Crete still played a part in the transfer of various cultural forms from the Near East to Greece: a Cretan variation of the Orientalizing phase of Aegean art is known as Daedalic (about 700-600 BC). During Athens' heyday, Crete fascinated Greeks as a source of myths, legends, and laws. Eventually, the Romans appeared and by 67 BC had completed their conquest of Crete, converting it into Cyrenica, a province linked with North Africa; after their empire had been divided, Crete passed to Byzantium (the Eastern Roman Empire) in AD 395. Christianity, traditionally introduced by St. Paul, who was driven ashore on Crete around AD 47, gathered momentum under the Apostle's appointee, Bishop Titus, but the island later subsided into the Dark Ages. After 824, a group of Arabs controlled at least parts of Crete, but Christianity triumphed in 961 under Nicephorus Phocas, subsequently a Byzantine emperor.

In the aftermath of the Fourth Crusade, which turned aside to sack Constantinople, Crete was sold to the Venetians in 1204; they called both the island and its main city Candia and fitted Crete into their commercial empire. Native Cretans, however, never abandoned the Orthodox religion, the Greek language, and their popular lore. In 1648 the Ottoman Turks, already possessing parts of Crete, began attempts to take Candia. After one of the longest sieges in history, Candia, and with it Crete, fell to the Turks in 1669. With the economy stagnant and many Cretans perforce nominal Muslims, native culture nevertheless survived. But uprisings were always frustrated, including the one that accompanied the Greek revolution of 1821 and another of 1866, which involved an explosion and massacre at Arkadhi, a monastery in central Crete, the symbol ever since of the island's motto, "Freedom or Death!" The Turks were finally ejected in 1898, and the island was granted autonomous status under a high commissioner, Prince George, the younger son of the King of Greece. But nothing short of union with Greece would satisfy many Cretans. Among them was Eleuthérios Venizélos, the tempestuous, Cretan-born politician who eventually forced Prince George out; and in 1913, as Greek premier, he presided over the official union of Crete with Greece.

Since then, Crete has shared most of Greece's history. Nevertheless, a unique moment came in 1941 during World War II when the Greek government, along with British, Commonwealth, and some Greek troops, were forced by the advancing Germans to retreat from mainland Greece to Crete. Shortly thereafter, on May 20, the Germans launched history's first—and still the only successful—purely airborne invasion, putting down all organized resistance within ten days. Most of the Allied forces were evacuated from the southern coast, but the Cretans were left to another occupation till the last German troops surrendered in May 1945. Postwar Crete made a slow recovery. Since the 1950s it has benefitted from growing international commerce, though its basic social and political patterns yield less readily to change.

**The landscape.** *Natural topography.* Crete is dominated by harsh mountains rising out of the sea, stark evidence of its geological origins, for the island is a remnant of a block thrown up in Tertiary times (2,500,000

to 65,000,000 years ago). Much of Crete's 650 miles of rocky coastline slopes down from the major mountains of Crete's east-west axis, a spine that breaks naturally into four main groups: the westernmost Lévka Óri (White Mountains); the central fdhi (or Psilorítis) Mountains, with Crete's highest point, the summit of Mt. fdhi, Stavros, 8,058 feet (2,456 metres) high; the east central Dhikti (or Lasíthi) Mountains; and the far eastern Thrifti Mountains. Another range, the Asterousia (or Kófinos) Mountains, runs along the south central coast between the Mesará Plain and the Libyan Sea (Libikon Pélagos). The more gradual slope of the northern coast provides several natural harbours as well as coastal plains, where major cities have grown up: Khaniá, Réthimnon, and Iráklion (the Candia of history). The major flatland, however, is the Mesarh Plain, which extends along the south central region for about 18 miles, averaging three miles wide. Also, on its northern side, Crete has several upland basins, including the Omalos in the Lévka Óri and the Nidha in the fdhi Mountains; the most notable is the Lasíthi Plain, an almost perfect stadium, measuring about 50 square miles ringed by mountains. Cretans have lived mostly on the edges of these plains to avoid seasonal flooding, while taking maximum advantage of the arable land.

**Soils and drainage.** Nomadic grazing occurs on 48 percent of Crete's total area, while 20 percent of the land is entirely unproductive. Over the centuries the islanders have so stripped the once thickly wooded slopes that the earth has eroded, leaving largely bare limestone. As a result, the surface is so porous and honeycombed that much of the water goes underground. This accounts for the springs and the many merely seasonal watercourses. There are only about six rivers on Crete, including the Platanias (near Khaniá), the Milopótamos (north central region), the Anapodhárís (south central), and the Yeropótamos (in the Mesarh).

The soil is largely rocky, with little alluvium or loam; it lacks nitrogen and phosphorus, though potassium and calcium carbonate are plentiful. Crete also is marked with many fissures and ravines, such as the gorge of Samaria, which extends about 11 miles inland from the southwestern coast. There are also caves, the source of many mythological and historical episodes. One freshwater lake, Kournás, lies west of Réthimnon. The island experiences occasional earth tremors, but only two serious earthquakes have occurred in the last 100 years.

**Climate.** Crete's climate varies between temperate and tropical. The mountains are colder and wetter than the lowlands, and snow remains throughout winter above 1,600 feet and is almost permanent on the highest peaks. Annual rainfall averages about 25 inches, mostly from October to March. In the hot, dry summer, prevailing northeasterly sea breezes (the *meltemi*, or etesian winds) keep the coastal regions pleasant but cannot break the drought of the interior. A dusty haze often pervades the atmosphere, with occasional sirocco winds blasting in from the Sahara. But by late October eastward-moving cyclones passing to the north or south bring more variable and tempestuous winds, with rain at sea level and snow in the mountains.

Frost is practically unknown on the coast; the south shore enjoys a particularly mild winter, with an average January temperature at Iráklion of 54° F (12° C). In summer, Iráklion's daily maximum averages 84° F (29° C).

**Vegetation and animal life.** Despite its demanding climate and man's abuse of the land, Crete supports a varied vegetation. Characteristic Mediterranean scrub (maquis or garigue), unproductive but flowery, dominates the landscape. Something is usually blooming, be it phlomis (a type of mint), thorny broom, spurges (cactus-like plants), asphodel, thyme, heath (a type of evergreen shrub), burnet (a kind of herb), or rockrose (a local shrub). Generally, Crete's flora is similar to that of the Peloponnese and Asia Minor, but the island is also noted for several native species, including *Acer creticum*, a dense, spiny maple shrub, and *Berberis cretica*, a barberry (a red-berried shrub). The quince (*Cydonia ob-*

Post-Minoan developments

Limited surface-water resources

Crete's moment in World War II

longa) is said to be indigenous to Crete. Perhaps the most prized local plant species is the Cretan dittany; related to marjoram, it is a small, perennial, gray-green plant with ruddy-pink flowers and clings to rocky cliffs and sparse patches of soil.

Crete once nurtured valued cypress and cedar forests, which, as late as the 16th century, supplied wood for the Venetian fleet. Now only small clumps of wild cypress survive on the *Lévka Óri*, and only about 2 percent of the total land area bears such trees as Aleppo pine, ilex, holm oak, chestnut, and plane trees. Olives, carobs (evergreens whose pods have a sweetish pulp), and orange trees are cultivated, along with several curiosities such as almond trees, wild palm, bananas, and the black mulberry.

The Cretan wild goat

The most spectacular of Crete's fauna is known as the *agrimi* ("the wild one"), a wild goat (*Capra aegagrus*) related to the ibexes that range across Asia Minor and down into Iran and Pakistan. This wild goat was hunted down to the 20th century but became nearly extinct and was confined to the gorge of Samaria; now three offshore islets serve as natural preserves. The smaller animals and birds are the ones usual in such an environment. There are no poisonous snakes, credit for which is traditionally awarded to St. Titus. The surrounding sea yields shellfish, squid, sponges, and edible fishes such as red mullet, surprisingly underexploited.

Traditional regions. Crete has contained varied lifestyles. *Réthimnon* is the "intellectuals' city"; *Anóyia* retains distinctive popular traditions. Perhaps the most special "pocket" of all, *Sfakákia*, the southwesterly region isolated by mountains, has a particular heritage of independence, boasting men taller and stronger than other Cretans. In any case, Crete divides traditionally into two regions: coast and mountain. This split is accentuated by the fact that coastal dwellers live mostly along the northern shore. The basic modern difference, however, is between those dependent on the land and those engaged in urban pursuits.

Land use. Only about 30 percent of Crete's total area can be actively cultivated. There are some regional specialties—citrus fruits in the west, carob trees in the east, for instance—but farming patterns are similar throughout the island: small patches of land, cultivated with little use of machinery, and women helping in the fields, some land still irrigated by hand-operated wells, though draft animals, gasoline pumps, and windmills are taking over that task. An exception is the Mesarb Plain; it is relatively well watered and one of the few parts of Crete that lends itself to modern agricultural practices, where large machinery is increasingly employed. Two deeply embedded traditions have hindered agricultural development: one is the Cretan preference for living together in villages, which incurs long journeys to the fields; the other is the splitting up of land in legacies, so that tiny lots are walled in stone and individual ownership of the small plots is commonly quite scattered.

Urban settlement. The eight or nine largest cities on the northern coast account for a third of the island's population, yet most of them are overgrown villages. *Iráklion* and *Khaniá* are the two exceptions, with almost one-quarter of Crete's population. *Iráklion* has become quite cosmopolitan, with tourists, hotels, restaurants, shops, and similar enterprises. Its broad streets, cafés, cinemas, museum, and market make it most lively, while the port is also bustling. Modern problems such as traffic congestion, pollution, and urban blight are also appearing on the heels of haphazard civic growth. *Khaniá*, half the size of *Iráklion*, is correspondingly more provincial.

City life in Iráklion

**The people.** Although claims have been made that Cretans are taller than other Greeks or have different head measurements, due to Dorian or other heritages, such differences are unverifiable. All Cretans speak Greek, albeit with variations of dialect, especially in rural or mountain areas.

**Religious affiliations.** Virtually all Cretans belong to a special branch of the Orthodox Church, directly responsible to the patriarchate of Constantinople. The archbishop of Crete has his seat in *Iráklion*, and most

Cretans are devout. There are a few Roman Catholics, but Crete's old Jewish population moved out long ago, as did the sizable Muslim Turkish community in the early 1920s as part of the population exchange between Greece and Turkey, when thousands of Greeks from Asia Minor were resettled on Crete.

**Demographic trends.** More and more Cretans share in such modern amenities as improved medical facilities, agricultural aids, communications and transport, and more are born with the chance to live longer, healthier lives. Crete's small population nevertheless is larger than the island can support. Along with a gradual flow of population to the larger towns, working class Cretans are leaving for mainland Greece or Europe, educated, ambitious youth are going to Athens or abroad, and families are emigrating to such traditional destinations as the United States and Australia.

**The economy.** Agriculture and natural resources. Most of the economy rests on agriculture: Crete is one of Greece's leading regions in the production of olives and olive oil, grapes (including seedless sultanas, raisins, and wine), citrus fruits, and the carob, or locust, bean, all exported mainly to Greece. For itself, Crete grows fresh vegetables, fruits, nuts (almonds and acorns), and some grains (barley and oats, but insufficient wheat). It also raises sheep and goats for meat, cheeses, wool, and hides. Fine as many of these products are, none carries much weight in modern commerce.

Major crops

Cretans also mine talc, lignite, and gypsum and even a little copper and iron. Deposits of lead, manganese, zinc, sulfur, gold, silver, tungsten, platinum, emery, graphite, tin, and magnetite have been discovered, but none in workable quantities. Crete is still further limited in its energy resources, for it has to import all its fuels.

Commerce and industry. Industry is largely confined to food processing (olive and grape presses), building materials (stone quarries and building blocks), and a few ceramics, textiles, soap, leather, and steel-tool enterprises. Most concerns are still run by their owners, employ only a few people, and are located along the northern coast. Some traditional handicrafts, such as weaving or embroidery, are done at home. The harbours, construction trades, transport, public services, and tourism also provide employment.

Crete has to import all but the most basic items, even building materials, fertilizers, and food. Increasingly consumer outlooks need higher incomes, but inflowing foreign and mainland capital must fight conservative ways, family-run enterprises, consolidation rather than expansion, and age-old distribution patterns. Tourism, however, has brought changes, with more large employers and some organization of labour.

Transport. Crete has no railways and no navigable rivers, but its road network is good. Private vehicles and commercial trucks are multiplying, but most Cretans still travel by bus. Olympic Airways flights link *Iráklion* with Athens and with Rhodes, and *Khaniá* with Athens; occasional charter flights also serve *Iráklion*. Small cargo ships and *caïques* (light skiffs) ply between Crete and other islands or ports, and there are almost daily ferries between *Khaniá* and *Iráklion* and Athens-Piraeus (and one ship weekly to Rhodes and to Thira); large merchantmen and liners frequently call, but mainly Crete remains tied to Athens.

**Administration.** Crete, itself an administrative region of Greece, consists of four prefectures (*nomoi*)—*Khaniá*, *Réthimnon*, *Iráklion*, and *Lasíthi*. Each has a somewhat powerless prefect (nomarch), appointed via Athens and responsible to the minister of the interior. *Khaniá*, the administrative capital, housing various government offices and the island's highest court of appeal, exercises little power. Crete is subdivided into 570 communities, administered by elected mayors or presidents and small councils with little authority. This want of power stems more from the general trend of state centralization than from any particular Athens government. Cretans—when given the choice—have taken the liberal, republican, antimonarchist side in Greek political life. In any case, physical remoteness from Athens and traditional skepti-

Nature of Cretan politics

cism about governments have always rendered local problems more pressing than mainland matters.

Notwithstanding, Crete has long provided disproportionately large numbers of government personnel, a result of the job shortage on the island. Military installations include a Greek army training school outside Iraklion and a large NATO naval base and a NATO anti-ballistic-missile training school around Souðha Bay, the large harbour near Khaniá. Educationally, Crete has nothing above lycée (gymnasium) or vocational school level, though every community provides some schooling. Similarly, health and welfare services deteriorate in remote districts, but doctors with some foreign study behind them are scattered throughout the island. With the only government representative in the villages a policeman, in most crises Cretans must rely on their own meagre family resources.

**Cultural life.** *The arts.* Perhaps the island's greatest resource is its popular culture. Crete also has attained respectable artistic "heights"—as during something of a renaissance that flowered from 1560 to 1660, when poems, plays, and paintings with a peculiarly Cretan tang were produced by Greek settlers from Constantinople or by Venetian-Cretans. Vitzéntzos Kornáros, born near Sitia, is credited with *Erotókritos*, a romantic epic that has become a national poem for some Greeks, and *The Sacrifice of Abraham*, a sturdy drama. Painting drew on the Byzantine tradition of Crete's churches. Some of the best artists went to paint in the monasteries of Mt. Áthos and the Meteora in Greece, although one late-16th-century artist who chose to work on Crete was Michael Damaskinos. The tradition's finest product was Doménikos Theotokópoulos, born on Crete in 1541. He studied and painted there until perhaps 1566, going on to Venice, Rome, Toledo, and universal fame as El Greco.

After a pause of some two centuries, Crete produced three notable writers, John Kondylakis, Pandelis Prevelakis, and the internationally known Nikos Kazantzakis. Two of Kazantzakis' finest works are specifically Cretan: *Freedom or Death*, a novel about one of the island's 19th-century revolts, and *Zorba the Greek*, whose hero has become the epitome of the Cretan spirit.

**The folk element.** Cretans are less attached to their ancient past than to Byzantine-Orthodox culture and their popular traditions: icons and sacred ground, name days and feast days, lore about spirits and vampires, legends about the centuries of struggle against foreign occupiers, *mantinades* (rhymed couplets in song), and *palikhari* (brigand-chieftains in folklore). Occasionally, high and popular culture join, as with the *Erotókritos*, which is still recited, or with *The Song of Daskaloyiannis*, a late 18th-century poem about another revolt. But on Crete, as elsewhere, this popular culture is slowly disappearing as the elderly die off. Some men still dress in boots, baggy pantaloons, sash, and embroidered vest and have a proverb or superstition for everything. Old motifs are embroidered into rugs, shoulder bags, or bridal linens, and there have been conscious attempts at folklore revivals. But the true Cretan spirit must survive naturally, in village festivals or in *cafés*, where people sing and dance to old tunes spontaneously.

**The outlook.** Crete today confronts the dilemmas of many underdeveloped, insular societies. Freed from foreign threats, it now must deal with itself, though economic advancement may seem indistinct from uniformity. Its immediate prospects rest in its archaeological treasures and its beaches and in their imaginative and sensitive exploitation. Alongside these assets, wiser land use and economic development rooted in native materials, skills, and patterns could resolve the problem. With accompanying restraint, development's ill effects may be avoided and Crete may well emerge a robust yet modern society.

**BIBLIOGRAPHY.** The most accessible general surveys of Crete are JOHN S. BOWMAN, *Crete*, rev. and enl. ed. (1969); R.W. HUTCHINSON, *Prehistoric Crete* (1962); and RAYMOND MATTON, *La Crete au cours des siècles* (1957). For the Minoan world, see ARTHUR J. EVANS, *The Palace of Minos*, 6 vol. (1921–36), is still the seminal (but unwieldy) work. More

accessible are R.W. HUTCHINSON, *Prehistoric Crete* (1962); J.D.S. PENDLEBURY, *The Archaeology of Crete* (1965); NICHOLAS PLATON, *Crete* (Eng. trans. 1966); and for fine photographs: S. MARINATOS and M. HIRMER, *Krētē kai Mykēnaikē Hellas* (1959; Eng. trans., *Crete and Mycenae*, 1960); and LEONARD VON MATT *et al.*, *Das antike Kreta* (1967; Eng. trans., *Ancient Crete*, 1968). For post-Minoan history, the Dorian world is discussed in R.F. WILLETTS, *Ancient Crete: A Social History from Early Times Until the Roman Occupation* (1965); the Venetian period in WILLIAM MILLER, *Essays on the Latin Orient* (1921); GIUSEPPE GEROLA, *Monumenti veneti nell'isola di Creta*, 4 vol. (1905–32); and DENO J. GEANAKOPOLOS, *Greek Scholars in Venice* (1962). For the struggle for independence and union, see EDWARD S. FORSTER, *A Short History of Modern Greece, 1821–1956*, 3rd ed. rev. by DOUGLAS DAKIN (1958); PRINCE GEORGE OF GREECE, *The Cretan Drama*, ed. by A.A. PALLIS (1959). For World War II, see ALAN CLARK, *The Fall of Crete* (1962); and GEORGE PSYCHOUDAKIS, *The Cretan Runner* (Eng. trans. 1955). The only readily available general survey of the geography, economy, and sociology of contemporary Crete is LELAND G. ALLBAUGH, *Crete: A Case Study of an Underdeveloped Area* (1953), although dating from 1948, many generalizations still hold true. For the popular culture of modern Crete, the best introduction is MICHAEL L. SMITH, *The Great Island* (1965). Translations of Crete's "renaissance" plays are in F.H. MARSHALL and JOHN MAVROGORDATO, *Three Cretan Plays* (1929). Travels on Crete include the classic, ROBERT PASHLEY, *Travels in Crete* (1837); and a modern experience, XAN FIELDING, *The Stronghold* (1953). JOHN S. BOWMAN, *op. cit.*; and STERGHIOS SPANAKIS, *Crete*, 2 vol. (1968), are guides to Crete.

(J.S.Bo.)

## Cribbage

Cribbage is a card game in which the object is to form counting combinations that traditionally are scored by moving pegs on a special Cribbage board, the dealer scoring an extra hand, the crib, formed of discards. The appeal of the game, usually played by two but with a popular variant played by four or, occasionally, by three, is evident from two facts: few changes have been made in the original rules, and it remains one of the most popular of all card games. In Great Britain, during the four years prior to 1970, the "Card Corner" in *News of the World* had more requests for information on Cribbage than for any other game. A 1970 appraisal indicated little overlap between devotees of Bridge and those of Cribbage. In the United States, Cribbage is played by more than 10,000,000 people, principally across the northern states, from New England to the Pacific, and the game has remained popular in Canada as well.

The game of Cribbage (earlier spelled Cribbidge) was invented by the English poet Sir John Suckling (1609–42). Although Cribbage quite clearly developed from Noddy, an older game for which a special scoring board also was used, it appears to be the only existing game in its family. Cribbage would quite likely have become the most popular of all two-hand card games if so many descriptions had not called the Cribbage board indispensable, which it is not.

Almost the only big change from the original rules is that in modern two-hand Cribbage each player is dealt six cards instead of five, as played originally.

**Scoring.** Scoring is traditionally called pegging, because it usually is done by moving pegs on a scoring device, the Cribbage board. This Cribbage board is essentially a tablet with 60 counting holes (in two rows of 30) for each player, plus one game hole for each, and often extra holes for holding pegs when not in play and for keeping track of games won. Game is 121 (twice around the board plus 1 for the game hole) or 61 in the less frequently played game of Once Around. Each player has two pegs, and each scoring point is marked by jumping the rearmost peg ahead of the other (thus showing at a glance the number of points scored on a move as well as the total). Scores must be pegged in order (see below *The showing*), because the first player to reach 121 (or 61) or, in some games, to pass it is the winner. Emphasis on the board as a scoring device created the idea that the game could not be played without it, but the score can be kept with pencil and paper or with chips or other counters; indeed, keeping score by discarding counters

Cribbage  
board

Notable  
writers

(each player starting with 121 or 61) is so efficient and simple a method that the enduring primacy of the board is difficult to understand.

**The cut and deal.** The customary deck of 52 cards is used, the cards ranking from king (high) to ace (low). Face cards and tens count 10 each; other cards count their index value (number of pips). The player cutting low card deals first, the deal alternating with each hand. The dealer deals six cards, alternately, to the non-dealer and to himself. Each player then discards two cards, facedown, to form the crib. In discarding to the crib, since it scores for the dealer, the nondealer tries to lay away "balking" cards, those least likely to create scoring combinations. After the discard, the undealt remainder of the pack is cut by the nondealer; the top card of the lower packet is turned **faceup** on top of the reunited deck and becomes the starter. If the starter is a jack, dealer immediately pegs (scores) 2, called "2 for his heels." If the starter is any other card, the jack of that suit—formerly called "knave noddie," an unmistakable link with the earlier game—is worth 1 point to the holder for "his nobs" but is not scored until later (see below *The showing*). This is followed by the two stages of scoring, the play and the showing.

**The play.** The nondealer begins the play by laying **faceup** before him any card from his hand, announcing its counting value. Dealer then plays a card (each adds cards to his own pile, so that his original hand may be counted later in the showing) and announces the total of the two cards. Play continues alternately, each player announcing the new total, until the total reaches 31, or until one player cannot play without increasing the total beyond 31. If either player cannot add a card without exceeding 31, his opponent must play any card(s) in his hand that may be added without exceeding 31. The last to play in each sequence scores a "go"—2 points if he reaches exactly 31, or 1 for any lesser total. After a go, count begins again at zero.

In addition to go, the object is to peg for certain combinations of cards played consecutively. These combinations score whether the cards are played in strict alternation or in succession by one player when his opponent cannot play. The score in every case is pegged by the player whose card completes the combination. Any player who can add to a combination, providing there has been no intervening card, can score the value of the new combination. Combinations are scored for playing a card that makes the count exactly 15 (score 2); for playing cards of the same rank to make a pair (2), three of a kind (6), or four of a kind (12); and for playing a third or later card to form a run, or sequence, regardless of suits and regardless of the order in which the cards are played (1 for each card in the run).

**The showing.** The next stage of scoring is the showing. After all four cards are played, the values in each hand are counted—the nondealer's hand first, then the dealer's hand, then the crib. The starter counts as a fifth card in each of the three hands. Every combination of two or more cards totalling 15 scores 2; each pair, 2; every sequence of three or more cards, 1 for each card in the sequence; four cards of the same suit, 4, or 5 if of the same suit as the starter (but only a five-card flush matching the starter counts in the crib); and his nobs (jack of the same suit as the starter), 1. Every possible different grouping of cards in the hand, plus starter, counts separately, except that a sequence of four or five cards may be counted only once, and not as two or more separate sequences of three.

As indicated above, the order of scoring on each hand is important and is as follows: (1) scoring of starter, if it is a jack, (2) scoring in play for various combinations, (3) scoring in play for go, (4) scoring of nondealer's hand, (5) scoring of dealer's hand, and (6) scoring of crib. When either or both players approach a score of 121 (or 61), whose turn it is to score becomes important. The game ends immediately if either player is able to count out in the play or the showing. If nondealer is able to count out in the showing, it does not matter if the dealer, with or without counting his crib, could have scored a higher

total. The loser scores only what he has already pegged before his opponent counts out, and if he has not already counted at least 61 (or 31), he is "lurched" ("left in the lurch") and, if the play is for stakes, loses doubly. (As sometimes played, the winner must be able to count out to exactly 121, just as, in playing for a go, he tries to reach 31 exactly. Thus, for example, if a player's score is 120, he can count out only if he can score exactly 1 point, as for his nobs or for go.) Some play that, if a player fails to claim his full score on any turn, his opponent may call out "muggins" and score for himself any points overlooked.

After each player has played all four of his cards, and the showing has been completed, the cards are put back in the deck and shuffled and dealt as before.

**Variants. Five-card Cribbage.** This was the original game. Each player discards two cards into the crib, remaining with only three, plus starter. At the beginning of the initial hand nondealer pegs 3 to offset dealer's advantage. Game is 61.

**Four-hand.** Play is in partnerships of two on a side, partners seated across the table from each other. The dealer gives each player five cards; each discards only one into the crib. The score is usually slightly less in the showing, but the average per side is about 9 points in the play. Game is always 121.

**Three-hand.** Each player is dealt five cards and discards one into the crib, and a single card is dealt blind to complete the crib, which belongs to the dealer. Each player scores for himself. Eldest hand (the one to the left of the dealer) shows first.

## Cricket

Cricket, generally considered to be England's national summer sport, is a game of skill played with bat and ball between two teams of 11 players each on a large field. It has devotees throughout the world, particularly in the British Isles and the Commonwealth.

For a list of major all-time batting, bowling, and fielding records in cricket see **SPORTING RECORD** in the *Ready Reference and Index*.

### THE GAME

**Grounds and equipment.** *The ground.* Cricket grounds vary in size from great arenas such as Lord's in London (5½ acres) and one in Melbourne that is even larger (9¼ acres) to village greens and small meadows. Level turf of fine texture is the ideal surface. The limits of the circular or oval playing area are usually marked by a boundary line or fence.

**Wicket and creases.** A wicket consists of three stumps or stakes, each 28 inches (71 centimetres) high and of equal thickness (about 1¼ inches [3.2 centimetres] in diameter), stuck into the ground and so spaced that the ball cannot pass between them. Two pieces of wood called bails, each 4¼ inches (11 centimetres) long, lie in grooves on the tops of the stumps. The bails do not extend beyond the stumps and do not project more than half an inch above them. The whole wicket is nine inches (23 centimetres) in width. There are two of these wickets, which a batsman defends and a bowler attacks, and they are approximately in the centre of the ground, facing one another at each end of the pitch (also sometimes called the wicket), which is an area 22 yards long and 10 feet wide (20 by three metres) between the wickets.

Lines of whitewash, known as creases, are marked on the ground at each wicket: the bowling crease is a line drawn through the stumps and extending four feet four inches (1.3 metres) on either side of the centre stump; the return crease is a line at each end of and at right angles to the bowling crease, extending a short distance behind the wicket; and the popping crease is a line parallel with the bowling crease and four feet in front of it. The bowling and return creases mark the area within which the bowler's rear foot must be grounded in delivering the

Bowling,  
return, and  
popping  
creases

Playing for  
go

Counting  
out

ball; the popping crease, which is 62 feet (19 metres) from the opposing bowling crease, demarks the batsman's ground.

**Bat and ball.** The blade of the paddle-shaped bat is made of willow and must not be broader than 4¼ inches (11 centimetres). The length of the bat, including the handle, must not exceed 38 inches (97 centimetres). The ball which has a core of cork built up with string, is encased in polished red leather, the halves of which are sewn together with a raised seam. Slightly smaller, harder, and heavier than a baseball, it must weigh between 5% and 5¾ ounces (156 and 163 grams) and be between 8¼ and 9 inches (22 and 23 centimetres) in circumference.

**Dress.** Players usually wear white flannel trousers and shirt, white boots (shoes) of buck or canvas, a white woolen sweater, often trimmed with club colours, and club caps of kaleidoscopic variety. The batsman wears white pads, or leg guards, a body protector, and articulated batting gloves, usually of thick tubular rubber or of leather stuffed with hair. The wicketkeeper also wears pads and reinforced gauntlets (cricketers, unlike baseball players, do not wear gloves when fielding).

**Language of cricket.** Cricket has evolved a vocabulary of its own. Many of the more important terms are explained in other sections of this article (see below Methods of dismissal). Some of the variant or multiple meanings of certain terms and some additional terms and phrases follow.

**Bowled for a duck.** Bowled for a duck is to be dismissed (put out) without scoring.

**Capped.** A player is said to be capped when he is selected to play for a representative team.

**Century.** A century is 100 runs scored by one batsman in a single innings.

**Follow on.** To follow on is to have a team bat second innings immediately after first innings (*i.e.*, out of turn) after scoring less than their opponents in first innings by a specific number of runs (75 in a one-day match; 100 in a two-day match; 150 in a match of three days; 200 in one of five or six days).

**Hzt a six.** To hit a six is to hit a ball over the boundary without its first touching the ground to score six runs.

**Innings.** Innings is either (1) a turn of a batsman to bat, (2) a turn of a team to bat, or (3) in recording a result, when one team still has a turn to bat but has scored more runs than the opposition, which already has completed its two innings, the result is recorded as an innings (to go) and so many runs (thus, for example, Hambledon beat "a representative England eleven by an innings and 168 runs").

**Pitch.** A pitch is either (1) an area extending five feet (1.5 metres) on either side of the centre line between the wickets, (2) the distance between wicket and wicket, or (3) the impact of the bowled ball on the ground (pitch).

**Representative team.** A representative team is a team of players selected, on the basis of ability, to represent a county, a country, etc. (as distinguished from a club team or a minor team).

**Sticky wicket.** A sticky wicket is a pitch drying after rain, when soft turf makes it difficult for a batsman.

**Wicket.** A wicket is either (1) the goal, consisting of three stumps (stakes) on top of which lie two sticks (bails), which the bowler attempts to hit and the batsman attempts to defend, (2) the area between two sets of stumps, synonymous with pitch, (3) a turn to bat (*i.e.*, the partnership between two batsmen for the first wicket, second wicket, etc.), or (4) in scoring, when a side is batting last, the number of batsmen still to be dismissed (put out) when the opponent's score is passed.

**Conduct of the game.** One player on each team acts as captain. There are two umpires, one standing at the bowler's wicket, the other at square leg near the batsman's wicket (see Figure 1), to control the game according to the laws and two scorers to record its progress. The object of the game is for one side to score more runs than the other.

At the start of a match, the captain who wins the toss of a coin decides whether his own or the other side shall take first innings (always plural); *i.e.*, proceed successive-

ly as batsmen—the first two as a pair together—to the wicket and try to make as many runs as possible against the bowling and fielding of their opponents. An innings is completed when ten batsmen have been dismissed (the remaining batsman, having no partner, is declared "not out"). The captain of the batting side may, however, declare his innings closed before all ten men are out if his side is far ahead on runs and he wants to bowl out the opponents before the time limit expires and the game is called a draw. Results are recorded by the margin of runs, or, if the side batting last passes the other side's total before all their batsmen have been dismissed, by the number of their wickets (*i.e.*, batsmen still to be dismissed) outstanding.

Matches are decided either by the number of runs scored in one innings each (usually one-day matches), or on the aggregate of runs made by each side in two innings. International (Test) matches last five or six days (30 playing hours), other first-class matches from two to four days, and the bulk of club, school, and village matches one day.

**How the game is played.** The nonbatting side takes up positions in the field. One man is the bowler, another is the wicketkeeper, and the remaining nine are positioned as the captain or the bowler directs (see Figure 1). The first batsman (the striker) guards his wicket by standing with at least one foot behind the popping crease. His partner stands behind the popping crease at the bowler's end. The bowler tries to hit the batsman's wicket or to dismiss him in other ways (see below Methods of dismissal).

**Runs.** The batsman tries to keep the bowler from hitting the wicket, while also trying to hit the ball sufficiently hard to score a run; *i.e.*, enable him to run to the other end of the pitch before any fieldman can pick up the ball and throw it to either wicket to knock off the bails. If the wicket is broken, either by a thrown ball or by the wicketkeeper or bowler with ball in hand, before either batsman is in his ground, the batsman is dismissed. The striker does not have to run after he has hit the ball nor does it count in any way if he misses the ball. But if he gets a good hit and thinks he can score a run, he races for the opposite wicket and his partner (the nonstriker) runs toward him. When each has made good his ground at the opposite end, one run is recorded to the striker; if there is time, they will run back for a second or more runs, crossing again. If an even number of runs is scored, the striker will receive the next ball; if an odd number, then the nonstriker will be at the wicket opposite the bowler and will face the next ball. Any runs thus made count to the batsman, otherwise they are extras. When a ball from a hit or any of the extras mentioned below goes as far as the boundary, the runners stop and four runs are added to the score. If the batsman hits the ball full pitch over the boundary (on the fly) he scores six runs.

**Extras.** Only runs scored from the bat count to the batsman, but to the side's score may be added the following extras: (1) byes (when a ball from the bowler passes the wicket without being touched by the bat and the batsmen are able to make good a run); (2) leg byes (when in similar circumstances the ball has touched any part of the batsman's body except his hand); (3) wides (when a ball passes out of reach of the striker); (4) no balls (improperly bowled balls; for a fair delivery the ball must be bowled, not thrown, the arm neither bent nor jerked, and in the delivery stride the bowler's front foot must land behind or covering the popping crease), off which a batsman cannot be out (except as noted under Methods of dismissal below) and which, apprized in time by the umpire's cry of "no ball," he may try to hit.

**Over.** When a bowler has bowled six balls (eight in Australia and South Africa), not counting wides and no balls, he has completed an over and a new over is begun by a different bowler at the opposite wicket, with a corresponding adjustment of the field. If a bowler delivers a complete over without a run being scored from the bat (even though the opponents may have scored extras by means of byes, etc.), he has achieved a maiden over, a feat of some accuracy.

**Methods of dismissal.** The nine ways in which a batsman or striker can be dismissed (put out) are as follows.

**Bowled.** The batsman is out bowled if the bowler breaks the wicket; *i.e.*, dislodges a bail with the ball.

**Caught.** He is out caught if a ball hit by the batsman is caught before it touches the ground.

**Stumped.** He is out stumped if, in playing a stroke, he is outside the popping crease (out of his ground) and the wicket is broken by the wicketkeeper with ball in hand.

**Leg before wicket.** Essentially, leg before wicket (**lbw**) is illegal interference, whether accidental or intentional, with a ball that otherwise, in the opinion of the umpire, would hit the wicket. The batsman is out lbw if he intercepts with any part of his person, except his hand, that is in line between wicket and wicket, a ball that has not first touched his bat or his hand and that has or would have pitched (hit the ground) in a straight line between the wickets or on the off side provided the ball would have hit the wicket.

**Run out.** Either batsman is out run out if, while the ball is in play, his wicket is broken while he is out of his ground. If the batsmen have passed each other, the one running for the wicket that is broken is out; if they have not crossed, the one running from that wicket is out.

**Hit wicket.** The batsman is out hit wicket if he breaks his own wicket with his bat or any part of his person while playing the ball.

**Handling the ball.** Either batsman is out if he touches the ball with his hands while it is in play.

**Hitting the ball twice.** Batsman is out if he hits the ball, except in defense of his wicket, after it has been struck or stopped by any part of his person.

**Obstructing the field.** Either batsman is out if he willfully obstructs the opposite side.

**Strategy and technique.** The disposition of the field will vary widely according to the technique of the bowler or of the batsman, the condition of the pitch, the state of the game, and the tactics determined by the captain. He may place his fieldsmen as he thinks best, and he may alter their positions, if he wishes, after each ball.

There are no foul lines in cricket so a hit in any direction is a fair ball. The objectives of the captain of the fielding side are: (1) to place his men in positions where the batsman may give a catch; *i.e.*, hit a straight drive or a fly ball to a fielder and (2) to save runs; *i.e.*, to block the path of the ball from the batsman's scoring strokes (intercept or trap grounders). The tactical possibilities for a thoughtful and ingenious captain in directing the battle of wits between his bowlers and fieldsmen and the batsmen are manifold and constitute one of the attractions of the game for player and spectator alike.

The names of the generally accepted positions are shown in the drawing. As there are only 11 players on a team and two of them must be the bowler and wicket-keeper, only nine other positions can be occupied at any

one time. The field is spoken of as being divided lengthwise into off and on, or leg, sides in relation to the batsman's stance, depending upon whether he bats right or left-handed; the off side is the side facing the batsman, and the on, or leg, side is the side behind him as he stands to receive the ball.

To sum up, the objective of the bowler is primarily to get the batsman out and only secondarily to prevent him from getting runs. The objective of the batsman is to protect his wicket and to make runs, for only runs can win a match, but to make runs he must stay in. The objective of each fielder (and of the general distribution of the field) is first, to dismiss the batsmen, and, secondly, to prevent the striker making runs. The arts of batting, bowling, and fielding are therefore a fusion of attack and defense, but ideally attack dominates.

**Bowling.** Bowling can be right- or left-arm. For a fair delivery the ball must be propelled, usually overhand, without bending the elbow. The bowler may run any desired number of paces as a part of his delivery, as in bowling (with the restriction, of course, that he not cross the bowling crease). The ball generally hits the ground (the pitch) before reaching the batsman, although it need not. The first requisite of a good bowler is command of length; *i.e.*, the ability to pitch (bounce) the ball on a desired spot, usually at or slightly in front of the batsman's feet, and varying with the pace of the bowler, the state of the pitch, and the reach and technique of the batsman. The second requisite is command of direction. On this foundation a bowler may elaborate with variations—finger spin, swerve, alteration of pace and flight, the path of the ball, and the manner in which it is propelled—that lend deceptiveness and uncertainty as to exactly where and how it will pitch. A good-length ball is one that causes the batsman to be uncertain whether to move forward to play his stroke or to move back. A half volley is a ball pitched so far up to the batsman that he can drive it fractionally after it has hit the ground without having to move forward. A yorker is a ball pitched on or inside the popping crease. A full pitch is a ball that the batsmen can reach before it hits the ground. A long hop is a ball short of good length or "short of a length."

The primary purpose of the spin in bowling is to bring the ball up from the pitch at an angle or in a direction that is difficult for the batsman to anticipate.

The two swerves are the inswinger, which moves in the air from off to leg, and the away swinger, or outswinger, which swerves from leg to off.

**Batting.** A batsman may hit right-handed or left-handed. Good batting is based on a straight (*i.e.*, vertical) bat with its full face presented to the ball.

The chief strokes are: forward stroke, in which the batsman advances his front leg to the pitch (direction) of the ball and plays it in front of the wicket (if played with aggressive intent, this stroke becomes the drive); back stroke, in which the batsman moves his rear leg back before playing the ball; leg glance (or glide), in which the ball, when pitched in a line with or outside the batsman's body, is deflected behind the wicket on the leg side; cut, in which the batsman hits a ball on the uprise (after it has hit the ground on the off side), over and down behind the wicket or through the slips with a vigorous whiplike action of the wrists.

**Fielding.** The ideal fieldsmen is a fast runner, with keen eyesight, quick reactions, and the ability to throw straight and far. He should be able to anticipate the batsman's strokes, to move quickly to cut off the ball in its path, and to pick it up and throw it to the stumps in one movement. He must be able to judge the flight of the ball in the air to make a safe catch. By his alertness and skillful play he can save runs and contribute to a batsman's downfall.

**Wicketkeeping.** The wicketkeeper is a specialist position requiring abnormally quick reactions, sharp eyesight, and courage. He is the hardest worked member of the team and must concentrate on every ball, whether standing 12 to 15 yards behind the stumps for the fast bowlers or crouching close to them for those of slow or medium pace.

#### CRICKET IN ENGLAND

**Early history.** Cricket has been played under recognized rules at least since the beginning of the 18th century. The first definite match of which there is record was played in Sussex in 1697, 11 a side, and for a stake of 50 guineas. In 1719 the "Londoners" met the "Kentish men" in what was virtually the first match between two county sides, London actually being synonymous with Middlesex.

At first the greatest enthusiasm and the most expert skill were concentrated in the southern counties near London. There, on the short turf of the open downs, cricket was discovered by "society" and transplanted to London and to the home grounds of its noble patrons. In London by far the most famous cricket centre was the Artillery Ground, Finsbury.

A feature of the play in those days was the heavy stake money and side bets that more often than not depended on big matches. The crowds were often disorderly and violently partisan.

The next stage in the game's development was marked by the rise of the Hambledon Club. On Broad-Halfpenny Down (a historic site later acquired by Winchester College) this little Hampshire village for 30 years challenged and was a match for all comers. Indeed, in June 1777 they beat a representative England eleven by an innings and 168 runs. This phenomenal ascendancy resulted in the main from the coincidence in the area of about a dozen men of extraordinary cricket genius who had a profound influence on the evolution of the game's technique. The club's historian John Nyren wrote the first prose classics in cricket's literature.

Hambledon played its last recorded match in 1793, appropriately enough at Lord's in London. This, the acknowledged Mecca of all cricketers, was first opened in Dorset Square as a private ground for certain members of the White Conduit Club by Thomas Lord, a Yorkshireman who was ground superintendent and bowler to the club. In 1809, to avoid a rise in rent, Lord removed to part of the St. John's Wood estate, and four years later moved again to the present location. In each case he relaid the original Dorset Square turf. He enclosed his last (the present) ground with a high fence and built a pavilion and a tavern. The Marylebone Cricket Club (MCC), with its home at Lord's, was founded in 1787. In its first year it revised the cricket laws, proving from its inception that its authority was paramount. Today it is accepted throughout the world as the authoritative source of all cricket legislation.

Lord's  
cricket  
ground and  
the MCC

For half a century at least, the MCC was the great match-making agency in cricket, inviting subscriptions from its members to meet match expenses and advertising in advance at the chief London social clubs. Most of the big matches were played for money and were a field for heavy wagering by professional backers.

In 1836 the first North counties versus South counties match was played, clear evidence of the spread of cricket. The missionary efforts of the MCC begun in 1846 were enhanced and extended by the touring cricket of the All-England eleven, which played all over the country and was the focus of attraction wherever it went. It brought knowledge and appreciation of the game into whole districts where hitherto it had been unappreciated or undeveloped, and its success led in 1852 to the secession of some of the leading professionals and their formation into the United All-England eleven. These two teams monopolized the best cricket talent in the country until, eventually, they both gave way before the rising tide of county cricket (see below History of county cricket).

Sport and General Press Agency

Figure 3: Sir Donald Bradman (Australia) at the finish of a cut. S.C. Griffith (England) is wicketkeeper and W.J. Edrich is at slip. Bradman established Australian and Test match records between 1928-48.

**Technical development.** Cricket was originally a game in which country boys bowled at a tree stump or at the hurdle gate into a sheep pen. This gate consisted of two uprights and a crossbar resting on the slotted tops, the crossbar called a bail and the whole gate a wicket. The fact that the bail could be dislodged when the wicket was struck made this preferable to the stump, which name was later applied to the hurdle uprights. Early manuscripts differ about the size of the wicket, but by 1706 the pitch was 22 yards (20 metres) long.

The ball was probably much the same in the 17th century as it is today. Originally it weighed between five and six ounces (140 and 170 grams). Its modern weight was laid down in 1774; its circumference, which had been standardized in 1838, was slightly reduced in 1927.

The primitive bat was no doubt a shaped branch of a tree, resembling a modern hockey stick but considerably longer and very much heavier. The change to a straight bat was made to meet the cult of length bowling (see above Bowling) which had been evolved by the Hambledon cricketers. The bat was shortened in the handle and straightened and broadened in the blade, which led to forward play, driving, and cutting (see above Batting). As few bowlers were able to combine length with break, swerve, and flight, batting continued to dominate bowling in the 18th century. About the same time the first leg before wicket law was promulgated requiring the umpire to perform the impossible task of deciding whether the obstruction had been deliberate. All bowling was underhanded early in the 19th century and most bowlers favoured the high tossed lob.

The next bowling development was "the round arm revolution" with which many bowlers deliberately threw.

Bowling  
methods

Controversy raged furiously, and in 1835 the MCC re-phrased the law to allow the hand to be raised as high as the shoulder. The new style led to a great increase in pace. Gradually bowlers raised the hand higher and higher in defiance of the law, until it became more honoured in the breach than in the observance. Matters were brought to a head when all nine professionals of an England eleven playing against Surrey left the field at the Oval in protest against one of their number's being no balled for throwing, and, as a result, in 1864 the bowler was officially accorded full liberty to bowl overhand. From time to time umpires have had trouble with bowlers who threw.

Most bowling continued to be fast throughout the middle of the 19th century, and, though the standard of wicketkeeping was high, the role of long stop, a fieldsman positioned to back up the wicketkeeper, became most important (the position was abolished after wicketkeepers learned to contain the fast bowlers). The batsmen now learned to protect themselves with additional armour. Pads and tubular rubber batting gloves were developed, and a cane handle greatly increased the resilience of the bat. Thus fortified, batsmen developed their strokes. Only the best professional batsmen, however, could cope with fast bowling because most pitches were bad. Until 1849, when permission was first given to sweep and roll the pitch at the beginning of each innings, it was unlawful to touch it from the beginning to the end of a match. Gradually the grounds improved because of the advent of the heavy roller and the perfection of the lawn mower, and in the 1870s fast bowling declined. The batsmen went over to the offensive, and the bowlers fell back on accuracy of length. They also developed "off theory," keeping the ball some distance wide of the off stump and concentrating the fieldsmen on the off side of the wicket. The batsmen countered by a policy of masterly inactivity, and the pace of some county cricket became so funereal that interest flagged and attendance fell off. The game was saved from a lingering death only by a transfusion of new and vigorous blood.

Profiting by the coaching of English professionals, Australians developed their cricket, especially their bowling, and, when in 1882 they travelled to England and defeated its best players, a further evolution in technique had taken place. Their great bowlers combined pace with spin and variety of flight. They bowled much straighter than the English and were much more adaptable in their field placing. With the wicket-taking *offspin*, many catches were made in the then unprecedented position of silly mid on or forward shortleg (see Figure 1).

**Developments in the 20th century.** The opening years of the 20th century produced such an orgy of run scoring that a reform of the leg before wicket law was debated, and the Marylebone Cricket Club (MCC) denounced the overpreparation of pitches. But the heavy scores were due primarily to the arrival of batsmen who triumphed over much formidable and varied bowling by methods both versatile and individual. This was cricket's golden age.

There now appeared in cricketing vocabulary the *googly*, a word coined in Australia when B.J.T. Bosanquet, on the 1903–04 MCC tour, first exploited his ability to bowl an *offbreak* with a leg-break action. This freak ball was brought to something like perfection in South Africa, where the matting used to form the surface of the pitch intensified its spin.

Contemporarily, bowlers discovered a new weapon for the discomfort of the batsmen—the swerve. Fast left-handers exploited inswerve, and right-handers learned to swing the ball either way, especially into a head wind or in a heavy atmosphere. A final development was the ball from the right-hander that swung into the batsman and dipped at the end of its flight. To supplement this inswinger, the field was largely reoriented, with the on side reinforced at the expense of the off.

To meet these new problems batsmen had to adjust their technique. At first players led the way by abandoning the long-striding forward stroke and making back play, together with a mastery of all on-side strikes (hits),

the foundation of their batting. With the less gifted majority of batsmen, a two-shouldered and right-handed defense off the back foot began to predominate, and batting lost its aggression and attraction. Such methods played into the hands of bowlers of real pace and of those who could flight as well as spin the ball, but the concentration on defense and the increasingly elaborate preparation of the pitch often thwarted all but the greatest bowlers. The most drastic and dramatic tactic was the so-called body-line attack in the 1930s (see below Test matches).

**Revision of rules.** The reaction of authority to the evolution of cricket in the 20th century was visible in a series of attempts to help the bowler and to quicken the tempo of the game. As early as 1902 the bowling crease had been extended in length; in 1907 the use of a new ball after every 200 runs had been legalized; during the MCC tour of Australia in 1924–25 the eight-ball over was first used (this became standard practice in Australia and in South Africa); in 1927 a smaller ball was authorized; in 1937 the leg before wicket law was extended to cover balls pitching outside the off stump; and in 1947 the size of the wicket, increased in 1931, was again increased to its present size (see above).

In 1947 the MCC issued a revised code of laws aimed at the clarification and better arrangement of the previous laws. The extension of the leg before wicket law encouraged the inswinging bowler and the offspinner, thus further restricting the batsman's more interesting off-side strokes. During the 1950s the rate of run getting deteriorated, as too many bowlers bowled short of a length, and the MCC and other governing bodies were much concerned about slow play. As attendance continued to drop there were widespread appeals for more positive cricket, and groundsmen were urged to prepare truer and faster wickets. The MCC's attempts by legislation to instill more enterprising tactics into county cricket failed through inadequate response by players, whose offensive spirit was being dulled by playing six days a week before diminishing crowds.

**Efforts to enliven the game.** The 1960s were a period of great change, with continued efforts to enliven the game. In 1966 the MCC and the counties introduced Sunday play, allowing 12 three-day matches to be played on weekends. This was sufficiently successful for a continuation in 1967 and 1968, with more weekend matches, and in 1969 a one-day, Sunday-afternoon league was established among the first-class counties. The prototype one-day competition had been launched in 1963 by the inauguration of the Gillette Cup Knockout Competition, limits being placed on the number of overs, 60 per side and 12 per bowler. This proved a valuable means of interesting spectators and increasing the tempo of the game and developed into a highly popular competition, with a cup final at Lord's. A similar model was adopted for the Player's Sunday League, each county playing all the others on Sunday afternoons throughout the season, 40 overs per side, and eight overs per bowler. The league was an equal success and good crowds attended many of the matches.

**History of county cricket.** The greater part of first-class cricket, aside from the Oxford versus Cambridge and Test matches, is played in the county championship between sides representing counties.

As the 1960s progressed, county cricket continued to be of a low standard, and the same reasons were given for diminishing public support—the dull defensive attitude of the players and the frequent bad pitches. Consequently, in 1968 three steps were taken to meet objections: (1) a change in the regulations for registration of overseas players; (2) a new system of bonus points in the county championship; and (3) the appointment of an inspector of pitches.

1. To inject new blood into the championship, the ban on residential qualification of overseas players was partially lifted and immediate registration of one per county was permitted, with the proviso that a second could not be engaged within three years and that at no time could more than two per county be registered, though under a

The  
googly and  
new  
batting  
styles

Use of  
overseas  
players

previous arrangement an overseas player ranked as **homeborn** after five years. To safeguard his interests, an overseas player could at any time, without breaking his qualification, play for the country of his birth. Although Yorkshire continued to rely on homeborn players, most counties accepted the change with alacrity, so that famous Test cricketers such as G.S. Sobers, L.R. Gibbs, R. Kanhai, and C.H. Lloyd of the West Indies; B.A. Richards and M.J. Procter of South Africa; and G.R. McKenzie and A.N. Connolly of Australia were seen regularly in county cricket. All played a notable part, especially Sobers, whose all-around gifts as player and captain lifted his adopted county, Nottinghamshire, from bottom of the championship table to fourth in his first year. The experiment was a resounding success, though Australia, South Africa, and the West Indies all sounded a warning note as to this deprecation of their best players to bolster what one Australian critic described as "England's archaic system of cricket."

2. As a reward for more positive cricket, it was agreed that during the first 85 overs of the first innings of each side, the batting side would be awarded one point for every 25 runs obtained over 150 and the bowling side one point for every two wickets taken. No other points were to be awarded on the first innings, which would not necessarily terminate after 85 overs. After two years' experiment there was a consensus that the players were learning to adjust to the new formula, thus providing better entertainment, and that spectators were coming to watch in increasing numbers.

3. A county pitches committee was set up and an **inspector** of pitches was appointed. Complaints to the committee from captains and umpires were investigated by him, and some grounds were banned as being below standard.

No doubt these innovations helped the counties to lift themselves from a depressing rut. The overseas stars all played a notable part, and the abolition of first innings points produced keener cricket in the early stages of a three-day match. It is noteworthy that players of other countries, with less cricket, were less affected by a defensive complex, which was basically an English problem.

**Early county champions.** The origin of county cricket may be found in local antagonisms of the so-called home counties (those counties in the London area). Successive county supremacies were enjoyed by Kent (about 1750), Hampshire (1780–90), Surrey (1790–1810), Sussex (about 1825), and the great Kent eleven of the 1830s and 1840s. Yorkshire first took the field in 1833 (club formed in 1863) and Nottinghamshire in 1835 (club formed in 1859). Surrey (club formed in 1845) enjoyed a renewed ascendancy in the late 1850s and early 1860s. Between 1867 and 1870 Yorkshire, with a wholly professional eleven, were three-time champions.

The modern county championship is generally reckoned to date from 1873, when the **MCC** first laid down rules governing qualification. In the next five years, **Gloucestershire**, owing almost everything to the legendary Victorian cricket-playing brothers E.M., W.G., and G.F. Grace, were champions three times, but it was another ten years before the honour went south again. From the 1880s up to World War I, Nottinghamshire, Surrey, and Yorkshire (which with Lancashire, Kent, and Middlesex constituted the Big Six) predominated, but in 1911 Warwickshire became the first county outside the Big Six to win the honour in 34 years.

The early years of the 20th century produced J.B. (later Sir Jack) Hobbs of Surrey and F.E. Woolley of Kent. Hobbs was the complete batsman for 30 years, during which he amassed records for Surrey and England (61,237 runs, 197 centuries) that into the 1970s had not been beaten. Woolley, whose aggregate was second only to that of Hobbs, was cricket's most graceful left-handed batsman.

**Reign of the northern counties.** After World War I, Middlesex had a brief period of triumph, but between 1922 and 1939 the championship was monopolized by the northern counties, especially Yorkshire and Lancashire, which fielded largely professional teams that re-

mained virtually unchanged throughout the season. They exhibited a toughness of fibre, an economical competence of technique, and a concentration on the game compared with which most of their rivals tended to appear, as in fact some of them continued to be, relatively unskilled. Above all they excelled in the accuracy and hostility of their bowling, supported by aggressive fielding and handled by captains who knew their jobs. During this era Yorkshire, with the help of W. Rhodes, greatest of all slow left-arm bowlers and also a good batsman, won the title 11 times, Lancashire five, and Nottinghamshire and Derbyshire one each, Derbyshire's victory in 1936 being the first outside the Big Six since Warwickshire's in 1911.

The nucleus of the Yorkshire side, which had won the championship in the last three seasons before World War II, was sufficiently strong to retain it in 1946, but thereafter it was gradually a waning force before the onslaught of Middlesex and Surrey, although Glamorgan, the youngest of the counties, surprised everybody by winning the championship for the first time in 1948.

In the meantime, amateurs good enough to be worth their place in first-class cricket and able to spare the time to play regularly were becoming increasingly difficult to find. Warwickshire in 1949 took the unprecedented step of appointing one of its senior professionals, H.E. Doolery, as full-time captain.

Two years later his team won the 1951 championship, 40 years after its only other success. Within a few years, five other counties had followed suit by appointing professional captains.

The 1950s belonged to Surrey; by 1958 it had been champion for seven consecutive years. Then, after a lapse of 13 years, Yorkshire came into its own again and won the championship seven times between 1959 and 1968. Enlivening this period were strong bids by other teams and the first-ever victories of Hampshire (1961), Worcestershire (1964 and 1965), and, in 1969, the return of 1948 surprise winner Glamorgan to the championship. Kent won in 1970 for the first time since 1913, and Surrey was back on top in 1971.

**Other first-class cricket.** For almost 150 years the annual Gentlemen versus Players match between two teams made up of the best amateur and the best professional players was the leading representative domestic fixture. Invariably the appearance of 22 of the leading cricketers in the same game produced high-class cricket without the tensions of intercounty competition and championship points. The series that began in 1806 and became annual in 1819 was ended in 1962 when the Marylebone Cricket Club (MCC) and the counties abandoned the distinction between amateurs and professionals.

The Oxford versus Cambridge match has been played at Lord's since 1827. These two universities rank with the counties as first-class and are the chief nurseries of amateur cricket. Until the outbreak of World War II, the match was one of the social occasions of the summer season in London.

**Reorganization: the Cricket Council.** A big reorganization of the overall administration of English cricket took place in 1969, resulting in the end of the MCC's long reign as the controlling body of the game, though it still retained responsibility for the laws. With the setting up of the Sports Council (a government agency charged with the rational promotion and control of sports in Great Britain) and with the possibility of obtaining government grant aid for cricket, the MCC was asked to create a governing body of the game on the lines generally accepted by other sports in Great Britain. Thus was inaugurated the Cricket Council, comprising the National Cricket Association, the Test and County Cricket Board (TCCB), and the MCC. The council consists of representatives from clubs, schools, Royal Army, Navy, and Air Force cricket, umpires, and the Women's Cricket Association. The Test and County Cricket Board amalgamated the Advisory County Cricket Committee and the Board of Control of Test matches at home. The board is responsible for all first-class cricket in England and for overseas tours which had previously been the respon-

sibility of the MCC, which continued, however, to play an important part.

Unhappily, the problem of apartheid arose when the Cape Coloured South African, B.L. D'Oliveira, who had qualified by residence to play for England, was not included on the English team chosen to tour South Africa in 1968–69. There was a great public outcry, and, when one of the players had to withdraw because of injuries, D'Oliveira was chosen but was declared unacceptable by the South African government, and, as a result, the tour was cancelled. An even more publicized crisis arose over South Africa's projected tour in England in 1970; the threat of widespread anti-apartheid demonstrations if the tour were to take place caused elaborate precautions to be taken on the cricket grounds where matches with the visitors had been arranged, and, eventually, the MCC was persuaded by the British government to cancel the tour. A similar situation arose in 1971 with the cancellation of a South African tour of Australia.

**Women's cricket.** Women first played cricket in England in the 18th century, and spasmodic references appear during the 19th century. In 1887 the first club, White Heather, was formed, and in 1888 two professional teams known as the Original English Lady Cricketers were in action. About the same time, women's cricket was first played in Australia and New Zealand.

In 1926 the Women's Cricket Association was founded after a successful cricket week at Malvern, and these weeks became an annual event. Representative meetings soon followed, and in 1933–34 the first team toured Australia and New Zealand. Australia paid a return visit in 1937. By the second half of the 20th century the Women's Cricket Association was a flourishing organization, responsible for the administration of the game in England and for organizing Test matches at home and away. Test matches take place at regular intervals against Australia and New Zealand, and new ground was broken in 1960–61 with a first tour of South Africa, where the women's game had begun only in 1951.

#### INTERNATIONAL CRICKET

The English introduced their national game wherever a pitch could be found and two teams collected. The firmest roots are in those countries that, with England, were members of the Imperial Cricket Conference, founded in 1909 and including Australia, New Zealand, and West Indies; India and Pakistan (after 1947); and South Africa until the latter's withdrawal from the Commonwealth in 1961. In 1965 the conference was renamed the International Cricket Conference to permit the election, as full or associate members, of countries outside the Commonwealth, and the United States, Ceylon, and Fiji were elected associate members followed in 1969 by Bermuda, Canada, Denmark, East Africa, Gibraltar, Hong Kong, Malaysia, and The Netherlands. Cricket also flourishes in West Africa, Brazil, and Argentina. The following account is concerned with cricket in the main countries that are members of the conference.

**Australia.** Cricket began in Australia in the early 19th century and was competitive between clubs from the start. The first interstate match took place in 1856 between Victoria and New South Wales. By the end of the century South Australia was playing with them in a triangular competition for the Sheffield Shield, presented by Lord Sheffield who took an English team to Australia in 1891–92. Queensland was the next to join, and Western Australia was accepted to membership after World War II. Despite the huge distances, all five states play one another home and away each season. New South Wales and Victoria are the dominant teams.

The real foundation of Australian excellence is club cricket. Each state has an association of affiliated clubs that controls players and grounds. Clubs are graded and competitions are arranged for each grade. First-grade teams, in which novices play with great cricketers, are the recruiting ground for the state team.

**New Zealand.** The game was first played in New Zealand in 1841, and the first representative game was between Auckland and Wellington in 1860. In South Is-

land, the discovery of gold in Otago brought many Australians, who helped to spread the game, and the first of the annual meetings between Otago and Canterbury took place in 1864. Canterbury and Wellington met for the first time in 1885.

The New Zealand Cricket Council was formed in 1894. Each province has its own association, made up of delegates from affiliated clubs. The Plunket Shield (named after a former governor general) is played for annually between Auckland, Wellington, Canterbury, Otago, Northern Districts, and Central Districts. The first English team visited the country in 1864, and others have gone at frequent intervals.

**West Indies.** Cricket has probably been played in the West Indies since mid-19th century, but the first inter-colonial match took place in 1865 between Demerara (British Guiana, now Guyana) and Barbados. By the end of the century, a triangular tournament was being held between Demerara, Barbados, and Trinidad. In 1926 a board representing all the islands was set up to control inter-island competitions and to organize foreign tours. One of its problems has been to agree upon a national captain, so intense is the rivalry between the islands.

After World War II air travel enabled Jamaica to play the other islands, and in 1956 Barbados, British Guiana, Trinidad, and Jamaica played a knockout tournament at Georgetown, which British Guiana won. In the 1960s these four were joined by the Windward Islands and the Leeward Islands in an annual competition for the Shell Shield, presented by the Shell Oil Company.

**India.** English settlers introduced cricket in India and the army helped to popularize it. The first all-Indian club was the Oriental Cricket Club, for Parsis (an Indian religious sect), formed in 1848. English professionals improved the standard of play, and there was a gradual sinking of jealousies of the various races and creeds in the cause of cricket. In 1877 the first match between the Parsis and the Europeans in Bombay was played, and the Parsis showed such improvement that Parsis teams went to England in 1886 and 1888.

In 1906 the Hindus competed with the Parsis and the presidency (the Europeans) in a triangular tournament, and by 1912 this had become quadrangular with the advent of a Muslim team. Pitches were uneven and gear crude, but enthusiasm was tremendous. In 1926 the MCC sent a team to India, and the princes began to pick their own sides—a sign that cricket was spreading. Since 1934 India has staged a national championship for the Ranji Trophy, named after famous Indian cricketer K.S. Ranjitsinhji, with "the Rest" joining the quadrangular in 1937.

National  
cups and  
trophies

**Pakistan.** Since partition in 1947, cricketers in Pakistan have had a difficult task of organization. An embryo test team was soon formed and during the first years of its existence it has had a good record. In an attempt to build up a cricket tradition and find reserves for the national eleven, the country has been divided into four groups for a championship for the Qā'id-e A'zam Trophy (meaning "the great leader" in honour of Mohammed Ali Jinnah, one of the creators of Pakistan).

**South Africa.** Cricket was taken to South Africa in the middle of the 19th century by British troops and was played in military and police centres of the Cape and Natal till 1889. Despite a delightful climate, interstate meets were difficult owing to wide distances and sparse population.

In 1889 Sir Donald Currie offered a cup to the team that put up the best performance against the first English touring team. Kimberley won, and next year Transvaal challenged and beat them. Thus began the Currie Cup competition, which is South Africa's provincial championship. Before the turn of the century, Cape Colony (now Cape Province) had entered two teams (Western Province and Eastern Province), and Natal had also joined. After World War I, a board of control became the ruling body for South African cricket. The three most powerful provinces are Transvaal, Western Province, and Natal.

#### TEST MATCHES

**History.** The first international, or Test, match between sides of players chosen on the basis of their ability to represent the best cricket each country had to offer was played in Melbourne in 1877, when a team made up of Australia's best players beat a team of England's finest by 45 runs. Australia's success was repeated in 1882 at the Oval, in London, in the game celebrated in the *Sporting Times* by an obituary notice announcing cricket would be cremated and the ashes sent to Australia, giving birth to the legend of "playing for the Ashes," which became the popular objective in games between England and Australia. The ashes, kept in an urn at Lord's, are those of a stump burned on the England tour of Australia in 1883. For the rest of the century, the two countries met almost yearly. With W.G. Grace in his heyday, England was generally too strong, though Australia had the greatest bowler of his era in P.R. Spofforth and the first of the great wicketkeepers in J.McC. Blackham.

In the meantime new opponents for England were gathering strength. In 1894 the South Africans first went to England, and their cricketers gained invaluable experience during two subsequent tours in South Africa, one by England and one by Australia. In 1905 the first MCC team to South Africa lost the rubber primarily because of googly bowling, which was too much for English batsmen on the fast matting wickets. The triumph won for South Africa the right to Test matches in England, and in 1907 they proved their ability to play England's best.

After World War I, England, Australia, and South Africa continued to play one another at regular intervals, and in 1928 the West Indies entered the Test match arena. In 1931 New Zealand joined them, followed by India in 1932. The result was a serious crowding of the schedule. England, with its county cricket for six days a week, was hardest hit, and life for the top players became a round of cricket and travel. Interest in Test matches was stimulated in the 1930s by the introduction of radio broadcasts of games and by the advent of the correspondent whose objective was news stories and off-the-field activities at the expense of straightforward cricket reporting. In 1930 Test matches between England and Australia were increased to four days' duration.

England was slow to recover from World War I, and Australia dominated the Test-match scene for six years, until England recovered the Ashes in 1926 and held them for four years. Then, in 1930, English crowds for the first time saw the new, young Australian phenomenon D.G. (later Sir Donald) Bradman. Between 1928 and 1948 he scored a record 29 centuries, 19 of them against England, and his average in all Tests was 99.94 runs. On his first English tour he made innings of 254, 334, and

232 in the Tests, and these, with the slow bowling of C.V. Grimmett, were sufficient to win the rubber.

D.R. Jardine, captain of the next MCC team to Australia (1932–33), evolved the plan known as body-line, with H. Larwood as chief protagonist: bowling very fast and accurately at the leg stump (the one nearest the batsman) with a majority of fieldsmen on the leg side, he effectively curbed Bradman and his colleagues and was largely instrumental in winning the rubber for England by four games to one. The new technique, however, savoured so much of direct attack on the batsman that it caused a storm of protest and was subsequently outlawed by the MCC as being contrary to the spirit of the game.

In the remaining Anglo-Australian rubbers before World War II, Australia won in 1934 in England and in 1936–37 in Australia; but in 1938 a new English batting star, Leonard (later Sir Leonard) Hutton, made history with an innings of 364 at the Kennington Oval, London, which ensured a record victory by an innings and 579 runs. Meanwhile, South Africa won for the first time at Lord's in 1935 by 157 runs.

Between these Tests against ancient rivals, England sandwiched three at-home matches against the West Indies and two each against India and New Zealand, plus return visits to New Zealand after each of the Australian tours and one to India, in 1933. In 1934–35 an MCC team toured the West Indies, which had been to Australia for the first time in 1930–31. In 1931–32 the South Africans toured Australia and New Zealand for the first time, and in 1935–36 they received Australia. Hence the pattern of continuous cricket was already being evolved when war broke out in 1939.

After World War II Test cricket began again, and in every summer since 1946 a touring side has engaged in Test matches against England. Before the late 1960s Australia made the trip twice in every eight years, South Africa every five years, and the other countries at longer intervals. Pakistan was admitted to the international association in 1952 and first toured England in 1954. In 1966 a four-year cycle of tours was announced, in which twin tours to England (by India and Pakistan, or by the West Indies and New Zealand) would alternate with single tours (by Australia or South Africa). England has continued to travel to Australia every four years, and visits to other countries have been a feature in two out of every three winters. The other members of the International Cricket Conference have gradually extended their schedules.

Test matches last 30 hours (six days in Australia and the West Indies and five days elsewhere), except by local agreement.

During the 1960s, violence among spectators gave increasing concern to cricketing authorities. Test matches in Pakistan, India, and the West Indies were drawn or abandoned owing to riots, part political, part nationalistic; and, as noted above, in the 1970s South African tours of England were canceled because of the threat of antiapartheid demonstrations.

**The test countries.** **Australia.** As in the 1920s, the first few years after World War II were dominated by Australia. Bradman was still a tremendous force, and the team he led to England in 1948 was as strong as any in history, with K.R. Miller and R.R. Lindwall as one of the great fast-bowling combinations of all time. This team held its own in world cricket until 1953 when, at the Oval, Australia at last relinquished the Ashes held since 1934. Australian recovery began with a successful tour of South Africa in 1957–58 and continued with victory over England in Australia in 1958–59. The next four series produced only eight results with 12 draws in 20 matches, Australia retaining the Ashes by winning two rubbers in England and drawing two at home. Australia was beaten for the first time by the West Indies in the Caribbean in 1965. However, at home in 1968–69, they had a successful series against the West Indies. Australia was beaten by South Africa in 1969–70, and lost the Ashes to England in 1970–71.

**England.** England took some time to recover after World War II, but returned to top form in the 1950s

and did not lose a Test rubber between 1952 and 1958 (in 1953 it recaptured the Ashes under Hutton, its first professional captain). After 1958 English teams were usually too strong for New Zealand, India, and Pakistan and had equality with South Africa but in the 1960s lost four rubbers at home, two each to Australia and the West Indies. In the period 1952–65, fast bowler F.S. Trueman took a world-record number of wickets (307) in Test matches. Having regained the Ashes, England lost for the first time at home to India in 1971.

**South Africa.** After World War II South Africa contested eight rubbers against England and achieved its first win in a three-match series in England in 1965. Australia had always been invincible in South Africa, until 1966–67, when South Africa for the first time won the Test series and overwhelmed Australia again in South Africa in 1969–70. But South Africa has done better in Australia, drawing series in 1952–53 and 1963–64. South Africa had an easy success in New Zealand in 1953–54 and played two drawn rubbers, home and away, in 1961–62 and 1963–64. South Africa's participation in Test cricket remained clouded at the beginning of the 1970s because of its adherence to the principle of apartheid and the resentment which this aroused abroad.

**West Indies.** The West Indies reached world class after World War II, and in the mid-1960s they were undoubted world champions. They owed their early success primarily to C.L. Walcott, wicketkeeper-batsman, E.D. Weekes, batsman, and F.M. (later Sir Frank) Worrell, all-rounder—and to two young spin bowlers, S. Ramadhin and A.L. Valentine. After beating England in England for the first time in 1950 and holding them to a draw in the Caribbean in 1953–54, they suffered defeats against England, both home and away, but in the early 1960s Worrell's team, though narrowly losing a rubber, won the hearts of Australian crowds with its joyous cricket and, at Brisbane, took part in the only tied match in Test history. Worrell's final triumph was the defeat of England in England in 1963. He was knighted for his services to cricket in 1964 and died in 1967. His successor G. Sobers, holder of the record Test score of 365 "not out" against Pakistan, led the West Indies to victory against Australia in the Caribbean and against England in England in successive years, by which time he was acclaimed the most gifted all-rounder of all time.

The West Indies were beaten by India for the first time in 1971. Pakistan won a Test in 1958 at Trinidad and a three-match rubber at home in 1958–59. Ironically New Zealand's first Test win was against the West Indies in 1956 at Auckland, and they won again at Wellington in 1969.

**New Zealand.** New Zealand won its first Test match in 1956, against the West Indies, and won two against South Africa in 1961–62 when it drew a rubber in South Africa. It has also toured England, India, and Pakistan without success and has entertained at home all the Test-playing countries except Australia. In 1969 at home it inflicted a second defeat on the West Indies in a drawn three-match rubber and then lost 0–2 in England. Leading players since World War II have included left-handed opening batsman B. Sutcliffe and fast bowler R.C. Motz, the only New Zealander to have taken 100 wickets in Test cricket.

**India.** In the years after World War II, India played rubbers against all countries except South Africa, and, while being no match for England and Australia away from home, proved hard to beat on its own pitches, where England was twice beaten in 1961–62 and Australia once in 1959–60 and once in 1964. Other wins have been against New Zealand (three) and Pakistan (two). It has yet to win a match against the West Indies. The pattern away from home was continued when it lost a short series in 1967 in England (3–0) and all four matches in Australia (1967–68) but it triumphed in 1971 over both the West Indies in the Caribbean and England in England, in each case for the first time.

**Pakistan.** Pakistan made an auspicious entry into world cricket by beating England at the Oval in 1954, Australia at Karachi in 1956, and the West Indies at Port-of-Spain in 1958. In Pakistan it beat the West Indies in 1958–59, and other victories have been against New Zealand (two) and India (one). Two consecutive drawn series with India were played in 1954–55 and 1960–61, neither side winning a match. It was beaten in England in 1967, and an English visit in 1969 had to be abandoned (0–0) due to political riots.

## Crime and Delinquency

There is no generally accepted definition of crime and delinquency that is of universal application. Within each culture the line between normal and criminal, or merely deviant, behaviour is drawn differently by varying codes or bodies of criminal law. In general, however, the term crime is used to refer to adult behaviour; the term delinquency is used to refer to criminal or, in some countries, precriminal behaviour by a juvenile. The age limit between juveniles and adults varies greatly from country to country, ranging, in general, from a lower limit of 15 years to a maximum of 18.

The definition of crime within a given culture depends largely on two sets of related norms: the legal and the moral codes prevailing within that culture. In legal terms, a crime is an act of human behaviour banned by criminal law. Even this deceptively simple definition is currently challenged as being too broad; not all acts that are penalized under the law are really criminal. Minor traffic offenses are an obvious example, and the range of acts to which penalties attach, but which are not legally or socially thought of as crimes, is widening. This is particularly true in industrialized countries, in which the emergence of huge urban areas and the increased involvement of government in all aspects of life has resulted in a new type of offense: the frequently unintentional violation of administrative rules, sometimes referred to as a public welfare offense. In addition, there are certain types of behaviour that, because of their increased frequency or because of increased public tolerance, have lost their former status as criminal. Some minor drug addictions, many abortions, and certain kinds of sexual behaviour may fall into this group.

Though the term crime should be reserved only for behaviour legally defined as criminal, criminologists must be concerned as well with all potentially criminal behaviour, regardless of legal definitions.

Because a broad social definition of crime is more widely used than a narrow legal one, moral and cultural elements, including value systems, mores, and religious attitudes operative in a given culture, are of central concern to the criminologist. Crime and morality may be likened to two circles overlapping with a wide common area. A large part of proscribed human behaviour is both criminal and immoral, but a considerable part of it is only one or the other. Whereas criminal law is primarily concerned with the external aspects of human behaviour, morality focusses on the inner aspect. The criminal law is negative—it forbids a certain act—whereas moral considerations may dictate that certain acts be performed.

The fate of the criminal offender is contingent on the uneven, and sometimes contradictory, functioning of the typical criminal-justice system, and the reaction of that system to crime is far from being uniform or certain. The response of society to crime reflects different ideologies concerning the treatment of offenders. Punishment and deterrence have prominent places within those ideologies. The punitive societal reaction has two major characteristics: it is inflicted by the group on a member of the group as an instrument of public justice, and it presupposes pain and suffering—justified by its retributive value.

Attitudes and reactions to the criminal offender have broadened, so that punishment alone is no longer the only motive informing society's response toward criminal behaviour. Crime prevention is largely viewed as involving much more than the prevention of further offenses and the deterrence of potential offenders by means of exemplary sentences. Crime prevention is now approached from two different perspectives—individual and general. Society's response to the individual offender is determined by a variety of cultural and social factors mentioned above (see also PUNISHMENT; and PRISONS AND PENOLOGY). General crime prevention is an aspect of social policy; mental- and physical-health policies and social-welfare programs, for example, contribute to general prevention, and the dividing line between criminal preven-

tion and social welfare is sometimes only a matter of definition. Delinquency in some countries includes conduct that is considered dangerous, inappropriate, or symptomatic of future criminality. There is, however, a general tendency to limit delinquency to conduct that, if carried out by an adult, would be identified as crime.

Most of the following considerations are taken from crime and delinquency studies in Western countries, particularly the United States. Few data are available from either Eastern countries or the developing nations. The article is divided into the following sections:

- I. Causes and patterns of crime
  - The measurement of crime
    - The administrative crime index
    - The research crime index
    - Crime indexes in Europe
    - Trends and comparisons
  - The analysis of crime

### I. Causes and patterns of crime

#### THE MEASUREMENT OF CRIME

Economists are able to construct a cost-of-living index and various other indexes that serve social administrators and policy makers as useful indicators of how an economy is functioning. Though without equally clear policy aims, criminologists have long urged the systematic collection of crime statistics, in the hope that an index could be constructed to provide a useful measure of the amount of crime in society and of its trends.

The difficulties in constructing a reliable crime index are immense. Criminal statistics are well-known for their unreliability, which results from a number of factors prominently including, first, the wide diversity in the definition of various crimes under different criminal codes and, second, the diversity of statistical sources, which may be local police departments, state or federal police departments, courts, or correctional institutions, and the fact that not all reportable crime is either properly or uniformly recorded by police. It has, in fact, been argued that crime statistics are merely an indication of the activities of the law enforcement agencies. Attempts, however, have been made to construct an index that would be of value from either an administrative or a research point of view.

The administrative crime index. In 1930 the Federal Bureau of Investigation (FBI) of the United States assumed responsibility for collecting and publishing reports of crimes "known to the police." These were voluntarily submitted by various police departments throughout the country. A standard form is now used, including standardized instructions for defining and classifying offenses. The offenses used to make up the overall crime index are murder, forcible rape, robbery, aggravated as-

Crime,  
law, and  
morality

Society's  
response  
to crime

statistics

sault, burglary, larceny over \$50, and auto theft; and the *Uniform Crime Reports*, as published, provides a breakdown of the index into violent crimes and crimes against property. Much research into crime trends usually devotes attention to the more serious crimes of violence, especially homicide, because this crime has a high reporting rate.

**The research crime index.** In the collection of criminal statistics there has long been a controversy about whether to count the number of offenses or the number of offenders. The favoured solution, so far, appears to be to concentrate on the delinquent event, which may be reconstructed from records of offenses known to the police and analyzed according to three main criteria—the presence of injury, of damage, or of theft. Because the purpose of measuring the amount of crime is to examine its relationship to the rest of society—that is, to determine the "social harm" caused by criminal conduct—it is necessary to make a further assessment of the "seriousness" of the crime involved, taking societal attitudes into account. The inclusion of auto theft in crime indexes has been criticized because the amount of social harm or seriousness of the conduct has been left unassessed. Research has shown that when people are asked to assess the seriousness of various criminal acts in comparison to one another, some crimes are more consistently rated as more serious or less serious than others. Forcible rape, for example, has been found to be rated about six times more serious than auto theft. The final research crime index is constructed by assessing each offense according to the criteria of injury, theft, or damage or to the seriousness estimated in public opinion surveys.

**Crime indexes in Europe.** It is difficult to speak of crime statistics in Europe without discussing the problem of collecting international crime statistics. Each country has its own tradition, or established way, of crime reporting. None have attempted to present an overall administrative crime index as has the FBI in the U.S. With the exception of Britain, crime statistics in Europe have in the past concentrated mainly upon court or prison statistics, not on police reporting statistics as have the *Uniform Crime Reports* and the research index.

Britain probably produces the most extensive set of crime statistics, mostly of the administrative variety. *Criminal Statistics in England and Wales* is published six months after the close of the year and presents a very detailed classification of offenses. It publishes both police and court statistics, crimes cleared by the police, and tables that allow comparison of police and court figures for individual offenses per million of population since the 1940s. In another publication, *Report of the Commissioners of Prisons*, extensive statistics on the prisoner population are presented.

The French volume entitled *Compte Général de l'administration de la justice civile et commerciale et de la justice criminelle* has been published since 1825 and contains criminal statistics based upon court, not police, statistics. These provide a distinction between repeaters and first offenders; detailed information of the "milieu social"—the occupation and other factors related to the offense; and a classification according to age, sex, offense, and sentence. In Italy the *Annuario di statistiche Giudiziarie* presents every year police and judicial statistics. Unfortunately there is usually a two-to-three-year delay in publication, and the criteria and method of reporting are changed frequently.

Denmark's annual publication, *Kriminalstatistik* (with English translations of tables), has for the past 20 years provided very comprehensive statistics, containing detailed breakdowns of offenses, police and judicial statistics, and such factors as residence at time of committal, the presence of alcohol, previous criminality, types of sentences and disposition, occupation of the offender, and many others.

Other countries in Europe have collected criminal statistics according to their own traditions. Because of the divergent ways in which the law is administered in the various countries in Europe, it has proved difficult to establish any standard procedure of crime reporting.

The Council of Europe has recently turned attention away from the insurmountable difficulties in obtaining a direct administrative solution to the problem of uniform crime reporting, to a close study of the research index, in the hope that this might provide the basis for an international agreement on the construction of an index of crime that is comparable from country to country, and from region to region. The suggestion has been made that it may be possible to apply the "seriousness" weights that the research index provides to already existing administrative crime statistics. Much work has yet to be done on this, but there is hope that in the future the research index may provide truly comparable international crime statistics.

**Trends and comparisons.** Although it is probably fair to say that, since the end of World War II, crime defined in the broadest of terms has increased substantially in most Western countries and in a number of developing countries as well, any interpretation of this trend must be made with great care. Apart from taking into account the sources of unreliability already described, it is necessary to consider such factors as changes in the structure of the population with regard to age, sex, and race. The *Uniform Crime Reports* of the United States for 1969 shows that, while the population of the United States rose 13 percent between 1960 and 1970, the overall crime rate indicated by the index of offenses described above rose 148 percent; violent crimes rose 130 percent, and property crimes 151 percent. In England and Wales from 1938 to 1960, crimes of violence increased by 130 percent, with substantial increases occurring over the latter ten years of the period. Substantial increases also have been reported in a number of European countries and Japan.

#### THE ANALYSIS OF CRIME

**The variety of approaches.** Since the beginning of the scientific study of crime, attempts have been made to isolate those factors that, alone or, more frequently, in complex interactions, appear to be associated with criminal behaviour. Many hypotheses have been presented, from those centred around the existence, in the offender, of biological, constitutional, or acquired anomalies to those that search for the "cause" of crime in economic and social factors or that identify the "causes" in psychological deviations.

Today, primarily as a consequence of the development of a "clinical," individualized approach to the study of offenders, the existence of several mechanisms in which many factors enter simultaneously into play or in different periods of the life of the individual is conceded. This has not, however, reduced interest in general theories about criminal behaviour. But the search for a single cause of crime has been largely abandoned as fruitless. Although, at an individual level, an interdisciplinary clinical study may establish cause-effect relationships and give useful indications for modifying or controlling criminal behaviour, no such attempt is successful at a general level.

Many theories that have been presented in the past are today of only historical interest because they have either been disproved or have been found to account only for a small percentage of criminal events. Early statements on the influence of geographical and climatic factors on crime rates, for example, have been negated by subsequent researches. Seasonal variations in crime have been repeatedly presented as pointing to a direct relationship, but again, these are now considered to be of little or no usefulness in explaining antisocial or criminal behaviour.

A search for biological and genetic factors in crime causation characterized the beginning of scientific criminology. Several factors, including such things as supposedly "criminal constitutions," physical type, organic brain injuries or diseases, endocrinal abnormalities, hereditary traits, and, more recently, chromosomal aberrations, have been postulated as causes of criminality. None of these attempts has been successful in presenting a valid general theory of crime causation. At an individual level, all the factors presented may help in understanding the

Biological  
and  
genetic  
factors

specific makeup of an offender or may explain a single offence, particularly if it is one of a violent, unpredictable, and seemingly motiveless nature. But, even when such factors provide an adequate explanation of a particular criminal personality or criminal act, it is invariably the case that the individual involved is in some way abnormal. Biological factors, therefore, at best appear to account for a minor group of offenders and offenses and leave unexplained the majority group of "normal" offenders and offenses.

Similar considerations are relevant to psychological, psychoanalytical, and psychopathological perspectives on crime. Criminal behaviour may occur as a symptom of several types of mental illness. Motiveless murder, for example, may indicate schizophrenia, and kleptomania may be a symptom of a compulsive neurosis. But such explanations account only for those cases in which the mental illness or the psychological abnormality has reached a causative level in the specific offender, and not for homicide or theft in general. Descriptive analyses of offenders in general, or of specific types of offenders, have been attempted by psychologists using psychodiagnostic tests or by psychoanalysts employing the theoretical approaches of dynamic psychology. Few general causative facts have emerged. At a descriptive level, psychological studies have been of some usefulness in presenting standard descriptions of offenders as types. Most typologies of offenders, however, fail to account for all the varieties of criminal behaviour. Recent typological efforts have tended to include sociological factors, leading sociologists to shift their perspective from the individual offender to the study of group societal processes affecting the individual and contributing to his criminal behaviour. The relationship between the offender, or offenders, and the social environment becomes the focus of the search for causative factors. Sociologists face the problem, however, that, regardless of the explanatory level of their theories, sociological factors can never account for individually different responses to supposed crime-causing factors. Faced with similar social factors—such as slums or social discrimination—only a minority of the individuals so exposed become criminals.

This difficulty has shifted modern research efforts away from causes toward processes and models. It has, at the same time, made clear that a causative explanation of crime must of necessity be "integrated," fusing sociological and psychological concepts and occasionally including biological factors in an individualized explanation of each criminal and each criminal offense. General theories, if they emerge, will follow this balanced interdisciplinary trend.

**Density and size** of the community. Statistics for the United States show a significantly high rate of crime in urban areas as against rural areas, and this is generally true for most industrial and urbanized countries, including, as far as information is available, eastern Europe. The reasons frequently put forth to explain this are that rural communities tend to be more homogeneous in moral behavioral patterns; that rural families are more closely knit because of tradition and because of the work they perform together; and that the rural community is less complex in organization, enabling the church and the school to exert the necessary external control. In addition, police control in rural areas may be exerted more informally and less strictly, and the police often have been considered as part of the community and not as an external agency. Within the city itself, some interesting patterns emerge. Studies in the 1920s and 1930s in America found that delinquency areas could be characterized by their proximity to industry and commerce, physical deterioration, decreasing neighbourhood population, non-ownership of homes, the presence of ethnic minorities, and the lack of community facilities. These observations gave rise to the theory that where populations are constantly shifting, people lose interest in the appearance and moral reputation of their neighbourhood. This implied an alienation from one's surroundings, so that the small neighbourhood ceased to act as a controller or regulator of individual behaviour the way it normally does

in the village or rural community. Thus, some important controls were removed and crime and delinquency erupted. This theory, however, is now criticized by those who assert that modern suburbs, with their emphasis upon privacy and anonymity, can hardly be said to promote neighbourliness, and although it is often argued that alienation in these areas is even more extensive, their delinquency and crime rates are generally lower than those of inner urban areas. One reason sometimes put forth to explain this anomaly is that the police may be more likely to let middle class suburban offenders off with a warning, whereas those offenders in the slum areas will more likely be arrested. Research has suggested that there are differences in the attitudes of the police and in enforcement policies between slum and middle class areas.

**The criminal population.** *Sex.* Throughout the world, most crimes are committed by men. Very roughly, the ratio of arrests for murder is six men to every one woman; for assault seven to one; robbery 22 to one; and burglary 30 to one. Although many interpretations of these ratios are possible, current opinion is that they attest to the importance of social rather than personality factors in crime. Another difference between male and female criminality is that women tend to commit their crimes in isolation rather than in the company of a group, as is the tendency for men. In the case of violent crimes, women tend to commit most of them upon members of their own family.

*Age.* Offenders committing serious crimes are most frequently under the age of 25. An important observation is that the age group 11 to 17 accounts for one-half of those arrested, and the group under 25 accounts for three-quarters of the arrests. On the other hand, two-thirds of those who commit homicide are 25 and over.

*Race.* Most crime statistics in the United States indicate a higher rate for blacks than for whites over a wide range of offences. Crimes that show the least difference in incidence as between blacks and whites are those that blacks have less opportunity to commit because of their minority status—embezzling and counterfeiting, for example. Two opposite interpretations of this difference are sometimes offered: first, that it represents the discriminatory attitudes of law enforcement officers, who are more prone to arrest blacks than whites; and second, that it is because the black is somehow predisposed to crime. Both of these explanations are simplistic, and, in light of the findings of geneticists, and because of the semantic confusion that always surrounds the interpretation of the findings of geneticists and environmentalists, both views must be regarded as definitely unproven.

Other alleged explanations of the high crime rate among blacks in the United States relate to the vicious circle of discrimination; the black in America, and other minority groups in America and elsewhere, generally suffer from lower wages and more unemployment than others and are forced into less desirable jobs, especially as a result of being kept out of white-dominated labour unions. Because of segregation, the quality of black education is generally inferior, which leads directly to lack of job opportunity. It should also be recognized that because blacks have been forced to live in cultural ghettos they have built up patterns of child rearing and moral teaching of their own. The use of physical punishment is extensive in teaching children right from wrong, so that certain violent ways of behaving are learned at an early age. Further, the vast majority of crimes committed by blacks are committed against other blacks, not against whites. In a study of homicide in Philadelphia, only 6 percent of homicides were found to be cross-racial.

*Class structure.* Traditional Marxist theory attributes crime to the frustration of the working class resulting from constant exploitation by the upper class. As a general statement it may be said that economic conditions and poverty have *not* been found to be the critical factor in the cause of criminal and deviant behaviour, with the possible exception of suicide. A number of studies have, however, shown that such crimes as robbery and other property offenses do increase when there is a large

Crime and  
discrimination

Dichotomy  
between  
rural and  
urban  
areas

amount of unemployment. Other studies have shown that crime increases during periods of economic prosperity.

Statistics on apprehended and punished offenders probably overrate the relationship between economic conditions and crime because the poor are more likely to be identified and arrested, are less able to raise bail, and may be assisted by inexperienced lawyers. But even when these factors have been allowed for, it is clear that crime most certainly occurs more frequently in the slums.

Among the specific variables that have been found to have some relation to delinquency are a higher proportion of working mothers, irregular employment, the existence of child labour, and lack of adequate child supervision. Distribution according to social class can occasionally be discerned for certain offenses. Studies in England have shown that homosexuality is more common in higher or professional classes. Some crimes, such as embezzlement and art fraud, require certain levels of educational and social status in order for them to be committed.

**Criminal subcultures.** A concept currently gaining wide acceptance and for which empirical evidence may be growing is that of the criminal subculture, in which a different set of rules or norms for conduct arise, along with different child-rearing patterns, family relationships, and traditions. Thus the subculture of violence may be one in which the quick resort to physical aggression in the face of frustrating circumstances has come to be the pattern of reaction acquired by the member of the subculture at a very early age through social learning and identification with criminal models. Certain other types of crime, such as safecracking, require that offenders spend a good deal of time in a hardened criminal's company in order to learn the skills of the trade. A subculture may thus arise to foster the development of a pattern of norms of conduct quite at variance with those of the prevailing culture.

Early investigations of the mobility of the criminal population concentrated upon migratory groups—either within a country (rural to city migration) or internationally—and claimed to demonstrate a close relationship between crime and migration. It is now clear, however, that migration itself does not have a significant statistical effect upon crime. This has been demonstrated in studies of black migrant populations in the United States and of the migration from south to north in Europe. One of the complicating factors in such studies is that those who do migrate tend to be young, adult males, the group most prone to high rates of criminality anyway. In analyses of the higher crime rates for migrant groups, the difference is often entirely accounted for by the selective age factor.

Crimes committed in the company of others also have received special study. In Europe, studies appear to have identified a common type of relationship in which two persons of opposite physical and psychological character collaborate, not uncommonly as lovers or partners, in perpetrating crimes against third persons. Such crimes as infanticide, parricide, and abortion are common in this category. Other research has suggested that the influence of the group in causing a person to partake in crime may be substantial, so that a crime that an individual on his own would not have committed may be encouraged by group support. Two examples of this type of crime are gang rape and robberies that require extensive cooperation and planning.

**Influence of the family.** It is a well-established canon among many social scientists that the family is the primary agent for the social control of conduct. Family structure and values may influence an individual's tendency toward criminality in a variety of ways. Family disorganization, resulting from desertion, the death of a parent or other important family figure, and extreme tension preceding divorce, is often a significant factor. A higher proportion of delinquents as compared to non-delinquents is found to be illegitimate, and studies indicate that the backgrounds of habitual criminals frequently include an abnormal amount of parental marital dis-

cord. Multiple-problem families, which are usually very large and headed by parents of low intelligence, poor health, and low and irregular incomes, are also frequently held to generate criminal behaviours. There is considerable disagreement as to whether these families display a higher rate of crime because of their internal structure, tensions, and shortcomings or because they are invariably situated in the higher crime areas. Both aspects are clearly important, but what is of interest is that the worst types of problem families do not often produce the most serious types of criminals.

The family is usually one of the agents that transmits conflicts of cultures. American studies conducted soon after World War II suggested that crime and delinquency were extensively a problem of poor immigrants, and particularly of their American-born children. Broadly speaking, criminality tends to diminish with each successive indigenously born generation.

Some families may train their children to commit crimes, and there is evidence that this may especially be so among professional thieves. Studies in many countries have shown that a very large proportion of delinquents and criminals have delinquents or criminals as members of their household. But there are other conflicting findings. The question that so far remains unanswered is this: why do some members of a family become criminal while others do not?

Family disciplinary policies may be either too lax, too severe, or too inconsistent. American research has suggested that unsound discipline may be related to about 70 percent of criminal men. But it must be remembered that the process by which the child learns to abide by the rules and to control his inner impulses (socialization) is still little understood, and factors that are hypothesized to contribute to a breakdown of socialization must be considered as only tentative. Reservations aside, it would seem that in Western societies consistency of discipline is of utmost importance. The process of socialization appears to be an extremely delicate one, so much so that its success may depend quite heavily on factors difficult to define—such as the mother-child relationship, the father-child relationship, and associated psychological ramifications of early childhood experience. Accidental or chance events that may occur at critical stages of development may in fact play a major part. In addition, this complex of factors must be seen against a background of variables related to country, social class, and fashion, which strongly influence child rearing. This makes the location of the cause of crime in the breakdown of any one aspect of the socialization process an extremely difficult, if not impossible task, particularly if general "laws" or principles are sought.

The family may also set the scene for later emotional disturbances. The potential offender may be revengeful because he feels that his parents were unjust to him; he may have felt deprived in many different ways (money, gifts, love); he may develop a poor self-image because of constant parental rejection. These are only a few possibilities, and psychoanalytically oriented criminologists propose many more explanations of criminal behaviour in terms of early family relationships.

Some modern theorists now argue that the role played by the family in transmitting the rules and values of society is becoming less and less meaningful as society grows more complex, as people become more alienated from one another, and as formal agencies outside the family increasingly begin to take over the responsibilities that were traditionally entrusted to the family. An example of this may be in the realm of sex education, in which the school in some countries is beginning to assume responsibility for imparting knowledge and values concerning sex behaviour. Furthermore, the enormous effect of the mass media in conveying values to both children and adults, often in a conflicting and indiscriminate pattern, may tend to slant responsibility away from the parents as the prime transmitters of values.

**Educational factors.** Does education help to prevent crime? The most pessimistic view is that a better education simply enables a criminal to be a more effective

The family and the process of socialization

Crime among migratory groups

Relation of  
education  
and crime

criminal. It was once believed that education for all would help to eliminate crime. Despite the fact that this hope has not been realized, there does appear to be a clear relationship between educational level and crime. Studies have generally suggested that prisoners as a group have poorer education and higher illiteracy rates than nonprisoners. Explanations of this relationship are many. Earlier theories suggested that the criminal achieved poorer educational levels simply because he was dull and lacking in intelligence. It has since been recognized that this explanation is an oversimplification, for while it is true that prisoners generally score lower on intelligence tests, the built-in social class bias of such tests is now recognized. Furthermore, inadequate schooling, commonly a factor related to performance on intelligence tests, is also closely related to criminality.

There is considerable evidence that delinquency and criminal behaviour first become visible to society in the school setting. Large numbers of repeating offenders have been found to have had unhappy school careers and truancy records. Those who consider the school more important than the family in teaching children self-control and obedience would presumably charge the school with failing to fulfill its functions as far as these particular children are concerned. It seems at least arguable that, while schools have been encumbered with more and more responsibilities of this kind, the extent to which their organization, curricula, and teacher attitudes have changed to meet the challenge is minimal, particularly in urban settings. The difficulty may be that many teachers consider the central function of the school to be to impart knowledge, and the transmission of anticriminal attitudes to be only a by-product of secondary importance. Furthermore, the way in which the transmission of social values may be most effectively achieved in the school setting awaits further study. This area of criminology has received little attention from researchers to date.

Victimology. Any significant study of crime in society must include an analysis of the victims of crime, as well as of the perpetrators. In certain specific crimes the distinction in law between criminal and victim, guilty party and innocent, is difficult to maintain. This applies especially to some crimes of violence which commonly occur between a victim and offender who are closely related to each other. In England, for example, two-thirds of female victims of violent crime were attacked by relatives. An extensive study of homicides in the United States revealed that half the victims had had previous arrests, and a very large number were either close friends or relatives of their assailant. A quarter of the homicides were found to have been precipitated by the victim. Homosexuals and other sexual deviants appear to be especially prone to violent attacks by others, quite often their partners. In the field of economic crime, a similar relationship between victim and offender is apparent. Large department stores that display goods on open shelves clearly invite their theft; art forgeries flourish because of the speculative habits of the victims.

In surveys conducted in the 1960s in the United States, 20 percent of the sample questioned reported that they had been victims of crimes. This represents a crime rate twice that reported by the FBI. Blacks were found to be twice as likely to be victims of both violent and property crimes. More striking was the finding that only 60 percent of the serious crimes were reported to the police. The main reason that people gave for this was that they thought that the police could do nothing.

England, Canada, and some states of the United States have introduced new legislation to compensate victims of crimes, especially violent crimes. Other countries have enacted, or are enacting, similar legislation. In the light of the information above, it can be seen that the assessment of the victim's role in the criminal episode is extremely complex and may often make it difficult to apportion responsibility and decide on compensation.

#### CRIMINAL CLASSIFICATIONS

Normal and abnormal offenders. The concept of normality is a very elusive one, and some recent schools of

thought have suggested that whether a person is normal or abnormal is merely a question of definition. Only recently has it come to be accepted that the diagnosis and labelling system used by mental health specialists is heavily laden with the social class and cultural values of the definers. This includes the moral judgment, most often implicit, of right and wrong, so that the apparently simple labelling of a person as "sick" may also imply that he is "bad." The proponents of this perspective tend to view antisocial behaviour not as a sickness but simply as behaviour that has come to be defined that way. The implication, to some extent substantiated empirically, is that criminals are not all that different from noncriminals, except for the fact that they have been processed through a system of criminal justice. The evidence is, in any case, conflicting. A number of studies have indicated no significant difference between the personality traits of prisoners and nonprisoners, and no definable personality makeup of delinquents compared to nondelinquents. Some accumulated evidence does suggest that traits of aggressiveness and feelings of inadequacy are common features in delinquent personality. But beyond this, there is really no agreement on what psychological factors differentiate criminals from noncriminals, and the reason for this could well be that there is no great difference between the two groups.

In advanced Western societies, more and more behaviour that was once defined as criminal is now often seen as behaviour requiring treatment, usually of a psychological type. Various legal codes recognize a number of forms of such mental abnormality as epilepsy, schizophrenia, mental defectiveness, and paranoia.

Offender careers. It is becoming increasingly apparent that such terms as delinquent or criminal have little real meaning. But, by taking into account the career of the offender, the support that his behaviour receives from his group, the correspondence between criminal behaviour patterns and legitimate behaviour patterns, and the societal reaction to criminal behaviour, one can construct a number of useful types of behaviour systems. The criminal career is made up of the social roles that the offender plays, his self-identification with crime, his self-concept, his relationship with others, and the degree to which criminal behaviour has become a part of his everyday life. Some offenders may have association almost entirely with other criminal types, whereas others may not. Some typical offender career patterns are those of (1) *the occasional offender*, who does not have a conception of himself as a criminal, does not play a criminal role, and does not have much group support for his activities; (2) *the habitual petty offender*, who has a long criminal career, but is generally not very sophisticated in his activities and tends to be more easily caught; (3) *the conventional criminal offender*, who displays a steady progression from juvenile gang delinquency to adult criminal behaviour of a more serious type. Such career offenders continually acquire new techniques of committing crime along with new self-justifications for committing them. Studies have shown that these career offenders usually have intimate associations with others of a similar type from whom they learn and to whom they impart the skills and justifications for their acts. Typically, these crimes reach their peak during the 20s, and terminate in the early 30s of the life history of the offender; (4) *the professional offender*, who has the most highly developed career and level of sophistication. Professional criminals are generally looked up to by conventional criminals. They engage in a variety of highly specialized crimes, such as pickpocketing, sneak-thieving from stores, banks, and offices, stealing from jewelry stores and hotel rooms, passing illegal checks, and extorting money from others who are engaged in illegal activity. These criminals are not usually connected with any "heavy rackets" or organized crime, although some, such as safecrackers, may be. In comparison to other criminals, an extremely high degree of consensus exists among professional criminals, who develop common attitudes toward themselves, toward their crimes, and toward the police, who are seen as the "common enemy." There is quite definitely a code

Typical  
criminal  
career  
patterns

Compensation  
for  
victims of  
crime

of honour among them and a highly specialized argot, developed and transmitted from one generation to another.

**Occupational offenders and white-collar criminals.** Offenders in this category include businessmen, politicians, government employees, doctors, and others who commit crimes that are closely related to their work. For occupations of relatively high status, the term white-collar crime is often used. Violations of the law by businessmen include those related to receiverships and bankruptcies, restraint of trade such as monopoly, illegal rebates, infringement of patents, trademarks, and copyrights, and misrepresentation in advertising. Norms concerning food and drugs sale and antipollution regulations also may be violated. Employers have been found to violate laws regarding wages, hours, and public contracts. Politicians and government employees may obtain illegal financial gains by furnishing favours or confidential information to business firms and obtaining illegal commissions. In the medical profession, doctors may give illegal prescriptions for narcotics and give false testimony in accident cases. Lawyers may misappropriate funds and secure perjured testimony from witnesses. Embezzlement is a common form of occupational crime.

The major difference between occupational offenders and other offenders lies in the offender's conception of himself. The occupational offender rarely sees himself as a criminal. He may, in fact, see himself as a respectable citizen. In addition, the usual middle or high social status of these offenders is such that it also makes it difficult for the public to conceive of them as criminals.

**Significance of white-collar crime**

The consideration of white-collar crime in criminology has introduced an important balance to an otherwise distorted picture that is presented by the exclusive study of conventional crime in society. Perpetrators of white-collar crime, who are usually better educated, are less often sentenced to imprisonment and are often not prosecuted formally by the system of criminal justice. Instead, they may be disbarred from their profession or receive fines that they are usually able to pay more easily than are conventional criminals. In purely monetary terms, it has been estimated that the cost of conventional crime is trivial compared to the millions involved in the crimes of fraud and embezzlement. Studies of the activities of large corporations have suggested that their illegal activities may be highly organized and persistent and, as a whole, show clear disregard for the government, the law, and the people who administer it. But the concept of white-collar crime has been strongly criticized from some quarters because it has expanded the concept of crime beyond what has conventionally been considered the proper area of study for criminology—the study of the overt acts of convicted offenders. These critics also insist that there is a basic incongruity involved in the proposition that implies that a community's political and business leaders may also be criminals. Proponents of the concept of white-collar crime are accused of being unrealistic and of having diverted attention away from the serious nature of conventional crime. This controversy, in fact, relates to the overlapping between criminal law and civil and administrative law, and to the question of which kinds of conduct are best controlled by the application of the criminal law, and which kinds by other means. There has been a tendency in most countries to delimit the range of conduct with which the system of criminal justice must be concerned. The trend in research, on the other hand, has been to broaden the concept of criminal behaviour, or, more accurately, to include it and many other types of behaviour under the more general rubric of "deviant behaviour."

**Organized crime.** The study of organized crime has been conspicuously neglected in British and continental criminology. A few studies in Germany and Scotland have suggested that the activities of well-organized professional gangs are extensive throughout Britain and continental Europe. Such gangs engage in well-executed robberies (such as the great train robbery near Aylesbury, England in 1963), in organized smuggling, art frauds, the drugging of racehorses, and so forth. Occasionally, it has

been noted that gangs of adult criminals are often active in times of political and social upheaval. The robber-knights of the German Middle Ages, the gangs of coiners in the 17th century, and the secret societies that terrorized the population of Germany and other continental countries during the 18th century are examples. Adult gangs flourished in France during the Revolution.

But organized crime is most prevalent in Western countries. Though it is widely believed that organized crime was imported into the United States via the immigration of Mafia members from Sicily, a number of writers have questioned this. Undoubtedly, many members of the Mafia did migrate to America, and many notorious criminals have been Sicilian. But it also should be noted that there are in America many other ethnic groups involved in organized crime. The proportions of Jews and Irish appear to be quite large.

The Mafia

The Sicilian Mafia is described as not so much a secret society as a "habit" of tackling all enterprises in an indirect and underhanded manner, by mediation, by recommendation, and by other dubious forms of "influence." It provides redress against evildoers but also protects criminals from the law and encourages their criminal behaviour. In Sicily it has been shown that, for a time, the Mafia was in fact able to safeguard the interests of the common people more effectively than a geographically remote and uninterested government. The Mafia enjoyed a revival just after World War II, but at present an organized, large-scale war is being waged against it by law enforcement agencies.

There are certain similarities between the Mafia and its American counterpart, but these may be common features of all organized criminal groups. The conspiracy of silence, the separate and highly effective system of group "justice," and the protection racket are typical not only of the Sicilian and American Mafia but have been present in the past in organized crime in India and China.

In the United States the term organized crime has come to mean something quite unique and is used to refer to large-scale rackets, extensively organized, carried on over long periods of time, and relying on political corruption for protection from the law. Crime syndicates have abundant capital, may have control of factories and warehouses, and control their own managerial personnel and employees. They operate rackets in drug traffic, liquor sales, protection, gambling, and prostitution.

Non-American students of organized crime have tended to be dubious that crime on such a scale exists in the United States. Although they usually concede that organized crime exists on a local basis, they are often skeptical about the claimed immense countrywide organization. On the other hand, "conventions" of notorious criminals in America do occur, and are reported by the press.

**Homicide and crimes of violence.** The majority of homicides are committed within the family or between close friends. About half occur as the result of trivial altercation. In the United States, the method is equally distributed among gunning, stabbing, and beatings. In contrast, guns are rarely used in England: assailants often use blunt objects that happen to be on hand at the time. The age of homicide offenders in America is predominantly 20 to 24, but in England it is a little higher, though both countries report an increasing use of violence by youthful offenders. Many early studies have reported that participants in homicide in the United States do not generally have previous criminal records, but one thorough study reported that nearly two-thirds of the offenders had prior arrest records. In England, more than one-half of convicted violent offenders have had previous records of arrest for nonviolent offenses; and 20 percent have had previous convictions for crimes of violence.

Of all crimes, homicide has the highest "clearance rate" (that is, more murders are solved than any other crime); the rate is around 90 percent in most countries for which statistics are available. The conviction rate, however, appears to be somewhat lower. About 80 percent of American blacks who are tried are convicted, as compared to a 60 percent conviction rate for whites. A low conviction rate for crimes of violence is also reported for London.

**Drug addiction.** The extent to which the taking of drugs is unlawful varies enormously from one country to the next, but severer sentences seem to be becoming more common in Western nations.

Certain types of crime are committed more often by narcotic addicts, mainly because they need money to support a habit made impossibly expensive by illegal trafficking and blackmarketing. But it is also possible, at least in some cases, that taking these drugs may deter a person from committing certain types of crime, especially those of violence. In the light of a very large amount of research evidence, criminologists have advocated that some drugs, marijuana in particular, should not be outlawed, that penalties should not be too severe, and that the legalization or controlled distribution of drugs to stamp out illegal trafficking should be introduced.

**Intoxication and alcoholism.** In many countries, drunkenness itself is not an offense, but there are usually many other kinds of conduct that are closely related to it, such as disorderly conduct or disturbing the peace. In England and Wales, there has been a decline in convictions for these offenses, but in the United States the situation is different. It has been estimated that of about 70,000,000 Americans who drink, 4,700,000 are alcoholics. A substantial proportion of these alcoholics is made up of skid row drunks, who, in an endless procession, are brought before the courts, given a few days jail, and released, only to be picked up again for vagrancy, disorderly conduct, or some other public nuisance offense. It is generally agreed that these people are not helped by incarceration, but there appear to be no ready solutions to the problem.

The relationship between drunkenness and motoring offenses is also complex, but it is apparent that many serious accidents and injuries on the road involve persons driving under the influence of liquor. Recent trends are toward a definite increase in the severity of punishment for drunk driving offenses. In cases of criminal homicide, American research suggests that in almost half the cases studied excessive drinking prior to the offense was evident in either the victim or the offender or both. Research in England suggests that the majority of alcoholics do not get into serious conflicts with the law, though research in Scandinavia suggests the opposite.

#### THE CONTROL OF CRIME

**Police and the public.** The attitudes and policies of law enforcement agencies vary widely between countries. The behaviour of police depends in large part upon their perception of how the public sees them. Who will be arrested depends on the policeman's attitudes, on the enforcement policy of his department, and on the area in which he is working. Observation of policemen on duty affirms that their job is extremely difficult and sometimes dangerous and, if done conscientiously, requires a great deal of skill and quick thinking. The decision as to whether or not to make an arrest depends upon an enormous number of factors that the policeman must take into account, often very quickly and in the heat of the moment. It is understandable that many police departments, in the face of rising defiance of police and questioning of their competence, have become organized along quasi-military lines. This provides the policeman with a definite, though possibly unwritten, set of rules that he may, with his superiors' approval, rigidly abide by when dealing with offenders. The result is that the policeman may remain completely detached from the public with whom he deals, interpret all situations according to the rules, and often appear callous or rigid to the public. The opposite type of police organization is one in which the policeman is allowed wide freedom of discretion and thus may enforce the law to whatever degree he thinks is suitable to the situation. Although this may sound like a more reasonable approach, the freedom may easily lead to the law enforcement officer exercising his own personal prejudice. In addition, the situation is complicated by the fact that the police departments that are organized along military lines are more formally structured, offer more professional training, and

offer greater chances for promotion. Thus, it happens that those police with the most training, and the best chance to make law enforcement a career, are allowed less discretionary powers.

Though there exists no formal research evidence, it is probable that more police corruption exists in a country such as the United States than in a country such as Great Britain. It would seem that the American policeman is less socially esteemed than his British counterpart and is likely to use violence more often, especially when his status is affronted by the offender. It appears to be a common factor with police in many countries that they remain socially apart from the rest of society. Whether or not this is by choice is still a matter of speculation. Studies have shown that the informal social and recreational life of policemen is almost exclusively carried on among themselves and that they feel themselves set apart from the rest of society. Despite this, public opinion polls in America suggest that the majority of people think that the police do a good job and hold them in higher esteem than the police themselves realize.

Another common feeling that police have is one of ineffectiveness. They commonly adopt the view that they are fighting a war against crime, yet find that of the many offenders they arrest, only a very small proportion are convicted and found guilty. In the United States, the President's Commission on Law Enforcement and Administration of Justice found in 1965 that for 2,780,140 crimes reported, only 727,000 persons were arrested and that of these, 290,000 were never charged. The courts in many countries are hopelessly clogged with cases, and it is common for an offender to wait months, and sometimes years, for his trial. A practical suggestion has been to set up a special court to deal solely with offenders who have been assessed as dangerous and hardened criminals, so that their cases may be dealt with speedily, to prevent their being free in the community on bail while they await their trial. There is some evidence that a disproportionate number of crimes of violence are committed by hardened criminals awaiting trial on bail.

Preventive detention — which is the denial of bail or the imprisonment of a person accused of an offense on the grounds that he is too dangerous to be free, even though he has not been found guilty — raises very difficult issues of individual rights. The only solution to the problem would seem to be to provide an efficient and swift system of bringing people to trial. Underlying this whole problem are two basic contradictory attitudes toward crime control. One school of thought, assuming that persons having contact with the police are more likely to be guilty than innocent, advocates an efficient control of crime by establishing wide freedom to arrest on suspicion, fewer restrictions on searching and entering people's residences, more freedom to use such methods as wiretapping for investigation and subsequent evidence in court, and more freedom to obtain confessions. In short, this view is oriented to seeking out the wrongdoer at almost any cost. Although it is recognized that mistakes may occur, it is obvious that with greater freedom to investigate, the police would catch more criminals and be likely to make less mistakes because they would have more information. In the long run, the argument goes, this method is fairer, especially because it would eliminate such doubtful procedures as negotiated pleas, or "bargain justice," in which the offender is encouraged to plead guilty to a lesser offense if the prosecutor agrees not to press a more serious charge.

But the contrary view argues that individual rights must be preserved at all costs, and insists that the presumption of innocence must be maintained right through to the end of the trial. The individual is conceived of as needing protection from the police, who are seen as representing the potential tyranny of the state. In general, this view tries to make obtaining a conviction more complicated, usually on the rationale that by doing so there will be less chance of miscarriages of justice. This approach sounds highly humanitarian and liberal and more protective of individual rights, but it may be that the disorganized and complicated machinery of police, courts,

Public attitudes toward police

Alcohol and driving offenses

Proposals for extending the power of police

and corrections is closely related to it. It has been argued that the insistence upon individual rights may lead to such injustices as long imprisonment while awaiting trial, or the increased risk of crimes committed by those on bail awaiting trial. The solution to this paradox appears to be issuing from the increasing agreement among criminologists and administrators that there exists an identifiable group of hardened criminals, who have long records, are often violent, and are the only types of criminal whom society needs to imprison because of their dangerousness. Fortunately, it is believed to be likely that they comprise only a very small proportion of the present criminal population. The future trend, therefore, may be to infringe less upon the individual's freedom by imprisoning only those offenders assessed as dangerous, but, on the other hand, to increase the efficiency with which these people are sought out.

**Corrections.** Though there is much controversy over the effectiveness of prisons and other forms of treatment-oriented sanctions, the resigned opinion of leading authorities on corrections now is that most forms of punishment and treatment have little or no discernible effect upon the rate of crime. The only possible exception may be fines for traffic offenses.

There is considerable evidence that prison may play a role in extending criminal behaviour rather than limiting it. The study of total institutions (that is, any institution that creates its own little society and system of values completely isolated from the rest of society, including monasteries, boarding schools, and mental asylums, as well as prisons) has shown that prisons sometimes place insurmountable obstacles in the way of rehabilitating the offender. The growing belief today is, therefore, that an offender cannot be taught to live in society by separating him from it. There is now a strong move in some countries to create "halfway houses" and other similar institutions, in which the offender may receive supervision but still work and live in the community.

The assumption at the bottom of all these studies of effectiveness of treatment is that in some way or other the offender is abnormal or significantly different from other people and that this "maladjustment" must be changed. But research now suggests that offenders may not be all that different from nonoffenders, so that what exactly these treatment programs seek to change is questionable. Certainly, some offenders can readily be identified as abnormal by many established psychological theories. Most, however, cannot (see also PRISONS AND PENOLOGY).

## II. Patterns of juvenile delinquency

### THE ANALYSIS OF DELINQUENCY

**Sex and age distribution.** In Western society, the age during which delinquent acts are most frequent is around 14 and 15 years of age, and this appears to hold true for both boys and girls. The peak may vary according to the class of offense. It has been found that the peak of 14 years is mostly comprised of juveniles involved in stealing or minor theft; however, a peak at 16 to 17 is found for such offenses as malicious damage, vandalism, illegal use of a motorcar, carrying an offensive weapon, and assaults against police. Although there is some evidence for an increasing amount of delinquency in late adolescence, it seems fair to say that delinquency for the majority is mostly an episode or phase through which some young people pass. Delinquent acts begin at about age 11, continue up to the peak of 15, then decline quickly at about 20 to 22 years of age. The majority of delinquents do not commit new offenses after this age. It seems evident that a younger child is likely to be warned rather than prosecuted by police, which may explain the rise to the peak of 15 as the age more likely to invite prosecution. Theories to explain the termination after adolescence are many and conjectural. It may be explained by maturation, marriage, obtaining a steady job, or cessation of the emotional turmoil that sometimes accompanies adolescence. Though the evidence is conflicting, it is likely that those who begin committing offenses at an

early age are more likely to continue them into adulthood.

Delinquency is also predominantly a male activity. In the United States, approximately 80 percent of delinquents are boys, and similar high ratios of boys to girls are apparent throughout Europe and Japan. Studies also suggest that there is a slightly higher female rate for blacks in America, and that the ratio of girls to boys for both races increases by about 15 percent from age 10 to 16.

**Lower and middle class delinquency.** The relationship between social class and delinquency is difficult to assess. When school children are asked confidential questions about offenses that they have committed, one usually finds a very large number of offenses distributed evenly across all social classes. When one considers the statistics of convicted delinquents, however, the picture is fairly clearly one in which the lower classes are overrepresented.

There are many theories that seek to explain delinquency in social class terms. One of these suggests that the delinquency of working class boys is a response to disappointing experiences in high school, when the delinquents were unable to meet the qualifications for social achievement in an essentially middle class school. Thus, working class boys coalesce into social groups and compensate for one another's failure by disavowing the values of the middle class. The result is academic indifference, rudeness, truancy, and property destruction. Alternatively, it is suggested that working class boys must adopt certain modes of behaviour and live up to the cultural values of their group, such as living dangerously, displaying masculine toughness, and showing contempt for external authority. Another theory argues that working class boys will become delinquent because they are required by modern society to pursue certain dominant goals, such as money and other status symbols, but are not given the opportunity to acquire them because of poor educational facilities, poor housing, poor job opportunities, or other discriminatory factors.

A basic disagreement among theorists is whether the lower class delinquent is mainly oriented to the goals outside his class (that is, those of the middle class) or to the values built up over generations within his own social class. The current prevailing trend is to postulate a degree of ambivalence about middle class and lower class values and to suggest that the delinquent has difficulty understanding what values his peers adhere to. It is apparent, in any event, that there are a large number of values that delinquents hold in common with many other people in society.

Middle class delinquency does occur but has been comparatively little studied. The most popular theory to date has been that of "masculine protest." Briefly, the idea is that children very early in life adopt as an overall model for their own behaviour the parent with whom they have the closest and most continuous relationship. Because of the isolation of the middle class family in suburbia, because of its smallness, and because of the daily separation of the working father from the home, the mother becomes the dominant figure. This system works well with girls because they are expected to behave in a feminine way. Boys, however, are thrust into conflict because society expects them to be "manly" and yet the model they are forced to adopt early in life is that of the female. The boy must, therefore, assert his masculinity, and, because his mother has represented from early in life what is "good," his delinquent behaviour acquires the function of denying femininity and asserting his masculinity. This theory might also explain why there is a much larger number of boy delinquents than girls.

**The delinquent gang.** Juvenile gangs are common among both delinquent and nondelinquent boys, though delinquents tend to be members of gangs more often than nondelinquents. It was earlier thought that delinquent gangs were highly disorganized groups whose members behaved impulsively, and in which there was no particular goal or organized direction for conduct. Thus, it was popularly thought that organizations, such as the

Delinquency and social class

The theory of masculine protest

Re-evaluation of penological techniques

### A typology of gangs

Boy Scouts, could channel this impulsive behaviour into constructive activity, thus preventing delinquency. Students of gangs now recognize that there are many different types of delinquent gangs, and many of these are highly organized and structured. Many urban gangs have been found to have a long history, with many behavioral patterns handed down from one group of gang members to the next. Types of gangs that have been proposed are the following: (1) "Criminal" gangs existing in slum areas in which there is a strong tradition of crime, so that adult criminal persons serve as models for the gang members. The activity of these gangs is clearly organized and directed toward such predatory crimes as extortion, theft, and burglary. (2) "Conflict" gangs, commonly existing in new urban housing developments, where a criminal tradition has not yet arisen. Members of these gangs, oriented, it is assumed, to the values of the middle class culture and not to their own, use other adolescents as their models. Because their situation is a conflicting one, they are more likely to "act out" their frustration in acts of violence and vandalism. (3) "Retreatist" gangs contain members who, again living in slums, use drugs and other "escape" experiences because they are unable to find any path, either legitimate or illegitimate, to obtain success. It has been noted recently, however, that retreatist groups are in fact predominantly a middle class phenomenon. (This typology is not applicable, however, to the study of gangs in all modern countries.)

Some evidence suggests that the explanation of gang delinquency does not lie in forces outside the group (such as middle class values), but rather within it, in the typical striving for status by adolescent gang members within the group. Delinquent boys have been found to value their peer-group status very highly. In other words, membership in the gang provides much needed satisfaction that cannot be obtained elsewhere in society's established institutions such as school and church. The membership not only offers rewards of status recognition but also excitement. Also, the development of an adolescent "subculture" with values and interests more and more removed from those of the rest of society, and often in conflict with them, accentuates the separation of groups that pronounced urbanization brings about.

An often neglected factor in delinquent behaviour is the role of the school in the delinquent's life. The majority of research points to the very unhappy school histories of a large number of delinquents. They have high records of truancy and poor school records and generally perform less well than nondelinquents. They display more problem behaviour at school, including social maladjustment, usually quite early in their school career. A relationship between deprived social and cultural conditions and school adjustment is well established, and what adds to the problem is that there are fewer manual jobs for lower class boys who are unable to succeed at school. They thus have no prospect of satisfactory adult adjustment through work. Furthermore, it seems that a great number of delinquent acts are committed by early school leavers, or dropouts, who have no job to go to. The compulsory age of school attendance continues to increase, though special curricula to deal with such young people remain only poorly developed.

Though it is popular to characterize the juvenile drug culture as retreatist, it is clear that many who smoke marijuana are certainly not retreaters but protesters and demonstrators. Whether one should apply the term juvenile delinquent to such persons who are subsequently prosecuted and convicted as a result of their drug taking or protesting is questionable. There is a danger that the important issues with which young people are concerned will be overshadowed by the application of such stigmatizing labels as "delinquent" or "criminal."

In conclusion, it may be fair to say that when criminologists are speaking of juvenile delinquents, they are speaking more of young adolescents, considerably less mature, both socially and emotionally, than today's usually sophisticated and well-informed youthful protester.

