s a number of private-enterprise developments at the scale of new cities were undertaken, primarily integral to expanding metropolitan areas rather than as truly independent cities. Notable were Reston, Virginia, and Columbia, Maryland, both near Washington, D.C., and the Irvine Ranch area near Los Angeles.

Also during the 1930s a number of European countries, especially France, The Netherlands, Germany, and the Soviet Union, undertook the building of new towns as governmental enterprises. Most of them (except in the Soviet Union) were residential suburbs rather than complete urban units. During the period following World War II, many European countries made strides in the regulation of new growth and in planned rebuilding of bomb-torn city centres.

After World War II, Great Britain embarked on a bold program. It reorganized the planning districts of the country; established sweeping new powers over private land use, almost nationalizing the right to develop undeveloped land; and undertook to build new towns to receive population and industry from congested great cities, which were planned for building at lower densities. By 1960, 15 new towns were under way, but the national program had suffered reverses. At first, economic exigencies interfered with the relocation of industry suggested by long-range environmental planning, and some of the controls over private land development, which appeared to impede investment and construction, had to be relaxed. Most of the new towns, nevertheless, had become centres of rapid industrial and population expansion and constituted important new work in city plan effectuation.

In countries that had sustained extensive war damage, there was much concern with planned rebuilding of obsolete areas. In the endeavour to rebuild devastated cities, several European countries, notably Britain, France, and The Netherlands, strengthened public powers to acquire land and redevelop it according to a new layout. Notable examples are Coventry in England and Rotterdam in The

Netherlands. Toward the end of the decade, many states of the United States granted urban redevelopment powers to their cities, which began to clear slums not only for public housing but also for any other public or private re-use that fitted a comprehensive plan.

Postwar urban redevelopment in the United States

By the early 1970s urban redevelopment and renewal in the United States had achieved some major successes in revitalizing the economy of central-city areas. Such programs were bitterly criticized, however, for displacing low-income families and for disregarding the network of social relationships that had meant more to these families than the squalor and danger of their physical shelter. Among the new programs evolved after the establishment of a new cabinet-level Department of Housing and Urban Development was the Model Cities program. This was an experiment, in several dozen U.S. cities, in attacking the problems of major blighted areas with massive federal financial aid. It included programs of physical improvement coordinated with social and economic upgrading through job training, school improvement, encouragement of economic enterprise, and a complete panoply of self-help and outside-help measures aimed at reducing poverty and all of its adverse concomitants.

Planning jurisdictions. Where a single municipal government included all of an urban area, tools for physical planning and effectuation seemed, in the second half of the 20th century, to be approaching adequacy. This condition, however, was exceptional. In Europe and the Americas, the metropolitan area was the typical urban form, composed of many independent municipalities, with overlapping jurisdictions of counties, school districts, and special authorities. During this period, European countries were groping toward solutions of the metropolitan planning and development problem, with some progress in Great Britain, Scandinavia, Germany (Ruhr), and The Netherlands. In the 1950s a limited metropolitan government was established for Toronto, Ontario, with planning as an integral function. As late as the early 1970s metropolitan planning efforts in the United States were still largely ineffective. Planning agencies had little voice in the decisions of not only the separate cities and suburbs but also larger public agencies, such as state highway departments, sewer and water supply authorities, and port and airport authorities. The U.S. planning movement had not yet evolved the governmental machinery for reconciling in a democratic way the conflicting interests of all of the constituents of a metropolitan area.

In Asia, the emerging industrial economies of the post-World War II period produced cities following many of the patterns of the West. These rapidly developing countries, however, are still preoccupied with political and economic problems and have made little progress in establishing an environmental planning function in city or metropolitan government effective enough to prevent the mistakes made earlier in Western cities. There are a few outstanding examples of planned new cities in such widely scattered places as India, Israel, and South America. There are also signs of increasing concern in Puerto Rico, India, Indonesia, and elsewhere for regional development programs.

Urmia, Lake

Lake Urmia, located in northwestern Iran, has an area that varies from 2,000 to 2,300 square miles (5,200 to 6,000 square kilometres) and is the largest lake in the Middle East. Like the Dead Sea, it is remarkable for the extreme salinity of its waters. Since 1967 it has enjoyed the status of a wetland protected region, and efforts have been made by the Iranian government to increase its wildlife. Lake Urmia (the old name for the lake as well as for the city near its western shore), has also been known since the 1930s as Daryācheh-ye ("lake") Reẓā'īyeh (the name given to the lake and the city at that time by Reza Shah Pahlavi, ruler of Iran). A third name, Daryācheh-ye Shāhī (also Persian), is derived from Jazīreh-ye Shāhī (Shāhī Island), situated in the central part of the lake.

Physiography. The lake lies in the bottom of the large central depression of the Azerbaijan region in northwestern Iran, at an elevation of 4,183 feet above sea level. The basin is surrounded by mountains in the west and north, by plateaus in the south, and by plateaus and volcanic cones in the east. The lake is about 87 miles long and 25 to 35 miles wide, with a maximum depth of 53 feet. In the south, there is a cluster of about 50 tiny islands. Jazīreh-ye Shāhī is a volcanic formation that attains an elevation of 7,182 feet; it becomes a peninsula at times of low water when its extension to the eastern shore is uncovered. The shoreline varies with the lake level; when the water is high, it extends into large salt marshes to the east and south.

Islands in the lake

Hydrography. The governing factor of Lake Urmia's hydrography is its lack of an outlet. It forms the dead end of a large drainage system that covers an area of about 20,000 square miles and is subject to great seasonal variation. The main affluents are the Talkheh Rūd (Ājī Chāī) in the northeast, which gathers the melted snows from the Sabalān and Sahand massifs, and the twin rivers Zarīneh Rūd (Jagātu Cham) and Sīmīneh Rūd (Tatavi Chāī) in the south. There are about eight other sizable rivers, mainly entering the lake from the west.

The volume of discharge of the rivers varies considerably during the year: during the spring the Talkheh Rūd and Sīmīneh Rūd may each discharge about 2,000 cubic feet per second, while the rate drops to only 130 or 60 cubic feet per second in the dry summer. This variation causes the lake itself to rise and fall, fluctuating by two to three feet.

In addition to seasonal variations, there are also longer periods of fluctuations, lasting from 12 to 20 years, with water-level fluctuations of six to nine feet. Between 1812 and 1912 at least six such long-range cycles occurred. Surface water temperature is also subject to seasonal change, varying from 28° F (−2° C) in January to 95° F (35° C) in July or August.

Because Lake Urmia's waters have no outlet, they are highly saline. The lake is one-fourth as salty as the Dead Sea, with a salt content ranging from 8 to 11 percent in the spring to 26 or 28 percent in the late autumn. The main salts are chlorine, sodium, and sulphates.

Salinity of the lake

Vegetation and animal life. Organic life in the lake's waters is limited to a few salt-tolerant species. Algae, which grow into masses in flood years, provide food for brine shrimp. It is this seaweed that causes the bad smell along the shores. There are breeding populations of sheldrake, flamingo, and pelican, as well as migratory birds. Jazīreh-ye Qūyūn (also known as Qoyun Daghi Island), the easternmost of the four largest islands south of Jazīreh-ye Shāhī (Shāhī Island), supports a population of sheep and rock partridges.

Human settlement. Settlement around the lake includes the bulk of the population of both the East Azerbaijan *Ostān* (province) and the West Azerbaijan *Ostān* of Iran. The people are mainly Azeri Turks and Kurds, and there are also Persians, Nestorians, and Armenians.

Their agriculture is not dependent upon the lake but upon the sweet water from the surrounding mountains that they use for irrigation. The cities are within easy reach of the lake's shores; they include Tabriz (which has a population of about 465,000), Reẓā'īyeh (140,000), Marāgheh (60,000), and Mahābād (35,000).

Resources and navigation. The only resource of the lake is salt, but this is not exploited because of the more accessible deposits of salt domes in the hinterland. Some charcoal has been obtained from the pistachio trees that grow on the islands. The lake's mud is used for the treatment of rheumatism and skin diseases. Navigation is limited to small motor craft that provide limited cargo and passenger service between a few places on the lakeshore.

Urodela

Salamanders, constituting the order Urodela (Caudata), together with frogs (order Anura) and caecilians (order Gymnophiona) comprise the three living groups of the class Amphibia. The relatively small and inconspicuous salamanders are important members of north temperate and some tropical animal communities. They are important as subjects of experimental studies in embryology, developmental biology, physiology, anatomy, biochemistry, genetics, and behaviour. Convenient size, low food requirements, low metabolic rate, and hardiness make them good laboratory animals.

General features. *Size range and diversity of structure.* The most typical salamanders are short-bodied, four-legged, moist-skinned vertebrates about 100 to 150 millimetres (about four to six inches) long. The tail is usually about as long as the body. There is much variation in size, and terrestrial salamanders range from 40 to nearly 350 millimetres (about 1.6 to 14 inches) in length. Some live in moist places on land but must go to water to breed. Others are completely terrestrial. Wholly aquatic salamanders attain larger sizes than do terrestrial ones, the former reaching a maximum of 180 centimetres (about six feet). Salamanders may retain gills throughout life, lose the gills but retain a spiracle (breathing pore) or gill slit, or completely metamorphose (*i.e.*, alter radically in structure and appearance) and lose both gills and gill slits. Many aquatic species resemble their terrestrial relatives in body form, but aquatic genera such as *Siren* and *Pseudobranchus* lack hindlimbs, and *Amphiuma* has an extremely elongated body, short tail, and diminutive legs; several cave-dwelling forms (*Proteus, Haideotriton, Typhlomolge*) are blind and almost without pigment.

Distribution and abundance. Salamanders are classic examples of animals with a Holarctic distribution (*i.e.*, in the north-temperate regions of both the Eastern and Western hemispheres); eight of the nine families (see below *Annotated classification*) are found almost entirely in northern regions that lie outside the tropics. Typically, they occur in moist, forested habitats, where they are often common in aquatic and terrestrial communities. Members of the family Salamandridae extend south to extreme northern Africa, the southern foothills of the Himalayas, North Vietnam, and the island of Okinawa. Some ambystomatids reach the southern margins of the Mexican Plateau, but only the lungless salamanders (plethodontids) have truly entered the tropics. One group of plethodontids, which occupies a wide variety of tropical habitats in the New World—from northern Mexico to southern Brazil and central Bolivia—contains nearly half of all recognized species of salamanders, an indication that the plethodontids have been highly successful in the tropical environment. Other areas in which salamanders have been successful include temperate North America (Appalachian and Ozark uplands; Pacific coast areas with a moist habitat), western Europe, Japan, and China.

Natural history. *Life cycle and reproduction.* Most salamanders are terrestrial or semiterrestrial as adults, but many return to aquatic habitats to breed. Courtship, which is simple or nonexistent in hynobiids and cryptobranchids, is increasingly elaborate and prolonged in the more highly evolved families. In primitive species comprising the suborder Cryptobranchoidea, fertilization of the egg is external. The females deposit sacs or strings of eggs that may be grasped by the male, who then sheds milt (which contains the sperm) over them. Nothing is known of courtship in sirens, but they, too, may have external fertilization, for the males lack the cloacal glands that produce the spermatophore, or sperm case, in species with internal fertilization, and the females lack spermathecae—chambers inside the cloaca used for sperm storage. All other species of salamanders have more complex courtship behaviour—often differing in details between species—and internal fertilization. The male deposits from one to many spermatophores on the ground or other surface. These consist of a gelatinous base, which is produced by cloacal glands, and a so-called sperm cap at the tip. The female moves by herself or is led by the male onto the spermatophore, and she takes the sperm mass into her cloaca. Breeding often occurs in ponds, but some salamandrids and most plethodontids breed on land. Egg deposition may take place shortly after mating but in many plethodontids may be delayed for several months, the eggs being fertilized by stored sperm. Eggs are laid in masses in streams or ponds, often in the shallows near shore. In most plethodontids and in some species of other families, eggs are laid singly, in short strings, or in small groups in terrestrial sites—*e.g.*, under surface objects, in rotting logs, or underground. Some species deposit eggs in tree cavities, and tropical species may deposit them in bromeliad plants, the leaves of which are arranged so that they often hold water. Frequently, the female stays with the eggs until they hatch, a period of several weeks. The number of eggs varies greatly and is correlated with adult size. Aquatic forms deposit as many as 400 eggs; terrestrial forms, as few as five or six.

Fertilization

Typical salamanders undergo an aquatic larval stage that lasts for a period ranging from a few days to several years. A short period of metamorphosis usually occurs before the terrestrial phase of the life cycle begins. The newly metamorphosed salamander is usually very small, and from one to several years elapse before it achieves sexual maturity.

Some salamander species never metamorphose and thus retain most of their larval characteristics. In other species, individuals or populations may occasionally fail to metamorphose. Still other species undergo partial metamorphosis. This phenomenon, known as paedomorphosis—*i.e.*, retention of larval or juvenile features by adults—characterizes all salamanders to a degree but is particularly evident in species such as *Necturus maculosus* (mud puppy) and *Ambystoma mexicanum* (axolotl), which retain gills and other larval structures throughout life. These animals breed in what is essentially a larval state. This extreme condition, which characterizes the Proteidae, Necturidae, and Sirenidae, is also found in several species of the Plethodontidae and Ambystomatidae. In most species the permanent larval state is determined by heredity, but in some it is induced by environmental factors, such as unfavourable terrestrial conditions resulting from drought or cold. The most complete metamorphosis is found in the families Hynobiidae, Salamandridae, Ambystomatidae, and Plethodontidae.

Paedomorphosis

Most species of the family Plethodontidae develop entirely on land, with no aquatic larval stage. The hatchling has either rudimentary gills that soon disappear or none at all and, in virtually all respects, is a miniature of the adult.

Females of the genus *Salamandra* (Salamandridae) may retain the fertilized eggs in the reproductive tract for a varying amount of time. The fire salamander (*Salaman-*

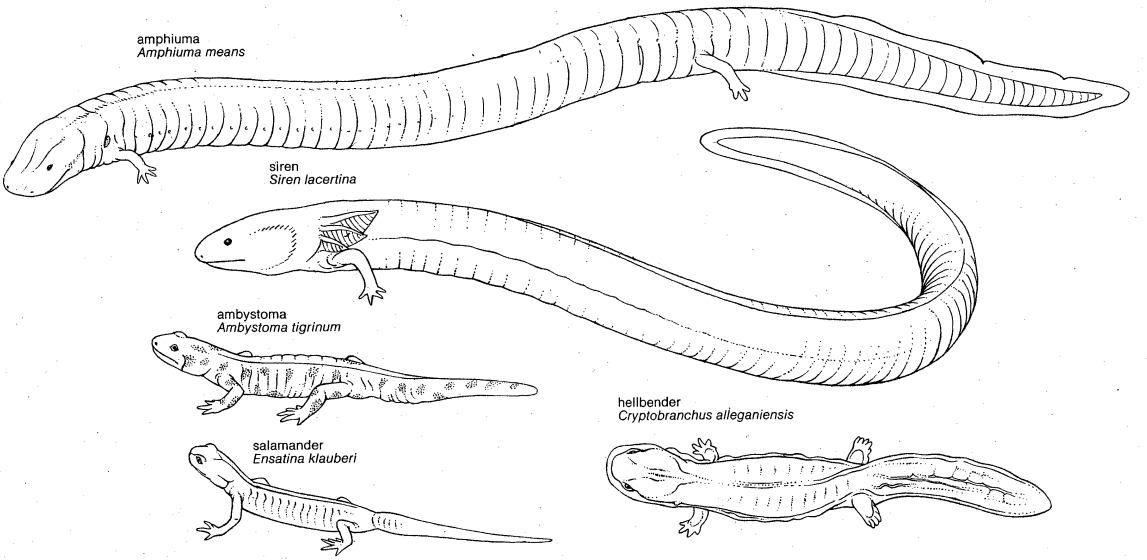

Figure 1: Representative urodeles.

dra salamandra) deposits a relatively advanced larva in the water. In the Alpine salamander (*Salamandra atra*) and some other *Salamandra* species, fully metamorphosed individuals are born. One individual develops from the first egg in each oviduct, the tube leading from the ovary to the outside. Initially, the young salamander lives on its own yolk supply; later it eats the yolk of the other eggs, and finally it develops enlarged gills that form an intimate association with the walls of the oviduct to convey nutrients to itself. The gills are lost shortly before birth. Such salamanders are the only live-bearing members of the order.

Larval feeding habits

Larval salamanders are exclusively aquatic. They may occur in a variety of habitats, from temporary ponds to permanent swamps, rivers, slow-moving streams, mountain brooks, springs, and subterranean waters. In all habitats they are exclusively carnivorous, feeding primarily on aquatic invertebrates. In most salamander larvae, feeding is accomplished by a "gape and suck" method, in which the throat is expanded, or gaped, to produce a suction that draws water and prey into the opened mouth. Skin flaps around the mouth direct the water movement. The larvae are well equipped with teeth, which aid in holding and shredding prey. Pond larvae have a high fin on the upper side of the tail that extends far anteriorly (toward the head) and large gills (see Figure 2, above). Limbs are rather slow to develop. By contrast, stream larvae have a low, short tail fin, small gills, and limbs that develop early.

Metamorphosis, although a period of major reorganization, is not so dramatic as that in frogs. In the final stages, metamorphosis is usually a rapid process; it is mediated by several hormones (*i.e.*, chemical substances that serve to regulate the function of various organs) produced by the thyroid and pituitary glands. The following typically occur during metamorphosis: loss of the gills; closure of the gill slits; appearance of a tongue pad and reorganization of the gill skeleton and musculature to produce a tongue; enlargement of the mouth and eyes; development of eyelids; and major changes in the structure of the skull and skin.

Locomotion. Locomotion is by means of limbs and by sinuous body movements. Some very elongated species of the genera *Phaeognathus*, *Batrachoseps*, *Oedipina*, and *Lineatriton* have reduced limbs and rely mainly on body movements for rapid locomotion. Species of the genus *Aneides* have arboreal (*i.e.*, tree-climbing) tendencies, and their long legs and digits, expanded toe tips, and prehensile (grasping) tails make them effective climbers. Some salamanders of the genera *Pseudoeurycea* and *Chiropterotriton*, found in the New World tropics, are similarly adapted. Others, members of the genus *Bolitoglossa*, have extensively webbed forefeet and hindfeet with indistinct digits, allowing them to move across moist leaves and other smooth surfaces.

Behaviour and ecology. Adult salamanders are nearly all nocturnal (*i.e.*, active mainly at night) animals. They may be highly seasonal, remaining hidden underground until the breeding season, or they may emerge from hiding places on any evening when moisture and temperature are at the proper levels. Fallen logs, rocks, crevices in soil, and surface litter commonly provide daytime refuge. Home ranges of salamanders are small, often less than three or four square metres (30 to 40 square feet), and, in favourable areas, some of the smaller species can be very abundant, occasionally numbering thousands per acre.

Insects are by far the most important food of salamanders. Primitive salamanders seize their prey by a combination of jaw and tongue movements. Some members of the Salamandridae and Plethodontidae, however, have evolved highly specialized tongue protrusion mechanisms. These are especially well developed in the tropical plethodontids, many of which are arboreal. The tongue can be extended from the mouth for a considerable distance and retracted almost instantaneously, with the prey attached to the sticky tongue pad.

Habitat

Most terrestrial species live near the surface of the ground, often in thick leaf litter and rock piles. Some enter subterranean retreats, sometimes by way of burrows made by mammals and invertebrates. Caves are often occupied during cold or dry periods. Climbing species live on rock faces and in crevices, in trees, on broad-leaved herbs and shrubs, and in bromeliads. Many species are semi-aquatic, frequenting streamside and spring habitats throughout their lives. The terrestrial species that have direct development have been able to free themselves entirely from reliance on standing or flowing wa-

ter. Among one group of plethodontids, species are found in habitats ranging from true deserts and frigid Alpine areas to tropical rain forests and from sea level to elevations of more than 4,000 metres (13,000 feet).

Form and function. *Skin and external features.* The most distinctive and important feature of amphibians in general and salamanders in particular is their smooth, moist skin. This organ consists of an epidermis, or surface tissue, that is several layers thick and a rather thick dermis containing mucus and poison glands as well as pigment cells. The integument, or skin, is highly vascular and serves a major respiratory function. The poison glands of some species produce some of the most virulent toxins known. The fleshy tongue pad contains many mucus-secreting glands.

Most species are drab gray or brown; but many species, especially the more poisonous ones, are spectacularly coloured, with bright spots, blotches, or streaks on a contrasting dark background. The few integumentary specializations include keratinized (*i.e.*, infused with a tough, horny material: keratin) skins of the terrestrial stages of many salamandrids; keratinized claws in stream-dwelling hynobiids; and so-called hedonic glands (believed to stimulate sexual activity of the opposite sex) that are variously distributed in many species. Cryptobranchids have large, lateral folds of skin that serve respiratory functions.

Bones and cartilage. The rather weak skull of adults is comprised of various paired bones. These bones may fuse or be lost in different groups, and their presence and arrangement are important in classification. Much of the fusion and loss of skull bones is frequently associated with a trend toward tongue feeding. Small, double-cusped teeth line the margins of the jaw and spread over parts of the palate. They are important in holding but not chewing the prey.

Cartilage plays an important role in the urodele head, especially in supportive structures in the throat region. These are ossified (bony) to different degrees, with more cartilage in the more highly evolved groups. Species that display tongue protrusion often have flexible, cartilaginous tongue skeletons. In larvae and permanently gilled species the tongue is not developed.

The vertebrae comprising the spinal column are generalized with centrums (*i.e.*, ventral, or lower, sections connecting with the adjacent vertebrae) that are rather poorly developed. The notochord (*i.e.*, a resilient, flexible cord of specialized cells passing through the vertebral column) is usually persistent in adults. An intervertebral cartilage forms the articulation between vertebrae. If it remains cartilaginous, the vertebrae are said to be amphicoelous (biconcave, or depressed on both the anterior and posterior sides), but, if it mineralizes or ossifies, the vertebrae are termed opisthocoelous (bulged on the anterior side and depressed on the posterior side). There is one cervical vertebra with a characteristic projection called the odontoid process and two large facets for articulation with the skull. There may be from 11 (*Ambystoma talpoideum*) to 60 (*Amphiuma*) dorsal, or trunk, vertebrae, all but the last one or two usually bearing ribs. Most salamanders have from 14 to 20 trunk vertebrae. One sacral vertebra, two to four caudosacral vertebrae, and from about 20 to over 100 (*Oedipina*) caudal, or tail, vertebrae complete the column. Many plethodontids are capable of autotomizing, or dropping off, the tail, a valuable defense mechanism in the event that the tail is grasped or bitten by a predator. These salamanders have various specialized features associated with the last caudosacral and the first caudal vertebrae, between which the break usually occurs.

The limbs and girdles are similar to those of generalized vertebrates. The pectoral, or chest, girdle, supporting the forelimbs, is relatively reduced; all elements are fused and remain largely in a cartilaginous condition. An ypsiloid cartilage, used in exhalation, is present in several groups, especially ambystomatids and salamandrids. Digits and digital bones have been lost in many different groups. There are never more than four fingers, but nearly all species have five toes.

Fingers and toes

Nervous system and sense organs. The nervous system is the simplest found in any four-legged animal. The generalized brain is rather small. The relatively large cerebrum (collectively, the two large anterior lobes of the brain) is associated with the large and important olfactory and vomeronasal organs, both of which are used for smelling. The eyes, usually large and well developed, are reduced and nearly lost in some cave-dwelling species. Certain parts of the inner ear are large and well developed. Hearing mechanisms of the salamander are not fully understood. There is no middle ear cavity and no external ear. One middle ear bone rests in the structure known as the vestibular fenestra. The other bone of the middle ear rests in the posterior part of the fenestra and is joined by muscles to the pectoral girdle. The elements are variously fused or lost in different groups. The spinal cord and the peripheral nervous system—*i.e.*, the paired cranial and spinal nerves—are generalized in their structure, and there are distinct brachial and sacral plexuses, both of which are important nerve networks supplying the limbs.

Muscles and organ systems. The generalized trunk musculature shows little differentiation. The abdominal muscles are increasingly differentiated in the higher groups. The hyobranchial and branchiomeric muscles and some abdominal muscles (rectus abdominis) are highly specialized in species that use the tongue to capture prey.

The simple digestive system includes a short, nearly straight gut. The lungs are relatively simple, saclike organs in primitive groups. In stream-dwelling members of several families, the lungs are greatly reduced; they are entirely absent in all plethodontids.

The circulatory system is characterized by a highly developed vascularization of the body surface. The heart is simple, with one ventricle (*i.e.*, a chamber that pumps blood out of the heart) and two atria (chambers that receive blood from the rest of the body); separation between the two atria is not distinct in lungless forms.

The urogenital system consists of an elongated kidney with a distinct sexual segment and a posterior concentration of large renal units, which filter urine from the blood. Testes, the male sex glands, are small and compact, increasing in size with age. Ovaries of females are thin sacs. The cloaca is relatively complex in highly evolved groups with a spermatheca in females and several sets of cloacal glands in both sexes.

Gonads

Evolution and classification. *Paleontology.* Fossils have contributed little, as yet, to the understanding of salamander evolution. The earliest definitive salamander is one of unknown affinities from the Jurassic Period (about 136,000,000 to 190,000,000 years ago). Several ambystomatoid families (Prosirenidae, Scapherpetonidae, Batrachosauroididae) are known only from fossils. The relationships of urodeles to other living and fossil amphibians are unclear, but recent workers consider the three living groups to form the subclass Lissamphibia.

Distinguishing taxonomic features. The features used to establish the limits of the order and of the groups within it include: general body size and organization—*e.g.*, presence or absence of external gills, numbers and relative proportions of limbs and digits, number and arrangement of skull bones; organization of the hyobranchial apparatus (cartilage in the throat region); structure and distribution of the teeth; structure of the vertebrae and intervertebral articulations; numbers of vertebrae; number and organization of the hand and foot elements; anatomy of the pelvic girdle; anatomy of external structures, such as hedonic (sex-attractant) glands, body and tail fins, webbing of hands and feet, and cloacal glands. Distinctive also is the general way of life, whether permanently aquatic, semi-aquatic, or terrestrial.

Annotated classification. The classification below is based on that of A.H. Brame, Jr. (1967). There is as yet no widely accepted scheme for classification below the order level. The plethodontids of the New World tropics remain poorly known, taxonomically.

ORDER URODELA (OR CAUDATA)

Tailed amphibians with 2 or 4 legs; moist, usually smooth, glandular skin; the most generalized of the living amphibi-

ans not only in structure but also in way of life; about 320 species.

Suborder Cryptobranchoidea

The most primitive salamanders; external fertilization; angular bone separate from the prearticular bone in the lower jaw; 2 pairs of limbs; no external gills; aquatic, semi-aquatic, and terrestrial.

Family Hynobiidae (Asiatic salamanders)

Generalized, medium-sized (to about 250 mm, or about 10 in.), semi-aquatic and terrestrial; lacrimal and septomaxillary bones present in skull; vomerine teeth not parallel to marginal teeth; Paleocene(?) (54,000,000–65,000,000 years ago) to present; northern Asia from Ural Mountains to Japan and Taiwan; about 30 species.

Family Cryptobranchidae (giant salamanders and hellbender)

Very large, to about 180 cm (about 6 ft.), aquatic; no lacrimal or septomaxillary bones in skull; vomerine teeth parallel to marginal teeth; Oligocene (26,000,000–38,000,000 years ago) to present; Japan, China, and eastern United States; 3 species.

Suborder Sirenoidea

Mode of fertilization unknown; angular bone fused with prearticular bone in lower jaw; only anterior pair of limbs present; external gills; aquatic.

Family Sirenidae (sirens and dwarf sirens)

Small to very large, to about 100 cm (about 40 in.), predators; inhabitants of lowland waters; Late Cretaceous (65,000,000–90,000,000 years ago) to present; southeastern United States from South Carolina to Tamaulipas, Mexico; 3 species.

Suborder Salamandroidea

Fertilization internal; angular bone fused with prearticular bone in lower jaw; no septomaxillary bones in skull; tooth replacement of vomerine teeth from medial side in metamorphosed forms; 2 pairs of limbs; external gills in a few species; aquatic, semi-aquatic, and terrestrial.

Family Proteidae (olms)

Blind; lacking pigment, cave-dwelling; elongated body, length to 30 cm (about 1 ft), and slender limbs (3 fingers, 2 toes); external gills present; Pliocene (2,500,000–7,000,000 years ago) to present; 1 species, native to Yugoslavia.

Family Necturidae (mud puppies)

Small to moderately large, to 45 cm (about 1½ ft), permanently aquatic, lake and stream dwellers; eyes and skin pigmentation present; 4 fingers and 4 toes; external gills present; no fossil record; eastern North America; 5 species, of genus *Necturus*.

Family Amphiumidae (congo eels)

Large, to over 100 cm (about 40 in.); very elongated, aquatic to semi-aquatic; predaceous, with powerful jaws and teeth; limbs diminutive, 1 to 3 fingers and toes; external gills absent, but spiracle open; Late Cretaceous to present; eastern North America; 3 species, of genus *Amphiuma*.

Family Salamandridae (salamanders and newts)

Generalized form and habit; moderate size, to 32 cm (about 13 in.); limbs with 4 fingers, 4 to 5 toes; usually no external gills or spiracle; Upper Cretaceous (?) to present; Europe, North Africa; Middle East; Afghanistan to Japan, China, and North Vietnam; eastern and western North America; about 42 species.

Suborder Ambystomatoidea

Fertilization internal; angular bone fused with prearticular bone in lower jaw; septomaxillary bones present primitively in skull; tooth replacement of vomerine teeth from posterior or lateral direction; 2 pairs of limbs; external gills in some species; aquatic, semi-aquatic, or terrestrial.

Family Ambystomatidae (mole salamanders and others)

Small to moderate size, to 35 cm (about 14 in.); usually with well developed lungs; no nasolabial grooves; ypsiloid cartilage present; Paleocene to present; North America; about 33 species, including *Ambystoma*.

Family Plethodontidae (lungless salamanders)

Very small to moderate size, 4 to about 30 cm (about 1.6 to 12 in.); includes the most specialized and most terrestrial salamanders, and the only truly tropical species; lungless; nasolabial grooves present; no ypsiloid cartilage; Pliocene to present; North America, Central America, and most of South America; 2 species in Europe (Sardinia, southern France, and north central Italy); more than 200 species.

Critical appraisal. Some controversy exists concerning the classification of salamanders below the ordinal level. Some authorities place the sirenids in a separate order, Trachystomata, while others separate the Necturidae from the Proteidae, but neither scheme has been widely accepted. Chromosomal evidence of proteidnecturid similarity has recently been presented. Close association of Ambystomatidae and Plethodontidae is now accepted, but placement of Amphiumidae remains controversial. Compare AMPHIBIA: *Annotated classification.*

Urticales

The flowering plant order Urticales, or nettle order, includes such important and well-known plants as the figs, breadfruit, mulberries, elms, stinging nettles, hops, and true hemp, or marihuana. Although the order is mainly tropical in distribution, many of its species are widely and abundantly dispersed in temperate regions, particularly in the Northern Hemisphere. The Urticales is distinctive morphologically and is considered to be among the more evolutionarily advanced groups of the woody flowering plants. It includes about 125 genera and about 3,100 species in four families.

GENERAL FEATURES

Size range and diversity of structure. Plants of the nettle order range from small herbaceous (nonwoody) species to large trees. The elm family (Ulmaceae) consists of shrubs and trees, including the elms (*Ulmus*) and hackberries (*Celtis*), some of which grow to 150 feet (45 metres) in height. A great diversity of mainly woody plants is found in the mulberry family (Moraceae), which contains the figs, with about 800 species. Figs are great trees of the tropical forests; some are buttressed by wide-ranging, and often finlike, spreading roots, as exemplified by *Ficus elastica*, the well-known India rubber tree. Many figs grow at first as epiphytes, or air plants, upon the branches of other trees, from seeds dropped by birds or bats. As these young plants develop, they send aerial roots down along the trunk of the supporting host tree, and in time the ever enlarging roots gradually crush the host to death. These are the so-called strangler figs, vinelike in youth but self-supporting large trees at maturity. The banyan, or Bengal fig (*F. benghalensis*), is another wide-spreading tree, an old specimen of which comes to resemble a dense grove of trees by dropping thick prop roots from its spreading branches. Some of the tree spe-

cies bear long, sharp thorns, for which feature these plants find use as hedgerow or fencerow trees to enclose livestock or discourage trespassers (*e.g.*, *Maclura*, osage orange).

The nettle family (Urticaceae) is well-known for its stinging hairs, which can cause severe pain on contact. Although the nettle family is most abundant in the tropics, where its species are shrubby and treelike, the temperate regions of the Northern Hemisphere contain large numbers of the herbaceous nettles, seldom more than a few feet tall and often weedy looking. The hemp family (Cannabaceae) is also herbaceous: one genus (*Humulus*, hop) is a vine and the other (*Cannabis*, hemp) a tall herb.

Distribution and abundance. The species of the order Urticales are unequally divided among the genera and families. One of the two largest families of the order is the mulberry family, with more than 1,400 species in about 54 genera. Of these genera the largest are *Ficus* (more than 800 species) and *Dorstenia* (about 170 species). *Brosimum* and *Artocarpus* each contain about 50 species, which are distributed in the tropics. About 12 more genera in the mulberry family contain between ten to 25 species each. The more than 30 remaining genera have fewer than four species each, and a third of these are known by a single species each.

The nettle family also contains about 54 genera, with more than 1,400 species of mostly herbaceous or softwooded plants. The largest genera are *Pilea* (400 species; the tropics,) *Elatostema* (200 species; the tropics), *Boehmeria* (100 species; the tropics and northern subtropics), and *Cecropia* (100 species; tropical America). The next 20 genera, in numbers of species, all contain between ten and 50 species each; the nettles themselves (*Urtica*) comprise a group of about 50 species. There is a large group of monotypic genera, about 14 in all.

Distribution of the elms

The largest genus of the elm family is *Celtis* (hackberries), with about 80 species distributed in the Northern Hemisphere and in southern Africa. The elms (*Ulmus*) consist of about 45 species, north temperate in distribution but extending as far south as the Himalayas and Indochina in Asia and to Mexico in North America. Other genera in the tropics and subtropics include *Trema*, 30 species; *Gironniera*, 15; *Ampelocera*, nine; *Parasponia*, six; and *Chaetachme*, four. The genus *Zelkova*, with seven species, is found in the eastern Mediterranean countries eastward to the Caucasus and into Asia. *Lozanella*, with two species, is native to Central and South America from Mexico to Peru and Bolivia. *Planera*, with a single species (*P. aquatica*), is native to the southern United States.