**Home conditions.** Some research suggests that delinquents more often have parents characterized by

drunkenness or criminality, ineffective household management, economic difficulties, and low self-respect. Delinquents often indicate that their families are not concerned about their welfare. Disciplinary practices were more erratic and physical punishments more frequent for delinquents. Since the methodology used in these studies has been criticized from many quarters, the confirmation of these findings awaits further research.

In Great Britain, delinquents have been found to come from families characterized by difficult social relationships. The delinquent frequently expresses the wish to run away from home and often does so; parents often complain of difficulty in early relationships.

Some physical and biological differences between delinquents and nondelinquents have been found, but these studies are highly controversial. Delinquents are found to have sturdier bodies than nondelinquents. They are somewhat more "masculine," and they tend to be mesomorphic (a muscular, well-knit body type). No significant difference in physical health has been found. Some evidence has accumulated to suggest that delinquents as a group have a different personality structure than nondelinquents, but because of added difficulties in defining and measuring personality traits the findings remain difficult to apply to treatment. Delinquents are possibly more extroverted, more narcissistic, destructive, and sadistic, more impulsive, and less able to delay gratification. Current opinion, however, prefers to view delinquents as not substantially different from the normal population. It is, of course, also recognized that a small proportion of them may display psychological abnormality.

**Prediction and prevention.** Within very narrow limits, it now appears that delinquency can be predicted, probably at quite an early age. Although some criminologists claim to be able to do this at the age of three or four, it seems more reasonable that the delinquency of certain types of children can be predicted at least by the time the child has been at school for two or three years. Teachers have informally made such predictions for many years, and over the past decade some researchers have developed instruments to refine these intuitive judgments. Basically, three types of delinquency prediction have been developed: (1) that which uses certain "background" variables, such as quality of the neighbourhood, absence of the father from home, and alcoholism in the family; (2) that which uses variables concerning the parental attitudes toward the child, such as the varieties of discipline or the quality of the parent-child relationship; and (3) that which relies upon close observation of the child's behaviour in school and in the classroom.

Much dissatisfaction has arisen concerning research on the prediction of delinquency. The ethics of the procedure may be highly questionable. Current research suggests that the mere act of labelling another person with a stigmatizing label, such as "delinquent," may cause people in authority to treat the child as though he were indeed a delinquent, when in fact he may not be. But by this process, he may come to see himself as one.

There is a popular belief that if a delinquent could be treated at a very early age, his delinquency might be prevented. The proposition has never been conclusively tested. To date, no treatment program has been shown conclusively to have prevented delinquency, so that the value of early identification of the delinquency prone itself seems questionable. It is only very slowly coming to be realized that, as long as society has laws and has to impose them, delinquency can never be prevented. Rather, delinquency is an integral part of society. It is pointless to speak of the prevention of delinquency, when, by definition, the act of preventing it by law enforcement agencies is also the act of defining it. In addition, the idea that persons may be "treated" during childhood, so that they will be good, law abiding citizens, envisages the doubtful Utopia of a stagnant society in which everyone meekly conforms to the rules.

### RESPONSES TO DELINQUENCY

**Probation.** Most Western countries today have a formally instituted probation system, usually supervised by

Methods of delinquency prediction

The juvenile drug culture

a local authority or by the state. Many countries, however, have retained a volunteer probation system alongside the formal system. Probation may be defined as a form of disposition whereby the court suspends the sentence for selected offenders and releases them conditionally upon good behaviour, subject to prescribed rules, and subject to their supervision by officers of the court (probation officers).

Probation is most often granted to first offenders and for less serious offenses. Eligibility for probation is sometimes clearly prescribed by the law; at other times, it is left to the discretion of the court. Children's courts tend often to institute informal probation following investigation by a probation officer, who avoids bringing the case before the court. Recent cases have suggested that miscarriages of justice, either by way of uncontrolled, arbitrary decisions or by sentimental leniency, may occur under this procedure. The court also may call for a pre-sentence report that requires the probation officer to investigate the offender's situation and to provide a recommendation to the court as to what disposition may best be applied to the offender.

The conditions of probation usually emphasize hard work, wholesome companions, moderate hours, and concern for financial obligations. These conditions make clear what is not to be done, under the threat of possible commitment to an institution. The relation between the probation officer and the probationer is, therefore, often an extremely **difficult** one, especially when probation officers are trained as social workers who have conceived themselves as helpers rather than as authoritarian figures. It is apparent that the typical probation officer has little chance of establishing any sort of close relationship with all but a few of his cases—partly, also, because of heavy case loads.

The effectiveness of probation

In light of this, it may be surprising that probation is a comparatively successful way of dealing with offenders, perhaps the most successful yet. Studies on probation show a success rate of 70 to 90 percent, though these figures also may be questioned because of inadequately designed studies.

Types of treatment that have been tried under the probationary system and within institutions include psychotherapy, or intensive individual sessions between the delinquent and a therapist who seeks to establish a close, warm relationship with him, and group therapy, which involves guided discussion in small groups of delinquents, from which those seriously disturbed psychologically are excluded. It is believed that in group therapy the discussion of common problems assists the delinquent to accept more readily the restrictions of society, and enables him to understand his own behaviour more easily in relation to others. This method of treatment, which has been extremely popular since the late 1950s, is conducted mostly within institutions, often in conjunction with psychotherapy.

Not all juvenile institutions, however, use such methods. Many are oriented toward obedience and conformity. Such institutions maintain high levels of staff domination and negative sanctions and an undifferentiated view of their inmates. The Borstal System in England is typical of this type.

Common in many countries throughout the world is the institution oriented toward re-education and individual development. The English Approved School is a good example. Attempts are made to change the inmates through training; and good staff-inmate relationships are fostered. There is an emphasis upon education, job training, and "team spirit." In England, many institutions have duplicated the "house" system of the traditional upper class private schools, in an effort to change values and attitudes and to promote the acquisition of new skills and personal resources.

At the other end of the continuum, there is the institution that focusses upon the psychological reconstruction of the individual. It emphasizes gratifications and varied activities, with punishments few and seldom severe. Emphasis is upon the individual and his self-insight.

Juvenile aftercare. Juvenile aftercare takes place after

the release of a youth from an institution, and at a time when he can most benefit from life in the community under the guidance of a counsellor. It is the juvenile equivalent to parole. Aftercare first began in the United States in the early 19th century but has become an integral part of the correction and rehabilitation of young offenders only in the past 15 years. The rationale recognizes the fact that institutions may have effects upon persons that are not conducive to adjustment in society. Some offenders may **learn** simply to be more delinquent by associating with other delinquents. Others may become highly dependent upon the institution and find it difficult to adjust to life outside. Most must face the inevitable stigma that attaches to confinement in a correctional institution. The majority of released juveniles receive very little aftercare supervision, mainly because of inadequate staffing and the great **difficulty** in coordinating community agencies.

Foster care. **Foster** care has become increasingly important in recent years. It has very often been used in a negative way in an effort to prevent a child from being sent to an institution. In the past, the ideal family for foster placement has usually fitted the stereotype of the well-adjusted, stable middle-class family. There is some question as to whether or not it is realistic to expect delinquents, who very often come from lower social classes, to fully adjust to the quite rigid requirements of middle-class conduct. It is usually advocated that the local community also must be well informed in order to cater specifically to children through the schools, churches, and youth groups. Without an enlightened attitude on the part of the community, the delinquent will be rejected and be unable to adjust.

Very little scientific research exists on the effectiveness of foster care. In fact, the whole area of the treatment and disposition of juveniles is in its infancy as far as scientific study is concerned. Generally, research on the treatment of delinquents has been largely anecdotal, relating the success of various treatments; and, where formal studies have been conducted, they have been poorly designed and thus have produced inconclusive results.

FERRACUTI, *Il comportamento violento* (1966; Eng. trans., *The Subculture of Violence*, 1967), an attempt to integrate many different perspectives in criminology within the frame of a subcultural hypothesis.

*Criminal careers*: H.S. BECKER, *Outsiders: Studies in the Sociology of Deviance* (1966), the basic statement of modern deviance theory, with an account of the lives of dance band musicians and how severe drug laws came about in America; CHIC CONWELL, *The Professional Thief* (1937), a classic of the field; E.H. SUTHERLAND, *White Collar Crime* (1949, reissued 1960), another classic text, which has widely influenced current criminological theory; DR. CRESSEY, *Theft of the Nation* (1969), an account of Mafia operations.

*Control of crime*: J.Q. WILSON, *Varieties of Police Behavior* (1968), an appraisal of three American police departments, each representing distinctly different kinds of orientation to their jobs, from the "watchman" style to the military model; MP. BANTON, *The Policeman in the Community* (1964), the authoritative statement upon the relationship between the policeman and the community in Britain.

*Delinquency*: D.H. SIOTT, *Delinquency and Human Nature* (1950), a proposed typology of maladjusted families and of types of social maladjustment displayed by children at school, based on the study of many delinquents and their families; H. MANNHEIM and L.T. WILKINS, *Prediction Methods in Relation to Borstal Training* (1955), a sophisticated study on the prediction of delinquency; S. and E. GLUECK, *Delinquents and Non-delinquents in Perspective* (1968), a summary of early work on juvenile delinquency, plus the report of a follow-up study of 500 delinquents; D.J. WEST, *The Young Offender* (1967), a comprehensive account of theories, incidence, and treatment of the young offender.

*Delinquent gangs and subcultures*: FM. THRASHER, *The Gang*, 2nd ed. (1936, reissued 1963), the early classic study of gangs, which emphasized their disorganization and the impulsiveness of their members; D.M. DOWNES, *The Delinquent Solution* (1966), a critical appraisal of the theories of delinquent subcultures; J.B. MAYS, *Crime and Social Structure* (1963), a presentation of the thesis that delinquency results from the lack of opportunity and deprivation as experienced by lower class boys in English industrial cities.

(F.F./G.Ne.)

## Criminal Law

Criminal law in a broad sense is the body of law that defines criminal offenses, regulates the apprehension, charging, and trial of suspected persons, and fixes penalties and modes of treatment applicable to convicted offenders. Criminal law is only one of the devices by which organized societies protect the security of individual interests and assure the survival of the group. There are, in addition, the standards of conduct instilled by family, school, and religion; the rules of the office and factory; the regulations of civil life enforced by ordinary police powers; and the sanctions available through tort actions brought by private persons. The distinction between criminal law and tort law is difficult to draw with any real precision, but in general one may say that a tort is a private injury while a crime is conceived as an offense against the public.

The traditional approach to criminal law has been that

crime is an act that is morally wrong. The purpose of criminal sanctions was to make the offender give retribution for harm done and expiate his moral guilt; punishment was to be meted out in proportion to the guilt of the accused. In modern times more rationalistic and pragmatic views have predominated. Writers of the Enlightenment such as Cesare Beccaria in Italy, Montesquieu and Voltaire in France, and P.J.A. von Feuerbach in Germany considered the main purpose of criminal law to be the prevention of crime. With the development of the social sciences, there arose new concepts such as those of the protection of the public and the reform of the offender. Such a purpose can be seen in the West German criminal code of 1969, which provides that the court "has to consider the consequences of the sentence upon the future life of the offender in society." In the United States, the Model Penal Code proposed by the American Law Institute in 1962 states that the objective of criminal law should be "to give fair warning of the nature of the conduct declared to constitute a crime" and "to promote the correction and rehabilitation of offenders."

Important differences exist between the criminal law of most English-speaking countries and that of other countries. The criminal law of England and the United States derives from the traditional English common law of crimes and has its origins in the judicial decisions embodied in reports of decided cases. Although legislation also played an important part in the development of the English law of crimes, England has consistently rejected all efforts toward comprehensive legislative codification of its criminal law. There was no statutory definition of murder in English law as late as the 1960s. But some Commonwealth countries, notably India, have enacted criminal codes that are based on the English common law of crimes.

The criminal law of the United States, derived from the English common law, has been adapted in some respects to American conditions. In about one-third of the states of the United States the common law of crimes has been repealed by legislation. The effect of such statutes is that no person may be tried for any offense not specified in the statutory law of the state. But even in these states the common-law principles retain great influence, for the criminal statutes often are simply codifications of the common law, and their terms and provisions are ordinarily interpreted by reference to the common law. In the remaining states, prosecutions for common-law offenses not specified in statutes are possible and do sometimes occur; such offenses include conspiracy, criminal solicitation, and breach of peace. In many states the so-called penal, or criminal, codes are simply collections of individual provisions enacted at different times in response to particular problems then current, with little effort to relate the parts to the whole or to define or implement any general theory of social control by penal measures. As a result, U.S. criminal legislation characteristically is poorly drafted and inconsistent.

In western Europe the criminal law of modern times has emerged from various codifications. By far the most important were the two Napoleonic codes, the *Code d'Instruction Criminelle* of 1808 and the *Code Pénal* of 1810. The latter constituted the leading model for European criminal legislation throughout the first half of the 19th century, after which, although its influence in Europe waned, it continued to play an important role in the legislation of certain Latin American and Middle Eastern countries. The German codes of 1871 (penal code) and 1879 (procedure) provided the models for many European countries and have had significant influence in Japan and South Korea, although after World War II the United States laws of criminal procedure were the predominant influence in the latter countries. The Italian codes of 1930 represent one of the most interesting legislative efforts in the modern period. English criminal law has strongly influenced the law of Israel and that of the English-speaking African states. French criminal law has predominated in the French-speaking African states. Ethiopia's criminal law is based on Swiss law. Italian criminal law and theory have been strongly influential in Latin America.

Comparisons of Anglo-American and continental European criminal law

Move-  
ments for  
codifica-  
tion and  
reform

In the last few decades the movement for codification and law reform has made considerable progress everywhere. In the United States the National Commission on Reform of Federal Criminal Laws established by the Congress in 1966 published a study draft in 1970. The American Law Institute's model penal code (1962) stimulated a thorough re-examination of both federal and state criminal law. New codes were enacted in Louisiana (1942), Wisconsin (1955), Illinois (1961), Minnesota and New Mexico (1963), New York (1965), and Michigan (1969). England has enacted several important reform laws (including those on theft, sexual offenses, and homicide), and its Law Commission is at work on the codification of criminal law. Sweden enacted a new strongly progressive penal code in 1965. In West Germany a reform of the general part of the Criminal Code was completed in 1969. France enacted important reform laws in 1958 and 1970. Other reforms have been under way in Italy, Austria, Switzerland, Brazil, and Japan. The Soviet Union's constituent republics began enacting revised criminal codes in 1960, as did Czechoslovakia and Hungary (1961), the German Democratic Republic, Bulgaria, and Romania (1968), and Poland (1969).

Comparisons among the systems of penal law developed in the western European countries and those having their historical origins in the English common law must be stated cautiously. Substantial variations exist even among the nations that adhere generally to the Anglo-American system or to the law derived from the French, Italian, and German codes. In many respects, however, the similarities of the criminal law in all states are more important than the differences. Certain forms of behaviour are everywhere condemned by law. In matters of mitigation and justification the continental law tends to be more explicit and articulate than the Anglo-American law, although modern legislation in countries adhering to the latter is reducing these differences. Contrasts can be drawn between the procedures of the two systems, yet even here there is a common effort to provide fair proceedings for the accused and protection for basic social interests.

#### PRINCIPLES AND DOCTRINES OF CRIMINAL LAW

This section deals with substantive criminal law. The elements of substantive criminal law are: the definitions of the types of offenses that are held to be punishable; the classification of crimes (as, for example, felonies and misdemeanours in the United States, or *crime*, *délit*, and *contravention* in continental law); the principles and doctrines applied to the judgment of crime that qualify the provisions of criminal legislation (such as self-defense, necessity, insanity, and so forth); and principles determining national jurisdiction over crimes with an international aspect (crimes committed by foreigners, nationals abroad, or on ships and aircraft).

**The definition of criminal conduct.** *Legality.* The principle of legality is recognized in almost all civilized countries as the keystone of the criminal law. It is employed in four senses. The first is that there can be no crime without a rule of law; thus immoral or antisocial conduct not forbidden by law is not criminal. The law may be customary, as in common-law countries; in most countries, however, the only source of criminal law is a statute (*nulum crimen sine lege*, "no crime without a law").

Second, the principle of legality directs that criminal statutes be interpreted strictly and that they not be applied by analogical extension. If a criminal statute is ambiguous in its meaning or application, it is often given a narrow interpretation favourable to the accused. This does not mean that the law must be interpreted literally, if to do so would defeat the clear purpose of the statute. The model penal code of the American Law Institute incorporates a provision that has been enacted in some U.S. state laws: abandoning the principle of "strict construction," it recommends that its provisions be construed "according to the fair import of their terms," which comes closer to the European practice.

Third, the principle of legality forbids the application of the law retroactively. In order that a person may be con-

victed, a law must have been in effect at the time the act was committed. This aspect of the principle is embodied in the ex post facto provisions of the U.S. Constitution and such international treaties as the European Convention for the Protection of Human Rights and Fundamental Freedoms (1950).

Fourth, the language of criminal statutes must be as clear and unambiguous as possible in order to provide fair warning to the potential lawbreaker. In some countries statutes may be considered inapplicable if they are vague. In *Lanzetta v. New Jersey*, 306 U.S. 451 (1939), the U.S. Supreme Court declared a statute that penalized membership in a "gang" to be unconstitutional.

*Protection against double jeopardy.* Legal systems generally include some restriction against prosecuting a person more than once for the same offense. In Anglo-American law the most difficult problems of double jeopardy involve the question whether the second prosecution is for the "same" or a "different" offense. It is held that acquittal or conviction of an offense prohibits subsequent prosecution of a lesser offense that was included in the first (e.g., manslaughter is included in murder and cannot be prosecuted separately). It is sometimes possible, however, to prosecute a more serious crime that was included in a lesser one for which the offender has already been tried. In European law, on the other hand, the question is whether or not the second prosecution concerns the same "material fact" or "historical event," and the state cannot subject a person to a second trial for any offense arising out of the same factual situation.

A problem under the federal system of the United States is whether or not an offender may be prosecuted under both state and federal law for the same conduct (the specific offenses being different). By the beginning of the 1960s an increasing number of state laws prohibited state prosecutions after acquittals or convictions in federal courts for offenses involving the same conduct. The European Convention on the International Validity of Criminal Judgments (1970) extended the protection against double jeopardy even to judgments made in more than one country.

*Statutes of limitation.* All systems of law have statutes restricting the time within which legal proceedings may be brought. These are commonly called statutes of repose, enacted to protect against stale claims after evidence has been lost, memories have faded, or witnesses have disappeared. The periods prescribed may vary according to the seriousness of the offense. In German law, for example, the periods range from three months for petty misdemeanours to 30 years for crimes involving a life sentence. General statutes limiting the times within which prosecutions for crimes must be begun are common in Europe and the United States. In England there is no general statute of limitation applicable to criminal actions, although statutes for specific crimes frequently have included time limits.

In many countries there are no statutes of limitation for particularly heinous offenses, including certain felonies in the United States, genocide in West Germany, and—in the Soviet Union and other Communist-governed countries—crimes against the peace, war crimes, and crimes against humanity. In 1968 the United Nations General Assembly adopted a Convention on the Non-applicability of Statutes of Limitation on War Crimes and Crimes against Humanity, despite strong opposition among the majority of Western members on the ground that it was retroactive.

*Requirements of jurisdiction.* The jurisdiction of a court refers to its capacity to take valid legal action. Most governments claim jurisdiction over the acts of their own nationals, even when these acts have occurred abroad. Accordingly, most states decline any obligation to surrender their nationals to the jurisdiction of other countries; the constitutions of Brazil, West Germany, and The Netherlands prohibit extradition of their nationals; and in other states extradition is prohibited by law, as in Belgium, France, and Switzerland. The Italian constitution permits extradition of nationals only if specifically agreed upon in international conventions.

Defining  
the  
application  
of the law

In Anglo-American practice, on the other hand, the jurisdiction of the courts is limited to acts occurring in whole or part within the geographical boundaries of the state. Nationals who commit crimes in foreign countries may be extradited, but only if this is required or authorized by treaty with the country concerned. Within the United States, jurisdiction over criminal conduct is primarily limited to acts occurring within the territorial limits of a particular state. Thus, if a person fires a bullet across a state line and kills someone in another state, sometimes only the latter state is considered to have jurisdiction. Both state and federal statutes have modified this principle in matters directly affecting state or federal interests. Federal statutes confer jurisdiction on U.S. courts in cases involving treason, forgery of ship's papers, enticing to desertion from military service, bribery of a U.S. official, and other acts, even though the conduct occurred outside the national boundaries. The United States also claims jurisdiction over crimes committed on U.S. vessels and aircraft on or over the high seas. The Tokyo Convention on Offenses and Certain Other Acts Committed On Board Aircraft (1963) recognizes that states have the right and even the duty of jurisdiction with respect to any crime committed upon a public or private aircraft that has its national character.

**The elements of crime.** It is generally agreed that the essential ingredients of any crime are (1) a voluntary act or omission (*actus reus*) accompanied by (2) a certain state of mind (*mens rea*). An act may be any kind of voluntary human behaviour. Movements made in an epileptic seizure are not acts. So also, movements made by a somnambulist before awakening, even if resulting in the death of another, are not acts and do not render the sleepwalker criminally liable. Criminal liability for the result also requires that the harm done must have been caused by the accused. The test of causal relationship between conduct and result is that the event would not have happened the same way without participation of the offender.

Criminal liability may also be predicated on a failure to act when the accused was under a legal duty to act and was reasonably capable of doing so. The legal duty to act may be imposed directly by statute, such as the requirement to file an income tax return, or it may arise out of the relationship between the parties, as the obligation of parents to provide their child with food.

**The mental element.** Although most legal systems recognize the importance of the guilty mind, or *mens rea*, the statutes have not always spelled out exactly what is meant by this concept. The American Law Institute's model penal code has attempted to clarify the concept by reducing the variety of mental states to four. Guilt is attributed to a person who acts "purposely," "knowingly," "recklessly," or "negligently." These terms correspond roughly to those used in European legal theory: purpose to *intention* in French and *Absicht* in German; knowledge to *dol éventuel* in French and *bedingter Vorsatz* in German (although in German law an additional element of consent is required); recklessness to *imprevoyance consciente* and *faute lourde* in French, the German equivalents being *bewusste Fahrlässigkeit* and *grobe Fahrlässigkeit*; negligence to *imprudence inconsciente* and *unbewusste Fahrlässigkeit*. These terms, singly or in combination, appear adequate to deal with most of the common *mens rea* problems. Their general adoption would greatly clarify and rationalize the substantive law of crimes.

**Liability without mens rea.** Some penal offenses do not require the demonstration of culpable mind on the part of the accused. These include statutory rape, in which knowledge that the girl is below the age of consent is not necessary to liability, and bigamy, which may be committed even though the parties believe in complete good faith that they are free to marry. There is also a large class of "public welfare offenses," involving such things as economic regulations or laws concerning public health and safety. The rationale for eliminating the *mens rea* requirement in such offenses is that to require the prosecution to establish the defendant's intent, or even reckless-

ness, would render such regulatory legislation largely ineffective and unenforceable. Such cases are known in French law as *infractions purement matérielles*. In German law they are excluded because the requirement of *mens rea* is considered a constitutional principle.

There has been much criticism of statutes that create liability without moral fault. To expose citizens to the condemnation of a criminal conviction without a showing of moral culpability raises issues of justice. In many instances, moreover, the regulatory objectives of such legislation can more effectively be achieved by civil sanctions such as suits for damages, injunctions, and the revocation of licenses.

**Ignorance and mistake.** In most countries the law recognizes that a person who acts in ignorance of the facts of his action should not be held criminally responsible. Thus, one who takes and carries away the goods of another person, believing them to be his own, does not commit larceny for he lacks the intent to steal. Ignorance of the law, on the other hand, is generally held not to excuse the actor; it is no defense that he was unaware that his conduct was criminal. This doctrine is supported by the proposition that criminal acts may be recognized as harmful and immoral by any reasonable adult. The matter is not so clear, however, when the conduct is not obviously dangerous or immoral; a substantial body of opinion would permit mistakes of law to be asserted in defense of criminal charges in such cases, particularly when the defendant has in good faith made reasonable efforts to discover what the law is. In West Germany the Federal Court of Justice in 1952 adopted the proposition that, if a person engages in criminal conduct but is unaware of its criminality, he cannot be charged with a criminal offense. Law and practice in Switzerland are quite similar, although the Swiss courts are rather reluctant to recognize mistake of law as a good defense. In Austria the argument is accepted as a defense in cases which involve regulatory legislation when the conduct is not obviously dangerous or harmful.

**Responsibility.** It is universally recognized that, in appropriate cases, persons suffering from serious mental disorders should be relieved of the consequences of their criminal conduct. Much controversy has arisen, however, as to the appropriate legal tests of responsibility. Most legal definitions of mental disorder are not based on modern concepts of medical science, and the psychiatrist accordingly finds it difficult to make his knowledge relevant to the requirements of the court. Various attempts have been made to formulate a new legal test of responsibility. The Durham rule, set forth by the court of appeals for the U.S. District of Columbia in 1954, held that "an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect." The American Law Institute's model penal code endeavours to meet the manifold difficulties of this problem by requiring that the defendant be deprived of "substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirements of the law" as a result of mental disease or defect. This resembles the Soviet formulation of 1958, which requires a mental disease as the medical condition and incapacity to appreciate or control as the psychological condition resulting from it. The same may be said of the West German law, although the latter includes in mental illness such disorders as psychopathy and neurosis in addition to psychoses and provides for various gradations of diminished responsibility. The English Homicide Act of 1957 also recognizes diminished responsibility, though to less effect. It provides that a person who kills another shall not be guilty of murder "if he was suffering from such abnormality of mind . . . as substantially impaired his mental responsibility for his acts or omissions in doing or being a party to the killing." The primary effect of this provision is to reduce an offense of murder to one of manslaughter.

Intoxication is usually not treated as a mental incapacity. Soviet law is especially harsh, holding that the mental-disease defense is not applicable to persons who commit a crime while drunk and that drunkenness may even be

The nature  
of a  
criminal  
act

an aggravating circumstance. In West German law, on the other hand, intoxication like any other mental defect is acceptable as a defense in criminal cases.

*Mitigating circumstances and other defenses.* The law generally recognizes a number of particular situations in which the use of force, even deadly force, is excused or justified. The most important body of law in this area is that which relates to self-defense. In general, in Anglo-American law, one may kill an assailant when the killer reasonably believes that he is in imminent peril of losing his life or of suffering serious bodily injury and that killing the assailant is necessary to avoid imminent peril. Some jurisdictions require that the party claiming exculpation must avoid danger by retreat when this can be made without increasing his peril. Under many European laws, however, the defendant may stand his ground unless he has provoked his assailant purposely or by gross negligence, or unless the assailant is acting under some incapacity such as infancy, inebriation, mistake, or mental disease. Other situations in which the use of force is generally held to be justifiable, both in Anglo-American law and in European law, include the use of force in defense of others, law enforcement, and protection of property.

When the use of force is not considered justifiable, it may nevertheless be excused if the defendant believed himself to be acting under necessity. The doctrine of necessity in Anglo-American law relates to situations in which a person, confronted by the overwhelming pressure of natural forces, must make a choice between evils and chooses to engage in conduct that would otherwise be considered criminal. In the oft-cited case of *U.S. v. Holmes*, in 1842, a longboat containing passengers and members of the crew of a sunken American vessel was cast adrift in the stormy sea. To prevent the boat from being swamped, members of the crew threw some of the passengers overboard. In the trial of one of the crew members, the court recognized that such circumstances of necessity may constitute a defense to a charge of criminal homicide, provided that those sacrificed be fairly selected, as by lot. Because this had not been done, a conviction for manslaughter was returned. The leading English case, *Regina v. Dudley and Stephens*, 14 Q.B.D. 273 (1884), appears to reject the necessity defense in homicide cases. In German or French courts, however, the defendants would probably have been acquitted on the excuse either of *P'état de nécessité* or of *contrainte morale irrésistible*.

In general the use of force may also be excused if the defendant believed himself to be acting under duress or coercion, or to be carrying out military orders believed by the defendant to be lawful.

*Some particular offenses.* All advanced legal systems condemn as criminal the sorts of conduct described in the Anglo-American law as treason, murder, aggravated assault, theft, robbery, burglary, arson, and rape. With respect to minor police regulations, however, substantial differences in the definition of criminal behaviour occur even among jurisdictions of the Anglo-American system. Comparisons of the continental European criminal law with that based on the English common law of crimes also reveal significant differences in the definition of certain aspects of more serious crimes. Continental law, for example, frequently articulates grounds for mitigation involving considerations that are taken into account in the Anglo-American countries only in the exercise of discretion by the sentencing authority or in the behaviour of lay juries. This may be illustrated with respect to so-called mercy killings. The Anglo-American law of murder recognizes no formal grounds of defense or mitigation in the fact that the accused killed to relieve the agonies of one suffering from an apparently incurable disease. Many continental and Latin American codes, however, provide for mitigation of offenses prompted by such motives, and in a few instances even recognize in such motives a defense to the criminal charge.

*Degrees of participation.* The common-law tradition distinguishes four degrees of participation in crime. One who commits the act "with his own hand" is a principal

in the first degree. His counterpart in French law is the *auteur* (literally, "author"), or *co-auteur* when two or more persons are directly engaged. A principal in the second degree is one who intentionally aids or abets the principal in the first degree, being present when the crime occurs; this is comparable to the French concept of *complicité par aide et assistance*, although in some countries such as West Germany and the Soviet Union that have adopted a wider (more subjective) interpretation of the concept it includes the activity of *co-auteurs*. In Anglo-American law one who instigates, encourages, or counsels the principal without being present at the time the crime is committed is called an accessory before the fact; in continental law this degree of participation is covered partly by the concept of *instigation* and partly by the above-mentioned *aide et assistance*. The fourth and last degree of participation is that of accessory after the fact, who is punishable because he receives, conceals, or comforts one known by him to have committed a crime so as to obstruct his apprehension or to impede his punishment. In continental legal systems this has become a separate offense, known as *Begünstigung* in German and as *recel des malfaiteurs* in French. Italian and Austrian law treat all participants in a crime as principals in the first degree, with the exception of accessories after the fact. The American Law Institute's model penal code proposes the same simplification.

*Conspiracy.* In Anglo-American law conspiracy is usually described as an agreement between two or more persons to commit an unlawful act or to accomplish a lawful end by unlawful means. This definition is deceptively simple, however, for each of its terms has been the object of extended judicial exposition. Criminal conspiracy is perhaps the most amorphous area in the Anglo-American law of crimes. In most jurisdictions, for example, the "unlawful" end of the conspiracy need not be one that would be criminal if accomplished by a single individual; but courts have not always agreed as to what constitutes an "unlawful" objective for these purposes. The European codes have no conception of conspiracy as broad as that found in the Anglo-American legal system. In some of the European countries, such as France or Germany, punishment of crimes may be enhanced when the offense was committed by more than one person acting in concert. In most countries the punishment of agreements to commit offenses irrespective of whether the criminal purpose was attempted or executed is largely confined to political offenses against the state. Some extension of the conspiracy idea to other areas has occurred, however. Thus in the Italian code of 1930 association for the purpose of committing more than one crime was made criminal. The Yugoslav code of 1951 makes criminal the organization of a group for the purpose of committing any offense punishable by more than five years' imprisonment. None of these provisions, however, has the generality of the Anglo-American concept. None, for example, condemns agreements to commit acts not otherwise criminal. The American Law Institute's model penal code restricts conspiracy to agreements to commit a crime or to aid other persons in the planning or commission of a crime.

*Attempt.* In Anglo-American law there is a class of offenses known as inchoate, or preliminary, crimes because guilt attaches even though the criminal purpose of the parties may not have been achieved. Thus the offense of incitement or solicitation consists of urging or requesting another to commit a crime. Certain specified types of solicitation may be criminal, such as solicitation of a bribe or solicitation for immoral purposes, or inciting members of the armed forces to mutiny.

The most important category of inchoate offenses is attempt, which consists of any conduct intended to accomplish a criminal result that fails of consummation but goes beyond acts of preparation to a point dangerously close to completion of the intended harm. The line between acts of mere preparation and attempt is difficult to draw in many cases. In Soviet law acts of preparation are punishable if they are socially dangerous. Attempt is a further step and is generally defined in Soviet legal

Varying  
definitions  
of criminal  
behaviour

Inchoate  
offenses

theory as an act that contains all the elements of an offense except the result. In both Anglo-American and European legal systems, attempt may also consist of conduct that would be criminal if the attendant circumstances were as the actor believed them to be; in such cases the "defense of impossibility" is allowed only if the mistake can be shown to be absolutely unreasonable. Unlike the law of some European countries, including the Soviet Union, no defense is granted in Anglo-American law to an offender who voluntarily desists from committing the intended harm after his conduct has reached a point beyond mere preparation. The American Law Institute's model penal code, however, provides for an affirmative defense if it can be shown that the actor "abandoned his effort to commit the crime or otherwise prevented its commission, under circumstances manifesting a complete and voluntary renunciation of his criminal purpose."

#### CRIMINAL PROCEDURE

The law of criminal procedure regulates the modes of apprehending, charging, and trying suspected offenders; the imposition of penalties on convicted offenders; and the methods of challenging the legality of conviction after judgment is entered. The law in this area is called upon to advance and reconcile interests of the greatest importance. It must, on the one hand, contribute effectively to the attainment of public peace and good order; at the same time it must afford realistic protection to the rights of persons proceeded against by the system of criminal justice.

**The investigatory phase.** Criminal procedure begins with investigation. In this phase the material elements of the crime (the *corpus delicti*) are examined by the competent authority (the police or officers of the court or the prosecuting attorney), and all available evidence is collected for the use of the prosecution.

**The role of the police.** In Anglo-American procedural law the police play a primary role in the pretrial stage, being responsible for the arrest of suspects, the execution of warrants, the questioning of witnesses, and the carrying out of searches and seizures. In Europe, however, the police generally act as the agents of the prosecuting authorities (*magistrature debout*) or examining judges (*magistrat instructeur*).

**The role of the prosecutor in the pretrial stage.** In Anglo-American law the prosecutor plays only a limited role in the preliminary investigation. In the United States the prosecuting attorney has to decide whether or not he has a case that will stand up in court. In England the director of public prosecutions undertakes the more difficult and important cases, but most charges are preferred and most prosecutions are undertaken by the police. In West Germany the police have acquired a considerable degree of independence in pretrial investigations, although they are nominally under the guidance of the prosecutor. In the Communist-governed countries of Europe, the procurator is both the prosecuting authority in criminal cases and at the same time the guardian of "socialist legality"—for which purpose he has wide control powers over the administrative and economic agencies of government.

**Warrants.** A warrant empowers a police officer to arrest a suspected criminal or to search premises and seize property for the purpose of obtaining evidence. Although arrests may be made without a warrant, particularly when a person is seen committing a criminal act, the laws of most countries limit the power of arrest in order to prevent the police from interfering with individual liberty except in cases of apparent necessity.

**The judge's role.** In Anglo-American law there may be a pretrial hearing before a judge in order to show the accused the nature of the charge and to determine whether or not the evidence presented by the prosecutor is sufficient to justify further action. This takes the form of an adversary proceeding by the attorneys for the prosecution and the defense. In continental law, however, the pretrial proceeding is inquisitorial—that is, it is an inquiry conducted by the prosecuting authority. In

France it is conducted by a special judge, the *juge d'instruction*; in West Germany it is carried out almost entirely by the police under the authority of the prosecuting attorney.

**Defense counsel.** The defense counsel is of the highest importance during the pretrial proceedings. It is his task to protect the defendant against unfounded testimony, to introduce evidence in his favour, to employ various procedural devices for his benefit, and to provide moral support. All legal systems give defendants the right to counsel, and normally the law requires that the prosecuting authority inform a defendant of this right. In the United States several supreme court decisions have broadened the rights of the defendant with respect to pretrial investigation; in *Miranda v. Arizona*, (1966) the court attached a number of restrictions to the admissibility of confessions obtained by police interrogation. There have been similar tendencies in European countries, especially in amendments made to the West German code of criminal procedure.

**Preparation of charges.** In all legal systems, criminal proceedings begin with a formal accusation made to the court. In the United States it is the responsibility of the prosecutor to prepare formal charges; he may decide which charges to press and may even refrain from pressing charges at all, or he may suspend a trial that is already under way. In England most charges are preferred and most prosecutions are undertaken by the police; the director of public prosecutions handles only the more difficult and important cases. In France, on the other hand, the *procureur de la République* is entrusted with the formal act of accusation; because of his discretionary power to decide whether or not charges are to be pressed, even in serious cases, he is called the judge of the advisability of the prosecution. In West Germany, again, the situation is quite different; the German prosecutor, like his colleague in Italy, is bound by the "legality principle," under which he is obliged to start an action whenever he can prove his case in court, except for petty matters.

In some countries the police have a discretionary influence in the pressing of charges. In the United States they frequently reduce the charges in order to make the prosecution easier. In England, the police can decide whether or not to prosecute depending on the importance of the case and their assessment of the evidence. In European countries, however, the discretionary role of the police is restricted to only minor cases.

The Anglo-American system provides for pretrial hearings, subject to waiver by the defendant, in the presence of the court. In these hearings evidence may be excluded if it does not meet prescribed rules. In England the pretrial examination may take place in writing with the exchange of documents and depositions without formal hearing. In those European countries in which the examining judge may also conduct the preliminary inquiry, particularly in France and Spain, he may handle the entire business of collecting the evidence and committing the accused person to the trial court if the charges seem warranted.

**Private charges.** Private citizens are always entitled to file charges. In England such a complaint, when signed by an appropriate officer of the court, has the force of an indictment. In France the victim of an offense may initiate action by filing a civil party complaint before the *juge d'instruction* or the trial court; in this way he exercises considerable control over whether or not charges will be pressed. In West German law some offenses are not prosecuted unless the victim makes formal complaint. In Communist-governed countries a deliberate effort is made to involve the public in combatting crime; heads of governmental departments, factory directors, and other administrative officials are often required to discuss with the procurator major crimes committed in the areas of their responsibility.

**Trial procedure.** The place of trial may be determined according to where the crime was committed, the defendant's place of residence, the place at which he was apprehended, or some other consideration. When an offense is committed on a moving vehicle, such as a train or a

Pretrial  
procedures

Role of  
the police

The  
criminal  
trial

boat, it may be impossible to determine precisely where it occurred; in such cases some laws require that the trial be held in a county or district through which the vehicle passed. In Anglo-American law the place of trial is called venue because formerly jurors had to "come" (in Latin *venire*) from the locality where the crime occurred, since they based their verdict on personal knowledge of the facts. But the traditional common-law rule that the defendant had to be tried at the place where the crime was committed has been amended by statute both in England and the United States for reasons of convenience or to avoid the influence of local resentments; indeed, the accused himself may request a change of venue because of prejudice against him in the community or in the court.

**The jury.** In a jury trial the functions of adjudication are divided between the presiding judge, who controls the admission of evidence and instructs the jury as to the applicability of the law, and the jury consisting usually of 12 laymen who decide the question of guilt. If the defendant is declared guilty, the judge usually determines his sentence.

The jury and the common law are sometimes said to be the two distinctive Anglo-American legal institutions. The Sixth Amendment to the U.S. Constitution guarantees the right of jury trial in criminal cases, as do the state constitutions. In the U.S., the defendant may waive his right to trial by jury, and consequently many trials are conducted entirely by the judge. In both the U.S. and England, no jury is called if the defendant enters a plea of guilty.

In Europe, however, the jury has been almost entirely abandoned. France abolished it in 1941, Italy in 1931, Spain in 1936; in Germany the jury was replaced in 1924 by a mixed court in which three professional judges deliberate and decide the questions of guilt and sentencing in common with six lay judges chosen at random. The jury survives today only in Austria, Belgium, Norway, and four Swiss cantons.

Something analogous to the jury has been introduced in the Communist-governed countries of Europe, where "comrades' courts," factory courts, and collective probation boards composed of laymen are used in order to secure public participation in the trial of petty offenses.

In the U.S. a jury is usually required to return a unanimous verdict. In England, under certain conditions, 10 jurors out of a panel of 11 or more can determine the verdict. Both the prosecution and the defense have the right to challenge a limited number of the jurors without giving a reason; and they have an unlimited right of challenge for cause (on the ground that a prospective juror is biased because of his religion, race, language, or some other factor). Objections may also be raised against the trial judge if there is reason to suspect him of bias or prejudice. In European law, judges may also be challenged (see also JURY).

**Public trial.** The guarantee of a public trial is generally recognized as an important human right, often provided for in constitutions. Only reasons such as state security or public morality are invoked to justify trials *in camera* or in secret. Trial must be in open court, which means that the public is admitted but that filming and broadcasting are generally not permitted.

**Right of counsel.** Legal systems generally guarantee the right of counsel in criminal prosecutions. This right is difficult to assure when the defendant is poor, but some countries now provide free legal aid for the indigent.

**Presentation of evidence.** In Anglo-American law, the presentation of evidence is left to the parties themselves. Witnesses are examined and cross-examined by counsel, not by the court. The functions of the trial judge are to enforce the rules governing evidence and to ask supplementary questions if he feels that the parties have failed to clarify the facts. The defendant may testify as a witness, if he chooses to, but he is not examined by the judge as he is in European procedure. If the defendant pleads guilty, and his plea is accepted by the court, no jury verdict is called for. A confession made outside the court but not accompanied by a guilty plea must be corroborated by other evidence.

European or civil-law procedure is quite different. One of the main tasks of the presiding judge is to elicit evidence by putting questions to witnesses and experts. (Exceptions to this are Spain, some Scandinavian practice, and Japan.) The defendant does not have the right to take the witness stand and testify as in Anglo-American law, but he is examined by the presiding judge. He may remain silent if he chooses.

**Establishing guilt.** A basic principle of both Anglo-American and European procedure is that in criminal cases guilt must be established beyond a reasonable doubt. The burden of proof rests upon the prosecution. On the continent this is true even in cases involving insanity, drunkenness, self-defense, or necessity, and in cases in which the question of intent arises. Anglo-American law is generally satisfied with the formula that the actor "is presumed to intend the natural and probable consequences of his act," but in continental law the prosecution must prove intent. Otherwise the axiom *in dubio pro reo*, corresponding to the Anglo-American "presumption of innocence," requires a ruling in favour of the defendant. In reaching a verdict as to the guilt of the defendant, U.S. law generally requires that the jury be unanimous; in Europe, however, a two-thirds majority of the judges' bench is generally sufficient.

**Sentencing.** A guilty verdict does not necessarily mean that the defendant will be sentenced to prison. In Anglo-American jurisdictions the court may order an investigation of the offender to see whether or not his background and character justify placing him on probation. The sentence of a person on probation is conditionally suspended upon promise of good behaviour and agreement to accept supervision and abide by specified requirements including, usually, reporting to a probation officer or to the court at regular intervals. European law emphasizes conditional sentencing rather than probation; under its procedure the sentence is imposed but with provision for suspending execution of the punishment subject to the offender's good behaviour.

**Postconviction procedures.** After conviction, a defendant may move in the trial court to arrest judgment or he may file a motion for a new trial. Among the grounds most frequently asserted in such motions are that the verdict is not supported by the law or the evidence; that newly discovered evidence has come to light; and that the court erred in its rulings on the admission of evidence.

The legality of the conviction may also be challenged by appeal to a higher court. Criminal appeals were unknown in the traditional common law, and even today the U.S. Supreme Court does not consider them to be required by that country's constitution. Not until 1879 were appellate proceedings in criminal cases introduced into U.S. federal courts, although in many states criminal review had been practiced much earlier. Under U.S. federal procedure, appeals may be made on two levels: the first is that of the court of appeals; the second is that of the Supreme Court, which may grant a review on a writ of certiorari if it feels some important reason requires it; for example, if there is a conflict between the decision rendered by the lower court and the provisions of the Constitution. In the U.S., as a rule, the prosecution cannot enter a motion of appeal after the defendant has achieved an acquittal because of the broad interpretation given to the protection against "double jeopardy." The defendant may appeal a conviction on the ground that the rules of evidence have been violated by the court or that new evidence has come to the attention of the defendant. In addition, the writ of habeas corpus may be employed to attack a conviction by challenging the jurisdiction of the trial court.

In England, the Criminal Appeal act of 1907 established an elaborate system of appellate procedure, proceeding from magistrates' courts all the way to the House of Lords, the supreme court of England. Extraordinary remedies in English procedure include the writ of habeas corpus, on the ground of unlawful detention, and the orders of mandamus, certiorari, and prohibition, which are directed against improper handling of fundamental questions of jurisdiction.

Motions  
for a  
new trial

In continental countries every criminal judgment is in principle subject to review except, in some countries, jury acquittals. Decisions of the supreme court sitting in first instance (mostly in political cases) are equally final and cannot be appealed. The principle of "equal arms" is widely applied in such a way that the appeal is open to the defendant and to the prosecuting authority as well. In some European countries there are two different kinds of appeal, the first of these pertaining to questions combining facts and law and the second relating to questions of law alone.

In the Communist-governed countries of Europe there is a supervisory appeal beginning after sentencing and designed to enforce the principle of socialist legality. The supervisory appeal is open only to the prosecutor and court chairmen, not to the defendant. It can be lodged either in favour of defendants or against them and may deal with both the findings of fact and the interpretation of the law on the part of the lower court.

#### THE RELATIONSHIP OF CRIMINAL LAW TO THE SOCIAL SCIENCES

Criminal law has been strongly influenced by the social sciences, especially criminology, sociology, and psychology. The empirical methods of the social sciences have been introduced into legal research and have done a great deal to improve the courts' approach to sentencing, as well as the planning methods of various law-enforcement agencies.

**Behavioral norms.** The crime rates in many countries have risen faster than the population, and this condition has brought into question the relevance of the law itself, and whether or not laws against crime actually influence behaviour. Various large-scale inquiries have been made into the relation between law and civil order: in the United States, the President's Commission on Law Enforcement and Administration of Justice; in Europe, several research studies sponsored by the Council of Europe; in West Germany, the hearings of the Criminal Reform Commission of the Bundestag. One conclusion emerging from these inquiries is that criminal legislation ought to be restricted to acts that pose a serious threat to public order and that can be effectively dealt with by the police, the courts, and various correctional institutions. The effort to punish all behaviour that is considered immoral or deviant, such as drunkenness, gambling, disorderly conduct, vagrancy, and petty sex offenses, multiplies the number of crimes without changing the norms of behaviour.

**The effectiveness of statutes.** Human conduct is determined by a number of factors that are not responsive to criminal statutes. Thus it appears that introducing or abolishing the death penalty does not have any appreciable effect on the murder rate. On the other hand, the severe British legislation on road safety in 1967, with its introduction of the "breath test" for drunkenness, apparently brought about a significant decrease in traffic accidents. This may have been less a consequence of the severity of the law than of its correspondence to generally accepted moral standards (that drivers should be careful) and its educational impact on the public. Much depends also on the way in which the laws are enforced. Any inquiry into the effectiveness of criminal statutes must examine the way in which police, attorneys, and the courts actually operate—for example, the manner in which they investigate suspects, gather evidence, instruct juries, and use their discretionary powers in "plea bargaining" and in sentencing.

**The effectiveness of punishment.** It is difficult to measure scientifically the extent to which punishment serves to deter convicted offenders from committing further crimes. The requirements of justice forbid any experimentation along that line. The prevailing opinion among criminologists is that short-term sentences are particularly harmful because they tear offenders away from their families and occupations and expose them to criminal indoctrination in prison and to social obloquy after their release. The new general part of the West German criminal code replaces short-term imprisonment (less

than six months) in most cases by fines. Long-term sentences are also viewed with growing skepticism, despite more than 150 years of prison reform, because of the adverse side effects of even the best institutions. These ill effects include acclimatization to the prison atmosphere, association with prison subcultures, infantilism, mental illness, and in general a decline in fitness for responsible life in a free community. It is now considered preferable to treat the convicted criminal in open institutions if the seriousness of the crime and the personality of the offender do not make this impossible.

**Treatment of mental deficiency and juvenile delinquency.** A large area of criminal behaviour involving mental deficiency and diminished responsibility cannot be dealt with through ordinary prison sentences. Mentally disabled offenders require hospitalization and psychiatric treatment; this is usually handled through the probation mechanism or by commitment to a hospital for the criminally insane. Similar problems arise in the case of crimes resulting from narcotics addiction; prison terms for addicts and "pushers" do not make sense unless some effort is made to treat the underlying condition.

Juvenile delinquency has been increasing throughout the world, particularly in urban and industrialized areas. Young offenders are generally dealt with through separate juvenile courts and sent to detention centres, training centres, and part-time homes. Others are handled through conditional sentencing and probation (see also CRIME AND DELINQUENCY; PRISONS AND PENOLOGY).

## Criminology

Criminology is the scientific study of the nonlegal aspects of crime (including juvenile delinquency). In its wider sense, embracing penology, it is thus the study of the causation, correction, and prevention of crime—seen from the viewpoints of such diverse disciplines as ethics, anthropology, biology, ethology (the study of character), psychology and psychiatry, sociology, and statistics. Whereas the traditional legal approach to crime focusses on the action of crime and the protection of society, criminology focusses on the person of the criminal and the essential interests of the individuals of whom society consists. Whereas criminal law has been a relatively conservative force, often slow to change even where change has seemed imperative, criminology as a part of the developing social sciences of the past hundred years has been a revolutionary force—its object being not to replace the legal system in dealing with crime and punishment but to supplement it, making it less rigid and more sympathetic to approaches wider than strictly legal ones.

Criminology and criminal law compared

### THE NATURE OF CRIMINOLOGY

**Functions and scope.** Although variously opposed to the rigidity of some of the criminal law, the social sciences are nevertheless in many respects incapable of forming a united opposition. Whereas psychiatry, psychoanalysis, and (to a lesser extent) psychology, for instance, emphasize the individual, sociology and anthropology focus more on society as a whole, its institutions and groups of individuals. Not only do many of the problems of the respective disciplines differ but also their techniques in trying to solve them vary greatly. In their scientific languages they are often far apart, and students in a few of them are even unwilling to accept certain other disciplines as scientific in any sense at all. True, one of the ambitions of criminology has been to provide a neutral territory for discussion and perhaps resolution of some of these difficulties of communication, but the fact is that criminologists themselves—coming as they do from diverse scientific backgrounds and thus torn between conflicting loyalties—are in need of "integration." The situation, however, has been improving with the growth of criminological studies in the 20th century and with the multiplication of institutes, congresses, conferences, journals, and literature; and, in some countries at least, criminologists seem to have become more than mere interpreters and coordinators and arrived as collectors and developers of their own vast body of scientific knowledge.

**Role of applied research.** Without denying the value of "pure research," one must point to criminology and particularly penology as primarily practical subjects or "applied" disciplines. This practical value of criminological research can make itself felt in several ways. Its accumulated findings can give judges, prosecutors, lawyers, probation officers, and prison officials better understanding of crime and criminals, leading hopefully to more effective and humane sentencing and methods of treatment. Criminological research and knowledge can be equally at the disposal of legislators and administrators to assist in their task of reforming the law and improving penal and reformatory institutions. Essentially this purveyance of information represents a neutral role for criminologists; they garner the facts, and the various governmental officials decide for themselves what kind of practical conclusions to draw from the facts. Increasingly, however, some criminologists—like their counterparts in such fields as the atomic sciences—are demanding that scientists fully shoulder the moral and political responsibilities for their discoveries and for the use made of them instead of leaving vital decisions entirely to their governments. Thus some criminologists, for instance, insist upon actively campaigning against capital punishment, given the facts as they see them. Opponents of this activist role, on the other hand, contend that penological arguments are not sufficient but must be weighed along with political, social, religious, and moral arguments and

that this all-round consideration should be left to responsible political bodies. The view does not deny the right of criminologists to express their opinions as ordinary citizens and voters; it does contend, nevertheless, that a government of officials responsive to the popular will, however fallible it may be, is less dangerous than a "government by experts."

Another question involving the scope and functions of criminology is whether or not it should extend to the study of crime detection, involving such measures as photography, toxicology, fingerprint study, and the like. In several countries, notably Austria and Belgium, and at the school of criminology of the University of California at Berkeley, this so-called criminalistics has long been an important branch of criminological teaching and research, and the distinguished *Journal of Criminal Law, Criminology, and Police Science (U.S.)* devotes much of its space to criminal investigation. Actually, the only reason for excluding it from criminology is perhaps the expense of staff and equipment, which can be better borne by police colleges and similar specialized institutions. On the other hand, in recent decades criminology has undergone an important and perfectly legitimate extension of its territory by devoting much attention to so-called victimology—the study of the victim of crime, his relations to the criminal, and his role as a potential causal factor in crime.

**Status among other disciplines.** Although the exclusion of criminalistics makes it easier to locate criminology on the map of scientific studies, its origin in, its close relations to, and its partial dependence on so many other disciplines result in considerable diversity and confusion regarding its proper place in the academic curriculum. Universities in continental Europe, when they do not ignore criminology altogether, tend to treat it as part of legal education; even where its principal teachers are not lawyers. In Great Britain the only existing Institute of Criminology is part of the law faculty of Cambridge University; in other schools criminological research and teaching are usually divided between departments of sociology or social administration, law faculties, and institutes of psychiatry. In South America the anthropological and medical elements predominate, and in the United States, criminology, with a few notable exceptions, forms an established section of departments of sociology.

Given this situation in which criminology is submerged in other fields, it is not surprising that most teachers and researchers in criminology regard themselves first as sociologists, psychologists, lawyers, or whatever and only secondarily as criminologists. Their education contributes to this status; although a number may have pursued some criminological studies in their undergraduate years, criminology is largely a postgraduate discipline, at least in terms of major concentration for students.

This floating character of criminology weakens its position and tends to lend doubt to its claim to scientific status. Nevertheless, other disciplines—such as psychology, psychiatry, history, sociology, and social anthropology—have gone through similar birth pangs and, even after having achieved more or less assured positions, still face challenges to their claim to being scientific disciplines. The answer lies perhaps in historian H.R. Trevor-Roper's remark, "there are sciences and sciences." If the results of research can be viewed relatively, it is possible to perceive science in the criminologist's systematic application of sound research methods and his development of a body of facts from which he interprets general trends on a subject of real importance to mankind.

### HISTORY

The origins of criminology are generally dated from the late 18th century, when those imbued with a spirit of humanitarianism began questioning the cruelty, arbitrariness, and inefficiency of criminal justice and prison systems. From this period arose the so-called classical school of criminology, composed of such reformers as the Italian Marchese di Beccaria and the Englishmen Sir

The role of criminalistics and victimology

Samuel Romilly, John Howard, and Jeremy Bentham, all of whom may be said to have sought penological and legal reform rather than criminological knowledge per se—that is, knowledge about crime and criminals. Their principal aims were to mitigate legal penalties and subject judges to the principle of *nulla poena sine lege* or "due process of law" and also to reduce the application of capital punishment and humanize penal institutions. In all this they were moderately successful, but in their desire to make criminal justice "just," they tried to construct rather abstract and artificial equations between crimes and penalties, thereby forgetting the personal characteristics and needs of the individual criminal. Moreover, the object of punishment was seen as being primarily retribution, with deterrence occupying second place, and reformation lagging far behind.

Positivist school

By the second half of the 19th century these deficiencies, together with the influential teachings of the French sociologist Auguste Comte, had prepared the ground for the positivist school, which sought to bring a scientific neutrality into criminological studies. Instead of assuming a moral stance that focussed on measuring the criminal's "guilt" and "responsibility," the positivists attempted a morally neutral and social interpretation of crime and its treatment. Their leading figure, Cesare Lombroso (1836–1909), professor of psychiatry and anthropology at the University of Turin, sought through firsthand observation and measurement of prison inmates to determine the characteristics of criminal types. Some of his investigations led him into anthropometric interpretations—for example, his oft-criticized deduction of the "born criminal" with cranial, skeletal, and neurological malformations—but largely he and other positivists helped to introduce the ideas that crime has multiple causes and that most criminals are not born criminal but are shaped by their environmental upbringing and associations. With the positivists, therefore, the emphases in criminology had turned to experimental case studies and to preventive and rehabilitative measures. Without the upheaval caused by the positivists not only criminological research in the modern sense but also the present-day alternatives to capital punishment and old-fashioned imprisonment such as probation, suspended sentence, fines, and parole, inadequate as some of them are, would have been unthinkable.

Today, nevertheless, the feeling is widespread that the battle of ideas fought by the classical and positivist schools has not yet produced the secure foundations on which the criminology and the penal systems of the future can be built. Thus a third school, the postwar movement of "social defense," also originating in Italy, has tried to combine their best features and eliminate their excesses. This school disapproves of any rigid typology of criminals and stresses the uniqueness of human personality; it refuses the "scientism" of the positivists in favour of a strong belief in moral values—most importantly in balancing the rights of criminals and the rights of society. The school still speaks with too many voices, however, to be conclusively labelled.

Independent of these debates between schools, however, are the advances accomplished by such great figures as the statisticians Adolphe Quetelet (1796–1874) and André Michel Guerry (1802–66), the sociologists Gabriel Tarde (1843–1904) and Émile Durkheim (1858–1917), and of course Sigmund Freud, all of whom introduced a wealth of new ideas into the old problems of the social and individual characteristics of human, including criminal, behaviour.

#### MODERN CRIMINOLOGICAL RESEARCH

**Objectives.** The objectives of criminological research are sometimes said to be threefold: descriptive, causal, and normative. The descriptive aspect consists of the collection of relevant and reliable facts, together with their interpretation. The collection does not begin as a random and meaningless running after whatever phenomena happen to rouse the researcher's interest. Rather it is preceded by some hypothesis or "hunch," an as-

sumption about what the researcher expects to find. The hypothesis "organizes" his inquiry. As the collection of facts proceeds, he may find either that his hypothesis is correct or that it requires revision or abandonment and thus the development of a new hypothesis to guide further research. The history of criminology reflects this perennial revision and renewal of inquiry, this continuous process of abandoning seemingly well-established theories in favour of new ones. Lombroso's theory of the "born criminal," the theory that all crime (or at least all economic crime) is due to poverty, and the theory that all juvenile delinquents come from broken homes had all to be drastically revised.

The causal aspect involves relating the effects of one body of facts on another. Although regarded nowadays with some suspicion or indifference (even in the natural sciences), the search for causes is not being dispensed with altogether. So long as one does not jump to causal conclusions when arriving at statistical correlations or does not pressure "facts" into some proof of a popular theory, theories of causation can be useful in planning for the alleviation of crime and criminality.

The normative aspect, however, is more decidedly suspect. Research aimed at formulating so-called laws governing criminological phenomena has been thus far futile and does not look promising. What is sometimes regarded as a "law" has in reality been a mere trend. To diagnose statistical trends may be useful so long as their possible ephemeral nature is recognized, but trends are not laws, and there is thus but little scope for the normative approach in criminology.

**The character of the research.** Criminology, as suggested earlier, is cross-disciplinary and indeed draws methods or techniques from both the natural and the social sciences and must continually take heed of developments in other fields. It also depends increasingly on cross-cultural approaches; there have been recent statistical (though admittedly controversial) comparisons of "delinquent generations" in England, New Zealand, Denmark, and Poland; various studies of the sociological and statistical aspects of homicide; and studies of the ecological significance of "criminal areas" and of the possibility of predicting criminality.

In common with other disciplines, criminology must face such distinctions as between pure and applied research and between statistical and intuitive ways of thinking, but what is almost unique to criminological research is its intense involvement with society and its difficulty in achieving "detachment." Not only do society's biases toward crime and punishment influence a criminologist's choice and execution of research but also he is dependent on the willing cooperation of governmental departments and other public authorities to secure essential raw material or data. There are only a few limited areas—such as adolescent delinquency and gang activities—in which research can be pursued privately without resort to official help.

**Techniques of research.** Seen in the light of the previous remarks on the history of criminology, the development of criminological research can be divided into three stages: the prescientific, lacking any theoretical basis and largely identifiable with the work of the classical school; the semiscientific, possessing theories and hypotheses but without scientifically sound techniques and largely characteristic of the efforts of the positivist school; and the scientific, hopefully trying to repair earlier deficiencies and developing or improving the techniques described below.

**Statistics.** Often serving as the initial step in any research and regarded by some researchers, perhaps incorrectly, as the one and only reliable technique, the collection and interpretation of statistics for social and criminological purposes began in Europe early in the 19th century. The reputed "father" of this criminological method is the Belgian astronomer Adolphe Quetelet, who is perhaps best remembered for his famous "law," developed from the French and Belgian statistics, which showed that crime in any given country remains fairly

Forming  
a  
hypothesis

Cross-disciplinary and cross-cultural approaches

constant over the long term (short-term fluctuations being insignificant). When he qualified himself, however, by saying that the volume and kind of crime were constant only so long as society's social, economic, and political conditions remained unchanged, he deprived the "law" of much of its significance for a rapidly changing modern world.

The manner and extent of data collection today differ considerably from country to country or, in federal unions like the United States, even from state to state or province to province. They differ in how often data are collected and published, in what items are given importance, in the choice between complete listings and sample surveys, in the ratio between governmental and private research, and so forth. Such far-reaching differences, together with the differences in law and its administration and in popular views and habits, have made it so far impossible to devise a meaningful system of international criminal statistics. Generally, however, there is increasingly less tendency to collect any and all data, regardless of reliability or practical value, and to concentrate on limited, reliable data involving matters of agreed upon importance.

Comparison of police and court statistics

A noteworthy distinction to be made is between police statistics and court statistics. Police data are nearer to the event but perhaps less reliable, and they usually describe the crimes only, not the criminals. The data from the courts, being based on convictions, do deal with the persons involved but include only the material brought forward by the prosecution and the defense. All criminal statistics indeed depend entirely on human factors such as the willingness of private individuals and officials to prosecute, on the popularity or unpopularity of the criminal laws at issue, and so forth. The figures also usually fail to rate very clearly the gravity of individual cases; except for such broad categories as "petty" and "grand," theft is theft regardless of the value of the objects stolen. Only recently have more detailed categories been attempted for criminological research.

**Case Study.** Also called the individual "case history," the case study concentrates on the career or life of one individual or group of individuals and is the method used primarily, though not exclusively, by psychologists, psychiatrists, and psychoanalysts. If well done, such histories can give deep insights into the personalities and motives of criminals, but the method does have shortcomings. Although the volume of case histories has grown large, their reliability is sometimes suspect—partly because of a criminal's natural reluctance to expose himself completely and partly because of the nature of the publication of case histories. Their publication is comparatively rare; professional ethics often forbid the exposure of details given confidentially, and those studies actually published may be too few to be typical and may even on occasion be designedly selective because of an investigator's wish to prove a theory.

Closely related to case studies are autobiographies and other books written by ex-prisoners, but in spite of their considerable human and scientific interest, they do suffer from even greater disadvantages, chiefly questionable objectivity. Sociologists have also contributed important studies of individuals in their social environments.

**Typologies.** The typological method involves classifying offenses, criminals, criminal associations, criminal areas, or whatever according to some criteria of relatedness or similarity. Thus there have been attempts to dichotomize criminals as either "normal" or "abnormal," "habitual" or "professional," or to form a continuum of criminals from the "insane" at one extreme through various career criminals, petty offenders, and white-collar criminals to "organized" or "professional" criminals at the other extreme. The typological method is less impersonal and heterogeneous than the statistical method and less individual or specific than the case study. Developed mainly in Germany and Austria and more recently in the United States, the method has been disputed; psychiatrists and psychoanalysts have especially questioned its value, primarily because it attempts to

reduce complex phenomena to simple terms and tends to ignore important individual differences. Nevertheless, employed with restraint, the method is indispensable as a bridge between the two extremes, and it is in fact often used unknowingly by both statisticians and case students.

**Experimental methods.** A controlled experiment involves taking two closely related situations or groups, subjecting one of them to a specific change and comparing the subsequent characteristics of both. In the past, so-called experiments by judicial, penal, and reformatory institutions were not really controlled or even experimental in the scientific sense, for public agencies, at least in theory, are bound by the idea of justice to give equal treatment to equals, not one kind of treatment to one group and another kind to another group. Thus, generally speaking, most controlled experiments must be left to universities and other private bodies, and indeed the need for strict control and variable treatment has been recently accepted in such researches as Harvard University's Cambridge-Somerville Youth Study, which sought the effects of counselling on "pre-delinquent" boys.

**Prediction studies.** Criminological prediction—not unlike actuarial prediction used by insurance companies—is intended to forecast, usually in percentages, the future conduct of persons under certain conditions. Based on statistics or case histories or both, the predictions attempt to indicate probabilities—how any specific individuals or groups are likely to be affected by certain conditions or treatments. Thus, for example, various categories of criminals are listed as likely to be recidivistic.

The techniques involved in constructing prediction tables are too complicated to be discussed in brief; they have been developed and refined in the past 40 years mainly by Sheldon and Eleanor Glueck of Harvard University and also by several other authors in various countries. Statistical prediction by itself can never be conclusive; it must be subjected to rigorous validation for any individual or group, and even then it can merely show certain probabilities, which should be used in penal decisions only with the greatest caution and along with the lessons of experience derived from other sources. Nevertheless, the method can be valuable in supplementing the inevitably limited personal experience of judges and administrators, and indeed in recent decades prediction research has probably nowhere in the social sciences been more popular and urgent than in criminology.

**Action research.** Action research, which is often contrasted with experimental research, consists of drawing upon the observations of field workers and other persons directly involved with delinquents, potential delinquents, or prisoners. Thus, for example, have social workers attempted to help slum children and adolescents with their problems and at the same time studied their delinquent behaviour, related it to their environment, and evaluated the results of the youth clubs or other services offered. The chief values of action research are that it aims at practical results through collaboration with fieldworkers, tries to build a bridge between theoretical and practical work, and may well dispense with formal hypotheses and simply aim at preventive tactics. Its best known and perhaps most successful example has so far been Clifford Shaw's Chicago Area Project, which, in close co-operation with the famous ecological studies of the University of Chicago, has tried to enlist suitable local people to deal with the social problems of their area.

**Sociological research.** Sociological research involves various methods—general surveys and personal interviews, as well as statistical, case-study, typological, experimental, and predictive techniques—and thus the purpose of classifying sociological research separately is chiefly to signal its focus or fields of interest. Mainly, criminology derives benefits from three fields of sociological study: (1) social institutions, involving such things as different conceptions of, or attitudes toward, property held by various societies or groups or the different effects of mass media on crime; (2) social groups, involv-

Problems of crime prediction

ing such things as the influence of juvenile gangs or criminal subcultures on individual criminal behaviour or the influence of prejudice on certain racial, national, or religious minorities; and (3) ecology, involving the study of different geographical areas and their rates and kinds of crime. Clifford Shaw's ecological studies of Chicago have been especially revealing in analyzing urban areas that either "breed" crime or "attract" crime.

**BIBLIOGRAPHY.** H. MANNHEIM, *Comparative Criminology*, 2 vol. (1965), covers the whole field suggested by this article; M.E. WOLFGANG and F. FERRACUTI, *Il comportamento violento* (1966; Eng. trans., *The Subculture of Violence*, 1967), a work dealing mainly with the theme of its title but also with several methodological questions; H. MANNHEIM (ed.), *Pioneers in Criminology*, 2nd ed. (1972), critical discussions of the work of some famous criminologists and penologists; L. RADZINOWICZ, *Ideology and Crime* (1966), a survey containing much historical material; J.T. SELLIN and M.E. WOLFGANG, *The Measurement of Delinquency* (1964), an attempt to find an operational definition of serious offenses and to construct a "crime index"; H. MANNHEIM, *Social Aspects of Crime in England Between the Wars* (1940), a detailed analysis of the structure, interpretation, and contents of English criminal statistics; F.H. MCCLINTOCK and N.H. AVISON, *Crime in England and Wales* (1968), partly an updating of the preceding work; L.T. WILKINS, *Social Deviance* (1964), an attempt to bridge the gap between social research and social action from the viewpoint of the statistician; H. MANNHEIM and L.T. WILKINS, *Prediction Methods in Relation to Borstal Training* (1955), a theory of prediction, with an introductory historical survey of criminological prediction studies in various countries; S. and E. GLUECK, *Predicting Delinquency and Crime* (1959), *Ventures in Criminology* (1964), surveys of the Gluecks' prediction studies; A.K. BOTTOMLEY, *Criminology in Focus: Past Trends and Future Prospects* (1979).

## Croce, Benedetto

Benedetto Croce, the foremost Italian philosopher of the first half of the 20th century, left his mark under a number of titles—historian, humanist, philosopher, critic, statesman; but even more influential was his stature as a person. Moral courage in defying a pretentious and oppressive political regime and again in rebuilding a nation demoralized by defeat in war made him the symbol of the spirit of modern Italy, of all that justifies its existence as a nation.

H. Roger-Viollet

Croce

Croce belonged to a family of landed proprietors with estates in the Abruzzi region of central Italy but chiefly resident in Naples. His background was religious, monarchical, and conservative. Born at the Abruzzi town of Pescasseroli on February 25, 1866, Croce spent almost his

whole life in Naples, becoming intimately identified with that city and a keen observer of its life and a biographer of its heroes. His life, of which he left a too-modest record in his autobiography, falls roughly into four phases; each develops the dual theme of his intellectual and moral growth and his gradual, ever-deepening identification with the moral character and destiny of the Italian nation.

**Early life and maturity.** The first phase (until about 1900) was the period of Croce's agony. Orphaned (with his brother Alfonso) by the earthquake of Casamicciola in 1883, his life became, in his words, a "bad dream." The stable world of childhood and youth was shattered; he was forever marked; henceforth, he was a solitary figure, despite his considerable activity in the world.

His salvation lay in work. Disillusioned with the university, he set out upon an austere course of study, to become one of the great self-taught students of history. His writings of this period are universally alert, intelligent, and engaging; although limited in scope, they show a fine sobriety of style, as well as wit, irony, and a fiery polemical spirit; lyricism, which he eulogized, eluded him. Ostensibly, he had little taste for politics; actually, several basic attitudes were forming. Disillusioned with the nationalistic liberal leaders of the period following the Risorgimento (the 19th-century movement for Italian unity), he began to develop his own convictions on how an ethical, democratic, liberal government should be structured. He "coquetted"—according to his autobiography—with Socialism (which generally advocates public ownership and administration of the means of production and the distribution of goods) and Marxism (which adds the notion of class struggle), eventually freeing himself from this infatuation, typically, by a thorough examination and severe criticism of both positions. Nevertheless, he was subject to a constant and profound malaise. Subliminally, he desired but saw no public relevance for his activity; the limited world of erudition palled on him.

He was delivered from this malaise, and the second phase of his life was opened in 1903 by the founding of *La Critica*, a journal of cultural criticism, in which, during the course of the next 41 years, he published nearly all his writings and reviewed all of the most important historical, philosophical, and literary work that was being produced in Europe at the time. At this same time he began the systematic exposition of his "Philosophy of the Spirit," his chief intellectual achievement. This term designates two distinct, but related, phases of his thought: (1) In the first phase, philosophy of spirit designates the construction of a philosophical system on the remote pattern of the Rationalism of classical Romantic philosophy. Its principle is the "circularity" of spirit within the structure of the system and in historical time. The phases, or moments, of spirit in this system are theoretical and practical; they are distinguished, respectively, into aesthetic, logical, and economic and ethical. The circular dynamic moves between both the lesser and the greater moments. The law of this circularity is that of absolute immanence. This system is documented in the volumes *Estetica come scienza dell'espressione e linguistica generale* (1902; *Aesthetic as Science of Expression and General Linguistic*, 1922), *Logica come scienza del concetto puro* (1909; *Logic*, 1917), *Filosofia della pratica. Economia ed etica* (1909; *Philosophy of the Practical: Economic and Ethic*, 1967), and *Teoria e storia della storiografia* (1917; *History: Its Theory and Practice*, 1960). (2) Croce gradually abandoned, without explicitly renouncing, this schematism in response primarily to methodological considerations in history. Its moments are not dissolved but rather are concretized into the flow of historical action and thought. History becomes the unique mediational principle for all the moments of spirit, while spirit—i.e., human consciousness—is completely spontaneous, without a predetermined structure. This change in Croce's thought is signaled by the publication of *La storia come pensiero e come azione* (1938; *History as the Story of Liberty*, 1941). To this phase some have attached the term historical positivism, but Croce himself has called it absolute historicism and identified it as the definitive form of his thought. The

First phase: agony and work

Second phase: founding of *La Critica*

philosophy of spirit in its asystematic form produced the effective method of Croce's later work, as in the anthology *Filosofia, poesia, storia* (1951; *Philosophy, Poetry, History*, 1966).

According to Croce, "The foundation of *La Critica* marked the beginning of a new period in my life, the period of maturity or harmony between myself and reality." Through this journal he found the larger public theatre he sought. "*La Critica* was the most direct service I could render to Italian culture. . . . I was engaged in politics in the broad sense . . . uniting the role of a student and of a citizen." Through *La Critica* Croce's public role as teacher of modern Italy emerged. Count Camillo Benso di Cavour, the prime minister who presided over the formation of a unified Italy, had said, "Having made Italy, we must make Italians." *La Critica* took up this task.

The image of the Italian which animates this work is severe and beautiful. Creative effort, a passion for freedom united to a profound sense of civic duty, a life-style purged of all rhetoric and sentimental romanticism, unambiguous norms of public and private truth, a sense of history united to an obligation to the future, unceasing but constructive self-criticism: these were its elements. This image strongly reflected the personal ideal that Croce had gradually formed for himself. But history was preparing to put this ideal to the test.

Later life. The test was to be Fascism, the political attitude that places the nation or race at the centre of life and history and disregards the individual and his rights. So gradual was this preparation that Croce himself did not at once perceive it. He confessed that he first saw in Fascism a movement to the right of the political spectrum that might restrain and counteract the leftist tendencies toward unrestricted individual freedom released by World War I. But as the character of the regime revealed itself, his opposition hardened, becoming absolute, beyond compromise. He became, within and without Italy, the symbol of the opposition to Fascism, the rallying point of the lovers of liberty. Fascist leaders recognized the quality of his opposition; they accepted the fact that against such moral determination, their own methods were powerless. In Fascism Croce saw not merely another form of political tyranny. He saw it as the emergence of that other Italy, in which egoism displaced civic virtue, rhetoric dislodged poetry and truth, and the pretentious gesture replaced authentic action.

His consciousness of his role as the moral teacher of Italy was strengthened. Instruction now took the form of the composition of the great histories—a history of Europe in the 19th century, of Italy from 1871 to 1915, and of the Kingdom of Naples. Their didactic character was unmistakable; in them Croce pointed out how the historical path of Italy had become *la via smarrita* ("the lost way"). Moreover, the lesson was intended for Europe and for the entire Western world as well.

In the maelstrom of conflict and ambiguity that followed defeat, a voice of moral authority that could speak for the true Italy was demanded. Croce's was unanimously recognized as that voice. And with authority that voice recalled Italy to the inner spiritual resources through which it might renew itself. It matters little that Croce's own project for the rebuilding of Italy—the retention of the monarchy with certain dynastic changes, the return to the principles of a revived Liberal party in government—was not the one realized in history. More important is the fact that the new Italy, in its democratic form, was inspired by his spirit.

This last public office fulfilled, Croce returned to his beloved studies. In his own library—one of the finest collections in Europe within its own scope—he established the Istituto Italiano per gli Studi Storici (Italian Institute for Historical Studies) as a research centre. The rhythm of his own life became again what it had always been: the rhythm of peaceful, laborious days. Asked his state of health, he replied with true stoic equanimity, "I am dying at my work." Work and death were the order of that last day, November 20, 1952.

Character and significance. One traumatic experience may well determine the cast of a man's character. This

was Croce's case and the traumatic event was the catastrophe of Casamicciola.

That night established him in the deep solitude that was the true key to his character. This solitude became in turn the rock upon which his absolute devotion to freedom rested. The mindless havoc wrought by nature on that night made clear to him that whatever meaning man's life might have must be the creation of his own free spirit, of his own action and decision. Because his solitude thus expressed itself in creative freedom, it did not isolate him. It provided the solid point from which he could survey all human life, suffering, and striving with universal comprehension and sympathy. His sympathy took the form not of melting compassion but of fraternal didacticism; it made him the critic, the teacher. And his solitude, moreover, sheltered a sensitivity both aesthetic and moral, both rare and unfailing; it flowered in his response to the basic beauty of all the creations of man's spirit; to him they were sacred. Inevitably, the final form of his thought and of his sentiment of life became "the religion of liberty." Religion alone could express the reverence in which he held the creative spirit of man, locked in the inviolate precinct of every individual but flowering in creations of universal meaning. This freedom alone could be ultimate and sacred.

**BIBLIOGRAPHY.** FAUSTO NICOLINI, *L'editio ne varietur delle opere di Benedetto Croce* (1960), the most scholarly bibliography; SILVANO BORSARI, *L'opera di Benedetto Croce: bibliografia* (1964), a very complete chronological listing that does not, however, supersede Nicolini.

**Biography:** FAUSTO NICOLINI, *Benedetto Croce* (1962), a quasi-official study, in Italian, written by a very close associate (not definitive, though sometimes spoken of as such); CECIL SPRIGGE, *Benedetto Croce: Man and Thinker* (1952), a compact, most informative account by a long-time friend and interpreter of Croce to the English-speaking world.

**Works about Croce:** CARLO ANTONI, *Commento a Croce* (1955), a careful analysis and criticism of salient points in Croce's thought by one of his most serious followers; ADRIANO BAUSOLA, *Etica e politica nel pensiero di Benedetto Croce* (1966), a careful and critical analysis of the most important single theme in Croce's philosophy; A. ROBERT CAPONIGRI, *History and Liberty: The Historical Writings of Benedetto Croce* (1955), considered by reviewers the most objective presentation of the whole range of Croce's historical writing, with careful evaluations relative to his theory of historiography; GIAN N.G. ORSINI, *Benedetto Croce: Philosopher of Art and Literary Criticism* (1961), the best book in English on Croce as literary critic.

(A.R.C.)

## Crocodylia

The crocodiles constitute an order of the vertebrate class Reptilia. They are generally large, ponderous, amphibious animals, somewhat lizardlike in appearance, and carnivorous in habit. They have powerful jaws with many conical teeth and short legs with clawed, webbed toes. The tail is long and massive and the skin thick and plated. About 20 species are recognized.

The group is of particular interest because of its evolutionary position: the crocodiles are the last living link with the dinosaur-like reptiles of prehistoric times. They are, at the same time, the nearest living relatives of the birds. A large variety of crocodile fossils have been discovered; three of the four suborders of Crocodylia are extinct. On the basis of this extensive fossil record, it has been possible to establish well-defined relationships between the crocodiles and other vertebrate groups.

### GENERAL FEATURES

**Size range and diversity of structure.** The crocodiles are the largest and the heaviest of present-day reptiles. In former times the Nile crocodile (*Crocodylus niloticus*) and the estuarine crocodile (*Crocodylus porosus*) attained a length of almost nine metres (about 30 feet), but today, specimens rarely exceed six metres (20 feet). Other species, for example, the smooth-fronted caiman (*Paleosuchus*) and the dwarf crocodile (*Osteoleaemus tetraspis*) are about 1.7 metres (six feet) in length.

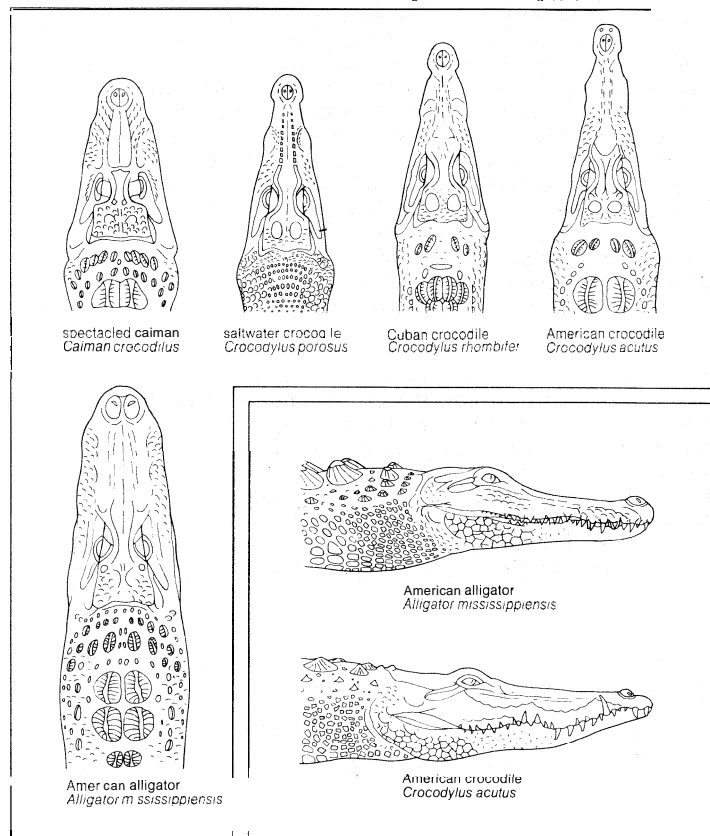

All crocodiles have a relatively long snout, or muzzle, which varies considerably in proportions and shape. The

large horny plates that cover most of the body generally are arranged in a regular pattern. Thick, bony plates occur on the back. The families and genera may be distinguished by anatomical features, principally those of the skull. Species are identified principally by the proportions of the snout; by the bony structures on the dorsal, or upper, surface of the snout; and by the number and the arrangement of the large neck scutes.

From *Mitteilungen aus dem Zoologischen Museum in Berlin*

Heads of representative Crocodilia.

**Distribution and abundance.** The habitat of the crocodile is mainly the tropics and subtropics of the northern and southern hemispheres. The Mississippi, or American, alligator (*Alligator mississippiensis*), the American crocodile (*Crocodylus acutus*), and the Chinese alligator (*Alligator sinensis*) are the only species found outside the tropics.

The true crocodiles (family Crocodylidae) occur in most of Africa south of the Sahara, Madagascar, India, Ceylon, Southeast Asia, the East Indies, northern Australia, Mexico and Central America, the West Indies, and most of South America east of the Andes and north of the mouth of the Río de la Plata. The caimans are confined to South America. The gaviol occurs in India.

As recently as several decades ago, crocodiles were plentiful in much of the tropics and subtropics, but today they are almost extinct in many areas, as the inroads of civilization continue to limit their natural habitat. Thousands are killed annually by man, either for sport or for their valuable skins, which provide leather for handbags, luggage, shoes, belts, and other articles. In some localities they are killed because of their depredation of domestic cattle. The governments of some countries have sought by legislation to protect the remaining crocodile populations from hunters.

The disappearance of the Nile crocodile from parts of Africa has resulted in an overabundance of the catfish *Clarias*, which in turn has greatly diminished the supply of popular food fishes. In an attempt to restore the original balance, crocodiles are bred and raised on farms. When they have grown to a length of about 1.5 metres (5 feet) the crocodiles are released to their natural habitat.

#### NATURAL HISTORY

**Life cycle.** The young crocodile emerges from the egg with a length of 20–25 centimetres (8–10 inches). At first it remains concealed at the edge of its water habitat in order to avoid various predators. Principal among these are fishes and birds, but larger crocodiles also prey upon the young. During the first three to four years, the young increase in length by about 30 centimetres (about one foot) per year. The growth rate then gradually decreases, but growth can continue throughout life. Sexual maturity occurs at about ten years of age and at a body length of about 1.5 metres (five feet).

Of the little information available on the longevity of crocodiles, most has been gained from observation of animals in captivity. Captive animals seldom live more than 40 years, possibly because of lack of proper exercise and diet. Statistics on the growth of the Nile crocodile suggest, however, that specimens about 6 metres (20 feet) long are probably much more than 100 years old.

**Behaviour.** Crocodiles are predators, mostly nocturnal (*i.e.*, active at night), and spend most of their time in the water; they are also known to take rather long journeys over land. In their first weeks of life crocodiles eat mostly worms and water insects, then frogs and tadpoles; finally, their main diet is fish. Older crocodiles are more apt to prey upon waterfowl and on mammals, and occasionally a member of one of the larger species eats a human. This happens so infrequently, however, that crocodiles cannot be generally regarded as man-eaters.

Crocodiles capture water animals in their jaws with a sideways movement of the muzzle. To catch land animals they remain motionless at the edge of a water hole from which the prey habitually drink, or they float passively in the water, resembling a drifting log. With a swift blow of the tail, they knock unsuspecting prey into the water. A number of crocodile species grip the legs of the victim in their jaws, then rotate themselves rapidly in the water, thus tearing the prey apart. When a crocodile cannot consume all of a victim at one time, it drags the carcass into its burrow.

The burrow is dug more or less horizontally at or just above the waterline and may extend for several metres, eventually ending in a chamber. The Mississippi alligator and the China alligator enter a state of inactivity (*i.e.*, hibernate) in these chambers during cold periods.

During the day, crocodiles often lie at the water's edge to sun themselves, frequently in large numbers. Otherwise, crocodiles live as lone individuals and establish individual territories. The extent of the territory is apparently defined for the animal's neighbours by its loud, vibrant roar, answered in kind by the crocodiles in adjacent territories.

When it roars, the crocodile tenses the musculature of its body so that the head and tail rise high out of the water; the flanks may vibrate so violently that water is sprayed high into the air from each side. Roaring can be provoked by similar noises, such as a deep note from a trumpet or the sound of artillery or supersonic aircraft. Crocodiles are also capable of deep grunting sounds, which apparently play a role during courtship, and a warning hiss. The young make squeaking sounds.

Of all reptile brains, the crocodile brain is the most highly developed. Crocodiles often show curiosity and are capable of being developed into tame animals—both attributes being measures of intelligence. If kept in captivity from birth, individuals of some species are known to recognize their keepers, show neither fear nor aggressiveness, beg for food, and permit themselves to be petted. In other words, they learn to adapt their behaviour to the unnatural captive environment.

**Locomotion.** The principal style of locomotion is that of swimming, in which the crocodile places its legs back against the sides of the body and moves forward by means of lateral wavelike motions of the tail. In walking on land, crocodiles hold themselves high on all four legs, and the body moves in waves, with a lateral swinging motion. When startled, crocodiles are able to run short distances, the two front legs moving forward and backward together as do also the two hindlegs, some-

Diet

Intelligence

Declining populations

what in the manner of a hopping rabbit. When moving quickly into the water from a bank, crocodiles slide on their bellies, pushing with the feet.

**Reproduction.** The sexes are outwardly different only in the Indian gaviol (*Gavialis gangeticus*), in which the males, during the reproductive period, have a bulbous knob at the tip of the muzzle. Copulation occurs in the water and lasts about ten minutes. It is preceded by a courtship in which the animals rub their muzzles against each other and over the neck of the partner. The male then mounts the back of the female, and both animals rotate their tails so that the respective bodily openings are brought into contact. The distensible male reproductive organ is then inserted into the female.

The nest

All crocodiles lay hard-shelled eggs, which may number more than 100, depending upon the age and size of the female. The female builds a nest as a shelter for the eggs. The Nile crocodile female digs a trench, which it refills with dirt after laying the eggs. The female estuarine crocodile builds a mound of mud and decaying plant material, in the centre of which are the eggs. With her tail the female splashes water onto the nest. This promotes the heat-generating process of vegetative decay. The trench and mound types of nest are extremes, between which intermediate types are made by the various other species. In every case the female remains close to the nest and protects the eggs from predators until the eggs hatch.

After two or three months the young are fully developed and ready to hatch. While still in the egg they utter squeaking sounds, perhaps signalling that they are ready to emerge. The female then removes the dirt or other debris from the eggs but thereafter provides no further care for her offspring.

**Ecology.** Crocodiles are mainly inhabitants of swamps, lakes, and rivers, although some species make their way to brackish water or to the sea. The estuarine (or salt-water) crocodile (*C. porosus*), which lives almost entirely in the ocean, may swim miles out to sea. Such crocodiles venture upriver only as far as the limit of the salt water. The smooth-fronted caiman (*Paleosuchus*) in South America prefers rocky, fast-flowing rivers. In West Africa the dwarf crocodile (*Osteolaemus tetraspis*) is found principally in the rivers of the forest regions.

#### FORM AND FUNCTION

The form of the crocodile is adapted to its amphibious way of life. The elongated body with its long, muscular paddle tail is well suited to rapid swimming. Other features, enumerated below, are also adapted to the animal's amphibious habit.

Sensory structures

The external nostril openings, the eyes, and the ear openings are the highest parts of the upper side of the head. These important sense organs thus remain above the water surface even when the rest of the head is submerged. The two nostril openings are close together on a raised portion of the point of the muzzle and may be closed by membranous flaps so that no water can enter when the animal dives. A long nasal passage enclosed in bone leads from the exterior nostril openings to the interior nostril openings, or choanae, located at the extreme posterior end of the palate; a membranous flap in front of the choanae constitutes the posterior closure of the mouth cavity. Thus, the crocodile can breathe even if its mouth is open under water.

Like many nocturnal animals, crocodiles have eyes with vertical, slit-shaped pupils; these narrow in bright light and widen in darkness, thus controlling the amount of light that enters. On the back wall of the eye the so-called tapetum lucidum reflects the incoming light, thus utilizing small amounts of light to the best advantage. In addition to the protection provided by the upper and lower eyelids, the nictitating membrane, a thin, translucent structure, may be drawn over the eye from the inner corner while the lids are open. The delicate eyeball surface is thus protected under water, but a certain degree of vision is still possible.

Unlike the ears of other modern Reptilia, those of the crocodile have a movable, external membranous flap.

By means of this structure the crocodile is able to protect its ears from the water.

The crocodile's relatively flat snout is usually quite long; in some species it is extremely elongated. The outer margin of the jaws in most species is jagged. Each jaw carries a row of sharp teeth, which may number more than 100 in species with very long muzzles. The teeth are held in sockets and replaced continuously, new ones growing from below and old ones being forced out. On the floor of the mouth is the thick, fleshy tongue, firmly attached and therefore almost immobile.

The posterior portion of the head forms a flat plate. Here the short, powerful neck is attached. On its upper side are two groups of knobby scales: the smaller postoccipital knobs (absent only in the estuarine crocodile); and the large nuchal knobs, which in some species may be connected to the adjacent horny plates of the back.

Body plates

The upper surfaces of the back and tail are covered with large, rather rectangular horny plates arranged regularly in longitudinal and transverse rows. Most of the dorsal plates have a longitudinal ridge, or keel. Under these plates lie bony plates of about the same size, except in the estuarine crocodile, in which the bony plates are much smaller.

The entire underside of the crocodile usually also has regularly arranged horny plates, which are smaller than those on the upper surface, entirely smooth, rectangular, and contain little or no bone material. An exception to this condition occurs in caimans of the genera *Melanosuchus*, *Caiman*, and *Paleosuchus*, in which the surface plates on the lower side are just as bony as those on the back. Slightly posterior to the attachment of the hind-legs, on the underside of the base of the tail, lies the anus, which extends longitudinally, surrounded by an oval area of small scales.

In contrast to the back and belly, the sides of the body have mostly small knobby scales. The flanks are thus distensible, a necessary condition for breathing and for the expansion of the body that occurs in the pregnant female.

The legs are short but powerful. The forefeet have five toes—the usual number for Reptilia. In their anatomical structure, however, the forelegs differ markedly from those of other reptiles. This departure suggests that crocodiles developed from ancestors with degenerate forelegs; it also supports the possibility of a close evolutionary relationship between the crocodiles and the birds, in which the forelimbs have been considerably modified. The hind-legs are more powerfully developed than the front pair. The hind feet have only four toes, which are wholly or partially webbed.

On its flat upper side the tail carries a comb which, in the anterior portion, is double, consisting of high leaf-shaped scales. Near the middle of the tail the two combs merge.

The heart of the crocodile is markedly different in structure from that of other reptiles: the two auricles and the two ventricles are completely separate.

There exists, nevertheless, a connection between the arterial and venous circulation by way of the so-called Panizzae foramen, which opens between the two vessels leading separately from the ventricles. This connection is necessary for equalization of pressure differences between the arterial and venous circulatory systems that arise during long dives in deep water.

Arterial-venous connection

#### EVOLUTION AND CLASSIFICATION

**Paleontology.** The crocodile skull exhibits distinctly developed upper and lower temporal (*i.e.*, behind the eye sockets) openings; the teeth arise from sockets, and the roof of the skull lacks an opening for the parietal organ, a median, dorsal outgrowth of the brain. The crocodiles thus show the most important characteristics of the group that includes the dinosaurs (Archosauria). Within the Archosauria the crocodiles are a separate order, since they have developed a secondary bony palate, which encloses the nasal passage from the exterior nasal openings to the choanae (internal nostrils).

These features occur even in the most primitive repre-

sentatives of the crocodile group, namely the *Protosuchia* of the Upper Triassic Period (about 190,000,000–200,000,000 years ago); but their muzzles were very short, and the choanae were relatively far forward on the palate. As the crocodiles continued to evolve, the openings of the choanae tended to move further back. In the *Mesosuchia* of the Jurassic (136,000,000–190,000,000 years ago) and Cretaceous periods (65,000,000–136,000,000 years ago)—to which the long-snouted ocean crocodiles also belong—the choanae had already moved to the posterior part of two bones of the skull (pterygoids). In the true crocodiles (*Eusuchia*), which appear in the Upper Jurassic, the choanae are entirely enclosed by the pterygoids. In modern species they have moved to the posterior border of the palate. In the *Sebecosuchia* of the Upper Cretaceous to the Miocene Epoch (7,000,000–26,000,000 years ago), a branch collateral to that of the crocodiles, the skull is laterally flattened, and the choanae lie in a depression in the anterior part of the pterygoids.

Distinguishing taxonomic features. The families and genera of the order *Crocodylia* are differentiated primarily by the anatomical peculiarities of their skulls. The classification of the species is based mainly upon external characteristics, such as the proportions of the snout, the bony structures on the dorsal side of the snout, the number of teeth, the number and arrangement of the large knobs on the nape of the neck, and the characteristics of the dorsal plates.

Annotated classification. Extinct groups represented only by fossils are indicated by a dagger (†).

#### ORDER CROCODYLIA

Heavy cylindrical body; large, triangular head; legs short, toes webbed; long, muscular tail; large flat plates on belly, keeled ones on back; heart 4-chambered.

##### †Suborder Protosuchia

Upper Triassic; muzzle very short; choanae (internal nostrils) in region of palatine bone.

##### †Suborder Mesosuchia

Jurassic to Upper Cretaceous; choanae in posterior part of pterygoid bone.

##### †Suborder Sebecosuchia

Upper Cretaceous to Miocene; skull laterally flattened; choanae in depression in anterior part of pterygoids.

##### Suborder Eusuchia

Upper Jurassic to Recent; choanae entirely enclosed by pterygoids.

##### Family Alligatoridae (alligators)

Four genera and 7 species; teeth of lower jaw fit inside those of upper jaw.

##### Family Crocodylidae (true crocodiles)

Three genera and 13 species; teeth of upper and lower jaws form one interdigitating row when mouth is closed.

##### Family Gavialidae (gavial)

One genus and 1 species; extremely long snout, more than 22 teeth in each jaw; nasal bones separated from premaxillaries.

Critical appraisal. One authority has separated the order *Crocodylomorpha* into two suborders, *Crocodylia* and *Paracrocodylia*. According to this scheme the *Crocodylia* include as infra-orders those groups given above as suborders. This scheme also contains a suborder, *Thalattosuchia*.

Widely different views prevail concerning the classification of the living groups of *Eusuchia*—i.e., the alligators, the true crocodiles, and the gavials. Of these, the alligators and the true crocodiles, without doubt more closely related to each other than to the gavials, are sometimes regarded as constituting two subfamilies of the family *Crocodylidae*. Some authors regard the gavials as a third subfamily. Others give the false gavial, or Sunda gavial, a special position with respect to the true crocodiles. For conciseness, these three groups have been treated here as distinct families.

## Cro-Magnon Man

Cro-Magnon man is the name that was first given to several prehistoric skeletons found in a rock shelter at Cro-Magnon, near Les Eyzies-de-Tayac, Dordogne, France, in 1868. Sent to the site, French geologist Louis Lartet began excavations in which he established the existence of five archaeological layers covered with ash. The age of the human remains found in the topmost layer—along with worked flint and the bones of animals of species now extinct—is Upper Paleolithic (35,000–10,000 years ago), but the attribution of these to a clearly defined Upper Paleolithic culture is less definite. Traditionally regarded as Aurignacian, since typically Aurignacian artifacts were found in the rock shelter, they could be more recent, and one study suggests that they should be assigned to the Perigordian (a separate industry covering approximately the same time period as the Aurignacian), which would suggest an age of about 25,000 BC.

On the basis of the Cro-Magnon remains and those of Neanderthal man, which had been discovered a little earlier (1856), a general overview of prehistoric man was presented in 1882, in which the Cro-Magnon remains were asserted to be representative of a Cro-Magnon race.

Examination and analysis of Cro-Magnon fossils. Although it appears that, at the time of discovery, the remains of about 15 individuals existed at Cro-Magnon, only fragments from some six individuals were preserved, among them the cranium and mandible of a male about 50 years old. Considered representative of the Cro-Magnon type, this specimen is known as the Old Man of Cro-Magnon. Also preserved were skull fragments of about four other individuals, some bits of bone from a fetus or newborn child, and an assortment of bones attributed variously to the individuals mentioned above. The first subject mentioned, the Old Man of Cro-Magnon, has been regarded as typical of the Cro-Magnon race.

The skull is longheaded and as seen from above has a pentagonal outline, with outward bulging of the parietal bones (at the sides of the skull). The forehead is straight, the brow ridges only slightly projecting, the cranial vault noticeably flattened, and the occipital bone (at the back of the head) projects backward. The cranial capacity is large, about 1,600 cubic centimetres (about 100 cubic inches). Although the skull is relatively long and narrow, the face appears quite short and wide. This is often regarded as a common feature of the Cro-Magnon race.

**Reconstruction of the appearance of Cro-Magnon man.**

By courtesy of the American Museum of Natural History, New York

Typical  
skull  
features

The forward projection of the upper jaw (maxilla) is also distinctive. The eye sockets are low-set, wide, and rather square in shape; and the nasal aperture of the skull is narrow and strongly projecting. The mandible is robust, with massive ascending **ramus** (the upward projection of the lower jaw, where it attaches to the skull), strongly developed points of muscular attachment, and a quite prominent chin.

The root of only one molar tooth remains in the jaw of the Old Man of Cro-Magnon, a fact that contributed to the idea of his extreme age. In fact, it is probable that the loss of the majority of his teeth occurred after death. The teeth of the other individuals found at Cro-Magnon, which are similar to the teeth of other fossil humans classed as Cro-Magnon, show that the dentition of Cro-Magnon man was nearly identical to that of modern man. Most of the teeth, however, especially the last molars, are distinctly larger than those of most modern peoples. Dental caries is sometimes apparent, and tooth wear was often extreme.

The remainder of the Cro-Magnon skeleton is not fully known from the remains found at the original site, which are incomplete and poorly preserved. Skeletal material attributed to the Cro-Magnon race from other sites, however, affords the general impression of robustness, probably combined with powerful musculature. The forearm is relatively long, as is the thigh; the femur (thighbone) has a very prominent **linea aspera** (a bony ridge that runs lengthwise down the back of the femur), and the tibia is flattened from back to front (**platycnemy**). The hand skeleton is large with short fingers, and the foot has a prominent heel.

Cro-Mag-  
non man's  
height

Early investigators were impressed by the stature of Cro-Magnon man, as some reconstructions suggest that the Old Man of Cro-Magnon may have been as much as 1.90 metres (six feet three inches) tall. A recent re-study, however, suggests that the stature of the original Cro-Magnon remains varied from 1.66 to 1.71 metres (five feet five inches to five feet seven inches). The stature of several skeletons from the Grimaldi Caves (in Italy, near the French frontier), which show clear affinities to those of Cro-Magnon, was noticeably greater, with an average height of 1.77 metres (five feet eight inches). It is thus reasonable to conclude that, on the whole, the Cro-Magnon peoples were relatively tall.

Lesions noted in the Cro-Magnon skeletal remains have been attributed to wounds, but one analysis has suggested that these lesions are pathological in origin and may have resulted from the action of a toxic mushroom, *Actinomyces israeli*.

Variant Cro-Magnon types. Two French prehistorians, A. de Quatrefages and Ernest Hamy, in 1882 took

the Cro-Magnon fossils to be prototypes of a Cro-Magnon (or Les Eyzies) race. As opposed to the Neanderthal (or, Cannstadt) race, the Cro-Magnon were then considered to be the most ancient form of *Homo sapiens*. To the Cro-Magnon race were assigned other remains discovered before 1868 at Paviland, Glamorganshire; Engis, Belgium; La Madeleine, France; and Bruniquel, France. Subsequently, further finds of human skeletal remains extended the geographical range of the Cro-Magnon peoples through much of Europe and into Asia and North Africa.

The place of Cro-Magnon man in human evolution. The question of the relation of Cro-Magnon man to earlier forms of *Homo sapiens* is still unclear. Thousands of years before the appearance of Cro-Magnon peoples, certain modern traits are seen in human remains of Middle Pleistocene age (500,000–100,000 years old). Such remains, however, are rare and usually fragmentary, so the question of the relationship of Cro-Magnon peoples to the Middle Pleistocene remains, often assigned to an early form of *Homo sapiens*, and to the distinctive Neanderthal peoples who preceded Cro-Magnon man in Europe, is still to be settled.

Perhaps as complex as the question of origin is that of the duration of Cro-Magnon culture and the disappearance of Cro-Magnon man. The latter question is, in a sense, more a matter of genetics than of descriptive anthropology, since it is assumed that the Cro-Magnon race or type was simply absorbed into later European populations. Individuals nearly resembling Cro-Magnon types are found in the Mesolithic (in Europe, 8000–c. 5000 BC), for example, at Muge, Portugal, and in the Neolithic (in Europe, roughly from 5000 BC to about 2000 BC). Human groups, more or less homogeneous and structured, that have retained a close relationship to Cro-Magnon types, at least in their cranial morphology, are still in existence today. Such groups have been noted and studied in France, England, Spain, and North Africa; but the most remarkable examples are the Dal race from Dalecarlia (now Dalarna, Sweden) and the Guanches of the Canary Islands, who may represent the last relatively pure Cro-Magnon stock.

The culture of Cro-Magnon man. The ties between *Homo sapiens*, and particularly Cro-Magnon peoples and the various Upper Paleolithic cultures (Castelperronian, Aurignacian, Gravettian, etc.—based on classification of stone and bone tools), are not entirely clear. It is currently impossible to establish a general outline of physical types and cultures for this period. There do appear, however, to be some detectable differences between populations of different late Pleistocene ages in western Europe and between roughly contemporaneous populations in western Europe as contrasted with those of central or eastern Europe.

Toolmaking. The Cro-Magnon peoples are generally associated with the Aurignacian culture tool industry, and perhaps with the Gravettian (also called upper Perigordian). The Aurignacian tool industry is characterized by retouched blade tools, end scrapers and "nosed" scrapers, **burins** (chisel-like tools), and fine bone tools, in particular long, flat points (spearheads) with cleft bases. Other bone and reindeer-horn implements are also seen: awls, tools for smoothing or scraping leather, and the so-called **bâtons de commandement**—bars of antler or bone with holes drilled in them, the use of which is still uncertain, but perhaps used for straightening arrow or spear shafts.

Dwellings. The dwellings of Cro-Magnon man were most often caves and shelters made by rock overhangs, but it is apparent that huts were also made; sometimes these were simply lean-tos against rock walls, but foundation stones and "pavements" of stone in the shape of houses are evidence of complete huts. These houses are not a new development with the Cro-Magnon people, however; both the Neanderthal people and earlier peoples of the Middle Pleistocene are associated with similar remains. It seems probable that the Cro-Magnon peoples lived fairly settled lives. Studies of occupation sites and the types and extent of remains found in these sites sug-

weapons

Animals  
hunted

gest that the rock shelters were inhabited all through the year rather than seasonally, and it is likely that these Paleolithic hunters moved their homes only when hunting or environmental conditions forced them to do so.

**Hunting techniques.** The climate in the habitable parts of Europe at the time of Cro-Magnon man was cool to cold. Plants and animals of types associated with tundra and steppe environments were usual. Bone remains found at Cro-Magnon occupation sites indicate that they were successful hunters of such animals as reindeer, bison, wild horse, and even mammoth. As yet, very little is known of Cro-Magnon hunting methods—individual or collective, use of the bow, use of traps, etc. It is obvious from the animal remains, however, that hunting techniques must have been efficacious.

**Aesthetics and religion.** Although earlier human groups certainly had religious practices of some sort—the Neanderthal people buried their dead, a practice merely continued and elaborated by Cro-Magnon and later peoples—and no doubt had some appreciation of aesthetics as well, the first examples of prehistoric art are Cro-Magnon. Small engravings, reliefs, and sculptures of animals have been found, as well as a few later statuettes of ivory or stone and occasional engravings in stone of female figures. These figures are usually large-breasted, wide-hipped, and most often apparently pregnant; they are assumed to be some sort of fertility symbol, perhaps used in religious or magical rituals intended to promote the fertility of the group. The many fine paintings of animals found in caves in France and Spain are generally considered to have magical efficacy also, perhaps to ensure the presence of game, perhaps to aid the hunters in catching it; but it is by no means true that art for these prehistoric people had only magical or religious significance. The Cro-Magnon people also appreciated the decorative aspects of art, as demonstrated by their frequent use of animal pictures and simple geometrical designs to ornament tools and weapons. Moreover, whatever the motivation of such art, it is surprising by its quality. Whether it is a great composition of cave art or a carved or painted art object, it does not represent a first artistic attempt but artistic work that reaches the level of the masterpiece, by its artistic realism or by its power of movement. Sculpture like the "Venus of Brassempouy" or the head of a neighing horse at Le Mas-d'Azil (Ariège) or the bison at La Madeleine are worthy of a place among the masterpieces of world art.

## Cromwell, Oliver

Oliver Cromwell, an English soldier and statesman of outstanding gifts and a forceful character shaped by a devout Calvinist faith, was lord protector of the republican Commonwealth of England, Scotland, and Ireland from 1653 to 1658. One of the leading generals on the

parliamentary side in the English Civil War against King Charles I, he helped to bring about the overthrow of the Stuart monarchy, and, as lord protector, he raised his country's status once more to that of a leading European power from the decline it had gone through since the death of Queen Elizabeth I. Cromwell was one of the most remarkable rulers in modern European history; for although a convinced Calvinist, he believed deeply in the value of religious toleration. At the same time his victories at home and abroad helped to enlarge and sustain a Puritan attitude of mind both in Great Britain and in North America that continued to influence political and social life until recent times.

Oliver Cromwell, painting by Robert Walker (1607–c. 1660). In the National Portrait Gallery, London.

### YOUTH AND EARLY PUBLIC CAREER

Cromwell was born at Huntingdon in eastern England on April 25, 1599, the only son of Robert Cromwell and Elizabeth Steward. His father had been a member of one of Queen Elizabeth's parliaments and, as a landlord and justice of the peace, was active in local affairs. Robert Cromwell died when his son was 18, but his widow lived to the age of 89. Oliver went to the local grammar school and then for a year attended Sidney Sussex College, Cambridge. After his father's death he left Cambridge to look after his widowed mother and sisters but is believed to have studied for a time at Lincoln's Inn in London, where country gentlemen were accustomed to acquire a smattering of law. In August 1620 he married Elizabeth, daughter of Sir James Bouchier, a merchant in the City of London. By her he was to have five sons and four daughters.

**Formative influences.** Both his father and mother came from Protestant families who had profited from the destruction of the monasteries during the reign of King Henry VIII, and it is probable that they influenced their son in his religious upbringing. Both his schoolmaster in Huntingdon and the Master of Sidney Sussex College were enthusiastic Calvinists and strongly anti-Catholic. In his youth Cromwell was not notably studious, being fond of outdoor sports, such as hunting; but he was an avid reader of the Bible, and he admired Sir Walter Raleigh's *The History of the World*. From his teachers and from his reading Cromwell learned that the sins of man were punishable on earth but that God, through His Holy Spirit, could guide the elect into the paths of righteousness.

During his early married life Cromwell, like his father,

Upbringing

"Venus"  
figurines  
and animal  
paintings

was profoundly conscious of his responsibilities to his fellow men and concerned himself with affairs in his native fenlands, but he was also the victim of a spiritual and psychological struggle that perplexed his mind and damaged his health. He does not appear to have experienced conversion until he was nearly 30; later he described to a cousin how he had emerged from darkness into light. Yet he had been unable to receive the grace of God without feeling a sense of "self, vanity and badness." He was convinced that he had been "the chief of sinners" before he learned that he was one of God's Chosen.

Career as  
a country  
squire

Cromwell also had financial worries until, at the age of 39, he inherited property at Ely from his mother's brother. Like other lesser gentry, he contended with bad harvests and a variety of taxes and impositions, such as ship money, exacted by the monarchy not only to pay for the upkeep of the navy but to sustain the lavish tastes of the court. Though in 1628 he had been elected a member of Parliament for the borough of Huntingdon, King Charles I dissolved this Parliament in 1629 and did not call another for 11 years.

During the interval, country gentlemen like Cromwell accumulated grievances. The Cromwell family was but one of a network of dissatisfied gentry who belonged to what one might call the political nation: for example, John Hampden, the wealthy Buckinghamshire squire who brought a test case against the crown over the levying of ship money, was Cromwell's first cousin. Thus, when in the spring of 1640 Cromwell was elected member of Parliament for the borough of Cambridge, partly because of the important social position he held in Ely and partly because of his fame as "Lord of the Fens," he found himself among a host of friends at Westminster who, led by John Pym, a veteran politician from Somerset, were highly critical of the monarchy. Little was achieved by the Short Parliament (dissolved after three weeks), but, when in November 1640 Cromwell was again returned by Cambridge to what was to be known as the Long Parliament, which sat until 1653, his public career began.

Cromwell in Parliament. Cromwell had already become known in the Parliament of 1628–29 as a fiery and somewhat uncouth Puritan, who had launched an attack on Charles I's bishops. He believed that the individual Christian could establish direct contact with God through prayer and that the principal duty of the clergy was to inspire the laity by preaching. Thus he had contributed out of his own pocket to the support of itinerant Protestant preachers or "lecturers" and openly showed his dislike of his local bishop at Ely, a leader of the High Church party, which stood for the importance of ritual and episcopal authority. He criticized the bishop in the House of Commons and was appointed a member of a committee to investigate other complaints against him. Cromwell, in fact, distrusted the whole hierarchy of the Church of England, though he was never opposed to a state church. He therefore advocated abolishing the institution of the episcopate and the banning of a set ritual as prescribed in *The Book of Common Prayer*. He believed that Christian congregations ought to be allowed to choose their own ministers, who should serve them by preaching and extemporaneous prayer. Though he shared the grievances of his fellow members over taxes, monopolies, and other burdens imposed on the people, it was his religion that first brought him into opposition to the King's government. When in November 1641 John Pym and his friends presented to King Charles I a "Grand Remonstrance," consisting of over 200 clauses, among which was one censuring the bishops "and the corrupt part of the clergy, who cherish formality and superstition" in support of their own "ecclesiastical tyranny and usurpation," Cromwell declared that had it not been passed by the House of Commons he would have sold all he had "the next morning, and never have seen England more; . . .

Attacks on  
the church

The Remonstrance was not accepted by the King, and the gulf between him and his leading critics in the House of Commons widened. A month later Charles vainly attempted to arrest five of them for treason: Cromwell was not yet sufficiently prominent to be among these. But

when in 1642 the King left London to raise an army, and events drifted toward civil war, Cromwell began to distinguish himself not merely as an outspoken Puritan but also as a practical man capable of organization and leadership. In July he obtained permission from the House of Commons to allow his constituency of Cambridge to form and arm companies for its defense, in August he himself rode to Cambridge to prevent the colleges from sending their plate to be melted down for the benefit of the King, and as soon as the war began he enlisted a troop of cavalry in his birthplace of Huntingdon. As a captain he made his first appearance with his troop in the closing stages of the Battle of Edgehill (October 23, 1642) where Robert Devereux, 3rd earl of Essex, was commander in chief for Parliament in the first major contest of the war.

#### MILITARY AND POLITICAL LEADER

During 1643 Oliver acquired a reputation both as a military organizer and a fighting man. From the very beginning he had insisted that the men who served on the parliamentary side should be carefully chosen and properly trained, and he made it a point to find loyal and well-behaved men regardless of their religious beliefs or social status. Appointed a colonel in February, he began to recruit a first-class cavalry regiment. While he demanded good treatment and regular payment for his troopers, he exercised strict discipline. If they swore, they were fined; if drunk, put in the stocks; if they called each other Roundheads—thus endorsing the contemptuous epithet the Royalists applied to them because of their close-cropped hair—they were cashiered; and if they deserted, they were whipped. So successfully did he train his own cavalymen that he was able to check and re-form them after they charged in battle. That was one of Cromwell's outstanding gifts as a fighting commander.

Military  
organiza-  
tion

Throughout 1643 he served in the eastern counties that he knew so well. These formed a recognized centre of parliamentary strength, but, unwilling to stay on the defensive, Cromwell was determined to prevent the penetration of Yorkshire Royalists into the eastern counties and decided to counterattack. By re-forming his men in a moment of crisis in the face of an unbeaten enemy, he won the Battle of Gainsborough in Lincolnshire on July 28. On the same day he was appointed governor of the Isle of Ely, a large plateau-like hill rising above the surrounding fens, that was thought of as a possible bastion against advancing Royalists. In fact, however, Cromwell, fighting alongside the parliamentary general Sir Thomas Fairfax, succeeded in stemming the royalist attacks at Winceby in Lincolnshire and then successfully besieged Newark in Nottinghamshire. He was now able to persuade the House of Commons, well pleased with these victories, to create a new army, that would not merely defend eastern England but would march out and attack the enemy.

This new army was formed under the command of Edward Montagu, 2nd earl of Manchester, early in 1644. Appearing in the House of Commons, Cromwell, besides commending Manchester for the command, accused some of his fellow officers as incompetents or being "profane" and "loose" in their conduct. Although not all members of the House of Commons approved of Cromwell's using his political position to defame other officers, his friends rallied round him, and in 1644 he was appointed Manchester's second in command, with the rank of lieutenant general, and paid five pounds a day. After an alliance had been concluded with the Scots, he was also appointed a member of the Committee of Both Kingdoms, which became responsible for the overall strategy of the Civil War. But since he was engaged at the front during the campaigning season, Cromwell took little part in its deliberations.

After Manchester's army had stormed Lincoln in May 1644, it marched north to join the Scots and the Yorkshire parliamentarians at the siege of York. But Charles I's commander in chief, Prince Rupert, raised the siege. He was, however, defeated in the Battle of Marston Moor, July 2, 1644, that in effect gave the north of En-

Removal  
of Lord  
Man-  
chester

gland to Parliament. Cromwell had again distinguished himself in the battle, and when Manchester's army returned to eastern England to rest on its laurels, Cromwell criticized his superior officer for his slowness and lethargy. He did not believe that Manchester really wanted to win the war, and in mid-September he laid his complaints before the Committee of Both Kingdoms. The quarrel was patched up, but after the defeat at Newbury, caused largely by the earl of Manchester's refusal to support Cromwell's cavalry with his infantry, it broke into the open once more.

Cromwell now expounded his detailed complaint about Manchester's military conduct in the House of Commons. Manchester retorted by attacking Cromwell in the House of Lords. It was even planned to impeach Cromwell as "an incendiary." Once again, however, these quarrels were patched up. In December 1644, Cromwell proposed that in the future no members of either house of Parliament should be allowed to hold commands or offices in the armed forces; his proposal was accepted, and it was also agreed that a new army should be constituted under Sir Thomas Fairfax. Cromwell, an admirer of Fairfax, put forward his name and then busied himself with planning the new army, from which, as a member of Parliament, he himself was excluded. But, significantly, the post of second in command was left open, and, when the Civil War reached its climax in the summer of 1645, Fairfax insisted that Cromwell should be appointed to it. He then fought at the battles of Naseby and Langport, where Charles I's last two field armies were destroyed. In January 1646 the House of Commons awarded Cromwell £2,500 a year in confiscated Royalist land for his services and renewed his commission for a further six months. Thus he was able to join Fairfax in the siege of Oxford, from which Charles I escaped before it surrendered.

Cromwell was delighted with the way in which the war had gone since Fairfax had taken command of the new army and the lethargic earls of Essex and Manchester had been removed from their commands. He attributed these victories to the mercy of God and demanded that the men who had served the country so faithfully should have their due reward. After Naseby he wrote to the Speaker of the House of Commons urging that such "honest men" should not meet with discouragement: "He that ventures his life for the liberty of his country, I wish he trust God for the liberty of his conscience, and you for the liberty he fights for."

Postwar  
discord

But once the war was over the House of Commons wanted to disband the army as cheaply and quickly as possible. Disappointed, Cromwell told Fairfax in March 1647 that "never were the spirits of men more embittered than now." He devoted himself to trying to reconcile the Parliament with the army and was appointed a parliamentary commissioner to offer terms on which the army could be disbanded except for those willing to take part in a campaign in Ireland. As late as May he thought that the soldiers might agree to disband but that they would refuse to serve in Ireland and that they were "under a deep sense of some sufferings." When the civilian leaders in the House of Commons decided that they could not trust the army and ordered it disbanded, while they hired a Scottish army to protect them, Cromwell, who never liked the Scots and thought that the English soldiers were being disgracefully treated, left London and on June 4, 1647, threw in his lot with his fellow soldiers.

**Mediation and the Second Civil War.** For the remainder of this critical year he attempted to find a peaceful settlement of the kingdom's problems, but his task seemed insoluble; and soon his good faith was freely called into question. The army was growing more and more restive, and on the day Cromwell left London, a party of soldiers seized Charles I. Cromwell and his son-in-law, Henry Ireton, interviewed the King twice, trying to persuade him to agree to a constitutional settlement that they then intended to submit to Parliament. At that time Cromwell, no enemy of the King, was touched by his devotion to his children. His main task, however, was

to overcome the general feeling in the army that neither the King nor Parliament could be trusted. When, under pressure from the rank and file, General Fairfax led the army toward the houses of Parliament in London, Cromwell still insisted that the authority of Parliament must be upheld; and in September he also resisted a proposal in the House of Commons that no further addresses should be made to the King. Just over a month later he took the chair at meetings of the General Council of the Army (which included representatives of the private soldiers known as Agitators), assured them that he was not committed to any particular form of government and had not had any underhand dealings with the King. On the other hand, fearing anarchy, he opposed extremist measures such as the abolition of the monarchy and the House of Lords and the introduction of a more democratic constitution.

But all Cromwell's efforts to act as a mediator between army, Parliament, and King came to nothing when Charles I escaped from Hampton Court Palace, where he had been kept in honourable captivity, and fled to the Isle of Wight to open negotiations with Scottish commissioners offering to restore him to the throne on their terms. On January 3, 1648, Cromwell abandoned his previous position and, telling the House of Commons that the King was "an obstinate man, whose heart God had hardened," agreed to a vote of no addresses, which was carried. The Royalists, encouraged by the King's agreement with the Scots and the failure of Cromwell to unite Parliament and the army, took up arms again and the Second Civil War began.

General Fairfax first ordered Cromwell into Wales to crush a rising there and then sent him north to fight the Scottish army that invaded England in June. Though his army was inferior in numbers to that of the Scots and northern Royalists, he defeated them both in a campaign in Lancashire; then he entered Scotland and restored order there; finally he returned to Yorkshire and took charge of the siege of Pontefract. The correspondence he conducted during the siege with the governor of the Isle of Wight, whose duty it was to keep watch on the King, reveals that he was increasingly turning against Charles. Parliamentary commissioners had been sent to the island in order to make one final effort to reach an agreement with the King. But Cromwell told the governor that the King was not to be trusted, that concessions over religion must not be granted, and that the army might be considered a lawful power capable of ensuring the safety of the people and the liberty of all Christians.

While Cromwell, still not entirely decided on his course, lingered in the north, his son-in-law Ireton and other officers in the southern army took decisive action. They drew up a remonstrance to Parliament complaining about the negotiations in the Isle of Wight and demanding the trial of the King as a Man of Blood. While Cromwell still felt uncertain about his own views, he admitted that his army agreed with the army in the south. Fairfax now ordered him to return to London; but he did not arrive until after Ireton and his colleagues had removed from the House of Commons all members who favoured continuing negotiations with the King. Cromwell asserted that he had not been acquainted with the plan to purge the House, "yet since it was done, he was glad of it, and would endeavour to maintain it." Hesitating up to the last moment, Cromwell, pushed on by Ireton, by Christmas Day finally accepted Charles's trial as an act of justice. He was one of the 135 commissioners in the High Court of Justice and, when the King refused to plead, he signed the death warrant.

**First chairman of the Council.** After the British Isles were declared a republic and named the Commonwealth, Oliver Cromwell served as the first chairman of the Council of State, the executive body of a one-chamber Parliament. During the first three years following Charles I's execution, however, he was chiefly absorbed in campaigns against the Royalists in Ireland and Scotland. He also had to suppress a mutiny, inspired by a group known as Levellers, an extremist Puritan party said to be aiming at a "levelling" between rich and poor, in the Common-

wealth army. Detesting the Irish as primitive, savage, and superstitious, he believed they had carried out a huge massacre of English settlers in 1641. As commander in chief and lord lieutenant, he waged a ruthless campaign against them, though when he refused quarter to most of the garrison at Drogheda near Dublin in September 1649, he wrote that it would "tend to prevent the effusion of blood for the future, . . . which otherwise cannot but work remorse and regret." On his return to London in May 1650 Cromwell was ordered to lead an army into Scotland, where Charles II had been acknowledged as its new king. Fairfax had refused the command; so on June 25 Cromwell was appointed captain general in his place. He felt more tender toward the Scots, most of whom were fellow Puritans, than toward the Catholic Irish. The campaign proved difficult, and during the winter of 1650 Cromwell was taken ill. But he defeated the Scots with an army inferior in numbers at Dunbar on September 3, 1650, and a year later, when Charles II advanced into England, Oliver destroyed his army at Worcester.

This battle ended the civil wars. Cromwell now hoped for pacification, a political settlement, and social reform. He pressed through an "act of oblivion" (amnesty), but the army became more and more discontented with Parliament. It believed that the members were corrupt and that a new Parliament should be called. Once again Cromwell tried to mediate between the two antagonists, but his sympathies were with his soldiers. When he finally came to the conclusion that Parliament must be dissolved and replaced, he called in his musketeers and on April 20, 1653, expelled the members from the House. He asserted that they were "corrupt and unjust men and scandalous to the profession of the Gospel"; two months later he set up a nominated assembly to take their place. In a speech on July 3 he told the new members that they must be just, and, "ruling in the fear of God," resolve the affairs of the nation.

The  
"Little  
Parliament"

Cromwell seems to have regarded this "Little Parliament" as a constituent body capable of establishing a Puritan republic. But just as he had considered the previous Parliament to be slow and self-seeking, he came to think that the Assembly of Saints, as it was called, was too hasty and too radical. He also resented the fact that it did not consult him. Later he described this experiment of choosing Saints to govern as an example of his own "weakness and folly." He sought moderate courses and also wanted to end the naval war begun against the Dutch in 1652. When in December 1653, after a coup d'état planned by Major General John Lambert and other officers, the majority of the Assembly of Saints surrendered power into Cromwell's hands, he decided reluctantly that Providence had chosen him to rule. As commander in chief appointed by Parliament, he believed that he was the only legally constituted authority left. He therefore accepted an "Instrument of Government" drawn up by Lambert and his fellow officers by which he became lord protector, ruling the three nations of England, Scotland, and Ireland with the advice and help of a council of state and a Parliament, which had to be called every three years.

#### ADMINISTRATION AS LORD PROTECTOR

Before Cromwell summoned his first Protectorate Parliament on September 3, 1654, he and his Council of State passed more than 80 ordinances embodying a constructive domestic policy. His aim was to reform the law, to set up a Puritan Church, to permit toleration outside it, to promote education, and to decentralize administration. The resistance of the lawyers somewhat dampened his enthusiasm for law reform, but he was able to appoint good judges both in England and Ireland. He was strongly opposed to severe punishments for minor crimes, saying: "to see men lose their lives for petty matters . . . is a thing that God will reckon for." For him murder, treason, and rebellion alone were subject to capital punishment. During his Protectorate, committees known as Triers and Ejectors were set up to ensure that a high standard of conduct was maintained by clergy and schoolmasters. In spite of resistance from some members

of his council Cromwell readmitted Jews into the country. He concerned himself with education, was an excellent chancellor of Oxford University, founded a college at Durham, and saw to it that grammar schools flourished as they had never done before.

Foreign and economic policies. In 1654 Cromwell brought about a satisfactory conclusion to the Anglo-Dutch War, which, as a contest between fellow Puritans, he had always disliked. The question then arose of how best to employ his army and navy. His Council of State was divided, but eventually he resolved to conclude an alliance with France against Spain. He sent an amphibious expedition to the Spanish West Indies, and in May 1655 Jamaica was conquered. As the price for sending an expeditionary force to Spanish Flanders to fight alongside the French he obtained possession of the port of Dunkirk. He also interested himself in Scandinavian affairs; although he admired King Charles X of Sweden, his first consideration in attempting to mediate in the Baltic was the advantages that would result for his own country. In spite of the emphasis Cromwell laid on the Protestant interest in some of his speeches, the guiding motive in his foreign policy was national and not religious benefit.

Conquest  
of Jamaica

His economic and industrial policy followed mainly traditional lines. But he opposed monopolies, which were disliked by the country and had only benefitted the court gentry under Queen Elizabeth and the first two Stuarts. For this reason the East Indian trade was thrown open for three years, but in the end Cromwell granted the company a new charter (October 1657) in return for financial aid. Satisfactory methods of borrowing had not yet been discovered; hence—like those of practically all European governments of his time—Cromwell's public finances were by no means free from difficulties.

Relations with Parliament. When Cromwell's first Parliament met he justified the establishment of the Protectorate as providing for "healing and settling" the nation after the civil wars. Arguing that his government had prevented anarchy and social revolution, he was particularly critical of the Levellers who, he said, wished to destroy well-tested institutions "whereby England hath been known for hundreds of years." He believed that they wanted to undermine "the natural magistracy of the nation" as well as "make the tenant as liberal a fortune as the landlord." He also thought that the spiritual anarchy that followed the destruction of the old Anglican Church had gone too far, for now ordained preachers were frequently interrupted or shouted down in their pulpits. A radical in some directions, such as in seeking the reform of the laws, Cromwell now adopted a conservative attitude because he feared that the overthrow of the monarchy might lead to political collapse.

But vociferous republicans, who became leaders of this newly elected Parliament, were unwilling to concentrate on legislation, questioning instead the whole basis of Cromwell's government. Cromwell insisted that they must accept the "four fundamentals" of the new constitution that, he argued, had been approved both by "God and the people of these nations." The four fundamentals were government by a single person and Parliament; the regular summoning of parliaments, which must not be allowed to perpetuate themselves; the maintenance of "liberty of conscience"; and the division of the control of the armed forces between the protector and Parliament. Oliver said that he would sooner be "rolled into my grave and buried with infamy, than I can give my consent" to the "wilful throwing away of this Government, . . . so owned by God, so approved by men." He therefore required all members of Parliament, if they wished to keep their seats, to sign an engagement to be faithful to a protector and Parliament and to promise not to alter its basic character. Except for 100 convinced republicans, the members agreed to do so but were still more concerned with rewriting the constitution than reforming the laws as desired by the protector. As soon as he could legitimately do so (January 22, 1655), Cromwell dissolved Parliament.

The four  
fundamentals

But with his second Parliament, which he convened in 1656, he encountered exactly the same difficulty in the

end, for the republican leaders, when they were allowed to resume their seats, tried to destroy the Protectorate on the ground that they were being forced to return to "an Egyptian bondage." Once again Cromwell emphasized that he had been "called" to power and that anarchy or an invasion from abroad would follow if his authority were not upheld. Thus in February 1658 he felt himself driven again to dissolve Parliament even though, as a former member, he understood only too well the gravity of his action.

Death and  
burial

Ever since the campaign in Ireland Cromwell's health had been poor. In August 1658, after his favourite daughter, Elizabeth, died of cancer, he was taken ill with malaria and taken to London with the intention of living in St. James's Palace. But he died in Whitehall at three o'clock on September 3, the anniversary of two of his greatest victories. His body was secretly interred in Westminster Abbey on November 10, 13 days before his state funeral. In 1661, after the restoration of King Charles II, Cromwell's embalmed remains were dug out of the tomb and hung up at Tyburn where criminals were executed. His body was then buried beneath the gallows. But his head was stuck on a pole on top of Westminster Hall where it is known to have remained until the end of Charles II's reign.

Assessment. Oliver Cromwell was by no means an extreme Puritan. By nature he was neither cruel nor intolerant. He cared for his soldiers, and when he differed from his generals he did not punish them severely. (For example, when he dismissed John Lambert he gave him a generous pension.) He was devoted to his old mother, his wife, and family. (The stories spread by Royalists that he was an admirer of a number of ladies have little substance to them.) While he concerned himself with the spiritual welfare of his children because he believed that "often the children of great men have not the fear of God before their eyes," he committed the mistake of not preparing for the practical tasks of government his eldest son, Richard, whom in the last days of his life he nominated to succeed him as protector. Music and hunting were among his recreations. He delighted in listening to the organ and was an excellent judge of horses. He was known to smoke, to drink sherry and small beer, and to prefer English food; he permitted dancing at the marriage of his youngest daughter. In his younger days he indulged in horseplay with his soldiers, but he was a dignified ruler. Sir Peter Lely, the famous Dutch painter, pictured him as he was in his prime (although the portrait was apparently not painted from life); the numerous paintings from life by Robert Walker dating from the beginning of the Civil War show him looking more of a fanatic.

As lord protector, Cromwell was much more tolerant than in his fiery Puritan youth. Once bishops were abolished and congregations allowed to choose their own ministers, he was satisfied. Outside the church he permitted all Christians to practice their own religion so long as they did not create disorder and unrest. He allowed the use of *The Book of Common Prayer* in private houses and even the English Roman Catholics were better off under the protectorate than they had been before.

Although many Quakers were kept in prison for disturbing the peace, Cromwell was on friendly terms with George Fox, the founder of the society of Friends, and explored religious questions with him. When in the winter of 1656 a Quaker entered Bristol in imitation of Christ's entry into Jerusalem, Cromwell tried, though unsuccessfully, to save him from the fury of Parliament, which voted heavy punishments on the blasphemer. The year before, Oliver interviewed two of the leaders of the Fifth Monarchy Men, an extreme sect: he pointed out to them that they had been imprisoned for sedition but emphasized that no one would hinder them from preaching the Gospel of Christ.

In politics Cromwell held no fixed views except that he was opposed to what he called arbitrary government. Before the execution of Charles I he contemplated the idea of placing one of Charles's sons upon the throne. Oliver also resisted the abolition of the House of Lords. In 1647 he said that he was not "wedded and glued" to

any particular form of government. After the Assembly of Saints failed, he summoned two elected parliaments (1654–55 and 1656–58), but he was never able to control them. His failure to do so has been attributed to "lack of that parliamentary management by the executive which, in correct dosage, is the essential nourishment of any sound parliamentary life" (H.R. Trevor-Roper). In between these two parliaments (1655–56) he sanctioned the government of the country by major generals of the Horse Militia who were made responsible for law and order in groups of counties. But he soon abandoned this experiment when it met with protests and reverted to more normal methods of government. In the spring of 1657 he was tempted by an offer of the crown by a majority in Parliament on the ground that it fitted in better with existing institutions and the English common law. In the end he refused to become king because he knew that it would offend his old republican officers. Nevertheless, in the last year and a half of his life he ruled according to a form of government known as "the Petition and Advice." This in effect made him a constitutional monarch with a House of Lords whose members he was allowed to nominate as well as an elected House of Commons. But he found it equally difficult to govern either with or without parliaments.

Although in the late 17th century Cromwell was execrated as a brave bad man, it was admitted that he had made his country great. In the 18th century, on the other hand, he was considered a nauseating hypocrite, while the 19th century, under the influence of the writer and historian Thomas Carlyle, regarded him as a constitutional reformer who had destroyed the absolutism of Charles I. Modern critics are more discriminating. His belief in God's providence is analyzed in psychological terms. Marxists blame him for betraying the cause of revolution by suppressing the radical movement in the army and resisting the policy of the Levellers. On the whole, he is regarded only in a very limited sense as a dictator, but rather as a patriotic ruler who restored political stability after the civil wars and contributed to the evolution of constitutional government and religious toleration.

Reputation

**BIBLIOGRAPHY.** SIR CHARLES H. FIRTH, *Oliver Cromwell and the Rule of the Puritans in England* (1900, many times reprinted), is generally accepted as the best and fairest biography. Other modern biographies include R.S. PAUL, *The Lord Protector* (1955), excellent on Cromwell's religious attitude; and MAURICE ASHLEY, *The Greatness of Oliver Cromwell* (1957 and 1966); embodying some of the results of research since Firth's day. CHRISTOPHER HILL, *God's Englishman* (1970), places Cromwell in perspective from a Marxist point of view. Other books on Cromwell include three by distinguished statesmen, French, American, and British: FRANÇOIS GUIZOT, *Oliver Cromwell and the English Revolution*, 2 vol. (Eng. trans. 1854); THEODORE ROOSEVELT, *Oliver Cromwell* (1900); and JOHN MORLEY, *Oliver Cromwell* (1900). Cromwell's letters and speeches are collected in *The Writings and Speeches of Oliver Cromwell*, 4 vol., ed. by W.C. ABBOTT (1937–47); these volumes also contain a sound and detailed narrative of his career.

(M.As.)

## Cromwell, Thomas

Thomas Cromwell, as principal adviser to King Henry VIII, was virtual ruler of England from 1532 to 1540. Purposeful, decisive, and essentially ruthless, Cromwell during these years established the English Reformation, confiscated the wealth of the monasteries, and effected a revolution in the administration of the kingdom. He was born in Putney, the son (probably) of Walter Cromwell, alias Smyth, a brewer, blacksmith, and cloth maker. His early life is obscure. It appears that he went abroad at an early age and spent some time in Italy. For several years after 1510 he was resident in the Low Countries, and he seems to have been closely connected with the London Merchant Adventurers. By 1520 he had entered Cardinal Wolsey's service as his solicitor, and from that time his career is well documented. Wolsey employed him in 1525 in the dissolution of some lesser monasteries, in which work he earned a good deal of dislike. The Car-

beliefs

Political  
views

dinal, however, continued to favour him, and Cromwell soon became his confidential adviser.

By courtesy of The Frick Collection, New York

Thomas Cromwell, painting by Hans Holbein, the Younger (1497/198–1543). In the Frick Collection, New York.

When Wolsey fell into disgrace in 1529, Cromwell entered Parliament, where his remarkable ability attracted the notice of the King. For nearly three years he worked his way up in the royal favour, entering Henry's service early in 1530. He was sworn into the council toward the end of that year and reached the inner circle of confidential advisers a year later. All the time, he was establishing his ascendancy in the House of Commons. In 1532 he obtained office as master of the jewels. Other offices soon followed: principal secretary and master of the rolls in 1534 and lord privy seal in 1536. The last office was combined with a peerage, and he took the title of Lord Cromwell of Wimbledon.

Cromwell's part in the English Reformation has been much debated. At one time he was credited with supplying Henry with a complete plan of action as early as 1529; later it became usual to see in him nothing but the King's most competent executive agent. The truth seems to be that he was in no way in charge until early in 1532, taking over when the King's policy of forcing the Pope to come to terms had proved to be a failure. It was, to all appearances, Cromwell who then came forward with a clear notion of how to achieve Henry's purpose without the Pope. His policy consisted in making a reality of some large and vague claims to supreme power that Henry had uttered at intervals. He proposed to destroy Rome's power in England and to replace it by the royal supremacy in the church. He was behind the first attacks on the papacy (1532) and the act against the payment by bishops of their first year's revenue to Rome. He secured the submission of the clergy to the King in matters of legislation, and, in 1533 he secured the passage of the Act in Restraint of Appeals to Rome, preventing appeals to Rome in matrimonial and testamentary cases. Its preamble embodied his political theory of the sovereign national state. Thereafter he was in complete control of the government, though he remained careful to pretend to be acting on the King's authority. In 1534 he completed the erection of the royal supremacy with the passage of the Act of Supremacy.

Political and financial reasons counselling an attack on the monasteries, Cromwell was appointed the King's vicar general with powers to visit and reform all monastic institutions. Despite serious opposition, especially in the north, the task was carried out relentlessly. During 1536–40 the surrender of the greater houses was obtained by pressure and persuasion, and by 1540 all monastic institutions had ceased to exist and their property had been vested in the crown. Cromwell and other crown officials

obtained valuable grants as rewards, but while the minister lived, the new wealth was not squandered.

In 1536 Cromwell was also appointed the King's deputy as head of the church. Cromwell's own religious views have been in much doubt. They certainly were not very strong, and his essentially secular temper subordinated religious to political considerations. Nevertheless, he came to be firmly associated with a radical policy of reform and Reformation. In the main, this resulted from difficulties abroad. While hostility between France and Spain had prevented foreign intervention during the critical years of the Reformation, 1533–36, there seemed a danger of an alliance against England after that date. Cromwell, whose forthright and clear-sighted temper was less well suited to the conduct of foreign affairs than Henry VIII's skillful opportunism, involved himself in projects of a Lutheran alliance distasteful to the King who wished to stand on Catholic orthodoxy. In 1539 Cromwell made the mistake of trying to force the King to his side by compelling him to marry Anne of Cleves. The King from the first hated his fourth wife, and by February 1540 it was clear that the alliance with the German princes that she represented was unnecessary. Thereafter, Cromwell's fall came quickly. He fought back for a few months, being created earl of Essex and lord great chamberlain in April 1540, but early in June his enemies persuaded Henry that his vicegerent was a heretic and a traitor. He was arrested on June 10, condemned without a hearing, and executed on July 28. His fall did not end the Reformation, but it marked the end of competent government and purposeful policy in Henry's reign.

The basis of Cromwell's thought was the notion of the sovereign national state that in practice he established by the expulsion of the papacy. He was greatly interested in political theory, though it seems improbable that he knew Machiavelli's writings, as was once alleged. In his conception of the English state and monarchy, his central idea was that of the supremacy and omnipotence of statute, or (as it came to be called) legislative sovereignty of the king in Parliament. In other words, he wanted to establish unlimited sovereignty in the hands of a monarchy limited by dependence on consent. His work in Parliament—managing elections, drafting statutes, piloting legislation—makes him the first of a long line of English parliamentary statesmen. He also demonstrated his awareness of the need of providing practical management of a new kind. No minister before him, and few after, exercised such pervasive influence over every detail of administration. Cromwell began, and to a large extent carried through, a reconstruction that replaced administration by the king's household with a national administration divorced from the person of the king and dependent on civil service departments. This aspect of his work endured, through many reforms, until the great changes of the 19th century.

**BIBLIOGRAPHY.** R.B. MERRIMAN, *The Life and Letters of Thomas Cromwell* (1902), prints the bulk of the surviving letters, but the biography, though full of relevant facts, is badly marred by the author's dislike of his subject and his little understanding of the age. A.G. DICKENS, *Thomas Cromwell and the English Reformation* (1959), provides a sympathetic and sensible picture, especially of Cromwell's contribution to the religious Reformation. Various aspects of Cromwell's career are dealt with in W.G. ZEEVELD, *Foundations of Tudor Policy* (1948), which throws light on Cromwell's political thought; G.R. ELTON, *The Tudor Revolution in Government* (1953), which analyzes his work as an administrator; and the same author's *Policy and Police* (1972), which deals with the problems of enforcement raised by the early Reformation and with Cromwell's dominant part in solving them.

(G.R.E.)

## Crossopterygii

The Crossopterygii constitutes a largely extinct subclass of the bony fishes that appeared at the beginning of the Devonian Period (395,000,000 years ago) but are now represented only by the coelacanth *Larimeria chalumnae*.

**General features.** One major trait of the subclass is the division of the skull into an anterior, or **ethmosphe-**

Foreign  
policy

Accom-  
plishments

Cromwell  
and the  
Refor-  
mation

noidal, unit and a posterior, or oto-occipital, unit, similar to the two cartilaginous prototypes found in the embryonic cranium. A strong joint unites the two regions at each side. The base of the skull and the vertebral column, which are incompletely ossified, allow the persistence, to various degrees, of the initial skeletal axis, or notochord. The subclass comprises three orders: Rhipidistia, Actinistia, and Struniiformes. Some authorities consider the Crossopterygii to be an order and what are treated here as orders to be suborders (see FISH). After being widely distributed around the world in the Mesozoic Era, which began about 225,000,000 years ago, the crossopterygians underwent a rapid decline and then almost became extinct after the Triassic Period (190,000,000 years ago).

Drawing by T. Kovacs based on (Top) *De tidiga fossila Rygggradsdjuren* (1959)

Devonian rhipidistian  
*Eusthenopteron fordsi*

modern coelacanth  
*Latimeria chalumnae*

#### Representative crossopterygians.

The Rhipidistia, predatory fishes of the Mesozoic, were ancestral to the terrestrial vertebrates, lived in freshwater, and probably had two respiratory apparatuses, a branchial (gill) system for aquatic respiration and a pulmonary (lung) system for air breathing. To facilitate air breathing the nasal cavities were provided with posterior nares (nostrils) homologous with the primary choanae (internal openings to the pharynx) of more advanced vertebrates. The skeletal structure of the paired fins clearly shows the ability for locomotion both on solid ground and in the water. The rhipidistians are thus credited, in the history of vertebrate evolution, with having made the great transition in anatomy and physiology involved in the emergence from water and resulting in the evolution of the amphibians. A Swedish paleontologist, E. Jarvik, has suggested that the rhipidistian Osteolepiformes gave rise to the Stegocephalia (the extinct ancestors of reptiles, birds, and mammals) and the Anura (frogs) and that the suborder Porolepiformes gave rise to the Urodela (salamanders).

The Actinistia, especially the family Coelacanthidae, unlike the Rhipidistia, have exhibited exceptional evolutionary stability. The same fossil deposits contain both marine and freshwater types, both already specialized during the Devonian. They were thought to have disappeared 50,000,000 to 70,000,000 years ago, but in 1938 a live specimen was taken in the Indian Ocean. South African ichthyologist J.L.B. Smith identified it as a member of the Coelacanthidae and named it *Latimeria chalumnae*, the generic name in honour of Miss Courtenay Latimer, an associate who first brought the strange fish to his notice, the species name recalling its capture near the mouth of the Chalumna River. Between 1952 and 1970, more than 60 specimens of *Latimeria* were caught on the volcanic slopes of the Comoro Islands, at depths of 200 to 300 metres (650 to 1,000 feet).

**Form and function.** *Latimeria* has made it possible to reconstruct, with a high probability of accuracy, the anat-

omy of the coelacanths in general, in particular that of the perishable organs. Among the most striking characteristics are those of the head. The brain exhibits a relatively simple and harmonious structure, has an extremely small volume by comparison with the cranial capacity, and shows considerable displacement of the forebrain relative to the floor of the skull. The snout contains a special sensory organ, the rostral organ. At the intracranial articulation are attached some fibrous connective tissues as well as a pair of powerful longitudinal muscles, the subcranial muscles. This pair of muscles encloses the imposing notochord (a slender skeletal structure), the morphology of which must have been largely the same throughout the crossopterygian group. The heart of the *Latimeria*, which is very primitive, exhibits almost perfect bilateral symmetry (mirror-image form). It lies within a substantial pericardial cavity that retains the primitive continuity with the peritoneal (abdominal) cavity. There is a series of small valves near the exit from the heart, and several small contractile organs attached to the branchial arteries apparently fulfill the necessary function of assisting the propulsion of blood. On the whole, an embryonic condition co-exists with specialized arrangements.

An enormous cylinder of adipose (fat) tissue, aligned with a short median diverticulum (a blind pouch) of the ventral wall of the esophagus, lies above the abdominal organs. It apparently is a result of the degeneration of a lung apparatus. The extraordinary size of this cylinder is related to a displacement of the kidneys that undoubtedly occurs in the course of development, these organs occupying an unusual ventral position, posterior to the anus. Segments of the sympathetic nervous system are carried along in this movement.

The body is covered with large rough scales. The powerful tail fin has three lobes, lying in the median plane. The posterior end of the notochord extends into the middle lobe, which is by far the smallest. Two pairs of fins, the pectoral and the pelvic, are attached to their respective girdles. The base of each fin consists of a fleshy stalk supported by several successive segments of bone or cartilage that are not homologous with the similar parts of the Rhipidistia. Median fins similarly formed grow from the posterior part of the body, the posterior dorsal (above) and anal (below) fins. Finally, there is an anterior dorsal fin which, in contrast to the foregoing, is of ray-finned (actinopterygian) type—i.e., lacking the fleshy, supportive stalk.

The Struniiformes, discovered only recently, lived in the Devonian. Their bony remains indicate considerable differences from both the Rhipidistia and the Actinistia. The fossil remains indicate, however, that they possessed the major characteristic of the subclass, the division of the cranium into an anterior and a posterior part.

**BIBLIOGRAPHY.** There is virtually no popular literature dealing with this group of fishes. The following are technical in nature: E. ## Crusades

The term crusade is commonly used to refer to military expeditions organized by Western Christians against Muslim powers in order to take possession of or maintain control over the Holy City of Jerusalem and the places associated with the earthly life of Jesus Christ. Between 1095, when the First Crusade was launched, and 1291, when the Latin Christians were finally expelled from their bases in Syria, historians have formally enumerated eight major expeditions. Many other lesser ven-

tures also took place, and even after 1291 there were attempts to recover what had been lost.

This period of roughly two centuries was one of significant social, economic, and institutional growth in western Europe. As a consequence, each of the Crusades reflected the particular conditions prevailing in Europe at the time, and their impact on Europe varied as new situations developed in the East.

This article is divided into the following sections:

- I. The crusading movement and the first four Crusades
  - The First Crusade and the establishment of the Latin states
    - Background of the First Crusade
    - Preparations for the Crusade
    - The siege of Antioch
    - The siege of Jerusalem
    - The establishment of the crusader states
  - The era of the Second and Third Crusades

## I. The crusading movement and the first four Crusades

### THE FIRST CRUSADE AND THE ESTABLISHMENT OF THE LATIN STATES

**Background of the First Crusade.** Politically, western Europe in the last quarter of the 11th century comprised several kingdoms loosely describable as feudal. While certain monarchies were already developing better integrated systems of government, many problems associated with feudalism, such as vassalage and inheritance, endemic private warfare, and brigandage, were still present. There were, of course, many variations, and in certain cases special conditions in a country precluded its significant participation in a crusade. Such, for example, were the problems of England's readjustment after the Norman Conquest in 1066, Spain's preoccupation with Muslim incursions from Africa, and civil strife in Germany consequent on long controversy with the popes. In fact, the principal support for the First Crusade came from France; and it was in France that the most typical aspects of feudalism, both negative and positive, could be found.

Europe in the 11th century was feeling the impact of a population growth that had begun toward the end of the 10th century and would continue well into the 13th century. Younger sons of the nobility, unless they married advantageously or entered the religious life, were more than ever disposed to adventure, organized or otherwise. At the same time, an economic revival was in full swing well before the First Crusade. Forest lands were being cleared, frontiers pushed forward, and markets organized, and the Muslim predominance in the Mediterranean was being challenged by Italian shipping. Nobles, bourgeois, and peasants were all seeking new outlets.

The 11th century also witnessed a far-reaching religious renewal. Especially significant for the Crusade was a general overhauling of the ecclesiastical structure, which enabled the popes to assume a more active role in society. In 1095, for example, Urban II, though still meeting resistance from the German Emperor, who opposed papal reform policies, was in a strong enough position to convoke two important ecclesiastical councils.

Thus it was that in the closing years of the 11th century western Europe was abounding in energy and full of confidence. What is more, as is evident in such achieve-

ment-as the Norman Conquest of England, Europeans possessed the capacity to launch a major military undertaking. Why this energy was channelled into a holy war against Muslims in a distant land is uncertain, though the answer in part involves a new challenge from Eastern Islam presented by the incursions of the Seljuq Turks. The Seljuqs, originally one of several Turkish tribes on the northeastern borders of the Muslim world, had embraced Islām and by the 11th century were moving south and west into Iran and beyond. In large part, however, the answer also lies in the nature of popular religious life and feeling in the West. The two developments are not unconnected.

The impact of religion on the lay person of the time is not easy to determine: his religion was unsophisticated, and he was moved by tales of signs and wonders and attributed natural disasters to supernatural intervention. At the same time, lay people were not indifferent to movements of reform, and there were instances of townsmen agitating against clergy whom they regarded as unworthy. There also developed, especially in France, under the leadership of certain bishops but with considerable popular support, what could be described as a peace movement. Many local areas proclaimed the Truce of God and the Peace of God, designed to halt or at least limit fratricidal strife and protect the lives of clergy, travellers, and other persons unable to protect themselves against brigandage. It is particularly interesting to note that the Council of Clermont at which Urban II preached the First Crusade in 1095 renewed and generalized the Truce of God.

While it may seem paradoxical that a council both promulgated peace and officially sanctioned war, it must be remembered that the peace movement was designed to protect those in distress, and a strong element in the Crusade was the idea of giving aid to fellow Christians in the East. Furthermore, there had developed in western Europe, partly under the influence of the Reconquista (the movement to reconquer Spain from the Muslims), the idea that war to defend Christian society was not only justifiable but a holy work, and therefore pleasing to God.

Closely associated with this Western concept of holy war was another popular religious practice, pilgrimage to a holy shrine. Eleventh-century Europe abounded in local shrines housing relics of saints, but three great centres of pilgrimage stood out above all the others: Rome, with the tombs of SS. Peter and Paul; Santiago de Compostela, in northwestern Spain; and Jerusalem, with the Holy Sepulchre of Christ's entombment. Moreover, pilgrimage, which had always been considered an act of devotion, had come to be regarded as a more formal expiation for serious sin, even occasionally prescribed as a penance to the sinner by his confessor.

Yet another element in the popular religious consciousness of the 11th century, one associated with both Crusade and pilgrimage, was a widespread belief that the end of the world was imminent. This belief was once thought to have been associated with the year 1000 (the millennium). Scholars now, however, tend to discount the idea that contemporaries had so precise a date in mind and emphasize the continuance of the idea through the 11th century and even beyond. Moreover, in certain late-11th-century portrayals of the end of all things, the "last emperor," now popularly identified with the "king of the Franks," the final successor of Charlemagne, was to lead all the faithful to Jerusalem and there await the Second Coming of Christ. Manifestly, Jerusalem, as the earthly symbol of the heavenly city, figured prominently in Western consciousness. And it was becoming clear, as the number of pilgrimages to Jerusalem increased in the 11th century, that any interruption would have serious repercussions.

By the middle of the 11th century the Seljuqs had wrested political authority from the 'Abbāsid caliphs of Baghdad. Their policy, originally directed southward against the Fāṭimids of Egypt, was increasingly diverted by the pressure of Turkman raids into Anatolia and Byzantine Armenia. A badly organized Byzantine army was

Factors in the growth of religious enthusiasm

The importance of Jerusalem

The economic revival of the 11th century

defeated at Manzikert in 1071, opening Asia Minor to eventual Turkish occupation. Meanwhile, many Armenians south of the Caucasus migrated south to join others in the region of the Taurus Mountains and to form a colony in Cilicia.

Seljuq expansion southward continued, and in 1085 the capture of Antioch in Syria was another blow to Byzantine prestige. Thus, although the Seljuq Empire was never successfully held together as a unit, the Byzantines, driven from all but the coastal regions of Asia Minor, and with Nicaea in Turkish hands by 1092, faced a resurgent Islam perilously close to the capital. It was this danger that prompted the Byzantine emperor Alexius Comnenus to seek aid from the West, and by 1095 the West was ready to respond.

The turmoil of these years disrupted normal political life and made the pilgrimage to Jerusalem difficult and often impossible. Stories of dangers and molestation reached the West and remained in the popular mind even after conditions improved. Further, informed authorities began to realize that the revived power of the Muslim world now seriously menaced the West as well as East. It was this realization that stimulated official and organized action.

Alexius' appeal came at a time when relations between the Eastern and Western branches of the Christian world were improving. Difficulties between the two in the middle years of the century had resulted in a de facto, though not formally proclaimed, schism, and ecclesiastical disagreements had been accentuated by Norman occupation of formerly Byzantine areas in southern Italy. A campaign of the Norman adventurer Robert Guiscard against the Greek mainland further embittered the Byzantines, and it was only after Robert's death in 1085 that conditions for a renewal of normal relations between East and West were reasonably favourable. Envoys of Emperor Alexius Comnenus thus arrived at the Council of Piacenza in 1095 at a propitious moment; and it seems probable that Pope Urban II viewed military aid as a means toward restoring ecclesiastical unity.

The  
Council of  
Clermont

The Council of Clermont convoked by Urban on November 18, 1095, was attended largely by bishops of southern France. There was also a scattering of representatives from the north and elsewhere. After the transaction of many important items of ecclesiastical business, which resulted in a series of canons, among them one renewing the Truce of God, there was included a canon that granted a plenary indulgence (the remission of all penance for sin) to those who undertook to aid Christians in the East. Then in a great outdoor assembly the pope, himself a Frenchman, addressed a large crowd. We are not certain what language Urban spoke to these people, but apparently it was a language they could understand.

Precisely what the Pope said can never be known, since the only surviving accounts of his speech were written years later. But he apparently stressed the plight of Eastern Christians, the molestation of pilgrims, and the desecration of the holy places. He urged those of his hearers who were guilty of disturbing the peace to turn their warlike energies toward a holy cause. He emphasized the need for penance, for the acceptance of suffering. No one should undertake this pilgrimage for any but the most exalted of motives.

The response was immediate and overwhelming, probably far greater than Urban had anticipated. Cries of "Deus volt" ("God wills it") were heard everywhere, and it was decided that those who agreed to go were to wear a cross. Moreover, it was not only warrior knights who responded; a popular element, apparently unexpected and probably not desired, also came forward.

The era of Clermont witnessed the concurrence of three significant developments: first, there existed as never before a popular religious fervour that was not without marked eschatological tendencies in which the Holy City of Jerusalem figured prominently; second, war against the infidel had come to be regarded as a religious undertaking, a work pleasing to God; and finally, from an organizational standpoint, ecclesiastical as well as secular,

western Europe possessed the capacity to plan such an enterprise and carry it through.

**Preparations for the Crusade.** Following Pope Urban's speech, preparations began in both East and West. Emperor Alexius, who had doubtless anticipated some sort of auxiliary force, apparently soon realized that he would have to provide for and police a much larger influx of warriors. In the West, as the leaders began to assemble their armies, persons who took the cross sought to raise money, often by selling or mortgaging property, both for the immediate purchase of equipment and for the long-term needs of the journey.

As this was being done, several less organized and generally miscellaneous bands, including some armed men, commonly known as the "People's Crusade," set out across Europe. The most famous of these, brought together by a remarkable popular preacher, Peter the Hermit, and his associate Walter the Penniless, arrived at Constantinople after causing considerable disorder in Hungary and Bulgaria. Alexius received Peter cordially and advised him to await the arrival of the main Crusade force. But the rank and file grew unruly, and on August 6, 1096, they were ferried across the straits. As Peter returned to beg for aid, they were ambushed at Cibotus (called Civetot by the Franks) and all but annihilated by the Turks. Other, even less well-disciplined bands, largely from northwest Germany, where they committed atrocities against the Jewish communities, were dispersed before reaching the Byzantine frontier.

The  
People's  
Crusade

The main Crusading force, which began to move as Urban had directed in August 1096, consisted of four major contingents. Hugh of Vermandois, brother of King Philip I of France, left first with a small following that was reduced by shipwreck while crossing the Adriatic from Bari to Dyrrhachium. Godfrey of Bouillon, duke of Lower Lorraine since 1089, the only major prince from the German kingdom, though he and his associates largely spoke French, was joined by his brothers, Eustace and Baldwin, and a kinsman, Baldwin of Le Bourg. Taking the land route, Godfrey crossed Hungary without incident. Markets and provisions were supplied in Byzantine territory, and, except for some pillaging, the army reached Constantinople without serious incident in late December.

Second, Bohemond, a Norman from southern Italy and the son of Robert Guiscard, was thus on familiar ground when he crossed the Adriatic, where he had fought with his father and was understandably feared by the Byzantines. But he was now 40 years old and determined to come to profitable terms with his former enemy. He arrived at Constantinople on April 9, 1097.

Third, the largest army was that assembled by Raymond of Saint-Gilles, the count of Toulouse. Fifty-five years of age, he was the oldest and most prominent of the Crusading princes, and he aspired and perhaps expected to become the leader of the entire expedition. He was accompanied by Adhémar, bishop of Le Puy, whom the Pope had named as legate for the Crusade. Raymond led his followers, including a number of noncombatant pilgrims whom he supported at his own expense, across north Italy, around the head of the Adriatic, thence southward into Byzantine territory. This large body caused considerable trouble in Dalmatia and with Byzantine troops policing the area nearer the capital, where Raymond arrived on April 27.

Meanwhile, the fourth army, under Robert of Flanders, had crossed the Adriatic from Brindisi. Accompanying Robert were his cousin Robert of Normandy (brother of King William II Rufus of England) and Stephen of Blois (the son-in-law of William I the Conqueror). No king took part in the First Crusade, and the predominantly French-speaking participants came to be known as Franks.

The presence near Constantinople of massive military forces, numbering perhaps 4,000 mounted knights and 25,000 infantry, posed a serious problem for Alexius, and there was occasional disorder. Forced to consider the permanent imperial interests, which, it soon became evident, were different from the objective of the crusad-

Latin-  
Byzantine  
friction

ers, the Emperor required each Crusade leader to promise under oath to restore any conquered territory that had belonged to the empire before the Turkish invasions and to swear allegiance to him for any lands occupied beyond the former frontiers. It was a reasonable demand, and all the leaders took the oath before crossing the straits, though Godfrey and Raymond did so only after some hesitation. Raymond, in fact, agreed only to a modified form of oath common in southern France, and in the end he remained of all the Crusade leaders the most loyal to Alexius.

**The siege of Antioch.** Late in May 1097, crusaders, accompanied by a Byzantine contingent, appeared before Nicaea. On June 19, when the city fell, it was surrendered, as had been agreed, to the Byzantines. Crossing arid and mountainous Anatolia proved a difficult task. At Dorylaeum, on July 1, 1097, Turks attacked the advance column of the crusader army. Despite the heat and a rain of arrows that fell on them, the crusaders held their ground, and, when the rest of the army drew up, the Turks were routed. A major victory in open warfare had been achieved by cooperation among the separate contingents and the Greeks.

Further advance across Anatolia was even more arduous, and it was only after suffering many casualties, especially in the region of the Taurus Mountains, that the crusaders arrived near Antioch on October 20. Meanwhile, Godfrey's brother Baldwin left the main army to become involved in Armenian politics and he became ruler of Edessa.

One of the great cities of the Levant, Antioch was surrounded by a great circle of walls, and despite reinforcements and supplies by Genoese and English ships and later by the Patriarch of Jerusalem, then in Cyprus, the siege proved long and difficult. Spring brought the threat of attack by a relief force under Karbūgah of Mosul, and some of the crusaders, among them Stephen of Blois, became discouraged and left for home. In Asia Minor, Stephen met Alexius, who had set out as he had agreed to do, and convinced him that Antioch's cause was hopeless. The Emperor's decision to turn back, however justified tactically, was a diplomatic blunder; when the crusaders learned of the Emperor's move, they felt free from any obligation to return the city to him.

Bohemond meanwhile had proposed that whoever first entered the city should have possession, provided the Emperor did not make an appearance. The Norman had, in fact, already made contact with a discontented commander within, who proceeded to admit him over a section of the walls. The other crusaders followed into the city on June 3, 1098, and massacred the Muslim inhabitants. Only the citadel held out.

Thus, Antioch was occupied, and it is significant that the Greek Patriarch who had been imprisoned was restored, suggesting that neither Adhtmar nor presumably Urban II had any plan to substitute a *lati* incumbent. The victory, however, was incomplete, and Karbūgah soon blockaded the city. Disagreements among the leaders persisted and were accentuated by unseemly arguments over the validity of what had come to be called the Holy Lance, which a Provençal priest found below the cathedral and insisted was the lance that, according to the Gospels, had pierced the side of Christ when he hung on the cross. Nonetheless, on June 28 the crusader army moved out of the city and after a day of fierce fighting defeated Karbūgah's forces. The citadel then surrendered to Bohemond, and its garrison was permitted to leave. Rejoicing was tempered by a devastating epidemic that took many lives, including that of the legate, Adhémar of Le Puy, who, as the spiritual leader of the Crusade, had been a wise counsellor and a stabilizing influence whom the leaders could ill afford to lose.

As the leaders continued to confer on the final disposition of Antioch, the rank and file of the army grew impatient. In January, following the siege of Ma'arrat an-Nu'mān, some miles to the south, there was a popular demonstration in favour of moving on. The army then set out for Jerusalem under the leadership of Raymond of Saint-Gilles. As they moved south, Tancred and

Robert of Normandy and, later, Godfrey and Robert of Flanders joined them. Bohemond, fearing for the safety of Antioch, turned back soon after leaving.

**The siege of Jerusalem.** Not far from Beirut, the army entered the territory of the Fātimid caliphs of Cairo, who, as Shi'ite Muslims, were enemies of the Sunni Seljuqs and the caliphs of Baghdad. In August 1098 the Fātimids had occupied Jerusalem. The final drive of the First Crusade, therefore, was against the Fātimids of Egypt, not the Seljuqs.

On June 7, 1099, the Christian army, by then considerably reduced to perhaps 1,200–1,500 cavalry and 12,000 foot soldiers, encamped before Jerusalem, the governor of which was well supplied and confident that he could withstand a siege until a relief force arrived from Egypt. The crusaders, on the other hand, were short of supplies and would be until six vessels arrived at Jaffa (Yafo) and managed to unload before the port was blockaded by an Egyptian squadron. On July 8 a strict fast was ordered, and, with the Muslims scoffing from the walls, the entire army, preceded by the clergy, marched in solemn procession around the city, thence to the Mount of Olives, where Peter the Hermit preached with his former eloquence.

Siege towers were brought up to the walls on July 13–14, and on July 15 Godfrey's men took a sector of the walls, and others followed on scaling ladders. When the nearest gate was opened, Tancred and Raymond entered, and the Muslim governor surrendered to the latter in the Tower of David. The governor along with his bodyguard was escorted out of the city. Tancred promised protection in the Aqṣā Mosque, but his orders were disobeyed. All Muslims, men, women, and children, as well as Jews, perished in the general slaughter that followed.

Thus it was that, three long years after they had set out, the crusaders attained their goal. Doubtless some participants had been moved more by hopes of material gain or sheer love of adventure than by religious devotion. Nonetheless, it is difficult to believe that the Crusade could have succeeded without an extraordinary dedication to the ultimate objective, the liberation of the Holy City of Jerusalem.

**The establishment of the crusader states.** After a successful surprise attack on the Egyptian relief army, which confirmed the occupation of Palestine, most of the crusaders, having fulfilled their vows of pilgrimage, departed for their homes and left the problem of governing the conquered territories in the hands of the few who remained. Initially, there was disagreement as to the nature of the government to be established, and some held that the Holy City should be ruled under ecclesiastical authority. As an interim measure, Godfrey was elected to govern, and took the modest title of defender of the Holy Sepulchre. Nevertheless, Raymond, who had previously declined the offer of the crown, chose to leave immediately.

In December 1099, in the midst of this somewhat confused situation, Bohemond and Baldwin of Edessa arrived in Jerusalem to fulfill their crusader vows. Accompanying Bohemond was Daimbert, the archbishop of Pisa, who was chosen patriarch and proceeded to receive the homage of both Godfrey and Baldwin. If Daimbert had ambitions to govern Jerusalem, they were thwarted when, on Godfrey's death, his brother Baldwin was summoned back to Jerusalem, where he assumed the title of king (November 11, 1100). Thus, there had come into being not a church state but a feudal Kingdom of Jerusalem.

Though the Crusade of 1101, which Pope Paschal II had organized to bring reinforcements, collapsed in Asia Minor, King Baldwin profited from the chronic rivalries among his Muslim neighbours. He was further aided in extending the coastline by Italians and in one instance by a Norwegian squadron that arrived under King Sigurd in 1110. By 1112 Arsuf, Caesarea, Acre, Beirut, and Sidon had been taken, and the entire coast except for Ascalon and Tyre was in Latin hands. Meanwhile, castles had been built in Galilee and the frontier pushed southward.

These same years witnessed the formation of three oth-

Massacre of Jerusalem's inhabitants

The death of Adhémar of Le Puy

The  
County  
of Edessa

er crusader states to the north. The County of Edessa, an ill-defined domain extending into the upper Euphrates region with a population consisting mainly of Armenians and Syrians, had been established by Godfrey's brother Baldwin. When Baldwin left to become ruler of Jerusalem he bestowed the county, under his suzerainty, on his cousin Baldwin of Le Bourg.

Antioch had not been returned to the Emperor, and Bohemond had consolidated his position there. The city was predominantly Greek in population, though there were also Syrians and Armenians, and the latent Greek-Latin friction was intensified when Bohemond replaced the Greek Patriarch by a Latin. When Bohemond was captured by the Muslims in 1100, his nephew Tancred became regent and expanded the frontiers of the principality to include the important port of Latakia, taken from the Byzantines in 1103. Not long after his release in 1103, Bohemond travelled to Europe, where he succeeded in winning over Pope Paschal II to the idea of a new Crusade. Whatever the original intention, there resulted not an expedition against Muslims but an attack on the Byzantine city of Dyrrhachium. Like its predecessor, the ill-fated campaign of 1081, the enterprise failed, and in 1108 Bohemond was forced to take an oath of vassalage to the Emperor for Antioch and to return to Italy, where he died in 1111. Though Tancred, again in power, disregarded his uncle's oath, Antioch and its patriarchate remained a source of controversy.

A fourth crusader state was established on the coast in the vicinity of Tripoli (Arabic: *Tarābulus*) by Raymond of Saint-Gilles, who had been outmanoeuvred in Jerusalem and had returned to Constantinople hoping for aid from the Byzantine Emperor to whom he had always been loyal. But the Crusade of 1101, which he led, had been another blow to his prestige. In 1102 he returned to Syria, took Tortosa (*Tartūs*), and began the siege of Tripoli. But he died in 1105, and it remained for his descendants to finish the task. Tripoli fell in 1109.

The establishment and protection of the frontiers was, for the new states, a problem conditioned by two factors, geography and the politics of Levantine Islām. From Antioch south, the crusaders had occupied a narrow strip of coastland bounded by mountains to the north and by the Jordan Valley in the south. To the east beyond the Syrian desert lay the Muslim cities of Aleppo, Hamāh, Homs, and Damascus. Though the Franks did push southward to Aylah (or Elim, modern al-'Aqabah), all attempts to move eastward failed, and it was necessary to erect castles at vulnerable points along the eastern frontier as well as along the coast and inland. Among the most famous of these were Krak de Montréal, in the Transjordan, and Krak des Chevaliers, in the County of Tripoli. Meanwhile, the hostility between Shi'ite Egypt and Sunnite Baghdad continued for some time, while the emirates in between remained divided in their allegiance and those in the north fearful of the Seljuqs of Iconium.

After Baldwin I's death in 1118, the throne passed to his cousin Baldwin of Le Bourg, who left Edessa to another cousin, Joscelin of Courtenay. In 1124, Tyre, the last great city north of Ascalon still in Muslim hands, was taken with the aid of the Venetians, who, as was customary, demanded a section of the city. Baldwin II was succeeded by Fulk of Anjou, a newcomer recommended by Louis VI of France, who married Baldwin's daughter Melisend. In 1131 Baldwin and Joscelin both died; they were the last of the first generation of crusaders, and with their passing the formative period in the history of the crusader states came to an end.

Fulk's policies represented an end of expansion and a stabilization of gains made, a wise course, because his reign coincided with the rise of Zangi, *atabeg* (governor) of Mosul, whose achievements earned him the reputation of a great champion of the *jihād* (holy war) against the Franks. When Zangi moved against Damascus, the recognition of their common danger resulted in a Jerusalem-Damascus alliance, a kind of diplomacy by then common with the second-generation Franks.

The north, however, was in great danger. The Byzantines had recovered their influence in Anatolia and were

putting pressure on Armenia and Antioch. Emperor Manuel Comnenus forced Prince Raymond of Antioch to acknowledge the imperial suzerainty. But the greater danger to both was dramatically brought home by Zangi's capture of Edessa in 1144. Attempts at recovery failed, and the northernmost crusader state was subsequently overrun.

#### THE ERA OF THE SECOND AND THIRD CRUSADES

**The Second Crusade.** It had long been apparent that Edessa was vulnerable, but its loss came as a shock to Christians both East and West. Urgent pleas for aid soon reached Europe, and Pope Eugenius III in 1145 issued a formal crusade bull, the first of its kind, with precisely worded provisions designed to protect crusaders' families and property and reflecting contemporary advances in canon law. Legates were designated. The Crusade, energetically supported by Louis VII, was preached by St. Bernard of Clairvaux in France and, with interpreters, even in Germany. As in the First Crusade, many simple noncombatant pilgrims responded. But, since Emperor Conrad III, though at first reluctant to leave Germany, had been won over by Bernard's eloquence, the Second Crusade, unlike the First, was led by two of Europe's major rulers.

The situation in the East was also different. Manuel Comnenus was favourably disposed toward the West and, because of his interest in Antioch, was concerned over the power of Zangi, the Muslim ruler of Aleppo. He was able to assist the crusaders with guides and supplies but contributed no troops. In anticipation of the arrival of the western armies and more aware than they of the delicate power balance in the Levant, he had made peace with the Seljuqs of Iconium in 1146. Above all, Manuel was alarmed by the possibility of an attack by Roger II, the Norman king of Sicily.

Conrad left in May 1147, accompanied by many German nobles, the Kings of Poland and Bohemia, and Frederick of Swabia, his nephew and heir. On leaving Hungary and entering Byzantine territory, he agreed to an oath of noninjury. Conrad's poorly disciplined troops created tension with the Byzantines in Constantinople, where they arrived in September. Both Conrad and Manuel, however, remained on good terms, and both were apprehensive about the moves of Roger of Sicily, who during these same weeks seized Corfu and attacked the Greek mainland.

Conrad, rejecting Manuel's advice to follow the coastal route around Asia Minor, moved his main force past Nicaea directly into Anatolia. On October 25, at Dorylaeum, not far from the place where the first crusaders won their victory, his army, weary and without adequate provisions, was set upon by the Turks and virtually destroyed. Conrad, with a few survivors, retreated to Nicaea.

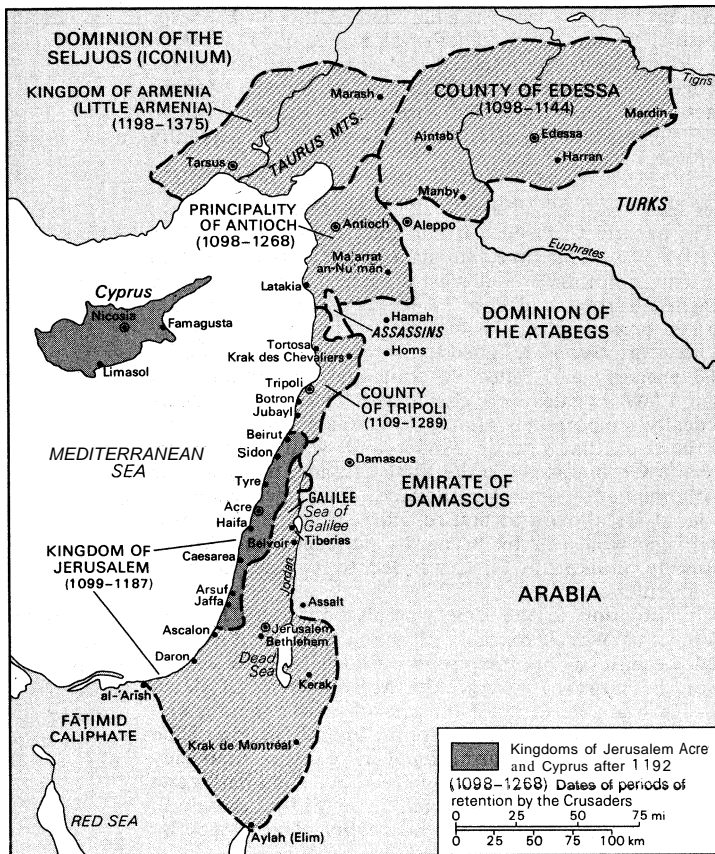

Meanwhile, about a month behind the Germans, Louis VII, accompanied by his wife Eleanor of Aquitaine, followed the land route across Europe and arrived at Constantinople on October 4. A few of his more hotheaded followers, on hearing that Manuel had made a truce with the Turks of Iconium and totally misunderstanding the motives, accused the Emperor of treason and urged the French King to join Roger in attacking the Byzantine emperor. Louis preferred the opinion of his less volatile advisers and agreed to restore any imperial possessions he might capture.

In November the French reached Nicaea, where they learned of Conrad's defeat. Louis and Conrad then started along the coastal route, the French now in the van, and reached Ephesus. Conrad became seriously ill and returned to Constantinople to the ministrations of Manuel, who prided himself on his medical knowledge. He eventually reached Acre by ship in April 1148.

The French passage from Ephesus to Antioch in mid-winter was harrowing in the extreme. Supplies ran short, and the Byzantines were blamed. But Antioch was finally reached in March 1148, and the crusaders were welcomed by Prince Raymond, Queen Eleanor's uncle. Raymond urged an attack on Aleppo, the centre of power of Nu-

reddin, son and successor of Zangi. But King Louis, who resented Eleanor's open espousal of Raymond's project, left abruptly for Jerusalem and forced the Queen to join him.

At Jerusalem, where Conrad had already arrived, a brilliant assembly of French and German notables assembled with Queen Melisend, her son Baldwin III, and the barons of Jerusalem to discuss how best to proceed. Despite the absence of the northern princes and the losses already suffered by the crusaders, it was possible to field an army of nearly 50,000 men, the largest Crusade army so far assembled. After considerable debate, which revealed the conflicting purposes of crusaders and Jerusalem barons, it was decided to attack Damascus.

How the decision was reached is not known. Damascus was undoubtedly a tempting prize, but Unur, the Turkish commander, also fearful of the expanding power of Nureddin and the one Muslim ruler most disposed to cooperate with the Franks, was now forced to seek the aid of his former enemy. And Nureddin was not slow to move toward Damascus. Not only was the campaign mistakenly conceived, it was badly executed. On July 28, after a five-day siege, with Nureddin's forces nearing the city, it became evident that the crusader army was dangerously exposed, and a retreat was ordered. It was a humiliating failure, attributable largely to the conflicting interests of the participants.

Conrad left immediately and stopped at Constantinople, where he agreed to join the Emperor against Roger of Sicily. Louis's reaction was different. His resentment against Manuel, whom he blamed for the failure, was so great that he accepted Roger's offer of ships to take him home and agreed to a plan for a new Crusade against Byzantium, a plan conceived in frustration and fortunately soon abandoned.

The Second Crusade had been promoted with great zeal and had aroused high hopes. Its collapse caused deep dismay, and subsequent expeditions, perhaps wisely, were more limited in their objectives. The Muslims, on the other hand, were enormously encouraged. They had

confronted the danger of another major Western expedition and had triumphed over it.

The crusader states to 1187. During the 25 years following the Second Crusade the Kingdom of Jerusalem was governed by two of its ablest rulers, Baldwin III and Amalric I. In 1153 King Baldwin captured Ascalon—the last major conquest of the Franks. The victory extended their coastline southward. But its possession was offset in the next year by the occupation of Damascus by Nureddin, one more stage in the encirclement of the crusader states by a single Muslim power.

In 1160–61 the possibility that the Fātimid caliphate in Egypt, shaken by palace intrigues and assassinations, might collapse and fall under the influence of Muslim Syria caused anxiety in Jerusalem. Thus, in 1164, when Nureddin sent his lieutenant Shirkhi to Egypt accompanied by his own nephew, Saladin, King Amalric decided to intervene. After some manoeuvring, both armies withdrew, as they were to do again three years later.

Meanwhile, Amalric, realizing the necessity of Byzantine cooperation, had sent Archbishop William of Tyre as envoy to Constantinople. But in 1168, before the news of the agreement that William of Tyre had arranged reached Jerusalem, the King set out for Egypt. The reasons are not clear, and there had been considerable division among the barons. At any rate, the venture failed, and Shirkhi entered Cairo. On his death (May 23, 1169), Saladin, then Nureddin's deputy, was left to overcome the remaining opposition and master Egypt.

When the Byzantine fleet and the army finally arrived in 1169, there was some delay, and both armies were forced by inadequate provisions and seasonal rains to retreat once again, each side blaming the other. In 1171, Saladin obeyed Nureddin's order to have the prayers in the mosques mention the Caliph of Baghdad instead of the Caliph of Cairo, who was then in his final illness. Thus ended the Fātimid caliphate and the great division in Levantine Islam from which the Latins had profited.

Ominous developments followed the deaths of both Amalric and Nureddin in 1174. In 1176 the Seljuqs of Iconium defeated the armies of Manuel Comnenus at Myrioccephalon. It was a shattering blow reminiscent of Manzikert a century earlier. When Manuel died in 1180, all hope of effective Byzantine–Latin cooperation vanished. Three years later Saladin occupied Aleppo, virtually completing the encirclement of the Latin states. In 1185 he agreed to a truce and left for Egypt.

In Jerusalem, Amalric was succeeded by his son Baldwin IV, a boy of 13 suffering from leprosy. Despite the young king's extraordinary fortitude, his precarious health necessitated occasional regencies and created a problem of succession until his sister Sibyl bore a son, the future Baldwin V, to William of Montferrat. Her marriage in 1180 to Guy of Lusignan, a newcomer to the East and brother of Amalric, the constable, accentuated existing rivalries among the barons. A kind of "court party" centring around the queen mother, Agnes of Courtenay, her daughter Sibyl, and Agnes' brother, Joscelin III, and now including the Lusignans was often opposed by another group composed mostly of the so-called native barons—old families, notably the Ibelins, Reginald of Sidon, and Raymond III of Tripoli, who through his wife was also lord of Tiberias. In addition to these internal problems, the kingdom was more isolated than ever. Urgent appeals to the West and the efforts of Pope Alexander III had brought little response.

Baldwin IV died in March 1185, leaving, according to previous agreement, Raymond of Tripoli as regent for the child king Baldwin V. But when Baldwin V died in 1186 the court party outmanoeuvred the other barons and, disregarding succession arrangements that had been formally drawn up, hastily crowned Sibyl. She in turn crowned her husband, Guy of Lusignan.

In the midst of near civil war, Reginald of Chhtillon, lord of Kerak and Montréal, broke the truce by attacking a caravan. Saladin replied by proclaiming *jihād* against the Latin kingdom. In 1187 Saladin left Egypt, crossed the Jordan south of the Sea of Galilee, and took up a position near the riverbank. Near Saffuriyah (mod-

The accession of Saladin

Attack on Damascus

ern Zippori) the crusaders mobilized an army of perhaps 20,000 men and including some 1,200 heavily armed cavalry, probably the equal of Saladin's. In a spot well chosen and adequately supplied with water and provisions, they awaited Saladin's first move.

On July 2 Saladin blocked the main road to Tiberias and sent a small force to attack the town, hoping, since Count Raymond's wife was there, to lure the crusaders into the open. Nevertheless, it was Raymond who at first persuaded the King not to fall into the trap. But, late that night, others, accusing the Count of treason, prevailed upon the King to change his mind. It was a fateful decision. For, after an exhausting day's march on July 3, a terrible night spent without water, surrounded and constantly harassed, and a long day of fighting near the Horns of Ḥaṭṭīn on July 4 with smoke from grass fires set by the enemy pouring into their faces, the foot soldiers broke and fled, destroying the essential coordination with the cavalry. When Saladin's final charge ended the battle, most of the knights had been slain or captured. Only Raymond of Tripoli, Reginald of Sidon, Balian of Ibelin, and a few others escaped.

The King's life was spared, but Saladin killed Reginald of Châtillon and ordered the execution of some 200 Templars and Hospitallers. Other captive knights were treated honourably, and most were later ransomed. Less fortunate were the foot soldiers, most of whom were sold into slavery. Virtually the entire military force of the Kingdom of Jerusalem had been destroyed.

Saladin quickly followed up his victory at Ḥaṭṭīn. Pausing only to take Tiberias, he moved toward the coast and seized Acre. By September 1187 he and his lieutenants had occupied most of the major strongholds in the kingdom and all of the ports south of Tripoli, except Tyre, and Jubayl and Botron (al-Batrūn) in the county of Tripoli. On October 2, Jerusalem, then defended by only a handful of men under the command of Balian of Ibelin, capitulated to Saladin, who agreed to allow the inhabitants to leave after paying a ransom. Though Saladin offered to release the poor for a specified sum, several thousand apparently were not redeemed and probably were sold into slavery. In Jerusalem, as in most of the cities captured, those who elected to remain were Syrian or Greek Christians. Somewhat later Saladin permitted a number of Jews to settle in the city.

Meanwhile, Saladin continued his conquests in the north, and by 1189 all the kingdom was in his hands except Belvoir (modern Kokhōv ha-Yarden) and Tyre. The County of Tripoli and the Principality of Antioch were each reduced to the capital city and a few outposts. The larger part of the 100-year-old Latin establishment in the Levant had been lost.

**The institutions of the First Kingdom.** The four principalities established by the crusaders—three after the loss of Edessa in 1144—were loosely connected, and such limited suzerainty as the king of Jerusalem exercised over the others became largely nominal after the midcentury. Each of the states was organized into a pattern of feudal lordships by the ruling minority. The institutions of the Kingdom of Jerusalem are best known, partly because its history figures more prominently in both Arab and Christian chronicles but especially because its documents were better preserved. In the 13th century there was compiled a collection of laws, the famous *Assises de Jérusalem*. Though this collection reflects a later situation, certain sections and many individual enactments can be traced back to the 12th century, the period known as the First Kingdom.

In the first half of the 12th century the kingdom presented the appearance of a typical feudal monarchy on the European model, with lordships owing military service and subject to fiscal exactions. There were, however, important differences, not only in the large subject population of diverse ethnic origins but also with respect to the governing minority. No great families with extensive domains emerged in the early years. Further, the typical noble's residence was not, as in Europe, the rural castle or manor house. Castles there were, but they were garrisoned by knights and, increasingly as the century ad-

vanced, by the religio-military orders. But most Jerusalem barons lived in the fortified towns. The kings, moreover, possessed a considerable domain and retained extensive judicial rights. As a consequence, the monarchy was a relatively strong institution in early Jerusalem.

Toward the middle of the century this situation began to change. Partly as a consequence of increased immigration from the west, the baronial class grew, and there was formed a relatively small group of magnates with large domains. As individuals, they were less disposed to brook royal interference, and as a class and in the court of barons (Haute Cour, or High Court) they were capable of presenting a formidable challenge to royal authority. The last of the kings of Jerusalem to exercise effective power was Amalric I in the 12th century. In the final years of the First Kingdom, baronial influence was increasingly evident and dissension among the barons, as a consequence, more serious.

Another serious obstacle to the king's jurisdiction and one not found, at least in the same form, in the West was the extensive authority of the two religio-military orders. The older of the two, the Knights of St. John of Jerusalem, or Hospitallers, was founded in the 11th century by the merchants of Amalfi to provide hospital care for pilgrims. The order never abandoned its original purpose, and, in fact, as its superb collection of documents reveals, the order's philanthropic activities expanded. But during the 12th century, in response to the military needs of the kingdom, the Hospitallers followed the example of the Templars and became, in addition, an order of knights.

The Poor Knights of Christ and of the Temple of Solomon, so called because of their headquarters in the former temple of Solomon, originated as a monastic-military organization to protect pilgrims on the way to Jerusalem. Its rule, composed by St. Bernard of Clairvaux, was officially sanctioned by the Council of Troyes (1123). Although Templars and Hospitallers took monastic vows, their principal function was soldiering.

The orders grew rapidly, and, as they acquired castles at strategic points in the kingdom and in the northern states and maintained permanent garrisons, they supplemented the otherwise not entirely adequate forces of the barons and king. Moreover, since they were soon established in Europe as well, they became international in character. Virtually independent, sanctioned and constantly supported by the papacy, and exempt from local ecclesiastical jurisdiction, they aroused the jealousy of the clergy and constituted a serious challenge to royal authority.

The crusaders introduced into the conquered lands a Latin ecclesiastical organization and hierarchy. The Greek patriarch of Antioch was, as has been mentioned, removed, and all the subsequent incumbents were Latin, except for one brief period before 1170, when imperial pressure succeeded in installing a Greek. In Jerusalem the Orthodox patriarch had left before the conquest and died soon after. All his successors were Latin.

Under the Latin jurisdiction was the entire Latin population and those natives (Greek in Antioch and Greek or native Syrian [Melkite] in Jerusalem) who had remained Orthodox. Outside was a larger number of Monophysites (Jacobite or Armenian) and some few Nestorians, all adherents of doctrines that had deviated from the decisions of 5th-century ecumenical councils. A number of Maronites of the Lebanon region accepted the Latin obedience late in the 12th century. After some initial confusion, the native hierarchies were able to resume their functions.

As in the West, the church had its own courts and possessed large properties. But each ecclesiastical domain was required to furnish soldiers, and the charitable foundations were considerable. The hierarchy of the Latin states was an integral part of the church of the West. Papal legates regularly visited the East, and bishops from the crusader states attended the Third Lateran Council in 1179. Western monastic orders also appeared in the crusader's states.

In addition to the nobles and their families who had

orders

The  
bourgeois

settled in the kingdom, a substantially larger number of persons was classified as bourgeois. A small number had arrived with the First Crusade, but most were later immigrants from Europe, representing nearly every nationality, but predominantly from rural southern France. In the East they became town dwellers, but a few were agriculturalists, proprietors of small estates, rarely themselves tillers of the soil, inhabiting the more modest towns. Some immigrants, it appears, perhaps poor pilgrims who remained, failed to obtain a reasonably settled status and could not afford the relatively small ransom offered by Saladin in 1187.

The townsmen of the First Kingdom did not, like their counterparts in Europe, aspire to political autonomy. There were no communal movements in the 12th century. The bourgeois were, therefore, subject to king or seigneur. Some did military service as sergeants; *i.e.*, mounted auxiliaries or foot soldiers. Bourgeois were recognized as a class in the more than 30 "courts of the bourgeois" according to procedures laid down in the *Assises de la cour des bourgeois*, which, unlike other parts of the *Assises*, reflects the traditions of Roman law in southern France.

The Italians, because they supplied indispensable naval aid and shipping essential to regular contact with Europe, had been able to acquire exceptional privileges in the ports. These privileges usually included a quarter that they maintained as a virtually independent enclave. Closely associated with the mother city, Venice, Genoa, Pisa, etc., its status guaranteed by treaty between the kingdom and the mother city, the Italian enclave more nearly resembled the modern overseas colony than any other establishment of the crusaders.

The European settlers in the crusader states constituted only a small minority of the population. If the early crusaders were ruthless, their successors, except for occasional outbursts during campaigns, acquired not only a remarkable tolerance but also a notable flexibility in dealing with the diverse sectors of the native population. Those Muslim town dwellers who had not fled were captured and put to menial tasks. Some, it is true, appeared in Italian slave marts, but royal and ecclesiastical ordinances at least laid down limits to what slave owners might do. Baptism brought with it immediate freedom.

Not all Muslims were slaves. Most of those who remained were peasants who for centuries had constituted a large part of the rural population and who were permitted to retain their holdings, subject to fiscal impositions not unlike those of the European serf, and usually identical with those originally levied by their former proprietors on all non-Muslims. Muslim nomads, or Bedouins, who from time immemorial had moved with their herds as changing seasons provided pasturage, continued to enjoy pasturage rights within the kingdom guaranteed by the king.

Most mosques were appropriated during the conquest, but some were restored, and no attempt was made to restrict Muslim religious observance. Occasionally a *mihrāb* (prayer niche) was retained for Muslim worshippers in a church that had formerly been a mosque. The tolerance of the Franks, noted by Arab visitors, often surprised and disturbed newcomers from the West.

Legal  
practices

The native Christians, predominantly townsmen, were governed according to the *Assises de la cour des bourgeois*. Each national group retained its customary institutions. The Syrians, for example, maintained a *cour du rais*, the *rais* (*raʾīs*) being a community chieftain and often a person of considerable importance under the Frankish regime. An important element in the kingdom's army, the corps of Turcopoles, lightly armed cavalry units, was also composed largely of native Christians, including, apparently, converts from Islām. The principle of personality of law applied to all. The Jew took oath on the Torah, the Samaritan on the Pentateuch, the Muslim on the Qurʾān, and the Christian on the Gospels.

The Jewish community of Palestine, which had already begun to diminish in the 11th century, was drastically reduced by the First Crusade. But gradually, as the Latin

kingdom settled into a routine of government, the situation improved. Indeed, there is reason to believe that the later, more stable regime made possible a not inconsiderable Jewish immigration, not, it seems, as in earlier times, from the neighbouring lands of the Middle East, but from Europe.

Thus, by the 1170s the crusader states of Outremer, as the area of Latin settlement came to be called, had developed well-established governments. With allowance made for regional differences (*e.g.*, Antioch in its early years under the Norman dynasty was somewhat more centralized), the institutions of the northern states resembled those of Jerusalem. The governing class of Franks was no longer made up of conquerors from abroad but of local residents who had learned to adjust themselves to a new environment, and were concerned with administration. A few—as, for example, Reginald of Sidon and William of Tyre, archbishop and chancellor—were fluent in Arabic. Many others knew enough of the language to deal with natives. Franks adopted native dress, ate native food, employed native physicians, and married Syrian, Armenian, or convert-Muslim women.

But the Franks of Outremer, though they sometimes acquired a love of luxury and comfort, did not lose the will or ability to confront danger; nor did they "go native." In fundamentals, they continued to adhere to the traditions of their French forebears. They were Latin Christians. Documents were drawn up in Latin. The *Assises* were in French. William of Tyre, born in the East but educated in Europe, wrote a celebrated *History of Deeds Done Beyond the Sea* in the Latin style of the 12th century.

The  
Franks'  
cultural  
identity

Artists and architects were influenced by Byzantine and Arab craftsmen, but Oriental motifs in their work are usually limited to details, such as doorway carvings. A psalter done for Queen Melisend in the 12th century, for example, shows certain Byzantine characteristics, and the artist may have lived in Constantinople, but the manuscript is in the current tradition of French art. Castles followed Byzantine models, often being built on the old foundations, but Western ideas were also incorporated. New churches were built or additions made to existing structures, as for example the Church of the Holy Sepulchre, in the Romanesque style of the homeland.

All in all, the Franks of the First Kingdom were developing a distinctive culture and achieving a real sense of identity. Until baronial dissensions weakened the monarchy in the later years—a human failing, not a deep cultural maladjustment—the Latin kingdom showed remarkable vitality and exceptional ingenuity. It was one of the more sophisticated governmental achievements of the Middle Ages.

**The Third Crusade.** The news of the fall of Jerusalem reached Europe even before the arrival there of Archbishop Josius of Tyre, whom the crusaders had sent with urgent appeals for aid. Pope Urban III soon died, shocked, it was said, by the sad news; his successor, Gregory VIII, issued a Crusade bull and called for fast and penitence.

Before a new Crusade could be organized, a modest recovery had begun in the East. Scarcely two weeks after Ḥaṭṭīn, Conrad of Montferrat, Baldwin V's uncle, had landed at Tyre with a small Italian fleet and a number of followers. He immediately established himself sufficiently to stave off an attack by Saladin, who was then intent on reaching Jerusalem without delay. When toward the end of 1188 Saladin released King Guy as he had promised, Conrad refused to submit to the King.

In a daring move to establish his authority, Guy suddenly gathered his few followers and besieged Acre. Saladin was taken completely by surprise. When he finally moved his army toward the city, the crusaders in their camp outside had begun to receive reinforcements from the West, many under the banner of Henry of Champagne. Since Saladin could neither enter the city nor dislodge the crusaders, by winter of 1190–91 neither side had made progress, but the crusaders had suffered losses from disease and famine.

Guy's  
siege  
of Acre

Among the victims of disease was Guy's wife, Sibyl, the source of his own claims to the throne. Many of the older barons who had thus far supported him now turned to Conrad. The marriage of Sibyl's sister, Isabel, to Humphrey of Toron was forthwith annulled, and she was constrained to marry Conrad. But Guy refused to abandon his claim to the throne. Such was the situation in May 1191, when ships arrived off Acre bringing welcome supplies and news of the approach of the armies of the Third Crusade.

The first ruler to respond to the papal appeal was William II of Sicily, who immediately abandoned a conflict with Byzantium and equipped a fleet that soon left for the East, though William himself died in November 1189. English, Danish, and Flemish ships also departed. Meanwhile, Gregory VIII had sent a legation to the Holy Roman emperor Frederick Barbarossa, now nearly 70 years old and approaching the end of an eventful career, which had included a protracted controversy with the papacy. But Frederick had made peace with the church, had participated in the Second Crusade, and for some time had been genuinely desirous of taking the cross again.

Frederick set out in May of 1189 with the largest Crusade army so far assembled and crossed Hungary into Byzantine territory. His troops caused disturbances in the Balkans, and there were subsequent misunderstandings with Emperor Isaac Angelus. Frederick was eventually persuaded to avoid Constantinople and cross the Dardanelles. In May 1190 he reached Iconium after defeating a Seljuq army. Thence his army crossed into Armenian territory. On June 10 Frederick, who had ridden ahead with his bodyguard, was drowned while attempting to swim a stream. His death broke the morale of the German army, and only a small remnant, under Frederick of Swabia and Leopold of Austria, finally reached Tyre. To Saladin and the Muslims, who had been seriously alarmed by Frederick's approach, Frederick's death seemed an act of God.

In Europe, Archbishop Josius had won over Philip II Augustus of France and Henry II of England. Henry died in 1189, leaving the cause to his son and successor, Richard I the Lion-Heart. But pending Anglo-French disputes were not easily settled. The extensive holdings of the English Angevin kings in France and especially Philip's desire to recover Normandy posed problems difficult if not impossible to lay aside even during a common enterprise. Thus, it was not until July 4, 1190, three years after Hattin, that the two kings met at Vbzelay, prepared to move with their armies.

The two kings who finally led the Third Crusade were very different persons. Richard was in many ways an unstable character. He had opposed his father and was distrustful of his brothers. He could be lavishly generous even to his adversaries but often violent to anyone who stood in his way. His abilities lay not in administration, for which he had no talent, but in war, at which he was a genius. The favourite son of Eleanor of Aquitaine, Richard epitomized the chivalrous crusader and represented the contemporary troubadour view of war with all its aristocratic *courtoisie*. Richard could honour his noble Muslim opponents but be utterly ruthless to low-born captives.

Philip II Augustus, with his untidy hair and defective vision, was not an attractive person. Unlike Richard, he had been king for ten years and was a skilled and unscrupulous politician. He had no love for ostentation. Though no warrior himself, he was adept at planning sieges and designing siege engines. But he was a reluctant crusader whose real interests lay in the expansion of his own domains.

According to the original suggestion of King William II, the two kings met at Messina, in Sicily, where they signed an agreement outlining their mutual obligations and rights on the crusade. Philip arrived with the French fleet at Acre on April 20, 1191, and the siege was begun again in earnest.

After a stormy passage, Richard put in at Cyprus, where his sister Joan and his fiancée, Berengaria of Navarre,

had been shipwrecked and held by the Byzantine ruler, the rebel prince, Isaac Comnenus. Isaac underestimated Richard's strength and attacked. Not only did Richard defeat and capture him, but he proceeded to conquer Cyprus. He then set sail and arrived on June 8 at Acre, where he gave new vigour to the siege.

A month later, after constant battering at the walls by siege engines and after Saladin's nephew had failed to fight his way into the city, the garrison surrendered in violation of Saladin's orders. Saladin was shocked by the news, but nevertheless he ratified the agreement, which provided for an exchange of prisoners and the restoration of the relic of the True Cross, which he had captured in 1187.

As the crusaders entered the city, there were disputes over the disposal of areas. Richard managed to offend Leopold of Austria, and Philip, who felt that he had fulfilled his crusader's vow and who was, in addition, unwell, left for home in August.

Though the English resented Philip's departure, it did leave Richard in control. When the first prisoners were returned by Saladin, Richard found some flaw in the selection of them and refused to free the Saracen captives. Subsequent negotiations failed, and Richard, impatient to move toward Jerusalem, ordered them all killed, along with their wives and children. Thus, the truce arrangements were voided, and Saladin did not return the True Cross.

Ths English king was never to reach Jerusalem. He won a victory at Arsuf in 1191, reoccupied Jaffa as a base, and took Daron in 1192 but failed to progress further. Messages from home were urging his return. He had been in constant communication with Saladin and his brother al-'Adil, and various peace proposals were made, which included marriage alliances. In fact, there seemed to be warm cordiality and considerable mutual respect. Finally, on September 2, 1192, the two opponents signed a treaty of peace to last five years. The coast from Jaffa north remained in Christian hands, but Ashkelon was to be demolished. Pilgrims were to have free access to the holy places. On October 9 Richard left. He was shipwrecked and finally fell into the hands of Leopold of Austria, who had not forgotten the slight at Acre.

The Third Crusade had failed of its major objective, the capture of Jerusalem. But the possession of Acre and much of the coast permitted the continued existence of a titular kingdom. Before he left, Richard had consented to the request that Guy, who had managed to lose the support of nearly all the barons, be deposed and Conrad immediately be accepted as king. No sooner was this done than Conrad was assassinated. Isabel was persuaded to marry Henry of Champagne, and Guy was given the governorship of Cyprus, where his record was far more successful than his ill-starred career in Jerusalem.

The most lasting achievement of the Third Crusade, however, was Richard's capture of Cyprus. In succeeding decades it gained in importance, not only as an outpost of the coastal possessions but also as a base for future crusades and finally as a kingdom in its own right.

#### THE FOURTH CRUSADE AND THE LATIN EMPIRE OF CONSTANTINOPLE

Pope Innocent III, despite manifold problems in the West, was the first pope since Urban II to be both anxious and able to consider the crusade a major papal concern. In 1198 he broached the subject of a new expedition through legates and encyclical letters. In 1199 a tax was levied on all clerical incomes — later to become a precedent for systematic papal income taxes — and Fulk of Neuilly, a popular orator, was commissioned to preach. At a tournament held by Thibaut III of Champagne, several prominent French nobles took the cross, and others joined later. Among them was Geoffrey of Villehardouin, who was to write one of the principal accounts of the Crusade. Contact was made with Venice to provide transport.

The involvement of Venice proved to be fateful. The republic had acquired considerable trading privileges

The  
Venetians'  
involve-  
ment

within the Byzantine Empire, and the growing number of Venetian merchants had long incurred the hostility of the Greeks. In 1171 Manuel Comnenus had ordered the arrest of Venetians, and 11 years later an aroused citizenry massacred a large number of Latins in Constantinople and insulted a papal legate. Further, following the advice of recently returned crusaders, the new Crusade was to be directed against Egypt, now the centre of Muslim power in the Levant but a government with which Venice was closely related commercially. Venetian policy under the aging and blind but ambitious Doge Enrico Dandolo was therefore potentially at variance with that of the Pope and the crusaders. Nevertheless, an agreement was made providing for payments to the Venetians for transportation and an equal division of conquests.

The crusader army that arrived at Venice in the summer of 1202 was somewhat smaller than had been anticipated, since some of the crusaders were travelling directly from France. Even so, there were not sufficient funds to pay the Venetians. Accordingly, the crusaders accepted the suggestion that in lieu of **payment** they assist the Venetians in the capture of the Hungarian city of Zara. This was done despite the opposition of many crusaders both to the diversion of the enterprise and to the attack on a Christian city. Innocent was informed of the plan, but his veto was disregarded. Reluctant to jeopardize the Crusade, Innocent gave conditional absolution to the crusaders—not, however, to the Venetians.

The fall of Zara (November 1202) added to the Pope's already considerable misgivings over the transformation of the whole undertaking from a Crusade under papal auspices to one under lay direction. After the death of Thibaut of Champagne, the leadership of the Crusade passed to Boniface of Montferrat, a friend of the Hohenstaufen Philip of Swabia. Both Boniface and Philip had married into the Byzantine imperial family. In fact, Philip's brother-in-law, Alexius, son of the deposed and blinded emperor Isaac Angelus, had appeared in Europe seeking aid and had made contacts with the crusaders.

Innocent was aware of a plan to divert the Crusade to Constantinople in order to gain the throne for Alexius, who, in turn, promised subsidies to the crusaders. Accordingly, Innocent ordered Boniface of Montferrat to publish immediately his original letter excommunicating the Venetians, which he had deliberately refused to do, and expressly forbade any attack on Constantinople. But the papal letter arrived after the fleets had left Zara, and in the summer of 1203 Constantinople fell, Alexius III was deposed, and "Alexius IV" was crowned as co-emperor with his father. All Innocent could do was reprimand the leaders and order them to proceed forthwith to the Holy Land. No doubt he hoped that a union of the churches would result and the Crusade be thereby promoted. A few crusaders did leave, but most did not.

Following the assassination of the new "emperor" by a resentful Greek population, the Venetians and crusaders themselves took over the city and the government of the empire. It was decided that 12 electors (six Venetians and six crusaders) should choose an emperor who would have one-quarter of the imperial domain. The other three-quarters were to be divided. The clergy of the party not belonging to the emperor elect were to have Hagia Sophia and choose a patriarch. A small amount of property was specifically designated to support the clergy. The rest was to be considered booty and divided. On April 13, 1204, the great city fell and with the permission of the leaders was subjected by the rank and file to pillage and massacre for three days. Many priceless icons, relics, and other objects later turned up in western Europe, a large number in Venice.

However much Innocent III may have hoped that a friendly Constantinople would aid the Crusade and promote the reunion of Eastern and Western churches, he was aghast at the sack of Constantinople and castigated the crusaders and Venetians in no uncertain terms. But the situation was beyond his control, especially after his legate, on his own initiative, had absolved the crusaders from their vow to proceed to the Holy Land.

When order had been restored, the crusaders and the Venetians proceeded to implement their agreement; Baldwin of Flanders was elected emperor and the Venetian Thomas Morosini chosen patriarch. But the lands parcelled out among the leaders did not include all the former Byzantine possessions. The imperial government continued in Nicaea, and an offshoot empire of Trebizond, at the eastern end of the Black Sea, lasted until 1461. There was also established a Byzantine Despotate of Epirus, and the Bulgarians remained hostile. Various Latin-French lordships throughout Greece—in particular, the duchy of Athens and the Principality of the Morea—did provide cultural contacts with western Europe and promoted the study of Greek. There was also a French impact on Greece. A collection of laws, the *Assises de Romanie*, was edited. The *Chronicle of the Morea* appeared in both French and Greek (and later Aragonese) versions. Impressive remains of crusader castles and Gothic churches can still be seen. Nevertheless, the Latin Empire always rested on shaky foundations, and in 1261 a sadly diminished domain was reconquered from the Latins by Michael Paleologus with the aid of the Genoese, the traditional rivals of Venice.

It is difficult to see in the Fourth Crusade anything but unmitigated disaster to the cause of either Christianity or the Crusade. Not only had a promising Crusade been diverted, but the new Latin principalities proved to be more attractive to Westerners who might otherwise have gone to the Levant and even to a number of former residents of the states of Syria. The rift between the Eastern and Western churches widened, and Greek popular resistance to any schemes of reunion with the empire intensified. The Byzantine Empire, for centuries a bulwark against invasion from the East, was damaged beyond repair.

## II. The decline of the crusading movement

### THE LATER CRUSADES AND THE DECLINE OF THE LATIN ENCLAVES

**The Latin East after the Third Crusade.** Saladin died on March 3, 1193, not long after the departure of the Third Crusade. One of the greatest of the Muslim leaders and a man devoutly religious and deeply committed to *jihād* against the infidel, he was, yet, respected by his opponents. His death led once again to divisions in the Muslim world, and his Ayyūbid successors were willing to continue a state of truce with the crusaders, which lasted into the early years of the 13th century. The truce was politically and economically advantageous to both sides, and the Italians were quick to make profitable trade connections in Egypt. The Franks were able to adjust themselves to a new situation and to organize what in effect was a new titular kingdom of Jerusalem centring at Acre, generally known as the Second Kingdom.

In 1194 Amalric of Lusignan succeeded his brother Guy as ruler of Cyprus, where he later accepted investiture as king from the chancellor of the emperor Henry VI. In 1197, following the death of Henry of Champagne, Amalric succeeded to the throne of Jerusalem-Acre, and in 1198 he married the thrice-widowed Isabel. He chose, however, to govern his two domains separately, and in Acre he proved to be an excellent administrator. The *Livre au roi* ("Book of the King"), an important section of the *Assises de Jérusalem*, dates from his reign. He also dealt wisely with Saladin's brother, al-'Adil of Egypt. On Amalric's death in 1205 the kingdoms of Cyprus and Jerusalem-Acre were divided, and in 1210 the latter was given to John of Brienne, a French knight nominated by Philip Augustus, who came east and married Conrad's daughter, Mary.

There were also readjustments in the two now-reduced northern states. When Raymond III of Tripoli died (1187), his county passed to a son of Bohemond III of Antioch, thus uniting the two principalities. In general, Antioch-Tripoli continued to pursue the relatively independent course laid down by Bohemond III.

Armenia was more closely involved in Latin politics, partly as a result of marriage alliances with the house of Antioch-Tripoli. King Leo II of Armenia joined the cru-

saders at Cyprus and Acre. Desirous of a royal crown, he had approached both Pope and Emperor, and in 1198, with papal approval, royal insignia were bestowed by Archbishop Conrad of Mainz, in the name of Henry VI. At the same time, the Armenian Church officially accepted a union with Rome, which, however, was never popular with the lower clergy and people.

**The Fifth Crusade.** In Europe after the Fourth Crusade something of the original crusading fervour could still be found in certain areas of society. Even children became the victims of mass hysteria, and in 1212, in the so-called Children's Crusade, thousands of youngsters from France and Germany set out to free the Holy Land, only to be lost, shipwrecked, or sold into slavery. But there was considerable disillusionment among the nobility, especially when the same religious indulgence was promised to participants in a "Crusade" against heretics in southern France and later against secular opponents of the popes. Innocent III, nevertheless, despite his preoccupation with the kings of England and France, a civil war in Germany, heresy, the advance of Islam in Spain, and his strenuous efforts to promote widespread ecclesiastical reform, renewed his efforts to organize another expedition. Preachers were designated; even troubadours contributed to the propaganda. The final canon promulgated by the Fourth Lateran Council of 1215 was an elaborate Crusade plan repeating earlier prohibitions on the transport of military supplies to Muslims. Levies on clerical incomes were again authorized.

The young emperor Frederick II had promised Innocent to go, but Honorius III permitted him repeated postponements to settle the affairs of Germany. Thus, the first contingents of the Fifth Crusade left without him. Nor did they accomplish anything significant until the arrival of a Frisian fleet with more German crusaders enabled an impressive force to set out for Egypt in May 1218 under the leadership of John of Brienne. An attack on Egypt had been in the forefront of all planning since the time of the Third Crusade, not as the objective of permanent conquest but as a bargaining point for the recovery of Jerusalem. By August the crusaders had captured a strategic tower at Damietta (Dumyāt).

In September the expedition organized under papal auspices and consisting mainly of French crusaders arrived under Cardinal Pelagius as legate. Since Pelagius regarded the crusaders as being under the jurisdiction of the church, he declined to accept the leadership of John of Brienne. Moreover, he was an imperious person who did not hesitate to interfere in military decisions.

By February 1219 the Muslims were seriously alarmed and offered peace terms that included the cession of Jerusalem. King John and many of the crusaders were eager to accept. But Pelagius, supported by the military orders and the Italians, refused. Damietta was finally taken on November 5, 1219. For over a year no progress was made, though Pelagius remained optimistic, still expecting the arrival of Frederick II and convinced, by rumour, of the imminent approach of a legendary oriental Christian "King David." In July 1221 he ordered an advance toward Cairo, but Nile floods forced him to retreat and to agree to a truce of eight years and an exchange of prisoners, terms far less favourable than those he had previously rejected.

The Fifth Crusade, the last in which the papacy took an active part, was an impressive effort against a divided Muslim opposition. Coming close to success, it failed largely because of divided leadership and the frequently unwise decisions of Pelagius. It might perhaps have succeeded if Frederick II had set out as promised, and it is significant that disillusioned critics blamed Emperor and Pope as well as Pelagius. All in all, it was a dreary episode, relieved only by the presence of Francis of Assisi, to whom Pelagius reluctantly gave permission to cross the lines, where he was courteously received by the sultan al-Kāmil. Francis' visit to the East was a preliminary step in the establishment of a Franciscan province in the Holy Land, a step soon imitated by the Dominicans.

**The Sixth Crusade.** The failure of the Fifth Crusade placed a heavy responsibility on Frederick II. His mo-

tives as a crusader are difficult to assess. Always a controversial figure, he was to some the archenemy of the papacy, to others the greatest of emperors. His intellectual interests included Islām, and his attitude might seem to be more akin to that of the Eastern barons than the typical crusader from the West. Through his marriage with John of Brienne's daughter Isabella (Yolande), he had a claim first to the kingship and then, on her death in 1228, to the regency of Jerusalem (Acre) for his son Conrad. As emperor he could claim a suzerainty over Cyprus by virtue of the cession by his predecessor Henry VI. Frederick had finally agreed to terms that virtually placed his expedition under papal jurisdiction. Yet his entire Eastern policy was inextricably connected with his European concerns: Sicily, Italy and the papacy, and Germany. Cyprus-Jerusalem became, as a consequence, part of a greater imperial design.

Most of the fleet of the Sixth Crusade had left Italy in the late summer of 1227, but Frederick was delayed by illness. During the delay he received envoys from Sultan al-Kāmil of Egypt, who, threatened by the ambitious designs of his Ayyūbid brothers, was disposed to negotiate. Meanwhile, Pope Gregory IX, less patient than his predecessor, had rejected the Emperor's plea of illness and excommunicated him. Thus, when Frederick departed in the summer of 1228 with the remainder of his forces, he was in the equivocal position of a crusader under the ban of the church. He arrived in Cyprus on July 21.

In Cyprus, John of Ibelin, the leading member of the widely influential Ibelin family, had been named regent for the young Henry I. Along with most of the other barons, he was willing to recognize the Emperor's rights as suzerain in Cyprus. But in Acre, since news of Isabel's death had arrived, the Emperor could, according to the barons' lawyers, claim only a regency for his infant son. John obeyed the Emperor's summons to meet him in Cyprus, but despite intimidation refused to surrender his lordship of Beirut and insisted that his case be brought before the High Court of barons. The matter was set aside, and Frederick left for Acre.

At Acre, Frederick met more opposition. News of his excommunication had already arrived, and many who might otherwise have supported him now refused to cooperate. Dependent, therefore, on the Teutonic Knights, an organization formed by Germans who remained in the east after an expedition in 1197 and now under the direction of Hermann of Salza, and his own small contingent of German crusaders, he was forced to attempt what he could by diplomacy. Negotiations, accordingly, were reopened with al-Kāmil of Egypt.

The resulting treaty of 1229 is unique in the history of the Crusades. By diplomacy alone and without major military confrontation, Jerusalem, Bethlehem, and a corridor running to the sea were ceded to the Kingdom of Jerusalem. Exception was made for the Temple area, the Dome of the Rock, and the Aqṣā Mosque, which the Muslims retained. The peace was to last for ten years.

The benefits of the treaty of 1229 were more apparent than real. The areas ceded were not easily defensible, and Jerusalem soon became a prey to disorder. Furthermore, the treaty was denounced by the devout of both faiths. When Frederick, still under excommunication, entered the city, the Patriarch placed it under interdict. No priest was present, and Frederick was forced to place a crown on his own head while one of the Teutonic Knights read the ceremony. Leaving agents to take over the administration, he hastily returned to Europe and at San Germano made his peace with the Pope (July 23, 1230). Thereafter, his legal position was secure, and the Pope ordered the Patriarch to lift the interdict.

What followed in Jerusalem and Cyprus, however, was not orderly government by the Emperor's agents but civil war. For Frederick's imperial concept of government was totally opposed to the now well-established pre-eminence of the Jerusalem baronage. The barons of both Jerusalem and Cyprus, in alliance with the Genoese and a commune formed at Acre that elected John of Ibelin as mayor, resisted the imperial deputies, who had the support of the Pisans, the Teutonic Knights, Bohemond of

Antioch, and a few nobles. The clergy, the other military orders, and the Venetians stood aloof.

The barons were able to win out in Cyprus, and in 1233 Henry I was recognized as king. Even after John of Ibelin, the "Old Lord of Beirut," died in 1236, the resistance continued. In 1243 a parliament at Acre refused homage to Frederick's son Conrad, unless he appeared in person, and named Alice, queen dowager of Cyprus, as regent.

Triumph  
of baronial  
rule

Thus it was that baronial rule triumphed over imperial administration in the Levant. But the victory of the barons brought to the kingdom not strength but continued division, the more serious as new forces were appearing in the Muslim world. The **Khwarezmian** Turks, pushed south and west by the Mongols, had upset the power balance and gained the support of Egypt. After the ten years' peace had expired in 1239, a poorly organized Crusade under Thibaut IV of Champagne and Richard of Cornwall accomplished little. In 1244 an alliance of Jerusalem and Damascus failed to prevent the capture and sack of Jerusalem by **Khwarezmians** with Egyptian aid. All the diplomatic gains of the preceding years were lost.

**The Crusade of Louis IX of France.** In June 1245, a year following the final loss of Jerusalem, Pope Innocent IV opened a great ecclesiastical council at Lyons. Although urgent appeals for help had come from the East, it is unlikely that the Crusade was uppermost in the Pope's mind for a combination of crises confronted the church: massive complaints of clerical abuses, increasing troubles with the emperor Frederick II in Italy, and the advance of the Mongols into eastern Europe. Nevertheless, when King Louis IX of France announced his intention to lead a new Crusade, the Pope gave it his support and authorized the customary levy on clerical incomes.

Character  
of  
Louis IX

As a crusader, the saintly Louis was the antithesis of his predecessor, Frederick. Possessed of a rare combination of religious devotion with firmness as a ruler and bravery as a warrior, he seemed the very ideal of the crusader. He was beloved by his subjects and respected abroad. He ardently believed the Crusade to be God's work, and he was far from sympathetic with the Pope's using Crusade propaganda against the Emperor.

It was three years before Louis was ready to embark. Peace had to be arranged with England, transport had to be provided by Genoa and Marseilles, and funds had to be raised from the King's domain and from the towns. When the King embarked in August 1248 he was accompanied by his queen; his brothers Robert of Artois and Charles of Anjou; many distinguished French nobles, including John of Joinville, author of the *Vie de St. Louis*; and a small contingent of English. His army was a formidable one, numbering perhaps 15,000. France was left in the experienced hands of the queen mother, Blanche of Castile.

The Crusade arrived at Cyprus in September, and it was again decided to attack Egypt. Since a winter campaign was not feasible and Louis rejected the suggestion that he attempt negotiations—though he did exchange envoys with the Mongols—it was not until May 1249 that an expedition of some 120 large and many smaller vessels got under way. Fortune favoured them at first, and Damietta was again in Christian hands by June. Shortly afterward, the army was strengthened by the arrival of Louis's third brother, Alphonse of Poitiers. Sultan **aṣ-Ṣāliḥ-Ayyūb's** death was followed by confusion in Cairo, which, after some argument, had become the crusaders' objective. In February 1250 Robert of Artois led a surprise attack on the Egyptian camp two miles (three kilometres) from **al-Manṣūrah** and, rejecting the advice of more experienced campaigners, **impetuously** moved ahead, only to be trapped within the city. Many knights lost their lives. Louis soon arrived with the main army and won another victory, albeit a costly one, near **al-Manṣūrah**. It was the last crusader success.

Meanwhile, **Tūrān-Shāh**, the Sultan's son, arrived and temporarily dominated dissident factions in Cairo. Frankish supply ships from Damietta were intercepted, and before long the crusaders were suffering from fam-

ine and disease. Louis, reluctant to abandon a work to which he had dedicated his very kingdom, perhaps delayed too long before ordering a retreat. But he refused the pleas of others to protect himself by moving out ahead. Instead, he led his soldiers and along with many of them was captured as the Muslim forces closed in.

The  
capture  
of Louis

The King and nobles were held for ransom, but many non-noble captives were killed. The Queen, who had just given birth to a son sorrowfully named John Tristan, managed with great courage to secure sufficient food and to persuade the Genoese and **Pisans** not to evacuate Damietta until it could be ceded formally by treaty and the King's ransom arranged. On May 6, 1250, the King was released and Damietta surrendered.

Despite the pleadings of his advisers, Louis did not return home immediately. He felt bound in conscience to negotiate the release of as many prisoners as possible, and he was able before he left in April 1254, four years later, to improve the defenses of the kingdom by strengthening a number of fortifications. Thus, he atoned in some small measure for the failure of the Crusade.

During these same years the southern wing of the Mongols under **Hülegü** overran Mesopotamia and in 1258 took Baghdad, thus ending the venerable **'Abbāsīd** caliphate. But two years later (1260) the **Mamlūks** of Egypt, a new dynasty that had arisen from the leaders of former slave bodyguards of the sultan, defeated the Mongols at 'Ain Jālūd in Syria and halted their southward advance. The Muslim states of Syria were caught in the middle, and the Latin states were in grave danger. King Hethum (**Hayton**) of Armenia threw in his lot with the Mongols, and his son-in-law Bohemond VI of Antioch-Tripoli followed suit. But the barons at Acre were still more disposed to deal with the Muslims, whom they knew, than with the terrifying and unknown Mongols.

In 1260, after murdering his predecessor, **Baybars** became sultan of Egypt. Though this famous Mamlūk sultan did not live to see the final fall of the Latin states, before his death in 1277 he had reduced them to a few coastal outposts. **Baybars** was ruthless and totally devoid of the generous chivalry that the crusaders had admired in **Saladin**. Most of his conquests were followed by massacre of the inhabitants, often including the native Christians, especially when they had been in league with the Mongols. In 1265 he took Caesarea, Haifa, and Arsuf. The following year he conquered Galilee and devastated **Cilician Armenia**. In 1268 Antioch was taken and all the inhabitants slaughtered. The great Hospitaller fortress of Krak des Chevaliers fell three years later.

The  
accession  
of **Baybars**  
as Mamlūk  
sultan

These disasters again brought pleas for aid from the West. King Louis, who felt a heavy responsibility for the collapse of his first effort, began to make new preparations in 1267. But the French king's second venture, the Eighth Crusade, never reached the East. For reasons that are not entirely clear but probably owed something to the influence of Louis's brother Charles of Anjou, the expedition went instead to Tunis. Charles had recently been, named by the papacy as the successor to the **Hohenstaufens** in Sicily. In 1268 he defeated Conradin, the last of the Hohenstaufen line, and was soon involved in grandiose Mediterranean projects, which ultimately included even Byzantium.

There was little support in Europe for Louis's Crusade, which embarked from southern France in July 1270. Moreover, soon after the French landed in North Africa, disease struck the troops and claimed the lives of both Louis and his son John Tristan. Charles arrived with the Sicilian fleet in time to bargain for an indemnity to evacuate the remnants of the army. Thus, the Crusade ended in tragedy and brought no help to the East. Moreover, except for the expedition of Prince Edward of England (1271–72), who had arrived in North Africa too late to be of assistance, Louis's Crusade was the last.

**The final loss of the crusader states.** Although Europe was aware of the gravity of the Eastern situation, it was both unwilling and unable to give substantial aid, as Pope Gregory X discovered following his pleas at the Council of Lyons in 1274. The sense of common endeavour that had produced the First Crusade was no

longer to be found. Not only had political tensions increased, but the reforms of the Fourth Lateran Council of 1215 had not produced the results hoped for. Criticism of ecclesiastical policies was more outspoken.

Crusading had also become more expensive. The time had passed when a Crusade army was made up of knights serving under a lord and paying their own way. Economic pressures were causing many nobles to seek royal service. Royal armies, therefore, tended to become more professional, and many knights as well as foot soldiers served for pay. King Louis's crusades had necessitated complicated financing, causing his successors serious financial trouble.

Inevitably, Outremer was affected by the general malaise of the West, and the chronic divisions that were a major cause in Outremer's downfall paralleled those of Europe. From the time of Frederick II, the kingdom had been governed by absentee rulers, in theory the Hohenstaufens represented in the East by agents, followed after 1243 by regents of the Jerusalem dynasty chosen by the High Court of barons. Finally, in 1268, on the death of the last Hohenstaufen, the crown was given to Hugh III of Cyprus. But in 1276 he returned to Cyprus, thoroughly frustrated. Then in 1277 Charles of Anjou, with papal approval, bought the rights of the nearest claimant and sent his representative. But Charles's principal interests at the time lay in Byzantium. Finally, after Charles's death in 1285, the barons once again chose a native ruler, Henry II of Cyprus.

Successive regents had failed to dominate the Jerusalem baronage, ultimately resulting in the disintegration of the entire structure of Outremer into separate parts. Antioch-Tripoli before its fall had been increasingly aloof and through intermarriage closely tied to Armenia. In Acre, the seat of government of the kingdom, there was a commune of barons and bourgeois. Immigration had ceased, and the barons were now reduced in numbers as old families had died out. Some resided in Cyprus, and others were nominal lords in Palestine of fiefsof lands actually under Muslim control. The military orders, habitually in conflict, were virtually distinct entities with extensive connections in Europe. The bourgeois population had also considerably altered in composition during the 13th century. Many criminals and other undesirables had found their way to Acre. More important, the earlier homogeneity of a French character had given way to an Italian predominance. But the Italians of Outremer were as divided as they were in Italy. The Genoese-Venetian rivalry extended to the Levant and occasionally, as in Acre in 1256, resulted in outright war.

Papal concern for Outremer was not confined to efforts to enlist military aid. Its financial support was continuous. Popes took an active interest in diplomacy and exchanged envoys with Eastern rulers, both Muslim and Mongol. Further, the 13th-century patriarchs of Jerusalem, commonly named by the pope, were also papal legates. But neither absentee king nor pope nor patriarch-legate could bring to the Latin East the unity necessary for its survival.

Thus, to the crusaders, divided among themselves and isolated, the death of Baybars in 1277 brought only temporary respite. In 1280 they again failed to join the Mongols, whom Sultan Qalā'ūn defeated in 1281. The ineffectiveness of the Jerusalem administration was becoming apparent even to Easterners, and the 11-Khan Abagha sent his deputy Rabban Sauma to the kings of Europe and the Pope to seek an alliance. The effort was fruitless. Tripoli fell in 1289, and Acre, the last crusader stronghold on the mainland, was besieged in 1291. After a desperate and heroic defense, the city was taken by the Mamlūks, and the inhabitants who survived the massacre were enslaved. Acre and all the castles along the coast were systematically destroyed.

Perhaps because they sensed their greater isolation, the Franks of the 13th century seem not to have developed further the distinctive culture of their predecessors. The remarkable palace of the Ibelins at Beirut, built early in the century, did boast Byzantine mosaics. But, no doubt partly because of King Louis's four-year stay in the king-

dom, existing remains of churches and castles indicate a close following of contemporary French Gothic, and manuscripts are more strongly French in style. Literary tastes were also distinctly French. At the coronation festivities for Henry II in 1286, in total disregard—or perhaps in chivalrous defiance—of the ruin surrounding them, the nobles amused themselves by acting out the romances of Lancelot and Tristan.

The greatest cultural achievement of the Second Kingdom was the famous collection of legal treatises the *Assises de Jérusalem*. Those parts that were compiled in the middle years of the century and, therefore, in the atmosphere of the wars against the agents of Frederick II constitute a veritable charter of baronial rights. In fact, two of the authors were members of the Ibelin family, and a third, Philip of Novara, was a close associate. These sections indicate a shift from the earlier *Livre au roi*, which more nearly reflects the attitudes of the 12th century. Nevertheless, the *Assises* belong to medieval Europe's legal renaissance.

In many respects, therefore, the Franks of the last days of Outremer were what in a modern setting might be called colonials, but they were entirely on their own, for there was no mother country to come to their rescue.

The later Crusades and the Kingdom of Cyprus. Europe was dismayed by the disaster of 1291 but not surprised and shocked as it had been in 1187, for the end had been foreseen. Pope Nicholas IV had tried to organize aid before 1291, and he and his successors continued to do so afterward, but without success. France, which had always been the main bulwark of the Crusades, was in serious conflict with England, which eventually led to the Hundred Years' War in 1337. Moreover, although it could scarcely have been understood at the time, western Europe around 1300 was experiencing the first impact of a population decline and what proved to be a prolonged economic depression.

In the East, the military orders could no longer offer a standing nucleus of troops. In 1308 the Hospitallers took Rhodes and established their headquarters there. In 1344, with some assistance, they occupied Smyrna, which they held until 1402. Meanwhile, the Teutonic Knights had moved their operations to the Baltic area. The Templars were less fortunate. In 1308 the French Templars were arrested by Philip IV, and in 1312 the order was suppressed by Pope Clement V.

It is not surprising, therefore, that such response as did follow papal urgings was largely in the form of Crusade theories. For some years after 1291 various projects were elaborated, all designed to avoid previous mistakes and explore new tactics. The Franciscan missionary Ramon Lull (died 1315), for example, in his *Liber de fine*, suggested a campaign of informed preaching as well as military force. Pierre Dubois (c. 1305–07) submitted a detailed scheme for a Crusade to be directed by Philip IV of France, and in 1321 Marino Sanudo in his *Secreta fidelium crucis* produced an elaborate plan for an economic blockade of Egypt. But none of these or any other such schemes was put into effect.

King Peter I of Cyprus finally organized an expedition that in 1365 succeeded in a temporary occupation of Alexandria. After a horrible sack and massacre, the unruly crusaders returned to Cyprus with immense booty. Peter planned to return, but no European aid was forthcoming, and after his murder in 1369 a treaty of peace was signed. No further crusades set out with Jerusalem as the objective. What followed were not really crusades in the old sense but campaigns such as the crusades of Nicopolis in 1396 and Varna in 1444, whose purpose was to defend Europe against the Ottoman Turks, a new power in the East.

With the failure of all attempts to regain a foothold on the mainland, Cyprus remained the sole crusader outpost, and after 1291 the island kingdom was faced with a serious refugee problem. It was in Cyprus that many of the institutions established by the Franks survived. For, although Jerusalem and Cyprus normally had separate governments, through intermarriage and the exigencies of diplomacy the histories of the two had become inter-

The fate of the military orders

The fall of Tripoli and Acre

woven. Regents of one were often chosen from among relatives in the other. It has been noted that many Jerusalem barons resided in Cyprus. With suitable modifications, the *Assises de Jérusalem* applied on the island. As on the mainland, the French character of the Cypriot Latins is evident in the remains of Gothic structures.

In one respect Cyprus did differ from the mainland. Whereas the First Kingdom had established a reasonable *modus vivendi* with its native population, such was not the case in the island kingdom. Many Greek landholders had fled, and those who remained apparently suffered a loss of status. All Greeks resisted the Latinizing efforts of the early-13th-century popes and their representatives. Innocent IV was more flexible, but tension persisted until the Turkish conquest in the 16th century.

#### THE RESULTS OF THE CRUSADES

The entire structure of European society changed during the 12th and 13th centuries, and there was a time when this change was attributed largely to the Crusades. Historians now, however, tend to view the Crusades as only one, albeit a significant, factor in Europe's development. It is probable, for example, that the departure of unruly elements on the First Crusade aided the King of France and the great feudatories in preserving order and extending their authority. It is also likely that the disappearance of old families and the appearance of new ones can be traced in part to the Crusades, but generalizations must be made with caution. It must, moreover, be remembered that, while some crusaders sold or mortgaged their property, usually to ecclesiastical foundations, others made it over to relatives. The loss of life was without doubt considerable; many, however, did return to their homes.

The sectors acquired by burgeoning Italian cities in the crusader states enabled them to extend their trade with the Muslim world and led to the establishment of trade depots beyond the Crusade frontiers, some of which lasted well beyond 1291. The transportation they provided was significant in the development of shipbuilding techniques. Italian banking facilities became indispensable to popes and kings. Catalans and Provençals also profited and, indirectly, so did all of Europe. Moreover, returning crusaders brought new tastes or increased the demand for spices, Oriental textiles, and the like. But such demands can also be attributed to changing lifestyles and commercial growth in Europe itself.

The papacy launched the First Crusade, and crusades remained a constant concern. While initial success undoubtedly enhanced papal prestige, later failures had the opposite effect, and the diversion of Crusade propaganda to war against heretics or the emperor aroused criticism. So also did the levies on clerical incomes, though it must be noted that papal crusade financing played an important role in Europe's economic development.

The establishment of the Franciscan and Dominican friars in the East during the 13th century made possible the promotion of missions within the Crusade area and beyond. Papal bulls granted special facilities to missionary friars, and popes sent letters to Oriental rulers soliciting permission for the friars to carry on their work. Often the friars accompanied or followed Italian merchants, and, since the Mongols were generally tolerant of religious propaganda, missions were established in Iran, Inner Asia, and even China. But, since Islamic law rigidly prohibited propaganda and punished apostasy with death, conversions from Islam were few. The Dominican William of Tripoli had some success, presumably within the crusaders' area; he and his colleague, Ricoldus of Montecroce, both wrote perceptive treatises on Islamic faith and law. Other missionaries usually failed, and many suffered martyrdom. In the 14th century the Franciscans were finally permitted to reside in Palestine as caretakers for the holy places, but not as missionaries.

The Crusades, especially the Fourth, so embittered the Greeks that any real reunion of the Eastern and Western churches was out of the question. But certain groups of Eastern Christians came to recognize the authority of the pope and were usually permitted to retain their native liturgies. Though most of the missions that grew out of

the Crusades collapsed with the advance of the Ottoman Turks in the Middle East in the mid-14th century, some of the contacts which the Western Church had made with its Eastern brethren remained.

The association of missions with Crusades posed a moral theological problem that troubled medieval thinkers. Thirteenth-century theologians held that conversion could not be forced, but most agreed that force could legitimately be used to preserve a situation in which peaceful propaganda was possible, and they continued to support the Crusade. Furthermore, such was Europe's fear of Muslim power that the Crusade idea persisted well into the 17th century, and the conviction that, in certain circumstances, war might be just became more deeply enrooted in the conscience of the West. Along with the now generally accepted use of the word crusade to denote any common endeavour in a worthy cause, this is one of the most enduring results of the movement.

Unlike Sicily and Spain, the Latin East did not, it seems, provide an avenue for the transmission of Arabic science and philosophy to the West. But the Crusades did have a marked impact on the development of Western historical literature. From the beginning there was a proliferation of chronicles, eyewitness accounts, and later more ambitious histories, in verse and prose, in the vernacular as well as in Latin.

It must be emphasized that the Crusades should not be viewed too exclusively in terms of cause and effect. If they were sometimes a factor contributing to changes in the West, so also they were affected by those changes. Rather, the Crusades and the Latin Kingdom should be considered as an integral part of the diversified culture of Europe in the Middle Ages.

**BIBLIOGRAPHY.** The standard bibliographical work on the Crusades, including sources, secondary studies, and journal articles, is H.E. MAYER, *Bibliographie zur Geschichte der Kreuzzüge* (1960). A similar study in English, somewhat briefer but well organized, is A.S. ATIYA, *The Crusade: History and Bibliography* (1962). The best full-scale treatments of the Crusades in English are S. RUNCIMAN, *A History of the Crusades*, 3 vol. (1951–54); and K.M. SETTON (ed.), *A History of the Crusades*, 2nd ed., vol. 1–2 (1969), a cooperative work by a number of historians. Additional volumes are in preparation. Briefer studies include: A.S. ATIYA, *Crusade, Commerce, and Culture* (1962), which places the Crusade movement in the context of contemporary developments, Eastern as well as Western; E. BARKER, *The Crusades* (1923); and R.A. NEWHALL, *The Crusades* (rev. ed., 1963). Two recent, significant studies are F. COGNASSO, *Storia delle crociate*, vol. 1 (1967, second volume in preparation); and H.E. MAYER, *Geschichte der Kreuzzüge* (1965).

On the institutions of the Crusader states, the most important recent work is J. PRAWER, *Histoire du Royaume latin de Jérusalem* (1969, French trans. of vol. 1 of the two-volume Hebrew work of 1963). Still indispensable are J.L. LAMONTE, *Feudal Monarchy in the Latin Kingdom of Jerusalem, 1100–1291* (1932); and J. RICHARD, *Le Royaume latin de Jérusalem* (1953). D.C. MUNRO, *The Kingdom of the Crusaders* (1935), ed. by A.C. KREY, contains the Lowell lectures given in 1924 by the dean of American Crusade historians.

J.A. BRUNDAGE (ed.), *The Crusades: Motives and Achievements* (1964), presents the points of view of different scholars. T.S.R. BOASE, *Kingdoms and Strongholds of the Crusades* (1971), is a recent study of Crusade architecture with illustrations. R.C. SMAIL, *Crusading Warfare, 1097–1193* (1956), is a study of the campaigns of the 12th century. E. SIVAN, *L'Islam et la Croisade, idéologie et propagande dans les réactions musulmanes aux Croisades* (1968), is an important analysis of the Muslim reaction to the Crusades.

Useful selections of sources in English translation are: J.A. BRUNDAGE, *The Crusades: A Documentary Survey* (1962); F. GABRIELI (comp.), *Storici arabi delle Crociate* (1963; Eng. trans., *Arab Historians of the Crusades*, 1969); R. PÉRON, *Les Croisades* (1960; Eng. trans., *The Crusades*, 1963).

## Crustacea

Crustacea is the name given to a large class of invertebrate animals of the phylum Arthropoda. They include the decapods (crabs, lobsters, shrimps, crayfish, prawns); amphipods (beach, or sand, hoppers); euphausiids (krill); isopods (pill bugs, wood lice, or sow bugs); cirripedes (barnacles); cladocerans (water fleas); anostracans (brine

shrimps, fairy shrimps); and a vast multitude of less familiar forms that are not distinguished by any popular names. Crustaceans are distinguished from the members of other arthropod classes by being generally of aquatic habit; by breathing through either gills or the general surface of the body; and by having two pairs of antenna-like appendages in front of the mouth and at least three pairs of **postoral** (*i.e.*, posterior to, or behind, the mouth) limbs, which act as jaws. There is so much diversity, both of structure and of habits, within the class that it is all but impossible to give a brief definition that would apply to all members.

#### GENERAL FEATURES

**Distribution and abundance.** The majority of crustaceans are aquatic animals, either marine or freshwater. Present in greatest diversity, often in vast numbers, in all oceans from the tropics to polar seas, they are most numerous in coastal waters and in the surface and upper layers of the open sea, where **copepods** commonly constitute 70 percent of the animal life. They decrease in number with increasing depths. No decapods live below 5,500 metres (18,000 feet), but some copepods, isopods,

and amphipods occupy deep isolated trenches at 7,000 to 10,000 metres (23,000 to 33,000 feet). Many species live in freshwater lakes, ponds, transient pools, and rivers throughout the world, some at altitudes of over 5,000 metres (16,000 feet). Large geographically isolated lakes and seas may have a rich endemic fauna. Nearly 300 species of amphipods occur in Lake Baikal in the Soviet Union, for example, and *Hyalella*, a genus of amphipods, shows the same sort of adaptive radiation in Lake Titicaca in South America, as do other species in other areas.

On tropical beaches some crabs are amphibious, emerging at ebb tide to feed; various land crabs and hermit crabs are more or less terrestrial, although their larval stages are marine. Best adapted of the terrestrial forms are the isopods; although the majority live in moist habitats, some can tolerate desert conditions.

**Size range and diversity of structure.** Crustaceans include some of the smallest and largest living arthropods. The adult water flea *Alonella* is less than 0.25 millimetre (about 0.01 inch) in length. The giant Japanese spider crab *Macrocheira*, on the other hand, sometimes exceeds 45 centimetres (18 inches) in shell width; its limbs extend 3.6 metres (12 feet) or more. The edible giant crab of Tasmania (*Pseudocarcinus*), with a shell width of 40 centimetres (16 inches), weighs as much as 13.6 kilograms (30 pounds), and the European edible crab (*Cancer pagurus*) may occasionally weigh 5.4 kilograms (12 pounds). The majority of crustaceans, however, are of small size, with an occasional large species in each order—*e.g.*, the deep-sea woodlouse, *Bathynomus giganteus*, 30 to 35 centimetres (12 to 14 inches) long; and *Pennella*, a copepod parasite of whales, 30 centimetres long.

The great diversity of crustaceans is reflected in the present classification, which includes eight subclasses and 36 orders (see below *Annotated classification*). Within many of the larger orders, marked diversity of form also occurs, depending on the different modes of life of the species. Certain parasitic copepods, cirripedes, and isopods are so extremely modified that the adults have lost most or all crustacean, and even arthropod, structure; the larvae, however, reveal the relationships.

**Importance to man.** The crustaceans of most obvious importance to man are the larger species, chiefly **decapods**. Important fisheries exist in many parts of the world for shrimps, prawns, spiny lobsters, and for the king crab (*Paralithodes*) of the north Pacific and its southern counterpart, the centolla, fished off the coast of Chile. Many species of true crabs—such as the blue crab, *Dungeness* crab, and the stone crab, all in North America, and the edible crab of Europe—are valuable sources of food. The most highly prized decapod is probably the true lobster (*Homarus* species), although overfishing early in the 20th century has greatly diminished the catches of both the North American and the European species. Freshwater crustaceans are of less economic importance. Included among them are crayfish and some river prawns and river crabs. Many species have only local market value. The mitten crab (*Eriocheir*), for example, although greatly esteemed as food in China, has been utilized primarily as animal fodder in Europe, where it was accidentally introduced and subsequently became a pest. Of the terrestrial decapods, some land crabs are eaten locally, and the robber crab, or coconut crab (*Birgus*), is valued on some Indo-Pacific islands. On other islands its use is forbidden on religious grounds. It is probable that no crustaceans are poisonous unless they have been feeding on the leaves and fruits of poisonous plants.

The large acorn shell (*Balanus psittacus*), a barnacle measuring up to 27 centimetres (11 inches) in length, is regarded as a delicacy in South America, and a stalked barnacle (*Mitella pollicipes*) is eaten in parts of France and Spain. In Japan, barnacles are allowed to settle and grow on bamboo stakes, later to be scraped off and crushed for use as fertilizer. Planktonic (*i.e.*, drifting) copepods such as *Calanus* and euphausiids, or krill, may be present in such great numbers that they discolour large areas of the open sea, thus indicating to fishermen where shoals of herring and mackerel are likely to be found. The water flea (*Daphnia magna*) and the brine

shrimp (*Artemia salina*) are used as fish food in aquariums and fish ponds, and the larvae of the latter are widely used as food during rearing in captivity of the larvae of larger crustaceans. Ostracods, of which numerous fossil and subfossil species are known, are of importance to geologists and oil prospectors.

#### Harmful and destructive crustaceans

Much damage may be done to rice paddies by burrowing crabs of various species and by the mud-eating, shrimplike *Thalassina* of Malaya. By undermining paddy embankments, they allow water to drain away, thus exposing the roots of the plants to the sun; if near the coast, salt water may thus be allowed to seep into the paddies. Tadpole shrimps (*Triops*) are often numerous in rice fields, where they stir up the fine silt in search of food, killing many of the plants. Land crabs and crayfish may damage tomato and cotton crops.

Barnacles play a dominant role in the fouling of ships' hulls. The speed of vessels with fouled hulls may be reduced by as much as 50 percent. The damage done to the submerged timbers of piers and jetties by the gribble (*Limnoria*), a small wood-boring isopod, is sometimes considerable. Even clay stone and reinforced cement may

be extensively damaged by species of the isopod genus *Sphaeroma* if certain types of rock or calcium-containing materials are used in the cement. (I.G.)

#### NATURAL HISTORY

**Reproduction and life cycle.** Sexual features. In most crustaceans the sexes are separate; in the cirripedes and in some parasitic isopods, however, hermaphroditism is the rule, and isolated instances occur in other groups, especially among decapods. Parthenogenesis (*i.e.*, development of individuals from unfertilized eggs) is common in branchiopods and ostracods and occurs in at least one genus of terrestrial isopods.

In species in which the sexes are separate, sexual dimorphism is often striking. The males often have claspings (prehensile) organs for holding the female; they may be formed by modification of almost any appendage—antennules, antennae, thoracic limbs, or even some of the mouthparts. Some of the appendages in the region of the genital openings may be modified for the purpose of transferring the sperm to the female, as, for instance, the first and second abdominal appendages in the decapods.

In the higher decapods the male is often larger than the female, but in other groups the reverse is more frequently the case. In some parasitic copepods and isopods the minute male is attached, like a parasite, to the enormously larger female.

In the Cirripedia some aberrant types of sexual relationship exist. Most cirripedes are hermaphrodites and are capable of both cross- and self-fertilization, but, in certain species, minute degenerate males exist and are attached to individuals of ordinary size. Since these dwarf males do not pair with females but with hermaphrodites, they have been called complemental males. In other species large individuals have become purely female by atrophy of the male organs and are entirely dependent on the dwarf males for fertilization.

Hermaphroditism in cirripedes

**Eggs.** Most Crustacea carry the eggs after extrusion. They are retained between the valves of the carapace in some branchiopods and ostracods or within the mantle cavity in cirripedes. Among the malacostracans the Peracarida have a brood pouch, which is formed by overlapping plates attached to the bases of some of the thoracic legs. In most decapods the eggs are carried on the abdominal appendages of the female. In a few cases (Cladocera, terrestrial Isopoda) the developing embryos are nourished by a special secretion while in the brood chambers.

The majority of crustaceans hatch from the egg in a form differing more or less from that of the adult and pass through a series of free-swimming larval stages. In many instances, however, the newly hatched young resemble the parent in general structure.

**Larvae.** In Crustacea with the most complete series of larval stages, the earliest stage is the nauplius, which has only three pairs of appendages. The nauplius usually has an oval nonsegmented body. The three pairs of limbs correspond to the antennules, antennae, and mandibles (jaws) of the adult. The antennules are simple, the other limbs each have two branches, and all three pairs are used in swimming. The antennae and mandibles have a spinelike projection at the base and seize food and push it into the mouth. The mouth is overhung by a large upper lip, or labrum. The paired eyes are not yet evident, but the unpaired eye is usually conspicuous.

A nauplius larva differing only in details from that just described is found in most of the Branchiopoda, Cephalocarida, Mystacocarida, Copepoda, Cirripedia, and, in a more modified form, in some Ostracoda. Among the Malacostraca the nauplius is found in the Euphausiacea and some of the most primitive Decapoda. Many crustaceans that hatch at a later stage exhibit evidence of a nauplius stage in the embryonic development. It seems certain, therefore, that the possession of a nauplius larva must be regarded as a very primitive character.

As development proceeds, the body of the nauplius elongates, and its posterior part becomes segmented, new somites, or segments, being added at successive molts (periodic shedding of skin) from a zone in front of the telsonic, or tail, region. The appendages, which appear as

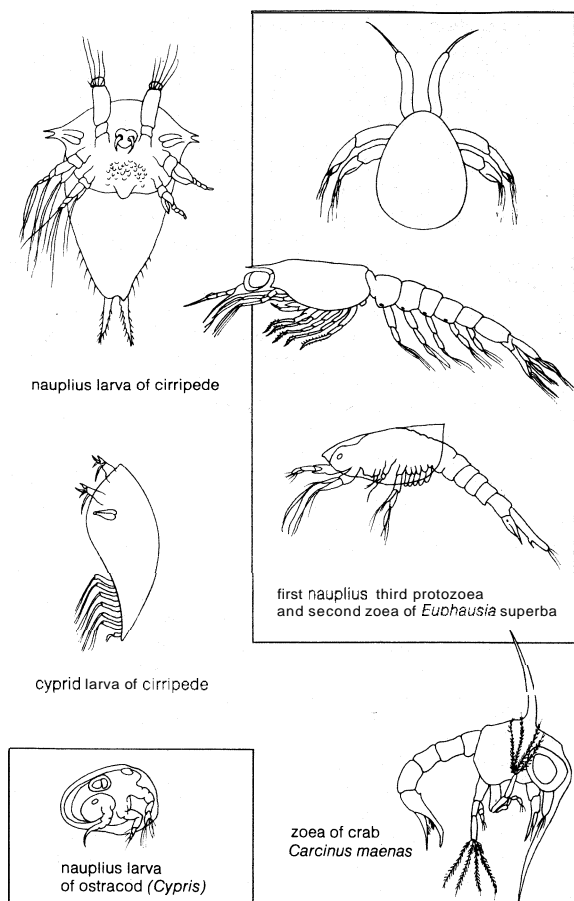

Figure 3: Crustacean larval stages.