The smallest family is the hemp family (Cannabaceae), which consists of only two genera and about five species. *Humulus* (hop) occurs in north temperate regions, especially in Europe and the northeastern United States. The genus *Cannabis*, with a single species (*C. sativa*), is thought to be native to Central Asia but is now widely cultivated and has escaped from cultivation as a weed throughout much of the Northern Hemisphere (see Figure 2, below).

Economic importance. *Wood products.* Valuable timber trees include the elms, among which the cork elm, or rock elm (*Ulmus thomasi*), is considered superior because it grows to a great height before branching, thus producing long lengths of clear (knot-free) wood. The keyaki (*Zelkova acuminata*) of Japan is much appreciated for the beautiful colour and grain of its wood. Wood of the osage orange is used for railroad ties and fence posts and has been used to carve high-quality hunting bows in times past. Flexible, strong, and also durable, it has a bright orange colour that eventually turns brown.

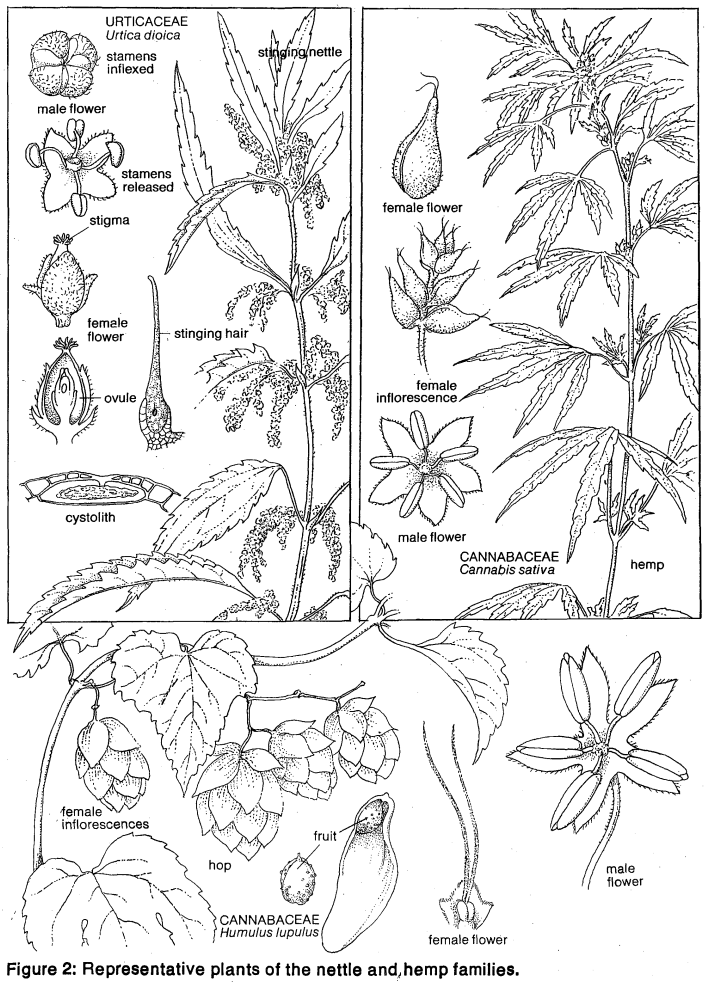

Figure 2: Representative plants of the nettle and hemp families.

Celtis occidentalis wood, sold under the name beaverwood, is used for boxes, furniture, and gift items. The wood of the African oak (*Chlorophora excelsa*), of tropical Africa, is heavy, tough, difficult to split, and resistant to termite attack. It has been used as a substitute for teak in shipbuilding and furniture making. *Chaetoptelea mexicana*, found in Mexico south of Panama, is a large tree, the wood of which is used as lumber. *Holoptelea grandis*, a tall tree of the Congo Basin, Uganda, Cameroon, and the Ivory Coast, has hard yellow wood used for house interiors and small-boat construction. *Phyllostylon brasiliensis*—San Domingo boxwood, or West Indian boxwood, of the lumber trade—is a tree ranging from the West Indies to Argentina. It produces a fine-textured, lemon-yellow, straight-grained wood valued for the high polish it will accept; stained black, it is often used as a substitute for true ebony. The wood of *Planera aquatica*, called false sandalwood, is fragrant and is used in cabinetmaking. The lightweight wood of *Chaetachme microcarpa*, a shrub of central and southern Africa, is used for the manufacture of guitars and other musical instruments.

Letterwood

Brosimum guianense, source of the expensive letterwood of the lumber trade, is a tree of the Guianas (Guyana, Surinam, and French Guiana). Its reddish-brown or brown wood, bearing black marks that resemble printed letters or hieroglyphics, is used for cabinetwork and small items such as handles, drumsticks, and violin bows. *Bosqueia angolensis*, a tree of the Congo Basin and Angola, produces yellow wood that turns pink on exposure to air; it is used in general construction and cabinetry. The wood of *Morus rubra*, the red mulberry of eastern North America, although light and not very strong, is durable and rot-resistant, qualities that make it useful in fence construction and boat building. *Brosimum paraense*, the Para breadnut tree of Brazil, produces wood called redwood or cardinal wood, used in fine furniture and fancy carpentry. Many *Ficus* species find use as lumber. *Ficus benghalensis* has wood that is durable in water. The wide, flat, finlike buttress roots of large specimens of *F. elastica*—the rubber tree grown as a houseplant—are used in tropical regions to make planks. *Ficus sycomorus*, a wood of great durability, was used by the Egyptians to make their mummy cases.

The hop and hemp. Among the most outstanding economically important plants in the Urticales is the hop (*Humulus lupulus*), the female flowers of which are used to flavour beer and to clarify it by precipitating protein materials that cause turbidity. The active principles of the hop also help prevent spoilage in beer by retarding the growth of bacteria.

The hemp, or cannabis (*Cannabis sativa*), used as a crude drug plant in Asia and Africa for centuries, has become increasingly widespread in Europe, North America, and South America since World War II. Parts of the plant are dried and offered under many names, including hashish, marihuana, pot, and grass. It is widely smoked, chewed, sniffed, or eaten to produce a mild euphoria (see NARCOTICS). The stems of the hemp plant also yield a fibre, called hemp, used mostly for rope, twine, bags, sacks, carpets, and other purposes suited to its coarseness. Hemp seeds are the source of hemp seed oil, which is used in paints, varnishes, soaps, and some edible products.

Fruits. Important fruits of the order are produced mainly by the family Moraceae. The edible fig (*Ficus carica*), cultivated since antiquity, is eaten raw, dried, preserved, or candied; when ground it serves as a substitute for tea or coffee. Numerous commercially grown varieties differ in flavour, size, colour, preserving qualities, appearance, and other features. Many other *Ficus* species also produce edible figs.

The breadfruit

An important tropical tree is the breadfruit (*Artocarpus altilis*). One of the highest yielding of food plants, a single tree may have more than 800 grapefruit-sized, seedless fruits each season. Breadfruits, high in carbohydrates, constitute one of the staple foods in many tropical regions. The fruit is filled with a starchy, pulpy, white mass that is usually cooked before eating. Closely related to the breadfruit is the jackfruit (*A. heterophyllus*), which produces fruits up to two feet long and weighing 40 pounds or more; they are not highly esteemed, however, because of their inferior flavour and seed-filled interior.

A number of lesser fruits of the order are also eaten, such as the breadnut (*Brosimum alicastrum*), mulberries (*Morus alba*, the white mulberry; *M. rubra*, the red; and *M. nigra*, the black), and hackberries (*Celtis occidentalis* and others). In addition, fruits are eaten from the following plants: *Debregeasia edulis*, a Japanese shrub that produces yellow fruits resembling strawberries; *Pourouma cecropiaefolia*, a Brazilian tree with round, fleshy berries; *Cudrania javanensis; Celtis selloviana* and *C. iguaneae; Myrianthus arborea;* and *Sahagunia strepticans.*

Fibres. Plant fibres for cloth, sacks, rope, and numerous other purposes are produced mainly by the nettle and the hemp families. The fibres of the hemp are similar to those of flax. A finer fibre is produced from the ramie, or China grass plant (*Boehmeria nivea*), also called the Chinese silk plant because its fibres make a cloth resembling silk. Ramie fibres, although eight times stronger than cotton fibres and much longer, are difficult to separate from the plant tissues. The fibres are also used to produce papers, cordage, and industrial bagging. Other plants with fibres like those of the ramie are sometimes used as substitutes for it; they include *Sarcochlamys pulcherrima* (duggal fibre) and *Pouzolzia occidentalis* (yaquilla). Olona (*Touchardia latifolia*) was formerly an important fibre plant of Hawaii, used for cloth, cordage, and especially fishnets because of its durability in water. Fibres are also obtained from the stinging nettle (*Urtica dioica*); *U. breweri*; *U. cannabina*; *Debregeasia hypoleuca*; *Villebrunea integrifolia*; and many others, including the wood nettle (*Laportea canadensis*), the fibres of which are claimed to be 50 times as strong as a cotton thread of equal diameter. Fibres extracted from the bark and aerial roots of many *Ficus* species are used locally.

Bark cloth, or tapa cloth, made from the inner bark of some trees, especially the paper mulberry (*Broussonetia papyrifera*), was once used by local populations mainly for clothing. It is still produced but now principally for religious purposes and for the tourist trade. Bark cloth is also made from the breadfruit tree, certain fig trees (*Ficus tinctoria* and others), *Pipturus albidus*, and several other genera, including *Antiaris, Sloetia*, and *Trema*. Paper is made from the inner bark of the paper mulberry and several other plants of the order (*e.g., Streblus asper, Ficus religiosa, F. petiolaris*).

Latex products. Among the earliest sources of rubber were species of the latex-bearing family Moraceae, especially *Ficus elastica*, but the Para rubber tree (*Hevea brasiliensis*, family Euphorbiaceae) has largely displaced it. Among numerous other rubber-producing trees in the order Urticales, however, are the Mexican rubber tree (*Castilla elastica*), one of the most productive of wild rubber trees; *C. lactiflora*; *C. nicoyensis*; *C. costaricana*; *C. ulei*; *Ficus nekbudu*, the latex of which becomes red when heated; *F. gnaphalocarpa*, a source of rubberlike gutta-percha; *F. rigo*; and *F. vogeli.*

Rubber-producing trees

Latex is used in many other ways, as for birdlime, a sticky substance used to catch birds (from *Ficus anomani, F. glumosa*, and others); as indelible red ink (*Bosqueia angolensis*); as a red dye (*B. phoberos*); as a base for chewing gum (*Ficus platyphylla*); as a component in glue and caulking compounds (*Artocarpus altilis* and *Brosimum utile*); as a beverage (the cow tree, *Brosimum utile*); and as medicines (*F. indica* and *F. involuta*).

Other uses. Silkworms are fed almost exclusively on mulberry leaves, *Morus alba* being preferred in Western countries. In Asia, the leaves of many species of *Morus*, some *Ficus* species, and *Maclura pomifera* are also used.

Ornamental plants of the order include about 50 species of *Ficus*, among which are *F. elastica* (the India rubber plant), *F. lyrata* (fiddle-leaf fig), *F. pumila* (creeping or climbing fig), *F. benghalensis* (banyan, or Bengal fig), *Ulmus* (elms), *Celtis* (hackberries), and *Morus* (mulberries).

NATURAL HISTORY

Pollination. Most members of the order Urticales are wind-pollinated, and some species have adaptations

that enhance this process. *Pilea microphylla* (Urticaceae), the artillery plant, for example, ejects its pollen in tiny explosive puffs. Many genera, particularly in the family Urticaceae, exhibit the same phenomenon. In the flower buds of the nettles (especially species of *Urtica*), the stamens (male, pollen-producing structures) are bent inward and held under tension (inflexed) in the bud. When the flower opens, the stamens are suddenly released and spring out with such violence that the anthers, or pollen sacs, are turned inside out, ejecting their pollen in a cloud. The pollen is then carried by the wind to the large, brushlike stigmas (pollen-receptive regions of the female flower parts) of other flowers. The flowers, like most wind-pollinated flowers, are inconspicuous, greenish in colour, and lack petals.

Explosive stamens

The genus *Parietaria* (Urticaceae) also has explosive stamens, but unlike most other members of the family it has bisexual flowers—flowers with functional organs of both sexes. Self-fertilization is averted by the early maturing of the pistil (female structure), a condition called protogyny. The elongated upper part of the pistil (the style) projects from the tip of the unopened bud, ready to receive pollen from other flowers that have already matured. Later, when the flower opens, the stamens are fully developed and release their pollen explosively, but the ovules of these flowers have already been fertilized, and the style has dropped off.

Some species of the Moraceae are insect-pollinated, particularly the figs. Pollination is accomplished by small wasps called fig wasps or gall wasps (*Blastophaga psenes*). In the figs, separate male and female flowers are borne in a specialized inflorescence, or flower cluster, which consists of a hollow, pear-shaped stem tip with the flowers on the inside. This structure, called a syconium, ultimately becomes a fig at maturity. The male flowers are usually arranged near the small opening at the upper end of the syconium, and the female flowers, much more numerous, line the interior. The female flowers are of two types, long-styled fertile flowers and short-styled sterile ones. The long-styled flowers eventually produce a single, small, one-seeded, hard-shelled fruit called an achene. The fig itself is actually a collection of many of these achenes surrounded by the fleshy tissue of the syconium. The short-styled flowers are called gall flowers; they do not develop fruits but are used as egg-laying sites by the gall wasps, which pollinate the other flowers in the process of egg laying. The gall flowers then become a mass of pulpy, abnormal plant tissue, the gall, on which the wasp larvae feed and in which they develop.

The three flower cluster types—male, long-styled female, and short-styled female or gall flowers—are produced in three distinctive syconia. The first type of syconium, produced in the spring, contains male flowers and gall flowers; each of the latter may contain one of the fig wasp eggs, deposited there in the spring by wasps that had just emerged from overwintering in another type of fig. These eggs produce wingless male and winged female wasps later in the summer. The male wasp bites through the wall of a gall containing a female wasp and mates with her. On leaving the fig to search for a suitable place to lay eggs, the female wasp becomes covered with pollen from the male flowers near the small exit hole, at the tip of the fig. The second type of syconium, the true fig, bears only long-styled fertile female flowers. The female wasp, searching for egg-laying sites in summer, enters these figs and pollinates the flowers inside but does not lay eggs because the styles are too long to suit the egg-depositing anatomy of the insect. The third type of syconium, produced in the autumn, contains only short-styled gall flowers. The eggs that are laid develop in the gall flowers and produce the next year's fig wasps.

Pollination of the fig by wasps

Symbiotic relationships. The close interdependence of figs and the fig wasps can be considered a form of symbiosis, or living together for mutual benefit. The fig is pollinated by the fig wasp and in return provides specialized flowers suitable for the wasp's reproductive requirements. Another kind of symbiosis, involving ants, occurs in several species of the family Urticaceae, including the trumpet tree (*Cecropia peltata*) of tropical America. This plant has hollow stems that are inhabited by ants of the genus *Azteca*, which rush out and attack any intruder that disturbs the plant. They provide protection against leaf-cutter ants, and the plant in turn provides not only living space for the ants but also special food bodies for them on the lower side of the swollen bases of the leafstalks. As the food bodies are eaten, new ones grow to replace them. The plant also has special thin areas in the walls along the stems that make it possible for fertile female ants to burrow inside to lay their eggs. Some other *Cecropia* species, which do not harbour *Azteca* ants, are protected from leaf-cutter ants by a thick coating of wax on the stem that prevents the leaf cutters from climbing up.

About 12 genera in the family Urticaceae have stinging hairs. The principal ones include *Urtica* (50 species), *Urera* (35 species), and *Laportea* (about 25 species). In addition, *Girardinia*, *Obetia*, *Gyrotaenia*, *Parsana*, and *Hesperocnide*, all with fewer than ten species each, have stinging hairs. In some species the hairs are found on all plant parts, but in others they may be restricted to the upper surfaces of leaves, to flowers, to fruits, or to the lower surfaces of leaves along the large veins.

FORM AND FUNCTION

Vegetative characteristics. *Stinging hairs.* The stinging hairs are hollow, glandular plant hairs tipped by a sharp-pointed, glasslike terminal cell that penetrates the skin at the lightest touch, like a hypodermic needle. The brittle tip breaks off in the skin, releasing an irritant liquid into the wound. The composition of this stinging fluid is not known in all cases, but in the wood nettle of eastern North America (*Laportea canadensis*) it is formic acid, and in the tree nettle of Australia (*L. photiniphylla*) it is a mixture of toxic substances, including 5-hydroxytryptamine.

Stinging nettles, such as *Urtica dioica* and the common nettle (*U. gracilis*), which are among the more widespread stinging species in temperate regions, usually produce an initial burning sensation that may disappear within an hour or may linger as an itch for hours or even days. The tree nettle of Australia, however, produces a sting so intense that the victim may dash about wildly, screaming in pain. Deaths from the tree nettle have been reported in a few cases; irritation from contact with the plant can last for months. *Urtica holosericea*, in the western United States, has been reported to have a sting powerful enough to kill a horse.

Effect produced by stinging nettles

Although the stinging hairs cause rashes and irritation when the plant is touched, some stinging species can be used for food. The leaves of many nettle species, for example, are often boiled and eaten like spinach. The stinging juice is not poisonous and boiling renders the hairs incapable of penetrating the skin as well. Wilted plants likewise have a greatly reduced capability of stinging because the hairs lack the rigidity needed to penetrate the skin.