From (*Euphausia superba*) F.C. Fraser. "On the Development and Distribution of the Young Stages of Krill (*Euphausia superba*).", *Discovery Reports* XIV (1936), Cambridge University Press; (others) W.T. Caiman. *A Treatise on Zoology* (1909), ed. Ray Lankester (copyright A. & C. Black Ltd., London; reprint Asher, Amsterdam, 1964)

buds on the ventral (belly) surface of the somites, become differentiated, like the somites that bear them, in regular order from front to rear. With the elongation of the body, its dorsal covering begins to project behind as a shell fold, the beginning of the carapace. The paired eyes appear under the cuticle at the sides of the head but become stalked at a comparatively late stage.

Because the course of development outlined above (in which the somites and appendages appear in regular order) is in good agreement with that in the *Annelida* (e.g., earthworms), it is regarded as the most primitive.

In crustaceans other than some branchiopods and copepods the primitive scheme is modified. The earlier stages, for example, may be passed within the egg; thus the larva, on hatching, has reached a stage more advanced than the nauplius. In other modifications the gradual appearance of somites and appendages may be accelerated so that comparatively great advances take place at a single molt, or individual somites or pairs of appendages may appear in advance of their neighbours, disturbing the regular order of succession. The last type of modification is especially evident in the Malacostraca, in which it leads to the very peculiar larva known as the zoea. In the usual zoea, found in the true crabs, the posterior five or six thoracic somites are delayed in development, being represented by a short unsegmented region of the body at a stage when the abdominal somites behind them are fully formed and may even carry appendages.

Most larval forms swim freely at the surface of the sea and show adaptations to this pelagic habit of life. Various spines and other projections from the surface of the body often develop; they are probably less important as defensive organs than as aids to flotation. Also considered as aids to flotation are the greatly developed carapace of stomatopod larvae and the extreme flattening of the body in the membranous larvae of the spiny lobsters and their allies.

Complete suppression of metamorphosis (transformation between larva and adult) is found in the freshwater crayfish and the river crabs but is by no means universal among freshwater Crustacea. On the other hand, a few marine crabs are known to be hatched in a form differing little from that of the adult. (W.T.Ca./W.L.Sc./Ed.)

**Ecology.** Many crustaceans play important ecological roles. Amphipods and mysids, for example, form a large part of the food of commercial fishes. Even more important are the crustaceans adapted to graze on microscopic organisms such as diatoms and dinoflagellates. The copepod *Calanus* and the krill, or euphausiid shrimps, provide food for many kinds of fishes, seabirds, and even for the great baleen whales. There is also a host of copepod fish parasites, and many copepods, water fleas, and ostracods may serve as intermediate hosts for helminth parasites of vertebrates, including man. In areas where the lung fluke (*Paragonimus*) is prevalent, freshwater crayfish, prawns, and crabs, if eaten raw or imperfectly cooked, can transmit the parasite to man. In the tropics, a freshwater copepod (*Cyclops*) is an intermediate host of the guinea worm (*Filaria* or *Dracunculus*), and man can be infected by drinking unboiled water. Crayfish prey upon the molluscan carriers of *Bilharzia*, the blood fluke parasite of man.

#### FORM AND FUNCTION

**General characteristics.** Because crustaceans are essentially aquatic animals, the same appendages can perform several functions simultaneously. In the fairy shrimps (Anostraca), for example, in which no shell fold, or carapace, exists, many similar foliaceous (i.e., flattened, leaflike) limbs function in locomotion and the gathering of food. The specialization of certain limbs for particular functions allows for adaptations such as reduction in their number or a shortening of the body. These modifications have occurred independently in most subclasses and in more than one way. The formation of a carapace, which protects and overhangs at least the anterior part of the body, facilitates the establishment of efficient respiratory currents. Although some groups (Cephalocarida, Syncarida) never possessed a carapace, others (amphipods, isopods) seem to have discarded it as incompatible with their mode of life.

**Somites and appendages.** As in all arthropods, the crustacean body consists of a series of segments, the somites or metameres, which may be free or more or less coalesced; each may bear a pair of jointed appendages. Body and limbs are encased in a continuous sheet of chitinous (tough, horny) cuticle, or integument, also known as the exoskeleton. Free somites are separated from each other by thinner areas of chitin, forming movable joints. Only in some small animals, such as *Bathynella* and harpacticoid copepods, are the somites almost circular; usually they are more or less depressed or compressed. Typical arthropod structures such as the dorsal plate, or tergum, and the ventral plate, or sternum, may or may not be distinguishable; between them are the lateral areas, or pleura.

In addition to the true somites is a purely embryonic

Figure 4: External and internal anatomy of a crustacean.

anterior presegmental part, the acron, on which are found the eyes (and perhaps the antennules). The posterior part, on which the anus opens, is not a true somite; rather, it is the posterior portion that remains after all the body somites have been budded off during embryonic development from the formative zone just in front of it; this telson, or tail, has neither nerves nor appendages; it often ends in two prongs, the caudal furca.

Formation  
of head

In no crustacean are all the body segments distinct and separate. At least four fuse with the acron to form the head, or cephalon. Of these, two segments are preoral (*i.e.*, are in front of the mouth) and carry feelers (antennules and antennae); the three segments bearing the mandibles, maxillules, and maxillae (all feeding or chewing appendages) are postoral. In species in which additional somites coalesce with the head to form a cephalothorax, the appendages (maxillipeds) usually show features of transition to those behind them. Since the shell fold, which forms the carapace, arises from the maxillary somite, only the first five are regarded as cephalic. The Mystacocarida are exceptional in that distinct traces of a more primitive cephalic segmentation are retained in both larva and adult. In adult mantis shrimps (Stomatopoda) two small movable pieces occur in front of the carapace; they bear the eyestalks and the antennules and are not present in the larva.

Throughout the subclass Malacostraca, the trunk is divided into two regions, or tagmata: a thorax of eight somites and an abdomen of six, rarely seven, somites. The female gonopores (openings that discharge eggs or sperm) are always on the sixth, the male ones on the eighth, thoracic somite. Often the sixth abdominal somite fuses with the telson to form a pleotelson; in some isopods other somites are included in the pleotelson. The trunk varies in the other subclasses from a few to more than 40 somites, or rings, and the limbs from one to as many as 71 pairs. The position of the gonopores also varies. The abdomen may be reduced to a mere stump, as in barnacles and the whale louse (*Cyamus*).

**Carapace.** The carapace, when present, varies greatly in size and shape. In primitive forms such as *Triops* (formerly *Apus*) and *Nebalia*, the shell fold remains free from the trunk, which it envelops to a large extent. It may form a bivalve shell enclosing body and limbs entirely, as in ostracods and clam shrimps (Conchostraca), or leaving the head free, as in water fleas (Cladocera). In the barnacles it is an enveloping fleshy "mantle" usually strengthened by shelly plates. In Malacostraca the carapace may fuse dorsally with some or all of the thoracic tergites, overhanging at the sides to protect the gill chambers. In this way the shell, or cephalothorax, of a lobster or crab is formed. Anteriorly, the carapace may form a beak, or rostrum.

**External features.** Appendages. Although the paired eyes of crustaceans are often borne on stalks, which may be movable and divided into two or three segments, they are not true limbs. The great diversity of forms assumed by crustacean appendages results from modifications of a fundamental type consisting of a peduncle, or stalk, the protopodite, bearing two branches, the exopodite and the endopodite. This simple form occurs in the cirri of barnacles and in the abdominal swimmerets of lobsters. The protopodite, of one, two, or rarely three segments, may have on its outer and inner margins additional lobes known as exites and endites. Thin-walled exites (epipodites) often function as simple or branched gills; the endites assist in transporting or chewing food material and are always present in the mouthparts. The cylindrical walking legs of many Malacostraca have become secondarily one-branched (uniramous) through loss of the exopodite in the adult; the series of segments belongs to both protopodite and endopodite. Leaflike thoracic limbs are found only in Leptostraca and Branchiopoda. The two-branched (biramous) limb occurs in the Leptostraca. In the fairy shrimp the protopodite and its well-developed endites and exites form most of the limb.

It has been suggested that all crustacean limbs can be derived from the generalized biramous limb of the Cephalocarida.

Specializations of the appendages. The antennules (first antennae) are uniramous in the nauplius larva and in the adults of all subclasses except the Malacostraca, in which they may have two or even three branches. Moreover, they are truly preoral in origin, being innervated from the brain or a preoral ganglion. In most cases they are sensory in function, but they may be used for swimming or, by the male, as claspers; in the cirripedes they form the organs of attachment to any solid surface.

The biramous antennae (second antennae) in the nauplius larva are situated at the sides of the mouth and may assist the mandibles in pushing food into the mouth. They become preoral in the course of development and normally retain both rami in the adult. They often serve as organs of locomotion, as claspers in the male, or as organs of attachment in parasites. In the Malacostraca the antennae are chiefly sensory; the endopodite is often a long lash, or flagellum; the exopodite either may be a flattened scale or may disappear.

The mandibles are biramous locomotor limbs in the nauplius of many crustaceans and may have masticatory, or chewing, lobes (gnathobases) on the protopodites. This form of mandible is retained in the adult mystacocarid and in some copepods and ostracods. In most cases, however, the exopodite is lost, and the endopodite, together with the distal part of the protopodite, forms a palp. The coxa, or first segment, of the protopodite with its gnathobase (endite) becomes a powerful jaw, often with distinct cutting and grinding processes. In bloodsucking parasites the mandibles are often piercing structures (stylets) enclosed in a tubular proboscis formed by fusion of the upper and lower lips.

The maxillules and the maxillae (first and second maxillae) tend to be flattened leaflike appendages. The first pair usually function in passing food to the mouth but may serve other needs; in males of the minute fossil *Lepidocaris* they formed claspers. The second pair perform various functions in connection with feeding and respiration.

The limbs behind the head region show little differentiation among themselves in the cephalocarids, most branchiopods, cirripedes, and many copepods. The ostracods, however, provide an excellent example of the plasticity and adaptability of crustacean limbs; the trunk is very short, and each of the five to seven pairs of limbs (including those of the head) may be specially adapted for specific functions in various groups. In the Malacostraca, the two series of eight thoracic and six abdominal appendages may be subdivided. The first one, two, or three pairs of thoracic appendages may be modified as additional mouthpart? (maxillipeds). The endopodites of the unmodified pairs are often walking legs; the exopodites, sometimes natatory (used for swimming) or respiratory, often are absent. One or more pairs following the maxillipeds may end in pincers, either chelae or subchelae (in which the terminal segment folds back against the next one); in raptorial (hunting) animals at least one pair may be a large and powerful weapon. The abdominal limbs are primarily biramous swimming organs. When the last pair differ from the others, they are called uropods. In shrimps and lobsters the uropods form, together with the telson, a tail fan. In amphipods the first three pairs are natatory pleopods, and the last three pairs are uropods. Some or all pleopods may be absent or reduced, unless modified in the male for sperm transfer.

**Integument.** The exoskeleton, which protects the body and provides attachment for muscles, is secreted over the whole body surface by a single layer of cells, the epidermis (hypodermis). It varies from a relatively thin, flexible, undifferentiated sac, as in parasitic copepods and cirripedes, to a rigid and massive shell, as in crabs and lobsters. The exoskeleton is composed of two parts: an epicuticle without chitin (a tough, horny material) or wax; and a chitinous cuticle. The lining of the foregut and the hindgut and the membranes separating the segments of the body and limbs undergo little modification during growth. Elsewhere, the integument is often stiffened by the deposition of calcium salts. Hardening by tanning (sclerotization) may occur at the tips of walking

Differenti-  
ation of  
limbs

The  
protopo-  
dite

legs or the pincers. In Cephalocarida and Branchiopoda, in which little or no calcification or hardening occurs, the shape of body and limbs is maintained by internal fluid pressure; muscular movements take place against this pressure.

In decapods with a thick limy shell, the structure of the integument is very complex. The laminated cuticle consists of three layers; an outer pigmented layer, a median heavily calcified layer that may also have pigment, and an inner membranous layer. The integument contains ducts of dermal glands and extensions from the epidermis that fill hollow sensory structures called setae. Other modifications of the integument include corneal lenses of the eyes and, in some Malacostraca, the lenses of luminous (light producing) organs.

An internal skeleton is usually present in the form of ingrowths of the integument, known as apodemes, which serve as points for the insertion of muscles. In decapods, especially crabs, the apodemes unite to form an elaborate framework, the endophragmal skeleton.

All integumentary structures are cast off at each molt. Only the Conchostraca and the thoracican cirripedes are able to retain and build up portions of the exoskeleton of the carapace with calcium carbonate, while frequently molting the chitinous exoskeleton of the rest of the body.

**Respiratory organs.** In many of the smaller crustaceans, such as copepods, and Lucifer among the decapods, in which no special respiratory organs occur, gas exchange takes place through the entire thin integument. The inner wall of the carapace, facing the trunk, is often highly vascular and may in many groups be the only respiratory organ. Gills, when present, are formed by modifications of parts of appendages, most often the epipodites. These thin-walled, lamellate structures are present on some or all of the thoracic appendages in cephalocarids, fairy shrimps, and many Malacostraca. In mantis shrimps (Stomatopoda), gills are found on the exopodites of the pleopods. In euphausiids the single series of branched epipodial gills are fully exposed. In decapods the gills, protected by the overhanging carapace, are arranged in three series at or near the limb bases. As an adaptation to aerial respiration, the branchial chambers are greatly enlarged in certain land crabs and serve as lungs, the inner membrane being richly supplied with blood vessels. In isopods the respiratory function has been taken over by the abdominal appendages; either both rami or the endopodite become thin and flattened. Most sow bugs and pill bugs have, in addition, trachea-like infoldings in some of the exopodites.

**Internal features.** **Alimentary system.** As a rule the gut runs straight through the body, except anteriorly where it descends to the mouth. In a few cases it is slightly sinuous, or twisted; only rarely is it actually coiled upon itself. An upper lip (labrum) covers the mouth anteriorly; at its posterior border there may be a lower lip (labium), which may have a pair of lobes (paragnaths). Both foregut and hindgut have a chitinous lining—a continuation of the exoskeleton. The midgut varies greatly in length; its functions of digestion and absorption are increased by a varying number of tubular outgrowths (ceca). Commonly there is one anterior pair of ceca, which may be more or less ramified and which forms a massive digestive gland.

The foregut is provided with the strongest muscles. Teeth and hairs may be present in animals that eat large particles. Malacostraca, especially the decapods, have a more complex "stomach," with a gastric mill for grinding the food and a filtering apparatus consisting of bristles that strain particles. The mill and the filter are often found in separate anterior and posterior chambers. In some extremely specialized parasites, which live entirely at the expense of their hosts (Rhizocephala and monstrillid copepods), the gut is either vestigial or absent.

**Circulatory system.** As in other arthropods, the circulatory system of crustaceans is largely lacunar; *i.e.*, the blood flows in sinuses, or channels, without definite walls. Cirripedes and many ostracods and copepods have no heart, the blood being kept in motion by either a blood pump or rhythmic movements of the body, gut, or ap-

pendages. When present, the heart lies in a blood sinus, or pericardium, with which it communicates by paired valvular openings, or ostia. In the more primitive crustaceans such as fairy shrimps or stomatopods, the heart is a long tube, with spiral muscles in its wall, and it extends almost the entire length of the trunk; there is a pair of ostia in each somite except the last. In more advanced crustaceans, however, shortening of the heart occurs, and the number of ostia may be reduced to three pairs or less. The position of the heart depends on that of the respiratory organs; it usually lies in the thorax or cephalothorax but is mainly in the abdomen of isopods. Malacostraca have a well-developed system of elastic-walled arteries including an anterior and usually a posterior aorta.

The red pigment hemoglobin has been observed in the blood of the Branchiopoda and in other subclasses except Malacostraca. Hemocyanin is the respiratory pigment (*i.e.*, the pigment that carries the oxygen) in decapods and stomatopods.

**Excretory system.** The principal excretory organs—two pairs of glands in the antennal and maxillary somites—open on or near the bases of the appendages. Rarely are both pairs present and functional in adults (lophogastrid mysids), although one may replace the other in the course of development. In Branchiopoda the antennal gland is functional in the larva, the maxillary one in the adult. In decapods the reverse may be true. Each gland has an end sac, representing a vestige of the coelom, and a convoluted duct, which may expand into a bladder before opening to the exterior. The antennal, or green, gland of decapods is usually very complicated, and prolongations from the bladder may ramify through the body.

The glands are not concerned particularly with nitrogen excretion or osmoregulation—*i.e.*, the balance of salts—but are instrumental in maintaining the ionic balance of the body fluids; conserving calcium, potassium, and glucose; and selectively eliminating magnesium and sulfates. Waste products such as ammonia and urea are eliminated through the gill epithelium, and other end products such as urea are stored in special cells (nephrocytes) in the gills and leg bases.

**Nervous system.** The nervous system varies from the simple ladderlike arrangement found in some annelids to great complexity. In the primitive Branchiopoda a simple "brain," or dorsal, preoral ganglionic mass, has nerve connections with the eyes and the antennules. The antennal ganglia are postoral, and the antennal nerves are situated on the connective ring around the gullet. The two halves of a ventral nerve chain are widely separated, and a pair of ganglia, united by double transverse bands, occurs in each limb-bearing somite. In higher groups the antennal ganglia are coalesced with the brain, and in many decapods additional centres develop and the brain is very complex. A system of nerves and ganglia associated with the heart and alimentary canal is well developed in decapods. Giant fibres are especially well developed in the central nervous system of shrimps and crayfish, which, by a sudden flexure of the abdomen with tail fan expanded, can travel backward rapidly. Many crustaceans exhibit this escape mechanism.

**Functional features.** **Sense organs.** The sense organs of crustaceans include visual, tactile, olfactory, and balancing organs. The eyes are of two kinds: an unpaired median, or nauplius, eye and paired compound eyes. Only the median eye is present in the earliest larva; it consists of a small group of three or four simple eyes (ocelli) innervated from the forebrain. Sometimes it persists as the only visual organ in the adult and may occasionally have conspicuous lenses as in Sapphirina and related copepods. Compound eyes, when present, appear at a later stage in development, at which time the median eye may degenerate or disappear. The compound eyes, which may be stalked or not stalked (sessile), are very similar in detailed structure to those of insects. The visual elements, or ommatidia, which vary in number from a few to 14,000, are separated by pigment sheaths. Their so-called crystalline cones are covered by a transparent cornea, which is usually divided into lenslike facets corresponding to the

Internal  
skeleton

Heart

Types of  
eyes

underlying ommatidia. Visual elements are reduced or lacking in cave-dwelling crustaceans, although the eyestalks may persist, and many small crustaceans, such as cephalocarids and mystacocarids, have no eyes.

Other sense organs are formed by modifications of the hairs (setae) that occur on the body and appendages. Rather stiff hairs respond to mechanical movement and are tactile. More complicated structures, such as the hair peg organs of decapods, sense the direction and speed of water movements over the body; still other structures detect distant disturbances in the water (*e.g.*, the approach of another animal). Special olfactory hairs, or esthetases, are found chiefly on the antennules, sometimes on the antennae, and may be better developed in the male than in the female. Other setae on mouthparts, pincers, and legs can detect food. Statocysts, found only in some Malacostraca, are for orientation with respect to gravity. These paired organs are situated at the base of the antennules in many decapods, on the inner branches of the uropods in most mysids, or on the dorsal surface of the telson in a few isopods. Each is an open or closed pit, with sensory hairs on the inner surface and with one or more statoliths, either sand grains introduced from the exterior after each molt or limy concretions formed within the pit. Various crustaceans can produce sound by rubbing together body parts (stridulation), but no definite auditory organs have as yet been detected.

**Dermal glands.** Secretions from dermal glands on various parts of the body serve a variety of purposes: to entrap food particles before they are swallowed, as in some branchiopods; to form a gelatinous capsule around the body to resist desiccation, as in some copepods; to form during oviposition, or egg laying, a protective chamber around the eggs until all are firmly glued to setae on the abdominal pleopods, as in crayfish; to cement the animal to a surface, as in cirripedes; and to cement together sand grains or algal filaments in the construction of burrows, as in some tanaids and amphipods. Cytherid ostracods are assisted in climbing over smooth surfaces by a thread, along which they can return, spider-fashion, if necessary. The silk, which is secreted by shell glands within the carapace, passes through the modified exopods of the antennae.

**Luminous organs.** Minute ostracods and copepods are responsible for phosphorescence of the sea—*i.e.*, a phenomenon in which the sea seems to give off light. Among the Malacostraca, most euphausiids and a few mysids and decapod shrimps also become luminous under excitation. The light-producing organs vary greatly in number, arrangement, and structure. In the open type, secretions that become luminous upon contact with seawater are produced by special dermal glands that are scattered over the body surface (as in copepods) or localized near the mouth (as in ostracods, the mysid *Gnathophausia*, and some decapods). Other decapods and the euphausiids have light-producing organs of the closed type, called photophores. They are either complex innervated lights—with reflector, condensing lens, and muscles for directing the beam—or simple linear streaks without a lens. In sergestid shrimps some tubules of the midgut ceca (organs of Pesta) are luminous.

The biological significance of luminescence in crustaceans is unknown, but it might serve for species recognition; to attract prey; to escape from predators under cover of the luminous cloud; to act as countershading, in which case light would have to be produced at all times (see also BIOLUMINESCENCE).

**Hormones and endocrine glands.** Hormones are blood-borne chemical agents that act on cells at a point distant from the site of formation. Two categories of tissues are involved: specialized neurosecretory cells of the central nervous system and tissues of non-nervous origin. Of the former, the most important is the X-organ–sinus-gland complex, situated in the eyestalks of many decapods. Only three non-nervous tissues are known to produce hormones: the ovaries of the female, the androgenic glands of the male, and a pair of ventral glands, the Y-organs, located in the maxillary somite in decapods. The hormones of these glands act directly on other tissues of

the body, but their activities are controlled by some of the neurohormones produced by the X-organ–sinus-gland complex. This complex also regulates maturation of the gonads, dispersal of pigments and colour change, and certain metabolic processes.

Hormonal control of maturation of the gonads and development of the secondary sexual characters has been studied only in some decapods, amphipods, and isopods. It is probable that the sex-determining genes determine only the formation or suppression of the androgenic glands. If the glands develop, the young animal becomes a male; if the androgenic glands are suppressed, the animal becomes a female.

**Molting.** A firm exoskeleton places severe restrictions on growth; hence, it must be cast off periodically. Unlike most insects, many crustaceans continue to grow long after sexual maturity is reached; the cyclical nature of crustacean molting is apparent and gives crustacean physiology its unusual and distinctive features. Studies on young and adult decapods have revealed that, far from being a brief interruption of the animal's normal existence, molting profoundly affects most or all of its life. Although molting—exuviation or ecdysis—is of very short duration, tissue growth and changes in the integument occur during 70 percent of the intermolt period; during the other 30 percent the animal stores metabolic reserves in preparation for the next molt.

The four stages of the molting cycle are: premolt (pre-ecdysis), characterized by thinning and softening of the old integument, with resorption of most of its calcium salts when present, and formation of some layers of the new exoskeleton underneath; molt (ecdysis), with rapid intake of water and shedding of skin; postmolt (metecdysis), a period of recovery when the new integument is soft but rapidly hardening; and intermolt, either di-ecdysis in species that molt throughout the year or an-ecdysis when molting is seasonal. Sometimes, as in the spider crab *Maia*, the molt of puberty is the terminal one, and an-ecdysis is permanent. Throughout most of the intermolt cycle, certain neurosecretory cells of the X-organs secrete a molt-inhibiting hormone that is stored in, and released by, the sinus glands. A fall in the concentration of this hormone stimulates the Y-organs to form and secrete their molting hormone. The hormone initiates and integrates the metabolic events leading to ecdysis; once pre-ecdysis has been initiated, the cycle must proceed. When terminal an-ecdysis is reached, either the Y-organs atrophy (*Maia*) or a high concentration of molt-inhibiting hormone must be maintained. Only in the latter case will removal of the eyestalks (*Carcinus*) result in continued molting and growth. A few crustaceans such as the lobster or the edible crab (*Cancer pagurus*) continue to molt throughout life, though at longer intervals; thus they may attain very large sizes. (I.G.)

Stages of the molting cycle

#### PALEONTOLOGY AND CLASSIFICATION

**Paleontology.** Although fossil remains of Crustacea are abundant in rock strata belonging to all the main divisions of the geological time scale from the most ancient up to the most recent, they disclose little regarding the phylogeny of the class. This results in part from the fact that many important forms must have escaped fossilization altogether because of their small size and delicate structure. Many preserved forms are known only from the carapace, or shell, the limbs being absent or represented only by fragments. The accident that preserved the minute branchiopod *Lepidocaris* in the Old Red Sandstone of northwestern Europe is not likely to have been often repeated. *Lepidocaris*, however, is of recent date as compared with the varied fauna of Crustacea discovered in the Middle Cambrian (about 535,000,000 years ago) layers of the Canadian Rockies.

There is reason to believe that many of the chief groups were already differentiated before the beginning of the geological record. Shrimplike forms that can be definitely referred to the Malacostraca begin to appear in the Upper Devonian (370,000,000 to 345,000,000 years ago). Syncarida and Hoplocarida can be recognized in the Carboniferous (345,000,000 to 280,000,000 years ago), and

true decapods appear in the Permian (280,000,000 to 225,000,000 years ago) and the Triassic (225,000,000 to 190,000,000 years ago).

In the dearth of evidence from paleontology, data afforded by comparative anatomy and embryology must be employed to reconstruct the course of evolution within the class. Conclusions reached in this way must of course remain more or less speculative so long as they cannot be checked by the results of paleontology.

Earlier attempts to reconstruct the genealogical history of the Crustacea were based on the theory of recapitulation, in this instance the assumption that the successive stages of the larval history, especially the nauplius and zoea, reproduced the actual structure of ancestral types. It is now generally agreed that this theory cannot be applied to the zoea, the characters of which must result from secondary modification. As regards the nauplius, however, the constancy of its general structure in the most diverse groups of Crustacea strongly suggests that it is a very ancient type, and the view has been strongly advocated that the Crustacea must have arisen from an unsegmented nauplius-like ancestor. Resemblances between the more primitive Crustacea and annelid worms, in such characters as the structure of the nervous system and the mode of growth of the somites, can hardly be ignored, however, and it is reasonable to suppose that the Crustacea originated from some stock that already possessed these characters.

The hypothetical ancestral crustacean has long been thought to have resembled, in general form, a branchiopod such as *Triops* (*Apus*), with an elongated body composed of numerous similar somites and ending in a caudal fork; with a carapace originating as a shell fold from the cephalic region; with eyes probably stalked; and with antennae and trunk limbs both biramous. More recently this claim has been made for the cephalocarids, of which the first described (1955) was *Hutchinsoniella*. Though similar in body form, cephalocarids are eyeless and have a much less well developed carapacial fold; in addition, the body ends in caudal rami instead of a caudal fork.

(W.T.Ca./W.L.Sc./Ed.)

**Classification.** *Distinguishing taxonomic features.* In classifying the Crustacea, taxonomists rely on a variety of characters: the form and extent of the carapace, if present; the number of trunk somites, or segments, and how many fuse with the head or with the telson; the number and degree of specialization of the trunk limbs; the presence or absence of paired eyes and of a caudal furca—*i.e.*, a forked-tail process; the position and kind of respiratory organs. The position of the genital openings, the mode of attachment of the eggs to the female, and the stage at which the first larva hatches may also be important. Parasitic and sedentary forms may differ markedly as adults from free-living species.

Annotated classification. The following classification of the Crustacea is that adopted in most modern textbooks—*e.g.*, those of T.H. Waterman (*The Physiology of Crustacea*, 1960–61) and A. Kaestner (*Invertebrate Zoology*, vol. 3, 1970). Categories represented only by fossils are inserted according to R.C. Moore (*Treatise on Invertebrate Paleontology*, 1969). Groups marked with a dagger (†) are extinct and known only from fossils.

#### CLASS CRUSTACEA

About 35,000 to 40,000 species known; mostly of aquatic habit, with 2 pairs of feelers in front of mouth; at least 3 pairs of appendages behind mouth, acting as jaws.

##### Subclass Cephalocarida

Recent; primitive blind shrimps, with head shield but no carapace; maxilla and all thoracic limbs alike; 11 abdominal somites, telson with furca; 2–4 mm; larva a nauplius; found on coasts of North America, Japan, and New Caledonia, intertidal to 300 m. Few known species.

##### Subclass Branchiopoda

Lower Devonian (395,000,000 to 375,000,000 years ago) to present; predominantly freshwater, all continents. Compound eyes usually sessile (*i.e.*, unstalked) and close together or coalesced; trunk limbs usually foliaceous (*i.e.*, leaflike); larva usually a nauplius; approximately 900 species. See BRANCHIOPODA.

**Order Anostraca** (fairy shrimp, brine shrimp). Lower De-

vonian to present. Carapace absent, eyes stalked; trunk limbs 11 to 19 pairs, all anterior to gonopores; antennae modified as claspers in male; furcal rami (branches) short. 5–100 mm.

†**Order Lipostraca.** Middle Devonian; Scotland, freshwater. One species, *Lepidocaris*, a minute blind form related to Anostraca.

**Order Notostraca** (tadpole shrimps). Carboniferous (345,000,000 to 280,000,000 years ago) to present. Carapace a broad shield above trunk; 35 to 71 trunk limbs of which 29 to 52 are posterior to the gonopores; furcal rami long and multi-articulate. 70–100 mm long. Two genera.

†**Order Kazacharthra.** Lias, Kazakh S.S.R.

†**Order Acerostraca.** Lower Devonian, Germany.

**Order Conchostraca** (clam shrimps). Lower Devonian to present. Bivalve carapace with hinge and adductor muscle, enclosing body; 10 to 32 trunk limbs, 1 to 16 postgenital; furcal rami clawlike. 6–17 mm long.

**Order Cladocera** (water fleas). Oligocene (38,000,000 to 26,000,000 years ago) to present. Carapace usually enclosing trunk, leaving head free; 4 to 6 pairs of trunk limbs; furcal rami clawlike; development direct, except in *Leptodora*.

**Subclass Ostracoda** (mussel, or seed, shrimps)

Lower Cambrian (570,000,000 to 550,000,000 years ago) to present; worldwide, marine, freshwater, and a few terrestrial species. Bivalve shell enclosing body and limbs; body short, unsegmented, never more than 2 pairs of trunk limbs; furca present or absent. Larva a nauplius with precociously formed shell; mostly 0.14–8 mm long; more than 2,000 living species.

**Order Myodocopa.** Marine. Antennal notch in shell; 2 pairs of trunk limbs; 1.8–8 mm long.

**Order Cladocopa.** Marine. No antennal notch in shell; no trunk limbs; 0.14–0.75 mm long.

**Order Podocopa.** Marine, freshwater, and terrestrial. Second trunk limb for walking or grooming; furca long and pointed or absent; 0.23–3 mm long.

**Order Platycopoda.** Marine. One pair trunk limbs; furca leaflike; 0.5–1 mm long.

†**Order Archaeocopida.** Cambrian and possibly Early Ordovician (about 450,000,000 to 500,000,000 years ago). North America and Europe.

**Order Leperditicopida.** Ordovician to Devonian. Europe and North America.

†**Order Palaeocopida.** Ordovician to Middle Permian (about 250,000,000 years ago). North America and Europe.

##### Subclass Mystacocarida

North and South America, Mediterranean, South Africa; intertidal beaches to 25 m. Blind interstitial forms; head retaining traces of segmentation; trunk of 10 somites, telson with furca; 0.5 mm long; larva a nauplius. Few species known.

##### †Subclass Euthycarcinoidea

Triassic. Freshwater, France and Australia; 5–65 mm long.

##### Subclass Copepoda

Miocene (26,000,000 to 7,000,000 years ago) to present, worldwide distribution, marine and freshwater; 10,000 species. Free-living and parasitic; without carapace or compound eyes; 1 or more trunk segments fused to head; typically 6 pairs of thoracic limbs, none on abdomen; telson with furca. Eggs carried in 1 or 2 egg strings; larva usually a nauplius.

**Order Calanoida.** Head and thorax wide, abdomen narrow, with major articulation between them; antennules long, one often modified in male. Usually pelagic. 6 mm long or less.

**Order Harpacticoida.** Usually benthic (*i.e.*, living on the bottom). Body generally elongated, articulation between thoracic somites 5 and 6, the latter joined to genital somite; short antennules, both modified in male. Less than 2 mm long.

**Order Cyclopoida.** Mostly free-living. Pear-shaped body with articulation between thoracic somites 5 and 6; antennules often modified in male; 0.6–5 mm long.

**Order Notodelphoida.** Marine, associated with ascidians (*e.g.*, sea squirts). Body cyclopoid or wormlike; sometimes with dorsal brood pouch. Female 2–12 mm long.

**Order Monstrilloida.** Adults planktonic, immature stages in polychaetes, ophiuroids, or gastropods. No mouthparts or gut.

**Order Caligoida.** Parasitic on marine and freshwater fishes. Body flattened; mouthparts suctorial. Female usually 2.6–30 mm long.

**Order Lernaepodoida.** Parasitic on fishes. Maxillae modified for attachment to host. Larva a first copepodid. Female to 32 mm long.

## Subclass Branchiura

*Order Arguloida* (fish lice). Temporary fish parasites with wide flat carapace, unsegmented abdomen, compound eyes and 4 pairs of thoracic limbs. Eggs deposited on substrate. 10–30 mm long; 120 species.

## Subclass Cirripedia (barnacles)

Upper Silurian (420,000,000 to 395,000,000 years ago) to present, worldwide, marine to brackish water. Sedentary or parasitic; head usually reduced and abdomen lost. Carapace usually an enveloping mantle; 6 pairs of trunk limbs (cirri); nauplius with a pair of lateral horns. Usually hermaphroditic; 900 species. See CIRRIPIEDIA.

*Order Ascothoracica*. Cretaceous (65,000,000 to 136,000,000 years ago) to present, marine ectoparasites or endoparasites of corals and echinoderms. Some species have long 4-segmented abdomen, telson, and furca. Sexes separate. Mantle bivalved. Females 3–12 mm long; about 30 species.

*Order Thoracica* (acorn, wart, and goose barnacles). Upper Silurian to present. Six pairs of cirri arranged evenly along thorax; permanently attached by preoral region, which may form a long stalk; mantle usually covered by permanent limy plates; stalked forms, 1–80 cm long; about 650 species.

*Order Acrothoracica*. Carboniferous to present. Small cirripedes that bore into coral, limestone, or mollusk shells. First pair of cirri near mouth, remaining pairs at posterior end of thorax; no limy plates. Sexes separate. About 30 species.

*Order Rhizocephala*. Parasitic on decapod crustaceans chiefly. No gut or alimentary canal at any time. Larva typical cirripede nauplius. About 200 species.

## Subclass Malacostraca

Lower Cambrian to present. Typically with compound eyes, stalked or sessile; a carapace covering the cephalothorax; 8 thoracic and 6 abdominal somites, each with paired appendages; about 19,000 species.

*Superorder Phyllocarida*

Lower Cambrian to present.

†*Order Hymenosthracina*. Cambrian to Ordovician.

†*Order Archaeostraca*. Ordovician to Triassic. To 75 cm in length.

*Order Leptostraca*. Upper Permian to present, marine. Small shrimplike forms with bivalve carapace, movable rostrum; a 7th abdominal somite without appendages; and furcal rami; 6–40 mm; about 10 species.

†*Superorder Eocarida*

Mid-Devonian to Permian; 2 orders.

*Superorder Syncarida*

Carboniferous to present. Primitive, without a carapace; eyes stalked, sessile (without a stalk), or absent; 5 or more pairs of thoracic limbs; more than 70 species.

†*Order Palaeocaridacea*. Carboniferous to Permian.

*Order Anaspidacea*. Triassic to present, freshwater, Tasmania and Australia. Eyes stalked or sessile; furca absent; first 2 pairs of pleopods, or swimmerets, of male copulatory, seminal receptacle in female; 8–50 mm long.

*Order Bathynellacea*. Freshwater, all continents except North America. Minute, blind, wormlike forms with 6th abdominal somite fused to telson, with furca; pleopods reduced or absent; 0.55–5.4 mm long. More than 60 species.

*Order Stygocaridacea*. Permian to present, freshwater, South America and New Zealand. Minute, blind, wormlike; head fused with first thoracic somite; 1.6–4.2 mm long.

*Superorder Hoplocarida*

Carboniferous to present.

*Order Stomatopoda* (mantis shrimps). Jurassic to present, marine, warmer coastal waters. Short, shallow carapace; abdomen well developed, 1.2–35 cm long. About 250 species.

†*Order Palaeostomatopoda*. Carboniferous. Subchelate limbs equal; telson with median spine and furca. *Perimecturus*.

†*Order Aeschronectidae*. Upper Carboniferous.

*Superorder Peracarida*

Permian to present. Carapace, when present, rarely fuses with more than 4 thoracic somites; a lacinia mobilis on mandible of adult; typically oostegites in female. Development direct. About 10,300 species.

*Order Thermosbaenacea*. Recent. Minute interstitial or subterranean forms, Tunisia, Italy, Dalmatia, Dead Sea, Texas. Carapace forms a temporary dorsal brood pouch; 4 mm long. About 6 species.

*Order Mysidacea* (opossum shrimps). Triassic to present; worldwide; marine, brackish, and freshwater. Shrimplike, with

large carapace, stalked eyes, antennal scale, natatory thoracic exopodites. 3–30 mm long, rarely to 180 mm long. More than 625 species.

*Order Cumacea*. Permian to present, mainly marine, all oceans, littoral to great depths. Easily recognized by the inflated head and thorax, long slender abdomen and uropods. 1.1–35 mm. About 770 species.

*Order Spelaeogriphacea*. Present. A small, blind shrimp from stream in Bats Cave, Table Mountain, South Africa. Carapace short, telson free, uropods long. To 7.5 mm long; 1 species, *Spelaeogriphus*.

*Order Tanaidacea*. Permian to present, mainly marine, coastal to 8,200 m. Carapace short, fused to first 2 thoracic somites, abdomen short; 2nd thoracic limb chelate; 2–25 mm long. More than 300 species.

*Order Zsopoda* (pill bugs, sow bugs). Triassic to present, worldwide, marine (free or parasitic), freshwater and terrestrial. Body usually flattened dorsoventrally; carapace absent; eyes sessile; thoracic limbs 2 to 8 cylindrical legs; abdomen short, 1 or more somites fused with telson; pleopods specialized for respiration. Usually 0.7 to 35 mm long. More than 4,000 species.

*Order Amphipoda* (beach hoppers, scuds, well shrimps). Upper Eocene to present. Worldwide, marine, freshwater and semiterrestrial. Typical members recognized by laterally compressed body; lack of carapace; sessile eyes; long thoracic limbs, some with platelike gills; 1–50 mm, rarely to 140 mm; about 4,600 species.

*Superorder Eucarida*

Carapace large, fused dorsally to all thoracic tergites; eyes stalked; development rarely direct.

*Order Euphausiacea* (krill). Marine, all oceans, pelagic. Shrimplike, carapace shallow, leaving the single row of branched gills exposed. Eggs usually shed freely, 1st larva a nauplius; 6–81 mm long. About 90 species.

*Order Decapoda* (Shrimps, lobsters, crabs). Permian or Triassic to present. Cosmopolitan, mainly marine, some freshwater and semiterrestrial. Carapace deep, enclosing the gill chambers. Abdomen varies from long and extended to short and tucked under cephalothorax. Includes the largest living arthropods; about 8,500 species. See DECAPODA.

*Critical appraisal.* The relationships of the various subclasses to each other are still largely conjectural. The close affinities of the Ascothoracica to the cirripedes as a whole are generally recognized, and there seems no valid reason for separating them as a subclass Ascothoracida. They retain the bivalve shell of the cyprid larva, and the positions of male and female gonopores are identical with those of Cirripedia. Some ascothoracicans have a thorax of six, and an abdomen of four, segments plus a telson and furca. This body plan they share with the Copepoda, and from it can be derived the other Cirripedia, the Mystacocarida, and the Branchiura. The term Maxillopoda has recently been proposed for these four subclasses; and perhaps the Ostracoda diverged from this line. The four recent orders of Ostracoda listed above may be regarded as suborders, arranged in the orders Myodocopida and Podocopida.

Opinions differ markedly with regard to the recent orders of the subclass Branchiopoda. Sometimes the Anostraca are separated from the other three, which are placed in the superorder Phyllopoda, a term that is sometimes used for the three non-cladoceran orders. Or again, the Conchostraca and Cladocera may be regarded as suborders of the order Diplostroaca. The superorder Pancarida has been proposed for the order Thermosbaenacea, but some specialists regard them as aberrant Peracarida.

## Cryogenics, Applications of

Cryogenics deals with the production of low temperatures and the utilization of low-temperature phenomena. The name is derived from the Greek *kryo*, meaning "icy cold" or "frost."

The cryogenic temperature range, in the sense of the term most often used, has been arbitrarily defined as extending from an approximate upper limit of  $-150^{\circ}\text{C}$  ( $-238^{\circ}\text{F}$ ) down to absolute zero ( $-273^{\circ}\text{C}$ ,  $0^{\circ}\text{Kelvin}$ ).

Cryogenic engineering deals with the many processes and devices utilizing these low temperatures. Examples of these include electrically superconductive devices and procedures for handling and processing of the fluids that have normal boiling points in this region.

Cryogenic temperatures customarily are listed on the absolute scale, in degrees Kelvin ( $^{\circ}\text{K}$ ). On this scale the absolute zero of temperature is at  $0^{\circ}\text{K}$ , corresponding to  $-460^{\circ}\text{F}$ , or  $-273^{\circ}\text{C}$ . Conversion from the Kelvin scale ( $^{\circ}\text{K}$ ) to the Celsius scale ( $^{\circ}\text{C}$ ) is accomplished by subtracting 273 from the Kelvin value.

The related study of low-temperature physics commonly involves physical research conducted at temperatures below the boiling point of oxygen; *i.e.*, below about  $90^{\circ}\text{K}$ .

Cryogenic temperatures are considerably below those encountered in common refrigeration processes. At these temperatures such physical and chemical properties of materials as strength, ductility, electrical resistance, and thermal conductivity are greatly altered from ambient conditions generally regarded as about  $300^{\circ}\text{K}$ . In finding applications for these changed properties, cryogenic engineering has become both a special discipline and a fast-growing industry.

Although cryogenic engineers have played major roles in the life-support and propulsion systems of missile and space programs, the utilization of cryogenics in the 1970s extends far beyond aerospace technology.

### HISTORY

Cryogenics is generally considered to have been born in 1877 with the announcement that oxygen had been liquefied in small quantities at a boiling point of  $-183^{\circ}\text{C}$ .

Other milestones in the development of cryogenics include the invention of the vacuum-jacketed glass flask in 1888, the liquefaction and separation of air into its components in 1895, the liquefaction of helium in 1908, and the discovery of superconductivity in 1911. In the 1920s and 1930s techniques were developed that led to the attainment of a temperature very close to absolute zero.

Although Goddard successfully used liquid oxygen to power rocket flight in 1926, it was Germany's use of liquid oxygen to propel V-2 rockets during World War II that awakened the world to the vast possibilities of cryogenics for space programs.

By 1947 the first commercially produced system for liquefying helium, at  $4.2^{\circ}\text{K}$ , was developed, and by 1960 cryogenic engineering had progressed to the point at which a temperature of  $\frac{1}{4} 000 000^{\circ}\text{K}$  was achieved.

Cryogenic engineering has broadened considerably, extending also to medicine and food preservation and many other fields during the past 10 years.

### THE PROPERTIES, PRODUCTION, AND STORAGE OF CRYOGENS

Liquid oxygen reacts violently under certain conditions with aluminum, titanium, and steel. Liquid fluorine is

even more reactive than oxygen. Liquid nitrogen and liquid helium are clear, nonflammable fluids; helium is inert and nitrogen relatively inert; liquid hydrogen is colorless, has about  $\frac{1}{14}$  the density of water, and can be violently reactive. The helium isotope helium-4 is most unusual; it is a normal fluid down to  $2.17^{\circ}\text{K}$ , the lambda point, but below that temperature it becomes the superfluid helium II, with properties exhibited by no other fluid.

At cryogenic temperatures the magnetic, thermal, and electric properties of most substances also are greatly altered. Some metals become perfect conductors of electricity; that is, they become superconducting. The behaviour at cryogenic temperatures of stainless steels, aluminum, copper, and nickel generally includes increases in tensile strength, yield strength, fatigue strength, and hardness, while impact strength decreases. These and other still-unexplored changes in materials promise many further applications of cryogenics in the fields of chemistry, physics, space technology, and medicine.

### PRODUCTION AND STORAGE OF CRYOGENIC FLUIDS

Gases used in cryogenic engineering are cooled to their boiling—or liquefying—points by three basic methods: liquid expansion, Joule-Thomson expansion, and expansion in an engine (see REFRIGERATION EQUIPMENT). Cooling below  $1^{\circ}\text{K}$  is generally required only for basic research on the properties of matter; a particle accelerator at Stanford University, California, uses refrigerators working at  $1.8^{\circ}\text{K}$ . Such systems are very large and have extremely high power requirements.

After production cryogenic liquids generally are stored in specially designed tanks using superinsulation or in Dewar vessels; *i.e.*, flasks with double walls of silvered glass or highly polished metal having an evacuated space between them, very similar except for size to the common thermos bottle. Liquid air, oxygen, nitrogen, and even hydrogen can be kept for several hours in such vessels without further thermal protection; liquid helium has such a low heat of vaporization that it can be kept for any length of time only if the Dewar vessel is in turn surrounded by a similar, larger flask containing liquid nitrogen or liquid air. It can be stored for long periods in superinsulated vessels.

Liquefying natural gas reduces its volume more than 600 times, offering obvious advantages in transportation and storage. Liquid natural gas (LNG) is chiefly methane and boils normally at about  $-260^{\circ}\text{F}$ . Pipelines for liquid natural gas have been proposed in North America, running from the far northern production fields south to the markets in the U.S. and Canada where the fuel is needed. Well-insulated pipelines, with recooling and pumping stations at intervals of perhaps 80.5 kilometres (50 miles), would be required.

In the early 1970s a small but increasing number of automobiles in the U.S. were running on liquid natural gas, which is stored in specially designed vehicle fuel tanks. The liquid is vaporized in a coil of copper tubing before it enters the carburetor of an automobile engine; ignition timing must be adjusted, but the conversion of autos to liquid natural gas is rather simple, unlike the major redesign necessary for jet aircraft power plants. Storage of liquid natural gas in service stations posed early problems. An advantage of natural gas is that its burning causes far less air pollution than does the combustion of gasoline.

By 1970 liquid natural gas was being moved not only by truck, tank car, and pipeline, but by ship from Alaska to Japan, and from North America and Africa to Europe. The first such oceangoing vessel, the "Methane Pioneer," made its initial voyage in 1959. Plans were also being developed for the large-scale transportation of liquid natural gas from South America to the U.S. and to Europe and Asia.

Storage tanks of up to 25,000,000 gallons were made part of the liquid natural gas energy-source network. The very large-scale production and subsequent large-scale storage, shipment, and utilization of this substance is un-

Cryogenic fluids

Dewar vessels

questionably the biggest facet of cryogenics' growth today. Tomorrow we may have a parallel growth in liquid hydrogen.

#### CRYOGENIC APPLICATIONS

**Food preservation and shipment.** Since 1955 liquid nitrogen has to some extent replaced conventional mechanical refrigerators for preserving food during shipment. The liquid nitrogen refrigeration system is simple and without moving parts. The storage tank is filled with liquid nitrogen, which when released from the spray headers, vaporizes immediately, refrigerating the truck's interior. Freezing temperatures are readily maintained, and temperatures as low as that of the liquid nitrogen are possible. Inert nitrogen gas in the storage compartments prevents oxidation loss and rodent activity. Another advantage of the system is that constant humidity is maintained so that wilting from dehydration is thus prevented. Even such perishables as lettuce and strawberries are delivered in good condition, at full weight, and with no change in appearance. Ships equipped with liquid nitrogen systems have carried produce across the Pacific with no losses. Precooling of the compartment to be refrigerated is not necessary. Other advantages of liquid nitrogen systems are simplicity of design, installation, and operation, with very accurate temperature control assured.

Quick-freezing tunnels for preparing frozen foods possess advantages that parallel those of the liquid nitrogen refrigerated vehicles (see Figure 1).

Figure 1: Tunnel freezer.

**Cryomedicine.** This discipline covers two distinct yet closely related categories: cryobiology, which is the study of the effect of low temperatures on biological materials, and cryosurgery, performed with a freezing probe instead of a cutting edge. Although the techniques employed in cryosurgery are quite modern, cold has been used in surgery for almost 100 years.

Freezing an aqueous solution, such as the content of a living cell, is a dehydration process. As water is converted to ice, the solutes present become more concentrated, until precipitation occurs. In a cell or tissue the dissolved colloids are subjected to increasing concentrations of electrolytes such as salt. Base-acid changes may occur, with the concentration of components contributing to the concentration of the hydrogen ion. The normal spatial arrangements of subcellular components may be disrupted by the volume change during expansion. All these and other phenomena introduce irreversible changes that can destroy the viability of a cell.

Selective  
tissue  
destruction

Even though very low temperature can destroy life, when selective tissue destruction is the end sought, as in surgery, cryogenics becomes a useful tool in well-being and in the prolongation of life.

Openchowski of Russia in 1883 developed an instrument utilizing evaporation of ether by warm air to produce cold for studies on the cerebral cortex of dogs. He applied his cold probe for periods of one to three minutes, freezing the area till solid. He noted that his treatment prevented hemorrhage and widespread tissue damage, which have become typical observations of cryogenic surgical treatment.

Cryogenic surgery, using a probe similar to that shown in Figure 2, has been performed in more than 5,000 cases of Parkinson's disease since April 1961. Relief

from trembling can almost be assured. Ninety-three percent of the operations resulted in abolition of tremor and rigidity without any untoward side effects. The mortality rate was only one percent. These results are even more impressive when we consider the fact that some of the patients were of advanced age.

Many applications of cryogenics in ophthalmology date from the early 1930s when work was thus done to correct retinal separation. Cryoextraction of cataracts is accomplished by establishing an ice bond between the probe and the lens. Corneal buttons are being preserved cryogenically for grafting.

In otolaryngology, tonsillar tissue was the first to be cryogenically treated because of the ease of application. Cryotonsillectomy is now commonplace. The treatment, which is now relatively simple, can be done in a doctor's office, and the patient's pain and discomfort are greatly reduced as compared with conventional operational procedures.

Figure 2: Principles of typical cryosurgery equipment.

Prostate malignancies have been treated cryogenically since 1964. The bladder is emptied, examined, and inflated with air, and the cryoprobe inserted into the urethra. The major advantages, as compared to conventional therapy, are the absence of hemorrhage and the need for less anesthesia. The disadvantage is the retention of dead tissue that can, in some cases, cause obstruction and infection.

**Space applications.** The principal space applications of cryogenic technology are in propulsion systems, fuel cells, life-support systems, system refrigerators, and space-simulation chambers.

**Rocket propellants.** Some cryogenic rocket propellants, such as liquid oxygen and liquid hydrogen used in combination, have a higher specific impulse (*i.e.*, provide thrust more efficiently) than do the solid propellants available in 1970. A nuclear-powered rocket that uses hydrogen as the working fluid would achieve a still higher specific impulse; the hydrogen would be carried in its liquid form because a smaller and lighter fuel tank is possible. Consequently, some current and proposed propulsion systems are, and will be, cryogenic. In some future systems the propellant tankage must also be reusable, and very large quantities of propellants will be required.

Designs for cryogenic storage on the ground, as in the case of liquid natural gas service stations, present no insoluble problems, but long-term storage in space will depend on better insulation and the ability to expel and transfer the fluid. Solutions for important problem areas, such as protection from meteoroids, leakage control, and

reliability in the weightless space environment, are necessary before long-term storage in space can be considered feasible.

For large-volume requirements in space, weight savings in tanks would accrue from storing cryogenics at less than critical pressure, and by utilizing insulation offering the lowest thermal conductivity-density factor. The construction materials must have high strength-to-weight ratios. Heat leaking into the cryogen must be minimized by control of any leakage along supports and piping, by evacuation of the system to prevent gas conduction losses, and by selecting the optimum radiation shielding to minimize radiation effects. Due to the degree of non-uniformity of superinsulation materials and installations, however, experimental measurements of a tank design are necessary to confirm predictions of thermal performance.

A small hydrogen vessel designed as part of a fuel cell is shown in Figure 3. The inner vessel can be titanium

Figure 3: Elements of a liquid hydrogen vessel.

for hydrogen storage but not for oxygen. The outer shell can be aluminum.

**Life-support systems.** Cryogenics in life-support systems are used to supply oxygen for high-altitude aircraft and for space cabin atmospheres. Liquid nitrogen and liquid helium are used as a source of pressurizing gas or to supply a two-gas atmosphere. Liquid hydrogen may be used in a process for recovering oxygen from expired carbon dioxide.

**Space refrigeration techniques.** Early in the space programs it became desirable to increase the sensitivity, reliability, and accuracy of some communication, mapping, and navigational devices by cooling certain sensors and optical components. Spaceborne refrigerators having one to two watt capacity at 77° K or lower were therefore necessary.

Significant accomplishments in adapting miniaturization techniques to the standard cycles, however, have been few. These systems must have high reliability, operate for very long periods of time, and must not introduce mechanical or electrical disturbances. Power requirements must be low. The Vuilleumier refrigerator, based on a 1918 U.S. patent, may meet these requirements. Although this type of thermal compression device was ignored for many years, in 1970 it was being used in aircraft and proposed for space. Basically, it employs two sets of low-speed piston displacers, a heat source, regenerators that connect the cylinders, and a drive mechanism. In most cases the electric motor is driven at less than 600 revolutions per minute to reduce wear.

Because of the critical power and reliability requirements of mechanical systems, solid cryogenics are especially attractive for short-term cooling and with small cooling loads. An example is the use of solid hydrogen. The reasonable life of a solid hydrogen icebox is from three to 12 months with a cooling load of less than one watt at 10° K.

**Cryogenic vacuum systems.** For several industrial and research purposes, including space simulation, cryogenic pumping is used to attain hard vacuums beyond the reach of mechanical pumps. Atmospheric gases will

condense on a surface if the temperature is low enough, much as moisture condenses on a cold windowpane. In one system an adsorbent, such as silica gel, is bonded to the surface of a cryopanel. The pumping speeds of cryogenically cooled adsorbents at very low pressures are sensitive to the amount adsorbed, but independent of the depth of the adsorbing material. The capacity of the material to adsorb increases rapidly with decreasing temperatures. By cooling the adsorbent to 77° K, all gases except hydrogen, helium, and neon can be efficiently trapped.

By cooling from 11° to 20° K, hydrogen can be trapped; and at the liquid helium temperature of 4.2° K gaseous helium can be adsorbed. Further studies of these cooling processes are needed to optimize cryosorption and cryopanel configurations.

Ultrahigh vacuums are used to study effects on materials, whereas chambers operating at high vacuums are used to test components and systems.

**Superconductive devices.** Kamerlingh Onnes, the Dutch physicist who investigated the dependence upon temperature of the electrical resistance of metals in 1911, observed that the resistance of mercury fell suddenly to zero when the metal was cooled to within a few degrees of absolute zero. Onnes coined the term superconductivity for this phenomenon. The temperature below which a material becomes superconductive has come to be designated the transition temperature, or critical temperature ( $T_c$ ).

Since the transition temperatures of all known superconductors are in the cryogenic range, cryogenic engineering is required for applications of the phenomenon. In 1970 the chief application was the construction of superconductive electromagnets, primarily for research in physics, as in magneto-hydrodynamic power generation experiments and bubble chamber systems. Superconductive power transmission was being studied and appeared promising for the future, although the costs for refrigeration of long cables would be high. Other potential applications are in bearings, motors, and transformers. Superconductive magnets can be used with infrared detectors, lasers, and masers. The use of superconductive magnets in medical research has also proved successful.

The bolometer, an instrument for measuring radiation, particularly in the infrared region, is more sensitive at low temperatures and most sensitive when it can be made superconductive. The first cryogenic bolometers used tantalum and required liquid helium for cooling. Later work on niobium nitride, which becomes superconducting at 14.3° K, appears to have produced a more practical device capable of operating on liquid hydrogen.

**Future applications.** There are at least four principal areas in which major advancements can be foreseen as the first century of cryogenics draws to a close: sources of energy, superconductivity, medicine, and pollution control.

It appears that worldwide petroleum production may peak shortly after the year 2000, with reserves decreasing in the United States in the 1980s. Hydrogen, which can be made available in almost limitless quantities by the electrolysis of water, offers an alternative chemical fuel, a major energy source for land, airborne, and space transportation systems. The necessary electrical energy for large-scale electrolysis can be supplied from nuclear power plants. The use of liquid natural gas in vehicles now seems to foreshadow such development.

Superconductive cables appear likely to play a role in electric power transmission and distribution systems, particularly if suitable materials can be obtained with transition temperatures higher than those currently available. In the early 1970s it was believed that hyperconductive cables of high purity aluminum cooled with liquid hydrogen could be utilized with existing technology dependent upon two factors: enough liquid hydrogen must be available and the costs of replacing existing power networks must not be excessive.

The magnetically suspended train—not quite a flying carpet, but nevertheless a unique form of high-speed

ground transportation—is a possible result of the future development of high-current and high-field superconductors. The train could be propelled magnetically by track currents.

Cryogenics technology also is being expanded in medicine; e.g., in cancer therapy. Leucocytes, grown outside the human body and stored in liquid nitrogen, may someday prove an effective treatment. Cryogenic biological archives may be established for certain organs and tissues. Kidneys, endocrine glands, corneal tissue, and even hearts will perhaps be successfully frozen with viability retained. With all these successes, however, the prolonged viable preservation of whole animals, especially man, is now considered impossible, due to the complex and varied nature of the body. Cryogenic storage of spermatozoa, already used in cattle breeding, will be greatly increased for domestic animals, and has been applied to man.

Pollution  
control

The "no smog" characteristics of cryogenic fuels offer hope that the environment can be made more livable. Through cryogenic applications pollution of air and water can be drastically reduced, and landscapes beautified with the installation of cryogenically cooled underground power cables.

Cryogenics will have ever greater effect on man's life as developments from today's research become essential commodities.

**BIBLIOGRAPHY.** R.W. VANCE (ed.) and H. WEINSTOCK (co-editor of vol. 1), *Applications of Cryogenic Technology*, 2 vol. (1969–70), a thorough review of the applications of cryogenics emphasizing LNG and including an analysis of the thermodynamics of refrigeration; R.W. VANCE (ed.), *Cryogenic Technology* (1963), a summary of the theory and applications of cryogenics, including comprehensive reviews of cryobiology and superconductivity, and co-edited with W.M. DUKE, *Applied Cryogenic Engineering* (1962), a review of the early applications of cryogenics to the U.S. missile and space programs; R.B. SCOTT, *Cryogenic Engineering* (1959), the first text on cryogenic engineering, analyzing liquefaction technology and serving as an introduction to cryogenics; K.D. TIMMERHAUS (ed.), *Advances in Cryogenic Engineering* (annual), experimental data for all disciplines covered by cryogenics; *Proceedings of the First International Cryogenic Engineering Conference, Kyoto, Japan* (1967), a useful summary of applications as provided by engineers and scientists on a worldwide basis; theories and applications of superconductivity were emphasized along with possible future developments.

(R.W.V.)

## Cryptology

Cryptology (from the Greek *kryptos*, "hidden," and *logos*, "word"), the science dealing with disguised or secret communications, is concerned with the methods and devices employed to camouflage communications (or even their existence), and to penetrate such communications contrived by others. Cryptology today plays a major role in the governmental and military affairs of nations and a lesser role in banking, industry, and commerce. Cryptology has also played a part in the deciphering of lost languages, and even in attempts to establish authorship of works, such as Shakespeare's plays. Although cryptology was concerned initially with secrecy of written messages, its principles apply not only to enciphered or encoded messages (cryptograms) but also to enciphered speech, enciphered facsimile, and enciphered television transmissions.

Cryptology embraces the twin or complementary sciences of signal security and signal intelligence. Signal security is concerned with all the methods of protecting one's own signals against interception and reading or utilization by unauthorized persons (generally called "the enemy"). Signal intelligence comprises all the methods employed in acquiring information or intelligence by intercepting and solving the enemy's cryptosignals or nullifying his signal security so the signals or information derived from them can be used against him.

### SIGNAL SECURITY

There are three important aspects to signal security. Physical and personnel security assures that physical ar-

rangements, facilities and procedures for safeguarding cryptomaterials (codes, ciphers, key lists, cipher machines) are adequate and that the personnel using codes and ciphers are trustworthy. Transmission security embraces the means, methods, and procedures for assuring that no information useful to the enemy is inadvertently disclosed either by indiscretions of operators or by equipment malfunctions. Cryptosecurity deals with the technical adequacy of the cryptography or cryptosystems employed.

**Cryptography.** Cryptography (from the Greek *kryptos*, "hidden," and *graphein*, "to write") deals with the methods involved in preparing cryptograms—messages or writings intended to be incomprehensible to all except those who legitimately possess the means to reproduce the original plaintext. Conversion of a plaintext message into a cryptogram is called encrypting (or, more specifically, enciphering or encoding); reconverting the cryptogram back into its intelligible form, when done by a legitimate or authorized communicator, is called decrypting (specifically, deciphering or decoding). Although in theory no sharp line of demarcation can be drawn between code systems and cipher systems, in modern practice the technical differences between them are sufficiently marked to warrant their being treated separately. Cipher systems will be discussed first, then code systems; only a very limited number suitable for serious usage can here be outlined.

**Cipher systems.** Generally speaking, cipher systems involve a cryptographic treatment of textual units of fixed length, usually one, two, or three letters. These textual units are treated as symbols without reference to their identities as component parts of words, phrases, and sentences. Every practical cipher system must combine two elements: a set of rules, processes, or steps constituting the basic cryptographic method of treatment or procedure, called the general system, agreed upon in advance by the communicators and constant in character; and a specific key that is variable in character. The specific key may consist of a number or a series of numbers, a word, a phrase, or a sentence.

General  
system,  
specific  
key

In encipherment, the key controls the steps under the general system and determines the specific nature or exact composition of the cipher message produced; in decipherment, the key similarly controls the steps and determines what the deciphered text will be. When all of these operations are performed correctly, the two plaintexts (before and after the cryptography) should be identical or nearly so. The general system should be so constructed that, even if it is known to the enemy, no properly enciphered message can be read by him unless he also knows the specific key or keys applicable to that message.

Despite great diversity in the external appearance and internal constitution of ciphers, there are only two basic classes of systems. These two classes are called transposition and substitution. A transposition cipher involves a rearrangement or change in the sequence of the letters of the plaintext message without any change in their identity; while a substitution cipher involves a replacement of the plaintext letters by other letters (or other symbols) without any change in their sequence. Transposition and substitution may be combined in a single cryptosystem.

**Transposition ciphers.** Almost all transposition ciphers involve the use of a geometrical figure or design in which the elements of the plaintext (usually single letters) are first inscribed according to a previously agreed-upon direction or method and then transcribed by another (and different) agreed-upon method. In nearly all cases the specific key controls (1) the use of designs of a specific nature and dimensions, and (2) variation in the manner of inscription or transcription or both.

One of the simplest forms of transposition ciphers is a route cipher. In the example given, the message plaintext, PACKAGE SENT TO YOU BY COURIER STOP ACKNOWLEDGE, is inscribed by an alternate horizontal route on cross-section paper into a rectangle of eight columns, and the letters are transcribed, as indicated, in

Route  
cipher

P	A	C	K	A	G	E	S
U	O	Y	O	T	T	N	E
B	Y	C	O	U	R	I	E
K	C	A	P	O	T	S	R
N	O	W	L	E	D	G	E

an alternate diagonal route starting at the upper left-hand corner. The final ciphertext, grouped in five-letter groups as a letter-check and for convenience in transmission, then reads: PAUBO CKYYK NCCOA GTOAO WPUTE SNROL ETIEE SDGRE. In decipherment the cipher letters are inscribed in an alternate diagonal route following that originally used for the transcription. Using this method, the plaintext will reappear in the alternate horizontal route originally used for the inscription.

Other routes that may be employed are simple horizontal or vertical, alternate vertical, simple diagonal, and clockwise or counterclockwise spirals from a corner or the centre of the diagram. In the very common keyed columnar transposition cipher, the plaintext letters are written into a geometrical design, most often a rectangle, in a simple horizontal route from left to right and top to bottom, and the letters are transcribed from the columns in the sequence determined by a numerical key. In the example below, involving an incompletely filled rectangle, the numerical key is derived from the key word CIGARETTE by numbering the letters in the sequence in which they appear in the normal alphabet:

C	I	G	A	R	E	T	T	E
2	6	5	1	7	3	8	9	4
P	A	C	K	A	G	E	S	E
N	T	T	O	Y	O	U	B	Y
C	O	U	R	I	E	R	S	T
O	P	A	C	K	N	O	W	L
E	D	G	E					

thus, A is 1, C is 2, the two E's are 3 and 4, etc. The final ciphertext is KORCE PNCOE GOENE YTLCT UAGAT OPDAY IKEUR OSBSW. In decipherment, a rectangle with the proper number of cells (determined by the length of the message and the length of the key) must first be prepared. The ciphertext is then inscribed vertically down the columns according to the numerical key. Thus, the first three cipher groups—KORCE PNCOE GOENE—when inserted into the rectangle, would look as follows:

C	I	G	A	R	E	T	T	E
2	6	5	1	7	3	8	9	4
P			K		G			E
N			O		O			
C			R		E			
O			C		N			
E			E					

When all of the columns have been inscribed, the entire plaintext of the cryptogram will reappear.

The foregoing examples involved single transposition. In double transposition ciphers, the ciphertext resulting from the first transposition is put through a second transposition in the same or a different key. In the case of the last example given above, if the second transposition used the same key as the first, the primary ciphertext KORCE PNCOE . . . would be inscribed in simple horizontals under the key, and then the columns taken off in

2	6	5	1	7	3	8	9	4
K	O	R	C	E	P	N	C	O
E	G	O	E	N	E	Y	T	L
C	T	U	A	G	A	T	O	P
D	A	Y	I	K	E	U	R	O
S	B	S	W					

numerical-key order. The final ciphertext would then be  
CEAIW KECDS PEAE0 LPOR0 UYSOG TABEN  
GKNYT UCTOR.

In decipherment the order of steps is reversed: the two

rectangles of the proper dimensions are prepared, and the cryptogram is inscribed in the columns of the second rectangle under the digits of the key according to their numerical order. When the second rectangle is completely filled, the rows of this rectangle are transcribed and written down the columns of the first rectangle according to its numerical key, and the plaintext will reappear in the rows.

Transposition ciphers exist in many modifications. In the diagonal-columnar variation example below, a key of 18 elements has been expanded from a shorter key phrase, and a variation in transcription has been employed:

	C	H	I	N	E	S	E	L	A	U	N	D	R	Y	C	H	I	N
	2	7	9	12	5	16	6	11	1	17	13	4	15	18	3	8	10	14
A	M	M	U	N	I	T	I	N	T	R	A	I	N	L	E	A		
V	I	N	G	G	R	E	N	V	I	L	L	E	A	T	O	N		
E	F	O	U	P	T	H	R	E	Z	R	O	T	O	D	A			
Y	S	T	O	P	T	R	O	O	P	T	R	A	I	N	A	R	R	
I	V	I	N	G	N	E	W	T	O	N	A	T	Z	E	R	O	S	
I	X	F	O	U	R	F	I	V	E									

The ciphertext is formed by taking off diagonals, alternating in direction, of the letters under the key numbers **1, 2, 3**, and **4** as shown, following which the remaining letters are taken off in columns according to the key, not duplicating the letters that already have been taken off in the diagonals.

The final ciphertext would then be OEHTG OAI00  
RNERR...ATIRT NNVEP OEIIZ.

In another variation, which is known as the **interrupted-key** columnar transposition cipher, the numerical key serves two purposes: it determines the cut-off point (and therefore the number of letters) in each row of the diagram; and determines the order of transcription of the columns.

[illegible]

The final ciphertext here is OVANT NNITE . . . ITOEX NILEO I. (Note, in the diagram, the final null X added to complete the row properly.) Other geometrical designs, such as triangles or trapezoids, have been used, as in the following examples:

A large triangle containing the words "CHINESE" and "INDONESIAN" spelled out in letters. The letters are arranged in a grid-like pattern within the triangle. Below the triangle, the words "CHINESE" and "INDONESIAN" are written in capital letters, with each letter corresponding to a number from 1 to 18.

2	8	10	13	5	17	6	12	1	18	14	4	16	19	3	9	11	15	7
C	H	I	N	E	S	E	L	A	U	N	D	R	Y	C	H	I	N	E

THE UNIVERSITY OF TEXAS

2 5 6 8 3 10 4 7 1 11 9

C H I N E S E L A U N

In the first example, the columns are taken off from their tops according to the key, so that the ciphertext would read MIAEO ENODI . . . . In the second example, the diagonals are read from the bottom, so that the final ciphertext reads AROEN NVRIA. . . .

Grilles

A type of transposition occasionally encountered involves the use of a square sheet of paper or cardboard called a grille, in which small square cells have been cut out in definite but irregular positions; the letters of the plaintext are inscribed on a sheet underneath the perforated design. Usually the grille is revolved 90 degrees in four successive operations so that the resulting square of letters inscribed beneath the grille is completely filled, and then the letters are taken out in groups of five, reading horizontally or otherwise, according to agreement. The perforations must, of course, be correctly disposed on the grille so every space on the sheet over which it is placed in inscribing the letters is filled after the four turns have been completed.

Monoalphabetic substitution. These systems make use of a single cipher alphabet consisting of a plain component, in which are found the plaintext letters to be enciphered; and a cipher component, in which are found the ciphertext equivalents of the plaintext letters. Cipher alphabets may be direct standard, as in the example below

Plain: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z  
Cipher: L M N O P Q R S T U V W X Y Z A B C D E F G H I J K

(one of the 25 possible slides or juxtapositions of the two sequences for monoalphabetic substitution), with which ARTILLERY would be enciphered as LCETWWPCJ; or they may be reversed standard, as in the example below

Plain: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z  
Cipher: C B A Z Y X W V U T S R Q P O N M L K J I H G F E D

(one of the 26 possible slides of these sequences), with which ARTILLERY would be enciphered as CLJURYLYE. Note that a sequence running against itself in reverse must always give rise to reciprocal substitution: here R plain is L cipher, and L plain is R cipher (or, in cryptologic notation,  $R_p = L_c$ , and  $L_p = R_c$ ), and so on for the 12 other reciprocal pairs. Cipher alphabets may also be systematically mixed in some fashion, such as in the example below

Plain: A T H E N S B C D F G I J K L M O P Q R U V W X Y Z  
Cipher: L M N O Q T V W X Y Z P I R A E U S B C D F G H J K

in which the plain and cipher components are two different keyword-mixed sequences (at the juxtaposition A, = L), or in the example below

Plain: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z  
Cipher: D A K S Y E B M T Z L C N U P F O V H G Q W I J R X

in which the cipher component is a transposition-mixed sequence based on the key word DELPHI and derived from the following diagram:

D	E	L	P	H	I
A	B	C	F	G	J
K	M	N	O	Q	R
S	T	U	V	W	X
Y	Z				

**Multiliteral systems.** The monoalphabetic systems just described are uniliteral systems; *i.e.*, the cipher equivalents for the plaintext elements consist of single letters. Multiliteral systems are those in which the cipher equivalents consist of two or more characters, typically pairs of letters or digits produced from biliteral or bipartite matrices or diagrams such as the following:

	B	L	A	C	K
W	A	B	C	D	E
H	F	G	H	I	J
I	L	M	N	O	P
T	Q	R	S	T	U
E	V	W	X	Y	Z

	0	1	2	3	4	5	6	7	8	9
0	C	I	G	A	R	E	T	B	D	F
1	H	J	K	L	M	N	O	P	Q	S
2	U	V	W	X	Y	Z	.	(	)	

Encipherment is accomplished by designating the row and column coordinates at which the plaintext element

appears; thus, in the diagrams above, plaintext E is enciphered as WK in the first diagram or as 05 in the second. (Note that in the first matrix the coordinates are systematically mixed whereas in the second matrix it is the interior that is mixed, based on the key word CIGARETTE—with repeated letters of course suppressed after their initial occurrence.) Multiliteral systems may also employ mixed-length units in the ciphertext, as in the following monome–dinome matrix (wherein the internal key is based on CIGARETTES, and the sequence for the column coordinates is the numerical key derived from the letters at the top of the columns, CIGARETSNO):

	2	5	4	1	8	3	0	9	6	7
—	C	I	G	A	R	E	T	S		
6	B	D	F	H	J	K	L	M	N	O
7	P	Q	U	V	W	X	Y	Z	.	.

In this system the letters in the top row are enciphered as single digits (monomes), whereas the other letters are enciphered by pairs of digits (dinomes). Thus, the word HEADQUARTERS would be enciphered as

613 1657574180389,

which would appear as 61316 57574 18038 9 . . . when grouped into five-digit groups for transmission. There is no ambiguity in decipherment, since the row-coordinate digits (here 6 and 7) cannot represent monomes. Multiliteral systems may be modified to yield two or more cipher values, called variants, for the plaintext elements, as shown in the example below:

	U	V	W	X	Z
	P	Q	R	S	T
A	F	K	A	B	C
B	G	L	F	G	H
C	H	M	L	M	N
D	I	N	Q	R	S
E	J	O	V	W	X

Here plaintext E has six variants, any one of which may be used at the whim of the encipherer: AT, AZ, FT, FZ, KT, and KZ. Furthermore, since this is a commutative matrix (*i.e.*, the row coordinates are distinct from the column coordinates), the cipher equivalents may also be taken in column-row order, providing a total of 12 variants for each plaintext letter. Another system for variant encipherment is the following table, which provides four dinome equivalents for each plaintext letter:

A	24	38	68	89	H	06	45	75	96	O	12	26	56	77	U	18	32	62	83
B	25	39	69	90	I	07	46	76	97	P	13	27	57	78	V	19	33	63	84
C	01	40	70	91	K	08	47	77	98	Q	14	28	58	79	W	20	34	64	85
D	02	41	71	92	L	09	48	78	99	R	15	29	59	80	X	21	35	65	86
E	03	42	72	93	M	10	49	79	00	S	16	30	60	81	Y	22	36	66	87
F	04	43	73	94	N	11	50	80	76	T	17	31	61	82	Z	23	37	67	88
G	05	44	74	95															

Here the plaintext sequence consists of 25 letters (combining I and J), and the cipher sequences consist of slides of the dinomes 01–25, 26–50, 51–75, and 76–00; the starting points of the four cipher sequences are set according to the specific key, which in this case is 01 = C, 26 = O, 51 = I, and 76 = N, spelling the key word COIN.

**Digraphic systems.** All of the preceding monoalphabetic substitution ciphers are monographic systems: the plaintext elements treated are single characters. In digraphic systems the plaintext being enciphered consists of a pair of letters forming an indivisible compound in the enciphering process. The encipherment may be accomplished through the use of a 26 × 26 square, such as the following one, which is shown in fragmentary form, in which the letters of the plaintext pair are found in the side and top sequences, and the digraphic cipher equivalent is the pair of letters in the cell at the junction of the row-and column coordinates. This table has been constructed so as to yield reciprocal substitution (*e.g.*, AB in plaintext is CH in cipher; and CH in plaintext is AB in

Variant systems

Figure 2: United States Army cipher disk.

Gronsfeld cipher

to be used in the operations of encipherment and decipherment. The system known as the Gronsfeld cipher is identical with a Vigenere system with direct standard alphabets, except that only the first ten alphabets are used in conjunction with a numerical key. The key digit indicates how much displacement the plaintext letters should have (as measured on the normal sequence); hence, the limitation of only the first ten rows of the Vigenere table. The example below shows an encipherment with the repeating 12-digit keying sequence 743189602512:

Key: 7 4 3 1 8 9 6 0 2 5 1 2 7 4 3 1 8 9 6 0 2 5 1 2 7  
 Plain: D I S R E G A R D M Y L A S T M E S S A G E X X X  
 Cipher: K M V S M P G R F R Z N H W W N M B Y A I J Y Z E

The advantages of the Gronsfeld cipher are that encipherment and decipherment may be accomplished without the use of a table and that easily available long numerical keys (e.g., the numbers in a telephone directory) may be used by the correspondents.

Aperiodic substitution

Aperiodic polyalphabetic substitution systems employ either long keys that do not repeat (as, for example, the text from a book) or keys used in such a way as to disturb or eliminate periodicity, even if the basic key is relatively short and therefore cyclic in nature. In a system involving a plaintext interruptor, for example, the occurrence of a predetermined plaintext letter might cause a skip of one position in the basic key, as in the following Vigenere encipherment, in which the letter A in plaintext (A,) is the interruptor letter and FLUTES the basic key:

Key: F L U T E S F L U T E S F L U T E S F L U T S F L U T  
 Plain: D I S R E G A R D M Y L A S T M E S S A G E X X X  
 Cipher: I T M K I Y F L W Q Q Q L L X E J D M T Y J I R Q

The interruptor letter may also be a designated cipher letter; furthermore, the interruptor letter may influence the key in a number of ways—e.g., it may cause the immediately preceding key element to be repeated, or it may cause the key to reset to its initial position. Autokey systems are those in which the key is automatically generated from the plaintext or the ciphertext, after an initial or priming key of one or more letters. In the plaintext autokey cipher below, for example, the first letter of the message

Key: X D I S R E G A R D M Y L A S T M E S S A G E X X X  
 Plain: D I S R E G A R D M Y L A S T M E S S A G E X X X  
 Cipher: A L A J V K G R U P K J L S L F Q W K S G K B U U

is enciphered in the key of X, after which the plaintext itself serves as the key for enciphering the rest of the message. In the following example of a ciphertext autokey cipher, the beginning of the message is enciphered

Key: F L U T E S I T M K I Y I K P W G J I C I I K B A  
 Plain: D I S R E G A R D M Y L A S T M E S S A G E X X X  
 Cipher: I T M K I Y I K P W G J I C I I K B A C O M H Y X

with the initial key FLUTES, after which the ciphertext being produced serves as the key. In the running-key cipher the key text is taken from a book in possession of the correspondents; it is necessary either to agree to the

starting point of the key or to designate this by means of an indicator that might specify the page, paragraph, line or word number in the particular book being used.

**Fractionation systems.** These systems employ a multiliteral substitution as the first step, transforming the plaintext into biliteral (or sometimes triliteral) equivalents, that are then subjected to a further encipherment, usually transposition. The following bipartite square and the encipherment of a message in vertical dinomes under the plaintext letters provide an example:

	1	2	3	4	5
1	F	L	U	T	E
2	S	A	B	C	D
3	G	H	I	K	M
4	N	O	P	Q	R
5	V	W	X	Y	Z

A L L Q U I E T I N T H I S S E C T O R  
 2 1 1 4 1 3 1 1 3 4 1 3 3 2 2 1 2 1 4 4  
 2 2 2 4 3 3 5 4 3 1 4 2 3 1 1 5 4 4 2 5

The ciphertext is formed by taking off all the digits in the top row, and then in the second row, as dinomes (21 14 13 11 34 . . . 42 31 15 44 25) and converting the dinomes thus formed into single letters using the same square; the final ciphertext would then read STUFK . . . OGEQD. The foregoing example is that of an aperiodic fractionation system, since the keying is dependent upon the message as a whole. In periodic fractionation the plaintext is divided into regular-length groupings, and the treatment is applied to the individual groupings in turn. Note the following example with a grouping-interval of 5:

Periodic fractionation

A L L Q U I E T I N T H I S S E C T O R  
 2 1 1 4 1 3 1 1 3 4 1 3 3 2 2 1 2 1 4 4  
 2 2 2 4 3 3 5 4 3 1 4 2 3 1 1 5 4 4 2 5

The dinomes taken off here are 21 14 12 22 43 . . . 12 14 45 44 25, which, when converted back into letters, become STLAP . . . LTRQD. A fractionation cipher may also make use of a tripartite cipher alphabet, such as that shown below:

F 111 A 131 I 221 O 233 W 322  
 L 112 B 132 J 222 P 311 X 323  
 U 113 C 133 K 223 Q 312 Y 331  
 T 121 D 211 M 231 R 313 Z 332  
 E 122 G 212 N 232 V 321 \* 333  
 S 123 H 213

Using this alphabet in a fractionation cipher with a period of five produces the encipherment shown below, wherein the equivalents of the plaintext letters are the vertical trinomes (i.e., three-digit groups) beneath them:

A L L Q U I E T I N T H I S S E C T O R  
 1 1 1 3 1 2 1 1 2 2 1 1 1 1 1 2 3  
 3 1 1 1 1 2 2 2 2 3 2 1 2 2 2 2 3 1  
 1 2 2 2 3 1 2 1 1 2 1 3 1 3 3 2 3 1 3 3

The trinomes are now recombined horizontally under each grouping of five letters as shown by the parentheses, 111 313 111 112 223 . . . 111 232 323 123 133; the trinomes are then converted back to letters, yielding the final ciphertext FRFLK . . . FNXSX. Should the grouping 333 occur in the recombination, its substitute will be either the 27th character in the alphabet (\*) or the result of a special convention; e.g., wherein the grouping 332 will always be represented by ZA as an inseparable compound, and the grouping 333 represented by ZB. The deciphering clerk, on encountering a Z, will take the next letter into consideration; therefore, no cryptographic ambiguity will be present.

A famous case of fractionation in combination with columnar transposition was a cipher used by the German Army high command in World War I, a system known to the Allies as the ADFGVX cipher because only those six letters—with easily distinguishable Morse equivalents—appeared in the ciphertexts. This system used a  $6 \times 6$  bipartite square containing the 26 letters and the 10 digits, with coordinates A, D, F, G, V, and X. The biliteral text produced in the first step was inscribed into a transposition rectangle, and the columns were taken off according to the numerical key to produce the final cipher text, as in the following example:

Germany's ADFGVX cipher

tional security for highly classified communications. Transposition methods involve either transposing the elements of each code group according to a fixed permutation or transposing the text of a code message by one of the transposition methods already described. Substitution methods may involve monoalphabetic, digraphic, or polyalphabetic encipherments, such as those discussed above. A favourite method with two-part codes is that in which the code group standing at a prearranged interval in the encoding section before or after the code group representing the actual word or phrase intended to be conveyed is substituted; the interval may remain fixed within a single message, or it may vary according to some predetermined key. The most important of the various methods of enciphering code are arithmetical methods. If the code groups are numerical, the addition (usually noncarrying or mod 10, so that, for example,  $8 + 7 = 5$ ) of an arbitrarily selected number (called an additive) to each code group in the code message constitutes a simple form of encipherment. In decipherment the additive is merely removed from the received enciphered code groups by subtraction, leaving the plain code groups, which can then be decoded with the code book. Instead of a fixed additive, the additive may be a sequence of digits used in the manner of a repeating key, the sequence being either agreed upon in advance or derivable from a literal key or by some other method. Additives may also be compiled in specially prepared key tables or key books, in which case an indicator would be necessary to designate the starting point of the key used.

**Cipher devices and cipher machines.** These range in complexity from simple rotating concentric disks such as that illustrated in Figure 2 to large machines and electrically operated cipher teleprinters. The Wheatstone cipher device, shown in Figure 3, incorporates a very

Figure 3: Wheatstone cipher device.

interesting principle. Although invented by the English physicist Sir Charles Wheatstone in 1867, a device identical in principle was constructed by an American, Decius Wadsworth, in 1817. Wheatstone's device incorporates two concentric circles of letters, a 27-character plain component including a word spacer, and a 26-character cipher component. The two hands, which may be set independently, are geared together so that, when the long hand (indicating the plaintext) makes a complete revolution, the short hand makes  $1 \frac{1}{26}$  revolutions, causing the short hand to point one letter in advance of where it pointed at the end of the preceding revolution of the long hand. In encipherment, the two hands are first set to prearranged initial positions and the long hand moved clockwise to the first plaintext letter; the short hand will then point to the cipher equivalent. The long hand is now moved clockwise to the second plaintext letter, and so on for each letter of the message; a word spacer is enciphered at the end of every word. An added convention is that, whenever a doubled letter is to be enciphered, a rare letter such as X, or Q<sub>p</sub>, is substituted for the second letter, so that the word ARTILLERY, for example,

would be spelled ARTILQERY. In decipherment, after the hands are set to their proper initial positions, the long hand is rotated clockwise so that the short hand points to each succeeding cipher letter, the long hand in each case indicating the plaintext equivalent. (The principle of the Wheatstone device can be duplicated with a pair of sliding alphabet strips—a 27-character plain component and a double-length cipher component. After the two strips are set to their initial prearranged juxtaposition, the cipher equivalent is found for the first plaintext letter. The cipher component strip is moved one position to the left for succeeding encipherments whenever a letter on the plain component is located to the left of the immediately preceding plaintext letter of the text.) The Wheatstone device is particularly interesting in that the motion of the cipher component is highly irregular and unpredictable, depending as it does upon the particular sequence of the letters of the plaintext and upon the particular arrangement of the letters in the plain-component sequence.

In 1891 the French cryptologist Étienne Bazeries invented his "cylindrical cryptograph," shown in Figure 4, based on principles enumerated earlier by Thomas Jefferson of the U.S. The Bazeries device consists of 20 numbered rotatable disks, each bearing a different alpha-

Figure 4: The Bazeries cylinder.

bet engraved on its periphery. The disks are arranged in an agreed-upon order on a shaft and rotated so that the first 20 letters of the message plaintext appear in a row; the ciphertext is then formed by arbitrarily taking off any other row. The remaining letters of the message are treated in the same fashion, 20 letters at a time. In decipherment, the disks are first arranged on the shaft according to the agreed-upon order, the first 20 cipher letters are set up across one row, and the other rows searched for the one and only row that contains plaintext all the way across; and so on for the rest of the decipherment. The Bazeries principle was embodied in a 25-disk cipher device, Type M-94, widely employed in the United States military services from 1923 until 1942.

In 1924 Alexander von Kryha of Germany invented a spring-operated polyalphabetic cipher machine having as its principle the irregular displacement of two concentric disks representing the plain- and cipher-components, easily changeable by means of tab inserts for the letters. The displacement of the alphabets occurring after each encipherment is accomplished through a selector wheel having on its periphery 17 toothed sectors consisting of from one to six teeth each, the sectors being designated by the numbers 1–17. These teeth serve to displace the components a distance equivalent to the number of teeth in the sector; because of the manner of spacing between the toothed portions of the wheel, however, an additional displacement of four positions is added at each operation of the machine. The selector wheel has the following effective displacements or skips between its 17 numbered positions:

Pos. 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 1  
Skips: 7 6 7 5 6 7 6 8 6 10 5 6 5 7 6 5 9

If the components were direct standard alphabets, for example, set initially so that A in plaintext is A in cipher (and therefore a key of A) and the selector wheel is set to position 1, the second key would be A + 7 or the letter H; the third H + 6 or the letter N; the fourth N + 7

Geared  
disk  
devices

Mechanical cipher  
machines

or the letter U; and so on. A subsequent model of the Kryha machine incorporates a selector wheel with 52 adjustable screws, or stops, each screw effecting a new displacement of the alphabets.

A compact, tape-printing, mechanical cipher machine invented by the Swedish engineer Boris Hagelin in the 1930s employs a complex mechanism to generate a long running key that is used in conjunction with reversed standard alphabets. In operation, the machine in effect subtracts each plaintext letter from the key to yield the cipher letter, and subtracts each cipher letter from the key to yield the plaintext letter; because of this, the machine has sometimes been called a "letter-subtractor machine." The machine has six wheels of identical diameters, with individual periods of 26, 25, 23, 21, 19, and 17. Equidistant around the peripheries of the wheels are engraved the following sequences:

"26 wheel": ABCDEFGHIJKLMNOPQRSTUVWXYZ  
 "25 wheel": ABCDEFGHIJKLMNOPQRSTUVWXYZ  
 "23 wheel": ABCDEFGHIJKLMNOPQRSTUVWXYZ  
 "21 wheel": ABCDEFGHIJKLMNOPQRSTU  
 "19 wheel": ABCDEFGHIJKLMNOPQRS  
 "17 wheel": ABCDEFGHIJKLMNOPQ

At each lettered position near the edge of the wheel is a small pin that may be set in an active or inactive position. Each operation moves the six wheels one step; if they are initially aligned at AAAAAA, the second alignment will be BBBBBB, the 18th RRRRRA, and the 27th ABDFHJ. Since the wheels are relatively prime (*i.e.*, none of the numbers have a factor in common) to each other, the cycle of the machine is the product ( $26 \times 25 \times 23 \times 21 \times 19 \times 17$ ) or 101,405,850; in other words, the wheels will not return to their initial position until after this number of letters has been enciphered.

Just behind the six wheels is a revolving drum, something like a squirrel cage, composed of two circular retaining plates holding 27 horizontal bars; on each are two lugs, one or both of which may be set at two of six effective positions (corresponding to the six wheels) on the bar or to neutral positions. When in the active position, the pins on a wheel engage those lugs that have been set opposite that wheel, causing the particular bars to be displaced: the displaced bars act as teeth of a gear wheel, shifting the reversed standard alphabets a corresponding number of positions. The number of lugs in the path of a particular wheel is known as the kick of that wheel; the total key is the sum of all the kicks contributed at a given position of the six key wheels.

Figure 5 shows the machine opened and with the inner cover raised to expose the mechanism. This machine was used extensively during World War II by United States forces under the name of Converter M-209 in the Army and CSP 1500 in the Navy.

Electrical cipher machines often employ components called wired rotors as a means of generating a multiplicity of alphabets. A typical rotor may be visualized as a disk approximately three inches, or 75 millimetres, in diameter and perhaps one-half inch, or 13 millimetres, thick, made of molded plastic or other insulating material. On each of the two faces of the rotor are 26 small metal studs, or contacts, arranged in a circle near its edge. The studs on one face are connected by wires in mixed order to the studs on the opposite face, thus producing a mixed alphabet by means of electrical wiring. The rotors may have the normal A–Z sequence engraved on their peripheries as a means of aligning them at specific positions against a bench mark. Several of these rotors are used side by side in a cipher machine, so the studs of each rotor come into contact with the studs of those adjacent: the entire set of rotors in the machine is contained between two endplates each with a circle of 26 contacts that touch the studs of the rotors placed next to them. In encipherment, pressing a letter of a typewriter keyboard sends a current to one of the points on the input endplate from which it goes through the maze of rotors (each of which contributes the effect of one monoalphabetic substitution) to a point on the output endplate, which is connected either to one of 26 lamps or to a printing mechanism, thus producing the cipher equivalent

of the plaintext letter. A three-rotor machine in schematic form is illustrated in Figure 6.

If the rotors never moved, the encipherment would be nothing more than simple monoalphabetic substitution with a mixed alphabet. After encipherment of each letter, however, one or more of the rotors will move one step, in effect generating a succession of different alphabets. The total possible number of alphabets is equal to 26 raised to the  $n$ th power,  $n$  being the number of rotors in the maze. Thus, for a three-rotor machine  $26^3$ , or 17,576, different alphabets are possible, and for a five-rotor machine  $26^5$ , or 11,881,376, different alphabets are possible. If the motion of the rotors is regular—*e.g.*, meter-like as in an ordinary counter or odometer—these numbers will

Figure 6: Three-rotor cipher machine (see text)

Cipher  
tele-  
printers

also represent the periods of the machines. (The rotor which moves one step with each operation is called the fast rotor; it controls the stepping of the medium rotor, which in turn controls the stepping of the slow rotor.) Figure 7A is a diagram of a three-rotor machine, in which the wiring of each rotor is represented by numbered contacts on the left- and right-hand faces; wires connect like-numbered contacts from one side of the rotor to the other. Figure 7B shows the machine after one letter has been enciphered and the fast rotor has moved one position; at this setting, the plaintext letters A, B, and C are enciphered as E, Q and T instead of as A, I and E in the previous setting. Machines for the automatic and simultaneous encipherment and decipherment of the Baudot telegraph code (see TELEGRAPH) used in teleprinter communications are usually constructed along the lines of key generators, and the key that is produced is applied to the plaintext Baudot characters according to the rule of Baudot addition (*e.g.*, where like impulses make a "mark" and unlike impulses a "space"). These machines often employ notched wheels to actuate relays that determine the substitution key for the plaintext Baudot character at each position of the message. One typical machine has as its cryptographic unit an assembly of ten notched wheels mounted on a common shaft so that each wheel steps one position with every operation of the keyboard of the machine. The first wheel has 96 positions, and each wheel thereafter has one more position than the preceding one, so that the tenth wheel has 105 positions. The depression of any key on the teleprinter keyboard actuates the mechanism, which moves the wheels one step each. (The period of this machine is the least common multiple of the wheel sizes, which is  $2^5 \times 3^2 \times 5^2 \times 7^2 \times 11 \times 13 \times 97 \times 101 \times 103$ , or approximately  $8.65 \times 10^{14}$ .) Behind each wheel is a cam switch, which is acted upon by an irregular arrangement of notchings on its periphery. At 26 of the positions of each wheel, spaced more or less regularly on the circumference, are the letters of the alphabet in normal order, permitting the wheels to be set at designated initial alignments against a bench mark. Each pair of wheels, 1-2, 3-4, . . . 9-10, is used in combination to produce a key stream for the five levels of a Baudot character. The key produced by the five pairs of wheels is applied by Baudot addition to the plaintext character to yield the enciphered character. At each operation of the keyboard, ten new notchings arrive at the sensing position to be combined into a new Baudot character.

**Ciphony, cifax, and civation systems.** Methods for the encryption of speech (ciphony), facsimile (cifax), and television (civation) signals employ the same general ideas of substitution and transposition which are to be found in literal cryptosystems, with one important difference. In literal cryptosystems the unit of encryption is usually a single character, whereas in ciphony, cifax, or civation, the corresponding unit is a limited portion of the continuously varying audio or image-scanning signal. Ciphony, cifax, and civation systems fall into two broad categories: privacy systems and security systems. The security afforded by a privacy system is minimal; it offers protection only against direct listening or direct viewing. Security systems, on the other hand, offer maximum—which in some cases might be absolute—protection against analysis.

Speech privacy systems are those systems that operate directly on the speech itself, in either the frequency dimension or the time dimension, or both. The earliest speech privacy systems incorporated the principle of frequency inversion, such as is found in certain commercial transatlantic radiotelephone systems. This principle involves modulating the audio signal with a fixed high audio frequency, so that the resultant signal is the difference in frequency between the two component signals; this has the effect of changing high frequency sounds into lower frequency sounds, and vice versa. Systems were then developed in which several frequencies are used in a changing pattern for the modulation or in which the modulating signal is continuously changing within a frequency band. Also widely used in commercial ciphony

equipments is band splitting: the entire speech band is split into several smaller bands, which are then shifted in the frequency spectrum. Both of the foregoing systems employ substitution; an example of transposition is time-division scrambling. In this system, speech can be recorded on a magnetic tape, and the transcription from the tape "read" in an irregular manner.

In speech security systems today the continuous speech wave is first converted into a series of binary impulses (similar to the impulses of the Baudot code) and these "binary digits" are then combined with a binary key stream (derived from a suitable key generator). Three principal methods by which speech is converted into binary form involve (1) pulse-code modulation, (2) delta modulation, or (3) a vocoder. Each converts the continuous speech wave into a digital approximation of the original wave.

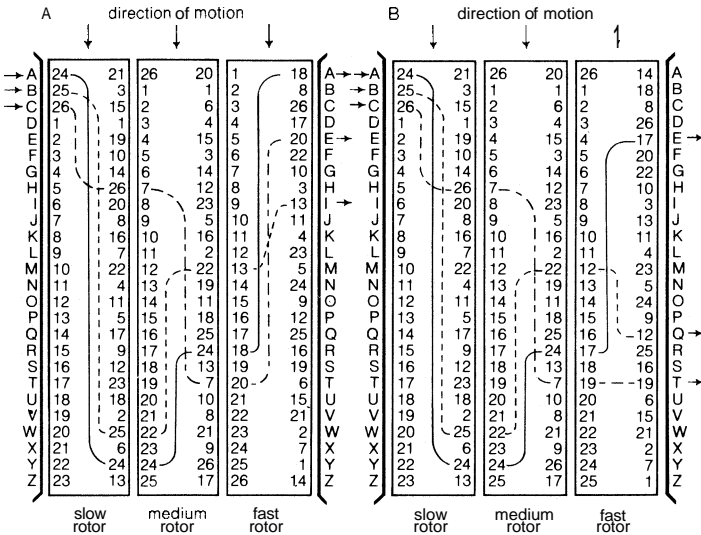

Figure 7: Three-rotor machine with wiring represented by numbered contacts. (A) Position as enciphering is begun. (B) Position after fast rotor has moved one position.

In pulse-code modulation, the amplitude of the speech wave is sampled at a rate equal to at least twice the highest frequency component in the wave; each sampled amplitude is then approximated by categorizing it as one of a number of discrete amplitude levels, represented by binary coding. In a typical system, the speech is sampled 6,000 times per second, and each sample is identified with one of 16 possible amplitude levels, represented by a four-element binary pattern; the output of this pulse-code modulation system is a stream of binary signals at the rate of 24,000 "bits" (*i.e.*, binary digits) per second.

In delta modulation, an approximating or synthetic wave is generated by comparing the amplitudes of the speech wave and the wave being generated. If the amplitude of the generated wave at the instant of sampling is less than that of the speech wave, the next fragment of the approximating wave is generated for a fixed interval (until the next sampling instant) with fixed constant positive slope; if the amplitude of the generated wave is more than that of the speech wave, the next fragment of the approximating wave is generated with a fixed constant negative slope—thus the generated wave being synthesized is constantly correcting itself, in zigzag fashion, so as to produce an approximation to the original speech wave. The positive and negative slope information is represented by binary digits; good quality speech can be obtained by the delta modulation process using approximately 25,000 comparisons per second.

The vocoder is a speech analyzer and synthesizer developed at Bell Telephone Laboratories Inc.; in a vocoder system the spectrum of the speech wave is separated into a number of nonoverlapping frequency bands, and the amplitude in each band is sampled and coded by the pulse-code modulation process. At the receiving end, a synthesizer creates artificial voice sounds from the in-

Privacy  
and  
security  
systems

coming digital information (see TELEPHONE AND TELECOMMUNICATIONS SYSTEMS).

The earliest facsimile privacy system, patented in 1928, involved variations in the velocity of the synchronized sending and receiving drums of the facsimile equipment; exact synchronism of the two drums is essential for proper transmission. Other facsimile privacy systems include pretransmission scrambling (in which the plaintext copy is optically disarranged before transmission) and time-division scrambling similar to that employed for ciphony purposes. In facsimile security systems, the plaintext copy is optically scanned and converted into a stream of binary digital signals; each square inch of the image is converted into approximately 10,000 binary digits of black-white information. A binary key is added to the binary intermediate plaintext; at the receiving end, the same key is added to the incoming cipher signals to produce the original plaintext copy.

Television privacy systems may use adaptations of any of the methods of speech privacy systems. Television security systems likewise employ the same general techniques that are found in secure speech and facsimile systems; but because of the broadness of the frequency spectrum necessary to transmit the secure digitalized television signals and the very high speeds necessary in the key generation for encrypting them, major difficulties are encountered in the development of these systems.

#### SIGNAL INTELLIGENCE

The principal components of signal intelligence are: communication intelligence, derived from the interception and analysis of messages or communications between persons, and therefore termed communications signals; and electronic intelligence, derived from the interception and analysis of electromagnetic radiations considered to be noncommunications signals, such as radar, identification and recognition signals, navigational beacons, and telemetry signals. In practice, it is often difficult to distinguish between these two types of intelligence.

**Communication intelligence.** Communication intelligence is evaluated information concerning an enemy, derived from a study of his signal communications. The principal components of communication intelligence are: interception of signals or messages and forwarding raw traffic to communication intelligence centres for study; traffic analysis, including radio direction finding and position finding (evaluated information from this source is called traffic intelligence); cryptanalysis (and translation, when necessary) of message texts; and evaluation of data, that is, analysis of results obtained from the preceding steps and their correlation, collation, and comparison with information from other sources.

**Traffic analysis.** A great deal of information of military value can be obtained from signal communications even without solving encrypted traffic. In general terms, traffic analysis is the careful inspection and study of signal communications to penetrate camouflage superimposed upon the communication network for purposes of security. Specifically, traffic analysis reconstructs radio communication networks by the following: noting volume, direction, and routing of messages; correlating transmission frequencies and schedules used among and within the various networks; determining directions in which transmitters lie, by means of radio direction finding; locating transmitters geographically, by radio position finding; determining the system of assigning and changing radio call signs; and studying all items that constitute messages originated by operators and exchanged among themselves on a radio net.

By means of these procedures, traffic analysis is able not only to ascertain the location and disposition of military units (technically called "order of battle") and important troop movements but also to predict with a fair degree of reliability the areas and extent of immediately pending or future activities. Through traffic analysis a nation can obtain information of value concerning an enemy and can determine what information concerning his own forces is made available to the enemy through his own signal communications. Unit movements and

preparations for military activity, for example, may be indicated by rising and falling traffic volumes and changes in the structure of the network; or the military function of a network may be revealed by the characteristic traffic pattern that results from transmissions incidental to planning, supply, and transportation; or a change of grouping, disposition of forces and fleets, and probable tactical developments may be manifested in the redeployment of the radio stations that serve military elements. These very important results are obtained without actually reading the texts of the intercepted messages. The cryptanalyst, on the other hand, is frequently able to make good use of bits of information disclosed by traffic analysis, such as faults noted in message routing and errors in cryptography that cause messages to be duplicated or cancelled. Cryptanalysis can provide important information for traffic analysis, since the solution of messages often yields data on such matters as impending changes in signal communication plans and operating frequencies and schedules. Cryptanalysis also yields data on specific channels, networks, or circuits that are most productive of intelligence.

**Cryptanalysis.** The solution of secret communications without any previous knowledge of the system or the key is the domain of cryptanalysis, requiring, in the case of modern cryptosystems, extensive theoretical study, unusual powers of observation, inductive and deductive reasoning, great concentration and perseverance, and a vivid imagination guided by good judgment, fused together by a special aptitude and intuition gained from long and varied practical experience. An isolated, short cryptogram may resist solution indefinitely, even if it is in a fairly simple system; but a large volume of material—even in a very complex cryptosystem—may well be solved with time and effort.

In general, the art of cryptanalysis may be reduced to three basic steps: arrangement and rearrangement of data to disclose nonrandom characteristics or manifestations (*e.g.*, in frequency counts, repetitions, patterns, and symmetrical phenomena); recognition of the nonrandom characteristics or manifestations when disclosed; and explanation of the nonrandom characteristics when recognized. The requirements for the first step are experience or ingenuity and time—which may be appreciably reduced by the use of machine aids; for the second step, experience or statistics; and for the third step, experience or imagination, and intelligence.

The cryptanalyst studies all the messages in the cryptosystem under investigation and the possible relationship with other cryptosystems of the same enemy. All available collateral information concerning the correspondents and their past and present activities is gathered, together with data on the transmission and interception of the traffic. Indicators, if present in the message texts, are given particular attention; traffic is separated into homogeneous groups of messages; a search is made for repetitions within and between messages; the beginnings and endings of messages are scrutinized for possible stereotyped language; the traffic is examined for messages likely to contain the same underlying plaintext but having different cryptographic texts; and various statistical counts are made of single letters, digraphs, trigraphs, tetragraphs, and groups.

The cryptanalyst also arms himself with the salient cryptolinguistic data in the language of the enemy; he has available the relative frequencies of single letters, digraphs, trigraphs, and tetragraphs; and he compiles lists of frequent words, either based on past solutions or hypothesized to be present in the messages. If the language were English, for example, he would know the following relative frequencies in descending order of the plaintext letters (based on a count of 50,000 letters of governmental plaintext telegrams and reduced to 1,000 letters):

E 130	I 74	C 31	Y 19	X 5
T 92	S 61	F 28	G 16	Q 3
N 79	D 42	P 27	W 16	K 3
R 76	L 36	U 26	V 15	J 2
O 75	H 34	M 25	B 10	Z 1
A 74				

Qualifications of the cryptanalyst

The relative frequencies in descending order of the 30 highest plaintext digraphs are the following (based on 50,000 letters and reduced to 5,000 digraphs):

EN 111	IN 75	NE 57	AT 47	CO 41
RE 98	TE 71	VE 57	TI 45	IO 41
ER 87	AN 64	ES 54	AR 44	TY 41
NT 82	OR 64	ND 52	EE 42	FO 40
TH 78	ST 63	TO 50	RT 41	FI 39
ON 77	ED 60	SE 49	AS 41	RA 39

The absolute frequencies of the 25 highest trigraphs in the sample of 50,000 letters are the following (note the prevalence of fragments of numbers, since the messages studied had a high incidence of spelled-out numbers in their plaintexts):

ENT 569	TIO 221	NIN 207	VEN 190	NTH 171
ION 260	FOR 218	STO 202	EVE 177	TWE 170
AND 228	OUR 211	EEN 196	EST 176	TWO 163
ING 226	THI 211	GHT 196	TEE 174	ATI 160
IVE 225	ONE 210	INE 192	TOP 174	THR 158

Similarly, the 25 highest frequency tetragraphs are shown below, accompanied by their absolute frequencies in the sample of 50,000 letters:

TION 218	WENT 153	IGHT 140	SEVE 121	REQU 98
EVEN 168	NINE 153	FIVE 135	ENTH 114	HIRT 97
TEEN 163	TWEN 152	HREE 134	MENT 111	COMM 93
ENTY 161	THRE 149	DASH 132	THIR 104	QUES 87
STOP 154	FOUR 144	EIGH 132	EENT 102	UEST 87

(Again note the effect of the prevalence of numbers in the plaintext, together with high-frequency words such as STOP, REQUEST, and COMMA.) In addition to letter-frequency data, the cryptanalyst has available lists of words arranged by word length in alphabetical and in rhyming order, lists of frequent word combinations, and lists of idiomorphs (word patterns). The idiomorphs are sorted by pattern, so that, for example, under the pattern *abaca* would be listed DIVISION and LOCOMOTIVE, and under the pattern *abba* would be listed BATTALION and SHIPPING.

Transposition ciphers, recognized from the fact that the distribution of cipher letters will approximate that of plaintext, are solved by experimenting with matrices of various types, by partial anagramming of portions of the ciphertext, and by assuming probable words. Messages involving cryptographic errors and their subsequent correction are often exploitable and therefore are particularly valuable to the cryptanalyst.

In substitution ciphers, the characteristic relative frequencies of single letters, digraphs, and longer polygraphs serve as a basis for the assignment of plaintext equivalents to cipher values, but only when the cipher has been reduced to simplest terms, such as a **monoalphabetic** substitution cipher. In the final analysis, the solution of every cryptogram involving a form of substitution depends upon its reduction to monoalphabetic terms, if it is not originally in those terms. In general, the solution of periodic polyalphabetic substitution ciphers depends upon three main steps: determining the number of alphabets involved; allocating the letters of the ciphertext into the cipher alphabets to which they belong; and analyzing the individual monoalphabetic distributions to determine plaintext values of the cipher letters in each distribution or alphabet. In the case of aperiodic substitution systems or those employing very long keys, the first step above might be either impossible or very difficult; the only recourse might be to superimpose enough messages on the basis of repetitions so that the letters in the columns of the resulting superimposition diagram are monoalphabetically distributed and thus solvable. The solution of codes is primarily a linguistic problem in which an expert knowledge of the language is of paramount importance; a considerable number of messages might be necessary for solution, especially if a large two-part code is involved.

The principles and techniques of cryptanalysis apply in the decipherment or reconstruction of lost languages; for example, in the solution of the cuneiform script by Georg Friedrich Grotefend in 1802 and Sir Henry Creswicke Rawlinson in 1838, the decipherment of the Egyptian hieroglyphs by Jean-François Champollion in 1822, and in the solution of Minoan Linear B by Michael Ventris in

1952. The ultimate test may come when a cryptanalyst is faced with a communication from an extraterrestrial intelligence, and the world awaits his solution.

## HISTORY

Because the official cryptologic work of all governments has always been kept secret, it is often impossible to ascertain the origin of cryptographic improvements or the development of cryptanalytic techniques, particularly those of modern times; these enter the public domain years after the fact, if at all. The classic cryptographic systems and elementary cryptanalytic techniques are described in the open literature, but the gap between the advent of a new cryptologic technique and its public revelation is an ever-widening one. It is incumbent upon cryptologic historians to trace developments as far back as open sources permit, knowing that in many cases the original attribution or date may be in error. Details of important and far-reaching cryptographic and cryptanalytic developments since 1940 are still shrouded in official secrecy and understandably so since the security of national communications and the continuance of successful intelligence efforts are adversely affected by public revelations.

**The development of cryptography.** The earliest cryptography was developed by the Egyptians, the ancient Hebrews, and the Indians, but the extent of its use is unclear. The first recorded use of cryptography for correspondence was by the Lacedaemonians, or Spartans, who at least as early as 400 BC employed a cipher device called the scytale for secret communications between military commanders. This device consisted of a tapered baton, around which was spirally wrapped a piece of parchment or leather, which was then inscribed with the message; when unwrapped, the parchment bore an incomprehensible set of letters, but when wrapped around another baton of identical proportions, the original text reappeared. Thus, the Greeks were inventors of the first transposition system. Aeneas Tacticus (4th century BC) wrote a work entitled *On the Defense of Fortifications*, one chapter of which was devoted to cryptography, making it the earliest treatise on the subject. The Romans used monoalphabetic substitution with direct standard alphabets: Julius Caesar used the setting in which plaintext A was enciphered as D, while Augustus Caesar used that in which plaintext A was enciphered as B.

Modern cryptography and the first systematic **crypto**-correspondence began around AD 1200 in the Papal States and the Italian city-states: the first ciphers involved vowel substitution (leaving consonants unchanged), and code symbols were introduced. The first manual on cryptography (c. 1379) was a compilation of ciphers by Gabriele de Lavinde of Parma, who served Clement VII; this manual, now in the Vatican archives, contains a set of keys for 24 correspondents and embraces symbols for letters, nulls, and several two-character code equivalents for words and names. The first brief code vocabularies (known as nomenclators) were gradually expanded into what were called repertories, and, later, codes. By 1400, variants for vowels were introduced, followed by a more extensive use of variants for all the plaintext letters, in addition to specific cipher equivalents for common plaintext digraphs, syllables, and words. By the middle of the 15th century, nomenclators were refined and became the mainstay for several centuries for diplomatic communications of nearly all European governments. Leon Battista Alberti published in 1470 his *Trattati in cifra* in which he described the first cipher disk, prescribing that the setting of the disk should be changed after enciphering three or four words, thus conceiving of the notion of polyalphabeticity; Alberti also used his disk to effect an encipherment of a small code of 336 groups, a concept four centuries ahead of his time. Further advances were made by the Abbot Johannes Trithemius (1462–1516) in his *Polygraphia* (the first printed book on cryptology), which contains the first description of a square table for polyalphabetic encipherment. Giovanni Battista della Porta published in 1563 his *De Furtivis Literarum Notis*, which contains a modified

The  
scytale

First  
cipher disk

Idio-  
morphs  
or word  
patterns

form of square table and the earliest example of a di-graphic cipher. The *Traicte' des chiffres* published in 1586 by Blaise de Vigenkre contains the square table commonly attributed to him, as well as descriptions of the first plaintext and ciphertext autokey systems. In the 17th century, two-part codes were used for the first time by France under Louis XIII and Louis XIV, and at the same time Papal repertoires introduced an innovation in which many of the cipher characters represented two or more different plaintext letters. Codes were expanded in the next three centuries, so that by 1860 large codes were used for diplomatic communications, and cipher systems were a rarity for this use. Cipher systems prevailed, however, for military communications except for high-command communications. In the early history of the United States, repertoires were used; during the Civil War the Federal Army used small codes and a word-transposition cipher, while the Confederate Army used the Vigenkre cipher with direct standard alphabets.

In the first two years of World War I, all the belligerents used cipher systems almost exclusively for their tactical communications; code systems were still used in the main for high-command and diplomatic communications, but by 1917 small codes became common for low-level communications. Nevertheless, certain complicated cipher systems were used for high-level communications through the end of the war—the first version of the famous ADFGVX cipher, for example, introduced by the Germans on March 1, 1918. In the postwar period, significant advances were made in cryptography, particularly in the realm of cipher machines. During World War II, cipher machines were used extensively, but not exclusively, by both the Allies and the Axis powers; a plethora of codes and manual cipher systems nevertheless prevailed on all sides. In the years since World War II, even more remarkable advances in cryptography have been made.

**Advances in cryptanalysis.** The technological advances in cryptography had their counterparts in cryptanalysis. The principles of cryptanalysis were known to the Arabs at the beginning of the 15th century: in 1412 Qalqashandi, a Persian living in Egypt, completed a 14-volume encyclopaedia in which appeared not only the first treatment of both substitution and transposition but also the first exposition of cryptanalysis in history. The use to which the Arabs put this information is, however, unknown. *Trattati in cifra*, mentioned above, contains cryptanalytic theories and procedures. The oldest treatise devoted entirely to cryptanalysis is by Sicco Simonetta, a cryptanalyst in the service of the Sforzas of Milan, who on July 4, 1474, wrote a brief paper setting forth rules of cryptanalytic procedure. Among early cryptanalysts whose documented successes have been preserved are Giovanni Soro (died 1544), Venice's principal cryptanalyst for almost 40 years; Giovanni Batista Argenti and his nephew Matteo Argenti, both of whom were in the papal service in the last half of the 16th century; the French mathematician François Viète, who served Henry IV at the end of the 16th century; Antoine Rossignol, France's greatest cryptanalyst of the 17th century, who served Louis XIII and Louis XIV; and the mathematician John Wallis (1616–1703), who for over five decades was England's greatest cryptanalyst. In 1863 the important work, *Die Geheimschriften und die Dechiffirir-Kunst* by Friedrich W. Kasiski, described for the first time the solution of the Vigenère cipher, hitherto regarded as impregnable, and indeed called "*le chiffre indechiffirable*." Nevertheless, in 1757, almost 100 years before Kasiski, a 13-alphabet polyalphabetic cipher was solved by Jacques Casanova, so the general method of solution must have been known in the "black chambers" of the period; it seems doubtful that there were breaches of security, since violations were often treated as capital offenses. In the United States, the first cryptanalysts were the Rev. Samuel West and Elbridge Gerry (later the fifth Vice President), who solved a cryptogram of a Tory spy for George Washington. During the Civil War, Federal Army cryptanalysts were said to have solved every message intercepted, while the Confederate Army had to

publish some cipher messages in the newspapers with a request for solution.

Poor cryptography—or good cryptanalysis—has often dramatically affected the course of history. In World War I, the Russians lost the Battle of Tannenberg, in August 1914, because of the failure of their cryptographic communications. The solution by the British of perhaps the most famous cryptogram in history, the Zimmermann telegram of January 16, 1917 (offering Mexico territorial gains if she would enter the war on the German side), was a major contributing factor to the entry of the United States into the war on April 6, six weeks after the revelation to President Wilson of the contents of the message. In World War II, the Battle of Midway was a stunning victory of intelligence, since cryptanalysis gave the United States full information on the size and location of the Japanese forces advancing on Midway, enabling the Navy to concentrate a numerically inferior force that otherwise might have been 3,000 miles (5,000 kilometres) away, and thus prepare an ambush that proved to be the turning point in the Pacific war. Admiral Isoroku Yamamoto, the commander-in-chief of the Combined Fleet of the Japanese Navy, was shot down when a highly secret message was solved, giving the itinerary of Yamamoto's plane on a tour of bases in the Solomon Islands. But the most spectacular role of cryptanalysis in World War II was revealed after the war in the hearings held by the joint congressional committee on the investigation of the Pearl Harbor attack. At that time it was made public that, shortly before the war, the United States, in a brilliant stroke of cryptanalysis, had been able to reconstruct the Japanese cipher machine that was used for the highest level diplomatic communications, enabling this traffic to be read throughout the war. It was also revealed that during the war, U.S. cryptanalysts had considerable success in solving other Japanese codes and ciphers. This success led the committee to state that all witnesses familiar with the intelligence produced throughout the war "have testified that it contributed enormously to the defeat of the enemy, greatly shortened the war, and saved many thousands of lives."

**BIBLIOGRAPHY.** The most important and authoritative works on the subject are classified governmental publications, unavailable to the general public. A comprehensive and scholarly bibliography of cryptologic literature covering practically all publicly available books and important papers on the subject is JOSEPH S. GALLAND, *An Historical and Analytical Bibliography of the Literature of Cryptology* (1945). Such a compilation is more helpful to specialists than to the general reader; therefore, a selection of items from the Galland bibliography may be useful. Also, after 1945 a few items of importance were published that should be mentioned. For a detailed history of cryptology, DAVID KAHN, *The Codebreakers* (1967), is outstanding. The best technical works in the public domain are LUIGI SACCO, *Manuale di crittografia*, 3rd ed. (1947); and CHARLES EYRAUD, *Précis de cryptographie moderne* (1953). The best work in English is HELEN F. GAINES, *Cryptanalysis* (1956). Other works are ANDRÉ LANGE and E.A. SOUDART, *Traité de cryptographie* (1925); MARCEL GIVERGE, *Cours de cryptographie* (1925); ANDRÉAS FIGL, *Système des Chiffriers* (1926); ROGER BAUDOUIN, *Éléments de cryptographie* (1939); HERCULES MARTHANS GARRO, *Tratado de criptografia* (1965); ABRAHAM SINKOV, *Elementary Cryptanalysis: A Mathematical Approach* (1968). "Communication with Extraterrestrial Intelligence," *ZEEE Spectrum*, 3:156–163 (1966), contains an extensive discussion on the subject by LAMBROS D. CALLIMACHOS from the point of view of cryptology.

(L.D.C.)

## Crystallization and Crystal Growth

Crystallization is a general term for the process that results in the formation of crystals—solid materials in which the component atoms or molecules are arranged in a definite pattern. Crystal growth, specifically, is the enlargement of crystals at the expense of materials in contact with them.

Even in amorphous, or noncrystalline, solids strong forces usually hold together the constituent atoms, or molecules, which therefore occupy definite positions relative to one another. Except for slight vibrations about

Intelligence  
in the  
Battle of  
Midway

First  
exposition  
of crypt-  
analysis

their normal positions, these component atoms and molecules do not move about. Thus, many amorphous solids, such as glass, have fixed shape, rigidity, and mechanical strength. In crystalline solids, however, the atoms (and molecules) are not only held in place, they also are arranged in a definite order that is constantly repeated throughout the sample.

Crystals  
and  
crystallites

In most crystalline solids, small, individually ordered regions, which are called crystallites, are oriented differently from one another, with the result that the crystalline pattern is repeatedly disarranged; such materials are said to be polycrystalline. In certain rare crystals, such as the gemstones, and in crystals man takes great care to prepare, however, a single ordered region makes up the entire solid object; in such cases a single crystal may range in size from fractions of an inch to a few feet. One of the identifying features of single crystals is that they usually have flat planes or faces that are set at fixed angles to one another. Quartz crystals, and other crystals displaying such regular faces, are most commonly seen in mineralogical collections.

Crystals are formed in many natural processes. Snow flakes, for example, are single crystals and, when the cooling is slow, large, single crystals of ice occur in frozen lakes. When cooling is rapid, however, many small crystals, or crystallites, form, and the solid blocks of ice are polycrystalline. Almost all crystalline solids of nature and commerce are polycrystalline rather than single crystals.

Comparatively slow rates of formation are required to produce large single crystals free of crystallite grains. Other more subtle imperfections occur to some extent in all crystals; these may be missing atoms or vacancies in the crystal structure, or foreign atoms present at sites that should be occupied by the atoms of the material located between the atoms of the material.

Disloca-  
tions

In addition to the above atomic or "point" defects, crystals may have more extensive "line" defects, in which the disorder or dislocation extends along a line or plane of atoms. These are of two principal kinds: edge dislocations and spiral, or screw, dislocations. Figure 1, top, is a representation of an edge dislocation. The imperfection may be thought of as resulting from the addition of an extra plane of atoms,  $ABB'A'$ , in the upper half of the crystal. Because of the added atoms in the upper half of the crystal, this portion is strained by compression; correspondingly, the lower half of the crystal is strained by tension as the fewer number of atoms seek to fill the same volume as that filled in the upper part of the crystal. If the dislocation consists of a gradually increasing shift of alignment between planes (as illustrated in Figure 1, bottom), the imperfection is called a screw dislocation. Dislocations are created when existing crystals are deformed or when new crystals are growing. In fact, dislocations are important in growth mechanisms. Under careful control several materials, including silicon (Si), germanium (Ge), gallium arsenide (GaAs), and quartz (silica,  $\text{SiO}_2$ ), have been grown in the form of crystals free of dislocation, but theoretical considerations require that all crystals have vacancies except at absolute zero temperature (approximately  $-460^\circ\text{F}$ ,  $-273^\circ\text{C}$ ). Indeed, the more rapidly a crystal is grown and the less pure its growth environment, the greater the number and variety of imperfections it acquires. In relatively perfect crystals the misorientation between adjacent grains may be undetectable—that is, the only imperfections are point defects and dislocations—but as the conditions of formation become less favourable, misorientations increase to the point where a polycrystalline mass is the product.