In addition to the stinging members of the nettle family, a few other plants in the order produce skin irritations. Contact with the fruits or leaves of the osage orange, for example, produces dermatitis in susceptible persons.

Cystoliths. Another feature characteristic of the nettle family and many members of the mulberry family is the presence of cystoliths, deposits of calcium carbonate inside enlarged epidermal (surface) cells. They are visible as dots or variously shaped marks, especially in pressed, dried leaves. Their function in the plant is unknown.

Calcium carbonate deposits occur in another form in *Chlorophora excelsa* (Moraceae), source of the iroko wood of commerce, which is very durable and practically immune to termites and wood-rotting fungi. About 3 percent of the trees carry streaks or lumps of calcium carbonate in the wood. These are called iroko stones and are hard enough to dull woodworking tools.

Fruit characteristics. The fruits of many members of the family Moraceae are multiple fruits; *i.e.*, they are formed by the fusion of several different flowers. In the mulberry this results in a small fleshy fruit that resembles a blackberry but is actually the enlarged floral axis of a

Multiple fruits of the mulberry family

whole cluster (inflorescence) of flowers, instead of the developed carpels (ovule-bearing structures) of a single flower, as in the blackberry. Among the most extreme examples of this type of fruit are the breadfruit, breadnut, jackfruit, fig, and osage orange.

The jackfruit is unusual in still another way: it is produced along the main trunk of the tree, a condition known as caulicarpy (cauliflory when considering the flowers). Such large fruits as the jackfruit could not be supported on the branches. The fig is a unique type of multiple fruit (syconium). Each "seed" in a fig is actually an individual fruit; the fig itself is the fleshy stem tip developed into a fruitlike structure.

In the family Ulmaceae the fruits are of two main types. Elms have a dry, membranous, windblown fruit called samara. In temperate regions, these fruits often mature early in the spring, before the leaves have fully expanded. The second type of fruit, found in *Celtis* and others, is a fleshy drupe, or stone-pitted fruit. These fruits are often eaten by birds and other animals, and the seeds are thereby spread.

EVOLUTION

Fossil record. One of the interesting observations to come out of the study of fossils of the earliest flowering plants, which appeared during the Cretaceous Period (from 65,000,000 to 136,000,000 years ago), is that most of them belong to plant genera living today and represent both primitive and highly evolved forms. Among the latter are many fossil members of the order Urticales, especially of the family Moraceae. It may be inferred from this that the highly evolved groups, at least, had experienced a long period of evolution and development before the great increase in flowering plants took place. So far none of this prior evolutionary history has been found in the fossil record. The earliest reliable fossils already show the differentiation of flowering plants into many distinct families.

Fossil leaves, fruits, and wood from the family Moraceae (including *Artocarpus, Morus, Artocarpidium, Ficus, Ficophyllum,* and *Ficoxylon*) are known from the Upper Cretaceous and show this group to be already firmly evolved into present-day forms. On the other hand, many fossils, particularly of leaves, have been called fig fossils with little basis for the designation except the resemblance of outline, and some records for this family may eventually be reassigned to other groups. The genus *Morus*, however, is well-known in the London Clay flora, a fossil deposit consisting mainly of fruits and seeds of some 500 species that lived during the Eocene Epoch (38,000,000 to 54,000,000 years ago). The late Eocene amber deposits in the Baltic region contain examples of plants belonging to the families Ulmaceae and Urticaceae. The family Moraceae is among the largest of about 18 families represented in the Wilcox flora of the early Eocene, a fossil deposit known from about 130 different localities in North America. Numerous fossils of the family Ulmaceae (including *Ulmus, Zelkova, Celtis,* and *Pteroceltis*) have been found in regions that suggest that these genera were formerly much more widely distributed than they are now. The genus *Ulmus*, for example, occurs in Eocene-age deposits in Spitsbergen and on the west coast of Greenland among other fossils that indicate a former cool temperate climate for these regions. The family Urticaceae is represented by flowers (*Forskohleanthium*) and fruits (*Urticarpum*) embedded in amber, both from the lower Eocene; fossil fragments of the genus *Urtica* date to the Pliocene (2,500,000 to 7,000,000 years ago).

Mulberry fossils

Phylogeny. The fossil record has so far served mostly to show the great antiquity of several of the groups that belong to the order Urticales, but it has not revealed links with any ancestral groups. Nevertheless, some hints of the course of evolution for the order (and within the order) are reflected in the form, structure, and growth of living members. At first sight the predominantly wind-pollinated families Ulmaceae, Cannabaceae, and Urticaceae seem primitive, especially the elm family. The small, relatively simple, mostly unisexual flowers are considered to be derived from a more complex condition rather than a primitive feature, however. This concept is supported by the presence of vestigial organs of the opposite sex in many functionally male or female flowers, indicative of a former bisexuality. Many members of the families Moraceae and Urticaceae show this feature. Based on these and other lines of evidence, the order Urticales is thought to be derived from the witch hazel order (Hamamelidales), or at least from some ancestor of that group.

Within the Urticales, the family Ulmaceae is considered to be the most primitive. The families Moraceae, Cannabaceae, and Urticaceae are more highly evolved. The Urticaceae is considered advanced over the Moraceae mainly because of its herbaceous growth habit compared to the predominantly woody habit of the mulberry family. The two families, however, are very closely related and are joined by a series of genera that are distinctly transitional. These genera (*Cecropia, Coussapoa, Poikilospermum, Musanga, Myrianthus,* and *Pourouma*) have sometimes been assigned to the Moraceae, sometimes to the Urticaceae. In the classification presented below they are considered as belonging to the Urticaceae.

CLASSIFICATION

Distinguishing taxonomic features. The order Urticales is distinguished from other orders mainly by floral characteristics. The presence of mostly unisexual (separate male and female) flowers that are wind-pollinated and produce a single seed each is a unifying feature. In the female flowers the ovary is composed of two carpels (ovule-bearing structures), but there is only one ovary chamber (locule), containing a single ovule. The male flowers have only a few stamens (pollen-bearing structures). All flowers are characteristic in having few flower parts; all lack petals.

Within the order, the family Ulmaceae is characterized by its woody habit, unequal-sided leaves, paired stipules (basal appendages to the leaves), early-appearing flowers with stamens erect in the bud, and dry, winged fruits (samaras) or fleshy, stony-pitted fruits (drupes). The family Moraceae is distinguished by its woody habit, milky sap, multiple fruits, and stipules that fall early leaving a characteristic inflated scar. The family Cannabaceae is composed of aromatic herbs with watery sap and distinctive flowers. Features characteristic of the family Urticaceae include its herbaceous or softly woody habit, stinging hairs, cystoliths, fibrous stems, and inflexed stamens that release their pollen explosively.

Recognition features for the families

Annotated classification. The following classification system is widely accepted with respect to the families presented for the order. Opinions differ, however, regarding the assignment of some genera between the families Urticaceae and Moraceae. Three small families, sometimes included in the order, are excluded here (see below *Critical appraisal*).

ORDER URTICALES

Trees, shrubs, vines, or herbs. Leaves usually simple, alternate, with stipules (basal appendages). Flowers male, female, or bisexual; regular, small, greenish; usually with 4 or 5 more or less united sepals (constituting the calyx) but lacking petals. Ovary positioned above other flower parts (superior), of 1 or 2 carpels (ovule-bearing units) but with only 1 interior chamber (locule) and 1 ovule (rarely 2), erect or pendulous. Stamens variable in number but usually few, mostly equal in number to sepals and opposite them; often inflexed in the bud. Fruit with 1 seed; at maturity a nutlet, drupe, achene, samara, or multiple. Seed with or without fleshy or oily endosperm (nutrient tissue for developing embryo). Four families, 125 genera, and about 3,100 species, with worldwide distribution.

Family Ulmaceae (elm family)

Trees or shrubs with watery sap. Leaves alternate, simple, often oblique (unequal-sided at the base), with paired stipules that fall soon after leaf buds open. Flowers bisexual (in *Ulmus*) or unisexual, solitary or usually arising in clusters (fascicles) from 1-year-old twigs. Petals absent. Sepals 4 to 8, persistent, joined into a short or long tubular calyx below. Stamens equal in number to or a few more than calyx lobes and opposite them; inserted at bottom of calyx tube; erect in the bud. Ovary superior, composed of 2 fused carpels, with usually 1 or sometimes 2 locules and 1 pendulous ovule; 2 divergent styles (narrow upper part of ovary) bearing pollen-receptive

surfaces (stigmas) on inner faces. Fruit a flattened, membranous, dry, often winged samara or a slightly fleshy drupe. Seed without endosperm. Fifteen genera and about 210 species, distributed throughout the northern temperate regions of the world and abundant in tropical and subtropical regions.

Family Moraceae (mulberry family)

Trees, shrubs, or rarely herbs, with milky juice (latex). Leaves deciduous (falling) or evergreen, mostly alternate, simple, with stipules that often fall early, leaving characteristic inflated scars on the stem. Flowers male or female, very small, lacking petals, commonly with 4 separate or sometimes fused sepals (sepals sometimes reduced or absent); flowers often in dense clusters ranging from spikes, heads, and disks to crowded masses covering the insides of expanded hollow branch tips or floral axes. Male flowers with 2 to 6 (but usually 4) stamens usually equal in number to and opposite calyx lobes, reduced to 1 or 2 in some, inflexed or straight in the bud. Female flowers with ovary of 2 carpels, 1 often failing to develop; 1 locule with usually 1 pendulous ovule; usually 2 styles and stigmas. Fruit an achene or drupe, many of which often participate with enlarged calyx segments and floral axes to form a multiple fruit or syconium (a hollow enlarged stem tip with numerous flowers, and later the true fruits, on the inside, as in the fig). Seed usually with fleshy endosperm; embryo often curved. Fifty-four genera and about 1,400 species, distributed mostly in the tropics and subtropics but with a few in temperate regions.

Family Cannabaceae (hemp family)

Erect or climbing aromatic herbs with watery juice. Leaves alternate or opposite; simple with palmate (radiating from a common point) venation, or palmately compound or lobed. Stipules present, persistent. Flowers male or female on separate plants (dioecious), without petals, arising from the upper angles between the leafstalks and plant stems (axils). Male flowers in many-branched elongate clusters (panicles), each with 5 sepals and 5 stamens; anthers erect in the bud. Female flowers in dense clusters, each with large, persistent, overlapping leaflike appendages (bracts) attached just below the flowers; sepals completely joined, forming a small, membranous, smooth-edged cup closely enveloping the ovary. Ovary of 2 carpels with 1 locule and 1 pendulous, curved ovule; and a central, 2-parted style bearing 2 stigmas on inner surfaces of style branches. Fruit an achene surrounded by persistent calyx. Seed with fleshy endosperm and large curved or spirally rolled embryo. Two genera (*Cannabis* and *Humulus*) and 3 to 5 species, widely distributed in temperate parts of the Northern Hemisphere.

Family Urticaceae (nettle family)

Herbs, rarely small shrubs or small trees, or (very rarely) climbing vines, with watery sap. Stems and leaves often armed with stinging hairs; stems often fibrous; some epidermal (surface) cells usually with prominent internal crystal-like concretions (cystoliths). Leaves alternate or opposite, simple, usually with stipules. Flowers small, greenish, usually functionally male or female but with rudimentary structures of the opposite sex usually present; with 4- or 5-lobed calyx and without petals. Male flowers with stamens usually equal in number to and opposite the calyx lobes; stamens inflexed in the bud and released suddenly when flower opens, forcibly ejecting pollen. Female flowers with ovary free or enclosed by calyx; ovary composed of 1 carpel with 1 locule and 1 erect ovule. Fruit a dry achene or fleshy drupe, often enclosed by persistent calyx. Seeds mostly with oily endosperm and straight embryo. Fifty-four genera and about 1,500 species, distributed throughout the world but mostly in the tropics.

Critical appraisal. The classification system presented above is widely recognized in its broader aspects, but viewpoints concerning the details differ among authorities; for example, the inclusion in the order Urticales of the four families recognized here is a feature of practically all systems. In some, however, particularly in older systems, the two genera here recognized as the family Cannabaceae (*Cannabis* and *Humulus*) are merged into the family Moraceae. There is also considerable difference of opinion as to which family—Moraceae or Urticaceae—should contain the genera *Cecropia, Coussapoa, Poikilospermum, Musanga, Myrianthus,* and *Pourouma.* These genera have characteristics intermediate between the two families.

Three small families have sometimes been included in the order Urticales by some authorities, singly or in various combinations. These are the Rhoipteleaceae (represented only by *Rhoiptelea chiliantha* found in southwest Asia), the Barbeyaceae (represented only by *Barbeya oleoides,* found in northeast Africa and Arabian Peninsula), and the Eucommiaceae (represented only by *Eucommia ulmoides,* found in China). The last two groups are sufficiently distinct, however, that they have been recognized as separate orders (Barbeyales and Eucommiales) in some of the most recent taxonomic systems, as is done here. The Rhoipteleaceae are generally believed to belong more properly in the walnut order (Juglandales).

Opinions are divided on the numbers of genera and species in each family, particularly the two largest. Estimates for the Moraceae range from about 1,000 to 2,300 species and from about 50 to 75 genera. The genus *Ficus* alone has been considered to contain anywhere from 800 to more than 2,000 species. Estimates for the Urticaceae range from 500 to 1,900 species. These differences reflect, in part, the growing numbers of newly described species and, in part, differences of opinion concerning the placement of genera in particular families and the validity of recognizing some genera and species at all.

Uruguay

Uruguay (officially known as the República Oriental del Uruguay and locally still called the Banda Oriental, the "eastern shore" of the Uruguay River) is the smallest independent state in South America. With an area of 68,536 square miles (177,508 square kilometres), it is bounded by Brazil to the north and east, by the Atlantic Ocean to the southeast, and by the Río de la Plata to the south, while to the west the Uruguay River separates it from Argentina. In 1972 Uruguay's population was estimated to be over 2,950,000. The capital is Montevideo (which at the same time had an estimated population of more than 1,459,000).

While throughout most of the 20th century Uruguay was known for its political stability and advanced social legislation, by the early 1970s mounting economic difficulties and social unrest had thrown a pall of uncertainty over its political future. The activity of the Tupámaros, an urban guerrilla movement named after Tupac Amaru (an 18th-century Inca who rebelled against Spanish rule) that was harrassing the government in a variety of ways, seemed to many to symbolize the new and violent element that had entered Uruguay's political life. (See the city article MONTEVIDEO; for an associated physical feature, see RIO DE LA PLATA; for historical aspects, see URUGUAY, HISTORY OF.)

(Ed.)

THE LANDSCAPE AND ENVIRONMENT

Relief and drainage. The eastern and southern half of Uruguay is a low hilly land, with a subsoil of weathered ancient schist (a crystalline rock) and granite, through

which protrude low ridges of less weathered rocks. In central and north central Uruguay a basement of ancient schist is overlain by nearly horizontal layers of rock dating from the Permian Period (from 280,000,000 to 225,000,000 years ago) that form a low plateau. The northwestern portion is occupied by a southward extension of the Paraná Plateau of southern Brazil. This plateau is formed of horizontal beds of Triassic red sandstone (from 225,000,000 to 190,000,000 years old) of continental origin, in places faulted and capped by sheets of Triassic basalt. The plains of Uruguay are covered with deposits of sand and clay of the Pleistocene Epoch (2,500,000 to 10,000 years old) and with alluvial beds.

The northeastern part of the country consists of low rolling hills, a southward extension of the Brazilian highlands. The coastline is fringed with tidal lakes and sand dunes; the banks of the two rivers are low, unbroken stretches of level land. The northwestern section of the republic presents greater variety of relief, with occasional ridges and low plateaus, alternating with broad valleys, a southward extension of southern Brazil. None of the hills and plateaus of Uruguay exceeds 2,000 feet in elevation.

The rivers

There are no large rivers entirely within Uruguayan territory. The Río Negro, the largest stream, is navigable only in its lower part. The Uruguay River, along the border, is navigable for steamers of 14-foot draft from its mouth to Paysandú and above that point for smaller vessels to the falls at Salto, 200 miles in all. No other streams are navigable except for vessels of light draft. The Santa Lucía, Queguay Grande, and Cebollatí are the other principal watercourses.

Climate. Uruguay has a truly temperate climate, the average temperature for the summer months of January and February being about 71° F (22° C) and that of the coldest month, July, being 50° F (10° C). Frost is almost unknown along the coast. The weather of both summer and winter varies from day to day, a result of the passing of storm centres associated with cyclones (large-scale wind and pressure systems characterized by low pressure at the centre and circular wind motion). Brusque wind shifts are common, a hot northerly wind sometimes being followed immediately by the chill pampero (wind from the pampas—the vast grassy plains of Argentina) from the southwest, which brings a sudden drop in temperature. These changes give a middle latitude character to the climate of Uruguay.

There are no decided rainy and dry seasons. Maximum rainfall occurs in the autumn (April and May), rather than in the winter months, as is often supposed. Winter rains are most frequent but autumn rains are heaviest. The mean annual precipitation is about 35 inches (890 millimetres), decreasing with distance from the sea but everywhere well distributed throughout the year. In summer there are frequent thunderstorms. Fogs are common from May to October but seldom last all day on land.