Single  
crystals

Single crystals are important in science because measurements of the fundamental properties of matter in such a highly ordered state are interpreted more easily than when irregularities in structure are present. Impurities that often segregate at the grain boundaries in polycrystalline materials may mask such subtle properties as semiconductivity of electricity. Properties of crystals that depend on the direction through which the crystal measurement is made (such as refraction of light) either are not exhibited in polycrystalline material or are much

harder to interpret. Partly for this reason, single crystals are of especial interest in electronics. Boundaries between grains in polycrystals scatter light to produce opacity, thereby generally making polycrystalline materials unsuitable for applications requiring optical transmission. Similarly, the laser and related devices have created new demands for single crystals for research and applications (see LASER AND MASER). Devices that depend on semiconductivity, such as transistors, utilize single crystals, as do devices such as piezoelectric oscillators and filters, which depend on unsymmetrical distribution of properties (anisotropy) with regard to the crystal structure. Indeed, it is fair to say that the electronics industry could not exist without single crystals. In addition, of course, the intrinsic beauty of natural crystals has fascinated man from prehistoric times to the present and the manufacture of synthetic gemstones is an expanding area of crystal technology.

Figure 1: (Top) Edge dislocation. The planes of atoms in a single crystal are represented as vertical layers.  $AA'$  is the dislocation line and the dislocation can be produced by pushing (shearing) on CDEF while pulling on GCFH. (Bottom) Screw or spiral dislocations.  $AA'$  is the dislocation line. The dislocation can be thought of as having been created by pushing ABCD while pulling AEGF.

All crystals are grown by disturbing a balance, or equilibrium, that exists between the crystalline material and the gas, liquid, or amorphous solid that exists in contact with it. Under the conditions of the equilibrium, the relative amounts of the crystal and the material in contact with it do not change. Disturbing the equilibrium by altering the conditions, such as lowering the temperature in the case of an equilibrium between water and ice, may result in an increase in amount of crystal with respect to the noncrystalline material.

Disturbing  
of equi-  
librium

The material that is crystallizing may be the only substance present in the growth system or other substances may be added to lower the temperature of the system or otherwise alter its properties.

Crystal growth from pure, or monocomponent, systems presents several important advantages and is widely practiced. The purity of the crystals obtained is high, because

no additional components are present to be incorporated during the growth process. Furthermore, the speed of growth can be relatively rapid because, in the absence of additional components, slow movement of the additional components away from the growing crystal surface is not required.

The most common monocomponent growth process is growth by the freezing of a pure liquid, or melt, of the material in question. In contrast to most other growth processes, freezing of a pure melt is uncomplicated and readily controllable; it is probably the most widely practiced commercial growth process. Freezing is also the easiest process in which to consider the distribution of undesired impurities and impurities deliberately added to impart desired properties (dopants) to the crystal. The most important consideration regarding distribution of impurities is whether the crystallization process is conservative or nonconservative. In a conservative process no material is added to or taken from the melt except, of course, for the crystalline material that separates as a result of the freezing process. In a nonconservative process, however, additional material may be melted into the liquid during crystallization, or material may be lost from the melt as, for instance, by evaporation during the process. (For discussion of actual growth methods, see below Preparation of crystals.)

Conser-  
vative and  
noncon-  
servative  
systems

#### THEORETICAL ASPECTS OF CRYSTAL GROWTH

Extensive theoretical work on crystal growth has been conducted, chiefly in the 20th century. One of the most important considerations seems to be the energy released by the attachment of atoms at different sites on a crystal face.

**Energy considerations.** When a new atom is added to a growing crystal, the most probable position for addition will be one that is energetically most favourable. Since energy generally is liberated during bond formation, the most favourable position for adding a new atom will be at the point where the greatest number of bonds to adjacent atoms can be formed, thus providing the most potential energy. Figure 2 may be considered as an example of

**Figure 2:** Positions for the addition of new atoms at the surface of a growing crystal (see text).

a developing crystal structure in which the atoms are identical and are represented as cubes. In this structure, the atoms are closely packed so that each has six nearest neighbours, which touch it on the faces of the cube. In this example, an atom is considered to bond only to its nearest neighbours. The most favourable position for the addition of a new atom, therefore, is at a "hole" in the crystal structure, such as position (1), at which the atom will be surrounded by neighbouring atoms on all sides but one. The next most favourable position is at a "notch" in one step of the crystal structure, such as position (2), in which location the new atom will find four neighbours. Growth at either of these positions, of course, cannot be repeated. The next most favourable position for the addi-

tion of a new atom is at a "kink" in a step, such as position (3), at which the new atom has three neighbours. In this case, the addition process can be repeated until the step in the structure is completed. The next most favourable position for addition is at a jog at the front of a step, position (4), and the least favourable position for addition, based on nearest neighbour considerations, is at a lone site on the surface, position (5).

Complications in the above picture arise in the case of ionic crystals, which are composed of ions carrying opposite electrical charges because, when an ion of a given charge approaches the face, it is attracted by ions of opposite charge while at the same time it is repelled by ions of like charge. Similar considerations apply to crystals composed of molecules bearing separate regions of positive and negative charge.

Ionic  
crystals

The problem of how crystallization begins on an already formed atomically smooth crystal surface is one that has received great attention. As seen in the discussion of Figure 2, the implantation of the first unit of a crystal, a process called nucleation, is energetically less favourable at a new step than at a kink in a step already partially formed. Once a step has grown across the surface, however, nucleation of a new step is required. Quantitative calculations indicate that either large supercooling (cooling far below the melting point) or supersaturation (addition of more of the crystallizable solid to a solution than it can hold) is required for the nucleation of a new step on an atomically smooth surface. Nevertheless, crystals are observed to grow at conditions of low supercooling or low supersaturation, contrary to what might be expected. What is obviously required in such cases is a step in the crystal structure that grows without coming to an end; that is, indefinitely. It was only recently realized that spiral dislocations, of the type pictured in Figure 1 (bottom), supplied locations at which growth could continue without completing the regular crystal structure. Careful observation of crystals grown under different conditions provided an understanding of how such growth took place.

The above energy considerations generally apply to circumstances in which a crystal is grown extremely slowly, so that new material is deposited on the crystal surface strictly in terms of the energy requirements of the system. In most cases, however, the growth of crystals is too rapid to achieve equilibrium, or balance, between the rate of addition to the crystal and rate of removal from it, so that the observed shape of crystals usually depends on the growth rate of the various individual faces. In the 1960s it was shown that the shape, or morphology, of the crystal could be correlated with a property known as the entropy of fusion, entropy being a measure of the loss of energy from an organized system, resulting in an increase of disorder. In particular, it was shown that the entropy of fusion could be used to distinguish four classes of materials: (1) in which growth is equivalent in all directions (isotropic) and cells and dendrites (see below) occur when impurities are added; (2) in which growth occurs as facets, or as faceted dendrites, when sufficient impurity is added; (3) in which facets are always observed; (4) in which growth of spherulites is usual. Cells, or bumps on the surface, result from an instability caused by supercooling. These produce a fairly regular pattern of segregation of impurities within the crystal. Dendrites are crystals with a branched, treelike morphology resulting from growth that is controlled by the rate of diffusion. Facets are flat faces parallel to the crystal planes. Spherulites are oriented spherical masses of crystals. Figure 3 illustrates some of these structures.

fusion

**Constitutional supercooling.** Supercooling that results from concentration changes within the crystallizing system is called constitutional supercooling. Constitutional supercooling is important in the crystallization of all polycrystalline systems and has been much studied, especially in melt systems. When growth takes place in the presence of a very high concentration of impurities, or in a polycrystalline system, there is a buildup of the components that are rejected from the growing crystal interface. Crystallization, therefore, depends on the rate of

Figure 3: Observed morphologies of crystals as related to the values of the entropy of fusion. As the entropy of fusion increases, it is possible to observe (top left) dendrites (carbon tetrabromide), (top right) faceted dendrites (tert-butyl alcohol), (bottom left) facets (benzil), and (bottom right) spherulites (tristearin).

diffusion of the impurities away from the growing crystal surface. If crystal growth is so slow as to be almost at equilibrium, diffusion has ample time to remove impurities, and the effect of diffusion, therefore, is negligible. In many cases, however, the diffusion problem is severe. Figure 4 shows the melting points of the compositions ex-

Figure 4: Relationship between melting point and distance in front of a growing crystal (see text).

isting near a growing crystal as a function of distance (in a system in which diffusion is important). As can be seen, the melting point of the solution decreases as the interface is approached. The broken lines AB and A'B are two different possible temperature gradients in the solution. For the larger gradient, AB, at all positions in front of the interface the temperature is above the melting point (*i.e.*, there is no supercooling); for the smaller

gradient A'B, the region CB is below the melting point; it is supercooled, and crystallization tends to take place in front of the solid interface. The region CB is referred to as constitutionally supercooled, and large temperature gradients, such as can be obtained easily in crystal pulling (see below *Preparation of crystals*), lessen the tendency toward constitutional supercooling. In a crystal growing from a solution in which the liquid is maintained at uniform temperature, supercooling is least near the crystal and increases farther from it. Supercooling should lead to instability of the crystal surface.

A crystal face that has a very slow intrinsic growth rate is not as susceptible to instability as are more rapidly growing faces of the same crystal. The crystal faces that become unstable under these conditions are the fastest growing faces and, as a result, they break up into small segments of more slowly growing faces. Under such conditions, the peaks of some of the facets will be in regions where the supercooling, or supersaturation, is greater than the valleys. The peaks then grow ever more rapidly, with a tendency toward extreme dendritic growth.

**The behaviour of eutectics.** A eutectic is a mixture of two phases that freeze together in a fixed ratio and at a constant temperature. A great variety of structures can be found among eutectics; the common feature, however, is that two phases can always be seen. These two phases usually form a structure in which they alternate by growing around and over each other, starting from a single pair of nuclei. The structures can be broadly classified as regular or irregular. The former includes both layered, or lamellar, structures and rod types, in which one phase is rod-shaped and is imbedded in a continuous matrix of the other. The irregular structures include a variety of complicated intertwinings of the two phases, as well as discontinuous eutectics, in which one phase consists of isolated crystals imbedded in a continuous matrix of the other. If the intrinsic growth rate of the two phases is iso-

Lamellar growth

tropic, eutectics can crystallize in the lamellar form with regular spacing between the lamellae. The boundaries between the lamellae are parallel to the growth direction; that is, lamellae of both phases crystallize at the same time. The lamellar widths are determined by the interaction of two opposing considerations: (1) diffusion of solids must occur over great distances to form thick lamellae, a factor that favours narrow lamellae, and (2) the narrower the lamellae, the more surface energy that is associated with boundaries between the two phases, a factor that favours wide lamellae. Rods occur whenever the volume fraction of one of the phases is small. Many complex and irregular eutectic structures result from unevenly directed growth rates of the two phases.

**Nucleation and impurities.** The formation of a crystal in the absence of a seed involves nucleation, or initiation of a crystalline centre. When nucleation occurs on a surface, such as a wall of the container, or on a foreign body, such as a dust particle, it is called heterogeneous nucleation. If the structure and interatomic spacing of the surface on which heterogeneous nucleation takes place approximate that of the crystal, growth on the surface can resemble growth on a normal seed crystal, a phenomenon called epitaxial growth. When nucleation occurs in the absence of a surface—i.e., in the bulk of a liquid—it is said to be homogeneous.

In some cases, nucleation can be looked upon as the aggregation of particles, and precursors of nuclei large enough to grow are formed by association of particles in the system. If the number of particles in the aggregate and the equilibrium constant for the crystallization reaction are large enough, the nucleus will tend to grow instead of redissolving. Aggregates too small to grow in the average supersaturation in the medium are sometimes called embryos. Most embryos never survive to grow. A few do so, however, because of statistical fluctuations of supersaturation or because energy is added locally to assist their growth (as, for example, when a beaker containing a supersaturated solution is scratched with a stirring rod). The higher the supersaturation, the larger the average embryo size and the greater the chance that statistical fluctuations will allow nucleation. Given enough time, there is a statistical chance that nucleation will occur in any supersaturated medium. In the presence of dust, of course, nucleation is heterogeneous and comparatively easy. Some form of particulate contamination appears to be inevitable in most actual nucleation. The deliberate, controlled addition of impurities is very important in controlling the properties of commercial crystals. In semiconductor crystals the type and degree of conductivity are controlled by the nature and concentration of impurities present.

The basis of most semiconductor devices, such as diodes and transistors, is a junction at which materials of different conductivity type meet. Such junctions are produced: (1) by growing material of one conductivity type and diffusing appropriate impurities into it or (2) by altering the concentration of impurities during growth. Single crystals of high perfection and carefully controlled impurities are the materials over which man has achieved the greatest control of structure and properties at the atomic level.

#### PREPARATION OF CRYSTALS

**Monocomponent methods.** *Liquid-solid.* Growing crystals in systems consisting of only one chemical component present in both the solid and liquid phases can be considered to be conservative or nonconservative depending upon whether the amount of material in the system is or is not altered during the process. Figure 5 illustrates the important conservative and Figure 6 the important nonconservative crystal processes. In a typical example of one of the conservative (the Bridgman-Stockbarger) methods (Figure 5, top), the container is a cylindrical crucible with a conical bottom. The material to be grown is melted in the crucible and lowered through a furnace with a temperature gradient such that the first freezing takes place in the conical tip of the crucible. In the ideal case, one crystallite comes to dominate the

Crystal embryos

Figure 5: Conservative growth processes. (Top) Bridgman-Stockbarger method, (bottom) Czochralski method. From R. Laudise, *The Growth of Single Crystals* (© 1970); Prentice Hall, Inc.

liquid-solid interface and this interface moves through the melt as the crucible is lowered.

Another conservative method is the crystal-pulling (Czochralski) method (Figure 5, bottom), in which a seed is introduced into a melt contained in a crucible arranged so that a temperature level corresponding to the melting

Figure 6: Nonconservative growth processes. (A) Horizontal zone melting using a boat-shaped crucible, (B) vertical zone melting, (C) Verneuil method or flame fusion.

Zone  
melting

point lies just above the liquid surface. The seed is then slowly withdrawn from the melt and growth takes place on it. In a third conservative (Kyropoulos) method a cooled seed is immersed in a melt and the temperature of the melt is lowered to cause growth.

Zone melting is an example of an especially powerful nonconservative process, which is used for purification and for the growth of single crystals. In horizontal zone melting (Figure 6A), the material is held in a boat-shaped crucible and the temperature profile is arranged so that a narrow molten zone is produced. This zone is moved down the crucible rather slowly in order to effect a purification or to grow a crystal. If further purification is required, the zone is re-established at the front end of the crucible and the process is repeated. Seeding may be effected by placing a seed at the front end of the crucible and beginning the zone so as to avoid completely melting the seed. Alternatively, the ingot to be melted can be arranged vertically (Figure 6B). This technique, called float zoning when no container is used for holding the melt, allows purification, homogenization, or growth without crucible contamination. The molten zone is held in place by surface tension. The diameter of the melting ingot and the growing crystal need not be the same.

Another nonconservative method is the flame-fusion process (6C). In this growth technique a molten puddle, which is held in place by surface tension, is produced on the surface of the seed by a flame, or plasma, or by radiant heating from a focussed high-intensity light. Solid particles of the material or molten droplets are added to the puddle.

**Gas-solid.** Gas-solid (or vapour transport) growth in a monocomponent system, a process called sublimation,

is of relatively limited applicability. Gas-solid growth in a polycomponent system (growth by reaction) is, however, a very powerful technique. Both reversible and irreversible reactions may be used.

**Solid-solid.** Growth by means of solid-solid transformation is difficult to control because the density of sites (nuclei) for growth in a solid is so high that growth tends to occur at many places in a transforming solid, with the result that good quality single crystals usually are not obtained. The most generally useful method is strain annealing, a process in which a polycrystalline material is deformed plastically by stretching it and then heating (annealing) the specimen to promote crystal growth as strain is relieved. Transforming an amorphous material to a single crystal by direct conversion from a glassy to a crystalline state (devitrification) is possible, but the high density of nuclei in amorphous materials has so far prevented the use of this method for the growth of crystals.

If a particular material can exist in several different structural modifications (polymorphs), it is often possible to convert a single crystal of one form to the other form by carefully moving the specimen from a region of temperature stability for the one polymorph to that of temperature stability for the other. The geometry and technique is analogous to that used, for instance, in lowering a liquid-solid sample through a temperature gradient (Figure 5, top). Such polymorphic transitions result in twins in the newly formed polymorph, or even in polycrystallinity, when the structures of the two polymorphs are too dissimilar, twins being composite crystals in which the individual parts are related to one another in a definite crystallographic manner. Sometimes appropriately

Figure 7: Solution growth methods.

(A) Glass-jar crystallizer; growth is produced by gradually lowering the temperature of the aqueous solution. (B) Gel growth; growth is by the reaction of the two solutions that diffuse toward one another through the gel medium. (C) Hydrothermal growth; the high-temperature-high-pressure aqueous solution moves by convection to the cooler region where it is supersaturated and growth takes place. (D) Flux growth; growth is produced by gradually lowering the temperature of the molten salt solvent.

applied stresses can be used to "de-twin" samples or convert them to single crystals.

**Polycomponent methods.** *Liquid-solid.* Polycomponent methods are particularly important in growth from liquids, in which the addition of a second component can lower the melting point of refractory material to a point where advantages in ease to growth are obtained. Such growth is ordinarily called growth from solution, and the driving force that makes it possible is supersaturation.

A useful classification of the growth methods can be made on the basis of the procedure used for bringing about supersaturation. It includes both isothermal and non-isothermal methods. The isothermal methods are: (1) solvent evaporation or change in solvent concentration, (2) temperature differential, and (3) chemical or electrochemical reaction. A non-isothermal method is slow cooling. Isothermal methods have an advantage over non-isothermal methods in that the concentration of impurities (or dopants) in the grown crystal is uniform. Non-isothermal methods, however, usually require less elaborate equipment and generally do not utilize such long diffusion paths, so that growth rates can be higher. Temperature-differential methods are capable of producing the largest crystals because, in this case, crystal size is not limited by the solubility of the material being grown.

Another convenient method of classifying solution-growth methods is based on the nature of the solvent used. This may be (1) water at ambient conditions, (2) water at high temperature and pressure (hydrothermal conditions), (3) molten inorganic salts at high temperature (flux) conditions, or (4) other nonaqueous solvents.

Figure 7 shows the various solution growth methods. The most generally used aqueous-solution growth apparatus is the glass-jar crystallizer (Figure 7A). In this apparatus a saturated solution is exposed to suitably mounted seeds and the solution is cooled a few degrees every day to produce growth. The seeds are rotated at the rate of a few revolutions per minute, first in a clockwise direction and then counterclockwise, to aid in mixing and to hasten diffusion.

If the solubility of a material is so low (less than 5–10 percent) that it makes growth by other methods impractical, growth by chemical reaction can be used; for instance, although the salt calcium tartrate is virtually insoluble in water, tartaric acid and calcium chloride are appreciably soluble, and the reaction between them can be used to form crystals of calcium tartrate. Direct mixing of solutions of tartaric acid and calcium chloride, however, inevitably results in such a large local supersaturation that many centres for growth form, and the product will consist of many small crystallites. In a similar reaction, however, solutions of calcium chloride and tartaric acid are allowed to diffuse through a substance called silica gel from the opposite ends of a U-tube (Figure 7B); the region of high supersaturation is localized near the centre of the tube, and a few comparatively large crystals are formed. This method is called gel growth and is quite useful for the growth of insoluble materials by means of a chemical reaction.

Single crystal growth by an electrochemical reaction, although little used, in principle also could be an important means of preparing certain crystals. Careful control of voltage and current, for example, could be used to grow single crystals of metals on an appropriate single-crystal seed electrode.

Under hydrothermal conditions the increased solvent power of water at high temperatures is used to dissolve refractory materials. The water is heated in a high-pressure autoclave where it expands and fills the vessel (Figure 7C). Depending on the temperature and on the percent of the free volume of the autoclave initially filled with water, the pressure can range from a few hundred to many thousand atmospheres. The solvent power of water can be increased further by the use of "complexers"—substances that react with the material to be crystallized in such a way as to form soluble complexes.

In flux growth a molten salt is used as the solvent (Figure 7D). Generally, flux growth is carried out in the absence of deliberately added seeds. Initial nucleation oc-

curs spontaneously when an appropriate saturation is reached in the cooling cycle, and these nuclei provide the centres for further growth.

*Gas-solid and solid-solid.* Gas-phase polycomponent growth has been referred to above (see *Monocomponent growth*). Solid-solid polycomponent growth (by solid-state precipitation) is difficult to control because of the high density of nuclei in solids, and it is slow because solid-state diffusion is slow. As a result, the process has not been used.

*Vapour-liquid-solid.* Vapour-liquid-solid growth makes use of a gas-phase reaction for the transport of material to a liquid solvent. The material dissolves in the liquid solvent, supersaturates it, and deposition takes place by a transformation from liquid to the crystal.

The choice of growth method. An important problem in crystal growth is the choice of the most suitable growth method. Generally, monocomponent methods are to be preferred because of their comparative rapidity and simplicity. In them, growth rate is limited essentially only by the rapidity with which the heat produced by crystallization can be dissipated. The purity of crystals grown in monocomponent systems is high, because the growth system does not contain additional components to contaminate the grown crystal. If the temperature required for melting or sublimation is too high, however, additional components must be added to produce growth from solution or by vapour-phase reaction. The reasons for growing crystals at lower temperatures include: (1) avoidance of undesired high-temperature polymorphs, (2) elimination of decomposition or irregular melting behaviour, (3) elimination of high vapour pressure, which would be present at the melting point, and (4) convenience of operation. When an additional component is added to make possible lower operating temperature, however, the rate of growth usually must be reduced, in order to accommodate diffusion of the growth component to, and the additional component from, the growing interface. If the additional component has appreciable solubility in the growing crystal, its inclusion may become a problem.

## Crystallography

The word crystal stems from the Greek word *krystallos*, meaning "clear ice." It was first applied to the clear crystals of quartz found in the Swiss Alps, because these were thought to be formed from water under conditions of intense cold. Such crystals actually reflect a highly symmetric and periodic internal arrangement of atoms; this is characteristic of all crystalline materials—metals, alloys, minerals, ceramics, and some organic materials. Crystallography is the science of crystals and of the crystalline state. It is concerned with the nature of the regular atomic or molecular arrangements within a crystal, the bonding of the atoms or molecules, and the physical and chemical properties that result from certain arrangements. Many rows and planes of atoms occur within a crystal, for example, and some rows (and planes) exhibit equal spacing of atoms in different directions, whereas others do not. Because the atomic arrangement is generally different in different directions, properties

such as elasticity or light transmission commonly depend on direction.

Crystallography is also concerned with atomic arrangements in amorphous materials, liquids, gases, and the structure of living matter and the stresses in metals. All forms of atomic arrangements are in the crystallographic domain; and patterns, arrays, and symmetry in general have fascinated thinkers down through the centuries. Interest initially was most keenly concerned with crystals, and Johannes Kepler wrote a monograph for one of his patrons on the symmetry of snowflakes in 1611. The versatile 17th-century British natural scientist Robert Hooke wrote:

There was not any regular Figure, which I have hitherto met withal, of metals, minerals, precious stones, salts and earths, that I could not with the composition of bullets or globules, and one or two other bodies, imitate even almost by shaking them together.

This article treats the classification, symmetry, and structure of crystals, including the determination of crystal structure by X-ray diffraction methods. It also includes a section on imperfections and crystal defects. For further information on the important properties of crystalline materials, see those articles treating properties—*e.g.*, MAGNETISM OR ELASTICITY and the theoretical articles CHEMICAL BONDING and SOLID STATE OF MATTER. See also METALS, THEORY OF and MINERALS for insight into some applications of crystallography and the article CRYSTALLIZATION AND CRYSTAL GROWTH for coverage of the formation of crystals from solution.

#### THE PATTERNS OF ATOMS IN CRYSTALS

One of the first activities undertaken by those interested in natural crystals was an attempt to classify their shapes. This was not easy because even crystals of the same compound may fail to resemble one another; the difference in shape results from different degrees of development of the several faces. In 1671 the Danish physician Nicolaus Steno took the first grand step in this field. He cut sections from a quartz crystal and discovered that, even when the shapes were vastly different, there was a constancy of interfacial angles (the angles formed by normals or perpendiculars from crystal faces). For this reason it is common practice to use "normals" drawn perpendicular to crystal faces to represent the relationship between faces. This can be accomplished by stereographic projection as shown in Figure 1. The intersection of normals with an imaginary sphere surrounding the crystal (Figure 1A) is represented on the two-dimensional map (Figure 1B) of the shaded plane. The high degree of symmetry present is evident.

Crystal planes and their notation. In the late 18th century the idea that a large crystal could be built of a basic unit or building block took hold. This block is now known to be the unit cell—the smallest group of atoms within a crystal that will yield the crystal structure and properties by simple repetition of pattern. This arrangement is indicated in two dimensions in Figure 2, in which two planes of atoms perpendicular to the page are shown by the dark lines. Such planes will appear perfectly flat to the eye (rather than composed of a series of steps) because the building blocks are very small, about  $10^{-9}$  to  $10^{-10}$  metre on an edge. The angle formed by the plane on the right is  $45^\circ$  with the horizontal plane. Note that it is not possible to have just any angle; a plane must contain atoms in the structure, and the intercepts on the edges of the crystal are ratios of whole numbers of blocks. The intercepts of the plane on the left and the horizontal plane have a ratio 1:2 and the angle involved is  $26'34''$ .

A simple notation for naming planes has developed based on the fact that the intercepts of planes on the edges of the crystal's unit blocks are ratios of whole numbers. A basic unit cell or block is assumed, and three non-coplanar edges ( $a_1$ ,  $a_2$ ,  $a_3$ ) are defined as unit lengths in Figure 3. These need not be equal in all directions. The intercepts of planes on these edges are written as

$$\frac{a_1}{h}, \frac{a_2}{k}, \frac{a_3}{l}.$$

Thus, if a plane intercepts the axes at their tips,

$$\frac{a_1}{h} = \frac{a_1}{1}, \frac{a_2}{k} = \frac{a_2}{1}, \frac{a_3}{l} = \frac{a_3}{1},$$

and (111) is the designation. If the intercepts are  $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$ , then  $h, k, l$  are 2, 2, 2. Common factors are cleared and the designation is still (111)—because all such planes are parallel and have identical atomic arrangements in the structure (Figure 3E). If a plane intercepts one axis at unit distance and is parallel to the other axes, as in Fig-

From E.E. Wahlgren, *Optical Crystallography* (1951); John Wiley and Sons, Inc.

Figure 1: A two-dimensional representation (stereographic projection) of a crystal and its symmetry that can be obtained by surrounding the crystal with a sphere, erecting perpendiculars to the planes until they intersect the sphere as in A, and then projecting these intersections through the shaded circle of the sphere. The appearance is then as in B. This process eliminates the shapes of the planes and their relative sizes, which depend on growth conditions and can confuse the similarity of crystals.

ure 3D, then two integers will be zero—for example, (001) in this case.

From F.C. Phillips, *An Introduction to Crystallography*, 2nd ed. (1956); Longman Group Ltd.

Figure 2: Two planes of atoms in a crystal represented by their edges (dark lines). Note that these make intercepts that are whole numbers along the edges of the cells or building blocks.

**Symmetry considerations.** Rotation of  $90^\circ$  around the centre of the map of normals to planes in Figure 1B leads to the same figure as before the rotation, as does rotation of  $180^\circ$ ,  $270^\circ$ , or  $360^\circ$ . This rotation is generally de-

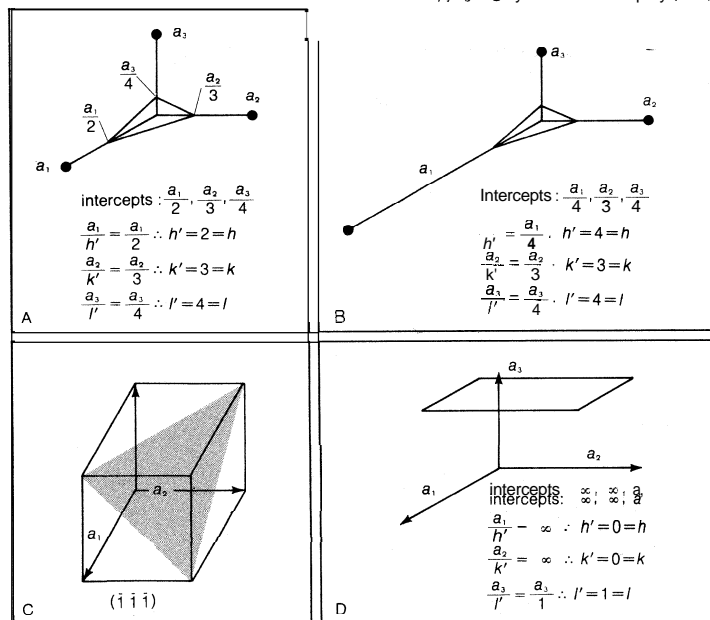

Figure 3: Some examples of planes in a crystal and the notation of their intercepts. The edges of the unit cell are defined by  $a_1$ ,  $a_2$ , and  $a_3$  (see text).

scribed by the number  $n$ , by which  $360^\circ$  (a complete turn) is divided. In this case  $360^\circ/n = 90^\circ$ , so that  $n$  is 4, and then this apparent rotational symmetry axis is thus called "4-fold." To return to the starting point after  $n$  rotations, it is then necessary that  $n$  be an integer. In examining

many natural crystals,  $n$  has been found to have values of 1, 2, 3, 4, or 6; sometimes several of these values are found to be present in one crystal. But the values are never 5 or 7, although certain flowers and starfish are excellent examples of these symmetries. In order to understand the reason such values are excluded in crystals, it is necessary to ask more precisely what results from periodic arrangements of atoms. One-dimensional arrays are easiest to consider, and the different ways a one-dimensional molecule can be periodically arranged in one dimension provides a suitable example.

A periodic set of crosses, as shown below, is first set down as a frame of reference; this imaginary collection is called a lattice.

+ + + + +

The actual spacing of the crosses is not important because it is the kinds of arrangements that need to be considered, not their sizes. The entire array can be constructed after one point and the spacing between the points are designated. This basic framework—a point and the spacing to the next point—is called a unit cell, and in one dimension there is obviously just one such cell. If a molecule (represented by a dot-dash) is placed within this framework, two arrangements may be considered, as follows:

(1) + · — + · — + · — + · —

(2) + · — — · + — — · + — — · + — —

In the second lattice the "molecules" are arranged at each lattice point, so that one molecule leads to another after rotation of  $180^\circ$  around an axis normal to the paper (at the crosses or halfway between them). This is called 2-fold rotation because repetition occurs twice in one complete ( $360^\circ$ ) rotation. There are two molecules per lattice point. A mirror can also be imagined at these locations, with the molecules related by reflection through the mirror. Two reflections yield the original molecule. This indicates that the interaction of symmetry leads to some redundancy—one symmetry element produces another; rotational symmetry at lattice points produces rotational symmetry between-lattice points, as well as the mirrors, but only one symmetry element or type is required to describe the figure. Only the unit cell and its contents are needed to produce the entire structure by translation, although the unit cell in lattice (2) contains two molecules.

Another possible pattern is the following:

(3) + · — — — + · — — — + · — — — + · — — —

But this is really not different from pattern (1); the unit in each cell is just longer—three molecules long. It might appear that there is rotational symmetry about an axis between  $a$  and  $b$ , but  $c$  would not be carried into  $d$  by the rotation. This is not a symmetry element of the whole structure. Hence the requirement of periodicity leads to only two patterns in one dimension. In these periodic structures, examination of some point within the structure, a lattice point, or any point on a molecule, reveals the same surroundings at every such point in every unit cell.

The entire array is called a space group, and the symmetry about a point is called a point group. There are one unit cell, two point groups, and two space groups in one dimension. Compact notations have been developed for these in one, two, or three dimensions and will be considered shortly. Symmetry in two and three dimensions will be treated first, however. Symmetry at a point in two dimensions involves the question: How many ways can a molecule be arranged periodically about a lattice point? Ways without any symmetry are also included because a 1-fold rotation axis produces this effect—i.e., the entire crystal will exhibit no symmetry at all. Arrangements that do include some symmetry are shown in Figure 4, in which a stick hand has been chosen as a general figure for two dimensions because it has no symmetry of its own. Hands A and C are related by  $180^\circ$ , or 2-fold rotation, and A and B are related by reflection through the

Rotational axes of symmetry

Symmetry in two and three dimensions

Figure 4: A set of stick hands arranged symmetrically around a point. Both mirror and rotational symmetries are present. The first relates **A** and **B** through  $m_1$ . The second relates **A** and **C**; the axis is normal to the page and is represented by the oval (see text).

imaginary mirror plane  $m_1$  perpendicular to the page. But **A** and **C** could also be related by reflections through  $m_1$  and then through  $m_2$ . A rotation of  $180^\circ$  and reflection still retain some equivalence, as in one dimension, but there is no way to get **B** from **A** except by reflection.

Another symmetry element has arisen at the intersection of the two mirror planes; figures **A** and **C** are related by inversion through this point of intersection. That is, **C** can be obtained from **A** by drawing lines from every point on **A**, through the intersection, over an equal distance on the other side of the intersection. In two dimensions then, **C** can be produced by starting with **A** and rotating  $180^\circ$ , or by inversion. The presence of one of these symmetry elements leads to the other. Inserting  $m_1$

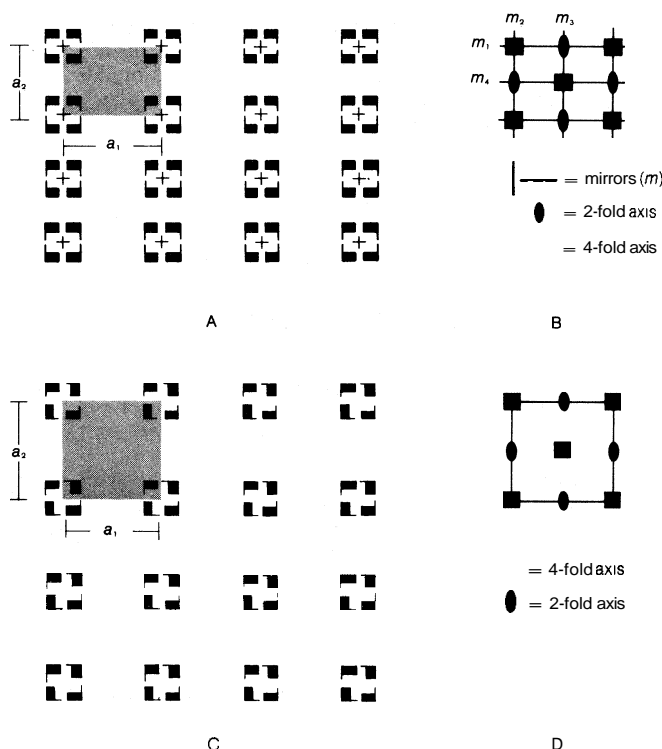

Figure 5: Two-dimensional space groups in which a unit cell is shaded (**A** and **C**). At each lattice point there are four molecules (flags). These are related by two perpendicular mirror planes,  $m_1$ ,  $m_2$  in **A** but additional symmetry arises, such as  $m_3$ ,  $m_1$  and 2-fold and 4-fold rotational axes normal to the paper (**B**).

and  $180^\circ$  rotation leads to all four hands and, in turn, to two other symmetry elements ( $m_2$  and an inversion centre) that were not needed in the construction. The mirror plane  $m_2$  leads to nothing new in terms of the pattern produced by  $m_1$  and  $180^\circ$  rotational symmetry, for example.

A periodic array, or space group, is shown in two dimensions in Figure 5A. A flag is employed to represent a two-dimensional molecule; one unit cell is shaded and contains four such molecules. To create the entire periodic array, the lengths of the two sides of the unit cell,  $a_1$  and  $a_2$ , and the angle ( $\alpha$ ) between them are required. One cell can then be constructed and translated in the directions of  $a_1$  and  $a_2$  to fill all space. If one molecule is placed near each lattice point and if each lattice point has two perpendicular mirrors, then the four molecules at each lattice point result, together with the additional symmetry elements shown in Figure 5B. Another arrangement, involving a  $90^\circ$  rotational axis without mirrors, is shown in Figure 5C.

It is clear that any axis of rotational symmetry in a crystal must be  $360^\circ/n$ , in which  $n$  is an integer, because to have periodicity at a point there must be a return to the original figure after  $n$  rotations. The reason that  $n$  is restricted to 1, 2, 3, 4, 6 in a crystal, excluding 5 or 7, becomes clear with the aid of Figure 6. Assume that there is a rotational axis, with rotation  $\alpha^\circ$  at each lattice point. Not only must all molecules or atoms around any lattice point be related by rotation of  $\alpha^\circ$  around this axis, but also this must be true for all points in the entire structure; otherwise, the symmetry would relate only to molecules at one point and not to the entire crystal. The lattice point itself must be carried by rotation to another lattice point; this preserves the internal periodicity and the external symmetry.

Figure 6: Rotational symmetry in crystals: rotation of  $\alpha$  around lattice point 1 must bring lattice point 2 into coincidence with some other point; the same is true for 4, around 3. If not, as shown here, the periodicity, and hence the external symmetry, is destroyed (see text).

In Figure 6,  $m$  is an integer and the relation between the distances  $a_1$ ,  $b$ , and the angle of rotation,  $\alpha$ , can be expressed by the equation:  $b = ma_1 = a_1 + 2a_1 \cos \alpha$ , or

$$\cos \alpha = \frac{m-1}{2} = \frac{M}{2} \quad (1)$$

in which  $M$  must be an integer if  $m$  is an integer. The cosine of an angle cannot exceed plus or minus unity; and with  $M$  an integer the possible values for the cosine are 0, plus or minus  $1/2$ , plus or minus 1. For  $\cos \alpha$  to be zero,  $\alpha$  must be  $90^\circ$  ( $n = 4$ ). Furthermore, for this 4-fold rotation axis, any side  $a_2$  must equal  $a_1$ , because after a  $90^\circ$  rotation  $a_2$  must coincide with  $a_1$ . The cell must be square—it cannot be a rectangle. The other allowable values for the cosine correspond to 1-fold, 2-fold, 3-fold, and 6-fold rotations and to two other shapes, or unit cells, a rhombus and a parallelogram. It is possible to have a molecule with 5-fold symmetry—like a 5-pointed star—at each lattice point, but the symmetry of the entire structure will not be 5-fold; similarly, 7-fold symmetry is prohibited.

Combined operations—other than just rotation, reflection, inversion, and translation—are also periodic in two dimensions. A glide, for example, is a combined opera-

Impossibility of 5-fold or 7-fold symmetry

Combined symmetry operations

tion in which the molecule is related to another by translation followed by reflection; the translation is half the spacing between lattice points, and thus two glides produce the same appearance at each lattice point. Proceeding from one lattice point to another, a molecule is seen in left-handed orientation, one halfway between lattice points is in a right-handed orientation, and at the next lattice point the original left-handed orientation appears. Other possible combined operations in two dimensions, such as rotation followed by reflection or rotation followed by translation, give rise to figures which are equivalent to rotation alone or to combinations of rotation plus reflection at each lattice point. It is possible to show that there are only 17 two-dimensional patterns or space groups and only ten point groups that are consistent with periodicity.

In three dimensions, two new kinds of arrangements of symmetry become possible. It is possible to have three rotation axes intersecting at a point in certain combinations, and axes can be combinations of rotation and translation called screws, as shown in Figure 7. As with glide,

Figure 7: Symmetry associated with screw axes. (A) Two lattice points in a structure with three molecules rotated by  $120^\circ$  around each; the whole group at the bottom is translated to every other lattice point (like the one at the top) by the periodicity of the crystal. (B) Periodicity can also be obtained with screwlike motions (rotation plus translation along the rotation axis) where there is only one molecule at each lattice point; each molecule is related to the other molecules by a  $120^\circ$  rotation and a translation of  $1/3$  the distance between lattice points. Triangular symbols at the top represent rotational and screw axes in A and B, respectively.

this operation in a crystal must bring a molecule to a definite location and orientation near a lattice point in every cell. This serves to limit the possible types or pitches of the screws.

Displacements of planes of atoms or molecules that result from screw axes in natural crystals are approximately equal to the magnitude of atomic spacing—i.e.,  $10^{-10}$  metre or one angstrom (Å). The effect, therefore, is indistinguishable from pure rotation to the naked eye, as shown in Figure 8.

Seven crystal systems and 14 unique unit cells arise, as shown in Figure 9. There are 32 point groups and 230 possible structures based on atomic position. Other arrangements can arise if such properties as the magnetic moment are considered, but the number of unique periodic arrangements is still finite.

**Optical determinations.** Optical techniques can be quite useful in the study of crystals of transparent materials, because only in cubic crystals does light travel at the same velocity in all directions. In a tetragonal structure, for example, light is broken into two rays for any direction of propagation other than that of the 4-fold axis. These rays travel at different velocities and vibrate in different planes. If light is transmitted through a sheet of Polaroid, which only allows passage of light vibrating in one plane (direction), then rotation of the crystal will lead to elimination of one ray when its plane of vibration is perpendicular to the vibrations passing through the Polaroid sheet. If another piece of Polaroid is placed over the crystal and turned  $90^\circ$ , the light passing through the crystal cannot pass this second sheet. Every turn of the crystal by  $90^\circ$  produces this extinction, but between these positions the crystal is visible. If a thin slice of the crystal is examined between crossed polarizing lenses along the

The seven crystal systems

4-fold axis, this splitting does not occur, and the crystal is always dark. This procedure can help distinguish the presence of a unique axis of symmetry. If a screw axis is present the position of the two Polaroids for extinction varies with the thickness of the crystal. Glide cannot be detected in this way, however.

#### SCATTERING OF RADIATION FROM CRYSTALS

In 1912 Max von Laue, an instructor at the University of Munich who was well versed in optics, particularly in the diffraction of light from ruled gratings, became intrigued with the question of what would happen when radiation with a wavelength equal to the spacing of the atoms in a solid was scattered from the atoms. Light scattering could not reveal atomic structure because atomic spacings are  $10^{-10}$  metre, whereas light has a wavelength  $10^{-7}$  metre. Laue thought, however, that scattering of radiation from a row of atoms in a crystal (if the wavelength of the radiation was the same size as the atomic spacing) would produce interference patterns. In a three-dimensional crystal, there are rows in three directions and, hence, such patterns in three directions. Only at their points of intersection will all the waves be in phase, and a set of dark spots should occur on a film placed in front of a small crystal when an X-ray beam impinges on it. It was not known whether X-rays had the proper wavelength, but Laue persisted in his experiment, and he succeeded on his second try. Laue and his associates demonstrated the existence of a new tool for examining the internal arrangements of atoms in crystals and proved that X-rays behave as electromagnetic waves (like light) but with a shorter wavelength.

Bragg's law and crystal structure. Laue's group had difficulties in understanding which planes of atoms and wavelengths produced the spots on the film. In England, Sir Lawrence Bragg was in his mid-twenties and finishing his studies in physics. His father was involved in research on the ionization of gases by X-rays, and it was quite natural for them to discuss Laue's exciting new result. The young Sir Lawrence was able to formulate a simpler and more physical understanding of Laue's discovery. The scattered waves from successive planes of atoms reinforce one another at certain angles if the path difference between rays from the two planes is a multiple ( $n$ ) of the wavelength. As shown in Figure 10, this construction

Relation of wavelength and angle of incidence

Figure 10: Incident rays (1 and 2) at angle  $\theta$  on planes of atoms in a crystal. Rays will reinforce if their difference in path ( $AB + BC$ ) is an integer times the wavelength (see text)

leads to a simple equation for diffractions or constructive interference. For diffraction the path difference,  $AB + BC$ , is equal to an integer times the wavelength, or  $n\lambda$ . But by simple trigonometry,  $AB = BC = d \sin \theta$ , and thus Bragg's law is derived:  $2d \sin \theta = n\lambda$ . As  $n$  increases from 1 to 2 to 3, etc., so does the scattering angle  $\theta$ . Each plane, for each  $n$ , selects in effect the appropriate wavelength from the X-ray beam (which must consist of many wavelengths). This selection depends on the angle of the

plane of atoms to the X-ray beam. With this formulation, Bragg was able to explain successfully all the spots from Laue's patterns from different planes of atoms. He then tried bouncing an X-ray beam from a crystal in reflection, as from a mirror, catching the scattering on a film. This was more like his formulation, and sharp increases in intensity were recorded at certain angles.

Bragg's law permits the atomic structure in crystals to be unravelled. If another set of planes is inserted at half the  $d$  spacing of the planes in Figure 10 and if these planes contain the same kind of atoms, then the prevailing conditions are as shown in Figure 11. If the angle em-

Figure 11: Reinforcement and cancellation of incident rays. (A) X-ray beams 1 and 2 are one wavelength difference in path; beam 3 to a plane at half the spacing is half a wavelength different in path with respect to 1, is thus out of phase, and cancels it. Similarly, beam 4 cancels beam 2, etc. (B) The angle of X-ray beam to crystal has been changed so that all rays are in phase and reinforce one another.

ployed is that for first-order diffraction without these additional planes—i.e.,  $n = 1$  in Bragg's law—then the path difference between rays 1 and 2 is one wavelength (Figure 11A). But the path difference between rays 1 and 3 (to the inserted plane) is half a wavelength. The scattered waves 1 and 3 are out of phase, and their sum is zero; thus, the reflection is extinct. When  $n = 2$  (Figure 11B) the scattering from the inserted plane differs in path length from plane 1 by one wavelength, and all planes are in phase. The second reflection is present and is even stronger than if there were no inserted plane because there are more planes (atoms) contributing. Reflections are labelled by multiplying the Miller ( $hkl$ ) indices by  $n$ . Thus, a second order ( $n = 2$ ) reflection from (100) planes is labelled (200). Bragg's law is rewritten:

$$\lambda = \frac{2d}{n} \sin \theta, \quad (2)$$

and these (200) planes have half the spacing of the (100) planes.

These simple ideas provided the solution of many inorganic structures almost immediately. Consider a cubic crystal with one of the three possible arrangements of atoms shown in Figure 9A and assume that there is only a single wavelength for the incident radiation. The spacing of planes ( $d$ ) in terms of the length of the edge of the unit cell ( $a$ ) and the indices of the reflection planes ( $hkl$ ) can be expressed:

$$d = \frac{a}{\sqrt{h^2 + k^2 + l^2}}. \quad (3)$$

Thus, Bragg's law can be restated by substituting this value of  $d$  as:

$$\lambda = \frac{2a}{\sqrt{h^2 + k^2 + l^2}} \sin \theta. \quad (4)$$

Now  $\lambda$  is a known, fixed quantity, and the larger the values of  $h, k, l$ , the larger the angle  $\theta$ . As shown in Figure 12, a face-centred structure contains (100) planes halfway between the faces of the cube. Thus, there will not be a (100) reflection as there would be for a cube with atoms only at corners; instead there will be a (200) reflection of larger intensity. The (100) reflection would also be missing for a cube with atoms at the corners and in the centre of the cube, however. How can

Determination of a cubic structure

Figure 12: Various planes in (A) face-centred cube, (B) simple cube, and (C) body-centred cube. Note that there are planes of atoms halfway between cube faces in A and C but not in B. Similarly there are (110) planes in A halfway between those in B and C, and in C there is a (111) plane containing the atom at the cube's centre halfway between those in A and B.

the proper choice of structure be made? The (110) planes for the face-centred cubic crystal, simple cube, and body-centred cube also are shown in Figure 12. Because planes halfway between these occur only in the first case, a (110) reflection will not occur from the face-centred structure but, rather, from a simple cube or a body-centred cube. If the first reflection from the cube faces of a natural crystal is obtained, then  $a$  can be calculated from equation (4) above and the angle of the observed reflection,  $\theta$ . Then  $\theta$  can be calculated for the (110) planes from the same equation. The crystal can then be rotated  $45^\circ$  to get a reflection from these (110) planes, because the (110) planes are  $45^\circ$  from the (100) planes. If the crystal actually is face-centred cubic, then the first reflection from the cube face was really a (200), not a (100). If this were not known, then the calculated value of  $a$  from Bragg's law would be half as large as that of the real unit cell. If this incorrect value of  $a$  is used to calculate the  $\theta$  position for the (110) reflection, the value obtained would actually be where a (220) reflection occurred, but this would not be known. If, however, the crystal were body-centred, the lowest angle reflection would be for a (110) reflection, which would be at a lower angle than calculated. Recalculation assuming that the first peak is a (200) reflection would give a correct value for  $a$ , from which the correct angle of the (110) reflection could be calculated. If this does not occur, then the crystal must be face-centred or simple cubic. Considering the (111) planes in the same way would distinguish these cases. If the atoms on these "in-between" planes are of a different species, a reflection will not be missing, only weakened. Scattering from different kinds of atoms is different, and the scattered waves do not exactly have the same heights, thus these waves cannot completely cancel the way the equal waves did in Figure 11.

The general method involved in such crystallographic detective work is repeated comparison of experiment and calculation for the angles and intensities of the various reflections. In this manner, it is possible to sort out some of the simpler structures. As the structures examined become more complex—involving in some cases thousands of atoms per unit cell—these simpler procedures provide

only limited information. The progress of crystallography from the 1920s consisted of developing in detail systematic methods of sorting out the diffraction pattern. The process divides itself naturally into two parts. First, it is necessary to find all the diffraction spots (and to identify which ones are missing); and, second, it is necessary to record the intensity of these spots and devise procedures for interpreting these.

Certain general information can be obtained from the indices of planes reflecting and not reflecting. If atoms are arranged with a face-centred cubic unit cell, for example, the only reflections that will appear are those with  $h, k, l$  all even or all odd. The (111), (200), and (220) reflections occur, but not the (100) and (110). Furthermore, the positions of reflections can be calculated with a single parameter, the edge of the unit cell. Other unit cells express themselves differently. Certain symmetry elements give rise to specific absences of reflections. A glide plane halves the spacing of planes perpendicular to it, and this requires  $h$  to be even for a reflection; for  $h$  odd, the molecules on the plane at half the spacing cancel the reflection. Such rules are tabulated for different symmetries and the different structures for easy reference. Those symmetries that are hard to detect from visual examination of a crystal—glides and screws—are revealed easily at this stage of a study. One way to determine which reflections are present and which are absent is to systematically tilt a crystal on a diffractometer and hunt for these. From the external appearance of the crystal it is often possible to decide if it is a cubic structure or one of the other crystal systems. It is then possible to choose dimensions for the cell edges that would give the measured reflection angles and to decide on the indices of reflections present and those that are extinct. If the crystal is orthorhombic (see Figure 9), for example, then the  $a_1, a_2, a_3$  axes (but not their lengths) can generally be assigned from the shape of the crystal. Then it is possible to mount the crystal to get the (100) or (010) or (001) reflections. It is known that the relation between the spacing of planes ( $d$ ), the indices of the reflections ( $h, k, l$ ), and the lengths of the edges of the unit cell ( $a_1, a_2, a_3$ ) for orthorhombic crystals can be expressed:

$$\frac{1}{d^2} = \frac{h^2}{a_1^2} + \frac{k^2}{a_2^2} + \frac{l^2}{a_3^2} \quad (5)$$

Substituting for  $d$  in Bragg's law then yields:

$$\lambda = 2\sqrt{\left(\frac{h^2}{a_1^2} + \frac{k^2}{a_2^2} + \frac{l^2}{a_3^2}\right)} \sin \theta \quad (6)$$

The (100), (200), (300), or (400) reflection will permit determination of  $a_1$ ;  $a_2$  is obtained from (010), (020), (030), or (040); and  $a_3$  from (001), (002), (003), or (004). These calculated values can then be tested in computing  $\theta$  for other reflections, to decide whether a reflection was (100), or (200), etc., and to decide on absences. A more common procedure, though, is to surround the crystal with film, to catch many reflections at once while continually moving the crystal, and then to examine the pattern for dimensions and shape of the unit cell and missing reflections.

**The powder method.** It is not always possible to obtain single crystals of suitable size and perfection for structural studies with X-rays or neutrons. This is the major problem in extending structural studies to enzymes and other biological molecules. It is far easier to obtain powders. Also, most engineering materials, such as steel and ceramics, are polycrystalline; that is, they are composed of many small crystals or grains that are held together across their faces by bonding. The way in which a diffraction pattern can be obtained from a random array of such grains or particles is illustrated in Figure 13. Uniform cones of diffracted intensity are produced instead of the spots characteristic of single crystals. An adequate specimen can be prepared by coating a hair with an adhesive and dipping it into the powder, which is, in effect, a randomly oriented array of crystals. A camera lens about 60 mm (2.4 inches) in diameter yields patterns of

Missing reflections

Com-  
mercial  
importance

lines in a few minutes; they are recorded on a thin film wrapped in a cylinder around the sample to intersect the diffracted rays. Such patterns are quite useful in solving simple structures. Also, the spacing and intensity of the lines are characteristic of the material doing the scattering—just like a fingerprint. A file of more than 21,000 patterns is available, and the routine use of these for identification of unknown specimens constitutes one of the major uses of X-ray diffraction. One interesting field for this method stems from the fact that paint pigments contain

Figure 13: X-rays directed on a powder sample diffracting from the same planes in different grains. Because these planes are oriented differently in each grain, the result is a continuous cone of scattering at each diffraction angle. The continuous cones of diffracted radiation produce patterns of characteristic lines on a strip of film in a cylinder wrapped around the specimen.

crystalline materials, as do glazes. The composition of these has changed over the years with the art of paint manufacture, and it is sometimes possible to detect a forged art object from the diffraction patterns of the sample or to trace an automobile from a streak of its paint left after an accident.

By exploring the entire cones of scattering, it is possible to learn how random a specimen actually is. This can be very important in controlling properties, because these depend on direction in a single crystal. Processing of a polycrystalline material is often adjusted in order to provide a certain deviation from complete randomness as an aid in obtaining desired properties in certain directions.

#### IMPERFECTIONS IN CRYSTALLINE MATERIALS

Most crystalline materials are not perfectly regular. Accidents in growth lead to imperfections. Common among these are vacant lattice sites (vacancies) and missing parts of planes of atoms, as shown in Figure 14. Mechanical and electrical properties can be highly dependent on the number and arrangement of such imperfections. None of these defects can be seen with the naked eye or with an optical microscope, although in many cases they can be observed with an electron microscope. The presence of defects was first postulated by investigators to explain certain properties of materials long before they were seen.

Arrangement of defects. If the defects have a regular arrangement on an atomic scale, these can give rise to extra peaks in the diffraction pattern from which their arrangement can be discovered. As an example, there are whole groups of oxide compounds whose specific compositions can be understood as due to a regular arrangement of blocks of simpler structures with defects between the blocks.

If the defect arrangement is less regular but the defects are still numerous, there will be no sharp X-ray lines from the arrangement; but, instead, weak extra scattering of a variety of forms may be found between Bragg peaks, or the peaks may broaden or shift in position. A great deal is being learned from this extra scattering about the density and arrangement of such defects in materials and how they change with treatment, essentially from mathematical analyses of the effect of various defects on diffraction and comparisons of the calculations with experimen-

tal patterns. In fact, it is even possible to learn a great deal about amorphous materials from diffraction. Local atomic arrangements or groupings in which there is only a tendency toward certain arrangements at short intra-atomic distances are adequate to cause fluctuations in scattered intensity. The structure of glass consists of linked  $\text{SiO}_4$  tetrahedra—that is, tetrahedra with silicon at the centre of each tetrahedron and oxygen at the corners. These corners are shared by two tetrahedra to hold the

Diffraction  
studies of  
amor-  
phous  
materials

Figure 14: Defects in a crystal caused by accidents of growth. (top) A missing atom, or vacancy. (bottom) A plane that does not pass entirely through the crystal; this dislocation leads to distortions of neighbouring planes.

structure together. This arrangement is similar to, but less periodic than, the structure of crystalline silica, as indicated from the analysis of scattering from amorphous glass. Considerable progress in understanding amorphous structures is expected in the near future because of increasing interest in amorphous materials. Glasses and also certain semiconductors and many plastics are amorphous.

Observation by electron microscopy and X-ray methods. Many materials have a sufficiently low density of defects to make attractive an exciting new expression of diffraction. With the electrons in modern electron microscopes operating at 50,000 to 1,000,000 volts, it is possible to penetrate foils of materials about 1000 angstroms and make pictures at magnifications of 1,000,000 times. Such foils can be prepared by electropolishing. The wavelengths of the electrons at these voltages are about 0.01 angstrom (the value depends on the voltage of the microscope). The diffraction angles, from Bragg's law, are very small, approximating one degree. Small tilts near an imperfection, such as the dislocation in Figure 14, can bring a group of planes into the proper orientation for diffraction. The diffracted beam is blocked, but the unscattered beam passes through an aperture. A dark line appears in the position of the dislocation on a fluorescent screen which is illuminated by the electrons to form the image. It is also possible to heat, cool, or deform the specimen in the microscope and observe the change in number and arrangement of defects, as well as their interaction.

With X-rays, quite similar pictures can be taken. One advantage of this approach is that it can be employed in reflection on thick specimens rather than on the foils needed for an electron microscope. One major disadvantage, however, is that the pictures are not taken at any enlargement. Photographic enlargement of the best of films is possible up to only about 200 times. Because this is far removed from the magnification of an electron

microscope, the density of defects must be much lower to resolve them. The principle of the method for the longer wavelength X-rays is also somewhat different. On scattering from a plane, there is a  $90^\circ$  phase change of the scattered wave compared to the incident wave. If a region is nearly perfect, the diffracted beam will rescatter back in the direction of the incident beam before leaving the crystal, but the  $90^\circ$  change in phase a second time leads to a total change of  $180^\circ$ ; this twice-scattered beam is thus out of phase with the incident beam and reduces it, lessening its penetration into the specimen. This effect reduces the diffracted intensity in two ways. First, less material "sees" the incident beam; and, second, some of the diffracted beam is rescattered. In the vicinity of an imperfection, less of this occurs, and the scattered intensity is larger than for the perfect regions, making a darker region on a film placed above the specimen.

Such techniques are of great importance in the semiconductor industry because the good electrical properties of these devices require low defect densities. The entire industry, in fact, is built on the ability to produce in quantity highly perfect crystals of such elements as silicon—a triumph for the modern science of materials.

*Texts on crystal structure, morphology, optical techniques, and properties:* E.A. WOOD, *Crystals and Light* (1964); ALAN HOLDEN and PHYLIS SINGER, *Crystals and Crystal Growing* (1960); E.E. WAHLSTROM, *Optical Crystallography*, 3rd ed. (1960); J.F. NYE, *Physical Properties of Crystals* (1957); M.J. BUEGER, *Introduction to Crystal Geometry* (1971); and F.C. PHILLIPS, *An Introduction to Crystallography*, 4th ed. (1972). The first two books are stimulating nonmathematical introductions; the last two are excellent accounts of crystallography with a minimum amount of mathematics.

*Basic texts on diffraction:* B.D. CULLITY, *Elements of X-Ray Diffraction* (1956), is an excellent introduction to diffraction, requiring a minimum of mathematics. It is particularly good for information on techniques not associated with structure determination. Four basic texts that require more advanced knowledge of mathematics are J.B. COHEN, *Diffraction Methods in Materials Science* (1966); L.V. AZAROFF, *Elements of X-Ray Crystallography* (1968); M.M. WOOLFSON, *An Introduction to X-Ray Crystallography* (1970); and H. LIPSON and C.A. TAYLOR, *Fourier Transforms and X-Ray Diffraction* (1958).

*Sources of information on specific structure and other data on crystalline materials:* W.L. BRAGG and G.F. CLARINGBULL, *Crystal Structures of Minerals* (1965); and C.S. BARRETT and T.B. MASSALSKI, *Structure of Metals*, 3rd ed. (1966), are excellent up-to-date summaries of the techniques and results of crystallographic studies on metals and alloys. The *International Tables for X-Ray Crystallography*, 3 vol. (1952–62), constitutes a compendium of brief descriptions of all techniques and theory in crystallography and diffraction with many references. Excellent tables and pictures of space groups are included.

*Texts on effects of imperfections on diffraction:* ANDRÉ GUINIER, *Théorie et technique de la radiocristallographie*, 2nd ed. (1956; rev. Eng. trans., *X-Ray Diffraction in Crystals, Imperfect Crystals, and Amorphous Bodies*, 1963); BÉ. WARREN, *X-Ray Diffraction* (1969).

*History of crystallography:* P.P. EWALD (ed.), *Fifty Years of X-Ray Diffraction* (1962), celebrating the 50th anniversary of Laue's discovery of diffraction, contains excellent histories of various aspects of the subject and personal reminiscences by many of the key people in the field. JOHN C. KENDREW, *The Thread of Life* (1966), presents an excellent non-technical account of structural studies on biological molecules.

(J.B.Co.)

## Ctenophora

Ctenophores, frequently called sea walnuts, sea gooseberries, cat's eyes, or comb jellies, are common inhabitants of the seas. Though they are, for the most part, of small size, at least one Mediterranean species, the Venus' girdle, may attain a length of one metre. One parasitic species is only three millimetres in diameter. Some ctenophores live in somewhat brackish water, but all are confined to marine habitats. They live in almost all ocean regions, but particularly in surface waters near shores. *At least two species (*Pleurobrachia pileus* and *Beroë cucumis*) are cosmopolitan, but most have a more restricted*

distribution. When abundant in a region they consume most of the young of fish, larval crabs, clams, and oysters, as well as copepods and other planktonic animals that would otherwise serve as food for such commercial fish as sardines and herring. In turn, however, ctenophores are themselves consumed by certain fish.

**Natural history.** A single ctenophore produces both eggs and sperms. The sex cells, earlier believed to be emitted through the mouth, are actually released by partial rupture of the meridional canals and the body covering over these canals (see below *Form and Function*). Only the highly specialized creeping species (order *Platyctenea*) have special gonoducts. Fertilization and embryonic development occur in the water. In *Pleurobrachia* and in other *Cydropida*, development is direct; there is no larval stage. More highly evolved ctenophores have a so-called cydippid larva that is similar in structure to the *Cydropida* adult. The cydippid larva undergoes metamorphosis to form the adult. Only in the parasitic *Gastrodia* has a free-swimming planula larva comparable to that of the coelenterates been reported.

Frequently comb jellies occur in vast swarms, especially in bays, lagoons, and other coastal waters. Except for a few creeping and parasitic species, comb jellies float freely suspended in the water, where they are important members of the plankton (see *PLANKTON*). Except for one parasitic species, all of them are carnivorous, devouring myriads of other small planktonic animals.

Some species are so extremely delicate that they are difficult to collect and preserve intact. Such forms avoid destruction in storms by descending from the surface into deeper waters.

**Form and function.** Most ctenophores are colourless, although *Beroë cucumis* is pink and the Venus' girdle (*Cestum veneris*) is delicate violet. The colourless species

Diversity among ctenophores.

are as transparent as glass, so that, except for their beautifully iridescent rows of comb plates, they are nearly invisible when suspended in the water.

Most of the 80-odd known species are spherical or oval, with a conspicuous sense organ (the statocyst) at one end (aboral) of the body and a mouth at the other end (oral). Typically, eight rows of comb plates (or ctenes) extend orally from the vicinity of the statocyst. These serve as organs of locomotion. The comb plates are rows of very large, fused cilia. When they beat, the effective stroke is toward the statocyst, so that the animal normally swims oral end first. The more primitive forms (order Cydippida) have a pair of long, branched tentacles that function in the capture of food. These are completely retractile into recessed tentacle sheaths. The tentacles are richly supplied with peculiar lasso cells (or colloblasts), found only among ctenophores. Lasso cells produce a sticky secretion, to which prey organisms adhere on contact.

The mouth leads into a wide pharynx, from the aboral end of which arises a complex, branched series of canals that form the digestive tract. Since this structure serves both digestive and circulatory functions, it is designated a gastrovascular cavity. There is no true anus; the central canal opens toward the aboral end by two small pores, through which a small amount of egestion can take place.

Gonads develop as thickenings of the lining of the digestive canals. The nervous system is a primitive nerve network, somewhat more concentrated beneath the eight rows of comb plates. It is similar to the coelenterate nervous system. There is no trace of an excretory system.

As in coelenterates, the outside of the body is covered by a thin layer of ectodermal cells, which also line the pharynx. A second thin layer of cells, constituting the endoderm, lines the gastrovascular cavity. Between the ectoderm and the endoderm is a thick gelatinous layer, the mesoglea. Because it contains not only many mesenchymal cells (or unspecialized connective tissue) but also specialized cells (*e.g.*, muscle cells), the mesoglea forms a true mesoderm. In this respect the comb jellies are more highly evolved than even the most complex coelenterates.

Most of the comb jellies are bioluminescent; they exhibit nocturnal displays of bluish or greenish light that are among the most brilliant and beautiful known in the animal kingdom. The bioluminescence begins only after the animals have been in the dark for at least 20 minutes; the ability to luminesce is terminated by exposure to light (see BIOLUMINESCENCE).

**Taxonomy and evolution.** The primitive order Cydippida, of which *Pleurobrachia* is a representative, has a pair of well-developed tentacles. In the order Lobata (which includes *Bolinopsis* and *Mnemiopsis*) the tentacles are greatly reduced and the oral lobes greatly enlarged. The body is somewhat flattened laterally. In the order Cestida the body is greatly extended, forming a thin band. Tentacles are very small in the adults. The cestids include the Venus' girdle mentioned earlier. The order Beroidea (*Beroë*) has no tentacles in the adult, the rows of comb plates are short, and the digestive canals are highly branched. The greatest modifications from primitive conditions occur in members of the order Platyctenea, in which the body is orally-aborally flattened, and the adults (*e.g.*, *Coeloplana*) creep around on solid surfaces.

The relationship of ctenophores to other animals has caused much speculation. Formerly they were considered to be a class or subphylum of the phylum Coelenterata (or Cnidaria). Although some textbooks still maintain this classification, most modern authorities separate Ctenophora as an independent phylum. The separation is based upon (1) the lack of the characteristic stinging cells (cnidoblasts) of coelenterates, (2) the existence of a definite mesoderm in the ctenophores, and (3) fundamental differences in embryological development between the two phyla.

It is, however, generally conceded that ctenophores and

coelenterates were derived from the same evolutionary stem. This is indicated by (1) the primitive radial or biradial organization of the body in both groups, (2) the extensive development of mesoglea between the ectoderm and the endoderm, and (3) the existence of a planula larva (characteristic of the coelenterates) in the ctenophore *Gastrodrea*.

The body shape of creeping species of Platyctenea has suggested to some authorities that the ctenophores are transitional forms lying between coelenterates and turbellarian flatworms (*Platyhelminthes*). Although there is a certain superficial resemblance between the body of the Platyctenea and that of free-living flatworms, as well as some similarities in certain aspects of their embryonic development, many fundamental differences between them make it improbable that the ctenophores lie directly in a coelenterate-platyhelminth line of evolution. It is more likely that both turbellarian flatworms and the creeping ctenophores have evolved by parallel evolution from completely different ancestors.

## Cuba

Territorially, the Republic of Cuba comprises the Cuban archipelago, a formation of no fewer than 3,715 islands, islets, and cays with a combined area of 42,827 square miles (110,922 square kilometres). The archipelago is situated near the geographical centre of the New World landmass, just south of the Tropic of Cancer at the entrance to the Gulf of Mexico, and forms an important segment of the Greater Antilles island chain, which continues east and then south in a great arc enclosing the Caribbean Sea. The island of Cuba itself—the "pearl of the Antilles"—is the largest island in the chain, covering 40,543 square miles (105,007 square kilometres). In general, the island runs from northwest to southeast and is long and narrow—777 miles (1,250 kilometres) long but only 119 miles (191 kilometres) across at its widest and 19 miles (31 kilometres) at its narrowest point. From Maisi lighthouse on the eastern tip, Haiti, the nearest neighbouring country, is visible 48 miles away across the Windward Passage. Jamaica, 87 miles to the south, is also visible on a clear day. The United States is about 90 miles to the north across the Straits of Florida.

The Isla de Pinos (Isle of Pines, now often called the Isle of Youth because of an influx of young settlers) is the second largest in the archipelago (849 square miles), rising to the southwest of Cuba itself. Other island and shoal groups are Los Colorados, to the northwest; the Archipiélago de Sabana-Camagüey, off the north central coast; the Jardines de la Reina (Queen's Gardens), off the southeast coast; and the Archipiélago de los Canarreos (technically including the Isla de Pinos), along the southwest coast.

Because of its geographical location and natural resources, Cuba was coveted by more than one foreign power over the centuries. A colony of Spain after its discovery by Columbus in 1492, it formally became a republic at the beginning of the 20th century, although its independent status was qualified by a high degree of political and economic dependence on the United States. On New Year's Day, 1959, the republic entered a new era with the victory of revolutionary forces led by Fidel Castro.

Cuban archipelago

Body covering

Relationship to coelenterates

This article deals with contemporary Cuba. For history see CUBA, HISTORY OF, and LATIN AMERICA AND THE CARIBBEAN, COLONIAL; see also HAVANA.

#### THE LAND

**The natural environment.** Topography. Mountains cover about a quarter of the total area of the island of Cuba, often interrupted by the extensive plains that cover some two-thirds of the surface. The coastal basins of Santiago de Cuba and Guantánamo lie in the extreme east; a great central valley also begins in the east and then combines with a peneplain, continuing westward across the entire island. It is these plains that have been hospitable to the raising of sugarcane and livestock.

The alturas—regions of moderate elevation—are in some cases residues of formerly higher surfaces. More rugged relief includes the Guaniguanico range in the west, comprising the Sierra de los Órganos and the Sierra del Rosario, which attains 2,270 feet (692 metres) at El Pan de Guajabón; the Sierra de Trinidad in the central region, with the 3,793-foot (1,156-metre) Pico San Juan; and the Sierra Maestra, more than 100 miles long, that rises abruptly from the southeast coast and contains the island's highest peaks, with Pico Turquino, at 6,476 feet (1,974 metres), pre-eminent.

Cuba possesses an irregular 3,570-mile (5,746-kilometre) coastline, made picturesque by the many bays, sandy beaches, mangrove plantations, swamps, coral reefs, and rugged cliffs. There are also some spectacular caverns in the interior, notably the Ensenada Don Tombs (Santo Tombs) of the Quemado ridge region, which has a linear extension of 16 miles. The 40,543 square miles of the island of Cuba are surrounded by a submerged platform that is an additional 30,000 square miles (70,000 square kilometres) in area; hence sea depths surrounding the island are no greater than about 650 feet (200 metres), dropping abruptly away at the outer edges of the platform.

**Drainage and soils.** Cuba's excellent supply of groundwater is utilized intensively throughout the island but especially in La Habana province. The rivers are generally short, with very meagre flow; of 563 watercourses classified as rivers, 236 discharge to the north, the remainder to the south.

The island's heaviest rainfall and therefore its largest rivers are in the southeast, where the Cauto (at 230 miles the country's longest) and its tributaries, notably the Salado, drain the Sierra Maestra and the uplands to the north. Other major rivers in this region include the Guantánamo, Sagua de Tánamo, Toa, and Mayari. Proceeding westward, the most important rivers flowing south are the Sevilla, Najasa, San Pedro (of Camagüey), Jatibonico del Sur, Zaza, Agabama, Arimao, Hondo, and Cuyaguatje; north, the Saramaguacón, Caonao, Sagua la Grande, and La Palma.

Cuban lakes are small and more properly classified as freshwater or saltwater lagoons. The latter include the 26-square-mile Laguna de Leche (Milky Lagoon), which is technically a sound, as it is connected to the sea by three natural channels. Sea movements generate disturbances in the calcium carbonate bottom deposits to produce the milky appearance.

The complicated Cuban topography and geology have produced soils of no fewer than 13 different major groups, the majority of which are fertile, in good physical condition, and amenable to year-round cultivation.

**Climate.** Cuba lies in the tropic zone, located on the southwestern periphery of the North Atlantic High atmospheric pressure zone and hence influenced by the Northeast Trade Winds in winter and east-northeast winds in summer. The warm currents that later form the Gulf Stream are a year-round ameliorating influence along the coasts.

Annual mean temperature is 77.9° F (25.5° C), with little variation between January (at 72.5° F [22.5° C] the coolest month) and August (the warmest month, at 82.0° F [27.8° C]). The November–April dry season abruptly changes to the rainy May–October season. Annual rainfall averages 54 inches (1,380 millimetres). Between June

and October, the country often is exposed to hurricanes, whose strong winds (up to 163 miles per hour) and heavy rains (up to 12 inches in a 24-hour period) have occasioned great economic damage and human suffering. In the western and central parts of the island, cold fronts occasionally induce precipitation even during the dry season.

**Plant and animal life.** Cuba's tropical plant life is very rich, with some 8,000 species represented, 6,000 of them "higher"; half of these are endemic. Much of the original vegetation has been replaced by sugarcane, coffee, and rice plantations, made possible by enormous and indiscriminate destruction of forests. The revolutionary government introduced extensive reforestation for both economic and conservation reasons, and official policy is to cover 20 percent of the island with forests. Significant planting is being carried out in Guane, in Pinar del Río province, and in Pinares de Mayari, in the north of Holguín province.

Cuban timber is of excellent quality. Pine is found in abundance, and the durable mahogany is of great economic importance, while ebony (*Diospyros*) and grana-dillo (cocus, or West Indian ebony; *Brya ebenus*) are both beautiful and valuable. The royal palm, of which there are more than 20,000,000 specimens, reaching heights of 50 to 75 feet (15 to 23 metres), is the national tree and a characteristic element of the rural landscape. The ceiba (kapok) tree plays a role in many legends, while the extremely rare cork palm (*Microcycas calocoma*) of the western regions is a "living fossil" thought to have survived since the Cretaceous Period, more than 100,000,000 years ago.

Fruit trees include such citrus varieties as lemon, orange, and grapefruit; some species of the genus *Annona*, including the *guanábana* (soursop) and *anón* (sweetsop); and avocado and papaya. Banana plants are also common. The lower Cuban coasts and the shoals of the archipelago are lent marked character by the mangrove, and the tobacco plant is valued for its product and as an ornamental.

Cuban animal life is extraordinary in its abundance and variety, particularly the invertebrate species. The archipelago is the home of more than 7,000 insect species and 4,000 species of land, river, and sea mollusks. Sponges (the basis of an industry) are important off the southwestern coast, and edible crustaceans abound. The similarly profuse Arachnida include the tarantula and scorpion. Fish (more than 500 edible species) are economically the most important vertebrate group, and there are 37 shark species. There are far fewer freshwater fishes.

Cuba is visited by many migratory birds, and only a third of the 300 or so species found on the island are typically Cuban; these include the flamingo, royal thrush, nightingale, mockingbird, and hummingbird.

Reptiles are distributed equally among sea, river, and dry land species. Marine species include the tortoise and hawksbill turtle; mud turtles inhabit the rivers; the marshes contain two species of crocodile (formerly almost extinct but now the object of a repopulation program); and land reptiles include the iguana and the non-poisonous *majá* de Santa María (*Epicrates angulifer*), Cuba's largest snake. Amphibians are similarly varied, with 60 frog and toad species, the former including the plantain frog (*Hyla septentrionalis*) and bullfrog. The solenodon (*Atopogale cubana*), an almost extinct, ratlike insectivore, is found only in the remotest eastern regions. Other mammals include the hutia (an edible rodent) and the manatee, or sea cow, which inhabits river mouths. Bats (30 species) destroy mosquitoes as well as insects harmful to agriculture and in their roosting caves produce accumulations of guano that is valuable as fertilizer.

**The human imprint.** The various areas of Cuba do not differ greatly in customs and traditions, making a clear regional division on this basis difficult. The eastern end of the island (provinces of Guantánamo, Santiago de Cuba, Las Tunas, Granma, and Holguín)—with its own speech patterns, music, and customs, resulting from regional isolation—is an exception. A more significant division might be that between city and countryside,

Mountain regions and the coastline

Invertebrates

Temperatures

especially between the dominant Havana metropolitan area and the rest of the country, a pattern of unequal development repeated on a much smaller scale in the various provincial capitals.

The homogeneity of Cuban society has been increased since the revolution of the 1950s by the emphasis placed by the government on the development of communications and on rural growth. Given these qualifications, a division of Cuba into five natural regions—Occidental (Western), Central, Camagüey-Maniabón, Oriental (Eastern), and Pínera (the Isla de Pinos, or Isle of Pines)—is still possible on the basis of natural endowment and human exploitation. Cuban specialists have made a further subdivision into 45 subregions and 38 physiographic zones.

**The Occidental region.** The largest of Cuban regions, the Occidental region is 332 miles (535 kilometres) long and includes the provinces of Pinar del Río, La Habana (Havana), Matanzas, and parts of Villa Clara and Cienfuegos. Its topography is notable for the *mogotes*, unusually shaped elevated hummocks, although it is primarily composed of an enormous plain that occupies its entire southern section. The 110-mile-long Cordillera de Guaniguanico and the serpentine highlands of northern and central La Habana and Matanzas provinces lend further character to the region. The Occidental region contains nearly 42 percent of the country's population and also Havana, the major Cuban economic, cultural, and administrative centre. The regional economy is based on agriculture (some of the best tobacco in the world, citrus fruits, sugarcane, cattle, rice, and coffee), copper and iron mining, and fishing.

**The Central region.** Central region extends from the Manacas plain (west of the city of Santa Clara) to the

Ciego de Avila plain in Ciego de Avila province and consists primarily of the Trinidad and Sancti Spiritus highlands and lesser uplands, interspersed with plains and boggy regions in the province of Sancti Spiritus. It also includes the Archipelago de Sabana-Camagüey.

The major Cuban tobacco-growing area, the Central region also produces sugarcane, cattle, citrus fruits, and coffee as well as marble, copper, iron, and limestone. Industrial activity in the region is varied, and petroleum exploration continues.

**The Camagüey-Maniabón region.** The Camagüey-Maniabón region, Cuba's main stock-raising area, centres on an ancient peneplain that extends over central Camagüey province and northwestern Las Tunas province between the Trinidad, Sancti Spiritus, and Maniabón highlands. Other economic activities include a major emphasis on sugarcane, cultivation of rice and grains, mining of chromium, and processing of cement, fertilizer, and gypsum.

**The Oriental region.** At the eastern tip of the main island, the provinces of Las Tunas, Granma, Holguín, Santiago de Cuba, and Guantánamo have the nation's highest mountains, fastest streams, richest mines, and most spectacular bays. The Sierra Maestra rises along the southern coastline, the Sierra de Nipe on the north, and between them lies the economically important Valle Central, its easternmost portion rising to the Sagua-Baracoa highlands, covered by the most extensive forests in Cuba. The region contains nickel reserves and also produces chromium, iron, copper, and manganese as well as sugarcane and other agricultural items; its industrial centres process minerals and food and generate electric power.

**The Pínera region.** The largest and most beautiful of

the islands surrounding the main island of Cuba, the *Isla de Pinos*, dotted with groves of pine and palm, has sand and clay plains in the north and hills in both the north-west and southeast; nearly 40 percent of the island, however, is taken up by the gravel bed in the south and by the bogs of the coasts and uninhabited interior. At one time sparsely populated, it had by the mid-1970s a population approaching 40,000, mostly young people whose migration was sponsored by the government. They are employed in fruit growing, stock raising, and fishing, as well as in small industries and in the mining of marble and kaolin.

THE PEOPLE

**Ethnic origins and national composition.** For more than four centuries diverse ethnic groups have been settling in Cuba. Not only Africans and Spaniards (the predominant elements) but also Chinese, European Jews, and Yucatecans have all superimposed their cultural and social characteristics on those of the earliest settlers. Contemporary Cuban society exhibits a remarkable diversity as a result.

**The indigenous heritage.** Cuba's original inhabitants came to the island from South America. They were the Guanahatabey and the Ciboney, the former living in the extreme west of the island of Cuba, the latter in various places in the island and particularly on the cays to the south. Both were hunter-gatherers. The Taino, who arrived later and who spread over not only Cuba but also the rest of the Greater Antilles and the Bahamas, lived in villages and had rudimentary agriculture; they also made simple pottery. The Taino constituted 70 to 80 percent of the island's population at the time of the Spanish conquest.

In 1511 the total indigenous population was estimated at between 80,000 and 100,000, very unequally distributed, with density decreasing westward. Half a century after the Spanish invasion, however, only about 4,000 scattered individuals remained. Harsh treatment by the invaders, hard labour in the gold mines, hunger resulting from low agricultural productivity, and contagious diseases introduced by Europeans had all taken their toll. A few families with Taino physical characteristics living in the Sierra del Purial of easternmost Cuba are perhaps the only surviving descendants.

**The African heritage.** The Spaniards soon imported African slaves (more than 800,000 in all, most of them for work on the sugar plantations) as a substitute for the rapidly disappearing Indians. The Africans came mainly from Senegal and the Guinea Coast, with diverse origins including Yoruba and Bantu tribal backgrounds. Between 1919 and 1926, some 250,000 black Antillean labourers, 90 percent from Haiti and Jamaica, arrived under labour contract; nearly all remained. The cultural influence of blacks has been considerable, especially in music and dance.

According to the census of 1899, 14.9 percent of Cubans were black and 17.2 percent mestizo (or mixed). By 1943—largely as a result of heavy white immigration—the proportions had dropped to 9.7 and 15.6 percent, respectively. By 1953, however, following a dramatic decrease in black death rates after World War II, accompanied by a continued high birth rate, the proportions had changed again to 12.4 and 14.5 percent. In contemporary Cuba, using more refined anthropological criteria, it may be estimated that about 45 percent of the population is either mestizo or black. With the removal of historic discrimination barriers, mixed marriages are tending to increase, and black racial identity is being lost in the general movement toward an integrated society.

**The European heritage.** White Cubans are almost entirely of Spanish origin. The white population rose from 66.9 percent of the total in 1899 to 74.3 percent in 1943; almost 1,000,000 Spaniards and Canary Islanders immigrated between 1900 and 1929. By 1953, however, the percentage had dropped to 72.8.

Throughout Cuban history, the dominant classes were recruited primarily from the Europeans and their descendants, white and mestizo (the latter being of particular

importance in the 20th century), who monopolized not only the direction of the economy but also access to education and culture.

**The Asian heritage.** In order to supplement the interrupted slave trade, the Hispano-Cuban landholders imported 125,000 indentured Chinese labourers, nearly all of them Cantonese, between 1853 and 1874, to work under contract for eight years. Bad living conditions reduced their numbers to 14,000 by the census of 1899. In the 1920s an additional 30,000 Cantonese and small groups of Japanese also arrived; both immigrations were exclusively male, and there was rapid intermarriage with white, black, and mestizo populations. In contemporary Cuba, the remaining Chinese element is aged and near extinction.

**Language and religion.** Spanish is the Cuban national language; there are no local dialects, although the diversity of ethnic origins has influenced speech patterns. Some words are of native Indian origin, and a few (such as *hamaca* ["hammock"]) have passed into other languages. Africans have also enriched the vocabulary and contributed the soft, somewhat nasal accent and the rhythmic intonation that distinguish contemporary Cuban speech.

Religions in Cuba include Roman Catholicism, Santería (a cult devoted to certain African divinities formally identified with Catholic saints), and a number of Protestant and other groups. In the early 1960s, church and state confronted one another with open hostility, the church seeing the revolutionary government as anti-religious (one aspect of this being the nationalization of all schools) and the government seeing the church (the largest mass organization in the country) as a repository of counter-revolution. Many priests and nuns, and some Protestant clergy, left the country; others were deported. By 1965, however, the church, with a clergy drastically reduced in number, and the government entered upon a period of better cooperation.

*Provincial areas exclude certain portions of the national territory (totalling 1,379 sq mi [3,571 sq km], approximately the area of outlying islands and cays). †Population figure for Havana is an estimate made in 1975; for this reason the total population figure disagrees with the 1970 population figure given in the text. ‡Special municipality administered by the central government. §First total includes areas under the administration of the province named; second total includes all areas under national sovereignty.   Detail may not add to total given because of rounding.			

**Demographic trends.** The 8,569,100 Cubans recorded in the census of 1970 represented a 47 percent increase over the figure in 1953 and a 2.16 percent annual geometric intercensal growth (compared with 2.09 percent in 1943–53 and 1.58 percent in 1931–43). Taking into account the fact that the pre-1953 national migration balance was always positive and that since 1953 the balance has tended to be negative (*i.e.*, there are more emigrants than immigrants, especially during 1959–73 when an estimated 600,000 persons left the country), it may be deduced that the population increase in 1953–70 was attributable to changes in birth and death rates. After

making further allowances for the change in Cuba's socio-economic structure after 1959 (which both broadened the social services available to the general population and simultaneously reduced demographic under-registration), it can be concluded that there has been an increase in the actual birth rate, coupled with a decrease in the death rate. By the mid-1970s, per 1,000 of population, these rates were 20.7 and 5.4 (compared with 36.9 and about 6.5 in 1962), respectively, according to the government's statisticians. Former areas of Oriente (the most populous) and Pinar del Río provinces have the highest birth rates, while La Habana province—the most densely populated—has the lowest.

In the 1953–70 period the age distribution of the population also changed, with a broadening of the base and the top of the age pyramid. Thus, the percentages in the 0–4 years, 5–9 years, and over 64 age categories were 12.6, 12.2, and 4.2 in 1953 but 13.5, 13.7, and 5.8 in 1970.

The most dramatic change, however, has been in internal migration trends. The former drain from the countryside to the slums of the Havana metropolitan area (paralleling the trend in many developing countries) has been halted by government planning, which calls for a more diversified net movement outward from the regions with high birth rates (area of the former provinces of Oriente and Pinar del Río) to all the other provinces, which now have actual net inward movements.

#### THE ECONOMY

**The pre-revolutionary economy.** The revolutionary authorities inherited an economy that was essentially agrarian and was widely held to be characterized by extensive production (*i.e.*, the utilization of large areas of land with minimal outlay and labour), by emphasis on a single crop, and by the presence of latifundios, large landed estates. These basic traits, the revolutionary government decided, had to be eliminated before any serious effort could be made to transform the essentially underdeveloped country. Two agrarian reform laws (1959 and 1963) made the state, by the 1970s, the owner of 70–80 percent of all farmland. Small-scale farmers were permitted to retain their farms, and many tenant farmers were given title to the land they had worked. With state control established over the former North American- and Cuban-owned latifundios, Cuban authorities initiated, through investment of resources and effort, a substantial modification of agriculture.

The structure of Cuban industry (especially the sugar sector) likewise was not in harmony with the new economic development plans. At the time of the revolution, industry was extremely dependent on foreign commerce, while foreign investments (notably of North American capital) were covering more than 50 percent of its costs. The structural deformations in the economy induced by this dependence were also evident in the prospects for future industrial development, which were then limited to those branches using domestic sugar, nickel, and tobacco resources.

During the 1960s the Cuban authorities devoted every effort to removing the dependence on Western capital. In 1972 a series of major agreements was concluded with the Soviet Union, postponing until 1986 repayment of an accumulated debt estimated at more than \$3,000,000,000 U.S.; payments would be spread over 25 years without additional interest. The agreements covered a further loan of some \$350,000,000 for industrial development and guaranteed prices for Cuban sugar and nickel.

**The extent and distribution of resources.** Cuban soil is very fertile, allowing for up to two crops a year, but agriculture was traditionally plagued by the unreliability of the annual rainfall. During 1959–75 dams with a total water-holding capacity of 139,600,000,000 cubic feet (3,950,000,000 cubic metres) were constructed, and it was hoped that the water-shortage problem finally was solved. Subterranean waters are an important additional resource for both agriculture and industry. Tractors and cane-gathering machines were imported, and there was an average of one tractor per 113 cultivated acres by 1973.

The search for new petroleum deposits continues; production in 1974 was only 167,968 metric tons, and the greater part of domestic needs is met by imports. Peat, concentrated in the Peninsula de Zapata, is still the most extensive fuel reserve. Nickel, cobalt, and iron are the most important minerals, the laterite (iron ore) beds in Holguín province having world significance. There are also major chromite, magnetite, manganese, and copper reserves and lesser amounts of lead, zinc, gold, silver, and tungsten. Abundant limestone, rock salt, gypsum, and dolomite reserves and large kaolin and marble beds are also found on the Isle of Pines.

Fishing resources (there are 500 different species of edible fish) are localized in four zones around the major shoal and island groups bordering the island of Cuba.

**Resource exploitation and sources of national income.** Agriculture and fishing. The most important agricultural crop is sugarcane. Between 1970 and 1974, production ranged between 44,000,000 and 80,000,000 tons annually. Vast areas have been levelled and brought under irrigation, thus greatly expanding the acreage in sugarcane, and yields per acre have been greatly increased with the application of ever larger amounts of fertilizers. Introduction of the Australian mowing system is expected to diminish the use of hand labour.

The number of cattle was increased by cessation of slaughter of reproducing cows, by irrigation projects that added to available pasture, by artificial insemination, and by expanded veterinary services. Crossbreeding was also very important, the aim being to produce acclimatized meat and milk producers. Thus Brahman (or Zebu) cattle, the dominant breed (resistant to tropical climate but low in milk yield), were crossed with Holsteins (productive but prone to illness in the Cuban environment) and also with Brown Swiss.

Apart from sugarcane, the chief agricultural products are rice (the main source of calories in the traditional diet) and citrus fruits. Tobacco, traditionally the country's second crop, is grown mainly in the Pinar del Río area in the west and also in the centre of the island. Other products include bananas, coffee, pineapples, sweet potatoes, potatoes, and beans. It is necessary, however, to import large amounts of food (especially grain) and oil-seeds and cotton.

Between 1958 and 1974 the Cuban fishing catch increased sevenfold, and it continues to increase, largely as a result of heavy investment in fishing vessels.

**Industry.** Processing of food and sugar are the two most important sectors of Cuba's domestic industry, and sugar is by far the most important export earner. In 1969–70, Cuba's record year (when personnel and resources from other areas of the economy were diverted to the sugarcane fields for the harvest), 8,537,600 metric tons of centrifugal sugar were produced. A combination of prolonged drought and dropping world prices led Cuban planners to try to develop more diversified sources of industrial income in the late 1970s. Other important industrial products include cement, electric power, machinery (linked to agricultural needs), food and beverages, tobacco, cigars and cigarettes, paper, fertilizers, textiles, and footwear.

The volume of expenditure on construction has increased in recent years, the portion spent on servicing (rather than on new projects) having fallen from two-thirds to a third of the total over the 1960s.

**Trade patterns.** In 1958 some 70 percent of Cuban imports came from the United States. By 1961 this was down to 4 percent, and it soon dropped to zero under United States government blockade measures. Communist bloc countries now account for between 65 and 70 percent of Cuban import and export totals. Import composition, too, has changed: production equipment accounts for about a fifth of the total, while food and live animals account for nearly a quarter. Principal exports include sugar (crude and refined and molasses), nickel, tobacco (especially the cigars for which Cuba is famous), fish, and coffee.

**Management of the economy.** The Cuban economy is centrally directed in accordance with a national plan

Internal  
migration

dence on  
foreign  
commerce

The  
national  
planning  
mechanism

worked up by the government under guidelines laid down by the directorate of the Partido Comunista de Cuba (PCC; Communist Party of Cuba). Practically all economic activities are state run, a small private sector existing only in agriculture. The institutional economic structure consists of the Central Planning Board (Junta Central de Planificación, or Juceplan), headed by the economics minister; the ministries and national organizations that control the economic sectors and basic activities; the various state enterprises (empresas); and the provincial delegations that direct the work of the factories and related services.

Each work centre follows a distinctly Cuban organizational pattern. It is managed by a collective organization: the administrative board is responsible for production and service activities; the cells of the PCC support the outlining of jobs and politically orient members of the work centre; and the trade union, representing the workers, acts as a vehicle for the expression of their opinions.

**Transportation.** **Maritime transport.** In 1959 there was a small merchant fleet of 14 ships with 63,800 deadweight tons and a cargo capacity of 53,100 tons. Sixteen years later the number of vessels had been multiplied by more than 19, and there was nearly 10 times as much deadweight tonnage and eight times as much cargo capacity; refrigerated cargo capacity had increased more than 14 times. These increases were accompanied by a major increase in foreign commerce. Authorities intend that ultimately half the total volume of freight entering and leaving Cuban ports will be carried in Cuban ships. Coastal trade movements are based on the vessels of the Empresa de Navegación Mambisa (Mambisa Navigation Enterprise) and the Empresa Cabotaje de Oriente (Oriente Coastal Trading Enterprise). A passenger service on the Cauto River was inaugurated in 1968.

**Rail transport.** The line constructed between Havana and Bejucal in 1837 was the first in the Americas after those of the United States. The railway system deteriorated in the first years after the revolution of 1959 but was being restored by the mid-1970s. Track mileage is approaching 10,000 (more than half of it connecting sugar fields and mills), and some 10,000,000 passengers and 11,000,000 tons of freight are transported annually.

**Other land transport.** Total road mileage increased by 50 percent during the 1960s. The most important highway is the Carretera Central (Central Highway), which runs along almost the entire length of the island. Other major routes are the Via Blanca (linking Havana with the Playa Varadero) and the Via Mulata (connecting Baracoa, at the east end of the island, with the rest of the country). There are eight state transport enterprises (seven of them for passenger traffic); one of these is national, the rest are provincial in scope.

Automobile transport has been substantially downgraded in an attempt to adjust transport facilities to the realities of Cuban life. In the 1950s automobiles, trucks, and buses accounted for 71, 10, and 19 percent of vehicle imports, respectively. In the 1970s the percentages were 9, 81, and 10 for the same categories.

**Air transport.** The Empresa Consolidada Cubana de Aviación (Cuban Aviation Enterprise) operates the former four private airlines. There are daily flights between Havana and the major Cuban cities, some subsidiary flights from Santiago, and weekly flights to a number of European and South American cities and to Rabat, Morocco. Among international flights, the Moscow-Havana nonstop flight of the Soviet Aeroflot line is the world's longest.

#### ADMINISTRATION AND SOCIAL CONDITIONS

The constitutional background. Until the adoption of the constitution of February 24, 1976, Cuba had for some 36 years been governed either by the constitution of 1940 or by the post-revolutionary Ley Fundamental (Fundamental Law) of February 7, 1959, modelled upon the constitution but centralizing governmental power. The 1940 constitution had been suspended twice—from 1952 to 1955 by the dictatorship of Fulgencio Batista, and after

1959 when it was supplanted by the Ley Fundamental and by legislation that included the Agrarian Reform Law (May 17, 1959), the Urban Reform Law (October 14, 1960), the Nationalization of Education Law (June 6, 1961), and the Second Agrarian Reform Law (August 3, 1963).

Drafting of a new constitution to succeed that of 1940 began in 1965 and continued for the next 10 years; a preliminary draft was approved by the Politburo of the Central Committee of the Communist Party of Cuba in 1975, and the final version was approved by referendum on February 15, 1976, entering into force on February 24.

In October 1976, for the first time in 17 years, representatives for 169 municipal assemblies "of the people's power" were elected to give the people a more effective role in the running of their urban centres. President Castro said the election was "a significant step forward in the process of consolidation and institutionalization of the revolution." These 169 assemblies met subsequently in November to elect a 481-member National Assembly, as they had somewhat earlier elected delegates to the 14 provincial assemblies; each of the bodies in turn elected executive committees to carry on the day-to-day work of their respective administrative organs.

The National Assembly, at its inaugural session in December 1976, appointed a State Council of 31 members, headed by Castro, as president, and a Council of Ministers, headed by a chairman, also Castro, who was thus both head of state and of government. The State Council is the executive body of the state, carrying on the daily administration of the country between the twice-yearly sessions of the National Assembly.

Following the revolution, political parties were dissolved, and a single party was created out of the participating revolutionary organizations: the Movimiento 26 de Julio (26th of July Movement), the Partido Socialista Popular (Popular Socialist Party), and the Directorio Revolucionario 13 de Marzo (13th of March Revolutionary Directorate). In 1965 this single national party was officially designated the Communist Party of Cuba (Partido Comunista de Cuba). In the elections of 1976, candidates represented both the Communist Party and mass organizations.

The mass organizations were created after the revolution to replace former social organizations and are under the supervision of the government. They include the Confederation of Cuban Workers (Confederación de Trabajadores Cubanos, or CTC), reconstituted in 1970, with stated objectives to support the government, help improve managerial performance and labour discipline, and raise the political consciousness of workers. The National Association of Small Farmers (Asociación Nacional de Agricultores Pequeños, or ANAP) is composed of independent farmers, outside the system of collectivized state farms, who own about 20 percent of the total cultivated land. In 1960 the Committees for the Defense of the Revolution (Comités de Defensa de la Revolución, or CDR), which now enroll about 70 percent of the adult population, were created to maintain vigilance against "enemies of the revolution"; they are organized in every city, factory, and place of work and in many rural counties. The objective of the Federation of Cuban Women (Federación de Mujeres Cubanas, or FMC) is "to raise the ideological, political, cultural, and scientific level of women in order to incorporate them into the tasks assigned by the revolution"; it replaced a number of social clubs.

Justice and the armed forces. In 1973 Cuba's judicial system was reorganized. The Tribunal Supremo Popular, divided into four chambers, became the main body of the new structure. Its jurisdiction includes criminal offenses, civil and administrative offenses, crimes against state security, and military offenses. The Tribunales Provinciales Populares deal with cases that warrant sentences of up to six years' imprisonment.

Cuban defense is based on the revolutionary armed forces, now equipped with sophisticated weaponry. The land forces are grouped in eastern, western, and central armies, and there is an effective air force and a navy.

The  
Communist  
Party  
of Cuba

Com-  
mittees for  
the De-  
fense of  
the Revo-  
lution

Auxiliary forces include a part-time civil-defense body. Military service is compulsory for citizens between 17 and 45 years of age.

The Ministry of the Interior is charged with the maintenance of public order and state security, rehabilitation of prisoners and prison management, and fire fighting.

**Social services.** *Education.* The eradication of illiteracy was given high priority by the revolutionary government. In 1961, the "Year of Education," 707,212 men and women were officially declared to have achieved literacy. Dissolution of all private schools was one of the first acts of the revolutionary government, and a fundamentally altered, state-directed education system was introduced. It includes general education, 12 grades preceded by a preschool stage; higher, or university, education; teacher-training education; adult education, directed toward the eradication of residual illiteracy and toward continued study by working people; technical education, parallel to middle-level general education; language instruction; and specialized education. Education is free at all levels, with supplementary scholarships to cover living expenses and medical assistance.

Fidel Castro once remarked that "education is the revolution," and the revolutionary government has acted on that view. Education expenditures are the highest in Latin America. In all schools, fewer than 1,000,000 students were enrolled in 1959, in contrast to nearly 3,100,000 in 1976.

*Health.* Medical care is free, and mortality rates have been reduced. It was reported that by 1974 infant mortality rates were about 28 per 1,000 live births—a rate that compares very favourably with the rest of the Americas, including some developed areas. By 1974 the official ratio of doctors to population was 1:1,000, a favourable ratio for a developing country. The Ministry of Public Health (Minsap) requires physicians to work for the rural medical service in needy areas for two years after graduation.

*Housing.* Urban real-estate rental was prohibited under the Urban Reform Law of 1960, and it was made possible for families to own their homes by paying the current rental sum for not less than five or more than 20 years. By 1970 some 270,000 families had acquired titles to houses and apartments in this fashion, and 100,000 rural families had achieved free use of formerly rented lands. The traditional rural *bohío* ("hut") is being slowly replaced by more modern housing units. New towns and fishing villages have also been constructed.

*Social assistance and welfare.* Homes for the aged are under the direction of Minsap, but the *círculos infantiles*, institutions for the day care of children under seven years of age, are run by the Federation of Cuban Women. The *círculos infantiles* and *jardines de la infancia* are both intended to free women to work. The women's federation also supervises more than 8,000 social workers. Physical education and sports, under a national body, are an integral part of Cuban education. The Ministry of Interior Commerce is in charge of the fixing of prices for, and distribution and sale of, foodstuffs and notions (*abarrotes*), working as closely as possible with community groups. In 1968 more than 55,000 till-then privately operated sales outlets were placed under the ministry.

**Social indexes.** Cuban society has been transformed since 1959. The traditional public graft and corruption and also prostitution, gambling, and vice became targets of a strenuous campaign, and the official claim that the campaign has been successful seems to be warranted. The long-term investment program has been accompanied by the elimination of mass unemployment as it existed in the 1950s and access to consumption by formerly economically marginal sectors of the population. There is, however, a marked imbalance between money in circulation and goods and services available. Wages and prices are rigidly controlled and quota systems strictly enforced. For example, workers are moved to areas where labour is scarce by simply assigning them ration cards valid only in the sectors where their services are required. Farm incomes are controlled by regulation of the storage of agricultural products and by production limits. Overall,

private ownership of the means of production is now limited to the 200,000 or so small farmers, and the working class is officially ascribed a leading role in Cuban society.

#### CULTURAL LIFE AND INSTITUTIONS

The cultural life of the Cuban people has also undergone a major transformation as part of what is regarded by the authorities as an ongoing revolutionary process. The government believes that mass culture is essential to the fulfillment of its economic and social aims and since 1959 has played a leading role in cultural life. This policy has been embodied in a set of directives, such as that creating a system of cultural organizations to take artistic displays to the remotest regions. Traditional Cuban culture, it was felt, was generally limited to Havana (and, to a much smaller extent, the provincial capitals), and was almost entirely privately endowed and thus subject to the vagaries of private fortunes, tastes, and interests. The National Cultural Council (Consejo Nacional de Cultura, or CNC) directs a program of education in music, plastic arts, ballet, dramatic arts, and modern dance; by 1970 more than 10,500 students were enrolled in provincial and regional schools of the National School of Fine Arts (Escuela Nacional de Arte Cubanacán). Amateur groups led by CNC instructors are also popular.

**The theatre.** Cuban theatre has been state-supported since 1959, coming under CNC direction, except in the case of the university cultural extension departments. There are six national dramatic groups, whose directing councils create their own repertory. Their activities are centred on Havana, but they travel frequently in the provinces. Provincial theatre groups characteristically present their entertainments on tour. Cuban critical opinion acknowledges that the national theatre suffers from lack of maturity but emphasizes that the drive to seek a unique national expression while utilizing the full range of tradition has produced a number of important works. The Casa de las Americas (House of the Americas) has held a number of Latin-American theatrical festivals. The Casa del Teatro (House of the Theatre; attached to the International Institute of Theatre) is a major centre of information and research on Cuban and international themes, while the lyric theatre stimulates interest in opera and operettas by conducting exchange programs with other countries.

**Music and ballet.** Cuban music has Spanish and African roots. Various organizations have disseminated modern influences, and soloists participate in exchange programs and tour rural areas under CNC sponsorship. Cuba's foremost contemporary artistic figure is undoubtedly the prima ballerina and founder (1948) of the Ballet Nacional de Cuba, and head of its school, Alicia Alonso, a dancer of international acclaim. The Ballet of Camagiiey was established in 1971.

The National Symphony Orchestra has a chamber orchestra and instrumental ensembles attached and accompanies opera, operetta, and ballet. It makes annual tours of the island, as do its provincial equivalents. Festivals of Cuban music and song are held at intervals, encompassing works of every genre from every period. Performing musical groups range from the traditional *charangas* to popular orchestras.

**Folklore.** In 1959 the Institute of Ethnology and Folklore was created within the Academy of Sciences of Cuba, with the aim of collecting and classifying the Cuban cultural heritage. It formed the National Folklore Group (Conjunto Nacional Folklórico), which performs Afro-Cuban dances nationally and internationally. The activities of the folklore group are complemented by the Institute of Literature and Linguistics of the Academy of Sciences. The legacy of Fernando Ortiz, a pioneer investigator of black customs, and the work of the Central University of Las Villas on popular culture deserve special mention.

**Art.** Cuba has some two dozen galleries, three art museums, and community cultural centres ready to display the works of Cuban painters. The Palacio de Bellas Artes and the Casa de las Americas both organize major

Folklore  
Group

Quota  
systems

exhibitions from time to time. The revolutionary government emphasizes that it is not enough to open the galleries for increased public attendance if there has not been some prior education of the viewers, and effort is directed toward increasing public interest and artistic awareness.

**Literature and publishing.** Publishing is centralized in the Book Institute, an arm of the government, which produced 33,900,000 volumes in 1974—34 times the 1958 figure. About 70 percent of the titles are reference works, usually with scientific or technical content, and many of them are distributed free in support of national educational goals. The government-controlled press includes *Granma* ("Grandmother"), organ of the Communist Party, named for the yacht that brought Fidel Castro to Cuba in 1956; and *Juventud Rebelde* ("Rebel Youth"), the organ of the Unión de Jóvenes Comunistas (Organization of Communist Youth), as well as a wide range of provincial newspapers, magazines, and specialized reviews. The National Union of Cuban Writers and Artists (Unión Nacional de Escritores y Artistas Cubanos, or UNEAC), founded by Nicolás Guillén (a "social" poet whom the government considers the national poet), sponsors writers' competitions.

Although Cuba's pre-revolutionary literary production had, in many cases, achieved a very high quality, activity was sparse and unintegrated. New, often younger, writers now make their living principally (and in some cases solely) by writing. The annual competition of the Casa de las Américas, one of the most important in the Spanish language, brings world figures to Cuba.

Cuban poets maintain, perhaps surpass, pre-revolutionary standards, but many critics feel that fiction writing began to decline in the early 1970s, when works tended to become more directly related to revolutionary topics. The winner of the Casa de las Américas prize in 1971, *La última mujer y el próximo combate* ("The Last Woman and the Next Battle"), by Manuel Cofiño López, has a typical theme: the efforts (successful) of a new state farm director to eliminate corruption in the enterprise and to draw the peasants into the revolution.

**Film making, radio, and television.** Cuban film making has been stimulated by the Cuban Institute of Cinematographic Art and Industry (Instituto Cubano del Arte e Industria Cinematográfica; ICAIC), which aims to make serious films and to see that those films are available to the general populace. The government program of distribution has 560 mobile film units. The ICAIC also has an extensive film library and supports a cinematographic studies centre, which trains future technicians for the industry. The very active Cuban Broadcasting Institute (Instituto Cubano de Radiodifusión; ICR) has five national stations and more than 30 provincial stations. Two national television channels are supplemented by a local channel in Santiago de Cuba. Both institutes are agencies of the government.

**BIBLIOGRAPHY.** RAMIRO GUERRA Y SANCHEZ, *Manual de historia de Cuba*, new ed. (1971), offers an analysis of the economic conditions, social and political institutions, and external influences from the discovery of Cuba until 1868; JULIO LE RIVEREND, *La Habana: biografía de una provincia* (1960), deals with the historical development of the province in which Cuba's capital is located; the same author's *Historia económica de Cuba*, new ed. (1975; English ed. 1967), is a very important source for the study of the economic development of Cuba to 1958; J.K. BLACK *et al.*, *Area Handbook for Cuba*, 2nd ed. (1976), presents basic facts about social, economic, political, and military institutions; *A Study on Cuba* by the CUBAN ECONOMIC RESEARCH PROJECT, UNIVERSITY OF MIAMI, contains serious papers contributed by knowledgeable scholars; *Cuba 1968* (1970), by the LATIN AMERICAN CENTER, UNIVERSITY OF CALIFORNIA, LOS ANGELES, is a compilation made possible by exchanges of statistical data with Cuban agencies; *La enciclopedia de Cuba*, 9 vol., 2nd ed. (1975), was edited in Puerto Rico; *Anuario estadístico de Cuba*, issued by the CENTRAL PLANNING BOARD, is an annual compilation of statistical data on the economy and society.

(I.E./R.E.Cr./Ed.)

## Cuba, History of

At the time of the Spanish discovery of Cuba, the native population formed two groups totalling 50,000. The Ci-

boney and Guanahatabey occupied western Cuba. The more numerous Taino, who occupied the rest of the island, were highly developed agriculturalists and a peaceful people, related to the Arawakan peoples of South America who had migrated to the Greater Antilles. Their houses, called *bohíos*, formed villages ranging from single families to communities of 3,000 persons. They had pottery, polished stone implements, and religious spirits called *zemís*, which were represented by idols of wood, stones, and bones. The Taino diet included potatoes, manioc, fruits, and fish.

**The Spanish colonial regime, to 1898.** Christopher Columbus discovered Cuba for Spain during his first voyage, on October 27, 1492. Diego Velázquez began permanent settlement in 1511, founding Baracoa on the northeastern coast with 300 Spaniards and their African slaves.

**Establishment of the colony.** Within five years the island had been divided into seven municipal divisions, including Havana, Puerto Principe, Santiago de Cuba, and Sancti Spiritus. Each municipality had its own *cabildo*, or town council, governing its legal, administrative, and commercial affairs. From 1515, elected representatives of each *cabildo* formed a body that defended local interests before the royal council, especially matters such as the slave trade and the *encomienda* (an estate of land and the Indians inhabiting it). A bishopric, subordinate to Santo Domingo, was founded at Baracoa in 1518 but later moved to Santiago de Cuba.

**Colonial life before 1763.** The island's limited gold deposits discouraged early settlement. The colony became a staging ground for the mainland exploration of Yucatán, Florida, and the Gulf Coast. Such expeditions as that of Cortés, which attracted 400 Spaniards and 3,000 Indians, depleted the colonial population. The small number of permanent resident Spanish colonists used the Indians in *encomienda*. But by 1550 the *encomienda* was no longer feasible, because the island's Indian population had declined dramatically to about 5,000 because of social dislocation, maltreatment, epidemic diseases, and emigration. Throughout the 17th century, colonial life was made more difficult by the ravages of hurricanes, epidemics, the attacks of rival European countries trying to establish bases in the Caribbean, and freebooters. By 1700 peace had returned, and the population had grown to about 50,000. The *flota* system (regularly scheduled fleets between Spain and Spanish America) increased the commercial and strategic importance of Havana, while ranching, smuggling, and tobacco farming occupied the colonists. The administrative costs depended, however, on irregular subsidies from New Spain until 1808.

**The plantation society, 1763–1898.** The 18th century brought intensified agricultural development. The main changes came with the growing dependence on sugarcane cultivation and the importation of African slaves. In 1740 the Havana Company was formed to stimulate agricultural development by increasing the importation of slaves and regulating the export trade. The company was unsuccessful, selling fewer slaves in 21 years than the British sold during a ten-month occupation of Havana in 1762. Reforms of Charles III of Spain (ruled 1759–88) further stimulated the development of the sugar industry.

Between 1763 and 1860 the island's population increased from less than 150,000 to more than 1,300,000. Slaves made the most dramatic growth, increasing from 39,000 in the 1770s to some 400,000 in the 1840s. In the 19th century Cuba imported more than 600,000 Africans, most of them after an Anglo-Spanish agreement to terminate the slave trade in 1820. The Cuban insistence on the slave trade raised considerable diplomatic controversy between Spain and Great Britain between 1817 and 1865.

In 1838–80 the Cuban sugar industry became the most mechanized in the world, utilizing steam-powered mills and narrow-gauge railroads. Expanding *ingenios* (sugar mills) dominated the landscape from Havana to Puerto Principe, expelling small farmers and destroying the is-

Pre-Columbian Cuba

*Rebelde*

land's famous large hardwood forests. By 1850 the sugar industry accounted for 83 percent of all exports and in 1860 Cuba produced nearly one-third of the world's sugar production. The sugar revolution propelled a new rich class of slave owners to political prominence. Mexican Indians and Chinese augmented the labour force, and in 1865 the African slave trade ended, although slavery was not abolished until 1886.

**The end of Spain's empire.** The demands of sugar—labourers, capital, machines, technical skills, and markets—strained interracial relations, aggravated political and economic differences between metropolis and colony, and laid the foundation for the break with Spain in 1898. Spanish colonial administration had been corrupt, inefficient, and inflexible. The United States had shown a lively and growing interest in the island, and expeditions by U.S. filibusters won support in the United States, especially in the Southern slave states. After the 1860s the U.S. tried many times to purchase the island.

Spain's failure to grant political autonomy, while increasing taxes, led to the outbreak of the first war of independence—the Ten Years' War (1868–78)—which led to a military stalemate. The rich sugar producers of western Cuba and the vast majority of the slaves failed to rally to the Nationalists, themselves divided over the questions of slavery, complete independence, and annexation to the U.S. Unable to find a military solution, Spain promised to reform the island's political and economic system at the Convention of Zanjón (1878). Many Cubans, including the Nationalist leader Antonio Maceo, however, refused to accept the Spanish conditions.

By 1895 the political and economic crisis had grown more severe. U.S. investment had reached \$50,000,000, and its annual trade with Cuba amounted to about \$100,000,000. Cuban political organizations in exile were coordinated and mobilized by the poet and propagandist José Martí. War broke out again on February 24, 1895.

Fighting quickly spread throughout the island. Spain deployed more than 200,000 troops. Both sides killed civilians and burned estates and towns. By 1898 commercial activity had come to a standstill. Excited by the "yellow press" and a mysterious explosion aboard the USS "Maine" in Havana Harbour, the U.S. declared war on Spain on April 25, 1898. In August Spain signed a peace protocol in Washington, ending hostilities.

**United States occupation, 1899–1901.** Cuban independence, granted by the Treaty of Paris (December 10, 1898), began January 1, 1899, under U.S. occupation. The military governor, Gen. John Brooke, tried to exclude Cubans from government. He disbanded the Cuban army and conducted a census before being replaced by Gen. Leonard Wood, a former military governor of Santiago City. Wood sought to mitigate political division and supervised elections that gave Cuba its first elected president, Tomás Estrada Palma.

The military occupation restored normality. The Americans built a number of schools, roads, and bridges; they modernized Havana and deepened its harbour, but they were primarily interested in preparing the island for incorporation into the U.S. American economic, cultural, and educational systems prevailed, and the franchise was designed to eliminate Afro-Cubans from politics. The Platt Amendment (1901) gave the U.S. the right to oversee Cuba's international commitments, economy, and internal affairs, and to establish a naval station (Guantánamo Bay).

**The Republic of Cuba, 1902–58.** A republican administration begun on May 20, 1902, under Estrada Palma faced difficulties over U.S. influence. Estrada Palma tried to retain power in the 1905 and 1906 elections, which were contested by the Liberals, leading to rebellion and a second U.S. occupation on September 29, 1906. U.S. Secretary of War William Howard Taft failed to resolve the dispute, and Estrada Palma resigned. For the U.S. Charles Magoon administered a provisional government of Cuban civilians under the Cuban flag and constitution. An advisory law commission revised electoral procedures, and on January 28, 1909, Magoon handed over the government to the Liberal president, José Miguel Gómez.

Meanwhile, Cuba's economy grew steadily, as sugar prices continually rose until the 1920s.

**Presidencies and dictatorships, 1909–58.** The Gómez administration (1909–13) set a pattern of graft, corruption, maladministration, fiscal irresponsibility, and social insensitivity—especially toward Afro-Cubans—that characterized Cuban politics until 1959. The Afro-Cubans, led by Evaristo Estenoz and Pedro Ivonet, organized to secure better jobs and more political patronage and to protest a ban of political associations based on colour and race. In 1912 government troops put down large demonstrations in Oriente; 3,000 Afro-Cubans lost their lives. The pattern of corruption was followed by María García Menocal (1913–21), Alfredo Zayas (1921–25), Gerardo Machado (1925–33), Fulgencio Batista (through puppets 1934–39 and himself 1940–44 and 1952–59), Ramón Grau San Martín (1944–48), and Carlos Prío Socarrás (1948–52). Machado and Batista, who overthrew Machado in 1933 with U.S. support, were the most notorious, holding power through manipulation, troops, and assassins.

The income from sugar was augmented by vigorous tourism based on hotels, casinos, and brothels; Havana became especially attractive during the years of U.S. Prohibition (1919–33). Yet the prosperity of the 1920s, '40s, and '50s enriched only a few Cubans—mainly politicians and their families. For the majority, poverty (especially in the countryside) and lack of public services were appalling: with a national per capita income of \$353 in 1958—among the highest in Latin America—unemployment and underemployment were rife, and the average rural worker earned \$91 per year. Foreign interests controlled the economy, owning about 75 percent of the arable land, 90 percent of the essential services, and 40 percent of the sugar production. Nevertheless, there was no widespread economic discontent in 1958, when Fidel Castro supplanted Batista.

**The Castro regime from January 1, 1959.** Batista's fall resulted as much from internal decay as from the challenges of Fidel Castro's 26th of July Movement (commemorating Castro's attack on the Moncada military fortress in Santiago on July 26, 1953), the Federation of University Students (later absorbed into the Young Communists Union), and other groups. Castro had been a candidate in the aborted elections of 1952. His defense argument for his part in the Moncada attack, edited and published as "History Will Absolve Me," was a political manifesto. Released from prison in 1955, Castro and some friends went to Mexico to prepare for the overthrow of the Cuban government. An enlarged group, including the Argentinian revolutionary Ernesto (Che) Guevara, landed in Cuba in December 1956 and were almost annihilated in their first attack. From the Sierra Maestra the survivors fought a guerrilla campaign. When the *Fidelistas* took control on January 1, 1959, they numbered fewer than 1,000.

The 26th of July Movement had vague political plans, relatively insignificant support, and totally untested governing skills. They quickly forged a strong following from among the poor peasants, the urban workers, the young, and the idealistic of all groups and ages. The Communist Party of Cuba (*Partido Comunista de Cuba*), dating back to 1925, assumed the dominant role in political organization, and the state modelled itself on the Soviet bloc countries, becoming the first socialist state in the Americas.

**Abolition of capitalism.** The first stage of the new regime was dominated by the progressive dissolution of capitalism, between 1959 and 1963. In those confusing and difficult years, the government eliminated the remnants of Batista's army as well as the former labour unions, political parties, and associations of professional persons and farmers. New institutions emerged: the confederation of Cuban Workers (*Confederación de Trabajadores Cubanos*, or CTC, reconstituted 1970), the National Institute of Agrarian Reform (*Instituto Nacional de Reforma Agraria*, or INRA, founded in 1959), the Cuban Institute of Cinematic Art and Industry (*Instituto Cubano del Arte y Industria Cinematográfica* or ICAIC, 1959), the Central Planning Board (*Junta Central de*

Planificacion, or Juceplan, 1960), the Committees for the Defense of the Revolution (Comités de Defensa de la Revolución, or CDR, 1960), the Federation of Cuban Women (Federación de Mujeres Cubanas, or FMC, 1960), the National Association of Small Farmers (Asociación Nacional de Agricultores Pequeños, or ANAP, 1961), the Revolutionary Armed Forces (Fuerzas Armadas Revolucionarias, or FAR, 1961), the National Union of Cuban Writers and Artists (Unión Nacional de Escritores y Artistas Cubanos, or UNEAC, 1961), the Young Communists (Unión de Jóvenes Comunistas, or UJC, 1962), and others. The nationalization of hundreds of millions of dollars in United States property and private businesses provoked a series of retaliatory measures by the U.S. government, including an unsuccessful invasion by Cuban exiles at the Bay of Pigs in south central Cuba (April 1961) and unexecuted plots to assassinate Castro and overthrow his government.

Within Cuba the erratic drift toward socialism and the growing economic dependence on the Soviet Union divided both the leadership and the country at large. Hundreds of thousands of Cubans, especially from among the skilled and the wealthy, emigrated to Spain, the United States, and other countries. INRA tried and failed to diversify the economic base, and the constant mobilization for war frustrated effective long-term planning. Attempts to foment revolution elsewhere, especially in the Dominican Republic, Venezuela, and Bolivia, alienated Cuba from most of the other Latin-American states until the 1970s.

Castro visited Moscow during 1963, but the next two years witnessed a period of ideological instability as the government consolidated its domestic position. A second agrarian reform terminated the attempts to diversify the economy. Shortages became acute. A professional army replaced the militias as the bastion of national defense. Guevara left Cuba in 1965, only to have some of his ideas implemented in modified form afterward. The meeting of Latin-American Communists in Havana in November 1964 and the civil war in the Dominican Republic in April 1965 (which culminated in the military intervention of the United States) rekindled the Cuban desire to export their revolution.

**Radicalizing the revolution.** Between 1965 and 1970 the revolution experienced a third, more radical phase. Cuba began to assume a significant leadership role among the so-called Third World countries, and in 1979 was host to the summit conference of nonaligned nations and its chairman from 1979 to 1982. By 1968 there was a strong campaign against bureaucrats and a renewed attack on private property, as hundreds of small businesses were nationalized. Military officers moved into the highest ranks of government, industry, and the party. Workers were organized into brigades and microbrigades. An attempt to produce 10,000,000 tons of sugar in 1970 failed, but scarcity and rationing had reached their worst.

**Institutionalizing the revolution.** Material conditions improved markedly beginning in 1970. The revolution institutionalized itself along orthodox Soviet lines. Bottlenecks and shortages were substantially eliminated, and diplomatic isolation gave way to technical, commercial, or military assistance between Cuba, the Soviet Union, and the states of Africa, Latin America, and the Caribbean (see below). The political system was reorganized, the functions of the party and the government being separated. A new family code was introduced in 1975, and the following year a new constitution and a new electoral code created 14 provinces (instead of 6) and 169 municipalities (including the Isle of Pines). Fidel Castro became president of the Council of Ministers and the State Council (the latter office combining the offices of president of the republic and prime minister). Nationwide elections in 1976—with a participation rate between 92 and 99 percent—returned municipal assemblies, which then elected members to the provincial assemblies and the National Assembly.

**Relationship with the Soviet Union.** Castro re-established full diplomatic relations with the Soviet Union in 1960, and thereafter that country was the major trading partner

and source of funds and military supplies for Cuba. From 1960 the Soviet Union bought the major portion of the Cuban sugar crop, generally at a price above that of the free world market. Soviet assistance to Cuba in loans, petroleum, war materiel, and technical advice amounted to several billions of dollars annually. The dominant Soviet role forced the Cubans to support the Soviet Union in its dispute with China, although pro-Chinese sentiment was very strong in Cuba in the mid-1960s. After 1968, when the Cubans supported the Soviet invasion of Czechoslovakia, the revolution did not deviate significantly from the pro-Soviet position.

Soviet military support was crucial in the early years, and Soviet manoeuvres often aroused strong antagonism from the U.S. The installation of Soviet missiles in Cuba in 1962 brought the world to the brink of war as the U.S. forced the removal of the missiles under threat of nuclear attack; in 1979 the U.S. objected less strenuously to the presence of Soviet combat troops in Cuba.