Vegetation. Uruguay is mostly covered with tall, rich prairie grass. There are more trees, however, both native and introduced, than on the pampas, but these are found chiefly in narrow ribbons along the bottomlands of the watercourses. The principal species are the ombú (a scrubby plant with capacity to survive in dry areas), alder, aloe, poplar, acacia, willow, and eucalyptus. The *montes*, by which are understood plantations as well as native thickets, produce, among other useful wood, the algarrobo (carob tree) and the quebracho (a tree the wood and bark of which are used in tanning and dyeing). Indigenous palms grow in the valleys of the Sierra de San José Ignacio and, to some extent, in the departments of Lavalleja, Maldonado, and Paysandú. The myrtle, rosemary, mimosa, and the scarlet-flowered ceibo are common.

The valleys within the hills are fragrant with verbena and aromatic shrubs. The prairies are gay with the scarlet and white verbenas and other brilliant wild flowers.

Animal life. As in most of the inhabited parts of the world, the wild animals have largely disappeared. Even the rhea (the American ostrich) is now seldom seen,

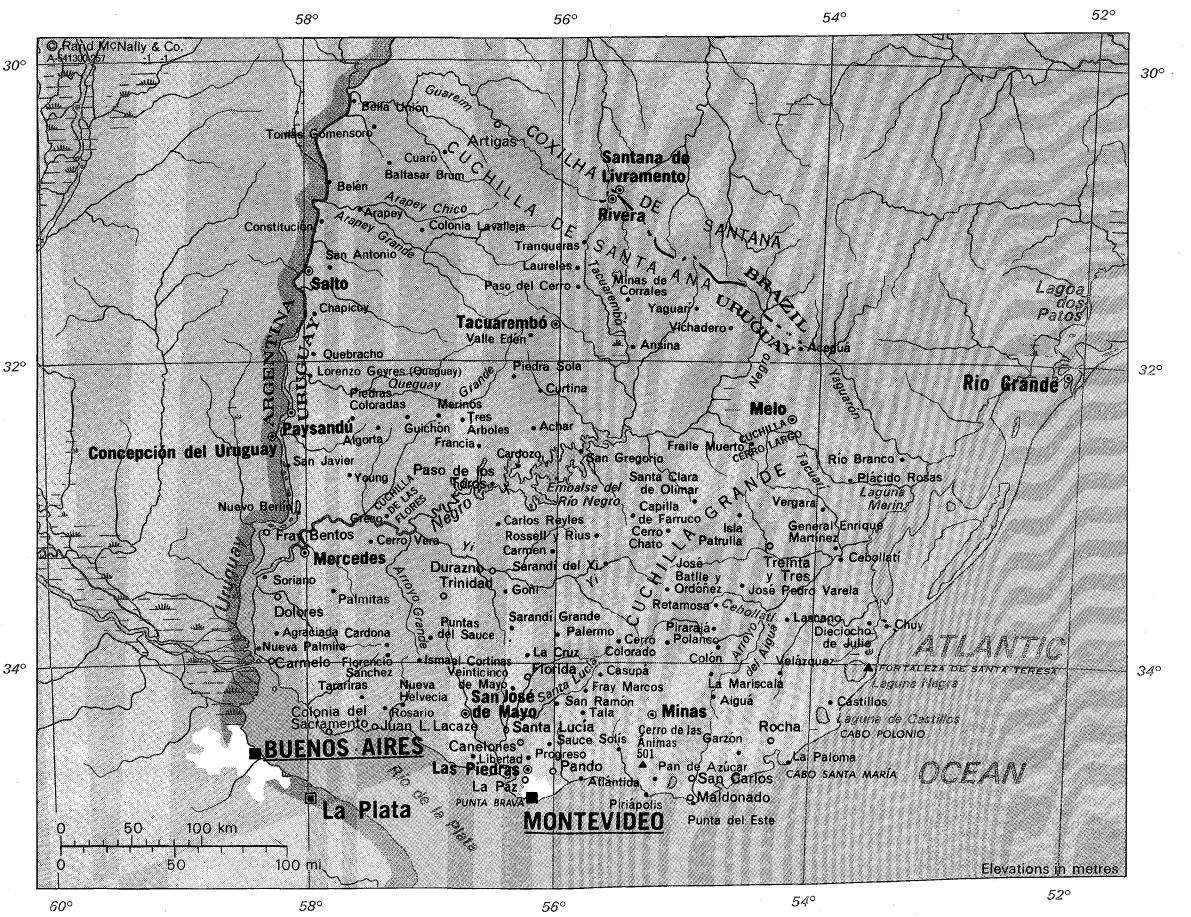
except in a semi-domesticated state. Pumas and jaguars are found on the wooded islets and banks of the larger rivers and along the northern frontier. The fox, deer, wildcat, the capybara (or water hog), and a few small rodents nearly complete the list of native quadrupeds. A small armadillo, the mulita, is the living representative of the extinct giants, mylodon and megatherium, the fossils of which are found over the pampa.

Birdlife

There are a few specimens of the vulture, a native crow (lean, tall, and ruffed), and many partridges and quails. Parakeets are plentiful in the *montes*, and the lagoons swarm with waterfowl. The most esteemed is the *pato real*, a large duck. A characteristic sight on the prairies is that of the tiny burrowing owl sitting on top of every little eminence. Large flocks of the lapwing terutero are common; they have the habit of warning other game of the approach of danger. Of birds of bright plumage, the hummingbird and cardinal—the scarlet, the yellow, and the white—are the most attractive. White herons are frequently seen in swampy lands. The scorpion is rare, but large and venomous spiders are common.

The principal reptiles are a lizard, a tortoise, the *víbora de la cruz* (a dangerous viper, so called from marks like a cross on its head), and the rattlesnake in the department of Maldonado in the southeast and the stony lands of the Minas region nearby. The caiman (alligator) is not uncommon along the upper waters of the Uruguay River. Seals are found on small islands off the southeast coast, particularly on the Isla de Lobos.

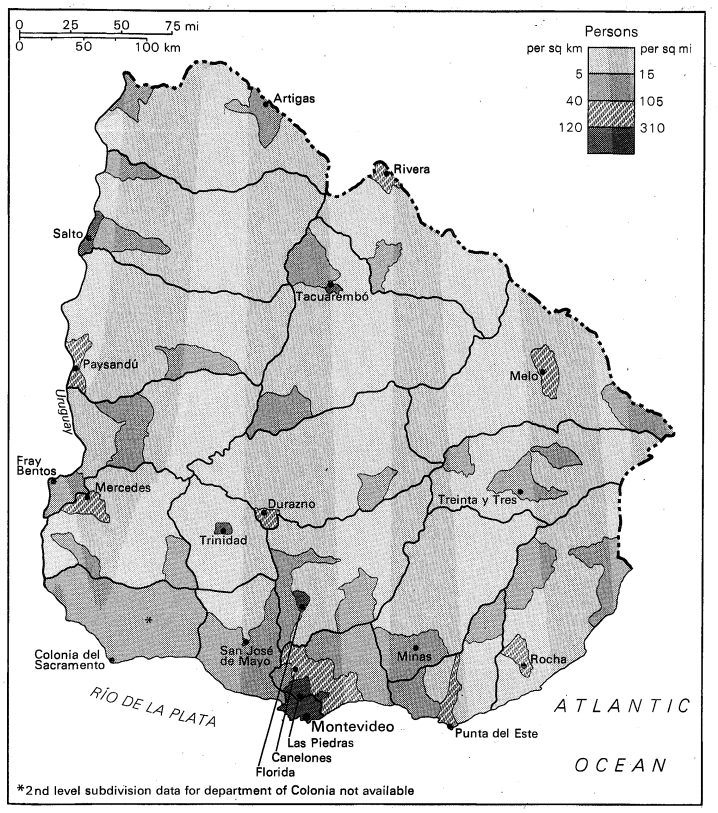
Traditional regions. Uruguay is one of the most coherent states in Latin America. When the country became independent in 1828, its national territory was used almost exclusively for the grazing of herds of scrubby cattle on the unfenced range, and there were few permanent settlements outside of Montevideo and Colonia del Sacramento and the villages along the Uruguay River. The grazing lands along the eastern shore of the Uruguay River constituted a kind of no-man's-land between the Portuguese in Brazil and the Spaniards in Argentina.



After independence, Uruguay received a small influx of immigrants, chiefly from Italy and Spain. This was during a time when Argentina was torn by civil strife and settlement on the pampas was not yet attractive. The newcomers entered Uruguay through Montevideo and settled in a zone along the Río de la Plata and Uruguay River. After 1852 the European immigrants to the Plata region went largely to Argentina. As a result, the argicultural zone in southern Uruguay remained static, because, unlike the situation in Argentina, livestock grazing and the cultivation of crops remained in separate geographic areas. Even as late as 1940, there was a notably sharp boundary between the pastoral region to the north and the agricultural region to the south, as at the town of Florida, only 50 miles north of the capital. After the mid-1940s, however, there was a great increase in the area devoted to agriculture. The sharp boundary between the two regions disappeared. Crops became more important than pasture as far north as Durazno, more than 100 miles north of Montevideo, and the crop zone also extended northward along the Uruguay River as far as Salto.

Cattle raising

The grazing of animals in the pastoral region is no longer on unfenced range. Barbed wire is used throughout the interior to separate one pasture from another and to border the highways and animal driveways. Planted pasture grasses have replaced the native grasses, and the carrying capacity is high—about one animal unit per acre. There are many large ranches, or estancias, some larger than 25,000 acres, in the pastoral region. Sheep are more significant than cattle in the northwest, especially on the relatively dry, low plateaus on diabase and red sandstone. South of the Río Negro cattle are of major importance.



The agricultural zone, on the other hand, has little land devoted to pasture. The chief crop is wheat, but there are also important areas of maize, flax (for linseed), oats, barley, and grapes.

Montevideo is the country's largest urban centre, and it

contains the chief concentration of manufacturing. Industries were also established at Fray Bentos, Salto, and Paysandú along the Uruguay River. (P.E.J.)

Population density of Uruguay.

PEOPLE AND POPULATION

Ethnic, linguistic, and religious groups. The people of Uruguay are predominantly white, most of them descendants of 19th- and 20th-century immigrants from Spain, Italy, and other European countries. The Indian population is almost completely extinct, and only a very small proportion of Uruguayans exhibit any noticeable Indian physical characteristics. There are few Negroes or mulattoes, probably not more than 10,000 of the former or 50,000 of the latter.

Comprehensive statistical data on religious affiliations of Uruguayans are lacking, but less satisfactory sources of information are sufficient to indicate that the large majority profess the Roman Catholic faith. Spanish is the official language and the one used in the home by an overwhelming majority of the families. In the sections along the Brazilian border, however, the language in daily use includes a large admixture of Portuguese words and phrases.

Demography. A census of population taken in 1963, the first since 1908, put the population of Uruguay at about 2,590,000. Since that time, the annual increment has amounted to about 40,000. In 1972 the official population estimate was 2,956,000. In 1963 the density of population was about 37 per square mile (14 per square kilometre). The 1963 census also furnished reliable data about the geographic distribution of Uruguay's population. The city of Montevideo contained almost half of the nation's people, with many thousands more residing nearby in the adjacent department of Canelones. The remainder of the inhabitants are concentrated in those departments that front upon the Río de la Plata, namely, Colonia, San José, and Maldonado (the chief town of which is Punta del Este), and among those adjacent to the Uruguay River, especially Soriano, Salto, and Paysandú. In addition to Montevideo, the most important cities are Salto, Paysandú, Punta del Este, Rivera, Las Piedras, Melo, Mercedes, and Minas. In 1963, 81 percent of the population was classified as urban.

Because Uruguay's birth rate has been fairly low (and stable) since 1900, the age distribution differs sharply from that of most of the other Latin American countries. In 1963 only about 28 percent of the population was less than 15 years of age, and only about 8 percent was 65 or over. This proportion of young people is only about two-thirds as high as is typically the case in Latin America, and that of the aged is almost double the percentages prevailing in most of the other countries. Between 1908 and 1963, the dates of Uruguay's two most recent censuses, the growth of population averaged only 0.7 percent per annum, by far the lowest during that period for any of the Latin American countries. In all probability, however, the current rate is much higher, or about 1.4 percent per year subsequent to 1963. For the 20 Latin American countries taken together the index is about 2.8 percent per annum.

The present increase of population in Uruguay is due almost entirely to natural increase, or the difference between a birth rate of about 20 per thousand population and a death rate of 9 per thousand. Only a very low proportion of the growth of population may fairly be attributed to immigration. In this connection, however, it is notable that Uruguay's data on immigration and emigration are involved and perplexing. It was the first of the Latin American countries to legalize divorce, and by the mid-20th century Montevideo and Punta del Este had become temporary places of residence for thousands of divorce seekers from Argentina and from other populous areas in the southern part of South America.

THE NATIONAL ECONOMY

A comparative view. The foundation of Uruguay's economy is said to have been laid in 1603, when a far-seeing governor of Paraguay, Hernando Arias de Saavedra, having observed the fertility of the empty southern pastures, shipped about 100 head of cattle and 100 horses downstream from Asunción. The animals were landed on the Uruguayan riverbank, where they were left to run wild. Later in the century, the herds were so abundant that they attracted gauchos, who crossed the Río de la Plata from Buenos Aires and began a trade in hides. The gauchos were nomads, with no desire to settle, but, gradually, merchants from Buenos Aires established themselves on the Uruguayan side of the estuary. As more cattlemen arrived, boundaries had to be fixed, and thus there came into existence the great estancias that are still characteristic of the country.

The relatively high standard of living enjoyed in and around Montevideo is closely related to the earnings

Structure of the economy

from pastoral and agricultural exports; prosperity is somewhat precarious because these primary products are subject to sudden fluctuations in world demand and prices. To reduce the nation's dependence on external trade, successive governments have encouraged the development of domestic industry by means of protective tariffs, import controls, exemptions of machinery from import duties, and preferential exchange rates. But, as there are no local sources of petroleum, coal, or iron and no heavy industries, Uruguay is obliged to import most of its fuel and industrial raw materials and all of its vehicles and industrial machinery. These essential supplies have to be paid for with the produce of the ranches and farms and the income derived from tourists. Uruguay is noted among Latin American countries for its highly developed social services, but these were placing an excessive burden on the country's resources.

Components of the economy. *Agriculture.* Pastoral farming is Uruguay's most important economic activity. Wool and beef are its chief products and the source of about three-fourths of its total earnings from foreign trade. All available land is in use for grazing or agriculture, and production can be increased only by improved techniques. Improvement has, in general, been slow; output has not kept pace with local demand, with the result that exports now account for only 26 percent of the total agricultural and livestock produce, compared with 46 percent in the 1930s. Government policy has generally sought to achieve national self-sufficiency in wheat. This has sometimes led to overproduction of this cereal and to a partial neglect of livestock farming, although, by contrast, wheat imports from Argentina were necessary, for example, in 1964. Other crops include corn (maize), linseed, sunflower seed, oats, barley, and rice. Fruits grown are oranges, lemons, peaches, grapes (sufficient for the local wine industry), pears, and apples.

The public corporations

Power and industry. The state operates a large number of public corporations. It controls electricity and the refining of imported petroleum; it manufactures alcohol and cement; it directs a meat-packing plant and the processing of fish; and it controls the railways (purchased from their British owners at the end of World War II), the principal banking institutions, and insurance.

Since the low, rolling countryside of Uruguay is not generally suited to hydroelectric development, most of the electric installations were formerly dependent on imported coal or oil; but two hydroelectric plants were built on the Río Negro.

The processing of food and other products of the land is the basic form of industry. The subsidized wool-combing industry has added to the country's exports. Consumer goods manufactured locally (mainly around Montevideo) include textiles, tires and other rubber goods, shoes, and household appliances.

Foreign trade. Wool exports in the late 1960s amounted to about 40 percent of the national total, while meat and by-products varied from 20 to 42 percent. Hides and skins were the other principal items. The chief markets were the United Kingdom, Italy, West Germany, Spain, The Netherlands, and the United States. The main imports were raw materials for industry, vehicles, machinery, and fuels. The chief suppliers of these imports were the United States, Brazil, West Germany, Argentina, and the United Kingdom. Despite import controls, the balance of trade up to the late 1960s was usually unfavourable. Uruguay was a founder-member of LAFTA (Latin American Free Trade Association), set up at Montevideo in 1960.

Banking and finance. The functions of a central bank are exercised by the state-owned Banco Central, formed in 1967. Another state bank, the Banco de la República, regulates many aspects of foreign trade and is the country's largest commercial banking organization. An admirable record of currency stability was reversed in the 1960s, when the inflationary effect of persistent budget deficits began to be felt. The rise in the cost of living index, together with the consequences of a decline in the gross domestic product as well as increasing inflation, led to social unrest and substantial emigration.

Transport and communications. In the early 1970s Uruguay possessed over 2,000 miles of railway and more than 8,000 miles of paved or surfaced highways, both systems radiating from Montevideo. The resultant competition has mainly favoured road transport, and international loans have been obtained to improve the highways, particularly those providing links with Brazil. About 775 miles of the country's inland waters are navigable. Local shipping handles only a small proportion of the country's foreign trade; in 1970 Uruguay's merchant fleet totalled about 198,000 tons. There is a hydrofoil service from Montevideo to Buenos Aires. The main airport is at Balneario Carrasco, 13 miles from Montevideo; a state airline, Primeras Líneas Uruguayas de Navigación Aérea (PLUNA), provides services within Uruguay and to neighbouring countries.

Telephone and broadcasting services

In the early 1970s the state telephone service had more than 235,000 subscribers (over four-fifths in Montevideo). Broadcasting services, including 9 television channels, are operated by state and private companies. Four cable companies provide foreign communication links; an international telex service was inaugurated in mid-1964. (I.C.Cn./G.Pe./C.P.D.)

ADMINISTRATION, SOCIAL CONDITIONS, AND CULTURAL LIFE

The 1966 constitution

The structure of government. *Constitutional framework.* In 1966 a new constitution restored the presidential system of government and repudiated a *colegiado* (plural-executive) system previously in use. The president is chief of state and commander of the armed forces. The legislative branch consists of a Senate of 31 members and a Chamber of Deputies of 99, elected for four years by universal suffrage, the political parties having proportional representation.

Local government. Uruguay consists of 19 departments, each governed by a departmental council, which exercises executive functions, and by a legislative assembly; both the councils and the assemblies are elected by popular vote.

The political process. The three principal political parties are the Colorado Party (which traditionally has had an urban base), the Blanco Party (supported by the landowners), and the Frente Amplio (Broad Front), representing a coalition of Christian Democrats, Socialists, Communists, and dissident members of the two other parties. In the 1971 presidential elections, the Colorado Party received 575,000 votes, the Blanco Party 565,000, and the Frente Amplio 262,000. The radical-revolutionary Tupámaros guerrilla movement operates outside the parliamentary system.

Justice. A Supreme Court of five judges is elected for a ten-year term by the General Assembly (*i.e.*, the two houses of the legislature). The death penalty has been abolished since 1907.

The armed forces. The army, with a strength of 12,000 (1971), composed of volunteers enlisting for one or two years, comprises regiments of cavalry, engineers, infantry, artillery, and tanks. There is a small navy (about 1,800 men) and an air force (about 2,000 men) of about 200 planes. A reserve force is trained every year under a compulsory military training law.

Social conditions. *Education.* Uruguay has long been renowned for its progress in education, after reforms instituted in the late 19th century that established a system of free, compulsory, coeducational, and secular education. This progress was reflected in the high literacy rate (about 90 percent).

Higher education

The Universidad de la República (founded in 1849) had an enrollment of more than 13,000 in the early 1970s. It has ten faculties, including a distinguished medical school that draws students from many South American countries. There is also a privately supported Instituto de Estudios Superiores (Institute of Higher Studies) devoted to scientific research. Vocational training is given by the Universidad del Trabajo del Uruguay, which organizes and controls a number of industrial and night schools.

Health and welfare. Since the early years of the 20th century, Uruguay has played a leading role in the de-

velopment of social security. The country's comprehensive program includes extensive provisions for unemployment insurance, compensation for injuries to workmen, family allowances, and aid to the aged and indigent. With respect to problems of health and sanitation, Uruguay is among the most fortunately situated of the Latin American countries. In 1960, for example, the infant mortality rate was about 47 per thousand births, but by 1970 the rate had dropped to 43 per thousand. In 1971 there was about one physician for every 800 people. Long a South American pioneer in international cooperation, Uruguay participates in the technical assistance programs of the United States, the Organization of American States, and the United Nations.

Living and working conditions. With 1953 figured as 100, the cost of living had risen to 314 by 1960. Between 1955 and 1970, inflation increased by 9,000 percent. The strength of the trade-union movement is reflected by the number of workers—approximately 45,000—who were members of internationally affiliated trade unions in the late 1960s. A severe economic depression began in the mid-1960s and by the early 1970s had created great unrest as government officials sought, apparently unsuccessfully, to cope with the growing economic crisis.

Cultural life. Uruguay falls within the same cultural context as other Spanish-speaking American states. Interest in literature and the arts has flourished. There is a thriving press, both in Montevideo and the provinces; censorship, to which the press in many South American countries is frequently subjected, has been virtually nonexistent. Recreational facilities are provided by the sandy beaches on the coast, as well as by the wildlife resources of the interior; both have served as tourist attractions. Football is the principal sport, but basketball and horse racing are also popular. (G.I.B./Ed.)

PROSPECTS FOR THE FUTURE

Whereas Uruguayans have long prided themselves on their national slogan, "*Como Uruguay, no hay*" ("There is no country like Uruguay"), in the early 1970s Uruguay's future appeared beset by uncertainties. Continuing economic crisis, the deterioration of the party system, the emergence of the small but significant Tupámaros guerrilla movement, and the emigration of many educated Uruguayans all gave cause for concern. On the other hand, the country's strongly rooted democratic and humane traditions, its level of education, and its temperate climate were among the factors that, to some extent, offset negative factors and encouraged hopes that the country would eventually experience a return to more favourable conditions. Uruguay, History of

Before the coming of the Europeans, the east bank of the Uruguay River was inhabited by a group of Indian tribes known collectively as the Charrúas. European settlers raised cattle there in the 17th century, and in 1680 the Portuguese founded a settlement at Colonia del Sacramento. With the establishment of Montevideo in 1726, Spain began the effective occupation of the country; from 1776, it formed part of the Viceroyalty of Rio de la Plata, capital of which was at Buenos Aires. The year 1810 marked the beginning of the wars of independence in the Spanish American colonies. Buenos Aires was one of the urban centres where the independence movement was strongest; from Buenos Aires, revolutionary sentiment spread to the interior of the Rio de la Plata Viceroyalty, and also to centres of Spanish crown rule beyond the Andes. Lima and Montevideo were both bulwarks of resistance to the ideas proclaimed by the new revolutionary power groups (see further LATIN AMERICA AND THE CARIBBEAN, COLONIAL).

The struggle for national identity (1811–90). Montevideo was the site of a Spanish naval installation; in 1811 an armed insurrection led by the rural spokesman José Artigas broke out in its hinterland, the Banda Oriental del Uruguay (the east bank of the Uruguay River). Spanish authority was challenged, and unresolved colonial problems were brought to the fore. The *estancieros* (ranchers) were joined in revolt by the gauchos (cowboys), the peons, and the slaves. Artigas proposed a plan for a republican federation of the Rio de la Plata territories and a democratization of rural life based on advanced social principles.

Artigas' revolt

The Buenos Aires oligarchy, realizing how Artigas' proposals would affect them, decided to crush his growing power; their forces defeated him in 1816, ending the first manifestation of Uruguayan autonomous government. The emancipation of the Banda Oriental eventually was achieved during the period of Portuguese-Brazilian occupation (1817–28). In 1825, Juan Antonio Lavalleja and his supporters (known as the "33 *orientales*") formed an army with Argentine help and defeated the Brazilians at Ituzaingó (February 20, 1827). A preliminary peace pact with Brazil (August 27, 1828) recognized Uruguay's independence. On July 18, 1830, a constitution for the new nation was approved. Uruguay had scarcely 74,000 inhabitants; its main economic resources, livestock and land, were concentrated in the hands of a few families who had acquired economic empires in the countryside during the colonial period. The first two decades of independence were a time of testing. There were frequent uprisings in the interior, and, in the urban areas, opposing factions grew up around their leaders Fructuoso Rivera and Manuel Oribe. The colours used by each faction gave rise to the present names of Uruguay's main political parties: red, or Colorado, for Rivera's group, and white, or Blanco, for Oribe's.

The Colorados and the Blancos

Antagonism between these groups led to the civil war of 1839–51, during which the Blanco Party controlled the interior and the Colorado Party controlled Montevideo. Several foreign powers intervened—Argentina on the side of the Blancos, England and France on the side of the Colorados.

The period ended without losers or victors, and the failure to achieve national unity opened a whole new era of turbulence and uprisings, frequently involving the country in Brazilian and Argentine affairs. This led to Uruguay's participation with Brazil and Argentina in war against Paraguay (1865–70). Successive attempts at political coexistence and internal order, indispensible to Uruguay's modernization and entrance into world economics, were frustrated. Internally the caudillos, (personalist leaders) struggled for power with liberal parliamentarians known as *principistas* or "doctors." In the 1870s, control of the government passed into the hands of the military.

During the administration of Col. Lorenzo Latorre (1876–80), power was more firmly centralized: pacification of the rural areas permitted advances in stock breeding and ended the power of the caudillos. Capitalist development and internal stability continued under the governments of Gen. Máximo Santos and Gen. Máximo Tajes (1880–90).

The prosperity of the export economy (1890–1954). By the time civilian rule was restored under Julio Herrera y Obes in the 1890s, the rural economic structure had adapted itself to the demands of external markets.

Wool and dried (or jerked) beef exports rose greatly. The population, as a result of immigration from Mediterranean Europe, more than doubled during the last quarter of the 19th century, rising from 450,000 people in 1875 to about 1,000,000 in 1900. The adoption of new fiscal policies and the development of transportation and communication facilities (railroads and telegraphs) stimulated foreign loans and investment, usually of British origin.

At the beginning of the 20th century, the country was again torn by a factional dispute, based on the Blanco (or Nationalist) Party's demands for greater participation in government affairs. After a Blanco uprising and the assassination of the Colorado president, Juan Idiarte Borda, in 1897, tension between the two parties reached a climax in 1904. At this time, a year after being elected president, the Colorado leader, José Batlle y Ordóñez, was confronted by a Blanco revolt headed by Aparicio Saravia. After eight months of bloody fighting and the death of Saravia, the conflict was ended by the Peace of Aceguá. This agreement was followed by a reorganization of the political parties and marked the beginning of a long period of internal peace and orderly government for Uruguay.

The influence of Batlle y Ordóñez

From 1904 until his death in 1929, José Batlle y Ordóñez dominated the political scene. Twice president of the republic (1903–07; 1911–15), he designed reform programs that became the objectives of the modern Uruguayan state.

Administrative reforms included the creation of a Supreme Court of Justice, greater municipal autonomy, and the creation of more public services. Social reforms included the removal of public education from the control of the Roman Catholic Church, the extension of free education on the secondary and university levels, a reform of the university system, extension of the right of divorce to women, and, finally, separation of church and state in 1917.

Advanced labour legislation that was passed (the right to strike, an eight-hour workday, obligatory accident insurance) emphasized the role of the state as mediator between management and labour.

Batlle's policies discouraged foreign intervention in Uruguay's economic affairs. While North American penetration pushed on the frozen meat industry, he promoted a strong policy of nationalism, by means of several government monopolies, assuring state control of areas usually dominated by private or foreign capital (mainly British, toward which Batlle showed an open disaffection).

During World War I, the agriculturally based economy flourished with the export boom. At the same time, domestic production and consumption of manufactured goods increased, in reaction to protective tariffs in other countries and the spiralling cost of imported goods. This economic expansion was accompanied by political reform. President Batlle, fearing the power of the presidency, proposed its abolition and the substitution of a nine-member executive council. A plebiscite defeated the idea (1916), but it was partially retained in the constitution of 1917 that, while retaining the presidency, provided for the creation of a National Council of Administration made up of nine elected members. This constitutional reform, combined with the extension of suffrage rights in 1924, gave new impulse to representative government in Uruguay.

At the same time the economy entered a bad period. Exports declined with the reorganization of European markets following the war. U.S. capital was used to finance road construction, in competition with the British railway system, and U.S. business investments heralded the shift from British to U.S. economic domination. The New York stock market crash of 1929 caused a further decline in exports and a price decrease for Uruguayan goods. Complicating the situation were the Ottawa Agreements (1932), which greatly limited the accessibility of Río de la Plata meats to British markets. An austerity program was instituted in an attempt to improve the economic situation. In 1933, however, Pres. Gabriel Terra, of the Colorado Party, proclaimed himself dictator. The constitution of 1917 was invalidated, and full power was restored to the president; this situation lasted until the middle of 1938, when Gen. Alfredo Baldomir was elected president.

With the beginning of World War II, President Baldomir kept Uruguay neutral. Many Uruguayans sympathized with the Allies, but the leader of the Blanco Party, Luis Alberto de Herrera, campaigned for strict neutrality and sought to prevent the installation of North American naval bases in the country. Other leading Blancos had definite Nazi-Fascist sympathies. Nevertheless, Uruguay, along with most of the other Latin American Republics, declared war on the Axis powers in 1945.

At the beginning of 1942 President Baldomir dissolved the Congress and prepared a new constitution. His support came not only from his own Colorado Party but also from the independent Blancos (members of the Blanco Party who, in 1933, had separated from it because of their opposition to the ideology of Herrera). The takeover of the government by Juan José Amézaga in 1943 marked a return to democratic liberalism. Once again, a war aided the Uruguayan economy. As had happened during World War I, the value of livestock products rose disproportionately, a lucrative European market opened up, and imports declined tremendously. Small industries prospered, filling the gap created by the import decline. The standard of living rose. Internal consumer markets grew; unemployment dropped, educational opportunities opened up; and labour legislation bettered the existing social security system.

Tomás Berreta, a disciple of Batlle y Ordóñez, was elected president in 1946, but his sudden death left the government in the hands of Batlle's nephew, the urban caudillo Luis Batlle Berres. The government readopted the principles of the 1917 constitution, and after reaching an agreement with the Blanco Party, created, in the constitution of 1951, the National Council of Government, which replaced the presidential office with a nine-member council.

In the early 1950s, Uruguay became a haven for anti-Peronist exiles from Argentina. They used the Uruguayan press and radio networks to win support for their cause, and had the tacit approval of the Uruguayan government. An opposition campaign and anti-Peronist committees, based in Montevideo, found support in the liberal temper of the country and were granted tacit government support. Uruguay's relations with Argentina deteriorated, reaching their lowest point just before Peron's overthrow in 1955.

Economic and political decline (1954–c. 70). The Korean War precipitated a brief economic boom, ending in 1954. Thereupon, Uruguay entered first a period of economic stagnation, then a period of recession, aggravated by the lowering of world prices on its chief exports (wools, meat, leather products) as well as by the rising price of manufactured goods. The economic deterioration resulted in labour riots, demonstrations, and general discontent among the populace.

The Blanco victory of 1958

The 1958 elections reflected this discontent. For the first time in 93 years, the Colorado Party was defeated, and the Nationalists (Blancos), promising an improvement in the economy, came to power under Martin R. Echegoyen. The change of government came at a time of tremendous inflation. In 1959, a monetary reform law was passed, providing for successive devaluations of the currency. Tension and discontent rose among all sectors of the population.

In the same year (1959), Herrera, former leader of the Blanco Party, died, and divisions within the party deepened. The Blanco government was unable to deal effectively with the crisis. Its free enterprise orientation allowed economic elite groups to import luxury items at a time when its policy was to limit imports to essential consumer goods.

The second Blanco administration (1963–66) was characterized by an even sharper disintegration of the traditional political parties, resulting in the proliferation of groups and subgroups under personalist leaders. Inflation was not halted. A 1965 bank failure staggered the

monetary economy. Furthermore, the cost of living rose, affecting those income groups (mainly urban) that were least able to afford it. The inflation and production slump continued into the 1970s.

The 1966 elections returned the Colorado Party to office. Another constitutional reform restored presidential power in full. The new president, Gen. Daniel Gestido, died of a heart attack in December 1967; he was succeeded by his vice president, Jorge Pachero Areco, who in turn was followed by Juan Maria Bordaberry in 1972. Bordaberry, during a crisis caused by the widespread terrorist activities of the Tupamaro revolutionary movement, staged a coup with military backing in June 1973.

Usman dan Fodio

Usman dan Fodio (in Arabic ʿUthmān ibn Fūdī), often simply referred to as "Shehu" or "the Shaykh," was the most important reforming leader of Africa's Western Sudan region in the early 19th century. His importance lies partly in the new stimulus that he, as a *mujaddid*, or renewer of the faith, gave to Islām throughout the region; partly in his work as a teacher and intellectual, the focus of a network of students, author of a large corpus of writings in Arabic and Fulfulde that covered most of the Islāmic sciences and enjoyed—and still enjoy—wide circulation and influence; partly in his activities as founder of a *jamāʿa*, or Islāmic community, which became a new polity, the Sokoto caliphate, and brought the Hausa states and some neighbouring territories under a single central administration for the first time in history.

Though involved in an active life of preaching and controversy, the Shaykh was also a serious Ṣūfī who underwent mystical experiences, was familiar with *jinns* (spirits), and lived ascetically without wealth or servants.

Early years

Usman was born in 1754 at Maratta in the Hausa state of Gobir, in what is now northwest Nigeria. His father, Muhammad Fodiye, was a scholar from the Toronkawa clan, which had emigrated from Futa Toro in Senegal in about the 15th century. While still young, Usman moved south with his family to Degel, where he studied the Qur'ān with his father. Later he moved on to other scholar relatives, travelling from teacher to teacher in the traditional way and reading widely in the Islāmic sciences. One powerful intellectual and religious influence at this time was his teacher at the south Saharan city of Agadez, Jibrīl ibn ʿUmar, a radical and controversial figure whom Usman both respected and criticized and by whom he was admitted to the Qādirīyah and other Ṣūfī orders.

In about 1774–75 Usman began his active life as a teacher, and for the next 12 years combined study with peripatetic teaching and preaching in Kebbi and Gobir, followed by a further five years in Zamfara. During this latter period, though committed in principle to avoiding the courts of kings, he visited the sultan of Gobir, Bawa, from whom he won important concessions for the local Muslim community (including his own freedom to propagate Islām), and also appears to have taught the future sultan, Yunfa.

Throughout the 1780s and '90s the Shaykh's reputation was increasing, as were the size and importance of the community that looked to him for religious and political leadership. Particularly closely associated with him were his younger brother, Abdullahi, one of his first pupils, and his son, Muhammad Bello, both distinguished teachers and writers. But his own scholarly clan was slow to come over to him. Significant support seems to have come from the Hausa peasantry. Their economic and social grievances and experience of oppression under the existing dynasties stimulated millenarian hopes and led them to identify him with the Mahdī (Divinely Guided One), whose appearance was expected at that time. Though he rejected this identification, he did share and encourage their expectations.