**Africa, Latin America, and the Caribbean.** The wide-ranging and confident Cuban foreign policy relied on strong Soviet support. In the late 1960s the Cubans began to redefine themselves as an "Afro-Latin-American people." By the mid-1970s this new definition was accompanied by assistance to a number of countries in Africa, Latin America, and the Caribbean. Cuban military assistance probably determined the outcome of the civil wars in Angola and Ethiopia, but civilian brigades of doctors, teachers, agronomists, construction workers, physical training instructors, and fishermen made more significant contributions in Algeria, Angola, Cape Verde, the Congo, Ethiopia, Guinea-Bissau, Guyana, Jamaica, Mozambique, Nicaragua, Panama, Tanzania, and Yemen (Aden).

**BIBLIOGRAPHY.** R. GUERRA Y SANCHEZ *et al.* (eds.), *Historia de la Nación Cubana*, 10 vol. (1952), is a lengthy, solid study from the colonial period to modern times. F.W. KNIGHT, *Slave Society in Cuba During the Nineteenth Century* (1970), examines the effects of the sugar industry from the middle of the 18th century until the abolition of slavery. DAVID F. HEALY, *The United States in Cuba, 1898-1902* (1963), analyzes the actions and personalities involved in the first military occupation. HUGH THOMAS, *Cuba: The Pursuit of Freedom* (1971), is a monumental narrative of the period from 1763 until 1970. LEE LOCKWOOD, *Castro's Cuba, Cuba's Fidel*, new ed. (1969), is a warm treatment of the Cuban leader, based on extensive tape-recording sessions, the transcripts of which had Castro's approval prior to publication. The most authoritative analysis of 20th-century Cuba is to be found in J.I. DOMÍNGUEZ, *Cuba: Order and Revolution* (1978). The fiasco of the Bay of Pigs is brilliantly described in P. WYDEN, *The Bay of Pigs: The Untold Story* (1979), while C. MESA-LAGO, *Cuba in the 1970s: Pragmatism and Institutionalization* (1974), examines the early years of the Revolution.

(F.W.Kn.)

## Cuculiformes

The bird order Cuculiformes is a cosmopolitan group containing two very distinct families, the cuckoos, Cuculidae, and the turacos, or plantain eaters, Musophagidae. Discussion of their relationship has led authorities increasingly to give the turacos ordinal rank. The family Cuculidae is much the larger group, containing about 127 species, found in the tropical and temperate zones of all the continents except Antarctica and on many oceanic islands; the Musophagidae contains 20 species, found only in Africa.

The cuckoos are an ancient group with uncertain phylogenetic affiliations and no living near relatives, even the turacos being quite distinct and with no intermediate, or connecting, species. The cuckoos are of unusual biological, especially ethological, interest because many species are brood parasites; *i.e.*, they lay their eggs in the nests of other species, which then rear the young cuckoos. Other cuckoos make their own nests, in which they incubate their eggs and rear their young as do most birds; and still others (*Crotophaga* and *Guiraca*) build communal nests. Some cuckoos are among the few birds that feed extensively on hairy caterpillars.

**General features.** The cuckoos cover a great range in size, from the small glossy or emerald cuckoos of the

Political  
reorganiza-  
tion

## Size ranges

genus *Chrysococcyx*, which are about 15 centimetres (six inches) long, to the large ground cuckoos (*Carpococcyx*) and the larger species of coucals (*Centropus*), which reach nearly 90 centimetres (three feet), including the tail, which is often strikingly long. Most cuckoos have fairly loose-webbed feathers, varying in colour from subdued browns, grays, olive, and black, to brilliant, iridescent greens and purples and bright yellow. The beak is of moderate length and often slightly downcurved. The turacos are all sizable birds, the smallest species having a total length of about 37 centimetres (15 inches) and the largest attaining a length of almost 75 centimetres (30 inches).

In keeping with the greater number of their included species and their worldwide distribution, the cuckoos show far more diversity in structure than do the relative-

ly homogeneous turacos. The cuckoos include the arboreal "typical" cuckoos of both the Old World and the New World, the terrestrial roadrunners (*Geococcyx*) of southwestern United States and Mexico, and the more compact but also largely terrestrial coucals (*Centropus*) of Africa and Australasia.

**Distribution.** Although the family Cuculidae is virtually worldwide in temperate and tropical regions, most of the subfamilies are restricted to one hemisphere or the other. Three (Cuculinae, Centropinae, and Couinae) are limited in distribution to the Old World; the subfamily Crotophaginae is wholly New World; the Neomorphinae is mostly New World, with one genus in Southeast Asia; and the sixth subfamily, Phoenicophaginae, is represented in the tropics of both hemispheres. Many cuckoo genera are peculiar to certain parts of the world; others are cosmopolitan. Three genera (*Rhamphomantis*, *Caliechthrus*, and *Microdynamis*), for example, are known only from New Guinea; *Dasylophus* and *Lepidogrammus* occur only in the Philippine Islands; and *Saurothera* (lizard cuckoos) is found only in the West Indies. Some other genera are wide ranging: the typical cuckoos of the genus *Cuculus* are found in Europe, Asia, Africa, and Australia; the small, brightly coloured *Chrysococcyx* species occur in Africa, Asia, Australia, and some Pacific islands; and the coucals (*Centropus*) live in Africa, Asia, Australia, and adjacent islands.

Most cuckoos are solitary, often furtive birds that are inconspicuous even when relatively common. They do not form large flocks or even, except for the communal nesting anis (Crotophaga), small parties. The turacos, some of which form loose bands, are often conspicuous because of their bright colours, large size, and loud voices.

**Natural history.** **Habitat utilization.** As a group, cuckoos are forest birds, often inhabiting dense thickets that may make them difficult to observe. Some species, such as many of the genus *Cuculus*, inhabit rather open woodland. The guira (*Guira guira*) of South America and many members of the Old World genera *Clamator* and *Chrysococcyx* are found in open savanna (grassland), but only where trees are present. The roadrunners live in open scrub and cactus desert, often in the absence of any large vegetation.

The green and iridescent turacos (*Tauraco*, *Gallirex*, *Musophaga*, and *Corythaecola*) are primarily residents of dense, evergreen, broad-leaved forest; the grayer forms (*Crinifer*), most of which are called go-away birds (because the calls of some are "g'-way, g'-way"), are found in more open woodland, including savanna.

**Food habits.** Cuckoos are largely insectivorous, preying mostly on crawling insects. Orthoptera (grasshoppers, locusts, and mantids) are often taken. The greater, or North American, roadrunner (*Geococcyx californianus*) is reported to take flying grasshoppers by leaping after them from the ground. The larger cuckoos, such as the lizard cuckoos, roadrunners, and coucals, take substantial numbers of lizards, snakes, and other small vertebrates, sometimes including birds. Alone among the Cuculidae, the Madagascar couas (*Coua*) are reported to eat some fruit.

Musophagids feed almost entirely on fruit; only a few species are known to take insects and small vertebrates.

**Vocalizations.** Compared with birds generally, cuckoos must be considered a highly vocal group, a fact consistent with their forest habitat. A variety of songs, contact calls, and alarm notes are known for most species, some melodious, many harsh and discordant. The "song," associated with territorial assertion and courtship, is usually characterized by the repetition of loud, short notes, often on a descending scale or with a downward break in the middle. The individual syllables have variously been described as whistling, piping, cooing, tooting, laughing, grating, and clicking, depending on the species. The familiar clear, two-note call of the common cuckoo (*Cuculus canorus*) of Europe, Asia, and Africa is uttered by the male alone, the female giving a low bubbling call; apparently in most other species of cuckoos as well, the song is given by the male alone.

Drawing by R. Keane

Body plans of representative Cuculiformes.

"Songs" of cuckoos

In addition to vocal sounds, at least one cuckoo, the North American, or greater, roadrunner, makes non-vocal sounds, clacking the mandibles to produce a rattling noise.

The calls of turacos are described as barking or laughing notes given in a series. A few species utter softer cooing notes.

**Courtship behaviour.** Except for features of parasitism, the behaviour of cuckoos is one of the least studied aspects of their natural history. A few species, in several subfamilies, have been observed closely, and some generalizations are possible. In territorial advertisement and in courtship, the singing male (in both parasitic and non-parasitic cuckoos) may posture, spreading the tail feathers, which are white tipped in most species, and dropping the wings. Courtship feeding of the female by the male has been observed in several species.

Courtship behaviour has been described for a few musophagids. In forest species, the male walks or leaps among branches with his tail fanned and with his wings half spread, displaying the crimson wing patches. Courtship feeding has also been observed, the male regurgitating fruit pulp or presenting whole fruit to the female.

**Nesting.** Two basic types of nesting behaviour are found among members of the order: parasitic and non-parasitic. About three-fifths of the Cuculidae and all of the Musophagidae mate, nest, and rear their young in the manner seen in most birds. About 50 species of cuckoos, including all of the subfamily Cuculinae (sometimes called "typical" cuckoos) and three species of the Neomorphinae, exhibit brood parasitism (*i.e.*, they lay their eggs in the nests of other species, which then rear the young cuckoos). Brood parasitism in the common cuckoo was recognized by Aristotle in the 4th century BC, and that of the koel (*Eudynamis scolopacea*) appears in the ancient Vedic literature of India, dating from about 2300 to 1800 BC, but the scientific study of this form of parasitism remained largely neglected until the late 19th century, when intensive study by many observers revealed a number of remarkable behavioral and physiological adaptations in the cuckoo.

In western Europe the common cuckoo is migratory, arriving at its breeding area in spring. The female establishes a territory and defends it against intrusion by other female cuckoos. The male is less restricted to an individual territory and more tolerant of other males; often more than one male will be in attendance on one female. Moving about within her territory, the female learns of potential host nests largely by watching their construction. Males of some species of cuckoos may accompany the females in searching for potential host nests. By the time she is ready to lay her eggs the female cuckoo has under surveillance several possible host nests and knows when the first eggs are laid by their owners. Most of the species parasitized by the common cuckoo are smaller than the cuckoo and lay their eggs at the rate of one each day until the clutch is complete, only then beginning incubation. Visiting when the hosts are away from the nest the cuckoo is able to place her egg in the nest after the host has started the clutch but before incubation has begun. It is well established that the common cuckoo lays eggs at 48-hour intervals, and apparently some glossy cuckoos lay one every 24 hours. The cuckoo places only one egg in each host nest and so must find a new nest for each of her 15 to 20 eggs. When parasitizing a species that builds a domed or globular nest, the female cuckoo clings to the outside of the nest and lays her egg through the opening without entering the nest. The repeated finding of cuckoo eggs in nests too small to admit a cuckoo or to bear her weight has led some authorities to maintain that the cuckoo lays the egg on the ground and carries it to the nest in her beak, but extensive observations have failed to substantiate this supposition. Some of the glossy cuckoos, however, parasitize nests so small and frail that mandibular egg placement cannot be ruled out.

In western Europe common cuckoos lay their eggs in the nests of many species, mostly songbirds (Passeriformes); more than 140 hosts species have been reported, including some that could hardly rear a young cuckoo

successfully. Careful study of this and several other cuckoos indicates, however, that despite the wide range of hosts recorded, a few host species bear most of the load of raising the young of each cuckoo species. In some instances, such as two of the little Australasian glossy cuckoos (*Chrysococcyx*), the parasite relies mainly on a single host species.

Many birds react to a foreign object in the nest by deserting the nest, building another nest on top of the first, or removing the offending object. It is therefore of great advantage to a brood parasite to lay eggs that resemble those of its host, or, conversely, to parasitize species whose eggs are the same colour as its own. The utilization of several host species by a single population of cuckoos presents a difficult adaptive problem, for the host species may have many different egg colours. Early naturalists noted that there was often a marked resemblance between the egg of a cuckoo and those of the host, and a German ornithologist, Eduard Beldamus, in 1892 showed that the frequency and degree of similarity were too great to be coincidental. Subsequent studies by a number of workers, especially by an English naturalist, Edgar P. Chance, have revealed much of the basis for the resemblance, which is now called egg mimicry.

Each female common cuckoo lays eggs of a particular shape and coloration throughout her life, but the eggs of different females vary widely. Most authorities now agree that a given female normally restricts her parasitism to the single host species by which she herself was reared, and that the common cuckoo population is composed of numerous clans, called gentes, each of which parasitizes only one species of bird, for which the females of that gente have evolved egg mimicry. Only the gente of the female is important in egg coloration; the foster parentage of the male (*i.e.*, his gente) has no effect on his choice of females, and his genetic makeup apparently does not influence the coloration of eggs laid by his female offspring. Gentcs are not given taxonomic designations but are sometimes known by their host species ("redstart cuckoo," "dunnock cuckoo," etc.). Evidence for this theory is largely circumstantial because of the difficulty in establishing the identity of individual cuckoos, but no plausible alternative theory has been proposed. The presence of cuckoo eggs in a wide variety of host nests in some small areas has been taken as evidence refuting the single-host hypothesis, but most of the nests with nonmatching eggs are found in areas in which the ecology has been seriously altered by human activity, with the result that female cuckoos have suddenly found themselves without adequate numbers of the proper host species and have been forced to utilize hosts for which their own egg colours are inappropriate. In the forested portions of northern Europe, where the habitat is relatively undisturbed and consists of homogeneous micro-ecological areas (*e.g.*, reedbeds, birch forests), the common cuckoo parasitizes mainly a small thrush, the redstart (*Phoenicurus phoenicurus*), and both lay unspotted bluish eggs; in the reedbeds around Hungarian lakes the usual host is the great reed warbler (*Acrocephalus arundinaceus*), and the cuckoo eggs are strongly blotched with gray and black, like those of the warbler.

Studies of the reaction of the host to the presence of a cuckoo egg have indicated that egg mimicry is of considerable importance to the success of the parasite. Only about 5 percent of well-matched eggs are rejected by their hosts, as compared with up to 72 percent of mismatched eggs. Few cuckoos have been studied intensively in terms of egg mimicry, but the phenomenon is known to occur in at least some species. The great spotted cuckoo has an egg pattern mimicking that of the magpie (*Pica pica*), its usual host in southern Europe. In Africa, where it is apparently a recent colonist, this cuckoo exhibits what has been termed "evolutionary escape from specialization"; its new hosts, certain starlings, nest in holes, in which the semidarkness renders the dissimilarity of eggs less visible and hence unimportant. Among the 12 species of emerald cuckoos, the degree of host specificity and egg resemblance is variable, some species being highly host adapted, others less so.

**Egg  
mimicry**

**Egg laying  
by the  
common  
cuckoo**

The genus as a whole shows no clear continuity of evolution in egg adaptation; individual species evidently have evolved their egg mimicry separately.

A notable feature of the egg of the common cuckoo is its small size; its weight is only about 2.5 percent of that of the adult cuckoo. The eggs of other parasitic cuckoos weigh more than 6 percent of the adult weight, and those of birds that rear their own young vary from 8 to more than 20 percent of adult weight. The adaptive value of small eggs is not well understood, but it is assumed to be related to the reliance of the common cuckoo on small hosts. Recent experiments have shown, however, that incubating birds show no adverse reaction to eggs significantly larger than their own.

Nest-mate  
eviction

Once the egg has been accepted and incubated by the hosts, the newly hatched cuckoo faces the problem of securing enough to eat from its small foster parents. The young cuckoo has evolved an astonishing form of behaviour, that of nest-mate eviction, that ensures that it will not have to compete with members of the foster brood for food. Within a few hours of hatching, the blind, naked, young cuckoo develops a strong urge to evict any objects, such as eggs or other nestlings, from the nest. It does this by working itself under the offending object and, aided by the presence of a depression between the shoulderblades, heaving the object over the rim of the nest. Within about 24 hours of hatching, the young cuckoo has the nest and the attentions of its foster parents to itself. The eviction habit is well developed in some parasitic cuckoos and seems to operate effectively in favour of the evictor but is surprisingly absent in many others, such as the crested cuckoos (*Clamator*).

Another habit that, like nest-mate eviction, tends to reduce the competition faced by the young cuckoo is the removal of one or more of the host's eggs by the female cuckoo, sometime before or after or at the time of the laying of her own egg.

Soon after hatching, the young cuckoo, while still in the nest, grows rapidly in response to the efforts of its foster parents, who regard it as their own. By the time it is ready to leave the nest, the young bird dwarfs its smaller hosts. Normally it does not receive attention from its real parents, but adult common cuckoos have occasionally been observed feeding young cuckoos; in the genus *Chrysococcyx* such behaviour appears to be more frequent than in other genera.

Social  
nesting in  
the guira  
and anis

Most of the nonparasitic cuckoos form stable pair bonds and defend territories, within which they build their nests and rear their own young. The guira and the anis are exceptional in that they live in flocks of five to 20 individuals, each flock defending a territory within which its members feed and nest. Several birds of the flock may cooperate in building a nest, in which two or more females may lay eggs and share incubation. Many members of the flock participate in feeding the young.

The nests of nonparasitic cuckoos are loose platforms of twigs placed in low vegetation or, rarely, on the ground. The coucals are unusual in that they build sizable domed nests of grass and twigs, on or near the ground, with side entrances.

The musophagids also build large twig nests, placed in trees often at considerable height. They lay unmarked whitish eggs, from which the young are believed to hatch completely covered with down; certainly they are downy from an early age.

Migration. Like most insectivorous birds in temperate climates, temperate-zone cuckoos migrate toward or across the equator for the winter. The migrations of some species are remarkable in that the young of the year travel completely independently of their parents and may cross up to 3,200 kilometres (2,000 miles) of open ocean unguided. Adults and young of some of the small Australasian glossy cuckoos separately migrate long distances to relatively small oceanic islands. It is obvious that the means of orientation and navigation must be unusually precise, but what they are remains as yet unknown.

**Form and function.** In general body plan, most cuckoos resemble the "perching birds" (order Passeriformes).

They are slender bodied, with medium to long wings and medium to extremely long tails, the latter sometimes constituting more than half the total length of the bird. The tail is usually graduated (the outer feathers shorter), and the individual feathers often are white tipped.

The foot structure of cuckoos and musophagids is distinctive and at close range distinguishes these birds from any with which they might be confused. The foot of cuckoos is zygodactylous, or yoke-toed (*i.e.*, the outer toe is directed backward); that of musophagids is semi-zygodactylous, the outer toe being movable into either a forward or a backward position.

The cuckoo bill, although usually slender, is occasionally quite stout, as in the ground cuckoos and coucals, in which it makes a formidable weapon for subduing prey. In the anis the bill is heavy, with a strong ridge along the culmen (top), and, in the channel-billed cuckoo (*Scythrops novaehollandiae*) of Australasia, it is extremely large, almost like that of toucans. The bill is strong and rather short in the Musophagidae, usually with serrated edges. In the genus *Musophaga* it extends onto the forehead as a broad shield.

Most musophagids have prominent crests, a feature rare in cuckoos and well developed only in the genus *Clamator*. A number of cuckoos and turacos have bare skin, usually brightly coloured, around the eye or between the eye and the bill.

Perhaps the most distinctive feature of the turacos is the presence of two unique feather pigments. Turacin, a rich crimson pigment found in the primary flight feathers of Tauraco and Musophaga, is a copper salt of the pigment uroporphyrin III; and turacoverdin, the green pigment in turacos, is an oxidized derivative of turacin.

pigments

**Paleontology and classification.** The order Cuculiformes is not well represented in the fossil record, but both cuckoos and musophagids apparently existed by the Early Tertiary Period, some 60,000,000 years ago. The dearth of fossil evidence is not surprising, in view of the group's preference for forest habitats; woodland animals, particularly small ones and particularly birds, are less frequently fossilized than those in open areas or aquatic habitats. Two species of musophagids have been described from the upper Eocene or lower Oligocene of France (about 40,000,000 years ago) and one from the middle Miocene (about 15,000,000 years ago). Three species of fossil cuckoos are known from North America, the earliest from the middle Eocene (about 45,000,000 years ago), and a fossil coua has been found in deposits from the Quaternary Period (the last 2,500,000 years) of Madagascar.

Although the cuckoos and musophagids are frequently united in a single order, as in the present article, most authorities acknowledge the distinctness of the two groups by placing them in separate suborders, Musophagi and Cuculi. The parrots (Psittaciformes) are often considered on osteological evidence to be the closest relatives of the cuculiforms, but even this relationship, if it exists at all, is not a close one.

**BIBLIOGRAPHY.** E. BALDAMUS, *Das Leben der europäischen Kuckucke* (1892); and W. VON CAPEK, "Beiträge zur Fortpflanzungsgeschichte des Kuckucks," *Orn. Jb.*, 7:42-72, 102-117, 146-157, 165-183 (1896), are two classic works, in German, about the common cuckoo. EP. CHANCE, *The Cuckoo's Secret* (1922), is an important and highly readable book about the common cuckoo. D. E. DAVIS, "Social Nesting Habits of the Smooth-Billed Ani," *Auk*, 57:179-218 (1940), presents the results of extensive field work on anis. H. FRIEDMANN, *The Parasitic Cuckoos of Africa* (1948); "Evolutionary Trends in the Avian Genus *Clamator*," *Smithson. Misc. Collns.*, 146:1-127 (1964), and "The Evolutionary History of the Avian Genus *Chrysococcyx*," *Bull. U.S. Natn. Mus.* 265 (1968), are technical papers on Old World tropical cuckoos. A.C. BENT, "Life Histories of North American Cuckoos, Goatsuckers, Hummingbirds and Their Allies," *ibid.* 176 (1940), provides readable accounts of the natural history of North American cuckoos and of some Asiatic *Cuculus* species. R.E. MOREAU, "A Contribution to the Biology of the Musophagiformes, the So-Called Plantain-Eaters," *Ibis*, 2: 639-671 (1938), is one of the few detailed studies of musophagids.

(He.F.)

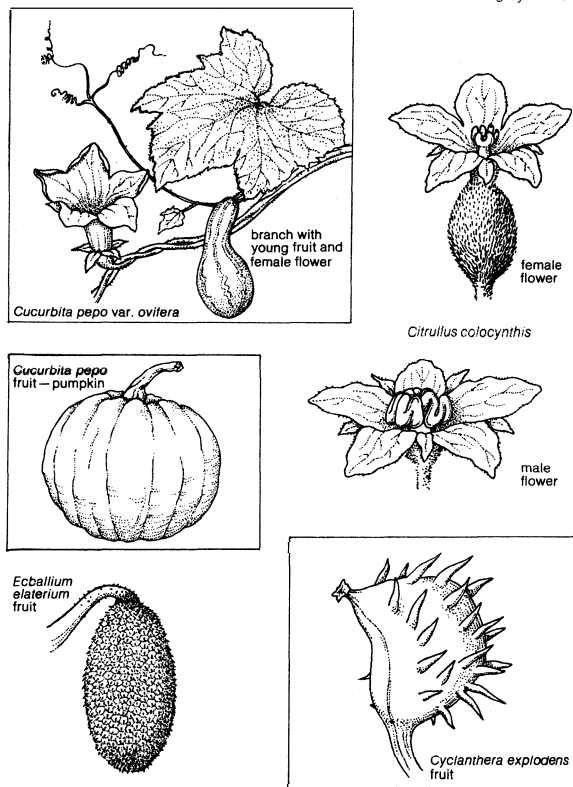

## Cucurbitales

Modern classification schemes of the flowering plants by most authorities suggest that the order Cucurbitales (the gourd order) is more or less isolated and composed of a single family, the Cucurbitaceae. The affiliations of the Cucurbitaceae are not well understood, and more research is necessary before its relationship within the system of flowering plant orders can be firmly established. Most authorities, however, have suggested a relationship with the *Passifloraceae* (Passiflorales order).

Plants of the Cucurbitales order for the most part are a homogeneous group, easily distinguished from other groups of flowering plants by amateur and professional alike. The plants are usually rapid growing, sprawling vines or climbers, annual or perennial, with palmate alternate leaves, long spiral tendrils, an inferior (or enclosed) ovary, and normally with unisexual flowers that have yellow or white petals. Seeds are without endosperm (a special nutritive tissue for the developing embryo) but have large cotyledons ("seed leaves"). The fruits are readily recognized; typical examples are the cucumber, muskmelon, watermelon, pumpkin, squash, and gourd. Because numerous cultivated varieties of most members of the gourd order exist, and because the group is popular and well known, many species have received several common names. It is likewise true that one common name has often been applied to several different species. Thus, the Latin or "scientific name" of a plant in this order provides the best guide to its exact identity.

Drawing by M. Pahl

Some representative plant structures in the order Cucurbitales.

### GENERAL FEATURES

Size range and diversity of structure. There is a great range in the size, shape, and colour in the fruits of the Cucurbitales order. Some of the species (e.g., pumpkin and winter squash of the species *Cucurbita maxima*, and the white-flowered gourd, *Lagenaria siceraria*), have fruits among the largest in the plant kingdom. *Cucurbita maxima*, variety Mammoth, has jumbo-sized fruit that may weigh 75 pounds (34 kilograms) or more, while the huge oval fruits of certain cultivars (varieties originating and persisting in agriculture) of *Lagenaria siceraria* may weigh as much as 50 to 125 pounds (23 to 57 kilograms).

The cylindrical fruits of some cultivars of *Lagenaria siceraria* attain a length of 2 to 3 feet (6 to 9 metres), with a diameter of 2 to 4 inches (5 to 10 centimetres). The "snake melon," a cultivar of *Cucumis melo*, has about the same dimensions but tends to be slightly thicker in the centre.

Fruit colours of cucurbits (members of the Cucurbitaceae family; hence, the Cucurbitales order) range from almost pure white to yellow, tan, brown, orange, dark orange, light green, and dark green. In the bicolor gourds, a single fruit has two distinct areas, usually green and white, or occasionally green and orange. Many fruits are striped or mottled, as in the watermelon and some gourds. Fruits of several species have prominent spines as in the chayote and certain species of *Cucumis* (cucumber, gherkin, etc.). In *Cucumis melo* var. *reticulatus* (cantaloupe) the fruit is covered with corky tissue, commonly known as the net.

The vines of most species of cucurbits are of modest size, with runners 10 to 15 feet (3 to 4 metres) long, but some species have thread-like, matted runners that are relatively short, as in *Brandegee* and *Echinocystis*. Others have giant runners 40–50 feet (12 to 15 metres) in length with a diameter of one to three inches (2.54 to 7 centimetres) at the base of the plant. Plants of such dimensions occur in some cultivars of *Lagenaria siceraria* (white-flowered gourd) and *Cucurbita mixta* (pumpkin, squash).

Distribution and abundance. There are 90 to 100 genera and about 700 species in the order. The species are about evenly distributed between the tropics and subtropics of both hemispheres. There is, however, an overlap into temperate regions. *Marah*, the chilicothe, occurs in North America as far north as southern Oregon, and in the Middle West of the United States, *Sicyos*, the bur cucumber, extends as far north as southern Canada. Some cultivars of *Cucurbita* (pumpkin, squash, gourd) thrive as far north as the Canadian border.

The Cucurbitales is essentially a tropical order, and for this reason it is assumed to be a relatively old one, but there are no fossil materials to substantiate this informed guess. While the cucurbits never become aggressive weeds in either the tropics or subtropics, certain genera such as *Cucurbita* (pumpkin, squash, gourd), *Cucumis* (cucumber, gherkin, muskmelons), and *Citrullus* (watermelon) retain a great deal of plasticity producing numerous variants in both vine and fruit as is demonstrated by their response to selection and hybridization under cultivation.

Economic importance. For a primarily tropical order, members of the Cucurbitales are of tremendous economic importance as food plants. Surprisingly, those of most importance for food grow well in temperate regions of the world. They are of minor importance for fibre and ornamentals, and one species is used for household purposes in primitive societies.

It is difficult to estimate the economic importance of cucurbits as food plants because they are used in such a manner that they do not enter into commerce; hence production statistics are not only unavailable, there are none. For instance, the huge quantities of cucumber, squash, pumpkin, watermelon, muskmelon and others, grown by almost every backyard gardener in North and South America go unreported, and there is no way to estimate the volume or value of such crops. Likewise, in several Latin American countries the perennial *Cucurbita ficifolia* (fig leaf gourd) is allowed by the peasants to grow around their dwellings, and the fruit, mostly immature, is hauled to the markets. This constitutes a sizeable trade that is never reported. Also, cucumbers, muskmelons, and watermelons are an important item in the diet, seasonally, for peoples in vast areas of Asia Minor, U.S.S.R., India, China and Japan. Obviously, these items are never reduced to trade statistics.

The use of cucurbits as food plants is not primarily for their caloric, mineral, or vitamin values, because they are poor or only modest sources of these nutrients. They are liked for their attractive appearance, pleasant taste, and refreshing qualities. As pickles they also add diver-

Range of  
fruit  
colours

sification to the diet for people with an otherwise undistinguished menu.

There are some exceptions to the generally low nutrient content of the fruits of the Cucurbitales order. The winter or baking squash (some cultivars of *Cucurbita maxima*, *C. moschata*, *C. pepo*, etc.) are relatively high in energy and carbohydrates, and they are an excellent source of vitamin A. Besides, they contain modest amounts of minerals and other vitamins. The winter squash along with maize and beans were the foundation diet of the great pre-Columbian civilizations in the Americas. For peoples lacking modern refrigeration, cucurbits such as squash are an ideal food because they can be stored intact for long periods of time. They can also be cut into strips and dried in the sun. In this dehydrated form they can be stored almost indefinitely.

Edible and  
useful  
species

Species used for food include the following: *Cucumis sativus* (cucumber); *C. anguria* (gherkin); *C. melo* (muskmelon, including the cantaloupe, Persian, casaba, and honeydew melons); *Citrullus lanatus* (watermelon); *Cucurbita pepo* (summer squash, pumpkin, yellow-flowered gourd); *C. mixta* (pumpkin, squash); *C. moschata* (pumpkin, winter squash); *C. maxima* (pumpkin, winter squash); *C. ficifolia* (fig leaf gourd); *Lagenaria siceraria* (white-flowered gourd); *Benincasa hispida* (Chinese preserving melon); *Sechium edule* (chayote); *Sicana odorifera* (cassabanana); *Momordica balsamina* (balsam apple, Chinese bitter melon); *Trichosanthes cucumeroides* (snake gourd); *Cyclanthera pedata* (achocha); and *Hodgsonia heteroclita* (lard fruit). There are other species used for food but in a minor way and mostly by primitive tribes in Africa.

Species used for ornamental purposes include *Momordica charantia* (balsam pear), and *Cucurbita pepo* (yellow-flowered gourd).

Species used for fibre include *Luffa cylindrica* (vegetable sponge, dishcloth gourd), and *L. acutangula* (vegetable sponge, dishcloth gourd).

The main species used for containers, rattles, floats, and cutlery is *Lagenaria siceraria* (white-flowered gourd).

#### NATURAL HISTORY

**Life cycle.** The life cycle of species of the Cucurbitales order is in general similar to that of other dicotyledonous plants. There are, however, certain unique features that deserve mention. For example, polyploidy (*i.e.*, the presence in the plant cells of three or more sets of chromosomes) is relatively uncommon in the family, and chromosome number is identical for species within many genera as in *Cucurbita*, *Citrullus* and others. It is true, however, that only a small number of species have been sampled for chromosome number, and a more broadly based study is needed, particularly of tropical species, to confirm these trends.

Nearly all species in the family have unisexual flowers, and the pollen is heavy and sticky. For these reasons, pollination is entirely dependent upon insects. Except for the genus *Cucurbita*, the cultivated species are pollinated by the domestic honey bee. For cantaloupes and other muskmelons raised commercially one or two hives of bees per acre are used to obtain adequate pollination of the crop. In *Cucurbita*, (squashes, pumpkins, gourds) in which the pollination system has been thoroughly investigated, an intimate relationship exists between the cucurbit species and solitary bees of the genera *Peponapis* and *Xenoglossa*. Solitary bees are structurally and physiologically well adapted for pollination of the large *Cucurbita* flowers, much more so than domestic honey bees. As a group the solitary bees are entirely dependent upon *Cucurbita* for their pollen economy. Even more interesting, there are some examples of species to species relationship, suggesting reciprocal evolution of the bees and the genus *Cucurbita*.

Seed dissemination takes on bizarre forms in several genera of cucurbits. In *Ecballium* (the squirting cucumber), the mature fruit separates from the stem with explosive force, and the seeds are ejected from the fruit under pressure, travelling a distance of 10 to 20 feet (3 to 6 metres). In the genus *Momordica*, at maturity the

fruit bursts, exposing the scarlet arils (structures attached to the seed, often enclosing it) that probably attract the attention of birds. In a similar fashion in the primitive forms of muskmelon (*Cucumis melo*), the fruit cracks longitudinally, exposing the seeds, which can be spread by birds or other animals.

There are several genera in the Cucurbitaceae that show unusual responses to environmental stimuli. The genera *Marah*, *Cucurbita*, and *Sechium* (chayote, mango squash, and other common names) respond to arid conditions by producing a large storage root. In *Marah* and the dry-habitat species of *Cucurbita*, the foliage, flowers, and fruits develop in a remarkably short period of time, while the huge, fleshy, storage root is perennial (*i.e.*, it lives through many growing seasons). The genera *Acanthosicyos* and *Dendrosicyos* respond to arid conditions by producing scalelike leaves and succulent stems. The only shrubby species of the cucurbits are in these genera. The female flower of *Cucumis humifructus* (the aardvark cucumber) responds to gravity, after being pollinated, by plunging into the soil, where the fruit is produced from 6 to 12 inches (15 to 30 centimetres) below the soil level. *Cucumis humifructus* is the only member of the Cucurbitales order having underground fruits. It has developed an interdependent relationship with a mammal, the ant bear or aardvark, *Orycteropus ufer*, of southern Africa. The aardvark digs up and eats the fruit of *C. humifructus*, probably in part to quench its thirst. Some seeds pass through the alimentary canal of the animal intact, and are thus distributed with the dung in the vicinity of the aardvark lairs. The animal carefully prepares a hole for its dung and after defecation covers it with loose soil. This behaviour pattern of the animal results in the making of a perfect seed bed for the germination of the young plants of *C. humifructus*. Thus the association between the plant and animal contains the basic elements of a symbiotic relationship, at least to a limited degree. It is significant that the local name of the species is "aardvark cucumber."

Life  
history  
of the  
aardvark  
cucumber

**Ecology.** The prime ecological fact about members of the Cucurbitales order, one that governs their geographical distribution and area of cultivation, is their relative sensitivity to cool temperatures. There is not a single species that tolerates frost, and they are extremely sensitive to temperatures near freezing. As a group the cucurbits are intolerant of cold soils, and they are rapidly victimized by root rots and bacterial diseases in such an environment. Some of the cultivated species of *Cucurbita* (pumpkins, squashes, and gourds) exhibit great genetic plasticity, however, and plant breeders have developed cultivars with cold tolerance and a capability to grow rapidly in cool soils, but none will withstand frost.

The cultivated cucurbits require light, well drained soils with a neutral or slightly alkaline reaction for best growth. These requirements also seem to be generally true of the uncultivated species.

#### FORM AND FUNCTION

The gourd family, and hence order, has a distinct set of morphological (*i.e.*, structural) characters that easily distinguishes it from other plant families. Such characters include the prostrate or climbing habit, the mostly palmately lobed leaves on herbaceous (nonwoody) stems, that have long spiral tendrils at each node. Quite as distinctive are the flowers, which are mostly unisexual, with fused yellow or white petals. The ovary is inferior, that is, enclosed with the rest of the flower parts appearing to join it at its apex. There are other good morphological characters such as the basic number of stamens—five, which are usually highly modified. Seeds are usually present in large numbers, except in *Sechium*, which has a single seed. The fruit is fundamentally a berry (pepo), with a generally soft or sometimes hard skin (as in gourds). It sometimes splits open at maturity and is even explosive in *Ecballium* (squirting cucumber), but more generally it does not split open naturally.

Biochemical substances, mostly bitter, exist in the Cucurbitales order. These substances have been used as purgatives since ancient times. Bitter substances are wide-

ly distributed in the order. A systematic search for these substances in the Cucurbitales order indicates that the great majority of species investigated contain bitter principles in some portion of the plant (root, shoot or reproductive organs), at some stage of development. The most extensive search of this nature has resulted in the isolating of ten crystalline bitter substances, called cucurbitacins. Chemically, the cucurbitacins are tetracyclic triterpenes (*i.e.*, three ten-carbon terpene units joined in such a way that four cyclic or closed ringlike structures result) and occur in nature as glycosides (compounds that may be variously broken down into sugar and nonsugar components) in complicated mixtures. A comparative study of the nature and distribution of the cucurbitacins in various species provides useful information for determining relationships when combined with conventional taxonomic techniques.

#### EVOLUTION AND ETHNOBOTANY

Specific studies concerning the evolution of the Cucurbitales order are lacking, but those species often grouped together into the subfamily Cucurbitoideae are generally considered to be more primitive than those in the subfamily Zanonioideae. That is, the Cucurbitoideae subfamily has a predominance of characters that are considered to have appeared early in the evolution of the order. These include horizontally positioned ovules (developing seeds), stamen filaments attached to the floral tube, a single style (upper part of the ovary), and simple tendrils that spiral above the point of branching. The characters of the subfamily Zanonioideae, considered to be more advanced or to have appeared more recently in the evolution of the order, include pendulous ovules, filaments attached to or near the central part of the flower, three styles, and forked tendrils that spiral below the point of branching.

The ethnobotany, or study of the uses of plants by humans, of the squashes, pumpkins, and gourds, especially of the genera *Cucurbita* and *Lagenaria*, has become an exciting field of research within the past few years. Archeologists engaged in field work in the Americas have commenced to search out and catalogue botanical specimens as they would the common artifacts. One result has been an accumulation of authentically dated cucurbit material that can be identified at the species level. Studies of this material have provided much information about the origin and domestication of *Cucurbita* and *Lagenaria*, and the time and place where these events occurred. It is also possible by means of known archeological specimens of these genera to trace the migration of peoples and to assign to each culture the species of squash or pumpkin in common use. The white-flowered gourd (*Lagenaria siceraria*) was among the earliest of man's cultivated plants, and problems connected with its pre-Columbian distribution in the Americas have engaged the attention of geographers, archeologists, ethno-botanists and others.

#### CLASSIFICATION

Annotated classification.

#### ORDER CUCURBITALES

Annual or perennial herbaceous vines, usually with tendrils, rarely erect or suffrutescent. Leaves alternate, simple, usually with petioles and palmately or pinnately 5-lobed. Tendrils lateral, stipular in position, one at each node, simple or variously forked. Roots fibrous or fleshy, some enlarged into small or huge storage organs. Flowers mostly unisexual, monoecious or dioecious, occasionally perfect. Staminate or male flower with calyx and corolla united to form a tubular receptacle, corolla lobes usually yellow, white or cream-coloured; stamens often 3, occasionally 4 with one sterile stamen, filaments free or united, anthers free or coherent in a head, stamens basically 5, alternate with the petals, inserted on the receptacle tube or on the basal disk, but always modified in one or more ways. Pistillate or female flowers with calyx and corolla similar to the male flowers; ovary inferior, connate with receptacle to form a globose to fusiform tubular structure, often separated from the remainder of the flower by a constriction; usually with 1 locule and 3 or 4 carpels (primarily 5); style terminal with 2- or 3-lobed stigma (many lobes in some *Cucurbita*). Fruit a dry or fleshy berry or hard-shelled pepo, usually indehiscent, or occasionally dehiscent (explo-

sive). Seeds large, numerous, rarely 1; with no endosperm, embryo with large cotyledons. One family, 90 to 100 genera (depending on the authority consulted) and about 700 species distributed mainly in the tropics and subtropics.

#### Family Cucurbitaceae

The only family in the order; it has the same characters as the order.

Critical appraisal. Prior to 1961 there were at least four well-known classifications of the Cucurbitaceae. In 1961, a new classification system was proposed because information from numerous recent studies permitted a re-evaluation of the relative merits of the characters used by earlier workers.

The disputed position of the Cucurbitales order within the classification system needs to be resolved. Some authorities include at least four families within the gourd order. In most of the modern treatments, however, only one family, the Cucurbitaceae, is assigned to this order. A comparative morphological study of those families obviously closely related to the Cucurbitaceae would be helpful. Such families as the Passifloraceae, Begoniaceae, and Caricaceae are good candidates for a study of this kind, along with the Campanulaceae. Comparative biochemical studies of these families might also yield data of significance for this problem.

To make progress in understanding the crucial problems of classification in the Cucurbitaceae more growth studies in experimental gardens and greenhouses are required. Such studies should include large collections of species of known origin. Collections of this kind are not easy to assemble because most species in the Cucurbitaceae are native to tropical areas. Also, the cucurbits are not the best of experimental subjects because the plants require a relatively large area to make normal growth. Thus the limitations of space, and the lack of suitable conditions for growth makes difficult the task of growing these plants for study. Nevertheless, a significant body of systematic knowledge is commencing to accumulate in several institutions particularly for the genera *Cucumis* and *Cucurbita*.

Nat., sér. 4, Bot.*, 11:5-87 (1859), "Revue des Cucurbitacées cultivées au Mustum en 1859," *ibid.*, 12: 79-164 (1859), two papers by the French botanist, Naudin, that were the forerunners of future biosystematic studies in the Cucurbitaceae; R.R. VON WETTSTEIN, *Handbuch der Systematischen Botanik*, vol. 1 (1901, rev. ed. 1933), a classical source of information on the classification of the flowering plants; T.W. WHITAKER and G.N. DAVIS, *Cucurbits: Botany, Cultivation and Utilization* (1962), a general discussion of the economically important species of the Cucurbitaceae.

(T.W.W.)

#### Cultural Areas, Theories About

A cultural area (or culture area) is an example of what human geographers call uniform or homogeneous regions. Similar concepts are found in anthropology and history although the actual terms used may vary ("culture realm," "culture province," "civilization"). The history of

the idea, if not of the term, reaches back into antiquity and typically involves three components: (1) a socially or culturally identifiable population, (2) a "natural" environment, and (3) some postulated, implied, or identified interaction between the two. Which of the three components is given the greatest emphasis, and the actual constitution of each, has varied. Areas and regions then are intellectual constructs and not real entities.

#### Nodal and uniform regions

The design and purpose of cultural areas. The fundamental problem of attempting to regionalize cultural phenomena involves the identification of two basic types of regions, one called by geographers nodal and the other uniform. Nodal regions are areas of the earth's surface that are conceived of as being formed around a central point, or node. The focus of the spatial activity that occurs in this area is their node and the limits of the region are the limits of the activity or activities that are connected by various channels of circulation to the node. Every individual in the world forms a nodal region, as does every household, village, city, or nation. The individual is the focal point of his daily movements to or from work, his social or religious activities, his consumption, his communications, and much more. He may be envisioned as a point from which lines of interconnection radiate outward. A boundary drawn so as to include all or most of the external ends of these lines would encompass that particular nodal region. Uniform regions are regions defined by the existence of one or more particular traits or complex of traits within an area. An example would be a region formed by all the members of one individual's family, or kin group, or the region within which all or most of the individuals with a given surname appear. All nation-states, in this sense, are uniform regions by virtue of a common body of laws, and often a common language and religion as well. In the former instance, the uniform region is postulated in order to contain the stipulated phenomena—a kin or surname group. In the latter instance, the limits of the uniform region exist in the form of recognized political boundaries.

#### Problems of delimiting cultural areas

It is immediately apparent that to establish regions, whether nodal or uniform, requires a series of careful definitions. First, the criteria to be used as defining variables must be carefully identified. For cultural features, this may be relatively simple (e.g., a point where at least 50 percent of the people read and write) or more complex (e.g., a social and political definition that requires the simultaneous existence of a number of phenomena, such as voting rights, a Parliament, etc.). Second, once the characteristic is identified, the intensity of the characteristic must be specified. Will literacy, for example, be defined as the ability of a person to write his name, the ability to read and write simple declarative sentences, or the ability to read and summarize a newspaper article? If the criteria used to determine an area are numerous, it must be decided if they all have equal weight and must all be present simultaneously and in equal intensity. It must be known, for example, whether in defining a region, the type of kinship grouping will be more or less important than other variables, such as economy or material culture, and whether mixtures of all will be considered. Finally, the time period must be specified. This is most evident in such ephemeral regions as, for example, "the American frontier," but it is also necessary for seemingly more permanent phenomena, such as "Chinese civilization" or "the arid regions of the world."

The artificial and temporary nature of regions is, thus, obvious. They are classification schemes designed by investigators in order to bring understanding to a chaotic mass of fact. They vary according to the purpose of the investigation, the time period involved, and the nature of the criteria used for delineation. This is as true for "natural" regions, those defined solely in terms of nonhuman criteria, as it is for cultural regions. Because of this artificiality it is valid to say that *all* regions are cultural; the delimitation of even natural regions is dependent upon a culturally biased decision with regard to the specifying characteristics.

Theories from earliest times to the 19th century. The need to classify human populations in an areal fashion

was recognized early in the expansion of the limits of the known world. The early Greeks, for instance, began to write about various non-Greek populations as their own sphere of discovery and activity expanded. As well as finding new peoples with different appearances and customs, they were discovering that the world had different climates. The frequent conjunction of new climates and new cultures suggested both a means of classifying the information and a causal relation between the two. This mode of reasoning stemmed in the first instance from early medicine and the "humour" theory, in which good humours or bad humours (that is, certain biological fluids) influenced the human body, and the body, in turn, influenced the mind. The origin of the humour was alleged to be in the "air, water, and places," and thus the characteristic of people could be deduced from the characteristic of place. While the first formulation of this belief is attributed to Hippocrates (flourished 400 BC), it is thought that he, in turn, was reflecting even earlier thinking. From this basic conceptualization there came a division of the known world into *klimata*, or "climates," which were held in most instances to correspond to racial and cultural differences between the human populations found in them. No new and comparable attempt at a logical and systematic classification of the culture areas of the world occurred again in the West until the middle of the 19th century. The intervening centuries saw the rise and decline of a number of regional classification systems, but none that implied or demonstrated a cause-and-effect relationship. Roman writers tended to compile or repeat the work of the earlier, more innovative Greek civilization. The resurgence of learning in the Western world, after its centuries-long lapse following the fall of Rome, brought little in the way of new ideas to the question of regional divisions. In the relatively static world that existed prior to the 16th century, knowledge of other people, places, and customs was limited to a handful of merchants, adventurers, and soldiers. The first pulse of change was faintly beating, however, and the intellectual island of European thought was about to become inundated by a wave of fact and fable from elsewhere, set into motion by the fleets of the Age of Discovery. In the 75 years between 1450 and 1525, a thriving sea trade was developed between Europe, West Africa, and Southeast and East Asia; a "New World" was discovered where none was thought to exist, and the earth was circumnavigated for the first time in history. These events and the attendant changes they brought served to call attention to the existence of great cultural and climatic diversity throughout the world. As the Greeks had done almost 2,000 years before them, men once again began to speculate on the apparent covariance of habit and habitat and to assume or imply a causal relation between them.

In 1650 a German scholar, Bernhardus Varenius, set forth a regional delimitation of the known world, dividing geographic knowledge into two parts: general (what is now called systematic) and special. Special geography was to investigate areas or regions in the world that were identifiable because of specific forms of interaction between human and environmental processes. One hundred years later the philosopher Immanuel Kant was to follow and elaborate on this division. For Kant, geography, the spatial association of phenomena, was one of the few possible ways in which to organize knowledge. He himself lectured mostly in physical geography, and only briefly in what Varenius had called special geography, but his use of the dichotomy was to give it a philosophic foundation for many years to come.

Various other 18th-century writers concerned themselves with the abstract division of the subject matter of geography, but it was not until the 1790s and early 1800s that their programmatic suggestions were transformed into factual studies. Although they had valuable predecessors from whom they drew much of their inspiration, the two leading figures of this era were Germans—Alexander von Humboldt and Carl Ritter, both of whom saw the world as an organic whole. Humboldt was primarily concerned with physical and biological phenomena, Ritter with human problems in a regional context. Their

Early attention to climatic regions

views were in most respects similar; and these similarities, in the intellectual context of the time, are of interest for the future development of the culture area concept. Both were empirically oriented; that is, whereas they believed that the world was an organic whole, functioning in accordance with fixed, if as yet unknown, natural laws, they saw the eventual unfolding of these laws as stemming from observation of fact—not from the development of a priori theory.

Ritter, whose work is shot through with teleological purpose, sought evidence of man's "progress," and this idea was reinforced in Western philosophy in 1859, when Charles Darwin's *Origin of the Species* was published. This work offered an explanatory natural law regarding the relation between organisms and their environment. Certain aspects of the thesis, particularly the idea of natural selection (a process that resulted in the "survival of the fittest," according to the social philosopher Herbert Spencer), were quickly adopted by students of human society, resulting in what has been called Social Darwinism—the doctrine that competitive struggle is as natural to social evolution as it is to biological evolution. It was primarily the materialistic aspect of Darwin that was influential in Social Darwinism. Man, by scientific "law," could now be viewed properly as just another part of nature—as an animal, highly evolved, to be sure, among other animals, but no longer as a special creation of God without precedent and unique in his very essence. He was now liable to investigation in his milieu just as were all other organisms; the interactions of man and environment differed only in quantity from the interactions of other animals with their environments.

Thus the regional division of the newly discovered peoples of the world was viewed as a complex problem requiring not only the determination of regional distributions of cultural traits—such as language, religion, clothing type, pottery form, or any of the myriad other material and nonmaterial items of man's equipage—but also the determination of his cultural set in the nonhuman environment. Although man the divine might be studied in isolation from the profane world, man the animal was meaningful only in a context of soil, water, climate, and food supply. So-called natural regions had somehow to be combined with cultural regions.

The main thrust of this recombination was postponed until after the turn of the century. The natural sciences were still leading the way, and the social sciences were following after. Studies concerned with interrelations between man and environment became almost solely studies of environmental influence over man. This was so-called environmental or geographical determinism. One of the more influential of the studies of this kind was the German geographer Friedrich Ratzel's *Anthropogeographie*, in the first volume of which (1882), under the influence of Darwinian ideas, man was seen as the end product of a long evolution, during which the conditions of the natural environment had worked to shape him. Although the second volume (1891), in treating such matters as migration, diffusion of culture traits, and other social phenomena, did give culture a more active determining role, it was volume one that influenced social thought.

The year in which volume one of *Anthropogeographie* was first published saw the death of an influential French scholar, Frédéric Le Play, whose work also reflected an environmental-determinist cast. Le Play, building on the natural regions of the world that others had delineated, suggested his formula of place, work, and people. The place, identified as a natural region (steppe, tundra, forest, plain, and so on), determined, by its very nature, the livelihood, activity, or work, of the family. The basic social unit, the family, was thus structured by the natural environment. Family structure, in turn, determined the type of people who resulted, and it was these individuals who constructed suprafamily organizations, or societies. To point out that both Ratzel and Le Play confused occasional correlations with lawlike causation is not to deny their significant contributions for the time and place. They at least chose to deal with the complex whole and not the simplistic parts.

Twentieth-century theories and attitudes toward cultural areas. *The geographers.* The beginning of the 20th century saw the growing influence of a number of writers on the general subject of cultural areas. Among the most important were Sir Halford Mackinder in Great Britain, William Morris Davis in the United States, Paul Vidal de La Blache in France, and Alfred Hettner in Germany. Each of these men was concerned with the interplay of man and nature as it served to form the earth's surface into analytically recognizable areal units.

Mackinder differed from the other three in that what was to become his major contribution to geographical thought was (1) on a scale, both spatial and temporal, much grander than that of any of the others and (2) concerned with what may be viewed as a nodal region, rather than a uniform one. In 1904 he presented the concept of "the geographical pivot of history" to the Royal Geographical Society. In this paper, the main idea of which was to be widely quoted for almost 45 years, he argued that the "pivot region of the world's politics [is] that vast area of Euro-Asia which is inaccessible to ships, but in antiquity lay open to the horse-riding nomads, and is to-day about to be covered with a network of railways." He had argued that historically the steppe region of what was then Russia determined the development of a nomad way of life, which in turn was the pivotal force acting, by sporadic warfare, upon the marginal civilizations surrounding this "heartland." This pivot area was now being re-formed into a cohesive region by rail communication, and its peoples were moving into more and more southerly and easterly territories. This expanded resource base, if ever coupled with access to the sea and the development of sea power, would then form the heartland, or nodal focus, of a worldwide political system. He was to put his ideas into a succinct form in 1919 when he wrote:

Who rules East Europe commands the Heartland;  
Who rules the Heartland commands the World-Island;  
Who rules the World-Island commands the World.

Although the scope and purpose of his writing differed greatly from other geographers, Mackinder's initial postulate—that the steppelands of Russian Asia produced a certain form of livelihood, which in turn led to specific types of social and political structure and action—place him, like Le Play, in the general class of scholars concerned with the interaction of man and environment and with the regions thus formed. An American, William Morris Davis, who may be included in this broad group for similar reasons, was a physical geographer. His definition of geography, however, as the science that dealt with the interaction process, which he saw as environmental cause producing social effect, was to have profound impact on a whole generation of geographers.

Unlike Davis, and perhaps unlike most human geographers of his day, Paul Vidal de La Blache did not view man as passive in the combination of man and environment. On the contrary, he argued, man substituted goal-oriented action, action purposefully directed toward specific ends, for the "incoherent effects of local circumstances." In so doing, he believed, societies eventually established regions that were reflections of social purpose. He emphasized that the environment offered man a variety of possibilities rather than a fixed, determinate path, and he and his followers were consequently known as environmental possibilists or, more simply, possibilists. To be sure, there were restrictions on man, but these restrictions were cultural—the values of his culture, his social organization, and his technology. Roughly similar to what the anthropologists called culture, Vidal called this mix of attributes a society's *genre de vie*, or "way of life." Over long periods of time, man and environment would develop a series of unique regions, each reflecting the initial environmental conditions from which men choose, but also reflecting the effects of the cultural instruments involved in that choice. If the determinist saw society as conditioned by environment, Vidal and his school saw society and environment as mutually influencing, each cultural region formed by a unique combination of natural and cultural elements.

The idea  
of the  
heartland

Vidal devised a regional division of all France, which provided for fifteen regions, each identified by "topography and human economic activities." These regions were nodal, each being centred upon a regional capital; and the most significant organizing principle of these nodal regions was the economic infrastructure—transportation, marketing, financing, and so forth—of a modern industrial state. The proposed regional boundaries, however, did take cognizance of older lines delineating a cultural area, an area that had developed a distinct *genre de vie*.

A major figure in geography in Germany during this period was Alfred Hettner, who denied the traditional division between physical and human geography. In asserting that environmental and cultural features were so complexly intertwined as to form a single subject, not a dual one, Hettner provided the synthesis needed between the concepts of Vidal and the natural or climatic concepts of other scholars.

**The anthropologists.** Within anthropology there developed four main concepts: the culture area, the age-area hypothesis, the area co-tradition, and the *Kulturkreis*. Whereas these are logically related in their basic purpose, they are distinct enough in underlying methodology and in substantive results as to require some comment.

By the beginning of the 20th century, archaeologists and anthropologists had already conceived of a need to design areal groupings reflecting the information derived from artifacts and fieldwork. Some museum exhibits were ordered in areal fashion, and there had been some initial attempts to divide American Indian populations into culture-area complexes. An anthropologist, O.T. Mason, had devised 11 culture areas for North America, designating them in part by locations (North Pacific coast, California, Oregon), in part by climate (Arctic), in part by physiography and drainage (Interior Basin, Columbia Drainage), in part by language (Athabaskan, Algonkian), and so on. Appropriately for the time, the work in which these were set out was entitled "Influence of Environment upon Human Industries and Arts." His basic subdivisions, if not his names for them, were echoed more or less in the classifications of other anthropologists; but the significant debate inhered not in the classifications per se but in whether the divisions were real and objective or merely analytical constructs. In 1917 another anthropologist, Clark Wissler, recognized, at least in his division of the peoples of the North American continent, that he was offering only analytical constructs:

It is customary to divide the continent into culture areas the boundaries to *which are provisional and transitional*, but which taken in the large *enable us to make convenient distinctions* (Italics added).

By 1923, however, another anthropologist, Alfred Kroeber, was claiming greater reality for his almost identical areal divisions. Justifying the emphasis on spatial distinctions on the grounds that for America there was little or no historical evidence available for developing temporal ones, he wrote:

The result has been the recognition of a series of culture-areas or culture-centers. . . . These geographically defined types of culture are gradual and empirical findings. They are not the product of a scheme or imagination, nor the results of theory. . . . They do represent a consensus of opinion as to the classification of a mass of facts . . . in short, a non-philosophical, inductive, mainly unimpeachable organization of phenomena analogous to the "natural" classification of animals and plants on which systematic biology rests. (From *Anthropology*; Harcourt, Brace and Co., 1923.)

This passage connects a number of themes in the development of the culture-area concept. First, there is no distinction as yet between uniform and nodal regions (culture areas and culture centres are equated). Second, there is a strong insistence upon the scientific, inductive, nonspeculative base of the concepts (a probable reaction against the highly speculative evolutionary schemes of 19th-century writers, as well as a probable attempt to forestall criticism from those who insisted on extremely high standards of evidence and, partly as a consequence,

rejected most contemporary attempts at generalization or theory formulation). Third, Kroeber continues to exhibit a fondness for using the biological sciences as the basis for analogy in anthropological study.

Wissler was to further the concept of the culture centre as well as that of the culture area. He fused the two in his so-called age-area hypothesis. In this view, culture elements diffused outward from an initial central point. The development of this central point, or node, as one would now call it, was accidental or "historical." Once established, however, culture and environment entered into an interaction, the dominant part of which was environmental because of the relative unchangeability of the natural environment. Nonetheless, argued Wissler, culture elements have a tendency to diffuse equally in all directions from this centre. From this it could therefore be inferred that, all things being equal, the element or elements having the widest distribution were the oldest—that is, had been in the process of diffusion the longest. This areal extent was the basis for inferring age, and this was called the age-area hypothesis.

Culture areas were time specific; that is, they attempted to organize cultural elements in a spatial framework frozen at a single instant in time. The age-area hypothesis was an attempt to introduce temporal depth by pure inference. In some parts of the New World, South America in particular, there existed a chronological sequence of culture areas. It was suggested that whenever such a sequence existed simultaneously for more than one culture area and wherever it could be shown or inferred that the cultures had been interacting through time, it should be called an area co-tradition. The application of the concept was limited to the New World.

In Europe, where there was much more archaeological and historical evidence upon which to base typological constructs, the spatially oriented culture-area concept got little attention, whereas the temporally oriented concept of *Kulturkreis* (culture circle) received a great deal. Whereas both approaches were attempts to explain the distribution of culture traits, they approached the phenomena from opposite philosophical and methodological directions. The culture-area concept suggested, among other things, that there existed a body of interrelated culture elements that, in interaction with the environment, produced a culture complex that may or may not have been unique, but that was produced *in situ*. The *Kulturkreis* group had its intellectual origins in the writings of Friedrich Ratzel, particularly in the second volume of *Anthropogeographie*. Ratzel and his group insisted that migration and diffusion accounted for the distribution of most culture traits, and, thus, that independent invention was extremely rare. There were, in fact, only a limited number of *Kulturkreise*, or founts of diffusion. According to the Austrian Father Schmidt,

One of the facts which has been established by culture history beyond all peradventure of doubt is that not only discrete culture elements or small groups of elements migrate and exert influence, but also whole compact culture complexes. If such a culture complex embraces all the essential and necessary categories of human culture, material culture, economic life, social life, custom, religion, then we call it a "culture circle" [*Kulturkreis*], because returning into itself, like a circle, it is sufficient unto itself. . . . (From Wilhelm Schmidt, *The Culture Historical Method of Ethnology*; Eng. trans. by S.A. Sieber, 1939.)

The distribution of cultural traits, in this view, is generally the result of the diffusion of a trait, set of traits, or entire culture complex from one or more of these original circles.

In sum, with the exception of the concept of area co-tradition, which did not appear until after World War II, by the 1930s anthropology was beset with two conflicting schools. In America there were culture-area and age-area scholars. In Europe the *Kulturkreis* school was attempting to explain world history in terms of migration and diffusion.

**The landscape school.** A different trend had developed in geography. By the early 1920s it was generally held that the study of areas or regions constituted the basis of geographic research. Simplistic environmental de-

Temporal theories: age-area and area co-tradition

*Kulturkreis*

Culture areas

The  
concept  
of land-  
scape

terminism was pretty well dead, but there was yet no commonly accepted subject matter that would serve to delimit the discipline. An attempt to fill this need was made by the American geographer Carl O. Sauer when he published a paper entitled "The Morphology of Landscape" in 1925. Rejecting a definition of geography as the study of relations between environment and man on the grounds that relations do not constitute a subject matter, he suggested instead the study of what he called landscape. By landscape he meant not (as in conventional usage) the totality of what the eye could see before it at any given time but rather something closely akin to what sociologist Max Weber had called an ideal type, "a summation of general characteristics" of a place, or a kind of purified image of a specific scene.

The study of cultural landscape became a genetic study of its formation and development. Cultural landscapes, for the geographer, were the result of cultural factors (populations, technology, etc.) working through time on the medium of the natural landscape. The base line from which such a study was to begin was the undisturbed natural environment that existed prior to the arrival of any human group. It was basically on this idea that the concept tended to founder, for such undisturbed landscapes are exceedingly rare anywhere on earth, and one could often only speculate on the character of such landscapes in past ages; research, in any case, tended to become removed further and further back in time and more and more remote in place. In a sense this landscape school provided an uneasy link between the culture areas of American anthropology and the *Kulturkreise* of the Europeans. In order to trace thoroughly the evolution of a given landscape, it became necessary to trace the origins and migrations of its successive inhabitants, and an interest in cultural origins and dispersals became a distinctive trait of this brand of cultural geography.

Decline of cultural area concepts. Although Darwin had provided some concepts for rigorous analysis, he had also provided an excuse for innumerable exercises in speculative history, most particularly when evolutionary ideas were applied to human society. In reaction to this wave of frequently groundless theorizing, geographers, anthropologists, and other social scientists sought refuge in an empiricism so strict as almost to deny the probability of the sun rising on any given day. Such terms as *a priori* and words like theory became anathema; and much that was written, particularly during the first decades of the 20th century, was prefaced by pronouncements of faith in empirical evidence and inductive reasoning, a denial of philosophical purpose or any pretense of establishing general principles of interaction. The observations in these disciplines, however, appeared to require explanation as well as description; and while frequently denying any attempt at generalization, a number of scholars attempted to imply or state the existence of general tendencies seemingly inherent in various phenomena. Such statements of generalizations or hypothetical tendencies are not theories, however, and they vary widely in their applicability or explanatory power.

Today the concepts of cultural areas, cultural landscapes, and the like are perhaps best known as teaching devices or as simple typological structures for ordering data. As such they remain useful analytical concepts. The fundamental areal assumptions of the concepts are still reflected in the curricular structure of courses in schools; and most professional scholars in geography and anthropology are identified as specialists in one, or perhaps two, culture areas. This is becoming less true in both disciplines, however, as systematic concepts are replacing what are now viewed as typological ones.

**BIBLIOGRAPHY.** For the pre-scientific era, RH. LOWIE, *The History of Ethnological Theory*, ch. 1 (1937), provides a critical summary from the anthropological viewpoint; although the same author's "The Renaissance Foundations of Anthropology," *Am. Anthropol.*, 67:1-20 (1965), presents a new interpretation of Renaissance foundations. A critical re-evaluation and comparison of the *Kulturkreis* and culture-area schools will be found in MARVIN HARRIS, *The Rise of*

*Anthropological Theory* (1968). In the geographical field, R.E. DICKINSON and O.J.R. HOWARTH, *The Making of Geography* (1933), similarly remains the standard text for developments prior to 1800. For 19th-century developments RICHARD HARTSHORNE "The Nature of Geography: A Critical Survey of Current Thought in the Light of the Past," *Ann. Ass. Am. Geogr.*, 29:173-412 (1939), is an exhaustive and standard guide that is indispensable for the consideration of the philosophical aspects of areal differentiation, particularly as seen in Germany. For the formative and classical periods of regional geography and culture-area theory in the first half of the 20th century, there are many studies. For the French school, a general survey and bibliography is given by R.J. HARRISON CHURCH in T.G. TAYLOR (ed.), *Geography in the Twentieth Century*, 3rd enl. ed. (1957). An excellent historical evaluation of Vidal de la Blache and his school is by E.A. WRIGLEY in RICHARD J. CHORLEY and PETER HAGGETT (eds.), *Frontiers in Geographical Teaching* (1965). For German geography under Hettner, see RICHARD HARTSHORNE, *op. cit.*, for an exhaustive treatment, with bibliography. For British regional studies, SIR C.F. FOX, *The Personality of Britain*, 4th ed. (1947, reprinted 1959); and C.B. FAWCETT, "Natural Divisions of England," *Geogr. J.*, 49:125-141 (1917), are type studies. For the American cultural-area school, R.F. BENEDICT, "Configurations of Culture in North America," *Am. Anthropol.*, 34:1-27 (1932), contains a useful introduction. E. BACON, "A Preliminary Attempt to Determine the Culture Areas of Asia," *SWest. J. Anthropol.*, 2:117-132 (1946), is an illustrative type study. There is a scattering of surveys on contemporary developments. Among them, R.T. ANDERSON, "Recent Trends in Ethnology," *Ann. Am. Acad. Pol. Soc. Sci.*, 369:141-148 (1967), is a brief survey; and SISTER MARY ANNETTE, "The Changing French Region," *Prof. Geogr.*, 17:1-5 (1965), reviews regionalist controversy in French geography. Alternative interpretations of trends in American geography may be found in B.J.L. BERRY, "Approaches to Regional Analysis: A Synthesis," *Ann. Ass. Am. Geogr.*, 54:2-11 (1964); and J.D. CLARKSON, "Ecology and Spatial Analysis," *ibid.*, 60:700-716 (1970); E.G. BOWEN, "Le Pays de Galles," *Publs. Inst. Br. Geogr.*, no. 26 (1959), represents recent British geographical and anthropological critiques of early regionalist studies. D.W. SCHWARTZ, "Culture Area and Time Depth: The Four Worlds of the Havasupai," *Am. Anthropol.*, 61:1060-1070 (1959), has a useful introduction; A. SPOEHR, "The Part and the Whole: Reflections on the Study of a Region," *Am. Anthropol.*, 68:629-640 (1966), surveys current thought relating to regions. J.H. STEWARD, *Theory of Culture Change: The Methodology of Multilinear Evolution* (1955), is an important critique of culture-area studies in America.

(J.D.Cl.)

## Cuneiform Law

Cuneiform law embraces the body of laws revealed by documents written in cuneiform script, a writing invented by the ancient Sumerians and used in the Near East in the last three millennia BC. It includes the laws of the majority of the ancient inhabitants of the Near East—especially the Sumerians, Babylonians, Assyrians, Elamites, Hurrians, Kassites, and Hittites—who, in spite of many ethnic differences, were in sufficient contact with one another to develop similar civilizations. In certain periods this cultural community was reinforced by the diffusion of Akkadian, a diplomatic and scholastic language written in cuneiform. Thus to group together a certain body of laws and name them cuneiform, far from being arbitrary, is a scientific necessity. No other term would do: "Mesopotamian law" would cover only part of the range of laws involved; the notion of ancient "Near Eastern laws" is too vast, for it would also include, for instance, both Judaic and Egyptian laws, which were separate developments (see JUDAISM; EGYPTIAN LAW).

The law with which this article is concerned involves those peoples who inhabited Mesopotamia, the "land between the rivers" (*i.e.*, the Tigris and Euphrates), as well as adjacent areas. Three main peoples contributed to the civilization of Mesopotamia. The earliest, dating from before 3000 BC, were the Sumerians, who lived in a small area lying near the mouths of the rivers. Early in the 2nd millennium BC political power began to move north up the Euphrates to the city of Babylon. The brilliant 1st dynasty of the Babylonians lasted some 300 years and reached its greatest height about the 18th century BC under Hammurabi. Hammurabi spread the rule of the Babylonians south into Sumer and westward into Syria

tions of  
Sumer,  
Babylonia,  
and  
Assyria

on the Mediterranean. After his death, the empire began to crumble, and wave after wave of tribes and nations swept down from the north and east—among them, the Hittites from Asia Minor, the Hurrians from the Caucasus, and the Kassites and the Elamites from Persia. Finally, a centre of power arose once again toward the end of the 2nd millennium BC, this time in Assyria, in the hill country of the upper Tigris. Lying at the nexus of a great trade and migratory route, Assyria was frequently attacked from both north and south, and the Assyrians developed as a warrior people governed by the strictest of laws. In their great periods of empire, from the 9th to the 7th century BC, their control extended over vast areas from the Mediterranean to the Persian Gulf.

Much of the evidence of these civilizations is relatively new. The nature of cuneiform law itself began to be revealed only about a century ago, more particularly since 1900, with the decipherment of inscriptions on stone and clay tablets unearthed in the Near East. These documents now number about half a million, three-quarters of them more or less directly related to the history of law—dealing, as they do, with contracts, acknowledgments of debts, receipts, inventories, and accounts, as well as containing records and minutes of judgments rendered in courts, business letters, administrative and diplomatic correspondence, laws, international treaties, and other official transactions. The total evidence enables the historian to reach back as far as the beginnings of writing, to the dawn of history. Unfortunately, however, the complexity of the writing system and the difficulties inherent in trying to understand an ancient mentality impose limits on present knowledge of cuneiform law. Moreover, because of the inconvenience of writing in stone or clay, Mesopotamians wrote only when economic or political necessity demanded it. There are no collections of juridical doctrines or historical and literary works of an interpretive nature comparable to those of the Greeks and the Romans, and thus the reconstruction of certain ideas and facts must be somewhat tentative.

#### THE COLLECTIONS OF CUNEIFORM LAWS

The various collections of cuneiform laws developed by the several nations and kingdoms have certain features in common: (1) The text of several collections contains a prologue and an epilogue in which the prince emphasizes the importance of his actions, explains the object of his work, and commands its observance by blessings or threats. (2) Though written as if inspired by the gods, the legislation is secular, composed of dispositions fixed and codified by the temporal lord. (3) Though the laws may derive from different sources—custom, judicial decisions, or deliberate legislation—the fact that they are introduced by the prince gives them all the character of legislation or enactment. (4) In contrast to modern codes, these ancient Oriental "codes" do not systematically treat all the rules applicable to a given area of law; that is, they treat a variety of matters but often ignore many highly important rules simply because such rules were so grounded in custom that they went unquestioned. (5) Because legal customs were generally known, the collections focussed on explaining individual cases, setting them up as examples or precedents, and did not represent an attempt to devise general, abstract formulas. (6) Because of this absence of doctrinal intent, the order of presentation of the cases often seems, at least to modern eyes, erratic. Although sometimes it appears that the draftsman arranged the material according to some juridical criteria or some association of ideas or concrete subjects, the arrangements often defy modern interpretation.

Here it is possibly only to illustrate some of the major laws or codes extant. The most ancient legislator known is Ur-Nammu, the founder of one of the Sumerian dynasties at the city of Ur. His code, dating about 2100 BC, dealt with witchcraft, the flight of slaves, and bodily injuries. A more ample vestige of Sumerian law is the so-called Code of Lipit-Ishtar (c. 1934–24 BC), which contains the typical prologue, articles, and epilogue and deals with such matters as the rights of persons, marriages, successions, penalties, and property and contracts.

Although earlier Babylonian codes are known, unquestionably the most perfect monument of Babylonian law is the Code of Hammurabi (c. 1758 BC), the main record of which was discovered on a stele, or stone monument, only in 1901–02. At the top of the stele a low relief represents the king in prayer before the god of justice; beneath it, engraved, is the text of laws, consisting, apart from the prologue and epilogue, of no less than 282 paragraphs. The fact that copies of parts of the code have been discovered elsewhere, in nations scattered over a millennium of time, confirms that the code had a lasting interest in the ancient Orient, even in countries where it no longer had force. Like some other Near Eastern codes, the Code of Hammurabi deals consecutively with penal law, the law of persons, family law, and price lists. It differs from earlier codes, as well as from the earliest laws of the Western world of Greece and Rome, with regard to the relative importance given to laws concerning property and other economic matters. Indeed, Babylonian society of the 1st dynasty is, in terms of its individualism, wealth of private property, and development of commercial exchange, far more "modern" than, for example, Roman society of the early republic.

Though developed later in time, the Assyrian laws sum up the image of a society of a lower cultural standard. The existing tablets, reflecting legal conditions of the 15th to the 13th century BC, before the Assyrian age of empire, deal with personal property, with questions of landed property, and with women and family law. The law is that of the patriarchal society, rather strict in its rules.

Among the laws of other peoples who invaded the area may be mentioned the Hittite Law Code, dating from about the 14th century BC. It reflects a society that had remained largely on the level of a rather closed rural economy, dominated by a feudal aristocracy. The penal laws, though less severe than those in Assyria, were nevertheless rather barbarous insofar as pecuniary compensations were concerned.

#### THE AREAS OF CUNEIFORM LAW

**Law of persons and family law.** At the dawn of the 3rd millennium BC the life and polity of Sumerian communities centred on the local temple, where citizens gathered in assembly not only to worship but also to decide matters relating to the creation and upkeep of the network of dykes and canals indispensable to life in the alluvial plain. Though there was a king, a kind of "president," society was founded largely on equality. Eventually, however, the king's power grew, and there developed privileged civil servants, and thus family property—the origin of economic distinctions. Stratification became even more noticeable when, as weaker cities were absorbed by stronger, territorial kingdoms took shape. In a typical principality, society came to be divided into three classes: (1) the free men who had high status, but whom one could hardly call a citizen, because increasing despotism had eroded his participation in governing public affairs; (2) the free men of inferior status, who paid or received lower sums in legal actions, as offender or victim; and (3) the slave, a human being who could be sold and was considered property. Slavery, unknown to the first societies founded on equality, developed in Mesopotamia when captives were taken in wars (the ideogram for "slave" mean: "the man from a foreign land," or "the enemy"). Slaves increased in number as children inherited their parents' bondage, as delivery into servitude became a common means of punishment, and as free children began to be sold into slavery. In some respects the conditions of a Mesopotamian slave was more favourable than that, for instance, of a Roman slave: he could own property, appear in court, and contract marriage, not only with another slave but also with a free person. This extraordinary legal capacity reflects an absence of dogmatism: the Orientals never thought of artificially classifying the slave among "things."

**Marriage and family.** The Mesopotamian family was patriarchal and established on marriage and adoption. Marriage was a union less of two individuals than of

The Code of Hammurabi

The general features of the law codes

Social stratification: free men and slaves

two families. This concept, for example, accounts for the levirate, a custom obliging or authorizing a man to marry his brother's widow, a custom found in such nations as Assyria. The practice occurred only if the widow had no male issue and might be explained as a means of safeguarding the family succession by offering the widow the possibility of procreating sons derived from the deceased husband's bloodline. The Babylonians and the Hurrians, who did not practice levirate, had an analogous practice: the head of the family could guard against the unfortunate effects of the premature death of his son by "adopting" his daughter-in-law and uniting her to one of his other sons.

In Sumer, marriage took place before judges; in Babylon it was concluded by a convention, often written, between the future husband (or his father) and the father of the bride. In most Mesopotamian societies the bride brought with her a dowry, and the man paid a bride-price as well. Besides the normal marriage, based on a written document, the Assyrians knew marriage that involved raising a concubine to the rank of a legitimate wife and marriage that resulted after a widow had cohabited with a man for two years. Monogamy was moderated in several ways: in Babylon, certain husbands could have a second wife; in Assyria, a man sometimes had a second wife ranking below the principal one; and the levirate, of course, could result in a man's being united with his brother's widow as well as having his own chosen wife.

Paternal  
and  
husbandly  
authority

The authority of the head of the family appears to have been less severe in Mesopotamia than it was, for example, in Rome and apparently did not last throughout his lifetime and the lifetime of his children. As punishment, the father could alienate or disown his child, but it seems that he could sell his children only in case of need; that is, sworn poverty. Husbandly authority, though strict in Assyria, was compromised elsewhere by the wide freedom of action at least tacitly given to the wife; in fact, she was generally subordinate only in the sense that everyone was under the authority of the head of the family. When a young girl, she was under the authority of her father, when married under that of her husband.

**Divorce.** In Babylon a husband might repudiate his wife if she committed certain offenses; in such cases, he could send her away without any compensation or even reduce her to servitude in her own house. He could also divorce her for reasons of alleged sterility, but he had to give her parting compensation. If he repudiated her for no reason, she was entitled to take back her dowry (if there were a dowry), and the judge could confer upon her the lifetime use of certain properties belonging to the husband, as well as the guardianship of the children. She could sometimes even succeed to his inheritance, even if she remarried. For the wife's part, she could obtain divorce for serious wrongs committed by her husband, but her risk was that a claim deemed to be unjustified exposed her to a death sentence. The Assyrian system was even less favourable to the wife; she was apparently never entitled to compensation, regardless of the nature of the divorce.

**Adoption.** Adoption served a variety of purposes: to create descendants or increase their number for the continuance of a family or business, to legitimate a bastard son, to liberate a slave, to establish an heir, to give a wife to a son, or to grant someone an inalienable property. One could adopt a son, a brother, a daughter-in-law, even a father.

**Inheritance.** The patrimony went first to all the sons or their male descendants (primogeniture, or preferential inheritance on the part of an eldest son, was known only in Assyria and a few Babylonian communities), but the exclusion of daughters was more apparent than real, since the dowry was considered an advance on the inheritance; in any case, if there were no sons, the daughters inherited. In the absence of descendants, the inheritance went to the brothers of the deceased.

A father might favour one of his sons, but a complete disinheritance was possible only if it were judicially established that a child had committed a serious offense.

Property law and contract law. Three kinds of property existed: state property, family property, and private (or individual) property. In certain ages and nations—such as the 3rd dynasty of Ur and among the Kassites—there existed a variety of state socialism, with most property owned collectively; in the earliest Sumerian period all land or soil belonged to the god of the city; that is, it was collectively owned. On the other hand, during the great 1st dynasty of Babylonia, private property assumed prime importance in the nation's economic wealth. At all times, records of real estate indicate the continuing importance of jointly owned family property.

In all Mesopotamian societies there existed land tenures, which were inalienable, though transmissible by inheritance, and which were granted by the prince to those whom he wished to reward for personal services. Among some of the more warlike nations of Mesopotamia, this system resembled feudalism; that is, as in many military societies of the past, the maintenance of expensive armament and chariots obliged a prince to grant his warriors the economic means to acquire and keep such equipment in good condition.

Among all Mesopotamian peoples, the different varieties of contracts—exchange, sale, loan, deposit, surety—were practiced without there having appeared the abstract notion that a contract engendered an obligation. A sale always remained an operation in cash. To obtain the effects of a sale on credit, for example, the buyer or seller resorted to fictions: the seller "loaned" the buyer the object in question or "deposited" it with the buyer until payment was made. Conversely, when payment was made in a purchase for future delivery, the seller might be considered a temporary "tenant" of the property, or he might be considered to have retained it on "loan."

**Penal law.** The most ancient societies sanctioned private revenge and the execution of severe punishments within the household. Although such practices survived for some acts (notably in Assyria), the state tended to take over more and more jurisdiction of crimes and other injuries and wrongs, introducing fines as well as corporal punishment.

In the Code of Hammurabi and the Assyrian laws, the ruling principle of punishment was the *lex talionis*, or "eye for an eye," though the death penalty was also freely inflicted not only on murderers but also on a variety of thieves, brigands, persons guilty of criminal negligence, false accusers, and so on. Corporal punishment was inflicted according to the nature of the offense: for example, the hand that struck a father was cut off. The notion of a "life for a life" extended to such extremes as the execution of a builder's son for negligence in construction causing the death of a purchaser's son.

Even in its most barbarous manifestations, however, penal law showed a concern for impartiality. The intention of the offender was taken into consideration: the man who was unaware that his sexual partner was a married woman was not guilty of adultery; a shepherd was not liable for damages inflicted by wild beasts on the cattle in his care. Penalties or rewards must be equitable; co-authors must suffer the same punishment or profit equally from an action.

**BIBLIOGRAPHY.** The chief bibliographical work is the *Introduction bibliographique à l'histoire du droit*, specifically vol. A/2, *Droits cunéiformes*, ed. by G. CARDASCIA and J. KLIMA (1966), and vol. A/3, *Hethitisches Recht*, ed. by R. HAASE (1967). Recent interpretive works include: J. GAUDEMET, *Institutions de l'antiquité*, pp. 13–95 (1967); R. HAASE, *Einführung in das Studium keilschriftlicher Rechtsquellen* (1965); and V. KOROSÉC, "Keilschriftrecht," in *Handbuch der Orientalistik*, pt. 1, suppl. vol. 3 (1964). A.L. OPPENHEIM, *Ancient Mesopotamia: Portrait of a Dead Civilization* (1964), describes the social, economic, and political structures. The best legislative sources are the following: R. HAASE, *Die keilschriftlichen Rechtssammlungen in deutscher Übersetzung* (1963); S.N. KRAMER, "Ur-Nammu Law Code," *Orientalia*, 23:40–48 (1954); F.R. STEELE, "The Code of Lipit-Ishtar," *American Journal of Archaeology*, 52:425–450 (1948); R. YARON, *The Laws of Eshnunna* (1969); G.R. DRIVER and J.C. MILES (eds.), *The Babylonian Laws*, 2 vol. (1952–55), *The Assyrian Laws* (1935); and E. NEUFELD, *The Hittite Laws* (1951).

## Curie Family

For 60 years, two generations of the French Curie family played a prominent role in the development of modern physics, beginning with studies of crystal symmetry and the discovery of polonium and radium, and extending to the building of nuclear reactors. Pierre and Marie Curie, their daughter Irene, and son-in-law Frédéric Joliot, all recipients of the Nobel Prize, provided fundamental insights into the constitution of the atom. Their research on radioactivity led to an increasingly close alliance between atomic physics and theoretical chemistry.

**Pierre and Marie Curie.** *Pierre Curie.* Born in Paris on May 15, 1859, Pierre was educated by his father, who was a physician. At 14 he developed a keen interest in mathematics and revealed a particular aptitude for spatial geometry. Matriculating at the Sorbonne at 16, he obtained his *licence ès sciences* (bachelor of science) at 18 and in 1878 became a laboratory assistant there. In the same year Pierre performed his first work on the calculation of the wavelength of heat waves. He then studied crystals with his elder brother Jacques. The Curie brothers associated the phenomenon of pyroelectricity, explained by Lord Kelvin—the appearance of electric charges due to heating—with a change in the volume of the crystal on which it appears; following this work, they discovered piezoelectricity—the generation of electric charges in a nonconducting crystal that is subjected to pressure and, conversely, the change in volume in certain crystals when subjected to an electric field. Later Pierre formulated the principle of symmetry, which states that it is impossible to bring about a specific process in an environment lacking a certain minimal dissymmetry characteristic of the process, and holds that this dissymmetry cannot be found in the effect if it does not exist in the cause. He then defined the symmetry of different physical phenomena, such as the relation between electrical field and electrical current in conducting crystals.

After his appointment in 1882 as supervisor at the *École de Physique et de Chimie Industrielle* at Paris, Pierre continued his research. He perfected an aperiodic, analytical balance in which the last decimal weight can be read promptly and directly, the oscillations of the beam being rapidly damped. Then, for his doctoral thesis he began the study of magnetism with the aim of discovering if transitions exist between the three types: ferromagnetism, paramagnetism, and diamagnetism. In order to measure how much force a magnetic field exerted on a sample, he constructed a very accurate torsion balance, which, in a simplified version, is now called the magnetic balance of Curie and Chèneveau. He discovered Curie's law—that the magnetic susceptibility of paramagnetic bodies varies in inverse proportion to the absolute temperature. He established an analogy between paramagnetic bodies and

perfect gases and between ferromagnetic bodies and condensed fluids, suggesting that the phenomenon of ferromagnetism could be represented by the same type of equation used for fluids, as it was later established by the physicist Pierre-Ernest Weiss. The demonstration given by Curie of the totally different character of paramagnetism and diamagnetism was later also explained theoretically by Paul Langevin, the French physicist. In 1895 Curie defended his thesis on magnetic properties at different temperatures and was granted a doctorate of science.

**Marie Curie.** *Manya Skłodowska* (familiarly known as Mania and later by her French name Marie) had been born on November 7, 1867, in Warsaw. From childhood she had been remarkable for her prodigious memory and at 16 had won a gold medal on completion of her secondary education at the Russian lycée. Because her father, a teacher of mathematics and physics, had lost his savings through bad investment, she had been obliged to help the family. While working as a teacher she had clandestinely taken part in a nationalist "free university" (*l'université volante*) by reading in Polish to women workers; and at 18 she had taken a post as governess, contributing her earnings to her sister Bronia's medical studies in Paris, on the understanding that Bronia later would help her.

In 1891 Marie Skłodowska had gone to Paris, where she attended the lectures of Paul Appell, Gabriel Lippmann, and Edmond Bouty at the Sorbonne. Marie often worked far into the night in her garret in the students' quarter, where she lived on a diet of bread, butter, and tea. She had achieved the *licence ès sciences physiques*, ranking first place, in 1893 and began to work in Lippmann's laboratory. In 1894, the year she met Pierre Curie, she had obtained the *licence ès sciences mathématiques*, ranking second.

**Joint work.** The marriage of Pierre and Marie on July 25, 1895, marked the start of a partnership that soon achieved world significance. Their first daughter, Irene, was born in 1897.

Looking for a thesis subject, Marie became intrigued by recent discoveries in physics: Henri Becquerel had discovered in 1896 a new phenomenon, the spontaneous emission by salts of uranium of rays similar to X-rays, and it was known that electrically charged bodies were discharged by gases submitted to those rays. Deciding to find out if the property discovered in uranium was to be found in other matter, she discovered that it was true for thorium at the same time as did the German chemist Gerhard Carl Schmidt.

As she began to study minerals, her attention was drawn to the mineral pitchblende, the emission of rays from which is superior to that of pure uranium; the activity of pitchblende could be explained only by the presence in the ore of an unknown substance. Pierre Curie joined her in the work she had undertaken to resolve the problem.

Discovery of piezo-electricity and principle of symmetry

Analysis of pitchblende

Discovery  
of  
polonium  
and  
radium

By using an ionization chamber and a piezoelectric quartz electrometer, he could compensate for the electric current produced by the active sample by adjusting the quartz. Thus the electric charges produced by the radioactivity were measured by weights applied to the quartz. While working with Marie to extract pure substances from ores, which they achieved using relatively primitive conditions, Pierre also concentrated on the physical study, including the luminous and chemical effects of the new radiations. By measuring the action of magnetic fields on the rays given out by the radium, he proved the existence of varying amounts of three types of particles—electrically positive, negative, and neutral ones that Sir Ernest Rutherford later called alpha, beta, and gamma rays. The varying amounts of particles were caused by radioactivity, a term first used by Marie in 1898, in the thorium. Moreover, the measurement techniques of Marie and Pierre in the same year led them to announce the discovery of two new elements, polonium (in honour of her country) and radium. Pierre studied then the radiations by calorimetry and also observed the physiological effects of radium.

Refusing a chair at the University of Geneva in order to continue his joint work with Marie, Pierre was appointed lecturer in 1900 and professor in 1904 at the Sorbonne. In 1900 Marie was appointed a lecturer in physics at a school for girls at Sèvres where she introduced a method of teaching science based on experimental demonstrations. In 1903 the Curies and Becquerel shared the Nobel Prize for Physics for the discovery of radioactivity; and in the same year Marie received her doctorate of science and Pierre and Marie were awarded the Davy Medal of the Royal Society of London. The Curies' second daughter, Eve, was born in 1904. In December 1904, Marie was appointed chief assistant in the laboratory directed by Pierre, who was elected to the Académie des Sciences in 1905. Pierre was run over by a dray in Paris on April 19, 1906, and died instantly.

*The work continued.* The sudden death of Pierre Curie, although it was a bitter blow to Marie, was also a decisive turning point in her career; henceforth she devoted all her energy to completing the scientific work they had undertaken. On May 13, 1906, she was appointed to the professorship that had been left vacant on her husband's death, becoming thereby the first woman to teach in the Sorbonne. In 1908 she became titular professor. In 1910 her fundamental treatise on radioactivity was published; the same year (with the help of the French chemist Andre-Louis Debierne), she obtained pure radium in the metallic state. In 1911 she was awarded the Nobel Prize for Chemistry, for the discovery of radium and polonium and the isolation of pure radium.

Medical  
application  
of radium

Throughout World War I, Marie Curie, with the help of her daughter Irène, worked on the application of X-rays for medical diagnosis, particularly in the treatment of wounded soldiers. In 1918 the Radium Institute, the staff of which Irène had joined, began to function in earnest. It was to become a major centre for nuclear physics and chemistry. Marie Curie, then at the height of her fame, in 1922 became a member of the Académie de Médecine; she devoted her researches to the study of the chemistry and medical applications of radioactive substances.

In 1921, accompanied by her two daughters, Marie made a triumphant journey to the United States, where President Harding presented her with a gram of radium bought as a result of a fund drive among American women. Continuing her travels overseas, she gave lectures and was made a member of the International Commission on Intellectual Cooperation by the Council of the League of Nations. She also had the satisfaction of seeing the development of the Curie Foundation in Paris and the inauguration in 1932 in Warsaw of the Maria Skłodowska-Curie Radium Institute, of which her sister Bronia became director. But her chief joy was the success of the new team formed by her daughter Irène and the brilliant Frédéric Joliot.

**Irène Curie and Frédéric Joliot.** *Irène Curie.* Born on September 12, 1897, Irène from 1912 to 1914 prepared for her *baccalauréat* at the Collège Sévigné. During

World War I, while working as an X-ray technician in the army, she began work toward a degree in physics. As Marie Curie's assistant in 1918, she served an apprenticeship in the manipulations and precision measuring of radioactive elements and proved to have her father's aptitude for using ingenious devices. She used the new cloud chamber, devised by the Scottish physicist C.T.R. Wilson, in which ionizing radiation induces the formation of droplets of moisture, giving an image of the trajectory of the rays in the chamber. In 1925 she presented her doctoral thesis on the alpha rays of polonium. In the same year she met Frédéric Joliot in her mother's laboratory; she was to find in him a mate who shared her infatuation with science, sports, humanism, and the arts.

*Frédéric Joliot.* Born on March 19, 1900, Jean-Frédéric Joliot was the last of six children. His father had passed on to him a fondness for hunting, fishing, and music. Frédéric's mother (*née* Roederer) held liberal republican opinions that greatly influenced him, and Frédéric had acquired a liking for painting from his gifted sister Marguerite. As a boarding student at the Lycée Lakanal, the young man had distinguished himself more in sports than in studies. Reversals of family fortune had then forced young Joliot to choose a free public education at the Lavoisier municipal school in order to prepare for the entrance competition at the Ecole de Physique et de Chimie Industrielle, where Pierre Curie had been supervisor. Frédéric had been accepted in 1919 but because of illness had not entered until 1920. There the director of studies, Paul Langevin, had influenced him in scientific, pedagogical, and social questions. Frédéric, who had acquired a great admiration for the work of the Curies, had been graduated, ranking first place, with a degree in engineering from the Ecole. After completing his military service, he had accepted a research scholarship and, on the recommendation of Langevin, had been hired in October 1925 as Marie Curie's assistant.

Joliot simultaneously pursued new studies to obtain his *licence ès sciences* in 1927, his teaching activities at the Ecole d'Électricité Industrielle Charliat in order to augment his finances, and the learning of laboratory techniques under the guidance of Irène Curie. His first work, which dealt with dilute solutions of radioactive salts, was used in his doctoral thesis, presented in 1930, on the electrochemical properties of radioactive elements.

Joliot had seen beneath the rough and cold exterior of Irène Curie "an extraordinarily sensitive and poetic creature" in whom he was to find "the purity, common sense and tranquility of Pierre Curie." They were married on October 9, 1926. Their daughter Héléne was born in 1927 and their son Pierre in 1932. Beginning in 1928 they signed their scientific work jointly.

**The Joliot-Curies.** Irène and Frédéric Joliot-Curie manifested a great interest in the study of atomic nuclei, along the lines of the pioneer work of Ernest Rutherford, who in 1911 and in the 1920s had devised techniques for bombarding nuclei with alpha particles (helium ions). They were aided in their research by the intensity of the radioactive sources at their disposal. One of the outstanding achievements of Marie Curie was to understand the need to accumulate intense radioactive sources, not only for the treatment of illness but also for research in nuclear physics. The resulting stockpile was an unrivalled instrument until the appearance after 1930 of particle accelerators. The existence at the Radium Institute of 1.5 grams of radium in which, over a period of several years, radium D and polonium had accumulated was a decisive contribution to the success of the experiments undertaken in the years around 1930. Frédéric and Irène were highly skilled in the use of radiation detectors. Frédéric used the ionization chamber. But the Wilson cloud chamber, which Irène had taught him to use, was his favourite instrument; it permitted him to obtain the first photograph, in 1932, of the simultaneous production of an electron-positron pair.

Their contribution to the discovery of the neutron was also decisive. Having studied in 1931 the strongly penetrating radiation described in 1930 by W.W. Bothe and H. Becker, the Joliot-Curies published on January 18,

1932, the surprising result that such a radiation is able to project heavy nuclei and is not composed of photons, the discrete particles of which light is composed. On February 27, 1932, Sir James Chadwick, having reviewed the experiments in the Cavendish Laboratory, interpreted the particles, in the journal *Nature*, as the neutrons postulated as early as 1923 by Rutherford.

In 1934, the year Frédéric Joliot-Curie was appointed lecturer at the Sorbonne, Frédéric and Irene directed an experiment in which a thin sheet of aluminum was bombarded with alpha particles from an intense source of polonium; neutrons and positrons were emitted, the latter continuing to appear after the withdrawal of the source of polonium at a rate that decreased exponentially with time. Radioactive phosphorus was thus formed. In the same way, radioactive nitrogen could be formed by bombarding boron, and radioactive silicon was formed when magnesium was the target. The radioactive elements were in fact produced also with particle accelerators in other laboratories, but their artificial formation was discovered in Marie Curie's laboratory. Thus, Marie Curie had the pleasure of seeing the first sample of artificial radioactive material a few months before she died of leukemia caused by radiation on July 4, 1934, near Sallanches.

Radioactive isotopes were developed, and their use soon became widespread; the Joliot-Curies saw their applications in medicine and biology. In 1935 they were awarded the Nobel Prize for Chemistry for the synthesis of new radioactive elements. The Joliot-Curies then moved into a home at the edge of the Parc de Sceaux. They left it only for visits to their house in Brittany at Pointe de l'Arcouest, where university families had been meeting together since the time of Marie Curie. And, for the sake of Irene's lungs, they visited the mountains of Courchevel during the 1950s.

Frédéric, appointed professor at the Collège de France in 1937, devoted a part of his activities to preparing new sources of radiation. He then supervised the construction of electrostatic accelerators at Arcueil-Cachan and at Ivry and a cyclotron of seven million electron volts at the Collège de France, the second (after the Soviet Union) installation of equipment of this type in Europe.

Irene then devoted her time largely to the upbringing of Hélène and Pierre. But both she and Frédéric had a lofty idea of their human and social responsibilities. They had joined the Socialist Party in 1934 and the Comité de Vigilance des Intellectuels Antifascistes (Vigilance Committee of Anti-Fascist Intellectuals) in 1935. They also took a stand in 1936 on the side of Republican Spain. Marie Curie had already favoured granting to women the right to vote. Irene was also convinced that women did not have the place in society they deserved. Considering it her duty, therefore, to accept the high offices that were offered her, she was one of three women to participate in the Popular Front government of 1936. As undersecretary of state for scientific research, she helped to lay the foundations, with Jean Perrin, for what would later become the Centre National de la Recherche Scientifique (National Centre for Scientific Research). She appeared two times in vain before the Académie des Sciences to affirm the right of women to become members.

Nuclear fission. Appointed professor at the Sorbonne in 1937, Irène continued her work on radioactive elements produced with neutrons. In 1938, along with Pavle Savić, she demonstrated on a target of uranium the transitory appearance of an element analogous to lanthanum. The result was interpreted in December 1938 by Otto Hahn and Fritz Strassmann, who conceived the process of nuclear fission. Frédéric immediately undertook to demonstrate fission by physical means. He succeeded in this as early as January 1939 while Otto Robert Frisch was independently obtaining the same result. Then came experiments carried on by Frédéric Joliot-Curie, with Hans von Halban, Lew Kowarski, and Francis Perrin, to prove that many neutrons are produced during fission, that the possibility exists of developing nuclear reactions in explosive chains, and that such nu-

clear reactions can be controlled in order to release great quantities of energy. These discoveries were then protected by five patents, which Joliot-Curie and his collaborators turned over to the Centre National de la Recherche Scientifique.

The war years. Pierre and Marie Curie had decided to publish everything. This was also the attitude adopted by the Joliot-Curies for the discovery of artificial radioactive elements. But anxiety resulting from the rise of Nazism and the awareness of the dangers that could result from the application of chain reactions led them to cease publication. On October 30, 1939, they recorded the principle of nuclear reactors in a sealed envelope, which they deposited at the Académie des Sciences; it remained secret until 1949. Joliot-Curie became the director of a group of scientific researchers at the beginning of the war in 1939; continuing the work, he convinced Raoul Dautry, minister of armaments, to purchase in Norway the world stockpile of 130 litres (140 quarts) of heavy water. Then, in June 1940 Joliot-Curie sent the stockpile of heavy water to England; the stockpile of uranium entrusted personally to him by the Union Minière du Haut Katanga was hidden near Toulouse.

Joliot-Curie chose to remain in occupied France with his family and to make certain that the Germans who came into his laboratory could not use his work or his equipment, whose removal to Germany he prevented. The Joliot-Curies continued their research, notably in biology; after 1939, Frédéric demonstrated, with Antoine Lacassagne, the use of radioactive iodine as a tracer in the thyroid gland. He became a member of the Académie de Médecine in 1943.

But the struggle against the occupying forces began to require more and more of his attention. In November of 1940 he denounced the imprisonment of the French scientist Paul Langevin. In June of 1941 he took part in the founding of the National Front Committee, of which he became the president. In the spring of 1942, after the execution by the Nazis of the theoretical physicist J. Solomon, Joliot-Curie joined the French Communist Party, of which in 1956 he became a member of the central committee. He created the Société d'Études des Applications des Radio-éléments Artificiels, an industrial company that gave work certificates to scientists and thus prevented their being sent to Germany. In May 1944, Irène and their children took refuge in Switzerland and Joliot-Curie lived in Paris under the name of Jean-Pierre Gaumont. His laboratory at the Collège de France, at which he organized the production of explosives, served as an arsenal during the battle for the liberation of Paris. In recognition, he was designated a commander of the Legion of Honour with a military title and was decorated with the Croix de Guerre.

Applications of atomic energy. In France, after the liberation in 1944, Joliot was elected to the Académie des Sciences and was entrusted with the position of director of the Centre National de la Recherche Scientifique. He helped to establish with G. Teissier a system that created for the centre a structure of democratic management and assigned to it the mission of coordinating research on a national scale.

Then, in 1945 General de Gaulle authorized Joliot and Dautry to create the establishment of the Commissariat à l'Energie Atomique to ensure for France the applications of the discoveries made in 1939. Irène Curie devoted her scientific experience and her abilities as an administrator to the acquisition of raw materials, the prospecting for uranium, and the construction of detection installations. In 1946 she was also appointed director of the Radium Institute. Frédéric's responsibilities also took him twice in 1946 to the United Nations. In spite of the difficulties encountered in France, where industry was only beginning to be reconstructed, his efforts culminated in the deployment, on December 15, 1948, of ZOE (*zéro, oxyde d'uranium, eau lourde*), the first French nuclear reactor, which, though only moderately powerful, marked the end of the Anglo-Saxon monopoly. Already Joliot-Curie had chosen at Saclay, near Versailles, the location for a large research centre envisaged as the

Artificial  
radio-  
activity

Uranium  
and heavy  
water

Political  
activities

French  
nuclear  
reactor

next step in the development of the Commissariat à l'Énergie Atomique. In 1949 the first weighable sample of plutonium produced in France was presented to Joliot, 15 years after the discovery of artificial radioactivity. But in April 1950, in the climax of the cold war, Prime Minister Georges Bidault removed him without explanation from his position as high commissioner, and a few months later Irène was also deprived of her position as commissioner in the Commissariat à l'Énergie Atomique. They devoted themselves henceforth to their own laboratory work and to teaching.

The danger that radioactivity, "in criminal hands," according to the expression used by Pierre Curie in his Nobel speech in 1903, could create a burden for the human race had been felt by the Curies, but for them it was a distant possibility. For the Joliot-Curies, it was a matter of conscience, which Frédéric had already expressed in his Nobel speech of 1935. They were committed to the struggle for the free circulation of ideas and discoveries, for using atomic energy in the service of peace, and for checking the nuclear arms race and the testing of atomic and hydrogen bombs. In 1946 Frédéric renewed contacts with his British colleagues to found the World Federation of Scientific Workers, became even more involved as president and founder of the World Peace Movement in 1949, and launched the "Stockholm Appeal" against nuclear armaments in 1950. In 1955, along with others, he helped to initiate the Pugwash conferences, named for the town in Nova Scotia where scientists from around the world first met to discuss international politics.

During the 1950s, following several operations, Irène's health began to decline. In May of 1953 Frédéric had the first attack of hepatitis from which he was to suffer for five years, with a serious relapse in 1955. In 1955 Irène drew up plans for the new nuclear physics laboratories at the Université d'Orsay, south of Paris, where teams of scientists could work with large particle accelerators under conditions less cramped than in the Parisian laboratories. Early in 1956 Irène was sent into the mountains, but her condition did not improve. Wasted away by leukemia as her mother had been, she again entered the Curie Hospital, where she died on March 17, 1956.

III, knowing that his days were also numbered, Frédéric decided to carry on Irène's unfinished work. In September 1956 he accepted the position of professor at the University of Paris left vacant by Irène, at the same time occupying his own chair at the Collège de France. He also successfully completed the establishment of the Orsay laboratories and saw the start of research there in 1958. Making one final gesture for peace, he took the chair at the inauguration in July of the International Congress of Nuclear Physics, the first one organized in France since World War II. He died on August 14, 1958, at Paris.

**BIBLIOGRAPHY.** The basic biographies are MARIE CURIE, *Pierre Curie* (Eng. trans. 1923); and EVE CURIE, *Madame Curie* (Eng. trans. 1937), both eyewitness accounts. EUGÉNIE COTTON, *Les Curies* (1963), contains recollections of the four Curies and an assessment of their scientific accomplishments. The author was a student of Marie Curie at the École Normale Supérieure at Sèvres, and remained a friend of the family for the rest of her life; she met Irène, as a child of five; and, toward the close of her life, she was associated with Frédéric Joliot in the Movement for Peace. See also PIERRE BIQUARD, *Joliot-Curie* (1961; Eng. trans., 1965), for an account of the friendship between the author and Joliot, which began when they were students at the École de Physique et Chimie; Biquard was Joliot's principal secretary at the French Atomic Energy Commission, and was closely associated with his activities for peace. A scientific evaluation is given in the address by FRANCIS PERRIN on the "Oeuvre scientifique de Marie Skłodowska-Curie et son influence sur les grandes conquêtes de la physique moderne" in *Centenary Lectures*, given in Warsaw 1967 (1968).

(F.Ne.)

## Curzon, Lord

Viceroy of India from 1898 to 1905 and foreign secretary from 1919 to 1924, George Nathaniel Curzon, 1st Marquess Curzon of Kedleston, was the last English statesman to belong in spirit to the 18th-century aristocracy.

Lord Curzon.  
Radio Times Hulton Picture Library

Though gifted with brilliant talents, Curzon possessed an aloofness and aristocratic disdain that belonged to the politics of a previous century and prevented him from achieving the premiership he felt he so richly deserved.

Curzon was born at Kedleston Hall on January 11, 1859, eldest son of the 4th Baron Scarsdale, rector of Kedleston, Derbyshire. His early development was strongly influenced by the benign neglect of his parents and the dominating character of his governess (whom he termed "a brutal and vindictive tyrant") and of his first preparatory schoolmaster (a firm believer in corporal punishment). At Eton, where he proved a wayward and emotional pupil, he clashed with his tutors but developed an extraordinary gift for assimilating the contents of books; by studying hard in private, he surprised everyone by winning more prizes (for French, Italian, and history, among other subjects) than had ever been carried off before.

Just before entering Oxford in 1878, he was struck down by a devastating pain in his back, the aftermath of a riding accident of four years previous. He refused to accept medical advice to rest and instead donned a leather harness, which he wore for the rest of his life. The back pain was to plague him from that time on, robbing him of sleep, forcing him to take drugs, and often making him querulous and unbalanced at some of the most vital moments in his career and in the affairs of the British Empire. It should be added that the pain sharpened his mind and never kept him from achieving remarkable feats of physical and mental endurance.

Curzon was elected president of the Oxford Union in 1880 and made a fellow of All Souls College in 1883. He had a gift for making friends in high places, and this was apt to be resented by his contemporaries. About this time a verse was circulated at Oxford of which he was to write later: "Never has more harm been done to one single individual than that accursed doggerel has done to me." It went as follows:

My name is George Nathaniel Curzon,  
I am a most superior person,  
My cheek is pink, my hair is sleek,  
I dine at Blenheim once a week.

(Blenheim is the residence of the dukes of Marlborough.) Two years later he was dining even more frequently at Hatfield House, ancestral home of Lord Salisbury, Conservative leader in the House of Lords, for whom he was now doing research and drafting speeches. His reward was Salisbury's recommendation of Curzon to the Tories of Southport, Lancashire, who agreed to adopt him as their candidate at the next election. It was a safe Tory seat, and in 1886 Curzon became a member of Parliament for the first time. With Salisbury's approval he neglected his parliamentary duties to embark on a world tour and came back infatuated with Asia. From this and sub-

Early life

sequent journeys emerged three books: *Russia in Central Asia* (1889); *Persia and the Persian Question* (1892), by far the most successful of his works; and *Problems of the Far East* (1894).

**Rise to political eminence.** On November 10, 1891, Curzon took his first step up the political ladder by accepting Salisbury's invitation to become undersecretary of state for India in the Tory government. The financial worries that beset him at the time (for he had developed extravagant tastes) were solved when he married Mary Victoria Leiter, daughter of Adolphus (Levi) Leiter, a Chicago millionaire. The marriage took place in Washington, D.C., on April 22, 1895, and the union involved marriage settlements of several millions of dollars. There was also a present from Lord Salisbury: the newly married couple returned from their honeymoon to find him waiting with an offer to Curzon of the job of undersecretary of state, Salisbury having just been appointed foreign secretary. Curzon accepted on the condition that he was also to be made a privy councillor, and on June 29, 1895, he was duly sworn in by Queen Victoria at Windsor Castle. From this moment his rise to political eminence was swift.

Viceroy of  
India

In 1898 it was announced that he would succeed Lord Elgin as viceroy of India, and, in September of that year, he was created Baron Curzon of Kedleston. He was the youngest viceroy of India in history, and he cherished the prospect of it, for it was an office filled with the pomp and ceremony he loved. India was the most treasured jewel in Queen Victoria's crown, and, after the pageantry of his arrival in Calcutta on January 3, 1899, Curzon wrote: "I suddenly saw what had come into my hands, and what prodigies of energy and inspiration would be needed on my part to guide them." He demanded obedience and a bent knee from the rajas, maharajas, and provincial governors he now ruled, but there was no doubt of his sense of mission toward the Indian people. He initiated commissions of inquiry into education, police, and civil services; he reduced taxes; he ordered immediate punishment of any Briton (including members of the army) who ill-treated Indian nationals. In external affairs he paid special attention to India's frontiers, toured the Persian Gulf, and sent a successful mission to Tibet to frustrate Russian ambitions there. On his return from what he called a "triumphal" tour of the Indian provinces, he ordered the restoration of the Tāj Mahal, which was decaying, and thereafter took a personal interest in India's artistic and cultural heritage.

At the end of his first five years in India, his successes were recognized by the government at home by a renewal of his term; but, in fact, the period of blazing glory was over, and now came political tragedy. At Curzon's personal request, the job of commander in chief of the Indian army and military member of the viceroy's Cabinet had been given to England's military hero of the day, Lord Kitchener of Khartoum. Curzon believed that to have such an illustrious soldier on his staff would embellish his own image, though his friends in England warned him repeatedly that Kitchener was, in Lord Esher's words, "an uncouth and ruthless man." It was a clash of personalities, and the two were soon unscrupulously intriguing against each other. A final confrontation between the two men, which ended in Curzon's bursting into tears, brought matters to a climax. Curzon, confident that the government would take his part, cabled that either his views must be accepted or he would go. On the morning of August 16, 1905, he received a cable from King Edward VII telling him that his resignation had been accepted. He delayed his return to England; and, by the time he was once again in London, the Tories were out of office, and his Indian achievements had been forgotten. He was not even given the earldom usually awarded to retiring viceroys.

Tempo-  
rary  
retirement

In the period of political eclipse that followed, he became an excellent and enlightened chancellor of the University of Oxford and filled many other important offices. But his temporary retirement from politics was marred by the death of his beloved wife, Mary. Her death affected him deeply, but the money that now came

to him enabled him to indulge in his passion for the collection of art treasures and old buildings. In 1911 he bought his first castle, Tattershall, in Lincolnshire, which he restored; and later he did the same to Bodiam Castle, Sussex, eventually presenting both of them to the nation.

His political ambitions had been damped down but never extinguished, and his hopes were stirred anew in 1911. In that year, after the coronation of King George V, Curzon received an earldom, along with the viscounty of Scarsdale and the barony of Ravensdale. He showed his gratitude to the Tories who had elevated him by persuading his fellow peers (against his own and their feelings) to abstain from voting against the Parliament Bill, which curtailed their powers, thus avoiding a constitutional crisis the government had feared. He joined the coalition Cabinet of H.H. Asquith in the summer of 1915, and, when Lloyd George took over that December, he became leader of the House of Lords with the office of lord president. From then on Curzon was one of the members of the inner Cabinet concerned with the policies and pursuits of World War I.

There had been a time when all fashionable London imagined that Curzon would marry the flamboyant red-headed novelist Elinor Glyn, but to everyone's surprise—not least that of Miss Glyn—he announced his engagement in December 1916 to Mrs. Alfred (Grace) Duggan, widow of a rich Argentinian rancher and daughter of J. Monroe Hinds, an American diplomat. They were married on January 2, 1917. His first wife had given Curzon three daughters. He hoped that his second would produce the son to inherit his title, and for both of them the years ahead were filled with hopes and disappointments.

**Disappointments.** There were disappointments in politics, too. Curzon had decided that the one lesson he must learn from his bitter experience in India was: never to resign. But in his case, it was a poor one. In the postwar government led by Lloyd George, he was appointed foreign secretary, a position for which he was eminently fitted. But time and again he was overruled or pushed aside by his boisterous leader, and his carefully planned policies thwarted. It was a time when resignation might well have gained him the overwhelming support of the Tories (who despised the Liberal coalition leader, Lloyd George) and taken him to the top. Instead he clung to office, and it was not until Tories took over in 1922 that he came into possession of the full powers of his office. He served with distinction until 1923, painstakingly dealing with the chaotic problems of postwar Europe and the Near East. When the Tory prime minister Bonar Law, a dying man, prepared to relinquish office, Curzon had good reason to believe that his efforts would be rewarded by the premiership that he felt he so richly deserved. It was not to be. Backstairs political intrigue (and the fear that a premier in the House of Lords would be "out of touch") resulted in the appointment of a House of Commons man, Stanley Baldwin, as prime minister.

It was a bitter blow to Curzon's hopes, and he might have been forgiven if he washed his hands of politics there and then and retired to his academic and artistic pursuits. Instead, he insisted on presiding at the meeting at which Baldwin was elected to the job for which he was so much better equipped. He hung on to his job as foreign secretary until 1924, when Baldwin replaced him with Austen Chamberlain, yet even then he did not resign but accepted the emasculating political role of lord president of the council. He kept silent in public but confided his grief and humiliation to his private diaries and notes.

He had been created a marquess in 1921, and more than ever he hoped for a son to inherit his title, but in this, too, he was to be frustrated. On March 9, 1925, he was operated on for an internal condition and, for the next eight days, seemed to be recovering. But then complications set in, and his doctor advised his wife, Grace, to tell him the truth, that he was dying. He took the news philosophically, repeating the Lord's Prayer; and then Curzon, who all his life had been a despairing insomniac, racked by the pain in his back, suddenly discovered the knack of it and went off into a deep and peaceful sleep. It was in his sleep that he died on March 20, 1925.

Death

With him died his marquessate and his earldom. The viscounty subsequently passed to his nephew and the barony of Ravensdale to his eldest daughter, Lady Irene Curzon.

**BIBLIOGRAPHY.** LORD RONALDSHAY, *The Life of Lord Curzon*, 3 vol. (1928), is the official biography. LEONARD O. MOSLEY, *Curzon: The End of an Epoch* (U.S. title, *The Glorious Fault*, 1960), made use of the collected Curzon Papers for the first time. HAROLD G. NICOLSON, *Curzon: The Last Phase, 1919-1925* (1934), is an acute and sympathetic study of Curzon during one of the post-World War I conferences. PHILIP M. MAGNUS, *Kitchener: Portrait of an Imperialist* (1959, reprinted 1968), gives a good account of the clash between Curzon and his Military Member during his Indian viceroyalty.

(Le.M.)

## Customs Unions and Trade Agreements

Many efforts have been made in modern times to promote trade among nations. The ways in which this may be attempted range from agreements among governments to reduce or eliminate trade barriers to more ambitious attempts to harmonize economic policies, as in the European Economic Community or the Council for Mutual Economic Assistance.

The article is divided into the following sections:

- I. Trade agreements
  - Bilateral trade agreements
  - Modern commercial policies
  - Multilateral agreements since World War II
- II. Economic integration
  - Integration between the states of federations
  - The economic integration of colonial empires
  - The Zollverein
  - The Benelux economic union
  - The European Coal and Steel Community
  - The European Economic Community
  - The European Free Trade Association
  - Economic Integration in Latin America
  - The Council for Mutual Economic Assistance
  - An appraisal of the European Economic Community

### I. Trade agreements

The term "trade agreement" or "commercial agreement" can be used to describe any contractual arrangement between states concerning their trade relationships. Trade agreements may be bilateral or multilateral—that is, between two states or between more than two states.

#### BILATERAL TRADE AGREEMENTS

A bilateral trade agreement usually includes a broad range of provisions regulating the conditions of trade between the contracting parties. These include stipulations governing customs duties and other levies on imports and exports, commercial and fiscal regulations, transit arrangements for merchandise, customs valuation bases, administrative formalities, quotas, and various legal provisions. Most bilateral trade agreements, either explicitly or implicitly, provide for (1) reciprocity, (2) most-favoured-nation treatment, and (3) "national treatment" of nontariff restrictions on trade.

**Reciprocity.** In a trade agreement, the parties make reciprocal concessions to put their trade relationships on a basis deemed equitable by each. The principle of reciprocity is extremely old, and in one form or another is to be found, implicitly at least, in all trade agreements. The concessions may, however, be in different areas. In the Anglo-French Agreement of 1860, for example, France pledged itself to reduce its duties to 20 percent by 1864. In return, Britain granted duty-free imports of all French products except wines and spirits. The principle of reciprocity implies only that the gains arising out of foreign trade are distributed fairly.

**The most-favoured-nation clause.** The most-favoured-nation clause binds a country to apply to its partner country any lower rate of import duties that it may later grant to imports from some other country, in place of the rate specified in the agreement. The clause may cover a list of specified products only, or specific concessions yielded to certain foreign countries. Alternatively, it may cover all advantages, privileges, immunities, or other

favourable treatment granted to any third country whatever. The clause is intended to provide each signatory with the assurance that the advantages obtained will not be attenuated or wiped out by a subsequent agreement concluded between one of the partners and a third country. It also guarantees the parties against discriminatory treatment in favour of a competitor.

The effect of the most-favoured-nation clause on customs duties is to amalgamate the schedules of duties annexed to the successive trade agreements concluded by a state. If the rates in different agreements are fixed at varying levels, the clause reduces them to the lowest rate specified in any agreement. Thus goods imported from a country benefitting from most-favoured-nation treatment are charged the rate of duty applicable to imports from another country which, in a subsequent trade agreement, has negotiated a lower rate of duty.

The coverage of the most-favoured-nation clause can be considerably reduced by a minute definition of a particular item so that a concession, while general in form, applies in practice only to one country. The best-known illustration of this technique is to be found in the German Tariff of 1902, which admitted at a special rate

large dappled mountain cattle, reared at a spot at least 300 metres above sea level, and which have at least one month's grazing each year at a spot at least 800 metres above sea level.

The advantages granted under the most-favoured-nation clause may be conditional or unconditional. If unconditional, the clause operates automatically whenever appropriate circumstances arise. The country drawing benefit from it is not called on to make any fresh concession. By contrast, the partner invoking a conditional most-favoured-nation clause must make concessions equivalent to those extended by the third country. A typical wording was that of the 1911 treaty between the United States and Japan, which stated that

in all that concerns commerce and navigation, any privilege, favour or immunity . . . to the citizens or subjects of any other State shall be extended to the citizens or subjects of the other Contracting Party gratuitously, if the concession in favour of that other State shall have been gratuitous, and on the same or equivalent conditions, if the concession shall have been conditional.

The conditional form of the clause may at first sight seem more equitable. But it has the major drawback of being liable to raise dispute each time it is invoked, for it is by no means easy for a country to evaluate the compensation it is being offered as in fact being equivalent to the concession made by the third country.

The effect of the unconditional form of the most-favoured-nation clause is, finally, to wipe out any relevance the principle of reciprocity may have had to the purely bilateral preoccupations of the negotiating parties, since the results of the bargaining process, instead of being limited to the participants, influence their relationships with other states. In practice, therefore, a country negotiating a trade agreement must measure the advantages it is willing to concede in terms of the benefits these concessions will provide collaterally to that third country which is the most competitive. In other words, the concessions that may be granted are determined by the minimum protection that the negotiating state deems indispensable to protect its home producers. This sets a major limitation on the scope of bilateral negotiations.

Protagonists of free trade consider that the unconditional most-favoured-nation clause is the only practical way by which to obtain the progressive reduction of customs duties. Apologists for protectionism are resolutely against it, preferring the conditional form of the clause or some equivalent mechanism.

The conditional most-favoured-nation clause was generally in use in Europe until 1860, when the so-called Cobden-Chevalier Treaty between Great Britain and France established the unconditional form as the pattern for most European treaties. The United States used the conditional most-favoured-nation clause from its first trade agreement, signed with France in 1778, until the passage of the Tariff Act of 1922, which terminated the practice.

Provisions  
against  
discrimina-  
tion

The  
making of  
trade  
agree-  
ments

**Decline of the most-favoured-nation clause.** The Geneva conference in May 1922 and the International Economic Conference in May 1927 both recommended that trade agreements should include the most-favoured-nation clause whenever possible. But the depression of the 1930s led instead to an upsurge of restrictions in world trade. Imperial or regional systems of preference came into being: the Ottawa Agreement of 1932 for the British Commonwealth; similar arrangements for the French empire; and a series of tariff and preference agreements negotiated in eastern and central Europe from 1931 on.

Henceforth, a major objection to the clause in its unconditional form was that it appeared to hinder the creation of preferential systems and customs unions. Paradoxically enough, a clause designed to promote the lowering of tariff barriers was found to have the opposite effect; those in favour of lowering or abolishing customs duties within regional groupings of countries therefore opposed it, and their opposition was an important factor when postwar arrangements were being worked out in 1947.

**The "national treatment" clause.** The "national treatment" clause in trade agreements is designed to ensure that internal fiscal or administrative regulations are not used to introduce discrimination of a nontariff nature. It forbids discriminatory use of the following: taxes or other internal levies; laws, regulations, and decrees affecting the sale, offer for sale, purchase, transport, distribution, or use of products on the domestic market; valuation of products for purposes of assessment of duty; legislation on prices of imported goods; warehousing and transit regulations; and the organization and operation of state trading corporations.

#### MODERN COMMERCIAL POLICIES

**Mercantilism.** Much of the modern history of international relations concerns efforts to promote freer trade among nations. The 17th century saw the growth of restrictive policies that later came to be known as "mercantilist." The mercantilists held that economic policy should be nationalistic and aim to secure the wealth and power of the state. The concept was based on the conviction that national interests are inevitably in conflict—that one nation can increase its trade only at the expense of other nations. Thus, governments were led to impose price and wage controls, foster national industries, promote exports of finished goods and imports of raw materials, and prohibit the exports of raw materials and the import of finished goods. The state endeavoured to provide its citizens with a monopoly of the resources and trade outlets of its colonies.

A typical illustration of the mercantilist spirit is the famous English Navigation Act of 1651, which reserved for the home country the right to trade with the colonies and prohibited the import of goods of non-European origin unless transported in ships flying the English flag. This law lingered on until 1849. A similar policy was followed in France.

**Liberalism.** A strong reaction against mercantilist attitudes began to take shape toward the middle of the 18th century. In France, the economists known as Physiocrats demanded liberty of production and trade. In England, Adam Smith demonstrated in his *Wealth of Nations* (1776) the advantages of importing goods when articles could be obtained more cheaply in this way than by domestic manufacture. Economists and businessmen voiced their opposition to excessively high and often prohibitive customs duties, and urged the negotiation of trade agreements with foreign powers. This change in attitudes led to the signature of a number of agreements embodying the new liberal ideas, among them the Anglo-French Treaty of 1786, which ended what had been a real economic war between the two countries.

After Adam Smith, the basic tenets of mercantilism were no longer considered to be defensible. This did not, however, mean that nations abandoned all mercantilist policies. Restrictive economic policies were now justified by the claim that, up to a certain point, the government should keep foreign merchandise off the do-

mestic market in order to shelter national production from outside competition. To this end, customs levies were introduced in increasing number, replacing outright bans on imports, which became less and less frequent.

In the middle of the 19th century, customs walls effectively sheltered many national economies from outside competition. The French tariff of 1860, for example, charged extremely high rates on British products: 60 percent on pig iron; 40 to 50 percent on machinery; and 600 to 800 percent on woollen blankets. Apart from the duties proper, transport costs between the two countries provided further protection.

A triumph for liberal ideas was the Anglo-French trade agreement of 1860, which provided that French protective duties were to be reduced to a maximum rate of 25 percent within five years, with free entry of all French products except wines into Britain. This agreement was followed by other European trade pacts, usually containing most-favoured-nation clauses.

**Resurgence of protectionism.** A reaction in favour of protection spread throughout the Western world in the latter part of the 19th century. Germany adopted a systematically protectionist policy and was soon followed by most other nations. Shortly after 1860, during the Civil War, the United States raised its customs sharply; the McKinley Tariff Act introduced in 1890 was ultra-protectionist. England was the only country to remain faithful to the principles of free trade.

But the protectionism of the last quarter of the 19th century was mild by comparison with the mercantilist policies that had been common in the 17th century and were to be revived between the two world wars. It is easy today to ignore how much economic liberty prevailed in 1913. There were no political barriers to international trade. Quantitative restrictions were unheard of; customs duties were low and stable. Currencies were freely convertible into gold, which in effect was a common international money. Balance of payments problems were nonexistent. People who wished to settle and work in a country could go where they wished almost without restriction; they could open businesses, enter trade, or export capital freely. Equal opportunity to compete was the general rule, the sole exception being the existence of limited customs preferences between certain countries, most usually between a home country and its colonies. Trade was freer throughout the Western world in 1913 than it was in Europe in 1970.

**The new mercantilism.** World War I wrought havoc with these orderly trading conditions. By the end of hostilities, world trade was in a straitjacket that made recovery very difficult. The first five years of the postwar period were marked by the dismantling of wartime controls proper. The 1920 crisis and the commercial advantages accruing to countries whose currencies had depreciated, as had Germany's, rapidly led to fresh measures in restraint of trade. The protectionist tide engulfed the world economy, not because policy makers consciously adhered to any specific theory but because of nationalist ideologies and the pressure of economic conditions. In an attempt to end the continual raising of customs barriers, the League of Nations organized the first World Economic Conference in May 1927. Twenty-nine states, including the main industrial countries, subscribed to an international convention that was the most minutely detailed and balanced multilateral trade agreement ever approved until then. It was a precursor of the arrangements made under the General Agreement on Tariffs and Trade in 1947.

The 1927 agreement remained practically without effect. During the Great Depression of the 1930s, unemployment in major countries reached unprecedented levels and engendered an epidemic of protectionist measures. Countries attempted to shore up their balance of payments by raising their customs duties and introducing a range of import quotas or even import prohibitions, accompanied by exchange controls.

From 1933 onward, the recommendations of all the postwar economic conferences based on the fundamental postulates of economic liberalism were ignored. The

The decline of free trade

The growth of free trade

planning of foreign trade came to be considered a normal function of the state. Mercantilist policies dominated the world scene until after World War II.

#### MULTILATERAL AGREEMENTS SINCE WORLD WAR II

Attempts  
at trade  
liberaliza-  
tion

When World War II ended, the lessons learned from the growth of protectionism since 1871, and most of all from the resurgence of trade restrictions in the interwar years, spurred the development of multilateral trade agreements and other forms of international economic cooperation. These developments culminated in the General Agreement on Tariffs and Trade (GATT).

**The General Agreement on Tariffs and Trade.** The General Agreement on Tariffs and Trade was signed at Geneva on October 30, 1947, by 23 countries, which among them accounted for four-fifths of world trade. On the same day ten of them, including the United States, the United Kingdom, France, Belgium, and The Netherlands, signed a protocol bringing the agreement into force on January 1, 1948.

The GATT takes the form of a multilateral trade agreement setting forth the principles under which the signatories, on a basis of "reciprocity and mutual advantage," shall negotiate "a substantial reduction in customs tariffs and other impediments to trade, and the elimination of discriminatory practices in international trade." With the adherence of additional countries (there were 80 signatories as of November 1971), GATT has become a charter governing almost all world trade except for that of the Communist countries.

The main principles underlying GATT are as follows: (1) There shall be no trade discrimination of any kind. The most-favoured-nation clause is regarded as fundamental. (2) As a rule, there is to be no protection other than that provided by the customs tariff (the "national treatment" principle). (3) Customs unions and free trade groupings are considered legitimate means of trade liberalization, provided that, *taken as a whole*, such arrangements do not discriminate against third countries. (4) Members of GATT are entitled to levy the following charges on imports: (a) an import tax equal in amount to internal taxes on the product concerned, subject only to the general principle embodied in (2) above; (b) "antidumping" duties in the case of imported products that are being sold at a loss or are benefitting from an export subsidy; (c) fees and other proper charges for services rendered.

These, however, are only the basic principles. The agreement also contains a variety of clauses providing exceptions from the rules in special situations. These include balance of payments disequilibrium; serious and unexpected damage to domestic production; the requirements of economic development or, subject to very broad reservations, of agricultural policy; the need to protect domestic raw material production; and the interests of national security. In the overall prosperity that reigned during the first 20 years of GATT's existence, members needed to make only limited use of these escape clauses. Were there to be a general economic downturn, however, all of GATT's accomplishments could be endangered.

Under GATT a series of conferences have been organized for the purpose of lowering trade barriers: at Geneva (1947), Annecy (1949), Torquay (1950–51), Geneva (1956, 1960–61, and 1964–67). The agreement provides an indispensable framework for simultaneous negotiation of bilateral tariff reductions, which thus take multilateral effect.

The formula for multilateral tariff bargaining applied in negotiations held under GATT auspices is a major innovation in intergovernmental cooperation. In appraising the concessions that they could afford to make, governments have been able to take account of the indirect advantages that they could expect to accrue to them from the full set of bilateral negotiations. Over the years since its inception, it has been successful far beyond its creators' expectations. It has made a major contribution to the growth of world trade.

**The Organization for Economic Co-operation and Development.** On April 16, 1948, sixteen European countries responded to a United States offer of economic aid

under the European Recovery Program by setting up the Organization for European Economic Co-operation. Although the immediate aim was to coordinate the distribution of U.S. credits, the Organization for European Economic Co-operation convention was also designed to foster free trade between the members and allow their participation in customs unions or similar institutions. The members by 1955 consisted of Britain, France, West Germany, Italy, Spain, the Benelux countries, Austria, Denmark, Sweden, Norway, Switzerland, Portugal, Greece, Ireland, Turkey, and Iceland.

The Organization for European Economic Co-operation did much to facilitate the recovery of intra-European trade, and particularly to abolish most of the quantitative restrictions on imports within the area. On September 30, 1961, it was converted into a new institution, the Organization for Economic Co-operation and Development (OECD), and its membership expanded to include the United States and Canada. Japan became a member in 1964, Finland joined in 1969, and Australia joined in 1971.

The three fundamental aims of the OECD are to promote the economic growth of member countries in conditions of financial stability, to contribute to the economic growth of less developed countries, and to foster the growth of world trade on a multilateral, nondiscriminatory basis. The organization proved to be a most useful vehicle for joint action on the many economic problems of the 1960s, particularly in the liberalization of economic relationships. Although its 23 members comprise only one-fifth of the world's population, they account for two-thirds of world trade.

**The Kennedy Round.** As the economic integration of western Europe progressed, opinion in the United States became concerned at the prospect of remaining outside. Pres. John F. Kennedy pursued the goal of an Atlantic partnership, and secured special negotiating powers under the Trade Expansion Act of 1962. The act authorized tariff reductions of up to 50 percent, subject to reciprocal concessions from the European partners. This marked a fundamental shift away from the traditional protectionist posture of the United States, and led to the so-called Kennedy Round negotiations in the GATT, held in Geneva from May 1964 to June 1967.

The Kennedy Round negotiations concerned four types of problems: (1) progressive reduction, to amount finally to 50 percent, in the duties on all but a few products, in place of the item-by-item bargaining that had prevailed in earlier GATT conferences; (2) inclusion of agricultural as well as industrial products in the scope of the negotiations; (3) discussion of nontariff obstacles as well as of customs duties; and (4) nonreciprocity for economically less developed countries. Fifty-four countries participated in the negotiations, which covered 400,000 tariff headings.

The final result was an average reduction of 35 percent in the duties levied on industrial products, to be implemented over a five-year period. This was less than the 50 percent originally envisaged. Further, the reductions were not geographically uniform: United States, European, and Japanese duties were to fall by an average of 35 percent, British scales by 38 percent, and Canadian by 24 percent. Little change was made in steel and textile tariffs, since the participants felt that reductions in those industries would create intolerable political and social tensions in most of the industrial countries. Problems arose with regard to chemicals because of a so-called American Selling Price which was used for appraising the dutiable value of some products (mainly derivatives of benzene), based on prices ruling in the U.S. market; in return for a reduction of 50 percent in the rates of duty charged by the U.S., Great Britain and the European countries agreed to lower their scales by 22 percent, with a further 24 percent reduction to become effective upon abrogation of the American Selling Price. Rather less spectacular results were achieved for agricultural commodities. These included the setting of a minimum price for wheat and a weighted reduction of between 15 and 18 percent in the duties charged on other agricultural and

lus of the  
European  
Recovery  
Program

Tariff  
negotia-  
tions

food products. In the area of nontariff barriers to trade the most significant result was the adoption of a uniform antidumping code.

The Kennedy Round all but completed the process of tariff reduction begun two decades earlier by the industrial countries. By the end of the transition period in 1972, it was anticipated, duties on industrial imports would range between 5 and 15 percent. While developing countries drew little immediate advantage from the Kennedy Round negotiations, they were able to obtain the addition of a new part titled "Trade and Development," to the GATT charter, calling for stabilization, as far as possible, of raw material prices; reduction or abolition of customs duties or other restrictions that differentiate unreasonably between products in their primary state and the same products in finished form; and renunciation by the advanced countries of the principle of reciprocity in their relations with less developed countries.

## II. Economic integration

Forms of  
economic  
integration

The economic integration of several countries or states may take a variety of forms. The term covers preferential tariffs, free trade zones, customs unions, common markets, economic unions, and full economic integration. The parties to a system of preferential tariffs levy lower rates of duty on imports from one another than they do on imports from third countries. For example, Great Britain and its Commonwealth countries operated a system of reciprocal tariff preferences after 1919. In a free trade zone, no duty is levied on imports from members, but different rates of duty may be charged freely by each member on its imports from the rest of the world. The European Free Trade Association is an example. A further stage is the customs union, in which free trade among the members is sheltered behind a unified schedule of customs duties charged on imports from the rest of the world. The 19th-century German Zollverein (see below) was a customs union. A common market is an extension of the customs union concept, the additional feature being that it provides for the free movement of labour and capital among the members; an example was the Benelux common market until it was converted into an economic union in 1959. The term economic union denotes a common market in which the members agree to harmonize their economic policies generally, as is the case with the European Economic Community (often referred to incorrectly as the "Common Market"). Finally, total economic integration implies the pursuit of a common economic policy by the political units involved; examples are the United States of America, or the cantons of the Swiss confederation.

Economic integration may be brought about by the political will of a state powerful enough to impose it, as under the Roman Empire or the European colonial systems of the 19th century, or it may result from freely negotiated agreement between sovereign states.

The attempts at economic integration made after World War II can be appraised only by reviewing them against the background of the long process through which, over the centuries, the nations of the world have progressively achieved economic integration. Thus, for instance, the world's greatest power in the 17th century, France, was divided into a number of provinces separated from one another by various customs barriers involving a multitude of duties, tolls, and prohibitions. Trade regulations and fiscal charges differed from one region to the next; there was not even a single system of weights and measures. Not until after the Revolution did the economic integration of France really get under way.

### INTEGRATION BETWEEN THE STATES OR FEDERATIONS

**The United States.** The economic integration of the United States was not achieved all at once, but as the result of a long process during which the powers of the federal authorities were constantly reinforced. The Constitution empowered the federal government to regulate the conditions of trade with other countries and to set up a single system of duties. It also abolished the right

of individual states to maintain separate customs legislation and to issue their own currencies. It authorized the federal government alone to issue currency, and established the principle of free movement of persons, merchandise, and capital between the federated states. But the conflict of interest between North and South was settled only by the American Civil War. Almost two hundred years were to elapse before the economies of the states could be considered as integrated for practical purposes, and even in the 1970s many economic and fiscal disparities still existed among them.

The difficulties faced by the 13 original states should not be underestimated. During the years prior to the adoption of the Constitution there were bitter trade disputes among the states, which imposed tariffs against each other and refused to accept each other's currencies. Everything seemed to justify the words of a contemporary liberal philosopher, Josiah Tucker, Dean of Gloucester (England):

As to the future grandeur of America, and its being a rising empire under one head, whether republican or monarchical, it is one of the idlest and most visionary notions that ever was conceived even by writers of romance. The mutual antipathies and clashing interests of the Americans, their differences of governments, habits, and manners, indicate that they will have no centre of union and no common interest. They never can be united into one compact empire under any species of government whatever; a disunited people till the end of time, suspicious and distrustful of each other, they will be divided and sub-divided into little commonwealths or principalities, according to natural boundaries, by great bays of the sea, and by vast rivers, lakes, and ridges of mountains.

**Switzerland.** The Swiss example is no less instructive. Although the Helvetic Confederation emerged as a political entity in the 14th century, its economic integration was achieved, only after many vicissitudes, with the constitution of 1848, which established a common currency, set forth the principle of a common protective system for the cantons, and provided for free movement of goods and Swiss citizens throughout the national territory. Swiss economic integration is all the more remarkable in that it comprises peoples who speak four different languages.

### THE ECONOMIC INTEGRATION OF COLONIAL EMPIRES

When the great colonial powers of Europe founded their empires from the 16th century onward, they attempted to monopolize trade with the colonies and to turn it to their own profit. This policy involved four main restrictions: (1) The colonies were to trade exclusively with the mother country. (2) They were not to undertake manufacturing; transformation of raw materials into finished goods remained a monopoly right of the mother country. (3) Imports and exports of the colonies were to be carried only in ships flying the mother country's flag. (4) The mother country exempted colonial products from duty, or imposed lower rates.

This system, although progressively attenuated, applied in various forms from the 16th to the 19th century. Based on force, it was to the benefit of the home countries and detrimental to the economic growth of their colonies.

### THE ZOLLVEREIN

The best known of all customs unions is the German Zollverein (literally, "customs union"). Even though Napoleon had reduced the number of German states from 300 to 40 at the beginning of the 19th century, those that remained were isolated from each other by their own customs systems. In addition, numerous internal customs barriers hampered trade within each state. At the same time there was no single external tariff, and the German industries that had sprung up during the Napoleonic Wars were being crushed by English competition. These difficulties were at the root of the creation of the Zollverein.

The starting point was Prussia's abolition of all internal duties and its adoption of an external tariff in 1818. In the next few years a number of other German states followed the Prussian example. Bavaria and Württemberg

The  
German  
customs  
union

set up a customs union in 1828, and by 1830 four separate customs unions were in existence. Prussia then sought to break up the local customs unions and attach them to a general customs union, the Zollverein. The coverage of the Zollverein increased until, by 1871, it included all the German states.

In its first phase, from 1834 to 1867, the Zollverein was administered by a central authority, the Customs Congress, in which each state had a single vote. A common tariff, the Prussian Tariff of 1818, shielded the member states from foreign competition, but free trade was the rule internally.

During a second phase, from 1867 to 1871 (following Prussia's victory over Austria at Sadowa), executive power was wielded by a federal council (Bundesrat) composed of governmental delegates, in which decisions were taken by an absolute majority. Prussia was entitled to 17 of the 58 votes, and held the chair of the council. Legislative power lay with a "customs parliament" (Zollparlament) composed of deputies directly elected by popular vote, and, like the council, taking decisions by a majority vote. This arrangement transformed what had been a confederation into a federal state.

After the victory over France and the proclamation of the German empire in 1871, the customs parliament and the federal council were replaced by the parliament and the executive council of the empire. The federal state had become a nation.

The progressive destruction of a tangled maze of regulations, prohibitions, and controls set the stage for the subsequent rapid development of the German economy. Although economic integration occurred before political unification, it would not have been possible had not many difficulties been swept away by irresistible pressure from Prussia with its military victories.

#### THE BENELUX ECONOMIC UNION

In 1921 Luxembourg, a former member of the Zollverein, signed the Convention of Brussels with Belgium creating the Belgium-Luxembourg Economic Union. Since 1921 Belgium and Luxembourg have, then, had the same customs tariff and a single balance of payments.

The union was expanded after World War II to include The Netherlands. At the beginning of 1948 most import duties within the Benelux area were abolished, and a common external tariff was put into operation. Exceptions were made, nevertheless, for a few agricultural products, and it was also felt necessary to introduce a system of quotas.

It was rapidly perceived that a simple customs union was inadequate, and a treaty on October 15, 1949, set as its target the progressive and complete liberalization of trade between the partners, systematic coordination of their international commercial and monetary policies, and the adoption of a joint bargaining position in negotiations with other countries. Though the experiment was optimistically viewed everywhere as the precursor of a wider European economic integration, it faced difficulties arising from the very different postwar situations of Belgium and The Netherlands. The two economies were competitive rather than complementary. Other problems arose in connection with the free access of Dutch agricultural products to the Belgian market. Moreover, the Belgian economic system was more liberal than the Dutch, where rigorous price control had long been a standard practice.

The development of Benelux received strong impetus from the formation of the European Economic Community in the 1950s. The Treaty of Rome in 1957 creating the EEC, or Common Market, spurred the members of Benelux to confirm and strengthen their own integration in the Benelux Treaty of Economic Union signed at The Hague on February 3, 1958. The Hague treaty, however, contained little that was new, and in outline was no more than the codification of results already achieved.

The Benelux Economic Union is an intergovernmental union associating three sovereign states. All of its decisions must be unanimous. The union has executive organs (a committee of ministers, the council of the eco-

nomic union, a number of commissions, and a general secretariat); consultative organs (the interparliamentary council and the economic and social council); and legal organs (the arbitration tribunal and its registry).

The progress of the European Economic Community in the 1960s attenuated the practical importance of Benelux, which seemed certain to diminish as the integration of western Europe proceeded.

#### THE EUROPEAN COAL AND STEEL COMMUNITY

An important step in European integration was taken in May 1950 when the French foreign minister, Robert Schuman, proposed that a common market for coal and steel be set up by countries willing to delegate powers over these sectors of their economies to an independent authority. The motive behind the plan was the belief that a new economic and political framework was needed if European unity was to be achieved and if the threat of a future Franco-German conflict was to be avoided. In April 1951 France, West Germany, Italy, and the three Benelux countries signed a treaty in Paris setting up the European Coal and Steel Community.

The signatories bound themselves to abolish all customs barriers and other restrictions on the movement of coal and steel between their countries; to renounce all discriminatory practices among producers, purchasers, or users (with respect to price and delivery conditions, transport charges, selection of suppliers, etc.); to end government subsidies or grants-in-aid; and to eliminate all practices interfering with the operation of markets.

**The constitution of the community.** The Coal and Steel Community was to be governed by a high authority, assisted by a consultative committee, a common assembly, a special council of ministers, and a court of justice.

The high authority was the permanent executive organ of the community. Its decisions, taken by a majority vote, were fully binding on all member countries, each of which was pledged to respect the "supranational character" of the high authority. The authority was to refer important substantive matters to the consultative committee before taking a decision. The latter was composed of coal and steel industry representatives, including producers, workers, users, and traders.

The assembly was empowered to exercise only parliamentary control, but could overrule the high authority by a two-thirds majority. Its delegates were composed of deputies of national parliaments.

The function of the council of ministers was to "harmonise the actions of the high authority and the governments responsible for the economic policy of respective countries." It was composed of representatives of member countries, each of which delegated a member of its government. Most decisions of the council were valid if voted by a majority of representatives of member countries, providing that the majority included at least one from a country accounting for one-sixth or more of the total value of the community's production of coal and steel—France or Germany. Unanimous agreement was required only on decisions concerning production questions and shortages.

Taken as a whole, the treaty was similar to a federal constitution, embodied in a long and complex document. It was inspired by three guiding ideas. The first was the concern to pursue a common policy for basic industries. The second was the belief that once the key steel and coal industries had been merged under one international authority, any major Franco-German conflict would be impossible. The third was the desire to prepare the ground for European political integration.

There is, however, a basic incompatibility between the community's provenance, limited to the coal and steel industries, and the sovereignty of the member countries, each of which is responsible for its own general economic policy. As a practical matter, during the first 17 years of the community's existence, authority on all substantive issues remained vested in the national governments. The high authority was autonomous only in matters of secondary importance. Thus the coal crisis of 1958—when West German, Belgian, and French stocks of unsold coal

Efforts toward further integration in Europe

rose to unmanageable proportions — was resolved at the national level. All the high authority could do was to confirm the measures taken, even when they were contrary to the provision of the treaty. Similarly, the reduction of the labour force in coal mining from 650,000 persons at the end of 1957 to 300,000 ten years later was effected by measures taken by the individual countries pursuing their own national policies, and there was no community-wide action.

The treaty reserved for member countries responsibility for their own trade policies toward third countries. This hindered the establishment of an effective common market since a common market requires a unified system of protection from foreign competition. At the height of the coal crisis, for example, when stocks of coal rose in Belgium, West Germany, and France, Italy nonetheless continued to buy cheap supplies from the United States.

**Later developments.** An assessment of the Coal and Steel Community is therefore difficult to make, since the political and economic realities with which it must work are so much more complex than the language of the treaty suggests. Much has been accomplished. The markets for steel and coal have been liberalized to a considerable degree, perhaps partly because of the general movement toward liberalization in the economies of the member countries. The community has been a useful forum in which questions of common interest could be examined. It fostered the growth of an international spirit and did much to facilitate the negotiation of the Treaty of Rome establishing the European Economic Community and the European Atomic Energy Community (Euratom).

In 1957 the Coal and Steel Community's assembly and court of justice were replaced by parallel institutions established by the European Economic Community. In 1967 its executive organs were merged with those of the European Economic Community and Euratom. The other provisions of the treaty remained unchanged.

#### THE EUROPEAN ECONOMIC COMMUNITY

The European Coal and Steel Community was only the initial step in the movement for European integration. On March 25, 1957, its six member governments signed the Treaty of Rome, under which they agreed to establish the European Economic Community, or "Common Market," which came into being on January 18, 1958. In 1973 it was enlarged with the entry of Great Britain, Ireland, and Denmark. The EEC is the most far-reaching attempt at economic integration among sovereign countries. Its founding treaty has been the model, in whole or part, for all subsequent attempts at economic integration.

The Treaty of Rome aimed to "establish a common market" and "progressively bring the economic policies of members into alignment" so as to

promote the harmonious growth of economic activity in the Community as a whole, regular and balanced expansion, augmented stability, a more rapidly rising standard of living, and closer relations between the participating states.

The treaty pledged the signatories to

abolish customs duties and quantitative restrictions on the entry and outflow of merchandise, to abrogate all other measures having an equivalent effect, and to fix a common customs tariff for imports from non-member states.

They also agreed to "abolish, as between members, all barriers to the free movement of persons, services and capital." This was to be accomplished during a transition period of 12 years. The transition period ended on January 1, 1970, and the community then entered into its definitive phase.

**Formation of a customs union.** The treaty set a timetable for the abolition of customs duties between member states. On balance, this timetable was met and in some areas exceeded so that, by the middle of 1968, tariff barriers had been abolished for agricultural as well as industrial products. By that date also, most quota restrictions had been lifted. The customs posts had not disappeared, however; they were still needed for such tasks as assessing and collecting the compensatory taxes that equalized the differences in taxes between member countries.

Tariffs on imports from outside the community were gradually brought closer, and on July 1, 1970, a common community tariff was put into effect. The treaty had envisaged that the common tariff would be a simple arithmetical average of the rates at the beginning of 1957 in the four customs territories of West Germany, Benelux, France, and Italy — about 14 percent. But international tariff negotiations under the auspices of GATT brought the EEC members' tariffs down to an average level of 10.7 percent by the middle of 1968, and they were scheduled to fall to 7.5 percent in 1972.

**Development of a common agricultural policy.** When the treaty took effect at the beginning of 1958, agriculture was subsidized in all six member countries. The various price-support mechanisms differed substantially, as did foreign trade policies and tariff levels. The cumulative impact of governmental intervention of various kinds over the years had led to major differences among the members in agricultural price levels. Taking the average price of wheat in the six countries in 1959 as 100, the relative price levels in individual countries were: Germany, 108; France, 78; Italy, 108; Belgium, 101; Luxembourg, 119; and The Netherlands, 86. The achievement of common policies in agriculture appeared to be so difficult that the treaty limited itself to setting forth a number of general provisions on which agreement seemed feasible. Despite this, in 12 years a common agricultural policy had been achieved: all tariff and quota restrictions on trade in farm products among member countries had been abolished; a common set of tariffs on agricultural imports from non-EEC countries had been established; and a common system of price supports had taken the place of the former national systems.

The price supports required difficult compromises among the member governments because of the differences in their domestic price levels for farm products. The EEC wheat price, for example, was set roughly halfway between the prices of the lowest-cost suppliers in the community, France and The Netherlands, and those of Germany, which was the highest. France exerted considerable political pressure to persuade Germany to accept a substantial lowering of the returns to its wheat producers. The community prices are supported by purchases from a common fund. The fund begins buying in any area where the price of a crop drops to a fixed intervention level. The cost of the price support program is financed by contributions from the members. The net cost for the Six of the price support was about \$2,000,000,000 in 1970, in relation to an agricultural output valued at approximately \$35,000,000,000.

**Toward an economic union.** A second fundamental aim of the Treaty of Rome was to achieve an economic union among the signatories. This would require a general harmonization of national economic policies. The treaty envisaged the working out of common rules covering such matters as competition, taxation, and economic legislation. It also called for the development of common policies in such areas as foreign trade, agriculture, and transportation. Members were asked to concert their economic policies in the fields of fiscal and monetary policy, balance of payments policy, and social welfare. A great deal of work had been done along these lines by the end of the 1960s.

**Relations with other countries.** *Privileged association with overseas countries and territories.* The treaty provides that overseas countries and territories having a special relationship with Belgium, France, The Netherlands, and Italy may be granted associate membership. The purpose of this was to eliminate preferential tariff arrangements of any of the six members with outside countries by extending the same preferential terms to all of the Six. The treaty also provides for a European Development Fund to assist the economic development of these countries. In December 1970 some 31 countries were associated with the community through this provision. There were 18 African states: Burundi, Cameroon, Central African Republic, Chad, Congo (Brazzaville), Dahomey, Gabon, Ivory Coast, Malagasy Republic, Mali, Mauritania, Niger, Rwanda, Senegal, Somalia,

The harmonization of agricultural policies

The Common Market

Togo, Upper Volta, and Zaïre. There were nine overseas territories: Netherlands Antilles, Comoro Islands, New Caledonia, French Polynesia, St. Pierre and Miquelon, Surinam, French Territory of Afars and Issas, French Southern and Antarctic Territories, and Wallis and Futuna Islands. There were four overseas French departments: Guadeloupe, French Guiana, Martinique, and Réunion.

**New members.** Any European state may request membership in the EEC. Acceptance requires a unanimous decision by the present members after "the conditions for entry and the modifications to be made to the Treaty as a result" have been agreed upon by the member states and the would-be entrant. Great Britain was a candidate for membership in 1961 and again in 1967. The first attempt failed in 1963, following a veto by France. Negotiations on the second application began in 1970 (see below *The issue of British entry*). Other countries that requested membership were Denmark (1961 and 1967), Ireland (1961 and 1967), and Norway (1962 and 1967).

**Associates.** The EEC may also conclude an agreement of association with a nonmember country, a union of states, or an international organization. The associate is entitled to special terms in its trade with the EEC and can send representatives to its meetings. Associate status providing for a custom union after a 12-year transitional period was granted to Greece in 1962 and Turkey in 1964. Partial association agreements have been signed with Nigeria (1966); the East African states of Kenya, Uganda, and Tanzania (1968); Tunisia (1969); Malta (1970); and Israel (1970). Negotiations for associate status have been undertaken with Austria (1961), Sweden (1961), Switzerland (1961), Cyprus (1961), Portugal (1962), Spain (1962), Algeria (1963), United Arab Republic (1970), and Lebanon (1970). In the case of Spain, association was expected to be a first step toward full membership.

**Constitution of the EEC.** The execution of the tasks to be undertaken by the European Economic Community is entrusted to a council, a commission, an assembly (the European Parliament), and a court of justice. The council and commission are assisted by an economic and social committee with advisory functions.

The council has decision-making power in all matters falling within the sphere of competence of the community. Each member sends one delegate. During the transition period before 1970, all important decisions had to be taken unanimously; they may now be taken by either absolute majority or "qualified" majority (*i.e.*, with weighted voting rights) or unanimously. Either a qualified majority or unanimity are required on certain matters by the treaty. Decisions must be taken unanimously on a very large number of issues.

The commission is a body of 13 members "selected by reason of their general competence and offering the utmost guarantees of independence." They are appointed by agreement among the member countries, not more than two being of the same nationality. Members serve a four-year term and may be reappointed. They are expected to act in the general interest of the community, without deference to any government or other organization.

The commission's basic function is to watch over the application of the treaty and to assist the council with recommendations or advice. Its powers for the most part are delegated to it by the council. The commission maintains a staff of several thousand employees in Brussels.

The assembly is formed of 198 delegates selected from the parliaments of the members. France, West Germany, Italy, and the U.K. each have 36 seats, Belgium and The Netherlands 14, Denmark and Ireland 10, and Luxembourg 6. In principle the assembly meets once a year. It passes recommendations and resolutions, and discusses the commission's annual report. It may pass a resolution of no confidence in the commission by a two-thirds majority, resulting in immediate dismissal of the commission members.

The court of justice is charged with the interpretation and application of the treaty. It is composed of nine judges appointed by mutual agreement of the govern-

ments of the member states for six-year terms. Actions may be brought in the court by any member state or by any physical or legal person. The court's powers are considerable since community law takes precedence over the national laws of each member country.

The economic and social committee is a consultative body composed of representatives of various economic and social strata, including manufacturing, agriculture, transportation, trade, handicrafts, the liberal professions, wage earners, and the public. Its members are appointed for a four-year term by unanimous decision of the council, and may be reappointed. Membership on the committee is fixed as follows: Belgium 12, Germany 24, France 24, Italy 24, the U.K. 24, The Netherlands 12, Denmark 9, Ireland 9, and Luxembourg 6.

#### THE EUROPEAN FREE TRADE ASSOCIATION

When the European Economic Community was being organized, Great Britain sought to organize a free trade area that would include 17 member countries of the Organization for European Economic Co-operation. This would have given Britain access to the benefits of the industrial common market on the continent while avoiding possible infringements of British sovereignty. The effort failed, mainly because of French opposition. Britain then undertook the formation of a free trade area in association with Austria, Denmark, Norway, Portugal, Sweden, and Switzerland.

The convention setting up the European Free Trade Association (EFTA) was signed at Stockholm on January 4, 1960. The preamble stated that one of the main purposes of the organization was to "facilitate the future establishment of a wider multilateral association for abolition of customs barriers." More specifically, it was intended as a mechanism for freeing trade with the six Common Market countries without subscribing to the commitments of political character embodied in the Treaty of Rome. In the meantime, EFTA gave its seven members a stronger bargaining position vis-à-vis the other six, as well as the means of creating a large market of their own.

**The EEC and the EFTA compared.** The European Free Trade Association and the European Economic Community differed in a number of important respects. Whereas the EEC included agricultural products in its scope, EFTA excluded them. Whereas the Treaty of Rome establishing the EEC provided for free movement of persons, services, and capital, the Treaty of Stockholm in general did not. The EFTA, unlike the EEC, did not establish a customs union and a common trade policy. Although tariff barriers were to be abolished between member states of EFTA, each maintained its own schedule of duties vis-à-vis outside countries. Thus, although the EEC was much more than a simple customs union, since it sought to develop common economic policies, the EFTA was much less than a customs union. The EFTA was, in effect, an association formed to deal with temporary concerns; it would cease to exist should Britain become a member of the EEC.

**Operation of the EFTA.** The European Free Trade Association was governed by a council composed of one member from each participating state. The council found it useful to set up a joint consultative committee composed of representatives of industry, business, and labour; a set of six permanent technical committees (on customs, trade, economic development, agriculture, economics, and budget); and some 40 working parties dealing with special topics.

The EFTA treaty, like that of the EEC, provided for a transitional period, set forth rules governing competition, and called for the abolition of all indirect protection and trade discrimination.

The EFTA had one special problem arising from its nature as a free trade area. Since the duties charged on imports from outside countries might differ from one member to another, traders could take advantage of the differences by channelling imports through the country levying the lowest rates and delivering them to customers in another member country. Rules were established to prevent this by classifying merchandise according to

A response  
to the  
Common  
Market

whether it was produced or fabricated in one of the member countries. In the case of goods made from imported raw materials, the rules required that the import content not exceed 50 percent of the export price of the finished product.

**The EFTA's record.** Although a ten-year transitional period was originally envisaged, internal customs barriers were eliminated on January 1, 1967, three years ahead of schedule.

The EFTA passed through two grave crises in the 1960s. The first was in 1961 when Britain, acting unilaterally, informed its partners that it had applied for membership in the EEC. The upshot was a joint declaration in which the EFTA members committed themselves to "coordinate their action and remain united throughout the negotiations." The second crisis occurred in October 1964, when, to shore up the pound sterling, Britain suddenly introduced a surcharge of 15 percent on all its industrial imports—an act that was in violation of the treaty. But the crises in EFTA were not as acute as those in FEC when France vetoed the British application for membership in January 1963, or during the conflict over majority voting (which eliminates the national veto) in the EEC council of ministers in July 1965.

#### ECONOMIC INTEGRATION IN LATIN AMERICA

Progress toward economic integration in Europe encouraged the Latin American republics to make similar attempts. By the 1970s four organizations had been established to work toward such integration: the Central American Common Market; the Latin American Free Trade Association; the Andean Development Corporation; and the Caribbean Free Trade Association. The Punta del Este declaration of 1967 set forth the principle that the various regional units should be integrated.

**The Central American Common Market.** On June 10, 1958, El Salvador, Guatemala, Honduras, Nicaragua, and Costa Rica signed a multilateral treaty aiming at free trade and economic integration. It provided for the establishment of a free trade area within ten years. The participating countries also agreed to the industrial integration of the region. These arrangements were completed by the signature on December 13, 1960, of the Treaty of Managua. Its aims were similar to those of the EEC in Europe, namely, the establishment of a common market within five years and the organization of integrated industrial development. The Central American Common Market included a total population of 14,000,000 persons in 1969. By November 1968, a series of overall tariff cuts had freed 98 percent of the region's internal trade, and a single customs tariff had been introduced for most products imported from outside the area.

**The Latin American Free Trade Association.** On February 18, 1960, Argentina, Brazil, Chile, Mexico, Paraguay, Peru, and Uruguay signed a treaty setting up the Latin American Free Trade Association. By 1970 the seven signatories had been joined by Ecuador, Colombia, Venezuela, and Bolivia. The treaty provided for a 12-year transition period during which all obstacles to trade were to be eliminated. It was based on the principle of reciprocity and most-favoured-nation treatment. Member states also committed themselves to progressive co-ordination of their industrialization policies. Special treatment was provided for agriculture and for the relatively least-developed member countries.

Liberalization of trade between the member countries was carried out initially through negotiation of product-by-product concessions. In 1967, however, the negotiations failed; they were postponed to 1968, when agreement was reached on a system of across-the-board automatic tariff reductions similar to those of the European Economic Community. But the Latin American Free Trade Association, which had been intended as the first step in a process that was to lead to a common market, had yet to become more than a series of preferential arrangements based on a large number of bilateral trade, industrial, and financial accords.

**The Andean Development Corporation.** In 1966 Bolivia, Chile, Colombia, Ecuador, Peru, and Venezuela,

all members of the Latin American Free Trade Association, agreed to form a regional subgroup. The Andean Group finally began its official existence in June 1969 without Venezuela, which had withdrawn.

**The Caribbean Free Trade Association.** In 1968 five former British colonies (Antigua, Barbados, Guyana, Jamaica, and Trinidad and Tobago) signed the Treaty of Antigua creating the Caribbean Free Trade Association. This organization has not yet developed any definite institutional link with the general movement toward economic integration in Latin America.

**Toward further integration.** The Declaration of the American Presidents at Punta del Este on April 14, 1967, recommended unification of the various movements toward economic integration. Seventeen countries, including the five members of the Central American Common Market, the 11 members of the Latin American Free Trade Association, and Panama, committed themselves to create a common market over a 15-year period by progressively integrating the Caribbean Free Trade Association and the Latin American Free Trade Association.

So far, attempts at economic integration in Latin America have encountered a number of obstacles, some of which are peculiar to the political and social conditions of that region. These include a heterogeneous and rapidly expanding population, very high rates of price inflation in some countries, a legacy of national antagonisms, and major differences among the countries in size and economic development. In consequence, economic integration is much more difficult to achieve in Latin America than in Europe.

#### THE COUNCIL FOR MUTUAL ECONOMIC ASSISTANCE

A Soviet-sponsored effort to integrate the economies of eastern Europe began as early as January 25, 1949, in response to the Marshall Plan. The founding states were Bulgaria, Hungary, Poland, Romania, Czechoslovakia, and the Soviet Union. Albania joined in 1949, the German Democratic Republic in 1950, and the Mongolian People's Republic in 1962. Albania ceased to participate after 1961. Mainland China, Cuba, North Korea, North Vietnam, and Yugoslavia participate in the organization as observers with associate membership. In its early years the activities of the Council for Mutual Economic Assistance (or Comecon) were limited mainly to the registration of bilateral trade and credit agreements among the member countries. After Stalin's death in 1953 it made efforts to promote industrial specialization and to reduce "parallelism" in the economies of its members. In 1956 and 1957, when most of its standing commissions began to operate, attempts were made to harmonize the long-term plans of the members.

The establishment of the European Economic Community in 1958, together with pressures from the eastern European countries for a greater degree of independence, induced the Soviet leadership to rethink the organization. A new charter was signed by the members in Sofia on December 14, 1959.

**Economic objectives.** The economic aims of the Council for Mutual Economic Assistance are

through unification and coordination of the efforts of its member countries to contribute to the balanced growth of their economies, more rapid economic and technical progress, increased industrialization of those countries which are least advanced in this area, the continued growth of labour productivity, and the regular improvement of the welfare of the peoples of member countries.

Its pursuit of these objectives has been hindered by certain political and economic constraints. One of the most serious is the absence of flexible and realistic price systems in the member countries. This has made it impossible to base trade on relative prices; instead it has been conducted mainly on a barter basis through bilateral agreements between governments. In negotiating such agreements, the parties have been led to use "world prices"; *i.e.*, the prices prevailing in the trade of countries outside the Council for Mutual Economic Assistance.

Another hindrance to economic integration is the highly centralized economic planning that is the rule in the

Integration  
in eastern  
Europe

member countries, which so far have had only limited success in coordinating their plans.

There have also been serious nationalistic tensions within the council. The Romanian government, for example, announced its intention to pursue all-around industrialization, including the development of its heavy industries, in opposition to the policy of specialization in raw materials and agricultural products that was said to have been the Council for Mutual Economic Assistance's policy for Romania.

Among the practical achievements of the Council for Mutual Economic Assistance, however, have been: the organization of railroad coordination (1956); construction of a high-voltage electricity grid (1962); creation of the International Bank for Economic Cooperation (1963); the pooling of 93,000 railway freight cars (1964); and construction of the "Friendship" oil pipeline from the Soviet Union's Volga region to the eastern European countries.

The constitution of the Council for Mutual Economic Assistance. The highest authority of the organization is the council-in-session. It is composed of delegations from all member countries, the composition of each delegation being fixed by the government concerned. The conference of representatives of member countries, composed of one representative of each member country, may issue recommendations and decisions. It may also submit proposals for examination by the council-in-session.

Various permanent commissions are composed of experts and official representatives of member countries. Some are general economic commissions; others deal with issues affecting specific industries. The headquarters of the various commissions are located in the capital cities of member countries. The central secretariat is in Moscow.

The Council for Mutual Economic Assistance is often called the eastern European counterpart of western Europe's EEC. Although the general aims are indeed the same, the two organizations differ radically in their approach to the problems involved. The EEC aims to achieve integration on a decentralized basis by means of an economic market in which goods, services, capital, and persons have full freedom of movement—a market regulated by uniform economic legislation. The Council for Mutual Economic Assistance seeks to achieve cooperation among national economies each of which is centrally planned and administered.

#### AN APPRAISAL OF THE EUROPEAN ECONOMIC COMMUNITY

Since the EEC has, in varying degree, served as the model for every subsequent attempt at economic integration, and since the problems it raises are of broad scope, some analysis of its accomplishments and difficulties will be useful.

The Common Market. By July 1970 a practically complete customs union had been achieved. All internal trade restrictions, whether tariffs or quotas, had been removed; a unified schedule of customs duties was in force on industrial and agricultural products imported from outside countries; and most quantitative restrictions on imports from outside the community had been abolished. There remained, nonetheless, six primary areas in which the Common Market was still incomplete. These had to do with prices, customs legislation, technical legislation, government contract letting, fiscal legislation, and trade policy.

1. Although internal customs barriers had been removed, there were still considerable differences in the prices of similar products among the member countries. In 1969 the prices of radio and television sets in France, for example, were almost 50 percent higher than they were in Germany. The price of food was 15 percent higher in Italy than in Luxembourg. Textiles cost 33 percent more in France than in The Netherlands.

2. The operation of a true customs union requires harmonization of customs legislation on such technical matters as bonded warehouses and systems for payment of duty. This is indispensable if trade is to flow on equal terms among the members.

3. Different technical norms among countries are an obstacle to true liberalization of trade. For example, in 1970 automobile windshields could not be exported from some countries of the community to others because of differences in specifications. It was estimated that the total volume of trade could be increased by one-third if homogeneous technical standards were adopted.

4. Government purchases and contracts for public works were administered on a highly discriminatory basis in each member country, preference being given to national suppliers.

5. Harmonization of fiscal legislation is also essential for the achievement of an effective common market. When taxes fall more heavily on some producers than on others, the effect is to make them less competitive. Thus it has been argued that a producer in a country in which the turnover tax rate is 25 percent cannot meet competition from another country in which the rate is only 10 percent. For this reason the EEC allows members to make drawback payments on exports up to the amount of direct and indirect taxation borne by the products concerned, and to levy taxes on imports up to the amount of direct and indirect taxation borne by similar national products. This is easy to do with respect to indirect taxes (sales and turnover taxes), but there is no practical way to assess the relative burden of direct taxes (income and property taxes) in different countries. Only similar tax laws in the countries can eliminate this distortion.

6. Although the six members of the EEC had adopted a common trade policy, there were still important gaps to be bridged, especially concerning trade with the Communist world. One issue in this was the desire of West Germany to have a free hand in its negotiations with eastern Europe.

From the Common Market to economic union. Further progress toward economic union would require new legislation in each of the member countries, the merger of the three treaties governing the Coal and Steel Community, the Economic Community, and Euratom (meaning that they must be revised), far-ranging agreement on industrial and agricultural matters, and, most important of all, a single monetary policy.

Although a common agricultural policy had been developed, it was based on the maintenance of relatively high prices. In 1967–68 the guaranteed prices for corn, wheat, sugar beets, and butter ranged from 1.6 to 4 times the level of world market prices. Although the labour force employed in agriculture fell from 20 percent of the total labour force to 13 percent between 1960 and 1970, the high prices, in association with rapid productivity growth, generated massive commodity surpluses. The mounting cost of the price support program caused increasing dissatisfaction in West Germany and Italy, the two countries on which the burden mainly fell. In addition, EEC was accused of dumping its commodity surpluses on the world markets at disastrously low prices. Despite its cost, moreover, the agricultural policy of the 1960s failed to provide all farmers with incomes equivalent to those enjoyed by the rest of the population.

Economic union would also require a unified policy on money and credit, leading to the introduction of a single currency. There were two major obstacles to be overcome. The first obstacle was political: a single currency would require the members to renounce some of their national sovereignty. The second obstacle was social: even if a common monetary policy could be applied, it would be viable only if the wage level in each country was fixed by the market, a policy difficult for the national trade unions to accept. A permanent liberalization of trade and investment within the EEC would in fact require that the national currencies be made fully convertible at an unvarying rate of exchange—which would mean the effective existence of a single currency.

Toward political union. The statesmen who drew up the Treaty of Rome regarded the EEC as a stage in the political unification of Europe. This view was made explicit in the provision for election of deputies to the European Assembly by universal suffrage. It also found expression in those clauses providing that at the end of the transition

The accomplishment in western Europe

Problems of sovereignty

period many decisions were to be taken by absolute or qualified majority vote and were to be binding on every member state.

The members of the EEC had not, by the beginning of the 1970s, shown themselves ready to give up their political independence. No member could, in fact, allow vital decisions to be imposed on it by majority vote of the council. To do so would mean allowing a treaty to override its constitution, and a vote taken by five foreign ministers to overrule a government elected by universal suffrage. This was the root of the 1965 crisis, when France left its seat on the council from June 30, 1965, to February 7, 1966. The nominal cause of the rupture was agricultural policy. The crisis was resolved at an extraordinary council meeting at which the six states tacitly agreed not to invoke the rule of a majority on issues in which the vital interests of a member were at stake.

Despite these difficulties, the cohesion of the EEC did become progressively more concrete. During the Kennedy Round tariff negotiations (1964–67), the community delegation spoke for the six member countries throughout, even though the transitional period had not yet expired and EEC's common tariff had not yet been put into force. Again, in the sensitive area of agriculture, the members relinquished autarkic national policies and adopted a liberally oriented common policy.

**The issue of British entry.** In August 1961 Great Britain applied for membership in the EEC. Denmark, Ireland, and Norway entered their applications shortly afterward. Negotiations began in November 1961, and were terminated in February 1963 by a French veto. Britain applied again in 1967, and negotiations resumed in July 1970; in June 1971 agreement was reached by which Britain would enter the EEC on January 1, 1973. The terms called for Britain's adoption of the common EEC tariff, the common agricultural policy, and the rules of the Community, by transitional stages over a period of five years. Britain's share of the Community budget would start at 8.64 percent in the first year, rising to 18.92 percent in the fifth year.

Four major economic considerations were involved: the interests of the British Commonwealth countries, the cost to Britain of importing European agricultural products, the matter of London's sterling balances, and the interests of Britain's partners in the European Free Trade Association. The transition period was expected to protect the Commonwealth countries from undue hardship in the gradual loss of their preferential trading advantages with Britain. Although the common agricultural policy would raise food prices in Britain, this would be offset by the opportunities opened to British industry on the Continent. The sterling balances, however, remained a barrier in the path of British financial integration with the EEC. And of Britain's partners in EFTA, only Denmark chose to enter the Community in 1973. In Norway a referendum in September 1972 rejected the country's proposed entry. The possibility remained that the other EFTA members, Sweden, Switzerland, Austria, and Portugal, would be granted associate membership in the EEC. Ireland, not an EFTA member, joined EEC along with Britain.

## Cutlery and Tableware

Cutlery is the general collective term applied to cutting implements, such as knives, razors, and scissors, used for industrial, commercial, and domestic purposes. Tableware comprises both hollow ware, including such items as dishes, platters, teapots, and coffeepots, and flatware, consisting of the various forms of spoons and forks used at the table.

#### ORIGINS AND DEVELOPMENT

Prehistoric implements used for cutting, hunting, and defense were fashioned from stone, especially flint; from obsidian, a volcanic glass; and from bones and shells. Cutting edges were formed by rubbing the implement in the hollow of a stone, a method still employed by aborigines of central Brazil, Australia, and New Guinea. In the earliest spoons, baked clay formed both the bowl-shaped receptacle portion and the supporting stem or handle. Later, spoons were made from suitably shaped bone or wood pieces. By 1500 BC bronze cutting implements were being used from the British Isles to China. Scissors with blades connected by a C-shaped spring at the handle end also originated at about this time. As various metals became known, the art of forging blades developed in China, India, and Europe. Pivoted scissors of bronze or iron, connected by a rivet or screw between the handles and blades, were known in ancient Rome and in China, Japan, and Korea.

The Egyptians fashioned cutting implements from flints chipped to form serrated edges and then glued into slots in wood that had been appropriately shaped for the intended purpose. Knives served mainly for hunting and as weapons, but the wealthy used small ornamental eating knives. Spoons were frequently made of bronze, some having spiked handles to extract snails from their shells. Elaborate cosmetic spoons had carved handles representing human or animal forms; long incense spoons served ceremonial functions.

The Greeks produced bronze knives, and the Romans spread blade-making techniques throughout the Mediterranean and Europe. As in Egypt, small ornamental eating knives were used by the wealthy. Both Greeks and Romans employed bronze and sometimes silver for spoons. Some Roman spoons, made of bone, had small holes in the centres of their bowls; the purpose of these holes is not known.

In western Europe the Celts used short bronze spoons with broad shanks formed to fit the hand. Knives were usually pointed, allowing food to be speared. Steel-bladed eating knives dating from the Roman period have been found in Italy and Britain.

As knowledge of techniques spread, cutlery production was established in areas able to offer plentiful timber to heat furnaces and provide charcoal, in addition to soft water for the hardening and tempering of steel. Medieval

Early  
scissors

grindstones were sometimes hand-operated, but animal or water power was frequently employed to revolve treadmills or wheels. From about 1200 cutlery manufacture began to settle in London and Sheffield in England; in Thiers and Paris in France, in Solingen, Germany; and in many other places where craft guilds were founded. Craftsmen produced elaborately ornamented blades and fashioned handles of such fine materials as gold, silver, ivory, ebony, agate, amber, and marble.

Table cutlery was not provided by innkeepers, and the affluent possessed elegant travelling sets. Others used plain knives with handles of bone or wood and crude molded forks and spoons made by tinkers from an alloy of lead and antimony. In the homes of the wealthy it became usual to provide knives for guests, though most men still carried their own. Serving knives made in pairs, sometimes called *présentoirs*, were used only for passing food. Sets known as "wedding knives," consisting of a pair of knives in a sheath, were common gifts from bridegrooms to their brides.

The invention of forks

Forks, which originally had a single point, were made with two prongs by the Romans. In the Middle Ages large forks with two flat prongs were used for serving. Smaller eating forks were gradually developed, replacing the traditional pair of pointed table knives that were part of the transition to knife and fork. Handles were sometimes made of precious or semiprecious materials.

Silver spoons originally had long, pointed bowls, but by the later Middle Ages the bowls were frequently fish-shaped, while the stems were often topped with decorative knobs. Matching sets of spoons and forks in standard patterns were common by the mid-18th century. The modern tablespoon, with its stem ending in a rounded curve and turned downward, was adopted about 1760. Table knives of the 18th century frequently had pistol-shaped handles and curved blades like those of scimitars. Although individual eating knives were no longer carried for ordinary use by the late 17th century, sets consisting of knife, fork, spoon, and drinking vessel were still being made for travellers well into the 19th century.

The rise of Sheffield as a manufacturing centre

By the 18th century Sheffield, England, had become an international centre of the industry. In the early 1700s Sheffield cutlers and silversmiths were making forks having two or three prongs and knives with hollow silver handles that were stamped in two halves, soldered together, and filled with pitch into which the tang, the projecting portion of the knife blade, was inserted. Large-scale production of pivoted scissors and shears began in 1761, when Robert Hinchliffe of Sheffield first used crucible cast steel for their manufacture. By the 19th century scissors with elaborately designed hand-filed and polished bows and shanks were made in Europe.

Steel razors were made with ornamental handles, and blades were individually hollow-ground, producing a concave surface behind the cutting edge. The forerunner of the modern safety razor, with a guard along one edge, was introduced in 1828. In 1880 a hoe-shaped safety razor was manufactured in the U.S., and early in the 20th century King C. Gillette began to manufacture a model with double-edged replaceable blades.

#### MATERIALS USED FOR CUTLERY AND TABLEWARE

**Plated materials.** Sheffield plate, produced by a process developed about 1743 by Thomas Boulsover of Sheffield, consisted of thin sheets of silver fused onto small copper ingots. The ingots were then rolled into sheets, and a thin coating of silver remained on the surface. Between 1750 and 1880 this material was employed for such items as knife handles, serving dishes, tea urns, and candelabra, manufactured mainly in Sheffield but also in Birmingham, England.

By about 1860 a new process of electroplating, the application of metallic coatings to base metals by means of an electric current, superseded Boulsover's fusion process. Electroplating of silver onto alloys of nickel and copper was soon common, followed by the plating of nickel onto brass. Sheffield plate was no longer commercially manufactured, and surviving pieces eventually became valuable antiques (see also ELECTROPLATING).

**Cutlery steel.** Cutlery steel consists of iron to which from 0.35 to 1 percent carbon has been added. Early methods involved hammering charcoal into red-hot iron bars. In the 18th century Benjamin Huntsman built new types of furnaces in Sheffield for making highly refined steel in clay vessels called crucibles. His process greatly increased both the availability and quality of steel during the first part of the Industrial Revolution. Mass production of steel was achieved in the 19th century by the open-hearth process.

**Stainless steel.** Harry Brearley of Sheffield, England, discovered one form of this steel in 1913 and others were developed during the following decade in Germany and the United States. Although not strictly "stainless," these steels are highly resistant to corrosion from common household acids and alkalis. Corrosion resistance depends upon such factors as the amount of chromium they contain, satisfactory heat treatment, and the quality of the grinding and finishing processes (for a description of the different types of steel and their methods of production, see STEEL PRODUCTION).

Martensitic stainless steels, widely used for both table knives and trade knives, contain from 12 to 18 percent chromium, imparting corrosion resistance, and from 0.12 to 1 percent carbon, permitting a great degree of hardening by heat treatment. Edge retention increases with higher carbon content; corrosion resistance is increased by higher chromium content but reduced with additional carbon.

Austenitic stainless steels contain about 18 percent chromium and 8 percent nickel. They can be hardened to a limited extent by cold-rolling or stamping but not by the application of heat. Such types have corrosion resistance superior to that of martensitic steels but cannot be adequately hardened and tempered to allow grinding to a cutting edge. They are, however, easily drawn out without breaking, making them suitable for both flatware and hollow ware production.

By 1928 the manufacture of carbon-steel blades was limited to commercial knives and some carving, hunting, and pocket knives.

**Flatware materials.** Though since about 1860 much flatware has been silver-plated by the electroplating method, the use of stainless steel has grown steadily since 1920. New designs for stainless-steel flatware developed rapidly in Europe and the U.S. By 1955, similar growth had taken place in Japan, Taiwan, Korea, and Hong Kong. In the early 1970s most of the world's cutlery was made of martensitic stainless steel and most flatware was made of austenitic varieties. Ferritic stainless steel, containing 12 percent chromium, was being used for less costly flatware, particularly in the Far East. Spoons and forks manufactured for use in food preparation were frequently made of stainless steel.

Other flatware materials include gold for luxury services and unplated nickel alloys, aluminum, tin-coated iron, and plastics for inexpensive ones. Wood and natural horn are popular for salad servers. Aluminum is especially useful where lightness and low cost are desired; lightweight plastic eating implements, made in various colours, are produced for picnic sets, ice cream spoons, and airline food service. The least expensive materials for metal flatware are regular steels electroplated with copper, nickel, or chromium.

Silver-plated flatware is manufactured by electroplating silver onto a base metal such as finely buffed nickel silver (an alloy consisting mainly of copper, zinc, and nickel) or stainless steel, its quality being determined by the strength and composition of the base metal, the standard of finish, and the thickness of the silver deposit.

Solid-silver flatware, utilizing essentially pure silver, is a luxury item. Standards for silver purity vary, the principal one being not less than 925 parts of fine silver in 1,000 parts, established by the British assay offices for silver hallmarked as "sterling." The balance is copper or other base metals that add strength to the finished piece. Similar controls exist in Austria, Czechoslovakia, Finland, France, Hungary, The Netherlands, Poland, Portugal, the Soviet Union, Sweden, and Yugoslavia. Some

Silver plate and sterling

European nations accept a lower standard of 800 parts of silver in 1,000 parts; others employ voluntary marking systems. In Europe, silver articles usually bear hallmarks indicating that the metal contains a prescribed amount of silver. Other marks record the year of manufacture and the maker. United Kingdom hallmarks include the lion passant, a symbol in heraldry, guaranteeing that the silver is not less than 92.5 percent pure; the assay office (town) mark; the monarch's head; the date letter recording the year of manufacture; and the maker's full name, initials, or trademark. In the United States, the word sterling when used by a reputable supplier is accepted as a sufficient guarantee, and there are no fixed standards.

#### MODERN FABRICATING TECHNIQUES

In the early 1900s, machine processes were rapidly adopted both in the United States and in the major manufacturing centres of Europe. Between 1920 and 1930, forging techniques were revolutionized and stainless steels rapidly supplanted carbon steels.

**Cutlery.** The many kinds of cutlery all have distinctive uses, the blade being the major determining factor. Retention of sharpness depends on the type of steel employed and the skill with which it is processed. Cost is determined by the quality of the blade steel, workmanship, material used for the handle, and ornamentation. In the early 1970s hand-fabrication methods predominated in such developing areas as India, China, and Africa. In industrialized nations, including the United States, Canada, Britain, Germany, France, Australia, and Japan, and also in Hong Kong, hand labour had been reduced to a minimum.

**Table cutlery.** In the production of table cutlery described below, processes include: (1) forging the steel into the desired blade shape; (2) hardening and tempering it correctly; (3) grinding the blade to a cutting edge and removing all traces of forging and heat treatment; (4) polishing the blade; and (5) making, fitting, and polishing the handle, a process known as *cutting*.

High-quality knife blades (Figure 1) are forged by mechanical hammers from bars of steel. After heating, a bar is placed between forging dies that rapidly hammer

from sheet steel so that a short flat tang without a forged bolster (the part of the knife blade that abuts upon the handle) is left. After forging, the blades are hardened by heating and then quenching in a cooling liquid or between metal plates cooled by an internally circulating liquid. The blades are then tempered by reheating to the correct temperature to give them flexibility and toughness.

Grinding consists of applying the blades to the rapidly revolving periphery of an abrasive wheel, removing the steel until the desired tapers from the back to the cutting edge and from bolster to point are attained. The blades are kept cool with water or a "cutting fluid" to maintain their temper.

After either machine or hand grinding, the surface of a blade is given a finer finish in successive operations known as glazing and buffing, followed, if desired, by mirror polishing, or "satin" finishing. The bolsters are also ground, glazed, and polished to fit the desired handle. The maker's name is then applied by acid or electric-arc etching.

Natural materials used for handles include animal horns and tusks, various woods, mother-of-pearl, and bone; manufactured handles range from gold, silver, and porcelain to stainless steel, silver plate, nickel alloys, compressed wood, and plastics. Some of these materials are processed mechanically and others by the cutler. Natural-stag-horn handles must be matched to each blade individually because no two are alike. Cellulose adhesives, cements, or resin mixtures are used to fix the tangs securely in the handles, except for hollow metal handles, which are secured by hard soldering or welding.

Scissors and shears. By the end of the 19th century mechanical methods of production had begun to simplify styles and patterns. Blanks (unfinished pieces) or scissors are now made by high-speed forging of red-hot steel bars between the dies of drop hammers. For ordinary scissors, steel containing 0.55 percent carbon is mainly used; for the finest scissors and shears for trade use, such as tailors' shears and trimmers, a harder steel containing 0.75 percent carbon is preferred. For cutting man-made fibres, harder and more blunting than natural fibres, the blades of tailors' shears are sometimes made of a composite material consisting of an even harder steel on the cutting side (1.03 percent carbon), backed by tough iron. Many scissors, including surgical varieties, are made of stainless steel, and some specialized scissors and shears are made of nonferrous alloys that will not produce a spark or interfere with magnetism (e.g., for cutting cordite and magnetic tape). Low-cost scissors are made from relatively soft steel wire that is pressed cold and is not hardened.

If scissors are to cut well, the blades must touch in two places only—at the joint and at a single spot along the blades wherever the cutting takes place. The blades are made to twist or curve toward one another, and, when completely closed, their points should touch. Both blades must be accurately tempered to equal hardness. In the finest scissors and shears, the two blanks and the screw, as well as the nut in large shears, are coded with an identification mark early in manufacturing to ensure being treated as a set.

**Modern razors.** In the early 1960s manufacturers in several countries produced stainless-steel blades for safety razors, allowing longer usage than the older steel blades. Further efforts to improve life and cutting edge led to the use of chromium and even platinum in the early 1970s. Electric razors, operating on a principle similar to that of the barber's hair clipper, were introduced as early as 1931. Steel razors with hollow ground blades continue to be made in most countries for use by barbers.

**Flatware.** Forming *blanks*. Modern flatware (Figures 2 and 3) is produced in all the cutlery centres of the world. During the 20th century, the processes used in its manufacture reached a high degree of mechanization. The metal, carefully refined, is formed into sheets of proper thickness and cut into strips of the required width. These processes involve the strictest control of metal behaviour and correct annealing to remove ex-

out the rough blade shape desired. The final blade shape is obtained by trimming the forgings. Some knives are made as complete forgings of blade and handle by one stroke of a large drop-forging hammer; others are cut

cessive strains. The strips are fed into machine presses that cut out each spoon or fork in its rough shape, one end being at first almost square for a spoon and rectangular for a fork. The ends of these "blanks" are rolled again in a direction at right angles to the centre line, reducing the thickness at this point without altering the thickness of the handle. The bowls of the more expensive spoons are no more than half as thick as their handles.

**Stamping.** After being trimmed, the blanks are stamped in alloy-steel dies that hollow the bowls and stamp a pattern on the handles. In the case of forks,

slots are cut out to form the prongs, which are then stamped in dies to the required curvature, tapered, and pointed on abrasive belts. These processes are approximately the same whatever metal is used, although in manufacturing cheaper products, made from thinner sheets, cross-rolling can be omitted and the stamping can be performed in one operation.

**Finishing.** Subsequent finishing processes vary according to the metal used. In the case of silver, successively finer stages of buffing prepare the surfaces for final polishing or satin finishing. In the case of alloys that are to be plated, the articles, after being buffed, are wired individually on frames; quantities of 100 or more can be immersed simultaneously in the series of cleaning baths and plating vats. In most factories the complete frames of articles are transferred automatically from baths to vats and finally to washing and drying. The thickness of deposit is increased by some makers at the points of maximum wear; for example, on the centre of the convex surface of spoon bowls. Although the deposit of silver is specified in grams or pennyweights per dozen pieces and sometimes in actual thickness in millimetres or thousandths of an inch, the more popular method of indication is use of the terms "30 years," "25 years," or "20 years" plate. The designation A1 is considered satisfactory as a guarantee of quality if given by a manufacturer of good repute.

**Final polishing.** After the pieces have been plated, their surfaces are dull and require polishing. Hand polishing is performed by holding the articles upon rapidly rotating mops dressed with an aluminum compound or rouge. The least expensive plating process is "bright plating," in which a very thin coating of silver or chromium is deposited bright, thus eliminating final polishing. Such coatings are of short duration, and the process is therefore restricted to the cheaper grades of flatware. Stainless steel is more difficult to polish than silver, silver plate, or unplated nickel alloys. Techniques have been developed for stamping the cheaper varieties of stainless-steel spoons and forks from prepolished sheet. In some countries stainless steel is polished electrolytically.

In the most modern finishing operations, various mechanisms stack, feed, and transport the pieces from one process to the next without damage. Edges are smoothed by stacking many spoons and forks together and pressing them onto a series of progressively finer abrasive belts or wheels. To polish the main faces, many spoons and forks are placed side by side, gripped at one end in a long clamp, and fed longitudinally, with a racking motion, into and out of the polishing rolls, so that every portion of the surface is reached. A series of machines is used to achieve progressively finer polishing.

**Hollow ware.** Many manufacturers of cutlery and flatware also produce hollow ware, in the production of which the principle of the potter's wheel has long been applied; thin sheets of metal are gripped between clamps and rapidly rotated. Pushing a wooden former against the side of the disk bends the metal over, producing the body of a jug or vase. Before soldering was developed, handles and mounts were made separately and rivetted to the body. Shallow dishes and bowls were stamped directly from sheet metal by dropping a large concave stone onto a sheet that had been placed upon a corresponding stone with a convex surface. By the late 17th century, such dies were widely used. Ornamentation, such as embossing or indentation, was added by hand.

In the 19th century the advent of press-tool machinery enabled the initial sheet or blank to be accurately formed by pressure methods. In the modern process stainless-steel blanks are pushed through a die hole by hydraulically operated shaping punches. After annealing, the process is repeated with a smaller but longer punch, producing a seamless drawn body of accurate dimensions.

Lids are stamped and spouts pressed in halves, subsequently combined by brazing or welding. Handles of low heat conductivity, such as wood or plastic, are attached to handle mounts joined in the same way. Polishing is similar to that used for flatware, with sand and pumice fed to polishing mops to produce smooth surfaces on nickel alloys prior to silver- or chromium-plating. Silver is worked similarly, and many handicraft methods continue in the production of trophies.

#### Forming lids and spouts

#### WORLD PRODUCTION

Cutlery production statistics are provided by only a limited number of nations. In the early 1970s, the estimated

overall value of Europe's cutlery and flatware production ranged from \$450,000,000 to \$600,000,000, with West Germany, the United Kingdom, and France the leading nations. The cities of Sheffield, Thiers, and Solingen continued to be major manufacturing centres. During the same period Japanese production of table knives and flatware in stainless steel amounted to about \$60,000,000, while United States production of cutlery was about \$270,000,000. Cutlery and flatware of every kind and quality were being manufactured on all continents. In technically advanced countries electric carving knives came into use. Stainless-steel, wafer-type safety-razor blades and electric shavers had largely supplanted forged-steel, hollow-ground razors; electric scissors, clippers, and shears were widely used in industry and elsewhere.

**BIBLIOGRAPHY.** C.T.P. BAILEY, *Knives and Forks* (1927), is a profusely illustrated treatise on the uses of cutlery and the work of cutlers from the 15th to the 18th century. H. RAYMOND SINGLETON, "A Chronology of Cutlery" (1965), is a short, illustrated pamphlet that traces the development of table cutlery from the 10th through the 20th century. J.B. HIMSWORTH, *The Story of Cutlery* (1953), provides a comprehensive account of the development and manufacture of various types of cutlery and flatware. D.S. DUGDALE, *The Cutting Tool Story* (1970), traces the development of cutting implements from the Stone Age to modern times. CAMILLE PAGE, *La Coutellerie depuis l'origine jusqu'à nos jours*, 6 vol. (1896–1904), is possibly the most comprehensive work of its type, profusely illustrated and covering cutlery throughout the world. HENRI LANDRIN, *Manuel du coutelier* (1835), discusses in detail the work of cutlery craftsmen, including processes and materials. Some of the world's major cutlery manufacturing centres are treated in: R.E. LEADER, *The History of the Company of Cutlers in Hallamshire in the County of York*, 2 vol. (1905), a comprehensive account of the activities of the cutlers of Sheffield, England (c. 1624–1905); and G.I.H. LLOYD, *The Cutlery Trades* (1913, reprinted 1968), a work describing and comparing the cutlery trades of Sheffield (England), Solingen (Germany), and Thiers (France). FREDERICK BRADBURY, *History of Old Sheffield Plate and Silver* (1912, reprinted 1968), is an early standard work treating this particular ware and silver; and NOEL D. TURNER, *American Silver Flatware, 1837–1910* (1972), a comprehensive survey of American silver flatware produced during the Victorian period that includes a brief history of tableware.

(W.G.Ib.)

## Cuvier, Georges, Baron

The French zoologist Georges Cuvier established comparative anatomy and paleontology as sciences. By systematically comparing the structure of living animals with fossil remains, he showed that the past must be taken into account when studying present-day life. Although he believed that species did not change, his work provided important evidence on which the doctrine of evolution was later based.

Cuvier was born on August 23, 1769, in Montbéliard,

France. He was named Georges-Léopold-Chrétien-Frédéric-Dagobert Cuvier. In 1784–88 he attended the Académie Caroline (Karlsschule) in Stuttgart, Germany, where he studied comparative anatomy and learned to dissect.

After graduation Cuvier served in 1788–95 as a tutor, during which time he wrote original studies of marine invertebrates, particularly the mollusks. His notes were sent to Étienne Geoffroy Saint-Hilaire, a professor of zoology at the Museum of Natural History in Paris, and at Geoffroy's urging Cuvier joined the staff of the museum. For a time the two scientists collaborated, and in 1795 they jointly published a study of mammalian classification, but their views eventually diverged.

Cuvier refused an invitation to become a naturalist on Napoleon's expedition to Egypt in 1798–1801, preferring to remain at the museum to continue his research in comparative anatomy. His first result, in 1797, was *Tableau élémentaire de l'histoire naturelle des animaux* ("Elementary Survey of the Natural History of Animals"), a popular work based on his lectures. In 1800–05, he published his *Leçons d'anatomie comparée* ("Lessons on Comparative Anatomy"). In this work, based also on his lectures at the museum, he put forward his principle of the "correlation of parts," according to which the anatomical structure of every organ is functionally related to all other organs in the body of an animal, and the functional and structural characteristics of organs result from their interaction with their environment. Moreover, according to Cuvier, the functions and habits of an animal determine its anatomical form, in contrast to Geoffroy, who held the reverse theory—that anatomical structure preceded and made necessary a particular mode of life.

Cuvier also argued that the anatomical characteristics distinguishing groups of animals are evidence that species had not changed since the Creation. Each species is so well coordinated, functionally and structurally, that it could not survive significant change. He further maintained that each species was created for its own special purpose and each organ for its special function. In denying evolution, Cuvier disagreed with the views of his colleague Jean-Baptiste Lamarck, who published his theory of evolution in 1809, and eventually also with Geoffroy, who in 1825 published evidence concerning the evolution of crocodiles.

Cuvier advanced rapidly. While continuing his zoological work at the museum, he brought about major reforms in education. He served as imperial inspector of public instruction and assisted in the establishment of French provincial universities. For these services he was granted the title "chevalier" in 1811. He also wrote the *Rapport historique sur les progrès des sciences naturelles depuis 1789, et sur leur état actuel* ("Historical Report on the Progress of the Sciences"), published in 1810. These publications are lucid expositions of the European science of his time.

Meanwhile, Cuvier also applied his views on the correlation of parts to a systematic study of fossils that he had excavated. He reconstructed complete skeletons of unknown fossil quadrupeds. These constituted astonishing new evidence that whole species of animals had become extinct. Furthermore, he discerned a remarkable sequence in the creatures he exhumed. The deeper, more remote strata contained animal remains—giant salamanders, flying reptiles, and extinct elephants—that were far less similar to animals that are now living than those to be found in more recent strata. He summarized his conclusions, first in 1812 in his *Recherches sur les ossements fossiles de quadrupèdes* ("Researches on the Bones of Fossil Vertebrates"), which included the essay "Discours préliminaire" ("Preliminary Discourse"), as well as in the expansion of this essay in book form in 1825, as the *Discours sur les révolutions de la surface du globe* ("Discourse on the Revolutions of the Globe"). Cuvier assumed a relatively short time span for the Earth but he was impressed by the vast changes that undoubtedly had occurred in its geologic past. His work gave new prestige to the old concept of catastrophism according to which a series of "revolutions," or catastrophes—sudden land upheavals and floods—had destroyed entire species of or-

Cuvier's principle of "correlation of parts"

Cuvier, portrait by Van Brae, 1798.

The problem of extinction of species

ganisms and carved out the present features of the Earth. He believed that the area laid waste by these spectacular paroxysms, of which Noah's flood was the most recent and dramatic, was sometimes repopulated by migration of animals from an area that had been spared. Catastrophism remained a major geologic doctrine until it was shown that slow changes over long periods of time could explain the features of the Earth.

Just before Napoleon abdicated, in 1814, Cuvier was elected to the Council of State, and in 1817 he became a vice president of the ministry of the interior. In 1817 he also published *Le Règne animal distribué d'après son organisation* ("The Animal Kingdom, Distributed According to its Organization"), which, with its many subsequent editions, was a significant advance over the systems of classification established by Linnaeus.

Cuvier showed that animals possessed so many diverse anatomical traits that they could not be arranged in a single linear system. Instead, he arranged animals into four large groups of animals (vertebrates, mollusks, articulate, and radiates), each of which had a special type of anatomical organization. All animals within the same group were classified together, as he believed they were all modifications of one particular anatomical type.

Although his classification is no longer used, Cuvier broke away from the 18th-century idea of the scale of nature. This scheme saw all living things as arranged in a continuous series from the simplest up to man.

The increasing theoretical differences between Geoffroy and Cuvier culminated in 1830 in a public debate in the Academy of Sciences over the degree to which the animal kingdom shared a uniform type of anatomical organization, in particular, whether vertebrates and mollusks belonged to the same type. Geoffroy thought they did and that all animals, in fact, were representatives of only one type, whereas Cuvier insisted that his four types were completely distinct. At issue in their controversy was how to explain similarity and diversity in animals. Darwin's doctrine of evolution eventually clarified this question by showing that similar animals were descended from common ancestors and that diversity meant that hereditary changes had occurred.

Assessment

Cuvier's lifework may be considered as marking a transition between the 18th-century view of nature and the view that emerged in the last half of the 19th century as a result of the doctrine of evolution. By rejecting the 18th-century method of arranging animals in a continuous series in favour of classifying them in four separate groups, he raised the key question of why animals were anatomically different. Although Cuvier's doctrine of catastrophism did not last, he did set the science of palaeontology on a firm, empirical foundation. He did this by introducing fossils into zoological classification, showing the progressive relation between rock strata and their fossil remains, and by demonstrating, in his comparative anatomy and his reconstructions of fossil skeletons, the importance of functional and anatomical relationships. Cuvier died on May 13, 1832, during the first cholera epidemic to strike Paris.

**BIBLIOGRAPHY.** WILLIAM COLEMAN, *Georges Cuvier, Zoologist: A Study in the History of Evolution Theory* (1964), is a lucid analysis of Cuvier's zoological ideas, with a partial bibliography. A general introduction to Cuvier's work is found in ERIK NORDENSKIÖLD, *Biologins historia*, 3 vol. (1920–24; Eng. trans., *The History of Biology*, new ed., 1935). RENE DUJARRIC DE LA RIVIERE (ed.), *Cuvier, sa vie, son oeuvre, pages choisies* (1969), contains a short biography, with selections from his works, and a partial bibliography. A collection of important papers on Cuvier's life and work was published for the centenary of his death in the *Archives du Muséum National d'Histoire Naturelle*, series 6, vol. 9 (1932).

(Ed.)

## Cycling

Cycling is the use of the bicycle for sports. The bicycle, improved throughout the years from the time of the first official contests set up in 1868, and the sport of cycling have both profited from progress in design and technology. For the history of the invention and development of

the bicycle and descriptions of various types, see the article **BICYCLE**.

Cycling has become a common means of transport, and, as a sport, with its rules and its classic races, it has continued to grow throughout the world. Its popularity, in spite of the constant improvement of public and private means of motorized transport, remains great, in the United States as well as in Europe. In the flat countries, especially, cycling is a common means of transport. In countries with varied terrain, such as France, cycling still remains popular and has become a traditional sport, in spite of the increasing use of motorbikes.

History of the sport. Cycling as a sport is more than 100 years old. Its exact birthdate could be fixed as May 31, 1868, when the first velocipede race was organized by the Oliver brothers, managers of the Michaux factory, which made the first real bicycles by attaching pedals to the axle of the front wheel. The race, held in the Saint-Cloud Park near Paris, was won by James Moore. The next day, according to the records, the first cycle race in England was held at Hendon, Middlesex. That same year Moore also achieved victory riding a *grand-bi*, or boneshaker, which has a front wheel much greater in diameter than the rear one, in the first town to town cycle race ever held, 135 kilometres (84 miles) from Paris to Rouen. Also in 1868 the first cycling periodical, *Le Vélocipède*, appeared in Paris; and the following year the magazine *Le Vélocipède Illustré* was founded.

Almost two decades later, in 1888, the pneumatic tire for bicycles was invented and bicycle riding became more comfortable and stable and thus a more popular sport.

The *grand-bi* vogue disappeared little by little. Although it had evolved into the more graceful wire-wheeled "ordinary," the vehicle was dangerous because of its instability, and it required an acrobat's skill to ride. Toward 1880 the rear-wheel-propelled bicycle, using a chain transmission from pedals between the wheels, was successfully produced in England. The new machine was called the "safety" because it was much more stable than the *grand-bi*. In 1891 the first races on bicycles with pneumatic tires were held. The first race, from Bordeaux to Paris (580 km [360 mi]), was reserved for British amateurs and won by G. Mills. Later the same year a race from Paris to Brest and back to Paris (1,200 km [750 mi]) was won by a Frenchman, Charles Terront, in 72 hr 22 min.

At the same time, the first cycle-racing tracks were built in New York and Paris. New York City in 1891 held the first six-day race, which was won by Charlie Miller, who covered 3,368 km (2,093 mi) in six days. Not only were *grand-bi* cycles ridden but the same person had to ride the entire race—a really superhuman effort. In 1894 the six-day race was transformed into a team event (American-type relay).

Soon the great modern, classic contests began: the Tour de France (1903) initiated by Henri Desgrange, manager of *L'Auto* (forerunner of the sports daily *L'Équipe*); and such town-to-town races as Paris–Rوباix, Paris–Tours, and Milan–San Remo.

*Organization and development.* The cycling sport, born in France, rapidly spread to Italy, Belgium, Spain, Switzerland, Germany, Great Britain, and The Netherlands and then to Australia and the United States.

In 1878 the Bicycle Union was founded in England; it was only in 1900 that a single international cyclist union was formed, the Union Cycliste Internationale, which gave cycling its modern rules and races.

In 1965 two different organizations were created: the Fédération Internationale du Cyclisme Professionnel and the Fédération Internationale Amateur de Cyclisme. This professional–amateur separation had been demanded by the International Olympic Committee so that cycling could remain in the Olympic Games. More than 100 countries have joined the amateur federation. Only about ten, all in western Europe, belong to the professional federation. The eastern European countries do not recognize professionalism in any sport and have not joined.

The World Championships are organized each year by the International Cyclist Union, which also is in charge

The first races

Cycling unions

of Olympic Games competition; national championships are controlled by the various national federations. All other cycling contests are organized by private firms or promoters. Most often they are financed by the press, and most of the promoters belong to the Association Internationale des Organisateurs de Courses Cyclistes (International Association of Organizers of Cycle Competitions).

**Outstanding performers and performances.** Since the beginning of the 20th century, legends have grown up around the champions of the great international events. Among the outstanding performers in touring races have been M. Garin (France), winner of the first Tour de France, in 1903; P. Thys (Belgium), who won that event three times (1913, 1914, 1920); and Fausto Coppi (Italy), who won the Tour de France twice (1949 and 1952) and the Tour of Italy five times (1940, 1947, 1949, 1952, 1953). Coppi also was a world champion in touring and track racing, and for a long time he held the one-hour distance record. Louison Bobet of France had three victories in the Tour de France (1953, 1954, 1955), and Jacques Anquetil, also of France, had a record five victories in this race (1957, 1961–64). In the 1960s and 1970s the Belgian Eddy Merckx dominated the international scene as no one had before.

But no doubt the greatest prestige still belongs to Italy's Coppi, who died prematurely in 1960. He excelled in any branch: track pursuit races, touring races, and against-the-clock races (one racer at a time runs the event and is clocked). Merckx, who took Coppi's place as a popular figure, was most of all a road racer. He won all the classic races within three years—the Tour de France, the Tour of Italy, Paris–Roubaix, and others.

Outstanding track performers in distance covered in 60 minutes include the Frenchman Henri Desgrange, first one-hour distance record (35.325 km [21.95 mi] in 1893); the American W.W. Hamilton, first to surpass 40 km (40.781 [25.346 mi] in 1898); the Italian G. Olmo, first over 45 km (45.090 [28.02 mi] in 1935); and the Danish Ole Ritter (48.65 km [30.24 mi] October 16, 1968, in Mexico City). Famous sprinters (speed racers) also deserve mention: the Dane T. Ellegaard, six times the world champion from 1901 to 1911; the American Frank Kramer, who held the U.S. title from 1901 to 1916 and won it again in 1918 and in 1922; the Belgian J. Scherens, seven times world champion; and the Italian Antonio Maspes, eight times world champion. The fastest speed achieved on a bicycle was 204.73 kph (127.243 mph), by Jose Meiffret (France), July 16, 1962, on the German Autobahn from Freiburg, behind a car (see below *Events*).

**Competition.** The national federations in each country organize cycling competitions as they wish, according to the international rules. Most of them set up separate contests for men and women. The most widely used age categories for amateurs are seniors (over 20), juniors (18–20), younger juniors (16–17), adolescents (14–15), and youngsters, or benjamins (12–13). Competitions usually are categorized as road races, track races, or cyclo-cross (cross-country) races. Road races may include town to town or circuit-team races, individual or team races against the clock, and stage races (run in stages over several days) such as the classic tours. Track events include sprints, or speed races; pursuit races; middle-distance races behind a motorcycle; and races against the clock. Cyclo-cross or cross-country races usually cover rough terrain—often crossing ditches, streams, or other water hazards—in which racers may change off walking and cycling.

World cycling championships are organized each year for amateurs as well as professionals. The Olympic events, strictly for amateurs, include an individual road race and a 100-km (62-mi) team race, a 4,000-metre team pursuit race, a 1,000-m time trial, a 1,000-m match sprint (or scratch sprint), and a 2,000-m tandem race. A cyclo-cross world championship is also organized each year (20 to 24 km [12 to 15 mi]).

**Stage races and the classics.** The best known stage races are the Tour de France (race around France), cre-

ated in 1903; the Tour of Italy (1909); the Tour of Spain (1935); the Race of the Future (France), reserved for amateurs; and the Peace Race (Czechoslovakia, Poland, East Germany), also for amateurs. Also important are the Tour of Egypt and the Tour of Tunisia.

Town to town races include Paris–Roubaix, Milan–San Remo, Bordeaux–Paris, and Paris–Tours.

The Tour de France went through some difficult first years after its inception in 1903. The racers were hesitant, fearing the long stages 500 to 700 km (300 to 450 mi) and the total distance of 5,200 km (about 3,200 mi). But gradually the formula improved and the event was accepted. In 1906, for the first time, racers went over mountain passes as high as 1,450 m (4,750 ft). Later they had to pedal up slopes 2,600 m (8,500 ft) high in the Pyrenees and the Alps. At that time, around 1910–12, mountain roads were extremely dangerous, and numerous accidents occurred.

In 1930 national team scores were added to the tour. These were replaced in 1962 by trademark team scores, for advertising reasons.

**The sport of racing. Equipment.** The road-racing bicycle is distinguished from a training or touring bike by its lightweight-alloy frame, its lack of mudguards, its double clutch and ten gears, its lighter wheels with narrow rims and thinner, more numerous spokes, and its slimmer, tubular tires. The bike's gearing depends on the racer's height, weight, and power. Usually, the bike travels 4.7 to 7.93 m (15.4 to 26 ft) for each turn of the pedal, depending on the gear used.

The track bicycle is even lighter than the road racer, for it has neither brakes nor gears. Its frame is lower, its crankshaft higher to avoid touching the ground when turning; the tires are extralight. It travels 7 to 8 m (23 to 26 ft) for each turn of the pedal. There is no rear wheel clutch but one fixed sprocket.

**Events.** Track events include the sprint, or speed, races, 1,000 m (about 1,100 yd), run individually; and, for amateurs only, tandem events, 2,000 m (2,200 yd), run by teams of two racers on tandem bikes. Time trials are run individually, 1,000 m, against the clock from a standing start (Olympic Games) or from a flying start in some events.

Pursuit, or chasing, races are 5,000 m (5,500 yd) for professionals and 4,000 m (4,400 yd) for amateurs. In pursuit events the individual racers (in team events, the two teams) start on opposite sides of the track and chase each other. The winner is the racer or team that has closed on or overpassed the other within a fixed distance (in the Olympics, 4,000 m).

Other track events include individual races of 5, 10, or 20 km (3, 6, or 12 miles) in which each racer is given points every kilometre, according to his place; eliminations, in which the last racer across the finish line every lap is eliminated; and handicaps, in which the competitors considered to be the best give up some ground to their opponents. The *omnium* is a combination including 10 km, 1 km from a flying start, a 5-km pursuit, and 20 km behind a motorbike. Points are awarded for each event toward an overall score.

In so-called American races, teams of two riders each take their turn whenever they wish. The result depends either on the distance covered or on points gained.

In dragging races, the racer is pulled along by the air current created behind either a motorbike, a motor scooter, or a motorcycle. The bicycles used are fitted with small front wheels and can travel a long distance with each turn of the pedal.

Speed record attempts are made at 5, 10, 50, and 100 km (3, 6, 12, 30, and 60 mi), as well as for distance covered in one hour.

Road events include races of 240 to 280 km (150 to 175 mi) for professionals and 180 to 220 km (110 to 140 mi) for amateurs. The equivalent event in the Olympic Games is the 100-km team race. In addition to the town-to-town and stage events, or tours, discussed above, road races include races against the clock, such as the annual Grand Prix des Nations, 140 km (90 mi), held in the Paris district.

The Tour  
de France

Pursuit, or  
chasing,  
races

Training  
for  
endurance

**Principles of technique and strategy.** The most important point in road-racing technique is the posture of the cyclist on the bicycle. The hands firmly grip the foremost part of the handlebar, ensuring a spinal curve as aerodynamic as possible and preventing tiredness. Training includes exercises for long-distance endurance, body building, and interval training (alternation of fast racing and resting periods so as to improve the cardiac rhythm and resistance to strain). On the road, strategy is mostly a matter of teamwork.

In sprint races the opponents keep close to each other during the first 700 or 800 m. Oncoming racers usually enjoy advantages over the leaders because they are sucked along by the draft of air their opponents create. This event can give rise to long periods when no racer wants to precede the other but tries to force less skillful opponents to pass.

Usually sprinters and, to a certain extent, chasers have enlarged hearts (more than 1,000 cubic centimetres [60 cubic inches], as compared with the average of 625–650 cubic centimetres [38–40 cubic inches]). These competitors use the interval-training method: repeating short distances that are covered at full speed, interrupted by short periods of rest.

**The drug problem.** In cycling the use of drugs by competitors has been a problem, not only on the road but also on the track. For a long time bicycle racers, whether they are amateurs or professionals, have had set ideas: they think that a cyclist cannot put forth an intense or lasting effort without the aid of drugs, such as the anti-fatigue drugs, which project beyond the usual limits the beginning of exhaustion, or stimulants, which add a push of energy. Professionals are tempted to overuse such drugs—especially in stage races—but many are dangerous (principally the amphetamines) and leave traces in the body.

As a result of an antidrug campaign within the sport, a wide list of prohibited drugs has been established. The use of banned drugs can be detected by gaseous state chromatography. Even amphetamines can be detected, although their by-products are numerous.

In 1966 the French Parliament promulgated a law that was aimed at repressing the use of stimulating drugs during sport contests. Other countries, such as Belgium and Italy, have also passed laws to that effect. In spite of the severe punishments inflicted—suspension, license cancellation, fines—newly discovered drugs are being used that may be unknown to the experts who are in charge of controls and may be difficult to detect by the usual analysis. Drug abuse continues to be a problem and has caused many fatal accidents, such as that of the Briton Tom Simpson, during one of the stages of the Tour de France in 1967.

**Cycling as recreation.** In Europe, bicycle touring clubs have enjoyed wide popularity. Hundreds of thousands of people have joined such clubs, especially in France, Belgium, Italy, and England. Certificates are awarded to participant members for covering various distances: 100, 200, 300 km (60, 120, 180 mi). Members ride in rallies, participate in youth camps, and stay in specially booked hotels. France's touring club has an uncommonly active cyclist branch. It constantly organizes excursions of various lengths in tourist areas and regions with varied terrain.

Touring is a sport that knows no borders. In Europe meetings of cyclists from various countries often attract participants who ride international routes (e.g., through France, Belgium, Italy) to attend. Since 1959 a Tour de France for excursionists has been held annually. A national certificate of cyclo-touring has been created: in this type of rally, the riders have to find their way with the help of a map.

The touring bicycle in Europe and North America has been much improved—it is lighter and fitted with gears. Once heavy and fitted with balloon tires, it now looks rather like a racing bike.

Touring by bicycle has also increased in the United States. Many doctors have asserted that cycling is the healthiest sport for the human body, and millions of

Americans practice cycling sports more or less regularly. Cycling clubs and organizations throughout the country have helped to create interest among people of all ages in the pastime.

It is not surprising to find that annual sales of bicycles rose in the United States from 200,000 in 1932 to about 9,000,000 by the early 1980s. Hundreds of bicycle touring clubs have been established, and several states and many municipal and other public park systems have established bicycle paths. Agreements have been reached with youth hostels and with managers of U.S. national parks and reserves, where thousands of miles of bicycle paths have been built.

In urban areas both in the United States and Europe, cycling—as both for recreation and transportation—has grown, but it seems quite unlikely that cycling will be able to relieve the strangling congestion brought about by automobile traffic.

## Cyclones and Anticyclones

Cyclones and anticyclones are large rotary wind systems that move across most areas of the earth outside the equatorial belt. Cyclones usually are associated with belts of cloud and rain or snow, whereas anticyclones, which generally have lighter winds, are typically free from precipitation. The diameter of these wind systems ranges from less than 1,000 kilometres to 3,000 or 4,000 kilometres. In the Northern Hemisphere the cyclonic winds rotate in a counterclockwise direction, and the anticyclonic winds rotate in a clockwise direction. In the Southern Hemisphere the directions of rotation are opposite to those in the Northern Hemisphere (see WINDS AND STORMS).

Cyclones of a somewhat different character occur nearer to the Equator, forming in latitudes 10 to 15 degrees north and south over the oceans. They generally are known as tropical cyclones but, more specifically, as hurricanes in the Atlantic and Caribbean, as typhoons in the western Pacific and China Sea, and as willy-willies off the coasts of Australia. These storms have a smaller diameter than the extratropical cyclones, ranging from 100 to 500 kilometres in diameter, and are accompanied by winds that sometimes reach extreme violence. These storms are more fully described in the article HURRICANES AND TYPHOONS.

The cyclones and anticyclones that form outside the equatorial belt may be regarded as large eddies in the broad air currents that flow in the general direction from west to east around the middle latitudes of both hemispheres. They are an essential part of the mechanism by which the excess heat that is received from the Sun in the equatorial belt is conveyed toward the higher latitudes. These higher latitudes radiate more heat into space than they receive from the Sun, and heat must be brought to them by winds from the equatorial belt if their temperature is to be maintained. If there were no cyclones and anticyclones, the north-south movements of air would be much more limited, and there would be little opportunity for heat to be carried poleward by winds of subtropical origin. Under such circumstances the temperature of the equatorial regions would increase, the polar regions would cool, and the temperature gradient between them would intensify.

Strong horizontal gradients of temperature are particularly favourable for the formation and development of cyclones. In the absence of cyclones and anticyclones the

Tempera-  
ture and  
pressure

Activities  
of touring  
clubs

temperature difference between pole and Equator would tend to build up until it was sufficiently intense to generate new cyclones. The new cyclones themselves, however, would tend to reduce the temperature difference. Thus, the wind circulation on the earth represents a balance between the effect of solar radiation in building a temperature difference between pole and Equator, and the effect of cyclones, anticyclones, and other wind systems in destroying this temperature contrast.

Cyclones and anticyclones are readily recognized on weather maps because of the centres of low and high pressure that accompany them. The atmospheric pressure is observed by means of barometers at several hundreds of weather stations throughout the world and is corrected to mean sea level. These pressures are plotted on weather maps, and lines of equal pressure (isobars) are drawn on them. As a consequence of the earth's rotation, any large-scale air current that is more or less steady during a period of several hours must flow with higher pressure on the right of the current than on the left (looking downstream) in the Northern Hemisphere. For this reason the rotary motion of the winds in cyclones and anticyclones appears on weather maps as sketched in Figure 1 in

Figure 1: (Left) Cyclone (or depression). (Right) Anticyclone.

relation to the isobars. In the Southern Hemisphere the direction of the circulation of the winds in both systems is reversed.

Because the cyclone is necessarily an area of lowered atmospheric pressure, with the lowest pressure at the centre of the wind circulation, cyclones are commonly known as depressions.

It has been recognized since weather maps were first drawn at the beginning of the 19th century that depressions are associated with bad weather. The reason has become apparent only recently. In order to understand this association it is necessary to think of the atmosphere ( $q.v.$ ) in depth and to consider what happens in a region where the air flows together (converges) at a level near the ground, then rises as a consequence of the convergence and spreads out (diverges) at some higher level, usually in the upper troposphere; that is, at 8 to 10 kilometres (26,000 to 33,000 feet) above the ground (see Figure 2).

Conver-  
gence and  
divergence  
of air

Figure 2: Formation of (left) cyclone and (right) anticyclone.

The air that is converging near the ground is rotating with the earth, as is the rest of the atmosphere; but as it is drawn inward into a smaller area during the convergence, its rate of rotation will increase in a way similar to that in which the rate of rotation of a weight twirled on the end of a string increases as the string is pulled in and the angular momentum of the weight is conserved. The region of convergence thus appears as an area of increased rotation of the winds. This increase in the rotation is the same as the rotation of the earth, counterclockwise in the Northern Hemisphere and clockwise in the Southern Hemisphere, and so the region of convergence appears as a cyclone or depression.

Figure 2 indicates that the convergence of the air in the lower atmosphere necessarily is accompanied by upward motion. As the air rises, it is subject to less pressure from the weight of the air above and it expands. Expanding air cools and is unable to carry as much water vapour as before; part of the water vapour therefore is condensed as cloud and rain. Thus the convergence of the air in the lower layers leads simultaneously to the generation of the cyclonic circulation of the winds and to the bad weather with which cyclones are associated. In order that the proper relation between the wind and the pressure field be maintained, the atmospheric pressure must fall at the centre of the cyclone as it forms. This is accomplished by a slightly greater outflow of air aloft than the inflow near the ground.

The process of formation of an anticyclone is precisely the reverse of that of a cyclone or depression. Anticyclone formation is associated with downward motion of the air and spreading out near the ground. The downward motion compresses, warms, and dries the air, and no thick rain clouds are likely to form. The spreading out slows down the rotation of the air until its rate is less than that of the earth itself. An observer, who of course is rotating with the earth, sees the anticyclone rotating in the opposite sense, namely, clockwise.

#### FORMATION AND STRUCTURE OF CYCLONES

The middle latitudes of the two hemispheres each contain a broad, generally westerly current of air in which the wind speed increases with height above the ground. This increase of wind with height is associated with the general gradient of temperature from Equator to pole. Cold air is denser than warm air and pressure falls more rapidly with increase in height near the poles than near the Equator. It follows that the pressure difference between the pole and the Equator is greater aloft than near the ground and, because the wind speed is related to the pressure difference across the air current, the wind speed also increases with height in the atmosphere.

The westerly current does not run smoothly, and there are areas where the temperature contrasts are increased. These are areas where the wind increases particularly rapidly with height and in which convergence in the lower layers and consequent upward motion are especially likely. These are the regions that give birth to depressions or cyclones.

The association between strong horizontal temperature contrasts and the formation of depressions was first noted by Scandinavian meteorologists working in Bergen about 1920. They developed the polar-front theory of cyclones. They recognized that strong temperature contrasts develop between air masses of different origin, and the division between such air masses is often sharp enough to be indicated on the weather map by a line and be known as a front. At the front the colder air mass lies below the warmer air, forming a wedge. The frontal surface separating the two air masses has a slope of between 1 in 50 and 1 in 200.

Polar-front  
theory

Depressions often are seen to form on or in the vicinity of fronts, the first sign being a wavelike distortion of the front. The principal front identified by the meteorologists of the Norwegian school separated air of polar origin from warmer subtropical air and was known as the polar front. It originally was envisaged as extending more or less continuously around the middle latitudes of the earth, but in fact there are usually many substantial breaks in it.

The various stages in the life cycle of a depression on the polar front are illustrated in Figure 3. The front is indicated by the thick line to which triangles or semicircles are attached. The line is placed where the frontal surface separating the two air masses intersects the ground, and the symbols are placed on the side toward which the front is moving. The triangular symbols are used where the cold air is replacing the warm air; the front is advancing as the leading edge of the cold air mass and is known as a cold front. Semicircular symbols are used where the warm air is replacing cold air; here the

Life cycle  
of a  
cyclone

Figure 3: (A) Undistorted front. (B) Wind circulation creates distortion of front. (C) Distortion increases and a warm-sector depression is formed. (D) Development of occluded front. (E) Final stage of a cyclone.

front is the leading edge of the warm air and is known as a warm front.

Figure 3A represents an undistorted front, initially moving slowly southeastward toward the warm air as a cold front. An early stage in the formation of a depression is shown in Figure 3B. The circulation of winds around the depression has created a wavelike distortion of the front. The thin lines denote the isobars, and the lowest pressure, or the centre of the depression, is located at the tip of the wave. At this stage the depression commonly is moving at a speed of from 40 to 90 kilometres per hour in the general direction of the arrow. The area affected by rain or snow is indicated by hatching.

Figure 3C represents a somewhat later stage in the development of a depression. The distortion of the front has increased and the winds have grown stronger. At this stage it is a typical warm sector depression, so called because of the sector between the warm front and cold front that contains warm subtropical air. The warm sector often is a region of much cloudiness, with drizzle on coasts and hills, and sometimes produces rain. Less commonly, the warm sector may contain relatively dry air of continental origin and be a region of high temperatures and sunny skies.

It is helpful to consider the structure of the atmosphere at this stage in terms of a vertical cross section along the line *ab*. The vertical section cuts through the cold and warm front surfaces, as indicated by the sloping lines. The clouds at the cold front and the warm front lie above the frontal surfaces as indicated, and rain falls through the lower parts of the frontal slope.

The horizontal temperature gradients that accompany a front also are associated with an increase of wind with height as indicated earlier, and a rather narrow band of strong winds is found at a height of about 10 kilometres above the ground. These are the jet streams (*q.v.*). At the stage of depression development illustrated in Figure 3C the jet lies as a somewhat distorted current along the line indicated by the double arrows. The jet stream intersects

the cross section *ab* obliquely above the upper parts of the frontal surfaces.

As indicated earlier, the development of a depression is always accompanied by the convergence of the air horizontally in the lower atmosphere. By the time the mature stage has been reached, the convergence has squeezed the warm air off the ground near the centre of the depression, and the arrangement of the fronts is as shown in Figure 3D. The front from *c* to *d* is known as an occlusion. Although the original warm air is lifted off the ground, there may still be some temperature contrast between the cold air mass ahead of the depression and that circulating round the back of it. A front may remain between these two cold air masses and is indicated on the weather map by the symbols for an occlusion, namely, alternating triangles and semicircles.

In the final stage of a cyclone most of the temperature contrasts that generated it have been lost, and its structure is as represented in Figure 3E. There still is a belt of thick cloud and rain along the line of the old occlusion running obliquely from the central region to the periphery of the cyclone. There also are other, narrower spiral bands of cloud that extend outward from the centre; these enable the final stages of such cyclones to be easily recognized on the satellite pictures of cloud distributions. At this stage, the cyclone is usually slow-moving or stationary.

Although the main belts of bad weather in depressions are associated with fronts, the circulation of the depression also includes showers and other local storms in the cold air behind the cold front, where the cold air mass is moving southward and is being rapidly heated from below. During the later stages of the depression these showers tend to spread around the centre in all directions. There may also be some rain in the warm sector in the earlier stages of the cyclone. At all stages the general convergence of air into the cyclone, in addition to the ascent of air, encourages the growth of showers and other precipitation.

Not all depressions and cyclones form on the polar front in the manner indicated. Some are induced by the effect of mountain barriers on winds crossing them, appearing first on the lee side of the mountain range. Tropical cyclones may also form in the absence of any associated fronts.

Apart from tropical cyclones, the initiation of which is still not understood, most cyclones in middle latitudes form in the presence of horizontal temperature contrasts. The wind circulation and convergence lead to the formation of fronts in the vicinity of the depression with a configuration rather similar to that illustrated in Figure 3, even when a front is not present initially. A glance at a series of daily weather maps will show that each cyclone has its individual characteristics, and only broad generalizations in regard to their structure are justified. Nevertheless, recent progress in meteorology is such that calculations can be based on the mathematical equations describing the air motion and the physical processes involved in the heat and water balance. Given a reasonably comprehensive description of the initial state of the atmosphere, such calculations can describe many of the detailed features of the individual cyclones as they develop. With this more specific information, the weather forecaster is becoming much less dependent on idealized descriptions.

#### ANTICYCLONES AND THEIR FORMATION

For various reasons, the formation of anticyclones is usually a slower process than the formation of depressions; anticyclones tend to be larger in area than cyclones and to persist longer. Whereas the upward motion in depressions is concentrated at the fronts and typically reaches ten centimetres per second, the downward motion in anticyclones is slower, perhaps one to three centimetres per second, and is spread over wider areas. To a great extent, the downward motion in the anticyclones can be regarded as a compensation of the upward currents in the neighbouring depressions.

Most actively developing anticyclones form in the region of cold air behind a depression as it moves away and before the next depression advances; these are known as cold anticyclones. A result of the downward air motion in an anticyclone, however, is compression of the descending air, and as a consequence of this compression the air is warmed. Thus after a few days the air comprising the anticyclone at levels two to five kilometres above the ground tends to become warm for its level, and the anticyclone is transformed into a warm anticyclone. The air near the ground cannot descend and is not much affected by this process.

Warm anticyclones move slowly, and depressions are diverted around their periphery. During their transformation from cold to warm anticyclones they usually move out of the main belt followed by cyclones in middle latitudes, often amalgamating with the quasi-permanent band of relatively high pressure that is found in both hemispheres around latitude 20 to 30 degrees—the so-called subtropical anticyclones. On some occasions the warm anticyclones remain in the belt normally occupied by the mid-latitude westerly winds. The normal tracks of cyclones are then considerably modified; depressions are either blocked in their eastward progress or diverted to the north or south of the anticyclone. Anticyclones that interrupt the normal circulation of the westerly wind in this way are known as blocking anticyclones. They frequently persist for a week or more, and the occurrence of a few such blocking anticyclones may dominate the character of a season. Blocking anticyclones are particularly common over Europe, the eastern Atlantic, and the Alaskan area.

The descent and warming of the air in an anticyclone might be expected to lead to the dissolution of clouds and the absence of rain. This occurs often, particularly in summer. Since the air near the ground cannot take part in the descent, it may become stagnant. In winter the ground cools and the lower layers of the atmosphere also become cold. Fog may be formed as the air is cooled to its dew point. Under other circumstances the air trapped in the first kilometre above the surface may pick up moisture from the sea or moist surfaces, and layers of cloud may form from near the ground to a height of about one kilometre. Such layers of cloud can be persistent in anticyclones (except over the continents in summer), but they rarely grow thick enough to produce rain. If precipitation occurs it is usually drizzle or light snow.

Anticyclones are thus regions of clear skies and warm sunny weather in summer; at other times of the year cloudy and foggy weather may be more typical. Winter anticyclones produce colder-than-normal temperatures at the surface, particularly if the skies remain clear. Anticyclones are responsible for periods of little or no rain, and such periods may be prolonged in association with blocking highs.

#### DISTRIBUTION OF CYCLONES AND ANTICYCLONES

Cyclones are primarily a feature of the midlatitude belts of the two hemispheres. In the Southern Hemisphere, where most of the earth's surface is covered by oceans, the cyclones are distributed fairly uniformly through the various longitudes. Typically, cyclones form initially in latitudes 30 to 40 degrees south and move in a generally southeastward direction, reaching maturity in latitudes around 60 degrees. Thus the Antarctic continent is usually ringed by a number of mature or decaying cyclones, and the belt of ocean from 40 to 60 degrees south is a region of persistent, strong westerly winds that form part of the circulation to the north of the main cyclone centres. These are the "roaring forties," where the westerly winds are interrupted only at intervals by the passage southeastward of developing cyclones.

Anticyclonic development over the southern ocean occurs only occasionally, and anticyclones are transient features of the weather regime.

In the Northern Hemisphere, the continent extend from the Equator to the Arctic, and mountain belts, such as the Rocky Mountains, interfere with the midlatitude air

currents. As a result, there is an important geographical variation in the occurrence of cyclones and anticyclones, and certain tracks are particularly favoured by the wind systems.

The main cyclone tracks lie over the oceans. This is partly because the surface of the oceans is smoother than that of the land and offers less resistance to the stronger winds around depressions. But the water evaporated from the ocean also provides heat when it is condensed into rain within the rain belts of depressions, and the latent heat thus released is an effective energy source for the cyclone. The arrangement of cyclone tracks is such that storms often reach maturity in the vicinity of Iceland or the Aleutians. These regions have a higher frequency of cyclonic weather than others; their climate is notably disturbed and rainy.

Anticyclone tracks are probably less clearly defined than the tracks of cyclones. An important feature of the general circulation of the earth's atmosphere, however, is the existence of a persistent circulation in which air rises in a belt near the Equator, spreads out poleward into both hemispheres in the upper troposphere at about 10 to 15 kilometres (33,000 to 49,000 feet) above the ground, and descends again in latitudes 25 to 30 degrees north and south. As previously explained, such descending air spreading out near the ground leads to the development of anticyclones. The subtropical anticyclones thus formed are found over the oceans throughout the year and are often well developed over the continents during winter months. The high temperatures reached over the continents in summer in these latitudes, however, lead to a different monsoonal type of air circulation, and the anticyclone belt is broken over the continents in summer.

#### HAZARDS OF CYCLONIC STORMS

Although the strongest winds occur in tropical cyclones, in which speeds of 60 metres per second are sometimes reached, exceptionally strong winds and considerable damage also can be caused by extratropical cyclones. Winds may reach 30 metres per second, with gusts up to 50 metres per second. In certain areas severe damage also can be caused along coastlines by the rise in the water level produced by the storm winds. At the end of January 1953, 307 lives were lost, 156,000 acres of land were flooded, and 25,000 houses were damaged along the east coast of England; again, in February 1962, at least 343 people died in Hamburg as a result of such a tide produced by cyclonic winds.

The weather hazards associated with anticyclones are of a different nature. The stagnant air occurring in anticyclones in winter sometimes leads to persistent fogs, but in industrial areas the greatest nuisance and hazard is probably due to smog, a combination of industrial pollutants and stagnant low-lying air. In December 1952, cold foggy air was stagnant for five days over London and 4,000 more people died than is usual at this time of the year. This increased death rate was largely attributed to the effect of the polluted air on persons already suffering from bronchial illness. The pollution was trapped near the ground beneath an anticyclone that extended westward from continental Europe.

**BIBLIOGRAPHY.** H.L. CRUTCHER and O.M. DAVIS, *U.S. Navy Marine Climatic Atlas of the World*, vol. 8, *The World* (1969), covers marine areas chiefly, but contains detailed worldwide maps of pressure and winds at sea level for each month, and seasonal maps of wind and topography for the main pressure surfaces up to 200 millibars (about 12 km., 40,000 feet).

## Cyclothems

A cyclothem is a complex, but orderly, succession of several lithologically distinctive sedimentary strata. These accumulated during one of several repeated depositional cycles, of a kind that was characteristic of part of the Carboniferous System (280,000,000 to 345,000,000 years ago) in many coalfields, particularly those of the Northern Hemisphere (see also CARBONIFEROUS PERIOD, UPPER; CARBONIFEROUS PERIOD, LOWER).

Historical  
back-  
ground

Some features of repeated sedimentary successions in strata of various ages were noted and reported upon during the latter part of the 19th century in both North America and western Europe. Most of these occurrences were repetitions of large dimensions that involved strata of a considerable part of a geologic system. The economic importance of coal beds, however, caused much attention to be directed to Upper Carboniferous or Pennsylvanian stratigraphy, and some features of more restricted sedimentary repetitions were recognized in England and later in Nova Scotia and Ohio. Subsequently, the earliest clear description of what are now termed cyclothems was included in a geological report published in 1912 and devoted to a restricted area in western Illinois adjacent to Peoria. There, a peculiar stratigraphic succession, including coal, was repeated with remarkable fidelity four times.

Little note was taken of this observation until 1926, when a similar repeated succession was distinguished in the Wabash valley of eastern Illinois and western Indiana. At about this time interest in Pennsylvanian stratigraphy revived in the central United States and programs of detailed fieldwork were begun. It was demonstrated clearly that repeated and related sequences of sedimentary strata characterize important parts of the Pennsylvanian System as this is developed from at least western Pennsylvania to northern Texas. As interest in Pennsylvanian stratigraphy expanded, a special term to identify these successions seemed desirable and cyclothem was proposed in 1932. This name gained immediate acceptance and it soon was in general usage in America and abroad.

### NATURE OF CYCLOTHEMS

Cyclothems vary greatly in their lithologic development, and some are so different in their makeup that their relationships might not be suspected if intermediate kinds and intergradation did not occur. Cyclic sediments that result from lacustrine processes are termed varved deposits (*q.v.*) and are not considered in this article. An intermediate type generally is considered to be most typical; it is well developed in Illinois and adjacent states. Marine and nonmarine strata are almost equally represented, indicating that in this region the sea probably transgressed repeatedly onto an extensive low-lying coastal plain. Ten members or strata that differ in rock type constitute this kind of cyclothem. Complete development, however, of all the members in any cyclothem at any place is rare, so that the typical or complete cyclothem is, in a sense, an idealized reconstruction. Nevertheless, these ten members and their individual relations to each other are so constant and have been observed at so many places in so many cyclothems that there can be no doubt concerning their order and continuity throughout extensive regions. Some other strata interrupt the sequence in a few areas or zones, but this is not considered to have any broad significance.

The members of a completely developed cyclothem (Figure 1) in the central United States, from base to top, are as follows: (1) *Sandstone*. This generally is fine-grained but massive within local channels cut into underlying strata and thin bedded or even somewhat shaly beyond the channel margins. The older sandstones of the Lower Pennsylvanian are extensive sheet deposits that commonly are conspicuously cross-bedded and consist of relatively pure quartz sand, which may enclose patches or lenses of rounded quartz pebbles. Younger sandstones generally contain much undecomposed feldspar and abundant mica flakes. They are without pebbles except for some that obviously are of local derivation in the lower parts of channels. (2) *Sandy and silty shale*. This member generally is thin and succeeds the sandstone without abrupt transition. (3) *Lower limestone*. Characteristic marine fossils are not present in this member, which is likely to be thin, fine textured, and restricted to small areas except in part of the northern Appalachian region. (4) *Underclay*. Where a lower limestone (member 3) is undeveloped, the sandy shale (member 2) grades upward into this member. The underclay is non-bedded, generally breaks with a blocky fracture, and may contain the compressed and carbonized traces of plant rootlets. Many underclays are vertically zoned after the manner of modern soils (*q.v.*). Sometimes a leached zone that is noncalcareous in its upper part is present. (5) *Coal*. Underclays and coal beds are closely associated with each other. Pennsylvanian coals that do not rest on underclays are rare. Underclays, if not overlain by coals, generally are topped by smutty zones indicating coal horizons.

Members  
of a  
typical  
cyclothem

From Third Conference on the Origin and Constitution of Coal (1961)

Figure 1: Fully developed "ideal" cyclothem of Illinois showing succession of ten members.

These five members constitute a lower hemicyclothem that seems to consist almost exclusively of nonmarine strata (see also COALS). Much, if not all, of the upper hemicyclothem is marine, however. (6) *Lower shale*. This member is rarely well developed, and it may not be recognizable if a middle limestone (member 7) is not present. It ordinarily is gray, silty, and unfossiliferous, except possibly for carbonized compressions of plant stems and leaves in the lower parts of some members when considerable thickness is attained. Fossils that are indicative of brackish water or marine conditions have been discovered at a few places. (7) *Middle limestone*. Many cyclothems lack this member, and it is unknown in the Appalachian region. In Illinois it is an impure, dark-coloured bed of discontinuous, lenticular character that contains marine fossils. In Kansas it is a compact, dark-coloured bed not more than two or three feet thick of remarkable uniformity and persistence. (8) *Middle shale*. This member is characterized by a bed of hard, black, sheety shale in its lower part, which may contain

fragmentary fish remains in some areas and fine-grained, very hard, black, calcareous concretions of considerable size. The black shale grades upward into soft gray shale that becomes more and more calcareous in its upper part and bears abundant marine invertebrate fossils at many places. (9) *Upper limestone*. This is a light-coloured, fossiliferous member that commonly is the thickest and most prominently exposed limestone of the cyclothem. (10) *Upper shale*. This ordinarily is the thickest member of the cyclothem. Immediately above the upper limestone (member 9) it may be calcareous and fossiliferous in a thin zone, but elsewhere it is dominantly silty; fossils are rarely present. Ironstone concretions occurring singly or at persistent horizons (continuous zones) are common. This member grades imperceptibly into the overlying sandstone (member 1 of the next cyclothem) outside of channels and beyond other areas of obvious erosion.

Complete cyclothems, however they may be developed, probably average less than 50 and rarely exceed 100 feet in thickness. As many as 100 or more cyclothems succeed each other in some regions.

**Boundaries.** The subdivision of such a repeated succession of distinctive lithologic members may be accomplished in several different ways. As originally proposed, a cyclothem was considered to begin at the base of the lower sandstone (member 1). This seems to provide a logical boundary that is an unconformity at some places. Therefore, it corresponds with at least a local interruption of a thick sedimentary deposit. This is significant from a dynamic, historical, and theoretical standpoint. Other boundaries that have been advocated are the top of the sandstone and the top of the principal limestone, either of which is more likely to be seen and traced in outcrops. The coal bed or coal horizon, which is particularly interesting for economic reasons, also has been suggested in this connection.

**Variations.** The principal variability of cyclothems is related to their position with respect to the more or less regular fluctuations of the ancient sea. Thus in one direction, where deposition was mainly above the most advanced shoreline, marine strata are poorly represented or completely lacking, whereas in the other, where marine conditions prevailed, nonmarine strata may exhibit equally poor development. Thus, the cyclothem becomes more incomplete in both directions and, eventually, may become unrecognizable. The members that are most important in the identification of a cyclothem (Figure 2)

Figure 2: Incomplete but clearly evident cyclothem of five "primary" members.

are the lower sandstone (member 1), the underclay (member 4), the coal (member 5), the upper limestone (member 9), and the upper shale (member 10). The cyclothem can be recognized even if one of these is ab-

sent; generally, the cyclothem will be fairly obvious if only three members are present, provided that the underclay (member 4) is one of them. Reduction beyond this limit leaves a succession or alternation of beds that is not uncommon in strata of many ages and may bear no relation to any more complex cyclic deposits.

**Distribution.** Cyclothems are most completely and persistently developed in an intermediate part of the Pennsylvanian System that reaches a considerable thickness. In both lower and higher zones they are likely to lose some of their identity, either because of incomplete development or because sedimentary deposition was less cyclical. The numbers of cyclothems in equivalent parts of the stratigraphic section in different areas do not correspond exactly, and reduction or expansion of the section seems to be accomplished in several ways, none of which is adequately understood.

Pennsylvanian cyclothems are best known in the central and eastern United States, where gently dipping strata can be traced for long distances both in outcrops and below the surface in the records of wells and drill holes. They occur in comparable parts of the stratigraphic section in some of the principal coalfields of Great Britain, western and eastern Europe, and perhaps in northern China. Somewhat similar sequences also have been recognized in the Permian and Mississippian systems, and less convincingly in the Devonian of several regions, but these are not as clear nor as widely developed.

The term cyclothem has been used for other repeated sequences of strata, particularly those including coal, that seem to reflect types of cycles that differ from those characteristic of the Pennsylvanian. One of the better known is that which occurs in the Upper Cretaceous (about 75,000,000 years ago) of Utah, Colorado, and some adjacent states. This sequence lacks limestone and underclay, and the sandstones below coal beds probably are marine. The question may be raised whether the name cyclothem should be applied to such sequences. Loose usage surely detracts from the meaning and usefulness of the term.

#### SIGNIFICANCE OF CYCLOTHEMS

Cyclothems are interesting mainly because they reflect some of the physical conditions that prevailed in certain regions in the geologic past and show how these conditions varied contemporaneously in space and time. The distribution, thickness, and types of sediments indicate something about the location and nature of ancient upland areas where the sediments originated, and of depressed areas where they were deposited. The extent, depth, and perhaps salinity of the fluctuating seas are also suggested by the rock units. In a more practical way, cyclothems provide continuous and easily identified stratigraphic units. These are useful for correlating strata, including coals, within large areas more precisely than generally is possible by tracing and matching individual beds. This is economically important. Estimates suggest that some cyclothems represent intervals of time on the order of 75,000 to 100,000 years. Comparisons of the fossilized remains of similar animals contained in several successive cyclothems may show minor morphologic differences that characterize more closely spaced steps in their progressive evolution than ordinarily can be detected.

#### INTERPRETATION OF THE ORIGIN OF CYCLOTHEMS

Sediments in all of the lower hemicyclothems decrease in coarseness upward from the sandstone (member 1). The overlying sandy shales (member 2) seem to indicate a periodic decrease in the supply of sediments and the efficiency of transportation from their sources. In the United States the principal source regions lay along the eastern and southern continental margins as shown by the general increase in the prominence and coarseness of most sandstones in those directions. These regions contributed enormous amounts of detrital material to the interior of the continent, demonstrating the rapid ero-

Source  
areas of  
clastic  
sediments

Recogni-  
tion of  
cyclothems

sion of prominent uplands of large extent or, more probably, of smaller highlands that were uplifted repeatedly. Mineralogy of the sandstone suggests that during the earlier cycles sediments were derived mainly from the removal of weathered material from a soil-covered ancient land surface. Later sandstones, however, indicate that their sediments probably were produced by the rapid erosion of uncovered fresh rocks of granitic types. Unconformable contacts below the sandstones are most general near the source regions but abruptly entrenched channels occur far from them. Some of the channels were eroded nearly 100 feet into underlying strata and are a mile or more in width. These channels are thought to be segments of normal drainage systems (see also RIVERS AND RIVER SYSTEMS).

The succeeding members of the lower hemicyclothems show that sedimentary accumulation almost ceased. The underclays (member 4) are generally thin and contain no coarse material. The original nature of their sediment seems to have been altered slowly by the growth of plants and other normal soil-making processes. Lower limestones (member 3) probably record the local existence of temporary shallow freshwater ponds or lakes that occupied slight depressions on a vast, very gently sloping alluvial plain. Coals (member 5) record the existence of great lowland forests; plant materials accumulated as peat in extensive swamps. These periodically blanketed the coastal plains at times when appreciable quantities of detrital material were not being contributed by the bordering uplands.

Coal swamp conditions were terminated by incursions of the sea. The water was brackish at first, as indicated by fossils in some of the lower shales (member 6). As more normal salinity was established, a restricted fauna mostly composed of small species of invertebrates became established, and their remains contributed to the middle limestones (member 7). The shallow sea seems soon to have been invaded by an abundant growth of kelp-like algae. The decomposing remains of these plants furnished much carbonaceous material that produced anaerobic conditions at the bottom and, together with fine mud, accumulated as a rich organic slime. Later, compaction produced the hard, black, sheeted strata in the lower part of the middle shale (member 8). As the shoreline advanced upon the land, water deepened, the growth of seaweed was much reduced, and the sea cleared. Black shale gave way to gray and finally to the upper limestone (member 9). The clear-water conditions at this time marked the culmination of a series of events in which, throughout an extended region, continental conditions were gradually supplanted by marine conditions.

The upper shale (member 10) demonstrates a complete reversal of the encroaching sea and deepening water that are recorded by all of the earlier members of the cyclothem. This member was deposited as the shoreline retreated seaward; the water became shallower, and the delivery of abundant detrital sediment was resumed. It is probable that the environment soon became brackish, and perhaps freshwater conditions followed. Finally, the sea withdrew and its bottom was exposed locally to channelling, or to less severe erosion, whereas elsewhere shaly or sandy sediments were deposited on its surface. Thus, the complete cyclothem seems to record a cycle of physical conditions first trending persistently and slowly in one direction and then suddenly and rapidly reversing (for further information see SEDIMENTARY ROCKS; SEDIMENTARY FACIES).

The widespread similarity of cyclothems on both sides of the Atlantic surely records a significant historical pattern of physical changes that followed each other regularly, at least in considerable parts of the Northern Hemisphere, during much of the Pennsylvanian and parts of the Mississippian and Permian periods. This general pattern may not have been restricted to Late Paleozoic time, but a special combination of conditions, including rapid but intermittent erosion of upland regions, sea level critically located with respect to continental platforms, the

existence of an abundant and vigorous land flora adapted to marshy conditions, and favourable climates, all combined to produce unique results that were never duplicated exactly either before or since. Other kinds of stratigraphic alternations or successions, at other times and at other places, may record somewhat comparable patterns resulting in widely variable but partly analogous conditions.

Recognition of the existence of cyclothems and their distribution, and identification of the environments that they record, are only remotely related to deductions of the causes responsible for cyclothem development. Evidence pertinent to the historical interpretation is incomplete, scattered, and subject to quite different conclusions. It is not surprising, therefore, that there is much disagreement concerning the basic cause or causes that were chiefly responsible for the production of cyclothems. All present attempts at explanation of cyclothem development are excursions into the realm of theory.

**Theories of origin.** The theories that have been proposed to account for the development of cyclothems can be classified roughly into three groups, each of which includes several variations. These are (1) diastrophic theories, involving subsiding basins and rising sedimentary source regions that were either continuous, intermittent, or reversing; (2) climatic theories, involving glaciation that led to sea-level oscillations, and rainfall cycles and variable erosion; (3) sedimentation theories, involving differential deposition related to depth of water, strength of currents, distance from a river's mouth, compaction of sediments, and so forth. None of these theories seems adequate to explain completely the origin of cyclothems. When a satisfactory theory is formulated, it probably will include elements derived from several of those that have been proposed.

Subsidence surely prevailed in coal basins where considerable thicknesses of sediment accumulated during extended intervals of times. Similarly, considerable elevation must have prevailed in the uplands where the sediments were produced by prolonged erosion. If basins subsided continuously and evenly, then the development of cyclothems resulted from other factors that controlled the kinds and quantities of sediment provided, and earth movements within the basins were not primarily important in the origin of cyclothems.

The oldest theory accounts for cyclothems and other similar sedimentary successions solely by intermittent subsidence in basins. This simple explanation supposes that deposition lagged behind relatively rapid local subsidence, so that the sea first transgressed low-lying areas and maximum water depth was soon attained. This was followed by a longer period of stability, during which deposition built up the bottom to above sea level and coal swamps developed on the newly emergent land. This theory infers nothing about conditions or the succession of events in the source areas of the sediments. Variations of this theory suggest that sea level fluctuated as the result of earth movements in regions beyond the basins. Such theories seem imperfect because most of the strata of the lower hemicyclothem should have accumulated under slowly shallowing marine conditions, whereas their nature indicates that they probably are nonmarine.