During the 1790s, when Usman seems to have lived continuously at Degel, a division was developing between his substantial community and the Gobir ruling dynasty. In about 1797–98 Sultan Nafata, who was aware that the Shaykh had permitted his community to be armed and who no doubt feared that it was acquiring the characteristics of a state within the state, reversed the liberal policy he had adopted toward Usman 10 years earlier and issued his historic proclamation forbidding any but the Shaykh to preach, forbidding the conversion of sons from the religion of their fathers, and proscribing the use of turbans and veils.

In 1802 Yunfa succeeded Nafata as sultan, but, whatever previous ties he may have had with the Shaykh, these did not bring about any improvement in the situation. The breakdown, when it eventually occurred, turned on a confused incident in which some of the Shaykh's supporters forcibly freed Muslim prisoners taken by a Gobir military expedition. Usman, who seems to have wished to avoid a final breach, nevertheless agreed that Degel was threatened and, like the Prophet Muḥammad, whose biography, he frequently noted, had close parallels with his own, carried out a *hijrah* (migration) to Gudu, 30 miles to the northwest, in February 1804. Shortly afterward, despite his own apparent reluctance, he was elected *imām* (leader) of the community, and the new caliphate was formally established.

Elected imām

During the next five years the Shaykh's primary interests were necessarily the conduct of the *jihād* (holy war) and the organization of the caliphate. He did not himself take part in military expeditions, but appointed commanders, encouraged the army, handled diplomatic questions, and wrote widely on problems relating to the *jihād* and its theoretical justification.

On this his basic position was clear and rigorous: the Sultan of Gobir had attacked the Muslims; therefore he was an unbeliever and as such must be fought; and anyone helping an unbeliever was also an unbeliever. (This last proposition was later used to justify the conflict with Bornu.)

As regards the structure of the caliphate, the Shaykh attempted to establish an essentially simple, non-exploitative system. His views are stated in his important treatise *Bayān wujūb al-hijra* (November 1806) and elsewhere: the central bureaucracy should be limited to a loyal and honest vizier, judges, a chief of police, and a collector of taxes; local administration should be in the hands of governors (amirs), selected from the scholarly class for their learning, piety, integrity, and sense of justice.

Initially the military situation was far from favourable. Food supplies were a continuing problem; the requisitioning of local food antagonized the peasantry; increasing dependence on the great Fulani clan leaders,

who alone could put substantial forces into the field, alienated the non-Fulani. At the Battle of Tsuntua in December 1804, the Shaykh's forces suffered a major defeat and were said to have lost 2,000 men, of whom 200 knew the Qur'ān by heart. But, after a successful campaign against Kebbi in the spring of 1805, they established a permanent base at Gwandu in the west. By 1805–06 the Shaykh's caliphal authority was recognized by leaders of the Muslim communities in Katsina, Kano, Daura, and Zamfara. When Alkalawa, the Gobir capital, finally fell at the fourth assault on October 1808, the main military objectives of the *jihād* had been achieved.

Return to private life

Although the *jihād* had succeeded, Usman believed the original objectives of the reforming movement had been largely lost sight of. This no doubt encouraged his withdrawal into private life. In 1809–10 Bello moved to Sokoto, making it his headquarters, and built a home for his father nearby at Sifawa, where he lived in his customary simple style, surrounded by 300 students. In 1812 the administration of the caliphate was reorganized, the Shaykh's two principal viziers, Abdullahi and Bello, taking responsibility for the western and eastern sectors, respectively. The Shaykh, though remaining formally caliph, was thus left free to return to his main preoccupations, teaching and writing. His five years at Sifawa were a productive period, to judge from the number of dated works that survive, most of them dealing with the practical problems of the community, including the series of books addressed to "the Brethren" (al-Ikhwān), arising out of the dispute with Bornu and its principal administrator and ideologist, Muḥammad al-Kanemi. At his weekly meetings on Thursday nights, he criticized aspects of the post-*jihād* caliphate (as indeed did Abdullahi and Bello), especially the tendency of the new bureaucracy and its hangers-on to become another oppressive ruling class. Around 1815 he moved to Sokoto, when Bello built him a house in the western suburbs, and where he died, aged 62, in 1817.

Serious study in English of Usman and the immense body of his writings has only recently begun. Much work remains to be done on his personal life and its relation to his public activities (his wife, 'Ā'isha, was a famous Ṣūfī, and his daughter, Asmā', a distinguished poet), on the range and quality of his scholarship, and on the various intellectual influences that were important for him, and on the relation of his movement to the whole radical and reforming tradition in the Sudan, as well as to currents of reform elsewhere. There is also much that needs to be known about the forces that stimulated the growth of the reforming movement, the extent of participation in it of various social groups at various phases of its history, and Usman's position in relation to these groups and their ideas.

Utah

A Rocky Mountain state of the United States, Utah became the 45th member of the Union in 1896 after decades of failure to attain statehood. In its earlier history, Utah represents a unique episode in American settlement, a story of a religious group that trekked and was driven across three-quarters of the continent in search of a "promised land." The state capital, Salt Lake City, is the world headquarters of the Church of Jesus Christ of Latter-day Saints, commonly known as Mormon, and the spiritual home of adherents throughout the world. With Mormons making up some 70 percent of the state's population of nearly 1,060,000 counted in the 1970 census, the beliefs and traditions of the Mormon Church continue to exert profound influences on many facets of the state's life and institutions.

Overview of the state

From the very beginning of settlement in 1847, the Mormon pioneers set about wresting a green land from the deserts, gradually supplementing their crops with the products of industry and the earth. The Utah of the 1970s was based on an economy in which manufacturing, tourism, and services were superimposed upon an earlier economic base of agriculture and mining. Although the state is generally conservative in political ideology, the two major parties are relatively well balanced.

Mountains, high plateaus, and deserts form most of Utah's landscapes, which show off many of the most spectacular geological phenomena on the North American continent. The state's 84,916 square miles (219,931 square kilometres) lie in the heart of the West, with Idaho to the north, Wyoming to the northeast, Colorado to the east, Arizona to the south, and Nevada to the west. At its "Four Corners," in the southeast, Utah meets Colorado, New Mexico, and Arizona at right angles, the only such meeting of states in the nation. For information on related topics, see UNITED STATES; UNITED STATES, HISTORY OF THE; NORTH AMERICA; GREAT SALT LAKE; NORTH AMERICAN DESERT; and ROCKY MOUNTAINS.

THE HISTORY OF UTAH

Prehistory and white exploration. As early as 10,000 BC, small, mobile groups of hunters and gatherers lived in caves by the great inland sea, prehistoric Lake Bonneville. This desert culture was replaced about AD 400 by the more advanced Pueblo, or Anasazi, culture, which came into Utah from the Southwest and Mexico. These Basket Makers constructed superb communal cliff apartments and raised corn, squash, and beans. They left Utah about 1250, perhaps because of an extended drought.

Early inhabitants and cultures

When white explorers and settlers came to Utah in the 18th and 19th centuries they encountered Shoshonean Indians—the Southern Paiute, Gosiute, and Ute (from whom the state takes its name)—practicing a desert culture like that of the earliest period. Some of them raised corn and pumpkins by a simple system of irrigation. Ute Indians in eastern Utah lived in a region of higher rainfall and had a better way of life. Having acquired horses from Plains Indians, their nomadic life centred around the buffalo.

After two Franciscan fathers, Francisco Atanasio Domínguez and Silvestre Vélez de Escalante, explored Utah in 1776, Utah was visited by occasional Spanish trading parties. Fur trappers and overland immigrants to California and Oregon were in the region in the 1820s and '30s. The first four of some 16 annual rendezvous between trappers and buyers were held in Utah from 1825 to 1828, indicating the early importance of the area to the industry. The "mountain men" who explored and established trading posts included James Bridger, who discovered Great Salt Lake in 1824, and Jedediah Smith, who first traversed the state from north to south and west to east in 1826–27. Explorers sent by the government included John C. Frémont, who led scientific expeditions to northern Utah in 1843 and the western Great Salt Lake area in 1845.

Mormon settlement and territorial growth. The period of settlement and territorial status is notable for the ending of the long quest (1845–47) for a Mormon homeland, wresting a civilization from an arid environment, the contest for sovereignty between Utah and the United States, and the conflict with indigenous Indians over the use of the land. Founded in Fayette, New York, in 1830, the Church of Jesus Christ of Latter-day Saints from the beginning had gathered its members together in religious,

social, and economic cooperation. In Kirtland, Ohio; Jackson County, Missouri; and Nauvoo, Illinois, the Mormons had grown rapidly, but wary neighbours eventually forced their removal from each such gathering place. From Nauvoo, which the Mormons had built up from Mississippi River swampland into a prosperous community, some 16,000 Mormons escaped violent mobs in 1846 by fleeing across Iowa to Council Bluffs. When wagonloads of Mormon pioneers under the leadership of Brigham Young first entered the valley of the Great Salt Lake in 1847, they were determined to transform the arid valley land into a green and wholesome "Kingdom of God." They succeeded.

From Salt Lake City settlers were directed to colonize in all directions until they had developed a prosperous and stable economy and political structure in a territory that was originally 210,000 square miles in area, stretching from the Rockies to the Sierra Nevada and from the Columbia River in Oregon to the Gila in Arizona. Immigrant converts continued to stream into Utah from Europe and the eastern United States; they were organized into colonizing parties based upon allocations of skills and leadership abilities and sent out to build the territory. By 1860 more than 150 self-sustaining communities with 40,000 inhabitants had been established, producing crops by means of water from mountain streams carried through canals to the alluvial valley lands. Utah's place in the national scene was symbolized by the driving of the golden spike at Promontory in 1869, uniting the eastward- and westward-reaching lines of America's first transcontinental railroad.

Conflict with the Indians was held to a minimum because of the Mormon view that it was cheaper to feed than to fight them. As the presence of the colonizers became more and more ubiquitous, however, some local Indians began to raid the settlements to obtain food. The Utes were eventually placed on a reservation in the Uinta Basin, the Southern Paiutes and Shoshoni on smaller reservations, and later the lands south of the San Juan River were incorporated into a Navajo reservation.

Mormons' federal conflicts

The propensity of the Mormons to establish their own political and social system and the incompetency of federal territorial officials led to an era of conflict with the federal government. In 1857, Pres. James Buchanan, believing the Mormons to be in a state of open rebellion, ordered some 2,500 soldiers to Utah to replace Young, who had served as governor during the early years. This episode is referred to as the Utah War, although no clashes occurred. With the outbreak of the Civil War in 1861, a new camp was established east of Salt Lake City under the command of Colonel Patrick Connor. Connor openly supported his troops in prospecting for minerals and sought to "solve the Mormon problem" by initiating a miners' rush to Utah. A substantial enclave of non-Mormon miners, freighters, bankers, and businessmen was the result, and three decades of Mormon versus non-Mormon conflict characterized the political scene until Utah attained statehood in 1896.

Toward and into statehood. The Mormon settlers applied for statehood in 1849 under the name Deseret, a word from the sacred *Book of Mormon* meaning "honeybee" and signifying industry. This bid was rejected, as were the efforts of five subsequent constitutional conventions between 1856 and 1887. Before Congress and the national administration would assent to statehood for Utah, Mormon leaders were required to discontinue the church's involvement in politics through its People's Party, withdraw from an economic policy in which Mormons dealt primarily with each other, and discontinue the practice of polygamy.

After its acceptance into the union in 1896, Utah moved rapidly into the larger social, political, and economic mainstreams of the nation. The political structure changed from theocracy to a conventional democracy: non-Mormons, including three governors, were elected to important positions. The Mormon Church has been officially neutral in politics in recent decades, and the influence of economic blocs—manufacturing and mining corporations, public utilities, stockmen, educators, and labour—has become far more important. The initial equal political division among Republicans and Democrats in the early 1890s is still reflected in the current political balance, though the state has tended to be Republican since World War II.

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Physiographic regions.* The Colorado Plateau comprises a little over half of Utah. Relatively high in elevation, this region is cut by brilliantly coloured canyons. Utah's growing tourist industry relies upon the attraction of the region's fiery, intricately sculptured natural bridges, arches, and other masterpieces of erosion.

Desert and mountain landscapes

The western third of the state is part of the Basin and Range Province (*q.v.*), or Great Basin, a broad, flat, desert-like area with occasional mountain peaks. Great Salt Lake lies in the northeastern part of the region; to the southwest is the Great Salt Lake Desert, some 4,000 square miles, which include the Bonneville Salt Flats, famous for land speed racing. During the Pleistocene Epoch, from 2,500,000 to 10,000 years ago, the huge freshwater Lake Bonneville here covered an area as large as present Lake Michigan. The Great Salt Lake and saline Sevier Dry Lake are the remnants of evaporation.

The Middle Rockies in the northeast comprise the Uinta Mountains, the only major mountain range in the United States running in an east–west direction, and the Wasatch Range. Along the latter run the series of valleys and plateaus known as the Wasatch Front. The Wasatch Range area and the red deserts of the east and gray deserts of the west make up more than 90 percent of Utah.

Altitudes range from 13,528 feet (4,123 metres) at Kings Peak in the Uintas to about 2,000 feet in the southwestern corner of the state. The Oquirrh and Deep Creek ranges of the Great Basin are important for their deposits of copper, gold, lead, and zinc.

Climate. Utah's geographical location in relation to the mountain systems of the West, which divert much of the precipitation, makes it basically an arid state. Anomalous southwestern Utah, which has a warm, almost semitropical climate, is referred to as Utah's "Dixie." The southern part of the Colorado Plateau experiences cool, dry winters with summer precipitation and frequent thunderstorms. Northern Utah is affected by air masses from the North Pacific and continental polar air; it receives most of its precipitation in the cool season.

The state experiences four distinct seasons. Average temperatures in July range from 65° to 80° F (18° to 27° C). In winter the state average is slightly below freezing except in "Dixie." Daily temperatures vary widely: when Salt Lake City has July highs of 90° F (32° C) or above, the nights are 55° to 65° F (13° to 18° C). Relatively low humidity prevails; average precipitation is 12 inches a year, varying from less than five inches annually over the Great Salt Lake Desert to 50 inches in the Wasatch Mountains. General average snowfall received is 54 inches a year, ranging from none in the southwestern valleys to more than ten feet at ski resorts. Average growing seasons are 128 days.

Soils and waters. The desert soil that covers most of the state lacks many organic materials but contains adequate lime. Lack of adequate drainage in the Great Basin has damaged surrounding soils with saline materials and alkali salts. The richest soils are in the old Lake Bonneville area, along the delta deposits of the Wasatch Front. Most farming is done in these alluvial soils. Mountain soils provide a rich habitat for conifers and other trees.

Utah contributes to three major drainage areas, the Colorado and Columbia rivers and the Great Basin. The Colorado and its tributary, the Green, drain eastern Utah. The Upper Colorado River Storage Project includes several dams and many lakes in that area. Great Basin rivers include the Bear, Weber, Provo, Jordan, and Sevier, all of which are landlocked. All the river systems are important for their irrigation and power potential.

Vegetation and animal life. Utah's 4,000 plant species represent six climatic zones, from the semitropical Lower

Sonoran in the southwestern Virgin Valley to the Arctic on mountain peaks. In the south are found creosote bush, mesquite, cactus, yucca, and Joshua tree; the alkaline deserts are the habitat of shad scale, saltbush, and greasewood. Juniper and sagebrush grow in the foothills and mountain valleys, as do piñon pine, cedar, and native grasses for grazing. In the mountains grow pines, firs, aspen, and blue spruce. Timber covers about 15,000,000 acres, but only about one-fourth of the forest land is commercially valuable.

The mule deer is the most common of Utah's large animals since elk, bison, timber wolves, and grizzly bears have largely disappeared. Coyotes, bobcats, and lynxes are hunted. Game birds include grouse, quail, and pheasants; golden eagles, hawks, owls, and magpies are numerous. Great Salt Lake bird refuges are the home of sea gulls, blue herons, and white pelicans. Certain species of game fish are native, while others have been introduced. Reptiles and amphibians, both poisonous and nonpoisonous, are native.

Human settlement and land use. In Utah's 29 counties, 66 percent of the land is federally owned, and 7 percent is owned by the state. About 4 percent of federal land is reserved for Indian use.

The Wasatch Front, extending north–south from Ogden to Provo and including also Salt Lake City, is the main area of urban and industrial development. With a 1970 population of nearly 176,000, Salt Lake City is the political, cultural, and religious capital of Utah. Historically a trade centre, it continues to be an ideal hub for industry, commerce, and interstate transportation.

The front also has not only the largest part of the population but also the best farmland in the state. Although over 60,000 acres of cropland have been urbanized since 1958 and an urban trend continues, a rural society is still observable. Rural settlements typically have a "Mormon village" flavour, with a readily recognizable Mormon chapel or tabernacle within the town, wide streets, and a cultivated area surrounding the town itself.

Irrigation, pollution control, and conservation

Irrigation was among the first Mormon pioneer efforts in 1847, and since then irrigation and water conservation have become increasingly important. The irrigation complex in Utah as of 1970 comprised a vast number of diversion dams, multipurpose dams, storage reservoirs, canals and ditches, pipelines, and flowing wells, exclusive of the large Glen Canyon and Flaming Gorge dams. In 1969 more than 1,000,000 acres of cropland were irrigated. State boards and departments regulate water use, while the division of health maintains quality water standards under the Water Pollution Control Act of 1953.

A state air-conservation program was begun in 1967, with special attention to the Wasatch Front. Other programs of federal, state, or joint jurisdiction include watershed management and conservation, protection of wildlife resources, conservation of oil and gas reserves, and reclamation.

THE PEOPLE OF UTAH

Racial composition. In 1970, the population was about 97 percent white, mainly of northern European ancestry, with slightly more than 1 percent (11,300) Indians and less than 2 percent Oriental, blacks, and other groups. In numbers, the nonwhite population rose from 16,700 in 1960 to 27,350 in 1970, but Utah remained essentially unchanged in its small percentage of nonwhites. The population of San Juan County, however, is about one-half Indian, containing some 42 percent of Utah's Indians.

Remnant Indian cultural activities

The Navajo, famous for their wool blankets, silverwork, and turquoise jewelry, reside primarily in the Four Corners region. About 1,500 Utes live on the Uintah and Ouray Indian Reservation. Having received a large settlement from the federal government for their lands, they have built new homes with modern conveniences. Annually sponsored events include the Bear Dance in the spring, the Sun Dance in July, and the Uinta Basin Industrial Fair in August or September. About 200 Southern Paiutes, among the most depressed of the tribes, live on six small reservations in southern Utah. Except for American Indians, nearly all of the minority racial population was in the three Wasatch Front counties of Salt Lake, Davis, and Weber.

One minority group included within the white statistics is that of about 25,000 Mexican-Americans. Increasing attention is being paid to the problems of educating and acculturating this group, many of whom are low-income workers in agriculture, mining, manufacturing, and the service trades.

Contemporary demography. The 1970 census revealed statistics in Utah that were similar to those in the country as a whole. In numbers, preschool children had declined during the 1960s, while persons over 65 increased. Birth rates and death rates declined, though the former remained well above, the latter well below, the national averages. For the most part, those counties with the highest growth rates over the decade (in the Wasatch Front) also had the highest ratio of young persons to old persons, suggesting that young people, unmarried or married, were migrating and leaving older persons in the rural counties, mainly in the central and southern portions of the state. Though Salt Lake City lost population, its surrounding county grew by 20 percent. About 70 percent of the population lived in communities of 2,500 or more, a finding conditioned somewhat by the fact that the historic pattern of Mormon life has been for people to live in compact towns or villages and to farm outlying areas. More than three-quarters of the population lived in the three front counties plus Utah County.

THE STATE'S ECONOMY

From 1847 to 1868 the Mormons, with a high degree of mutual cooperation, built a self-sufficient economy based on agriculture, handicraft, and small industry. From 1869 to 1896 this cooperative economy was supplemented by a non-Mormon enclave devoted to mining and trading. After statehood, the exportable resources of the state were exploited to an increasing extent by outside corporations and enterprisers, and the agriculture of the state turned toward such commercial crops as sugar beets, wool, and range cattle. The depressions of 1921 and 1933 were severe, but federal programs and the welfare program of the Mormon Church helped the state to recover. During World War II, several defense plants and air bases were built, and Utah had a uranium boom, followed in the late 1950s by the erection of several large plants to build rocket engines for missiles.

The state's economy emerged in the 1970s with strong diversification. The large agricultural and mining sectors were supplemented by light and heavy manufacturing, finance, transportation, and tourism. Salt Lake City is a regional centre of finance and trade, and many large enterprises have offices there. Utah workers, in the Mormon tradition, have the reputation of being industrious and well disciplined, and the productivity per man-hour is high. With the many summer and winter recreational opportunities, Utah was well above average as a desirable place to work.

Components of the economy. About 38 of Utah's more than 200 minerals are mined commercially, and in 1970 it ranked 15th nationally in mineral production. About one-fifth of the nation's new copper is produced annually in Utah, accounting for more than one-half of the value of its mineral production. Utah is the nation's largest producer of beryllium ore and ranks in the top four states as a producer of gold, silver, lead, and molybdenum. Heretofore, salt was once the only mineral extracted in quantity from the Great Salt Lake, but plants were being built in the early 1970s to extract magnesium and other minerals. When these plants are completed, Utah will have one-fourth of the nation's magnesium-production capacity.

Mineral reserves and sources of income

Utah is a major producer of coal west of the Mississippi, with estimated reserves exceeding 115,000,000,000 tons. Petroleum has replaced coal as the leading mineral fuel, however, with reserves estimated at 410,000,000 barrels. Utah is the only state producing Gilsonite, a source of road oil, paving binder, and asphalt tile. In addition to steam plants, Utah has many hydroelectric plants.

Personal income in Utah rose more than 70 percent during the 1960s and early 1970s, but per capita income was about 18 percent below the national average and 25 percent below the average of the Western states. The large size of families in Utah, together with the low wage scales and the less significant role of trade unions in the state, help to explain this disparity. When personal income is computed on a per household basis, Utah fares better in national and regional comparisons.

State and federal government employment, increasing at a faster rate than any other sector of the economy, is the largest employer in Utah. The state remains below average, however, in the proportion of personal income derived from manufacturing: in 1970 only 12 percent, compared with 20 percent nationally. Food processing, transportation equipment, nonelectrical machinery, petroleum refining, and fabricated-metal products were, in that order, the major manufacturing sectors.

Following the national trend, farm employment in Utah has declined since 1960, but farm size and productivity have increased. In 1971, Utah ranked 40th among the 50 states in total farm receipts. Almost 85 percent of Utah's farm income comes from livestock products, the remainder from field crops, fruit, and canning crops.

Utah's present broadly based tax structure appears to distribute the costs of government without discrimination against, or hardship to, any segment of the economy. Present rate structures for the various taxes are generally competitive with those of neighbouring states. The corporate-income-tax rate is lower than that of any other Western state. Legislation providing for a phase-out of the state's inventory tax and a liberal free-port tax law granting tax exemptions on goods warehoused and processed in Utah are incentives to commerce.

Transportation. Utah's transportation industry, with easy access to all national markets, is the basis for the state's development as a major distribution centre for the West. More than 3,000 miles of rails cover the state, and the Amtrack passenger system includes Ogden. Road traffic is expanding rapidly; several interstate highways supplement the state system. In addition to the major airport serving Salt Lake City, excellent feeder line facilities exist in Ogden, Logan, Provo, Cedar City, and St. George.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional framework of the government

Structure of government. Utah's constitution, dating from 1896, guarantees basic personal freedoms consistent with the federal Bill of Rights, prohibits sectarian control of public schools, forbids "polygamous or plural marriages," and grants equal civil, political, and religious rights, including suffrage, to both male and female citizens. Voting requirements follow national patterns, though for elections affecting tax levies a voter must have paid a property tax the previous year.

Executive, legislative, and judicial branches. The governor is aided by a secretary of state, auditor, treasurer, and attorney general, while much of the administration of routine state affairs is done through more than 50 state agencies. Each of these officials serves a four-year term.

The governor has the right to veto any bill, but his decision may be overruled through repassage of that bill by a two-thirds majority of each house of the legislature. Any bill passed by the legislature and not acted upon by the governor within five days while the legislature is in session automatically becomes law. The governor, secretary of state, and the attorney general, together, form the State Board of Examiners, which reviews all official state transactions.

Legislative power is vested in the Senate and House of Representatives, as well as in the voters, who have the power to initiate legislation and to hold a referendum on all laws not passed by a two-thirds majority of both houses. After reapportionment in 1972, the legislature comprised 30 senators serving four-year terms and 75 representatives serving two-year terms.

The legislature meets annually, with regular 60-day sessions in odd-numbered years and 20-day budget sessions in even-numbered years. Special sessions may be held subject to call by the governor. Four full-time councils provide interim work on investigation and research of specific legislative and state problems, advice on budgetary matters and appropriation requests, with legal counselling and legislative accuracy, and legislative administration. In 1971, the legislature was rated by a nonpartisan committee reviewing all state legislatures as 15th in overall effectiveness, fifth in accountability to the citizenry, and eighth in being informed.

The highest judicial authority is the state Supreme Court, composed of five justices elected to ten-year terms, one every two years. Judges of the seven district courts are elected for six-year terms. There are also county and city courts and, in rural areas, justices of the peace. A juvenile court system has its own districts and judges.

Local government. The constitution requires that each county have a county-commission form of government comprising three commissioners and several other elected officials to carry out administrative, judicial, law enforcement, financial, and health, education, and welfare functions.

Forms of municipal government vary according to population. Cities with populations over 90,000—Salt Lake City only—elect a mayor and four commissioners. Cities between 15,000 and 90,000 elect a mayor and two commissioners, while smaller cities elect a mayor and five councilmen. Incorporated towns are governed by a president and four trustees. Any city commission or town council has power to appoint a city manager.

Political life. Although Utah is referred to frequently as a Republican state, in actuality no party can claim dominance. Elected officials from both parties work well together and exhibit a reasonable degree of harmony. This has been true since the early 1890s, when the normally homogeneous Mormon populace was divided into political parties by church leaders to comply with federal requirements for statehood, a remarkably even division being achieved for the 1896 election by volunteers for each party. Nearly 80 percent of the state's eligible voters cast ballots in election years, far above the national average.

The social milieu. Although minority races are little noticed and politically insignificant in Utah, the state, county, and local governments have developed programs to improve the economic and social status of Indians, Mexican-Americans, blacks, and other groups.

Health, welfare, and housing

Public services. Health, welfare, and housing services are administered by the Department of Social Services. County health services are supervised and coordinated through the state Board of Health, which also works with school boards for child health care. Outstanding hospital systems are administered by the Mormon, Roman Catholic, and Episcopal churches.

The state administers a substantial welfare program, including comprehensive old-age assistance, unemployment insurance, workmen's compensation, and other social benefits. Efforts have been made to improve and upgrade outdated labour and hazardous-occupation laws. A division of low-income housing was created within the department of community affairs in 1971 to facilitate better planning and coordination in that area. The Mormon Church also has an extensive welfare program that provides assistance to many persons per year.

Education. More than one-half of Utah's governmental expenditure is for education. In recent years Utah has had the highest proportion of its population in public schools, the highest proportion of high school graduates, and the highest medial level of school years completed of any state in the nation.

The school districts are allowed to levy local taxes to support public education; these pay for almost one-half of educational expenses, the remainder paid by the state. General public school regulations are administered by the State Board of Education, while elected local boards exercise more specific control. The U.S. Department of the Interior maintains the Intermountain Indian School in Brigham City, a secondary school for Navajo Indians of Utah and neighbouring states.

Higher education

The largest of Utah's state universities is the University of Utah, in Salt Lake City. Founded in 1850 as the University of Deseret, it enjoys a reputation for outstanding graduate and professional schools of medicine, law, and pharmacology. Utah State University, in Logan, founded in 1888 as a land-grant school, has achieved national status in the fields of agriculture, forestry, education, engineering science, and the fine arts. Brigham Young University, in Provo, is owned and operated by the Mormon Church. The largest of Utah's universities, it has a campus that is among the most beautiful in the Western states. More than 500 Indians attend the university, the largest number in any institution of higher learning in the United States.

Weber State College (1889), in Ogden, is a four-year school with rapidly expanding programs and facilities. Technical schools are located in Salt Lake City and Provo, while Westminster College (1875), in Salt Lake City, is operated by three Protestant denominations.

CULTURAL LIFE AND INSTITUTIONS

Impact of Mormonism on the cultural milieu

With more than two-thirds of the population adherents of the Mormon Church, that institution has a strong influence on the state's cultural life and traditions. The church is divided into "stakes," consisting of six to ten local congregations, or "wards," of about 500 members each. Each stake has a "tabernacle," or stake centre, with one or more chapels and recreational and cultural facilities. Each ward, or occasionally two or three wards together, owns a chapel with a centre for collective worship, classrooms, basketball court, and dance hall. Mormon culture emphasizes close-knit family life, widespread interest in family genealogy, no consumption of alcoholic beverages and tobacco, relatively small amount of "night life," and participation in sports and personal-development programs. Other denominations also are active in cultural areas. Particularly notable is the annual three-week-long St. Marks Arts Festival, which includes music, dance, poetry reading, drama, and other creative arts.

The large number of Indians gives a unique flavour to Utah life. About 4,000 Indian children are taken into Mormon homes during the school year, putting Indian pupils into nearly every grade school classroom. They are active in sports, public speaking, and school government, and almost every block has a family with an Indian foster child. In the summer, these children return to their families.

Sports and outdoor life. Salt Lake City has professional basketball, hockey, and baseball teams, and auto racing on the Bonneville Salt Flats has gained international importance. The Mormon Church sponsors competitive team sports involving thousands of players and one of the largest basketball, softball, and golf tournaments in the nation.

Utah's nine national forests and other undeveloped areas offer great tracts of land for hunting, fishing, camping, hiking, skiing, and snowmobiling. Among the other natural attractions are five national parks (Arches, Bryce Canyon, Capitol Reef, Zion, and Canyonlands), with two more planned for the future; six national monuments (Cedar Breaks, Dinosaur, Natural Bridges, Timpanogos Cave, Rainbow Bridge, and Hovenweep); two national recreation areas (Flaming Gorge and Glen Canyon); and the Golden Spike National Historic Site. There are 43 state parks, including the Pioneer Monument State Park at Salt Lake City.

Historical institutions and celebrations. The Utah State Historical Society has an outstanding collection of manuscripts, publications, and photographs. It publishes the *Utah Historical Quarterly*, monographs, and full-volume diaries. The Daughters of Utah Pioneers and their counterpart, the National Society of the Sons of Utah Pioneers, with 1,000 branches throughout the nation, maintain monuments, preserve old landmarks, mark historical sites, collect relics and histories, establish a library of historical matter, and secure unprinted manuscripts, photographs, maps, and data to clarify the truth about Utah pioneers. Their 38-room museum depicts pioneer implements and way of life. *The Western Historical Quarterly*, official organ of the Western History Association, is published by Utah State University.

Park City and Pioneer Village in Salt Lake City are Old West towns using the original buildings and furnishings. Every county holds a fair in the autumn, highlighted by displays and competitions, concessions, and often a rodeo.

On July 24, nearly all communities hold Pioneer Day, commemorating the entrance of the Mormon pioneers into the Salt Lake Valley. It includes parades, fireworks, rodeos, orations, and colourful reminders of Utah's early settlers.

The arts. The Division of Fine Arts is a department of state government whose purpose is to promote all branches of the fine arts and to cooperate with the federal government in these matters. It sponsors the Utah Governor's Conference on the Arts, and it allocates funds advanced to the state by federal agencies to finance cultural activities.

The buildings of Utah are rarely beautiful, and few show individuality in design. The most famous buildings are the many-spired Mormon Temple and the turtleback Mormon Tabernacle, both in Salt Lake City. The latter was built in the 1860s without nails, holds up to 10,000 persons, and has rare acoustical qualities to enrich the sounds of its world-famous organ with 10,700 pipes. Mormon temples in St. George, Manti, Provo, Ogden, and Logan reflect architectural magnificence. Homes reflect the usual sequence of styles in American domestic architecture.

Music, dance, and theatre

Among the performing arts, music is emphasized. The Mormon Tabernacle Choir, consisting of 375 persons with trained but nonprofessional voices, presents a national weekly radio and television broadcast; gives concerts in the United States and abroad; and records with a major company. The Utah Symphony Orchestra and the Salt Lake Oratorio Society are other major ensembles. Annual tourist-oriented performances include the Mormon musicals *Promised Valley*, presented for 50 performances in July and August, and *All Faces West*, presented in Ogden in July. The major universities have symphonies and choral groups performing in winter, as well as summer festivals and concerts.

The Repertory Dance Theatre, organized in 1967, is the only professional modern-dance company in the West. The University of Utah Children's Dance Theatre has performed on the East and West coasts as well as in Utah schools. The Brigham Young University folk-dance troupes, founded in 1956, have toured the United States and most parts of the world. Salt Lake City's Ballet West is ranked among the best in the nation.

Utah gained an early start in drama with the opening of the Salt Lake Theater in 1862. A replica has been constructed on the University of Utah campus, and performances are held there regularly. The Mormon Church emphasizes folk drama in its youth organization; more than 2,000 wards produce at least one play a year, many of them written locally. These culminate biennially in a large drama festival in Salt Lake City. An annual event that is gaining national fame and reputation is the Utah Shakespearean Festival, held since 1960 in Cedar City. Brigham Young University Motion Picture Productions centres on topics of Mormon Church interest.

Communications media. The state has 54 weekly newspapers, while five dailies are published in the northern cities. The most influential are the *Salt Lake Tribune* and the *Desert News*, both published in Salt Lake City. Utah has three commercial-television channels as well as educational stations at the three universities.

Prospects. Having survived over a long history of conflict, the Mormon and non-Mormon residents of Utah live in an atmosphere of harmony and goodwill. The state government is generally trusted by the people and rates high in terms of efficiency and concern. Though balanced economically, Utah still lacks the light manufacturing industry essential to further growth. Its location in the centre of the mountain West makes it a present and potentially increasing hub of transportation, commerce, and finance. Such untapped minerals as the oil shale in eastern Utah offer other portents of growth.

Cradled by stately mountain ranges and nourished by wilderness areas and recreational parks, the state enjoys a delightful and healthy environment. Less troubled and perplexed than most states, Utah will almost certainly find its population swelled by vacationers and former residents who come back to stay.