The distinct asymmetry in the succession of cyclothem members has been considered evidence that dominant slow subsidence in basins was interrupted periodically by more rapid and lesser local uplifts. Moreover, the kinds of sediment delivered to the basins can be reasonably explained if movements in the adjacent uplands were similar to and in phase with those of the basins. Thus, as the basins subsided and were progressively submerged, the bordering uplands decreased in height. Consequently they were eroded more slowly and contributed finer grained and lesser amounts of detrital material. Subsequently, as the basins rose, the borderlands were more greatly uplifted, erosion accelerated, and increasing quantities of coarse sediment built up the sea bottom and effected withdrawal of the sea. This theory has been crit-

Implications of coals and black shales

Diastrophic theories

## Climatic theories

icized as invoking a repeated series of earth movements so regular and mechanistic as to be unreasonable.

Climate certainly has played an important part in the production and transportation of most detrital sediment. No matter what other factors were involved, it probably influenced the development of cyclothem. Some theories, however, have relied almost exclusively on climate in attempts at explanation.

Late Paleozoic glaciers spread over considerable parts of Antarctica, South Africa, Australia, India, and perhaps some other regions in the Southern Hemisphere, which may at this time have been combined as a single large continental mass (see CONTINENTAL DRIFT). If these glaciers were as extensive as those of the much later Pleistocene Epoch, they caused worldwide sea level to fall as the glaciers grew and withdrew water from the oceans, and to rise as they subsequently melted and the water was returned. This must have resulted in the alternate flooding and emergence of lowland regions in the Northern Hemisphere where cyclothem occur. The suggestion has been made that these sea level fluctuations can explain the alternation of nonmarine and marine hemicyclothem. One variant of this theory supposes that two glacial advances and retreats were necessary for the production of one cyclothem. Doubts are cast upon these explanations because it is uncertain whether the glaciers were sufficiently extensive to have effected sea level greatly or that glaciation and cyclothem deposition were exactly synchronous. More seriously, it seems highly unlikely that there were as many glacial advances and retreats as the large number of cyclothem requires (see also CLIMATIC CHANGE; PLEISTOCENE EPOCH).

## Sedimentation theories

Alternating humid and arid epochs resulting from glaciation or some other cause have been presented as either the main factor or an important contributory factor in the development of cyclothem. Thus, aridity related perhaps to the low temperature extremes of a glacial epoch would be unfavourable for plant growth in upland regions. A scant vegetative cover would permit maximum erosion of an ill-protected land surface and much detrital sediment would be swept out into a basin. On the other hand, the humid climate of an interglacial epoch probably would favour luxuriant vegetation that would protect uplands from severe erosion. Sea level would be high and submergence extensive at this time, so that conditions would be proper for limestone deposition. Nothing is known, however, about the nature of Late Paleozoic upland floras, so that these responses to climatic cycles are uncertain. In fact, the opposite conclusion has been reached, and it has seemed likely that epochs of aridity might be represented by the limestones and epochs of humidity by detrital strata.

All sedimentation theories are more or less complex. They relate the production, delivery, and deposition of different materials to a variety of factors such as earth movements, fluctuating climate, physiographic development of the land, changing sea level, strength of currents, distance from source, compaction of sediments, and the building and breaking of barriers to the distribution of sediments. Several of these theories include some elements of the foregoing.

Successive uplifts of the land each followed by a period of stability during which erosion reduced its surface to low level might account for a supply of sediment whose coarseness and amount both declined with reduction of the height of land. Under proper conditions, which need not be detailed here, deposition of these sediments in an adjacent basin might produce cyclothem or cyclothem-like sequences. The time estimated as being represented by an individual cyclothem, however, is relatively brief by geologic standards, and it is hardly conceivable that erosion during such an interval could reduce an elevated source region so effectively.

Several theories relate coarseness of sediment and the development of cyclothem to settling in different depths of water and explain vertical changes in the deposits by the advance and retreat of shorelines and the resulting variation of water depth. Finer grained sediments were

transported farther out from shore and deposited in deeper water. One theory proposed that because vegetable material floated, it was carried far out to sea, where it finally sank, and, next to limestone, coal might record the deepest water environment. This last, of course, is contradictory to good evidence that peat accumulated where the vegetation grew and later was transformed in place to coal.

Strength of currents in the sea would have much the same effect as depth of water in determining the kind of sediment deposited. Thus as currents failed, the coarser sediments settled out progressively and only the finer material was carried on. All theories of these kinds neglect the implications of alternating nonmarine and marine conditions in the better developed cyclothem.

The distributary channels in a growing delta shifted from side to side, so that detrital sediments were delivered to the sea first in one area and later in another, where sand bodies were built up. There the sedimentary surface rose to or above sea level and coal swamps may have formed. At the same time, normal marine conditions prevailed elsewhere. Lateral shifting of the delta front from time to time and submergence of its older parts resulted in the development of cyclothem. Under conditions of this kind, contemporaneous sediments must have varied greatly from place to place. This does not accord with the observation that many cyclothem and some of their members are remarkably persistent and continue with little change for distances of much more than 100 miles.

The different sedimentary environments existing simultaneously in deltaic areas commonly are separated by physical barriers. These include natural levees, bordering distributary stream channels, and sandbars along coasts. The building or destruction of such barriers is likely to result in sudden and extreme environmental changes that might be recorded in the succession of different lithologic members of a stratigraphic sequence. Thus, erection of natural levees might permit the development of adjacent coal swamps, and the breaching of a coastal barrier might result in their inundation and burial beneath marine deposits. The suggestion also has been made that a dense growth of swamp vegetation could act as a filter and prevent the distribution of detrital sediment far from the channel of a stream. The results of all such actions probably would not be felt beyond the limits of local areas, and they are not likely to have been the principal influences in the development of cyclothem or their members that are persistent throughout large areas.

The implications of sandstone-filled channels at the base of lower hemicyclothem are disputed. The linear extent of some sandstone bodies, commonly termed shoestring sands, and the abrupt entrenchment of others have been interpreted as evidence that the channels were first eroded and later filled by streams flowing across emergent alluvial plains. The contrary contention that channels were cut below sea level by submarine density currents (*q.v.*) necessitates a different explanation for cyclothem development. In either case, preference in interpretation is likely to be influenced strongly by theoretical considerations concerning the sequence of events and environments in cyclothem development. Marine fossils have been found in a few sandstones, and some sand bodies comparable to those occupying channels have been considered offshore bars. Most of them, however, generally are conceded to be nonmarine.

Differential compaction of sediment has been included as a more or less important part of several theories. Most newly deposited sediments, and especially peat, are highly porous and contain much entrapped water. When this is squeezed out, either by settling or, more effectively, by compression beneath the load of other subsequently deposited sediment, the sediments are compacted and reduced in thickness. Thus, the compaction of a thick bed of peat that had accumulated at or very close above a shoreline might have had the same effect in a basin as subsidence or rising sea level, and this may explain the presence of undoubted marine strata immedi-

Shapes of sandstone bodies

ately overlying coal beds. Not explained is why compaction of the peat, resulting from settling alone, was delayed until a considerable thickness had accumulated or the reason for marine beds above a smut streak, indicating that no peat had been preserved.

#### OTHER CYCLIC UNITS

**Megacyclothems.** The depositional cycle recognized in the Middle and Upper Pennsylvanian of Kansas includes four or five closely spaced marine limestone members, separated by relatively thin and dominantly shaly intervals. These members are termed the "lower," "middle," "upper," "super," and "fifth" limestones. The interval between the "middle" and "upper" limestones is particularly noteworthy and differs from the others because it generally includes a bed of hard, black, sheeted shale. Thin coals are likely to occur close below the "lower" limestones, which are marine. Each sequence of this kind is separated from others higher and lower in the stratigraphic section by thicker shaly intervals that are poorly characterized and may contain thin beds of sandstone, limestone, and coal. Originally, each of the four or five limestones was supposed to be part of an incompletely developed cyclothem of the kind that is well-known in Illinois, and the whole Kansas cycle was termed a megacyclothem.

The relations of these cyclic units of Kansas and Illinois are disputed, and the detailed correlation of most of the Pennsylvanian strata in these two states is quite uncertain. There are fewer megacyclothems in Kansas, however, than there are cyclothems in what seem to be equivalent parts of the section in Illinois. This does not favour the conclusion that megacyclothems are in some way more fully and elaborately developed cyclothems. Also, if such equivalence were so, any explanation of the origin of cyclothems would be much more complicated with respect to rising and falling sea level and other changing depositional conditions.

A much less conspicuous repetition of differently developed cyclothems has been noted in Illinois. All have basal sandstones, many include coals, and the limestones of successive cyclothems are more widely spaced than the limestones in Kansas. One of the cyclothems is particularly characterized by the succession of middle limestone (member 7), middle shale (member 8) with hard, black, sheeted strata, and a thin upper limestone (member 9). This at once suggests comparison with the "middle" and "upper" limestones and intervening shale of the Kansas megacyclothem. The next higher Illinois cyclothem is especially noteworthy for its thick, light-coloured upper limestone (member 9). This is suggestive of the "super" limestone of Kansas, which generally is also a thick, light-coloured member. Separating successive pairs of cyclothems of these two kinds in Illinois are one to three less individualistic cyclothems, some of which include strata with brackish water rather than typical marine fossils.

If the foregoing comparisons of Illinois and Kansas limestones are significant, the shale interval between the Kansas "upper" and "super" limestones might be equivalent to the upper shale (member 10) of the first Illinois cyclothem and all of the members of the lower hemicyclothem of the second cyclothem. Close examination of these Kansas shale intervals reveals the intermittent and local occurrence in several of them of thin sandstone or sandy shale, poorly developed underclay, thin coal or smut streak, and reddish shale. All of these are types of strata that normally occur between the upper limestone (member 9) of one Illinois cyclothem and the middle limestone (member 7) of another. Thus it seems possible that at least two cyclothems whose detrital members are very poorly represented constitute parts of a Kansas megacyclothem and include three of the limestones that have been mentioned.

Similar consideration of the lithologic nature of other shale intervals in the Kansas megacyclothem indicate that the "lower" and "fifth" limestone, where this is present, also are probably upper limestones (member 9) of

incompletely developed cyclothems. The entire Kansas megacyclothem, therefore, seems to consist of three or more ordinary cyclothems that lack the greater part of their nonmarine and detrital members. Also, the succession of different cyclothems that is repeated in Illinois seems to be a comparable but more fully developed megacyclothem deposited closer to the source of the detrital sediments. Seventeen of these units are clearly evident in Kansas. There are only about seven in Illinois, but the stratigraphic section is truncated above and may not include equivalents of the higher Kansas units. No suggestion of megacyclothem development has been recognized in the Appalachian region or in foreign coalfields. Little thought has been devoted to explaining the origin of megacyclothems.

**Hypercyclothems.** The Kansas stratigraphic section reveals a still greater Pennsylvanian cycle that has been termed a hypercyclothem. Each consists of four successive megacyclothems and an alternating detrital sequence of more than ordinary thickness and complexity. This is likely to include one or more sandstone members that may occupy erosion channels. Four hypercyclothems increasing in perfection upward are recognizable in Kansas and there is the beginning of a fifth. Nothing suggestive of such large cyclic units is known in other areas, and no explanation for them has been ventured.

**BIBLIOGRAPHY.** No books have been written on cyclothems as such, and although cyclic sedimentation is treated briefly in textbooks on sedimentology, the best sources of information are within the somewhat technical literature. Articles of greatest relevance include the following: J.R. BEER-BOWER, "Origin of Cyclothems of the Dunkard Group (Upper Pennsylvanian-Lower Permian) in Pennsylvania, West Virginia, and Ohio," *Bull. Geol. Soc. Am.*, 72:1029-1050 (1961), a review of various theories explaining cyclothems with a suggestion that climate and discharge rate are the most important factors; D.F. MERRIAM (ed.), "Symposium on Cyclic Sedimentation," *Bull. Kans. Geol. Surv.* 169, 2 vol. (1964), a collection of papers discussing the general and specific aspects of cyclothems and cyclic sedimentation; M.H.P. BOTT and G.A.L. JOHNSON, "The Controlling Mechanism of Carboniferous Cyclic Sedimentation," *Q. Jl. Geol. Soc. Lond.*, 122:421-441 (1967), a discussion of the theory that varying rates of crustal subsidence can result in eustatic rises in sea level and are responsible for Carboniferous cyclic sedimentation; B.A. SILVER and R.G. ## Cyprian, Saint

Cyprian, bishop of Carthage in the mid-3rd century, led the Christians in North Africa through the crises of the persecutions under the Roman emperors Decius (249-251) and Valerian (253-260). His teaching on the nature of the church and its sacraments and on the office of a bishop molded Christian thought, and in particular the theology of the Donatists, a North African schismatic movement, until the time of St. Augustine in the 5th century. A collection of 81 letters, including some from his contemporaries, a dozen treatises, and his "Life," written by the deacon Pontius, provide a vivid record of Christianity in North Africa at a decisive stage in its history.

*Bishop during the Decian persecution.* Cyprian (Thascius Cqecilius Cyprianus) was born of wealthy pagan parents about AD 200. Educated in law, he practiced as a lawyer for some time in Carthage. He was converted to

St. Cyprian, detail of a polyptych by Girolamo di Giovanni da Camerino, 1473. In the church of Sta. Maria del Pozzo, Monte San Martino, Italy.

Problem  
of apostasy  
and the  
confessors

Christianity about 246, finding in Baptism complete release from the sinful and useless life he believed he had led hitherto. Within two years he was elected bishop of Carthage and a few months later, early in 250, was confronted by the Decian persecution. He went into hiding. Bereft of his leadership, thousands of Christians apostatized (rejected their faith) or obtained libelli *pacis* (certificates), by which they declared that they had sacrificed to the pagan gods. When the persecution began to diminish, the confessors—i.e., those who had stood firm for their faith—reconciled the lapsed on easy terms, claiming that as "friends of Christ" they had the right of granting pardon, even more than did priests and bishops. Cyprian returned to Carthage (early 251) and at a council of bishops in May 251 was able to regain his authority. The decision of the council was that, though no one should be totally excluded from penance, those who truly had sacrificed (the *sacrificati*) should be readmitted only on their deathbeds, and those who had merely accepted certificates (the *libellatici*) were to be readmitted after varying periods of penance. Three important principles of church discipline were thus established. First, the right and power to remit deadly sins, even that of apostasy, lay in the hands of the church; secondly, the final authority in disciplinary matters rested with the bishops in council as repositories of the Holy Spirit; and, thirdly, unworthy members among the laity must be accepted in the New Israel of Christianity just as in the Old Israel of Judaism.

In 252 a renewed threat of persecution by the emperor Gallus encouraged a more speedy reintegration of the lapsed, because many now wanted to prove themselves as martyrs. In the same year, the steadfastness of the Christian clergy in face of a plague won for the church further popular support, and Cyprian defeated internal enemies who had set up a rival bishop in Carthage.

Relations with Rome. In the summer of 254 his position was tested again by a dispute with Stephen, bishop of Rome (254–257). Until then relations between the churches of Carthage and Rome had been cordial. In 251 Cyprian had supported Bishop Cornelius against his rival, Novatian, and had written on his behalf the treatise *On the Unity of the Church*, which stressed the centrality of the see of Peter (Rome) as the source of the episcopacy. Though Cyprian may have written two drafts of an important passage concerning the primacy of the

chair of Peter, he implied no acceptance of Roman jurisdictional prerogatives. When in 254 two Spanish congregations (Mérida and Leon) appealed to him against a decision by Stephen to restore bishops who had lapsed during the persecution, he summoned a council to consider the case. The council decided that the congregations not only had a right but a duty to separate themselves from a cleric who had committed a deadly sin such as apostasy. Cyprian wrote (Letter 67) that the Holy Spirit was no longer in such a priest and that his sacraments would lead to perdition and not salvation. The church as the "pure Bride of Christ" might be obliged to absorb a sinful laity, but a sinful priest making offerings on behalf of the people was unthinkable.

Within months there was an even more serious dispute with Rome. For a few years the supporters of Novatian had been active in Africa, asserting against Cyprian that no forgiveness for lapsed Christians was possible. With the recovery of Cyprian's prestige, however, their threat began to fade. Many of those whom they had baptized clamoured to be admitted to the church. Was their Baptism valid or not? In Rome, Stephen, confronted by the same problem, decided that all Baptism in the name of the Trinity was valid. The Africans at first were of two minds. Cyprian held three councils between the autumn of 255 and September 256. The last, at which 87 bishops were present, decided unanimously that there could be no Baptism outside the church, just as there could be neither faith, hope, nor salvation for those outside it. A minister could not dispense what he himself did not possess, namely, the Holy Spirit. Those who had received Baptism from Novatianists must be baptized anew. Behind this clash over rites lay the more fundamental question concerning the nature of the church. Though Rome emphasized the church's universal and inevitably mixed character on earth, the North Africans stressed its integrity under all circumstances. Baptism entailed total renunciation of the world and the reception of the Spirit. Persecution under Valerian. A complete breach between Rome and Carthage was averted by Stephen's death on August 2, 257, and his successor, Sixtus II, was more conciliatory. Meanwhile, persecution had been renewed by the emperor Valerian (253–260). On August 30, 257, Cyprian was summoned before the proconsul, Aspasius Paternus, and assigned an enforced residence at Curubis (Kurba) on the Gulf of Hammamet. Following a more severe edict the next year, he was brought back to Carthage, tried, and condemned to death. He was executed in the evening of September 14, 258, and became the first bishop-martyr of Africa.

During the previous seven years his character had matured. Though not the "man of moderation" eulogized by his biographer, he had shown himself a brave and resourceful leader of the church in Africa. His theology was based on the central idea of the unity and uniqueness of the church: "He no longer has God for his Father, who does not have the Church for his mother" (*On the Unity of the Church*). Unity was expressed through the consensus of bishops, all equally possessing the Holy Spirit and sovereign in their own sees. There was no "bishop of bishops." The church consisted of the people united to their bishop. Schism and rebellion against the priesthood were viewed as the worst of sins. These views—associated with an uncompromising insistence on the integrity and exclusive character of the church, which are believed to have been derived from the North African theologian Tertullian—received divine sanction for most North African Christians through his martyrdom.

## Cyprus

The island of Cyprus (Greek Kipros, Turkish Kibris), a striking setting for often dramatic events, lies in the eastern Mediterranean Basin, about 40 miles (64 kilometres) south of Turkey, 60 miles west of Syria, and 250 miles (400 kilometres) north of the Nile Delta, at about the same latitude as Tokyo and San Francisco. Its maximum length, from Cape Arnauti (Akros Arnoutis) in the west to Cape Andreas (Akros Apostolou Andrea) at the end of the narrow, dagger-like northeastern peninsula, is 140 miles (224 kilometres); maximum north-south extent is 60 miles. With an area of 3,572 square miles (9,251 square kilometres), it is the third largest Mediterranean island.

The island's history prior to the 14th century AD is obscure, though archaeologists date the earliest settlements found in Cyprus from Neolithic times, in about 5800 BC. Since then it has been colonized, occupied, or dominated by virtually every one of the peoples who have, over the centuries, successively exercised power in the region—the Greeks, Phoenicians, Assyrians, Egyptians, Persians, Romans, Byzantines, crusaders of Richard I the Lion-Heart, Lusignans, Venetians, Genoese, Turks, and, more recently, the British.

The British occupation began in 1878, and it was from Great Britain that the Cypriots finally achieved independence in August 1960, largely by means of an armed rebellion launched in 1955 by the EOKA (Ethniki Orgánosis Kipriakou Agónos, or National Organization of Cypriot Struggle).

See further CYPRUS, HISTORY OF.

### THE ENVIRONMENT

**Topography.** The island's unique shape is due, geologically, to the occurrence of two ridges, once part of two much greater arcs running from the Asian mainland toward Crete. These remnants—the Kyrenia Mountains in the north and the imposing Troodos Massif in the south—form the two dominant features of the island. A flat lowland, open to the sea at east and west and known as the Mesaoria Plain, lies between the two ranges. It was here that the ancient city-state of Ledra—now the capital city, Nicosia (Greek Levkosia; Turkish Lefkoşa), encircled by a great wall built in the 15th century during the Venetian occupation—was established.

The Kyrenia range, known as the Pentadaktylos (Five

Fingers) from the five-pointed eminence that is one of its main features, is a narrow fold of limestone with occasional deposits of marble; it has a maximum height of just over 3,000 feet (900 metres). The range stretches 80 miles from east to west, leaving along the northern coast a narrow, fertile plain, largely evergreen but also containing olive, carob, and citrus trees.

The Troodos range, fragmented by geologic folding, is mainly igneous rock, impervious to water, but it has a thicker soil and a covering of pine, dwarf oak, cypress, and cedar forest. The highest point is 6,401-foot (1,951-metre) Olympus (Olimbos; formerly Chionistra). The range stretches about 50 miles from near the west coast, culminating in the 2,260-foot (678-metre) eminence of Stravrovouni, 12 miles from the east coast. The general pattern of the 486-mile (778-kilometre) coastline is indented and rocky, with long, sandy beaches.

The Mesaoria Plain, which spans the island from Morphou Bay (Kolpos Morfou) in the west to Famagusta Bay (Kolpos Ammokhostou) in the east, is about 80 miles long and from 15 to 30 miles in breadth. Between autumn and spring it is green and colourful, with an abundance of wild flowers and flowering bushes and shrubs; there are also patches of woodland in which eucalyptus and many types of acacia, cypress, and lowland pine predominate.

The plain is overlooked by the Kyrenia Heights, on which the ancient medieval castles of St. Hilarion, Bufavento, and Kantara are situated. The plain also furnishes the major supply of grain, principally wheat and barley. About 300,000 acres (120,000 hectares) are cultivated under irrigation, and the remainder is devoted to dryland farming.

**Climate.** Mean average rainfall is about 19 inches (483 millimetres), the highest precipitation (44 inches) being on the Troodos range and the lowest (12 inches) in the central plain. Temperatures range between an average daily maximum of 97° F (36° C) and an average daily minimum of 69° F (21° C) at Nicosia, though during the high summer in July and August the maximum is often as high as a scorching 105° F (41° C) in the plain, with as much as 30° F variation between maxima and minima. During winter (December to March) Troodos experiences several weeks of below-freezing night temperatures.

Between December and April the weather pattern is variable, influenced by prevailing conditions in the Aegean Sea and on the Turkish mainland and sometimes by complexes affecting Libya, Egypt, and Syria. From mid-June to mid-September, a low-pressure trough becomes established over the eastern Mediterranean and brings high temperatures and steadily increasing humidity with little or no rain.

There are no running rivers, although the island is crisscrossed by dry river valleys that become fast-flowing torrents during periods of heavy rainfall, with consequent severe erosion of soil.

**Animal life.** Although fossil remains of elephant and hippopotamus have been found in the Kyrenia area, and early writers speak of deer and boar roaming the island in some abundance, the only large wild animal that has survived is the mouflon, a species of wild sheep now believed unique to the island. The mouflon came near to extinction in 1937 and is now under strict protection; its last refuge is the Paphos Forest. Small game abounds but is mercilessly hunted, and by the 1970s it appeared that game laws were inadequate to prevent great annual destruction.

In spring and autumn the island experiences the migration of millions of birds, but experts believe that indiscriminate shooting and poor protection laws are likely to change the pattern of migration. There are many species of birds native to the island, but these also are subjected to the pressure of almost unrestricted hunting.

### THE PEOPLE

**Ethnic and religious heritages.** The people of Cyprus represent two main ethnic groups, Greek and Turkish.

The former are descended from the earliest inhabitants but have blended substantially with the various waves of invaders, especially with Ionian colonists from Greece. The Turkish Cypriots are the descendants of the Ottoman Turks who conquered the island in 1571 and occupied it until 1878.

Cypriots are a people of rugged individuality, gregarious and friendly and almost embarrassingly hospitable to strangers. Family ties are very close, and the dowry system, under which the woman brings a home to the marriage, is a strong tradition among the Greeks, persisting in spite of efforts by the church to discourage it. By contemporary standards, the Cypriots tend to marry relatively late, average ages being 26 for men and 23 for women, the latter predominating in the population in the ratio of 50.5 to 49.5 percent. Divorce is comparatively rare, the ratio being 0.25 compared with a marriage rate of 8.7 per 1,000.

The Greek Cypriots are Eastern Orthodox Christians. Since about AD 478 they have enjoyed a degree of autonomy under an ethnarch elected by the bishops of the island, and a 20th-century incumbent, Archbishop Makarios III, became a world-famous political figure. This autonomous authority was bestowed after the remains of the Apostle Barnabas, who was born in Cyprus and met his martyrdom there—at Salamis, near modern Famagusta—had been discovered and restored to the care of the patriarchate. The island was among the earliest converts to Christianity: the Apostles Paul and Barnabas preached there as early as AD 45, achieving the conversion of the Roman proconsul Sergius Paulus.

The Turkish Cypriots are practicing Muslims who follow the secular observances established on the Turkish mainland by Kemal Atatürk. There are also small groups of Maronites, Armenians, and Roman Catholics.

Modern Greek is the language of the Greek majority, and Turkish is spoken by the Muslim minority; but, as a result of the 82 years of British rule, English is widely spoken and understood as a second language. Illiteracy is very limited, thanks to an education system that provides free elementary instruction for all children.

**Demographic trends.** At the census of 1973 the population was 631,778, a density of almost 160 to the square mile; Greek Cypriots comprised 77 percent and Turkish Cypriots 18 percent of the total. Cyprus has a relatively youthful population, with about 56 percent under the age of 30.

The natural growth rate over the decade 1965–75 declined from 1.5 to 0.9 percent, with an average of 21 births per 1,000 and a death rate of 10 per 1,000. A survey in 1973 disclosed that birth rates had long been substantially overestimated, while death rates, formerly supposed to be among the world's lowest, had been underestimated by a corresponding amount. The death rate, however, is low, which can be attributed in part to a remarkable decrease in the infant mortality rate—from 71.7 per 1,000 births in 1949 to 28.4 in 1973.

Cypriots have long shown an urge to emigrate, largely because of the limited economic opportunity offered in their homeland in the past, and it is estimated that there are almost as many of them living overseas as there are on the island itself.

There was a marked increase in emigration immediately after independence (14,589 in 1960 and 13,489 in 1961); the effect of subsequent economic progress slowed the rate to 1,312 in 1973, but political events of 1974 led to a sharp upsurge of Greek Cypriot emigration in the second half of that year.

The Cypriots are still largely a rural people, despite a marked drift from the countryside. There are more than 600 villages and only six main towns. Nicosia, the capital, lies about 12 miles (19 kilometres) from the north coast; Famagusta, the principal port, is on the east coast 38 miles (61 kilometres) from the capital; Limassol (Lemesos), the port serving the southern area, is 50 miles (80 kilometres) by road from Nicosia; the other towns are Larnaca (Larnax) in the east, Kyrenia on the north coast, and Ktima-Paphos in the southwest. Each of the six towns is a district headquarters.

#### THE NATIONAL ECONOMY

**Policies since independence.** Cyprus maintains a free-enterprise economy, and the private sector was allocated a major role in the First (1962–66), Second (1967–71), and Third (1972–76) Five-Year plans. The success that attended this policy is reflected in the growth of trade and financial stability after independence. Exports rose from 220,200,000 in 1960 to £55,200,000, and imports from £39,000,000 to £148,000,000, in 1974. Revenues showed a similar increase, in spite of a levelling down of direct taxation in 1969, which reduced the maximum payable from 75 to 60 percent and also cut company taxes. Government expenditures almost trebled, to about £59,000,000 in 1973, and there was a consistent budget surplus position. Although the visible trade deficit appeared to be of alarming proportions, the overall balance of payments regularly produced a credit until late 1973, thanks to income derived from overseas earnings and remittances from Cypriots living abroad, plus substantial earnings derived from the presence of British and United Nations military forces. Foreign exchange reserves at the beginning of 1975 totalled 2103,900,000, having shown in 1973 a net decline for the first time in any year since independence. Customs and excise duties and a direct tax on incomes represent the major part of government revenues. The public debt at the end of 1974 stood at £25,400,000, of which £8,000,000 was external loans.

The economy is predominantly agricultural, and this sector provides full- or part-time employment for nearly 95,000 persons, the main production being wheat and barley, potatoes, carrots, and other vegetables, carobs, citrus fruits, and vine products. During the years following independence, the island achieved a per capita standard of living higher than most of the Middle East, with the exception of Israel, and maintained economic growth till 1973.

This progress was substantially assisted by various agencies of the United Nations, operating through the UN Development Program. Generous financial assistance was given by the World Bank and International Monetary Fund in the form of loans for specific development projects (electricity supply, port development, sewerage, etc.). Experts were made freely available to advise on economic planning and to initiate productive projects, and training for Cypriot specialists was encouraged by scholarships and grants.

Landholdings are very small, highly fragmented, and dispersed under the traditional laws of inheritance. In 1967, on the advice of UN experts, a program of land consolidation was begun; but because of the break with tradition and fear that the program might create problems of rural underemployment, the first phase was expected to take about 25 years to complete. Turkish opposition did not cease, but consolidation gained support from Greek Cypriots. Turkish landowners were encouraged to join.

One-half of the island's manufacturing capacity, as well as the citrus-growing areas and the main tourist centres, fell into Turkish hands in the invasion of 1974. Total losses to trade and industry as a consequence of the invasion were assessed at as much as £350,000,000.

Orthodox  
traditions

Cypriot  
emigration

**Resources and industry.** Raw material resources are very limited, restricting the scope for industrial activity; but there has been useful development of light manufacturing, and the contribution of this sector to the economy more than doubled between 1961 and 1973. Electric power production more than quadrupled between 1960 and the mid-1970s.

Cyprus has for many centuries been a producer of copper (in fact, the metal takes its name from that of the island). As early as 2500 BC the island's mines were being exploited, and traces of Phoenician and Roman workings and surface slags are still to be seen. With the discovery of other sources, the mines remained neglected for many generations until they were reopened by an American prospector in 1925. After World War II they were brought back into production, and since then copper and other minerals—iron pyrites, asbestos, gypsum, chrome ore—have contributed some 40 percent annually to the export trade. Reserves of cupreous ores are fast declining, and it is anticipated that by 1982 the industry will have ceased to be economic. Despite systematic prospecting since 1963, no important new deposits have been located. There are, however, substantial reserves of asbestos, chrome, gypsum, and iron pyrites, which will sustain these branches of the mining industry for many years to come.

There are extensive sandstone quarries, the golden-hued product of which was widely used for building the older style of Cypriot houses before the cement age came to Cyprus. There is now a thriving and expanding cement industry.

Defores-  
tation

Cyprus was once an island of abundant forests, but the demand for timber for shipbuilding, by successive conquerors from the pharaohs onward, and extensive felling for building and for fuel have destroyed the greater part. By the 1970s a policy of conservation and reforestation was being pursued. The forests cover some 670 square miles (1,735 square kilometres), a large proportion of them being found in the mountain areas and in the south-western district of Paphos.

**Transportation.** The earliest roads in Cyprus were built by the Romans (58 BC to AD 395), and traces of them still exist. At the time of the British occupation (1878), the only carriage road was between Nicosia and Larnaca; today the island has one of the most comprehensive road networks in the region. All transport is dependent upon the roads, and motor transport has multiplied enormously. In 1907 a narrow-gauge government railway was opened between Famagusta and Nicosia and later extended to Evrykhou in the Troodos foothills, but the installation proved uneconomical and was closed in 1951.

There is no coastal shipping. Some progress has been made toward building up a merchant marine, but the tonnage registered under the Cyprus flag remains small, and most of it is foreign owned. Cypriots, although an island people, have no seafaring tradition.

International air services have expanded greatly since independence; the international airport at Nicosia provides connections to all parts of Europe and the Middle East and some points in Africa, and there is steady expansion of airfreight services.

The great bulk of the island's trade, however, remains seaborne, through the main port of Famagusta on the east coast and Limassol in the south. There are no internal air services.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**Constitutional framework.** The constitution of 1960 established an independent republic with a Greek Cypriot president and a Turkish Cypriot vice president; a Council of Ministers (Cabinet) of seven Greek and three Turkish members; and an elected House of Representatives of 50 members, 35 Greek and 15 Turkish. It also set up Greek and Turkish communal chambers to control community affairs; an army of 2,000, with 60 percent Greek and 40 percent Turkish personnel; and an urban police force and a rural gendarmerie recruited on a 70:30 ratio. It incorporated a Treaty of Guarantee that named Greece, Tur-

key, and Great Britain as guarantor powers and a Treaty of Alliance between Cyprus, Greece, and Turkey.

Under the Treaty of Establishment of the Republic of Cyprus, Great Britain retained sovereign military enclaves—comprising 99 square miles (256 square kilometres)—at Episkopi and Akrotiri, near Limassol in the south, and also at Dhekelia (Dekeleia) near Larnaca in the east.

There was no acclaim for independence; the anniversary (August 16) is not celebrated, nor is the flag of the republic flown except on government buildings. The EOKA rebellion had been basically a campaign for union of the island with Greece (knosis), a union unacceptable to the Turkish Cypriots. Because of this fundamental conflict, the constitution fell into abeyance early in 1964 after political and constitutional disagreement had rendered it unworkable.

**The political process.** The constitution of 1960 provided for the president and members of the House of Representatives to be elected every five years on a basis of universal suffrage, every national over the age of 21 being entitled to vote. Archbishop Makarios III became president at independence. Before 1970 there was only one political party—the Cypriot Communist Party (AKEL). Other parties emerged in the elections of that year, and three were represented in the legislature: Unified Party (right wing), Progressive Front (right wing opposition), and a socialist party known as the Democratic Centre Union Party (EDEK).

Political  
parties

**Local government and the judiciary.** Local government is at district, municipal, rural municipality (improvement board), and village levels. District officers are appointed by the Cabinet, while—according to the constitution—local councils are to be elected; in practice, though, there were no such elections from independence to the end of 1975.

Justice is based on Roman law, dispensed by judges appointed by the president, and the judiciary is entirely independent of the government establishment. The judiciary of the early 1970s, however, was composed only of Greek Cypriot judges. There is a supreme court and an appeals court, district assize courts handling criminal matters, and district courts exercising summary jurisdiction.

**The army.** The 2,000-member Cyprus Army established by the constitution never actually came into being because of the intercommunal dispute. In 1964 a small but relatively powerful Greek Cypriot National Guard of about 15,000 was organized under an officer corps recruited from mainland Greece, and the Turkish Cypriots established a "freedom fighter" force of about 10,000. There are also Greek and Turkish army contingents—numbering 950 and 650, respectively—stationed on the island under the constitution. Unification of the police force on a 70:30 ratio ceased after 1963, and two separate de facto forces emerged, that of the Greeks—totaling about 2,500 officers and men—and a Turkish unit of about 500.

The number of British servicemen remaining in Cyprus in the sovereign base areas declined by 1975 to "around 5,000." Of these, the greater proportion are Royal Air Force personnel based on RAF Akrotiri in the south. Their presence is officially stated to be in support of NATO in southeastern Europe and of Cento (Central Treaty Organization) in the Middle East.

There are no formal boundaries between the British sovereign area and the territory of the Cyprus republic. Under the 1960 agreements, if Britain at any time relinquishes control of the bases, the area reverts to the Cyprus government's control.

**Social development.** Education. Compulsory elementary education was introduced under the British regime, and some 99 percent of children from nine to 12 were enrolled by the 1970s. Planning envisages the early extension of free education to the age of 15. Secondary education is on a fee-paying basis, and about 80 percent of those completing elementary school continue their education in some manner. Postsecondary facilities include schools for teacher training, technical instruction, hotel

Compul-  
sory  
elementary  
education

catering, and nursing and midwifery; there is also a forestry college, generally acknowledged as the best in the Middle East.

There is no Cypriot university, but there is a steady flow of students taking degree courses in Greece, Great Britain, and elsewhere, though there is growing difficulty in absorbing graduates into suitable employment.

**Health.** Health standards are high, because of a favourable climatic situation and a well-organized public health service, but there is still a relative shortage of medical practitioners in rural areas. The ratio of doctors to populace is one of the best in the Middle East but below what the World Health Organization has laid down as the desirable minimum. Since malaria was eradicated shortly after World War II, the island has been free of major diseases, but there is some anxiety about the rapid rise in the incidence of hydatid disease (echinococcosis), a disease caused by the dog tapeworm that causes a cyst and may be fatal. It has spread in Cyprus to epidemic proportions because of an excessive population of stray dogs. A stringent campaign has been undertaken, and thousands of strays have been destroyed by municipal dog shooters.

**Living conditions.** Before independence, Cyprus was a low-income country with a low cost of living, but the surge of prosperity and development after 1964 created an inevitable inflationary pressure that was reflected in substantially increased wages and incomes, a steadily advancing cost of living, and an improving standard of living. There is in rural areas a certain degree of poverty among the elderly, but this is susceptible to steady eradication with the advance in per capita income. Average unemployment is very low.

Trade unionism was introduced in 1932, and by the 1970s it was a vigorous movement with a membership representing almost 60 percent of the nominal labour force. There is no restriction on the right to strike, except in essential services, but efficient conciliation machinery under the Labour Department enables labour relations to be maintained on a fairly peaceful level.

In 1961 employers formed a consultative association that became the Cyprus Employers Federation in 1970. It is recognized by both unions and government and takes part in all government committees that deal with labour matters.

Rapid social and economic development has stimulated housing construction, with the growing trend toward urbanization, but an accompanying unprecedented boom in land prices and building costs has led to the predominance of multi-unit apartment housing in place of the traditional Cypriot single-family dwelling. High-cost accommodation has had an adverse influence on a large proportion of the people who wish to own their own homes on an island in which there are virtually no mortgage facilities available. The greatest problem in meeting housing needs has been the lack of a comprehensive town and country planning authority.

#### CULTURAL LIFE

The arts in Cyprus have benefitted from the activities of the British Council, the Goethe Institut (Federal Republic of Germany), and the American Center, and from a growing interest on the part of the government, which has established an art gallery, a public library, a state theatre, and a state orchestra. Frequent visits by internationally known artists, orchestras, and ballet and theatrical companies have stimulated public interest. A useful contribution is also made by Cyprus Television, which makes generous use of imported educational and cultural film material. Some talented local artists have emerged, and their work has appeared in such international salons as the Milan Biennale.

The ancient theatres of Salamis, Curium, and Soli have been restored and are used for the staging of Greek and Shakespearean plays. A Greek theatre has been built in Nicosia.

Broadcasting within the jurisdiction of the republic is a monopoly service operated by the quasi-government Cyprus Broadcasting Corporation, founded in 1953. Broad-

casts in Greek, Turkish, Armenian, and English are under strong official influence. A television service was introduced in 1957, and both this and radio are operated on a commercial basis.

There is also a station of the British Forces Broadcasting Service (BFBS), established in 1948 and directed chiefly to British servicemen on the island, and a Middle East relay station of the British Broadcasting Corporation (BBC). Neither of these two stations initiates news broadcasts. The Turkish Cypriots operate a radio station known as Radio Bayrak.

It is official government policy to encourage a free press, and there are daily newspapers in Greek, Turkish, and English and weeklies in Greek and Turkish. There is no formal press censorship.

#### PROSPECTS

At the end of 1975 the political and economic outlook for Cyprus appeared troublesome. The economy had suffered a severe decline after the Turkish invasion of 1974, and an estimated 70,000 Greek-Cypriots were unemployed. Greeks displaced from the north were concentrated in the towns and villages of the south, with some 50,000 living in camps and temporary accommodations supported by the government and by refugee aid funds from international sources.

The situation of the Turkish Cypriot community was difficult, and the community was dependent upon an annual subvention from Turkey of about £14,000,000. Industrial establishments in the area occupied by the Turkish army were almost entirely idle, and there was little agricultural production.

(H.W.G.)

**BIBLIOGRAPHY.** *General and reference:* There is no current Cypriot national bibliography. The fullest listing of earlier materials on Cyprus is NEOCLES G. KURIAZES, *Kypriake bibliographia* (1936), containing about 5,000 titles. Among the most useful general descriptions of the country are the *Area Handbook for Cyprus* (1971), of the FOREIGN AREA STUDIES DIVISION OF THE AMERICAN UNIVERSITY; *Nagel's Encyclopedia-Guide to Cyprus*, designed for travellers but containing much well-organized background information, revised regularly; and MICHAEL and HANKA LEE'S *Cyprus* volume in the DAVID and CHARLES "Islands Series." The most complete statistical description is the annual *Statistical Abstract*, published by the MINISTRY OF FINANCE.

*The environment:* The geological background is summarized in *A Synopsis of the Stratigraphy and Geological History of Cyprus*, by F.R.S. HENSON and others (1949); for botanical information, the only comprehensive survey is J. HOLMBOE, *Studies on the Vegetation of Cyprus* (1914), but ESTHER F. CHAPMANN, *Cyprus Trees and Shrubs* (1949), is also useful; detail on wildlife may be found in *Birds of Cyprus*, by D.A. and W.M. BANNERMAN; no comprehensive study of animal life is available.

*The people:* For the historical background of the development of Cyprus' demographic situation, the best exposition is *The Population of Cyprus (1570-1881)*, by T. PAPADOPOULLOS (1965); for detail on the situation before the invasion of 1974, the reports of the censuses of 1960 and 1973; for materials on the minority community EMEL ESEN, *Aspects of Turkish Civilization in Cyprus* (1965), is recommended.

*The national economy:* In addition to the *Statistical Abstract* cited above, see also the MINISTRY OF FINANCE'S *Economic Report* (annual), as well as its more specialized serials covering other aspects of Cyprus' economic life. The best general discussions of the economy are to be found in A.J. MEYER, *The Economy of Cyprus* (1962), and D. JENNES, *The Economics of Cyprus* (1962). The materials published in the First, Second, and Third Five-Year plans (1962-66, 1967-71, and 1972-76) detail the programs established by the national government to improve the country's situation domestically and internationally.

*Administration and social conditions:* For background on Cyprus' situation in the region, JACOB C. HUREWITZ, *Diplomacy in the Near and Middle East*, 2 vol. (1956), provides extensive coverage; problems of constitutional government during the first decade of independence are examined in STANLEY KYRIAKIDES, *Cyprus: Constitutionalism and Crisis Government* (1968), and CRITON G. TORNARTIS, *Constitutional and Legal Problems in the Republic of Cyprus* (1968). Access to data on health and education is primarily through the statistical publications of the government (annually). Living

Trade  
unions

conditions are examined in the *Household Survey*, 3 vol., of 1971.

## Cyprus, History of

The earliest remains so far discovered in Cyprus belong to the Late Neolithic Period. An important settlement not far from the south coast, near the village of Khirkitia, has been dated by carbon-14 tests to the mid-6th millennium BC. Architecture is represented by beehive dwellings, and the utensils in use were of stone. Flint and obsidian implements were current, and stone celts were found in great numbers. This earlier period, which may be called pre-ceramic, was followed by another period marked by the appearance of well-made pottery with painted patterns.

A new era is represented by the introduction of combed pottery, mostly found at the settlement of Sotira about five miles north of the classical town of Curium near the south coast. The Sotira culture has been dated to the second part of the 4th millennium BC. In the early 3rd millennium the combed pottery was gradually replaced by painted pottery, most of which has been found at the settlement of Erimi not far from the south coast. Houses were circular, and the general aspect of the culture shows substantial development. Copper then made its first appearance.

About 2500 BC red and black pottery, probably influenced by the Khirbet Kerak ware of Palestine, began to take the place of the painted wares, and in the 23rd century pottery shapes of western Anatolian types found their way into the island, probably introduced by people in search of copper. This period represents the Early Bronze Age.

The Middle Bronze Age (early 2nd millennium BC) is characterized by the return of painted pottery. In the Late Bronze Age (c. 1600–c. 1050 BC) Cyprus became the emporium of the East. The most important event during this period was the appearance of Mycenaean traders about 1400 BC, followed by successive waves of Achaeans, who colonized the island and introduced Greek culture and language.

During the Late Bronze Age Cyprus appears in Egyptian records under the name of Asi as a conquest of Thutmose III of Egypt (c. 1500 BC). Alashiya (Alasia), mentioned in Egyptian, Hittite, and Mesopotamian records, has also been identified as Cyprus, although doubts of this identification have been expressed.

The culture as reflected mostly in the ceramic production of the first part of the Iron Age (c. 1050–c. 950 BC) shows a fusion of Cypriot and Achaean characteristics, with some Syro-Anatolian elements. It appears, however, that the Achaean element gained the upper hand. The Cypriot institution of kingship, as it is known from later evidence, was established by the Achaean colonists, although pre-Achaean kingdoms did exist in Cyprus—for example, at Paphos. The character of the kingship, originally Mycenaean, developed later into an autocracy of Oriental type with the king as the head of the state, although the city-state of Idalion, in the south, enjoyed a more democratic form of government. Art, as reflected in pottery and other crafts of the Early Iron Age, is first dominated by the Achaean–Mycenaean features, but later (950–700 BC) Cypriot characteristics are seen to come to the fore.

Commercial relations with Syria, Palestine, Egypt, and Anatolia were at first rare, but from the 9th century onward they became closer. Sidon and Tyre on the Syrian coast and Tarsus in Cilicia were centres through which Cypriot wares were transmitted to the interior of the continent. The relations with Greece followed a similar course, Rhodes being the main intermediary between Cyprus and the Greek mainland and islands.

The beginning of Phoenician penetration into Cyprus may be dated to about 800 BC, although a funeral inscription of the 9th century BC shows the appearance of Phoenician elements already in that century.

The city of Citium (Kition), a Tyrian colony, was the main centre of Phoenician activity, and the overwhelming

majority of Phoenician inscriptions have been found in that city.

Assyrian domination. The year 709 BC marks the end of political independence with the submission of the Cypriot kings to the Assyrian king Sargon II. The event was commemorated at Sargon's capital, Dur Sharrukin (Khor-sabad), as well as in Cyprus, where, at Citium, a stele, now in Berlin, was erected. On the stele Cyprus is referred to as Yatnana; *i.e.*, the isles of Danaoi.

The hold of Assyria over Cyprus continued during the reigns of Sargon's successors. Thus Esarhaddon's prism, written in 673–672 BC, refers to 10 kings and kingdoms of Cyprus, among which is Qarthadast (Citium). Although Cyprus appears as one of the countries paying tribute to Ashurbanipal (667 BC), the Assyrian domination may have ended in 669. From that date Cyprus had almost 100 years of virtual independence—one of the most brilliant periods of Cypriot culture (the first part of the Cypro-Archaic period). The power of the kings became greater, a fact reflected in the monumental tombs built of ashlar masonry. Palaces were built, and shipbuilding and mining attained a high level of production. Ceramic art produced some of the island's finest and most richly ornamented vases, while metalwork, as evidenced by some remarkable silver bowls, reached great perfection under Egyptian and Phoenician influence. The output of Greek epic poetry is also noteworthy; Stasinus, to whom the epic called *Cypria* is attributed, belongs to the 7th century.

Commercial and cultural relations with the East and West were intensified and Cyprus maintained close intercourse with Rhodes, which continued to be the chief stepping-stone of Cypriot commercial expansion to the West. Mainland and eastern Greek pottery found its way to Cyprus, and Cypriot products were widely distributed in Greece, thus transmitting Oriental characteristics to Greek art.

Egyptian, Greek, and Persian influence. Following the breakup of the Assyrian Empire, Saite Egypt became the great power. Cyprus was necessary to Egypt for minerals and material for shipbuilding, and Ahmose II conquered the island in about 560. This meant a new orientation of Cypriot culture, and the influence of Egypt is reflected mostly in the sculpture and the increased importation of Egyptian goods, chiefly from the Greek colony of Naukratis in the Delta. The Cypriot kings and kingdoms were allowed to exist, but they paid tribute to the Egyptian ruler.

Around 525 BC the island passed to the control of Achaemenian Persia (see also IRAN, HISTORY OF). It formed a satrapy of the Achaemenian Empire, but the Cypriot kings were left undisturbed and struck their own coinage. The Greek cities joined the Ionian revolt about 498 BC, but the Phoenician colonies Citium and Amathus remained loyal to Persia. The rising was soon put down; in 480 Cyprus furnished 150 ships to the fleet of Xerxes and remained subject to Persia during the 5th century. But the Greek cities—the principal of which were then Salamis, Curium, Paphos, Marion, Soli, Kyrenia, and Chytri—retained monarchical governments throughout. Phoenicians held Citium and Amathus on the south coast, Tamassus and Idalion in the interior. At the end of the 5th century a league of Cypriot cities was formed by Evagoras, who became king of Salamis about 410. Aided by the Athenians, he revolted openly from Persia. But the Phoenician states supported Persia as before, the Greeks were divided by feuds, and by 381 the attempt had failed; Evagoras was assassinated in 374, and his son Nicocles died soon after. After the victory of Alexander the Great at Issus in 333, all the states of Cyprus welcomed the conqueror.

These political events are reflected in cultural and artistic development. Architecturally, this period is exemplified by the palace of Vouni, the history of which is interwoven with events of the 5th century. Excavations at Kouklia (Palaipaphos) have shown more evidence of the political history of these times. Sculpture, after first producing remarkable works under Ionian influence encouraged by the annexation of Cyprus to the Persian Empire,

After J.B. Bury, *A History of Greece* (1934); Macmillan London Ltd

passed into relative stagnation. Evagoras' accession to the throne of Salamis encouraged Hellenic cultural relations but the effects were meagre. At this time Greek symbols and alphabet were introduced into the local coinage.

After Alexander's death in 323 Cyprus passed, after several rapid changes, to Ptolemy I, king of Egypt. Under Ptolemaic rule Cyprus was usually governed by a viceroy of the royal line, but it gained a brief independence under Ptolemy Lathyrus (107–89 BC) and under a brother of Ptolemy Auletes (80–58 BC). The great sanctuaries of Paphos and Idalion and the public buildings of Salamis, which were wholly remodelled in this period, have produced but few works of art. It is in this period that Jewish settlements are first heard of; these later became well populated. Following the annexation of Cyprus to Ptolemaic Egypt the local coinage ceased to exist and artistic production, mostly illustrated by sculpture, was chiefly dependent on the workshops of the Hellenistic world.

**Roman period.** In 58 BC Rome, which had made large unsecured loans to Ptolemy Auletes, annexed the island. Under Rome, Cyprus was at first appended to the province of Cilicia; after the defeat of Mark Antony at Actium (31 BC) by Octavian (Augustus), Cyprus became a separate province that remained in the hands of Augustus and was governed by a *legatus Caesaris pro praetore* as long as danger was feared from the East. In 22 BC, however, it was transferred to the Senate, so that Sergius Paulus, who was governor in AD 46, was rightly called proconsul.

**Christianization** Christianity reached Cyprus very early. Barnabas, the colleague of the Apostle Paul, was a native of the island, and Paul himself preached there. In 115–117 the Jews of Cyprus, with those of Egypt and Cyrene, revolted, massacred 240,000 persons, and destroyed a large part of Salamis. Hadrian, afterward emperor, suppressed them and expelled all Jews from the island. For the culture of the Roman period there is abundant evidence from Salamis and Paphos, from tombs everywhere, and from the glass vessels, which almost wholly supersede pottery in tombs. Of the sculptural works, the most remarkable are the bronze statue of Lucius Septimius Severus in the Cyprus Museum and two marble sculptured sarcophagi in Cyprus. The most important of the types of coin struck in the island is that with the Aphrodite Temple on the reverse. (P.Di.)

**Medieval period.** After the division of the Roman Empire (AD 395), Cyprus remained subject to the Eastern emperors, with brief intervals, for more than 700 years (see also BYZANTINE EMPIRE). During the 5th century it formed part of the diocese of the Orient. under the *comes Orientis*, whose seat was at Antioch. This subordination was probably the basis of the claims advanced by the patriarch of Antioch to appoint and consecrate the metropolitan of Cyprus. These claims were successfully resisted by the Cypriot hierarchy. Both the Council of Ephesus in 431 and Council in Trullo in 692 recognized the autocephaly of the Cypriot church and its right to elect and consecrate its own archbishop and bishops.

The island seems to have enjoyed a peaceful existence until the Muslims began their attacks during the 7th century (see further ISLAM, HISTORY OF). The first was launched during the years 647–649, when Mu'a-wiya,

amir of Syria, overran Cyprus and laid it under tribute. In 653 it was attacked again, and an Arab garrison was established there. This was withdrawn after 680, and for nearly 300 years Cyprus was to be neither under the full control of Islām nor of Constantinople. Each used Cyprus as a springboard for attacks on the other. The Byzantine fleet prevented permanent Muslim occupation, but their raids were frequent and sometimes prolonged, and it was not until 965 that the emperor Nicephorus II Phocas was able to deliver the island from the constantly renewed attacks. For the next 200 years it remained an integral part of the Byzantine Empire. As an outlying province, it was not infrequently used as the base for revolt against the imperial government. From about 1185 Isaac Comnenus, an ambitious Byzantine governor, held it against two successive emperors, his kinsman Andronicus I and Isaac II Angelus, but in 1191 he showed hostility to the English crusaders led by King Richard I, who then conquered the island. Richard first sold his conquest to the Knights Templars and then, as they could not pay, bestowed it on Guy de Lusignan, the dispossessed king of Jerusalem.

Guy founded a feudal monarchy in Cyprus that survived until the end of the Middle Ages. Much of its recorded history during that period concerns the life of the court and of the territorial aristocracy, which, in contrast to the peasantry, was French in speech and culture. Because of the island's trade, however, Italian merchants, especially those of Genoa and Venice, assumed an ever increasing economic and political control until, in the 15th century, Cyprus became part of the Venetian Empire.

The kings of Cyprus kept alive the crusading idea (see also CRUSADES, THE). Some, such as Amalric II (1194–1205) and Hugh III (1267–84), were also kings of Jerusalem, but they were unable either to impose unity on the warring factions that weakened the Syrian kingdom or to prevent its extinction in 1291 by the Mamlūks of Egypt. Even then, Cyprus remained a base for counterattack against the Muslims. Hugh IV (1324–59) formed an alliance with the papacy, Venice, and the Knights Hospitallers of Rhodes, and in 1344 an expedition fitted out by this league retook Smyrna (Izmir) from the Turks. His son Peter I (1359–69) devoted himself to the organization of a crusade. In 1361 he took Gorigos (Korykos) and Adalia (Antalya) in Anatolia. In 1362 he recruited an army and fleet in western Europe and took Alexandria (Oct. 10, 1365). But he could neither retain the conquest nor persuade the rulers of western Europe to equip another crusade.

After Peter's assassination in 1369 the fortunes of the royal house declined, while those of the Italian republics rose to new heights. The economic activity in Cyprus was a result not only of its own silks, sugar, and salt but also of its importance as an entrepôt for the Eastern trade, especially after the Christians lost the Syrian ports. All the important commercial communities of the Mediterranean therefore established stations and bought trading privileges in Cyprus. In 1373 the Genoese took advantage of the local political situation to acquire complete control of Famagusta, the principal port, and were able to dominate trading and government in the island for 90 years. In 1426 an expedition launched from Egypt overran the island, and for a generation its kings were nominally the tributaries of Cairo.

The situation was redeemed by King James II (1460–73), a bastard of the royal house who in his father's lifetime had become archbishop of Nicosia. With the help of a Muslim force from Egypt he seized power in Cyprus and expelled the Genoese from Famagusta (1464). In 1472 he allied himself to Venice, by marrying a Venetian noblewoman. On his death Cyprus was ruled from Venice in the Queen's name until in 1489 the republic caused her abdication; the island remained a Venetian possession until its conquest by the Ottoman Turks in 1570–71.

**Medieval relics.** From the period between the peace of the church and the devastating Arab raids of the mid-7th century there survive numerous remains, including basil-

The Latin kingdom

Venetian rule

ican churches, an apse mosaic at Lythrangomi comparable to those of the 6th century at Ravenna, Italy, a bath complex at Curium with fine mosaic pavements, and a treasure from the site of the ancient Lapithos consisting of gold ornaments and silver plate. Wall paintings of Byzantine and later styles exist in churches still in use, some domed in the Byzantine fashion, some wood-roofed and tiled. Outstanding monuments of the Latin kingdom are the Gothic cathedrals of Nicosia and Famagusta, and the abbey of Bellapais. Of military architecture, Byzantine, Frankish, and Venetian, a good deal remains, foremost being the walled city of Famagusta. (Ed.)

**Ottoman and British rule.** On March 7, 1573, Venice recognized Ottoman sovereignty over Cyprus. The Turkish administration lasted for 300 years. At first comparatively enlightened (serfdom was abolished, the Orthodox archbishopric restored, and the Christian population granted a large measure of autonomy), it became neglectful and often oppressive during the period of Ottoman decline. There were serious risings in 1764, 1804, and 1821. In 1838–39 and 1856 attempts were made to introduce reforms and some self-government with a local *dīwān* (council). The reform movements lagged, however, and there were few internal improvements, since the imperial treasury retained most of the island's income. In the courts, Christian testimony was seldom honoured.

On June 4, 1878, Great Britain took over the administration of Cyprus and occupied it by agreement with the Ottoman sultan, who was promised British help against Russia in return. Cyprus remained under Turkish sovereignty, but from the start elements of the Greek population (80 percent of the total) asked the British to grant *e'nosis* (union with Greece). For many years this demand was of little more than academic significance.

Cyprus was annexed to the British crown in November 1914, when war with Turkey broke out. The British government offered the island to Greece 12 months later, if Greece helped Serbia, then invaded by Bulgaria. Greece refused to help Serbia, and the offer lapsed. Turkey formally recognized the annexation under the Treaty of Lausanne on July 24, 1923, and in the following year Cyprus was made a crown colony.

In 1931 serious disturbances arose out of the demand put forward by sections of the Greek population for *e'nosis*. The Legislative Council was abolished and power to legislate was vested in the governor alone.

**Archaeological exploration.** This began before the British occupation (T.B. Sandwith, R.H. Lang, L.P. di Cesnola), but it was after the occupation that systematic work was started (under the Cyprus Exploration Fund and by O. Richter). In the early part of the 20th century Sir J.L. Myres and M. Markides carried out excavations for the Cyprus Museum, and later a Swedish expedition devoted several years (1927–31) to exploring many sites. The Cyprus Museum and (from 1935) the department of antiquities investigated many prehistoric and later sites, while expeditions sponsored by the Pennsylvania University Museum, the British School at Athens, and the Louvre, Paris, explored Bronze Age cemeteries and towns. After 1950 the British excavated sites at Myrtou and at Kouklia (Palaipaphos), and Swedish and French missions undertook excavations at Kalopsida, Ayios Iakovos, and Enkomi. The department of antiquities conducted large-scale excavations at Salamis.

**The *énosis* movement.** Apart from a few air raids, Cyprus remained immune from enemy attack throughout World War II. After the war agitation for *e'nosis* was resumed. Archbishop Makarios III, patriarch of the Orthodox Church in Cyprus, emerged as the leader of the movement, with the support of various political groups. The campaign for *e'nosis* grew more violent, with persistent attempts to smuggle arms from abroad. This provoked great sympathy in Greece and resentment in Turkey. At the London Conference in September 1955 the British, Greek, and Turkish foreign ministers failed to agree on a solution, and an atmosphere of terrorism, repression, and mistrust prevailed. In this the lead was taken by EOKA (Ethnikí Orgbnosis Kípriakou Agónos, or

National Organization of Cypriot Struggle) headed by Col. Georgios Grivas ("Digenes" or "Dighenis"), formerly an officer in the Greek Army. EOKA enjoyed wide support in the Greek Cypriot community and included a guerrilla body that carried out terrorist attacks on British servicemen and establishments. British reinforcements were sent to the island to suppress the guerrillas, and in the autumn of 1955 Field Marshal Sir John Harding was appointed governor. Emergency regulations were introduced. Negotiations opened with Makarios, the main issue being self-determination, which the British government refused to concede at that time although it was ready to grant a large measure of self-government.

In March 1956 Makarios and the Bishop of Kyrenia were deported to the Seychelles. For a year terrorism raged throughout Cyprus, but all attempts to suppress EOKA failed. In the meantime Lord Radcliffe had been asked to advise on a new liberal constitution. His proposals, published in December 1956, were accepted by the British government. On March 14, 1957, EOKA offered to suspend its activities if Makarios was released from exile. A few days later he was freed and permitted to go where he liked except Cyprus. Terrorist activities ceased, and many restrictions were lifted, but progress toward a settlement was slow. Sir John Harding was succeeded in December 1957 by Sir Hugh Foot. By this time the Turkish Cypriot community (about 17.5 percent of the island's population), led by Fazıl Küçük, was thoroughly aroused at the prospect of *énosis* and put forward the demand that the island should be partitioned. Renewed efforts in 1958 by the British government and by NATO to produce a settlement came to nothing in face of the Greek community's desire for union with Greece and the Turkish for partition. Terrorism broke out again and fresh restrictions had to be imposed. But later that year the Archbishop proposed that after a fixed period of self-government Cyprus should become an independent state.

This led to negotiations between the Greek and Turkish governments and to a conference in Zurich, Switzerland, in February 1959, at which the British were not represented. Agreement in principle was reached, which was immediately approved by the British government. British sovereignty was to be retained over the two military bases at Dhekelia and Akrotiri, in all an area of 99 square miles (256.4 square kilometres). The new republic would not participate in a political or economic union with any other state, nor would it be subject to partition. Greece, Turkey, and the United Kingdom guaranteed the independence, integrity, and security of the republic, and Greece and Turkey undertook to respect the integrity of the areas remaining under British sovereignty. Executive power was vested in a Greek Cypriot president and a Turkish Cypriot vice president, to which posts Makarios and Kiitchuk had previously been elected. They would have a council of ministers comprising seven Greek and three Turkish Cypriots. It was later agreed that the decisions of the council would be binding on the president and vice president, who could, however, impose a veto in matters relating to security, defense, and foreign affairs. There would also be a House of Representatives elected for five years consisting of 50 members, of whom 70 percent were to be elected from the Greek and 30 percent from the Turkish Cypriot communities, and the civil service was to consist of 70 percent Greek and 30 percent Turkish Cypriots. A Turco-Greek military headquarters was to be set up to train the Cypriot Army.

**The Republic of Cyprus.** The first general election took place on July 31, 1960. Of the 35 seats allotted to the Greek Cypriots 30 were won by supporters of the Archbishop, five by agreement being allotted to AKEL (Anorthotikón Kómma Ergazoménon Laoú), the Cypriot Communist Party. All 15 seats allotted to the Turkish Cypriots were won by supporters of Kutchiik. The republic came into being on Aug. 16, 1960, and Cyprus was admitted as a member of the United Nations. It remained a member of the sterling area, and the British

pendence

Foreign influences

government agreed to make £12,000,000 of financial assistance available, payable over five years. Cyprus was admitted to membership in the Commonwealth of Nations in March 1961. (B.S.-E.)

The new nation was not to know peace for long. The tensions between the Greek and Turkish Cypriots continued, backed by their mother countries with their own areas of conflict. Members of the NATO alliance, particularly Great Britain and the U.S., were concerned about two fellow members at such constant odds and the vulnerability of their southern flank to Soviet pressure. Outbreaks of violence continued to be frequent, and in March 1964 the UN Security Council agreed to send to Cyprus a mixed force (Unficyp, called the United Nations Peace-Keeping Force in Cyprus); its mandate was extended repeatedly over the next decade.

Makarios as president. Archbishop Makarios had been a leader of *énosis* in the Cypriots' struggle against Great Britain, but after he became president of an independent country his position grew increasingly toward the maintenance of this independence. With Athens' support, primarily through Gen. Georgios Grivas, who led the movement from 1964 to 1967 and again from 1971 until his death in January 1974, the underground terrorist activities of the former EOKA (later known as EOKA B) were a major cause of turmoil. The Turkish Cypriots, with strong support from Ankara, tried repeatedly to assure and improve their minority status and were also responsible for numerous incidents, including a near invasion by Turkey in 1967. Attempts on the Archbishop's life in 1970 and 1973, the assassination of a former government minister (probably involved in the earlier attempt on Makarios), and the kidnapping of an incumbent minister in 1973 (all assumed to be backed by the Greek Cypriots) were only a few of the frequent acts of violence. In contrast, however, the Archbishop was re-elected president for a second five-year term in 1968 by an overwhelming 220,911 votes to 8,577, and in 1973 he won an uncontested third term.

Conflict with churchmen

Makarios also came into conflict with churchmen. In 1972 three Cypriot bishops demanded that he renounce the presidency because it conflicted with his role as spiritual leader. He steadfastly refused to give up the presidency, so in April 1973 the three bishops called a council and declared that the Archbishop was deposed from his spiritual office. This action prompted the convening in July of a synod of the Eastern Orthodox churches under the Patriarch of Alexandria. The synod voided the earlier deposition and stripped all three of the rebel bishops of their jurisdictions and even their priestly offices.

Relations between the president and the Cyprus National Guard, which was officered by Greeks, deteriorated steadily. On July 15, 1974, the inevitable coup occurred. The guard placed Nikos Sampson, a Cypriot newspaper publisher and former guerrilla leader, in the presidency, and Makarios barely escaped with his life. Five days later, with the professed aim of overturning Sampson's government, Turkish forces landed on Cyprus, at Kyrenia. On July 23 the President of Greece dismissed his Cabinet and recalled the self-exiled Konstantinos Karamanlis to form a new government. That same day Sampson was relieved of his post by the Cyprus National Guard, and Glafkos Clerides, president of the House of Representatives, was made interim president. Meetings in Geneva of the three guarantors of the Cyprus constitution, Great Britain, Greece, and Turkey, resulted in several cease-fire agreements, but none was effective until August 16, by which time Turkey controlled the northern third of the island.

Intercommunal talks. Intercommunal talks had begun in 1968 between Clerides and Rauf Denktash, leaders, respectively, of the Greek and Turkish Cypriots, to find a solution to the impasse. The Turks had established a "transitional administration" to administer the affairs of the Turkish Cypriot community until the constitutional provisions of 1960 were fully effective; the Greek community refused to recognize this body. The talks were deadlocked and resumed repeatedly through the years. Early in 1974 the new Turkish prime minister, Bulent

Ecevit, demanded that Cyprus form a bi-zonal federation of two separate states with a weak central government. The Greek Cypriot position seemed to evolve into a desire for nationalistic cantons to be held together by a strong central government, a plan that Makarios had earlier opposed. After the Turkish invasion, with Clerides as acting president, the talks centred on the exchange of prisoners and the relocation of refugees. Even after Makarios returned triumphantly to resume the presidency in late 1974, negotiations settled very little. In February 1975 the Turkish Cypriots proclaimed their occupied area to be a separate state. Denktash explained that their intention was not to become independent but, in effect, to accomplish the federation under the 1960 constitution that they had been advocating. The Greek Cypriots objected strongly to the action, as did Greece, but the separate state was now an accomplished fact. Negotiations on the fate of refugees continued. (Ed.)

**BIBLIOGRAPHY.** The most comprehensive history is that of GEORGE F. HILL, *History of Cyprus*, 4 vol. (1940–52). The later period, covering the acquisition of independence, is dealt with in official publications, notably *Tripartite Conference on the Eastern Mediterranean and Cyprus* . . . , Cmd 9594 (1955), and *Cyprus*, Cmd 1093 (1960), giving text of agreements relating to independence. Since independence, the periodical reports to the United Nations Security Council of the Secretary General requesting renewal of the mandate of UNFICYP (1964– ) are indispensable. See also the ROYAL INSTITUTE OF INTERNATIONAL AFFAIRS, LONDON, *Cyprus: The Dispute and the Settlement* (1959); L. DURRELL, *Bitter Lemons* (1957); GEORGE GRIVAS, *The Memoirs of General Grivas* (1964); R.H. STEPHENS, *Cyprus: A Place of Arms* (1966); and P.N. VANEZIS, *Makarios: Faith and Power* (1972). On economics until independence, the annual reports of the Government of Cyprus are informative; since independence, see W.L. THORP, *Cyprus: Suggestions for a Development Programme* (1961); and *The Second Five Year Plan (1967–1971)* (1967). On archaeology, see especially P. DIKAIOS, *A Guide to the Cyprus Museum*, 2nd ed. (1953), and E. GJERSTAD *et al.*, *Swedish Cyprus Expedition*, 4 vol. (1934–37).

(B.S.-E.)

## Cyrus II the Great, of Persia

Conqueror and Persian statesman, Cyrus was the founder of the Achaemenian dynastic empire, the first "world state," which included all of the Near East from the Aegean Sea to the Indus River. He is also remembered in the Cyrus legend—first recorded by Xenophon, Greek soldier and author, in his *Cyropaedia*—as a tolerant and ideal monarch who was called father of his people by the ancient Persians, and in the Bible as the liberator of the Jews captive in Babylonia.

Cyrus was born between 590 and 580 BC, either in Media or, more probably, in Persis, the modern Fars province of Iran. The meaning of his name is in dispute, for it is not known whether it was a personal name or a throne name given to him when he became a ruler. It is noteworthy that after the Achaemenid empire the name does not appear again in sources relating to Iran, which may indicate some special sense of the name.

Most scholars agree, however, that Cyrus the Great was at least the second of the name to rule in Persia. One cuneiform text in Akkadian—the language of Mesopotamia (present-day Iraq) in the pre-Christian era—asserts he was the

son of Cambyses, great king, king of Anshan, grandson of Cyrus, great king, king of Anshan, descendant of Teispes, great king, king of Anshan, of a family [which] always [exercised] kingship.

In any case, it is clear that Cyrus came from a long line of ruling chiefs.

The most important source for his life is the Greek historian Herodotus. The idealized biography by Xenophon is a work for the edification of the Greeks concerning the ideal ruler, rather than a historical treatise. It does, however, indicate the high esteem in which Cyrus was held, not only by his own people, the Persians, but by the Greeks and others. Herodotus says that the Persians called Cyrus their father, while later Achaemenid rulers were not so well regarded. The story of the childhood of

Cyrus, as told by Herodotus with echoes in Xenophon and the Greek historian Ctesias, may be called a Cyrus legend since it obviously follows a pattern of folk beliefs about the almost superhuman qualities of the founder of a dynasty. Similar beliefs also exist about the founders of later dynasties throughout the history of Iran. According to the legend, Astyages, the king of the Medes and overlord of the Persians, gave his daughter in marriage to his vassal in Persis, a prince called Cambyses. From this marriage Cyrus was born. Astyages, having had a dream that the baby would grow up to overthrow him, ordered Cyrus slain. His chief adviser, however, instead gave the baby to a shepherd to raise. When he was 10 years old, Cyrus, because of his outstanding qualities, was discovered by Astyages, who, in spite of the dream, was persuaded to allow the boy to live. Cyrus, when he reached manhood in Persis, revolted against his maternal grandfather and overlord. Astyages marched against the rebel, but his army deserted him and surrendered to Cyrus, about 550 BC. So much for the Cyrus legend.

Cyrus' conquests

After inheriting the empire of the Medes, Cyrus first had to consolidate his power over Iranian tribes on the Iranian plateau before expanding to the west. Croesus, king of Lydia in Asia Minor, had enlarged his domains at the expense of the Medes when he heard of the fall of Astyages, and Cyrus, as successor of the Median king, marched against Lydia. Sardis, the Lydian capital, was captured in 547 or 546, and Croesus was either killed or burned himself to death, though according to other sources he was taken prisoner by Cyrus and well treated. The Ionian Greek cities on the Aegean Sea coast, as vassals of the Lydian king, now became subject to Cyrus, and most of them submitted peacefully. Several revolts of the Greek cities were later suppressed with severity. Next Cyrus turned to Babylonia, where dissatisfaction of the people with the ruler Nabonidus gave him a pretext for invading the lowlands. The conquest was quick, for even the priests of Marduk, the national deity of the great metropolis of Babylon, had become estranged from Nabonidus. In October 539 BC, the greatest city of the ancient world fell to the Persians.

In the Bible (*e.g.*, Ezra 1:1–4), Cyrus is famous for freeing the Jewish captives in Babylonia and allowing them to return to their homeland. Cyrus was also tolerant toward the Babylonians and others. He honoured Marduk and conciliated the local population by supporting local customs and even sacrificing to local deities. The capture of Babylon delivered not only Mesopotamia into the hands of Cyrus but also Syria and Palestine, which had been conquered previously by the Babylonians. The ruler of Cilicia in Asia Minor had become an ally of Cyrus when the latter marched against Croesus, and Cilicia retained a special status in Cyrus' empire. Thus it was by diplomacy as well as force of arms that he established the largest empire known until his time.

Cyrus seems to have had several capitals. One was the city of Ecbatana, modern Hamadan, former capital of the Medes, and another was a new capital of the empire, Pasargadae, in Persis, said to be on the site where Cyrus had won the battle against Astyages. The ruins today, though few, arouse admiration in the visitor. Cyrus also kept Babylon as a winter capital.

No Persian chauvinist, Cyrus was quick to learn from the conquered peoples. He not only conciliated the Medes but joined them with the Persians in a kind of dual monarchy of the Medes and Persians. Cyrus had to borrow the traditions of kingship from the Medes, who had ruled an empire when the Persians were merely their vassals. It is probable that a Mede was traditionally made an adviser to the Achaemenid king, as a sort of chief minister; on later reliefs at Persepolis, a capital of the Achaemenid kings from the time of Darius, a Mede is frequently depicted together with the great king. The Elamites, indigenous inhabitants of Persis, were also the teachers of the Persians in many ways, as can be seen, for example, in the Elamite dress worn by Persians and by Elamite objects carried by them on the stone reliefs at Persepolis. There also seems to have been little innovation in government and rule, but rather a willingness to borrow,

combined with an ability to adapt what was borrowed to the new empire. Cyrus was undoubtedly the guiding genius in the creation not only of a great empire but in the formation of Achaemenid culture and civilization.

Little is known of the family life of Cyrus. He had two sons, one of whom, Cambyses, succeeded him; the other, Bardiya (Smerdis of the Greeks), was probably secretly put to death by Cambyses after he became ruler. Cyrus had at least one daughter, Atossa (who married her brother Cambyses), and possibly two others, but they played no role in history.

When Cyrus defeated Astyages he also inherited Median possessions in eastern Iran, but he had to engage in much warfare to consolidate his rule in this region. After his conquest of Babylonia, he again turned to the east, and Herodotus tells of his campaign against nomads living east of the Caspian Sea. According to the Greek historian, Cyrus was at first successful in defeating the ruler of the nomads—called the Massagetai—who was a woman, and capturing her son. On the son's committing suicide in captivity, his mother swore revenge and defeated and killed Cyrus about 529 BC. Herodotus' story may be apocryphal, but Cyrus' conquests in Central Asia were probably genuine, since a city in farthest Sogdiana was called Cyreschata, or Cyropolis, by the Greeks, which seems to prove the extent of his Eastern conquests.

It is a testimony to the capability of the founder of the Achaemenid empire that it continued to expand after his death and lasted for more than two centuries. But Cyrus was not only a great conqueror and administrator; he held a place in the minds of the Persian people similar to that of Romulus and Remus in Rome or Moses for the Israelites. His saga follows in many details the stories of heroes and conquerors from elsewhere in the ancient world. The manner in which the baby Cyrus was given to a shepherd to raise is reminiscent of Moses in the bulrushes in Egypt, and the overthrow of his tyrannical grandfather has echoes in other myths and legends. There is no doubt that the Cyrus saga arose early among the Persians and was known to the Greeks. The sentiments of esteem or even awe in which Persians held him were transmitted to the Greeks, and it was no accident that Xenophon chose Cyrus to be the model of a ruler for the lessons he wished to impart to his fellow Greeks.

In short, the figure of Cyrus has survived throughout history as more than a great man who founded an empire. He became the epitome of the great qualities expected of a ruler in antiquity, and he assumed heroic features as a conqueror who was tolerant and magnanimous as well as brave and daring. His personality as seen by the Greeks influenced them and Alexander the Great, and, as the tradition was transmitted by the Romans, may be considered to influence our thinking even now. In the year 1971, Iran celebrated the 2,500th anniversary of the founding of the monarchy by Cyrus.

**BIBLIOGRAPHY.** R.N. FRYE, *The Heritage of Persia*, pp. 78–87 (1963), gives a general survey with archaeological discoveries at Pasargadae and elsewhere in Iran. HERODOTUS' *History*, XENOPHON'S *Cyropaedia*, and CTESIAS' *Fragment* are not only the principal but practically the only sources on Cyrus; later works only copy these. A.T.E. OLMSTEAD, *History of the Persian Empire*, pp. 34–67 (1948), is a highly readable and scholarly, occasionally imaginative, account of Cyrus.

(R.N.F.)

## Czechoslovakia

The position of Czechoslovakia in the heart of Europe has been of great significance, affecting the economic, political, and cultural development of a country in which the most varied of influences and traditions have encountered one another. The elongated shape of the country—its east–west extent is more than 465 miles (748 kilometres), whereas its maximum north–south extent is barely 171 miles—has further differentiated its internal physical and human geography, western European influences being strong in Bohemia while those of eastern Europe predominate in eastern Slovakia. The nation's position on the boundary between Communist and capitalist systems has added a new element to this situation.

The legacy of Cyrus

An inland country, Czechoslovakia (formally the Czechoslovak Socialist Republic) lies across the great ancient trade routes of Europe, following the Elbe (Labe) River to the North Sea, the Oder (Odra) River to the Baltic, and the Danube (Dunaj) River to the Black Sea. There were also routes to the Mediterranean. Modern Czechoslovakia came into being at the end of World War I, following the collapse of the Austro-Hungarian Empire. By the mid-1970s its area of 49,374 square miles (127,877 square kilometres) held a population of well over 14,850,000. It is subdivided into the Czech Socialist Republic (EsR), of about 30,450 square miles (78,863 square kilometres), comprising the historic lands of Bohemia and Moravia (often called the Czech Lands) and the Austrian portion of Silesia; and the Slovak Socialist Republic (SSR) of about 18,920 square miles (49,014 square kilometres), which before World War I was a part of Hungary inhabited mainly by Slovaks.

Czechoslovakia is a member of the Council for Mutual Economic Assistance (Comecon), the Communist-bloc trade group, and also of the Warsaw Treaty Organization. Three-quarters of its frontiers are with other Communist countries—the German Democratic Republic in the northwest, Poland in the north, the Soviet Union in the east, and Hungary in the southeast—the remaining borders being with Austria in the southwest and the Federal Republic of Germany in the west. The capital is Prague.

This article is concerned with the contemporary country. For history, see *BOHEMIA AND CZECHOSLOVAKIA, HISTORY OF*. For information on related subjects, see *CARPATHIAN MOUNTAINS*; *DANUBE RIVER*; and *PRAGUE*.

#### THE LANDSCAPE

**The natural environment.** Topography. Czechoslovakian geographers divide the country into two large provinces, the Bohemian Massif (České masiv) in the west and the Carpathian Mountains in the east; each of these provinces is divided into several smaller regions.

Bohemian  
Massif

The Bohemian Massif, also called the Bohemian Highlands (Česká vysočina), forms a large elevated basin (the Bohemian Plateau, or Česká tabule) encircled by mountain ranges that occasionally reach heights exceeding 3,000 feet (900 metres) above sea level. These include the Sumava, Český les (Bohemian Forest), Krušné hory (Ore Mountains), Krkonoše, Hrubý-Nizký, Hrubý Jeseník, Nizký Jeseník, and the Bohemian-Moravian Uplands.

The massif may be divided into seven major orographic units. The largest is the Southern Bohemian Highlands (Jihočeská vysočina), which comprise the older, crystalline core of the massif and of which the most important parts are the Bohemian-Moravian Uplands, the Central Bohemian Highlands (Středočeská pahorkatina), the Southern Bohemian Basin (Jihočeské pánve; centred on the lake district to the east of České Budějovice), and, encircling the southwestern end of the country, the Šumava Subsystem (Podsoustava Šumavy; comprising the Český les and Sumava proper).

Northwest of the Southern Bohemian Highlands are the Berounka River Highlands (Pobereňská vrchovina). The city of Plzeň lies at the centre of this region. To the northwest of these ranges are the Krušné hory, which form the frontier with the German Democratic Republic, comprising two elongated subsystems paralleling the border. The lowest point in the Bohemian Highlands (384 feet [117 metres]) is found here, where the Elbe (in Czechoslovakia called the Labe) breaches these ranges as it enters East Germany.

To the east of the Krušné hory are the Sudeten (Czech and Polish Sudety) mountains, which form most of the border between these two countries west of Ostrava and in which is found the greatest altitude in the Bohemian Highlands, 5,256 feet (1,602 metres), at Sněžka in the Krkonoše range.

The Brněnska (Brno) Highlands, south of the central Sudeten, are the fifth and last of the uplands which enclose the Bohemian Plateau; here is found the spectacular Moravian Karst.

The plateau itself, also called the Labe plain, or Polabí, after the Labe River, which traverses it from east to

west, receives the Vltava on its left bank, about 18 miles (30 kilometres) below Prague, which stands among the hills at the southern edge of the Polabí.

The seventh, and smallest, region is the Oder Lowland (Oderská nížina), a small fringe along the Polish border that may be considered to be a small foreland of the eastern Sudeten.

The Carpathian Mountains dominate the eastern part of the country; they comprise a system of east-west ranges separated by valleys and intermontane basins. The highest ranges are the Nizke Tatry (Low Tatras), reaching about 6,000 feet, and the Vysoké Tatry (High Tatras), containing the highest point in the republic, Gerlachovský štít (Gerlach Shield), 8,711 feet (2,655 metres).

Four orographic regions are recognized in this province: the Outer Carpathian Depressions (Vněkarpatské sníženiny), the Inner Carpathian Depressions (Vnitrokarpatské sníženiny), the Outer Carpathians, and the Inner Carpathians.

The Outer Carpathian Depressions, from the geographer's viewpoint called the Moravian Corridor, are the narrow lowlands that separate the Bohemian Massif from the easternmost Carpathians; these include the valleys of the upper Oder (Odra) and Morava rivers and the headstreams of the Dyje (although not the lower courses of the last two, as these belong to the Inner Carpathian Depressions). Two other large lowland areas comprise the remainder of the Inner Carpathian Depressions region; these are the Danubian Lowland (Podunajská nížina) and the Eastern Slovakian Lowland (Východoslovenská nížina), which are probably better classified as outliers of the Hungarian Plain, to the south, than as intermontane basins.

The Carpathian Mountains proper consist of two regions, the Outer Carpathians, to the north, composed of flysch, with a well-developed nappe (horizontally overthrust and folded sedimentary beds) structure; to the south, the Inner Carpathians, composed of a crystalline core mantled by Mesozoic sediments and, farther south, by Neogene volcanic series.

According to the definitions of Czechoslovak geographers, mountains and high mountains (lands above 600 metres [1,968 feet]) occupy 23 percent of the country, uplands (200 to 600 metres [656 to 1,968 feet]) occupy 67 percent, and lowlands (below 200 metres [656 feet]) only a scant 9 percent.

**Climate.** The Czechoslovak climate is mixed, its continental tendencies being masked by large fluctuations in both temperature and precipitation and oceanic influences diminishing from west to east. Relief variations show up in temperature figures: the mean annual temperature drops to 25.4° F (−3.7° C) in the High Tatras, rising to 50.9° F (10.5° C) in the Danube lowlands. Average July temperatures exceed 68° F (20° C) in the Danube lowlands, and average January temperatures can be as low as 23° F (−5° C) in mountain basins. The growing season is about 200 days in the south and less than half that in the mountains. Annual precipitation ranges from 18 inches (450 millimetres) in the central Bohemian basins, to more than 60 inches (1,500 millimetres) on windward mountain slopes in the Krkonoše (Giant Mountains). Maximum precipitation falls in July, minimum in February. There are no recognizable climatic zones but rather a succession of small and varied districts; climate thus follows the topography in contributing to the diversity of the natural environment.

**Soils.** Rich, black chernozem soils (10 percent of the total) and good-quality brown soils (another 20 percent) occupy the drier and lower portions of the country. The soils known as podzols, occurring in regions with more than 23 inches (600 millimetres) of rainfall annually, constitute 50 percent of all of the soils in the country but only a third of the agricultural land. Stony mountain soils in the highest regions and rich alluvial soils alongside river courses are characteristic. This soil variety is again further complicated by topographic variations, with loamy-sandy soils commonest in the Bohemian Massif and heavy clay soils predominant in peripheral zones of the Carpathians.

Danube  
River

Drainage. Czechoslovakia lies in the headwater area of the main European watershed, with the Elbe draining 39 percent of the country, the Oder and Vistula 7 percent, and the Danube 54 percent. There are many small rivers of little economic importance, and only five rivers have a mean annual discharge of more than 3,500 cubic feet (100 cubic metres) per second. Only the Danube, which barely touches Czechoslovak territory, stands comparison with the great rivers of the world, with a discharge of 78,000 cubic feet (2,200 cubic metres) per second at Bratislava. The greatest flows generally occur in spring, when the rivers are swollen by melting snow, and the lowest in summer. Weather variations can seriously affect water supply, as the ratio of minimum to maximum flow can approach 1:250. The country is rich in mineral springs, and good use is made of the groundwater reserves.

Plants and animals. Czechoslovakia's vegetation may be divided into three major groups: Hercynian (central and western European), Pannonian (steppe), and Carpathian (eastern Europe and Siberian). Each of these groups is modified by altitudinal and other climatic influences. Although large areas of original forest have been cleared for cultivation, forests still cover more than a third of the country. The major forest types include the oak (*Quercus robur*), steppe oak (*Q. pubescens*), and oak-grove assemblages of the lowlands and uplands adjoining the Danubian Plain; the beech forests of the Carpathians (*Fagus sylvatica*); and the spruce (*Picea abies*) forests of the Carpathians and adjoining areas of Bohemia and Moravia. In the very highest elevations can be found taiga and tundra assemblages characteristic of more northerly or more elevated regions elsewhere in Europe. Since cultivation is mostly restricted to areas of level terrain, the proportion of original forest cover is highest in mountainous areas.

The timberline runs at about 4,500 feet above sea level

in the west, rising to about 5,000 feet in the east. At these higher elevations, particularly in the Tatras, the tree cover below the timberline consists of little more than dwarf pine (*Pinus mugo*). The alpine zone contains grass and bushes (*Vaccinium*, *Calluna*, *Salix retusa*, and others); above 7,500 feet, lichens predominate.

Czechoslovakia's wildlife is extensive and varied; the High Tatra National Park probably shelters the most exceptional collection of wild animals, including bear, wolf, lynx, wild cat (*Felis silvestris*), marmot, otter, marten, and mink. Most of these may be hunted, although the parks themselves are fully protected. Certain other animals, however, are protected everywhere; the chamois, for example, very near extinction for many years, now appears to be increasing in numbers. Birdlife is everywhere; game birds are common in forests and marshes, especially pheasant, partridge, wild goose, and duck. All may be hunted, but larger species such as eagle, vulture, osprey, stork, eagle owl, bustard, and capercaillie are much rarer and often protected.

Although the history of wildlife protection in Czechoslovakia is not long, and although tourism is one of the major purposes of these areas, much attention is devoted to the preservation of the natural heritage. Game reserves exist for the breeding of rare or endangered species such as the mouflon. Nature reserves have been created to preserve especially important landscapes: the Sumava Forest, Moravian Karst, and Jizerské hory (mountains and peat bogs) are among the most significant.

The two largest and most important areas, however, are the High Tatra and Krkonosé (Giant Mountains) national parks. The former, established in 1948 and occupying 190 square miles (500 square kilometres), is an international area, being contiguous with, and jointly administered with, the Polish Tatrzanski Park Narodowy. It preserves most of the species of wildlife mentioned above, together with a glacial landscape, alpine flora and fauna, and relict species from the Pleistocene glaciations. Krkonosé National Park, established in 1963 and occupying some 147 square miles (380 square kilometres), protects glacial and alpine landscapes and vegetation and some relict boreo-Arctic species, such as the alpine shrew (*Sorex alpinus*); it is most extensively developed, however, as a ski resort.

Traditional regions and the human imprint. Industrialization and urbanization have wiped out many of the former traditional regions of Czechoslovakia, although, reflecting differing national and cultural heritages, Bohemia, Slovakia, and to a lesser extent Moravia are still recognizable entities. Local traditions are preserved in the mountainous parts of Slovakia in the wearing of folk costumes on holidays and in the preparation of local dishes, the making of cheese, and the preserving of fruits and vegetables. Similar traditions have been preserved in southern Bohemia and in southeastern Moravia.

The country has a high density of settlement, with communities lying, on average, only a few miles apart. The total number of separate settlements exceeds 20,000, but there are fewer than 11,000 communes. Rural settlements are characteristically compact, but in the mountainous regions, colonized during the 13th and 14th centuries, straggling row villages are common. Dispersed rural settlements tend to be exceptional, occurring mostly on the Moravian-Slovakian boundary and in central Slovakia and reflecting the later colonization of the 17th and 18th centuries. Rural settlements with fewer than 500 inhabitants tend to prevail except in south Moravia and southwest Slovakia. The collectivization of farmland that took place in the decades following World War II has resulted in a pattern of large, regularly shaped fields, replacing the centuries-old division of land into small, irregular, privately owned plots.

Urbanization in Czechoslovakia is not particularly high for an industrialized country, only 47 percent of the population residing in communes with more than 5,000 inhabitants (1970) and 15 percent living in communes with 2,000-5,000. Even the smallest urban centres, however, usually contain some manufacturing industry. There are six cities with more than 100,000 inhabitants (accounting

for 16 percent of the national population, and nearly half of this is attributable to Prague), but there are 64 in the 20,000–100,000 range (15 percent). Urbanization is greater in Bohemia than in Slovakia, although postwar industrialization in the latter has reduced the disparity. Prague, with a population of 1,170,000 (1976), is the national capital, historically occupying a predominant role. Bratislava, capital of Slovakia, has a population of 341,000, and Brno, chief city of Moravia, 360,000. The other large cities are Ostrava (301,000), the leading Czech coal-mining and steel centre; Košice (174,000), with its large steel complex; and Plzeň (156,000), with old established engineering and brewing industries.

#### THE PEOPLE

Composition. Archaeological findings confirm that what is now Czechoslovakia contains regions with some of the oldest settlements in Europe; in particular, a continuous agricultural settlement of the forest-steppe areas, up to 900 feet above sea level, can be dated back to the 4th millennium BC. An ensuing series of invading waves of population was brought to an end by the West Slavs, who settled the whole territory—with the exception of the mountainous regions—in the 5th and 6th centuries AD. The later German and Hungarian minorities were the result not only of immigration but also of some assimilation of the native population.

Differing economic and political developments resulted in a differentiation of the originally uniform Slav population into Czech and Slovak components, the latter people forming one of the youngest such entities in Europe. The very similar Czech and Slovak languages belong to that group of Slavic languages that uses the Roman rather than the Cyrillic alphabet. The literary Czech language dates from the beginning of the 15th century, Slovak from the 19th.

Anthropologically, the population of Czechoslovakia is very mixed, about half the people exhibiting the physical traits of the Alpine local race and thus reminiscent of western Europe, while east European Baltic elements predominate farther east, and Dinaric elements manifest themselves in Slovakia. Cultural exchanges resulting from dependence on the Austro-Hungarian monarchy until 1918 resulted in an influx of German and west Eu-

ropean influences, whereas the linguistic affinity, together with political developments since World War II, has cemented ties with eastern Europe.

Czechs and Slovaks form the great majority (more than 94 percent) of the population, in contrast to the situation before World War II when minorities made up 39 percent. The postwar expulsion of Germans, an exchange of populations with Hungary, and the cession of Ruthenia (with a Ukrainian population) to the Soviet Union brought about the present homogeneous state. By the mid-1970s Czechs numbered 9,500,000 and Slovaks 4,400,000. There were about 580,000 Hungarians in southern Slovakia, small groups of Ukrainians near the Soviet frontier, and a few Poles in northeastern Moravia. Fewer than 80,000 Germans remain, living in northwestern Bohemia. Gypsies—who have no legal status as an ethnic group—are estimated to number between 200,000 and 300,000; according to some sources, they constitute the largest Gypsy population in any one country.

Religion. No official statistics on religion are kept, though the activities of the churches have been financed by the government since the nationalization of all church property in 1949. Roman Catholics are preponderant, but there is an Evangelical element in Slovakia, and a significant number of people have no formal religion. Atheism is the official government philosophy, and the churches' role is largely restricted to religious rites. Clergy are civil servants and required to take an oath of loyalty to the government.

Demographic trends. Although Slovakia shows a natural increase that is higher than that in the rest of the country as a whole has a moderate to low rate of natural increase. The annual rate decreased from nearly nine per thousand in 1955–59 to only five in 1965–69, essentially because of a falling birth rate. The rate of natural increase had recovered significantly by the mid-1970s, however, to about eight per thousand, owing to a rising birth rate (19.5 per thousand in 1975), which is attributable in large part to pro-natalist government policy. The mortality rate, about 11.5 per thousand, conceals an important difference between the ČSR (12.4) and Slovakia (9.5), this being largely attributable to the more youthful age structure of the latter. Infant mortality, at about 21 per thousand, is comparable to that of the more advanced countries.

A serious demographic problem is created by the fact that there are few families with more than two or three children, and the number of children per family is decreasing. Although the marriage rate is rather high, the divorce rate is climbing; by the 1970s (as in other European countries) it exceeded 20 percent of new marriages. This factor, together with the changes in way of life associated with urbanization and employment of women in the labour force, helps to explain the rather low rate of population increase.

Internal movements of population are of increasing significance with the further modernization of the economy. Migration is directed from the country to the towns and from the smaller towns to the larger cities. In fact, there is a net decline in the number of local inhabitants in most Czechoslovakian communes. Although the lower natural growth rate in the west has been supplemented by immigration from Slovakia, this movement has declined with the growth of urbanization in Slovakia itself.

In the past, population growth was slowed by emigration to the urban centres of the Austro-Hungarian Empire and farther afield, especially to the United States. The main emigrant regions were eastern and central Slovakia, and by the 1970s it was estimated that there were about 1,000,000 Czech and 1,500,000 Slovak emigrants and their descendants living in the United States, although only fragile ties were retained with the homeland after the second generation. Emigration now is a mere trickle.

The most complicated demographic problems in contemporary Czechoslovakia stem from the fact that, with only moderate birth rates and a prolongation of average life-span (approaching 67 for men, 74 for women), the population is aging. In 1950 less than 12 percent of the people were over 60; in 1975 the figure exceeded 17

tion  
move-  
ment

The  
Czechs  
and the  
Slovaks

Female  
employ-  
ment

percent. The highest percentage of old people occurs in central and eastern Bohemia; the Slovak population is generally younger because of the higher birth rate.

Half of the total population is in the labour force, a total of 7,435,000 people. The female employment rate is among the highest in the world, almost half of all the employed people being women. Industry and construction take up about 48 percent of the total labour force, with agriculture, transport and trade, and services taking almost 52 percent of the remainder. There are considerable regional variations to this pattern, with industry predominating in urban areas and the number of persons engaged in agriculture increasing eastward, although only a third of the rural population works, on the average, in agriculture. Independent small producers and co-operative farmers represent only 2 percent and 11 percent, respectively, of the labour force.

Geographic conditions make possible the settlement of almost the whole of Czechoslovakia, but the population tends to be concentrated at lower altitudes, more than half the population living below about 1,300 feet above sea level. There is an abrupt decline in population density with increasing altitude. A notable feature is the low density in some frontier areas, partly reflecting the induced emigration of minorities in the post-World War II years; the CSR was one of the few European political entities to have fewer people (9,800,000) in 1970 than in 1910 (10,080,000), a circumstance explained by war losses and the expulsion of 2,500,000 Germans.

The demographic outlook for Czechoslovakia is not dynamic; the total population will grow only slowly, and the aging of the population will continue unless the recent revival of the birth rate can be maintained. The situation is most serious in agricultural areas and the interior of the CSR, and there are prospects that the Slovak share of the national population will increase, shifting the demographic centre of gravity eastward. (M.Bl./R.H.O.)

#### THE NATIONAL ECONOMY

Although Czechoslovakia is not rich in natural resources, its economy is one of the most advanced in eastern Europe. It uses more chemical fertilizers and machinery per acre and boasts higher agricultural yields than most other east European countries. Its industry is highly developed, providing a substantial share of total east European production. It is a very important supplier of a wide range of machinery for fellow Comecon members and is eastern Europe's largest manufacturer of a number of engineering products. National income has grown relatively slowly since World War II, if compared with the performance of other European countries in the Communist bloc, but in the 1970s it was estimated that, after the German Democratic Republic, Czechoslovakia was the second most prosperous country in the entire Communist world. It is also eastern Europe's largest foreign trader in per capita terms.

Coals

Natural resources. *Mineral resources.* Black and brown coals are produced in significant quantities, output in relation to population being high by world standards, but deposits of petroleum and natural gas are small. Most of the black coal is derived from the Ostrava-Karviná coalfield, though it is also mined near Kladno, in the Plzeň basin, near Trutnov, and near Brno. A high proportion of the black coal is of coking quality. Production of brown coal (including small quantities of lignite) increased rapidly up to the mid-1960s but remained static thereafter; open-pit methods are used. The main mining areas are around Chomutov, Most, Teplice, and Sokolov. The brown coal is used extensively for thermal power stations and for domestic fuel, and large quantities are also utilized as raw material in the chemical industry. New investment should lead to increased brown coal output by the late 1970s. Petroleum and natural gas are produced near Hodonín, but only in small quantities. There is a great reliance on pipelines importing Soviet oil and natural gas, the latter supplementing existing coal gas supplies.

Czechoslovakia has a limited endowment of metallic ores. Iron ore is mined chiefly in the Slovak Ore Moun-

tains (Slovenské Rudohorie), while areas between Prague and Plzeň are historically important. Because of the gradual exhaustion of reserves, annual production fell after 1960 and remained static through the late 1960s and mid-1970s at about 1,700,000 tons. There is a great reliance on imported iron ore, especially from the Ukrainian S.S.R. Copper and manganese ores are also mined in the Slovak Ore Mountains. Lead and zinc ores are mined near Kutná Hora, Příbram, and Banská Štiavnica and in the Jeseník Mountains. Uranium is also mined near Příbram. The Ore Mountains (Krušné hory) of Bohemia yield small quantities of tin. Imported bauxite and nickel ore are refined at Žiar nad Hronom and Sereď, respectively. Other mineral resources include salt in east Slovakia, graphite near České Budějovice, and kaolin near Plzeň and Karlovy Vary.

*Biological and hydroelectric resources.* Just under 55 percent of the country's total land area consists of agricultural land, and the bulk of this is arable land, with few meadows and pastures. On the lowlands the soil is generally fertile, but in the mountainous regions it is considerably less productive. More than one-third of the country's surface is wooded (see also above *Soils; Plants and animals*). Hydroelectricity plays a small part in the country's total energy supplies. Power stations are located on the Váh and Vltava rivers, but their output represents less than a tenth of total electricity production.

Sources of national income. *Agriculture.* At the beginning of the 1960s, agriculture accounted for 16 percent of total net material product, but by the end of the decade its share had dropped by a quarter. Growth in this sector—which employed only about 14 percent of the economically active population by the mid-1970s—has been adversely affected by the government planners' emphasis on industry and, in the opinion of Western observers, by the disincentives associated with collectivization. Commentators also avow that another weakness of the authorities' farm policy has been the low prices paid to farmers and that, although these have been revised upward, there is still a considerable difference between rural and urban incomes.

Czechoslovak agriculture is, nevertheless, unquestionably one of the most advanced in the Communist bloc, and yields tend to be better than the average for eastern Europe as a whole. The program of rural collectivization was completed by 1961, although much consolidation of cooperative farms took place afterward (between 1971 and 1976 their total number fell from 6,200 to 2,200, while land held by them rose by 7 percent). Production is organized on the basis of these 2,200 cooperatives and a small number of state farms. Cooperatives in 1975 owned 63 percent of the total agricultural land (including 2.4 percent that is allotted to personal use of individual members) and accounted for 61 percent of total farm output (in addition, private production, 5 percent). State farms worked 30 percent of the land and provided 27 percent of food production. For private farms and plots, the percentages were 6.7 and 7, respectively.

On the fertile lowlands, wheat, barley, sugar beets, maize (corn), and fodder crops are the most important, but on the relatively poor soils of the mountains the principal crops are rye, oats, and potatoes. Cereals lead in total production, with wheat, barley, oats, and rye, in that order, as the most important crops. Other important agricultural items include potatoes. The country also raises a sizable amount of livestock.

*Industry.* By the mid-1970s industry accounted for nearly two-thirds of the country's net material product and employed nearly 40 percent of the economically active population. The period from 1955 to 1970 was characterized by a very rapid growth in industry, the index of industrial production advancing more than 160 percent. Growth tended to be fastest in heavy industry, but it fell behind—in terms of both quality and quantity—in light industry and in consumer goods. Engineering is the largest branch of industry, constituting more than a quarter of total industrial production. In close second place is the food industry, followed by ferrous metallurgy (about 10 percent of the total), fuel mining and process-

Declining  
share of  
agriculture

ing, and the chemical, rubber, and asbestos industries. Czechoslovakia's iron and steel industries are the second largest in eastern Europe, after the Soviet Union, based largely on imported ores. Steel production is centred on the plants of the Ostrava area, with lesser amounts produced at Kladno, Plzeň, and Chomutov (all in Bohemia); the major centre in Slovakia is Košice.

Czechoslovakia is eastern Europe's largest producer of a number of engineering products, including electric and diesel locomotives and passenger cars.

**Energy.** Czechoslovakia is dependent on solid fuels for 70 percent of its energy supplies, which are not adequate to meet domestic requirements. The importance of liquid fuels and natural gas is expected to grow, while it is estimated that the share of hydroelectricity will remain unchanged at 1.5 percent. Electricity output has risen substantially, but shortages still pose a serious problem. The bulk of this output is derived from brown coal. There is a nuclear power station near Trnava. Oil and natural gas imports from the Soviet Union are necessary.

**The financial sector and foreign trade.** Banking is nationalized, with the State Bank of Czechoslovakia (Státní banka československá) as the most important of the country's financial institutions; it is the sole bank of issue, provides credit to enterprises, manages the foreign-exchange reserves, and administers the government's overall financial policy. Some loans are also provided by the Investment Bank, while the Commercial Bank of Czechoslovakia (Československá obchodní banka) specializes in trade and related transactions. There are also the Czech and Slovak State Savings Banks (Česká i Slovenská státní spořitelna) and the Trade Bank (Zivnostenská banka), which provides banking service for foreigners.

The country is highly dependent on foreign trade; in per capita terms it is the largest foreign trader in the Communist bloc. The foreign-trade account has generally been in surplus, although trade with the advanced capitalist world usually yields a deficit. The rising prices of raw material imports had become an adverse factor by the mid-1970s. The lion's share of foreign trade—about 70 percent—is accounted for by Communist countries, including the Soviet Union (about one-third), followed by the German Democratic Republic and Poland. Outside the Communist bloc, its largest trading partner is the Federal Republic of Germany, which accounts for more than 6 percent of total imports and exports.

About 47 percent of all of the imports are raw materials, of which fuels, minerals, and metals are the most important. The second largest group consists of machinery and tools, followed by food and consumer goods. On the export side, about one-half is made up of sales of machinery—including motorcars and machine tools, electric-power machinery, switchgear, and textile and leather machinery—much of which is shipped to fellow Comecon countries. This is followed by sales of raw materials (*i.e.*, wood, metalliferous ores and scrap, and some chemicals), which accounted for about 30 percent of the total, and consumer goods (about 18 percent).

**The management of the economy.** The state plays an extremely important role in the economy. Approximately 90 percent of all of the agricultural land is in the hands of the state farms and the cooperatives, and industry, banks, and most trading and service enterprises are owned and closely controlled by the government. Private enterprise is tolerated on a very small scale only and mainly in certain specified areas such as handicrafts, some service trades, and some farming activities. All in all, the private sector accounts for less than 5 percent of the net material product and employs no more than 4 percent of the country's labour force. Economic planning is based on detailed five-year plans, which lay down a large number of targets in all the areas of the economy but, as elsewhere in the Communist bloc, are less centralized than they were in earlier years.

**Taxation.** As the state derives substantial revenue from the profits of the state enterprises, taxes play a relatively small role in the budget—less than 15 percent of total budgeted revenue. The principal tax is the turnover tax on consumer goods that is levied on producer,

wholesaler, retailer, and ultimate buyer and that accounts for 63 percent of all tax receipts. This is followed by the payroll tax on enterprises, with a 28 percent share; the remainder is made up of a large number of different levies, the yield of which is insignificant.

**Trade unions.** Most workers belong to the trade-union movement, which is organized by industry and, as in other Communist countries, plays a central role in implementing national economic policy. The major function of the unions is to mobilize the working force to support the regime.

**Economic policies, problems, and prospects.** Up to 1960, economic progress was fairly rapid, but the subsequent years brought a slowdown in growth, and the authorities drew up an extensive program for reforming the system of economic management. In broad terms, the avowed aim was to reduce reliance on rigid central regulation of the economy—which had proved to be unable to match supply and demand or to ensure maximum efficiency—and to replace it with greater emphasis on a balancing of economic forces. A program embodying these goals came into effect from 1966; its principal features were a revision of the pricing system, which freed some prices from central control, and the granting of greater independence to individual enterprises.

By 1968, however, it became apparent to both Czechoslovak economists and Western commentators that the reform program had run into serious trouble. It led to a much faster rise in prices than anticipated, and it expanded consumer and investment demand to levels that could not be satisfied. After the invasion of the country by Warsaw Pact forces in August 1968, the newly installed government introduced firmer control over prices, investment, and the whole economy; according to the new plans, trade with the Soviet Union would grow faster than that with the West. As a result of these and other changes, the system of economic management is, in the opinion of Western observers, somewhat more rigid than that of some other east European countries, although it is generally accepted that it is still more flexible than it was before the ill-fated reform program.

It is also generally accepted that the Czechoslovak economy, like the economies of many other countries, both East and West, is faced with a number of difficulties in the 1970s. The reforms outlined by the Dubček regime of January–August 1968, along with earlier defects in the economic system, have been decisively rejected. Yet a new, comprehensive strategy was, not unexpectedly, slow to evolve. The difficulties of the 1960s left a heritage of lack of purpose and confidence, a problem made even more serious by widespread industrial apathy and poor labour discipline. Among the more pressing specific problems acknowledged by both Czechoslovak economists and outside observers in the 1970s were the low level of productivity, the lack of advanced equipment in many industries, the shortage and poor quality of consumer goods, and the neglected state of the country's infrastructure.

In spite of such difficulties, the Five-Year Plan for 1971–75 was a notable success, national income rising by about one-third. The plan for 1976–80 envisaged further economic expansion, aided by selective industrial re-equipment, a continued export drive, and greater collaboration within the Comecon bloc. (E.I.U./R.H.O.)

#### TRANSPORTATION

Czechoslovakia has a typical inland transport system, the modernization of which has taken place only in recent decades. Transit functions, whereby the country was merely a link in trans-European trade, lost much of their importance in the new political and economic conditions that prevailed on the Continent after 1945.

**The railways.** The most important element of the transport system is the railways, which are especially important in freight transport, notably of coal (about 40 percent of the total), ores, metals, and building materials. Density of the railway network is fairly high at 26.8 miles per 100 square miles (10.3 kilometres per 100 square kilometres) but is not always effective. The rail-

Banks

The role of the state in the economy

Continuing problems of the economy

ways developed in the second half of the 19th century and mostly ran from north to south, to Vienna and to Budapest, whereas the main trend of present-day transportation runs east-west. Communications with the main trading partner of Czechoslovakia, the Soviet Union, have been facilitated by an extensive program of reconstruction and electrification; more than 20 percent of all lines had been electrified by 1975. Most freight moves along main-line routes, but short journeys in the vicinity of the larger towns are of decisive importance in passenger traffic.

**Road, water, and air transport.** The density of roads and the number of scheduled bus routes are also high, and the transport of passengers and freight by state-owned vehicles predominates. Again, the urban centres are the focus of the most intensive road networks. Although Czechoslovak roads are of good quality, there are few of the throughways and expressways familiar in the West, and the Western visitor is surprised by the small number of private cars seen on the Prague-Brno road. Only in Prague and its surroundings and on weekends in other large cities does traffic flow approach the west European level; the emphasis on cheap mass transportation is an attempt to forestall in Czechoslovakia the traffic paralysis that plagues many countries.

Czechoslovakia's position in the headwater area of the main European watershed means that the potential of water transport is small; of the rivers flowing through the country, including the Danube, only small portions actually in the country are navigable. Freight is transported on the Elbe to Hamburg, which functions as a port for mixed cargo, but Danube river transport, with Komárno the largest Czechoslovak port, now predominates, carrying raw materials imported from the Soviet Union and its neighbours. Although natural conditions would facilitate the construction of canals linking the Danube, Oder, and Elbe, such projects would be very expensive, and their construction—which would make Czechoslovakia the centre of European waterway routes—would also require international cooperation.

Air connections between Prague, Bratislava, and other regional centres are of considerable importance, and Prague itself is a major international air centre. Finally, major changes in freight transportation have been introduced by the Družba (Friendship) oil pipeline running into the country from the Volga River region of the Soviet Union, and also by a gas line from Siberia, which runs beyond Czechoslovakia to western Europe.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**The constitutional framework.** According to the constitution of 1960, as modified by the Constitutional Law of 1968 and by subsequent amendments in 1970 and 1975, Czechoslovakia is a Socialist federative republic, with all power derived from the people. The head of the federation is the president, elected by the two-chamber Federal Assembly, which consists of the Chamber of the People (Sněmovna lidu) and the Chamber of the Nations (Sněmovna národů). The latter consists of equal delegations from the national councils; *i.e.*, the legislative bodies of the Czech and Slovak Socialist republics.

The government of the federation (*i.e.*, the president, with the premier, deputy premiers, and ministers), appointed by the president, is theoretically responsible to the Federal Assembly. In practice, however, the power of the government is greater than that of the assembly, and the power of the Communist Party is greater than that of either. Individuals often occupy seats of rank in both government and party.

Political life is organized by the National Front, a union of political parties and mass organizations, including the trade unions and women's and youth groups. The Communist Party of Czechoslovakia (Komunistická Strana Československa, or KSČ), with more than a million members, is the dominant element in the National Front, and its leading position is embodied in the constitution. It thus has an effective monopoly of political power. Though there are several other political parties, they function as auxiliaries to the KSČ rather than as an op-

position. Organizations that are not members of the National Front are not permitted to function.

The president of the Central Committee of the National Front is also the general secretary of the Communist Party, and the front controls elections at all levels, presenting single lists of candidates, one candidate for each seat. All of the component organizations of the front have constituent branches representing the local government units, as well as individual plants and economic enterprises.

**Local government.** Local administration is controlled by "national" committees that operate on three levels. Czechoslovakia is divided into seven Czech and three Slovak *kraje* (regions), the capitals, Prague and Bratislava, each occupying independent positions; the regions are subdivided into *okresy* (districts); and these, in turn, are subdivided into numerous *obce* (local communities, or communes). The last named came into being in the 18th century as basic groups of settlements and are being merged. The administrative division underwent changes in 1948, 1960, and 1968.

**Justice.** In the civil division, the lawcourts are most concerned with family affairs, including divorce cases; the criminal courts deal with crime and traffic accidents. Conflicts in the sphere of economic law between the various components of the Communist system are dealt with by independent, government-organized arbitration.

**The armed forces.** The four military forces are integrated as the National People's Army, including ground forces, air and air defense forces, frontier guards, and interior guards (the two last under the Ministry of the Interior till 1965). Their numbers were estimated by Western experts at 180,000 in 1976. Two years of service in the military forces are required from men over age 18 who are physically and otherwise fit and who are called. Discharged conscripts usually remain in the reserves till age 50.

**Services.** The management of houses and apartments is one of the more critical areas of social policy in Czechoslovakia. Local "national" committees control the housing policy, including the 60 percent of apartments that are in private homes as well as the state-owned urban housing projects. Cooperative housing projects are increasingly popular, and private ownership remains important. The housing problem continues to be one of the most severe afflicting the country: by the early 1970s, the average age of housing units was about 60 years, and 10 percent or more of the apartments were more than a century old, although almost a quarter had been built since 1945. About eight new apartments per 1,000 inhabitants are built each year. Almost all housing units are now supplied with electricity, two-thirds with water, and about half with bathrooms and gas connections. There is little regional variation in this regard.

A centrally organized police force, the National Security Corps, under the Ministry of the Interior, takes care of public safety and is supplemented by the voluntary organization of the People's Militia in factories and similar enterprises. The police also combat unauthorized political activity.

Consumer goods and services are made available through national and cooperative retail stores; more than half of the 70,000 or so shops are food outlets. Large department stores and shopping centres are found in the cities and in the new housing developments, and remote settlements are served by travelling stores. Specialized stores and service centres tend to be concentrated in larger urban areas.

**Education.** The system of schools in Czechoslovakia has been built up in the tradition of the great 17th-century European educational reformer John Amos Comenius, who was born in Moravia. Compulsory education, which has existed since the middle of the 18th century, lasts nine years. Preschool education is an important consideration with the children of employed mothers, and there are some day nurseries in operation. Study in secondary schools lasts three or four years. The secondary schools are so located as to be accessible from all the districts. Specialized schools include technical, agricultural,

Waterways

The housing problem

The Communist Party

and commercial schools and schools of social hygiene (which hold nursing classes). The larger towns, as well as traditional cultural centres, are the areas served best.

#### Colleges and universities

Eight undergraduates per 1,000 inhabitants attend the nearly 40 universities and colleges. In the mid-1970s, most students were studying teaching, medicine, engineering, social sciences, and agriculture. The leading educational institutions, providing four to five years of intensive study, have very ancient traditions. Charles University (Universita Karlova, founded 1348) and the Czech Technical University in Prague (Ceskt vysoké učení technické v Praze, founded 1707) are the oldest in central Europe. After World War II, however, higher educational institutions increased in number, especially in Slovakia, where by 1975 about two dozen universities and colleges existed, in comparison with one university before the war. The largest student populations are at Prague (about 51,000) and Bratislava (36,000).

In small nations, instruction in languages is very important. Language teaching starts in Czechoslovakia with Russian in the third year of school, followed later by another major language, usually German or English.

The emphasis on adult education is not so strong as it was in the early years of the Communist regime, but the opportunities are still good.

Research work in Czechoslovakia is organized not only in the universities but also in special research institutions. Basic research is carried out by the Czechoslovak Academy of Sciences, which has institutes in Prague, Brno, and Bratislava.

**Health, recreation, and tourism.** Czechoslovakia is traditionally among the very best equipped countries medically, although Slovakia is somewhat less well served than the Czech Lands. One-half of all of the doctors work in specialized medical establishments and in district and regional hospitals. Czechoslovakia has more than 50 sanatoriums, most of them in the Czech Lands, where more than 360,000 patients, including children and pensioners, as well as more than 19,000 visitors from abroad, are treated each year. For most patients, treatment is free. Half of the spas are in northwestern Bohemia, in such internationally known resorts as Karlovy Vary, Mariánské Lázně, and Františkovy Lázně.

Football (soccer), ice hockey, track-and-field sports, and skiing are among the most popular sports, and playgrounds and gymnasiums can be found in all of the larger communities. The larger towns have winter stadiums and sports grounds. Camping is also popular. The rest centres run by the trade unions are visited by 400,000 persons annually and their summer camps for children by more than 250,000. The main tourist regions are the Krkonoše, the Tatras, and other scenic mountain regions, although many citizens continue to be attracted by the beauty of Prague and other ancient centres.

Half of the families of Prague, Ostrava, and Bratislava have a cottage or cabin in the country near the city. Excursions into the country and the picking of wild berries and mushrooms are favourite forms of recreation, as is gardening: not surprising, as much of the urban population of Czechoslovakia originally came from the country.

Foreign tourists numbered some 8,500,000 annually in the mid-1970s, not a great number considering the attractions of the country. There were about 13,000,000 foreign visitors every year (including those coming for reasons other than holiday), two-thirds of them from other Communist countries, notably the German Democratic Republic, Hungary, and Poland. A considerable number of tourists also come from the Federal Republic of Germany. Czechoslovak citizens themselves mostly visit Hungary, Yugoslavia, the German Democratic Republic, Poland, and Bulgaria.

**Living standards.** Czechoslovakia has a generally good standard of living as compared to the other Communist-bloc countries, about 52 percent of the real national income going to personal consumption. The mean monthly wage shows some variation, industrial workers as a whole getting above-average wages, though lower wages can be found, for example, in the clothing industry and in some services; coal miners receive maximum wages. Farmers'

incomes are about average. Unearned income is forbidden. All workers participate in pension insurance, and the retirement age is 60 years for men and 55 for women. Old-age pensions, however, remain low, approaching only 50 percent of mean wages. Regional variations in income may be up to 40 percent above or below the average, as, for example, between mining districts and cities, on the one hand, and predominantly agricultural districts, with families with many children, on the other; some peasants in remote areas of Slovakia live at subsistence level.

In the average Czechoslovak household of the 1970s, the greater part of the family income is provided by the husband and his working wife. Sick benefits, old-age and disability pensions, and child allowances represent most of the remainder. In farmers' families, the income structure is different, about 15 percent of the income coming from crops they grow and sell privately. In addition, medical care, medicines, and education are free, and there are reduced fares for transportation to and from work. Vacations range between two and four weeks per year, and there is generous paid maternity leave.

About 30 percent of average family expenditure goes to relatively costly food and drink; about 30 percent to manufactured goods; and 30 percent to services, rent, and taxes. As much as 10 percent of the income is reserved for savings. The national beer consumption per capita is the highest in the world. The high rate of calorie intake is largely accounted for by consumption of bread and wheat products, including the ubiquitous national dish, dumplings, of which no fewer than 345 pounds (156 kilograms) per person are eaten each year.

#### CULTURAL LIFE AND INSTITUTIONS

**The setting.** The rich cultural milieu in contemporary Czechoslovakia is rooted in history and the geographic position of the Czechs and Slovaks in Europe. The earliest preserved writings in Czech are hymns dating from the 13th century. The most varied artistic schools have penetrated the country, and Prague and other historic cultural centres exhibit a mixture of architectural styles. The threat of doom to the Czechs and Slovaks as peoples in the 18th and 19th centuries gave national cultural life a strong patriotic element.

**Literature and the theatre.** Literature has occupied an important position in Czechoslovak cultural life since the late 18th century, when the development of an urban middle class created a public for it. Romanticism in the early 19th century was best exemplified by Karel Hynek Mácha, whom some regard as the greatest Czech poet of all time. Janko Kral' was a major Slovak poet of this period. The reaction to Romanticism came in the 1840s with the Realist writings of the Czech novelist Božena Němcová and the political journalist Karel Havlíček. National traditions were reasserted by the Czech poets Jan Neruda and Svatopluk Cech and by the Slovak poet Pavel Országh (whose pen name was Hviezdoslav). After independence in 1918 came the plays and novels of Karel Čapek, well known in the West for R.U.R. (Rossum's Universal Robots), and the plays of František Langer. Jaroslav Hašek's novel *The Good Soldier Schweik* is still highly popular. After the establishment of the Communist regime in 1948, Socialist Realism became dominant stylistically, and interest in literature declined. The period of the "thaw" brought a number of writings critical of the events of Stalin's era, the first success among which was that of *The Taste of Power*, by Ladislav Mňačko. From 1969, literature again declined.

Editorial activities are concentrated in numerous specialized government publishing houses, and books are among the cheapest goods in Czechoslovakia. Translations of foreign literature predominate, and there is interest in both Western and Soviet literature. Asian and Latin-American books and publications from other parts of the developing world are also available.

**Music and films.** The Czechs and Slovaks are traditionally musical, and operas and symphonies have a high place in cultural life. Such composers as Bedřich Smetana, Antonín Dvořák, Leoš Janáček, and Bohuslav Mar-

Translations

#### Wages and pensions

tinů have international reputations, and their works are often played in the annual spring music festival in Prague. In addition, jazz and related musical forms, and their performers, are also very popular, as is folk music.

Czechoslovak motion pictures are noted for their delicate and sympathetic treatments of basic human situations. In fact, modern Czechoslovak literary, theatrical, and film creations are all characterized by an interest in everyday life combined with the application of new forms of expression. A notable example of this has been the continued success of the combination of film, ballet, and theatre known as *Laterna magica*, which first attracted international attention at the world expositions in Brussels (1958) and Montreal (1967).

**Fine, applied, and popular arts.** In painting and in sculpture, abstract schools have made themselves felt, but Realism generally prevails. One of the best known painters before independence was Josef Manes, and after his time Alphonse (Czech, Alfons) Mucha gained world renown, as did the half-Czech Oskar Kokoschka. The glass designer and sculptor Rene Roubíček is also world renowned in his restricted field. In the applied arts, manufactured glass ornaments, the traditional north Bohemian costume jewelry, and toys are probably best known. Popular art has been preserved above all in useful objects in ceramics and wood; embroideries and traditional costumes are now of less importance.

**Libraries and museums.** The largest library is the State Library of the Czech Socialist Republic in Prague, created in 1958 by merger of several older libraries (one of which, the University Library, was founded in 1348); its collections include 4,600,000 volumes. The National Museum Library, also in Prague and founded in 1818, has about 2,400,000 volumes. Other major collections are in the Slovak National Library in Martin (4,000,000 volumes), the Slovak Technical Library of Bratislava (2,200,000), the University Library in Bratislava (1,500,000), and the State Scientific Library in Brno (4,000,000). Public lending libraries are found in every community.

Among the many museums, in both Prague and the provinces, may be mentioned three in Prague: the National Museum (founded 1818), the National Gallery (1796), and the Museum of Decorative Arts (1885), the last housing one of the world's largest glass collections.

**The media of mass communication.** Among the more than 1,000 varied periodicals published in Czechoslovakia, there are only 30 newspapers, the leader of which is the KSČ organ *Rudk Právo*. The national television network reaches the whole country; about two-fifths of the programs are devoted to the arts and about one-third to news and reportage.

#### PROSPECTS

Czechoslovakia, a rather small country situated in the centre of Europe, is characterized by a great internal variation, a fact that Czechoslovaks feel justifies the words of the national anthem, which claim that the country is "a paradise to look at." Complicated natural conditions, limited resources of raw materials, and a landlocked position are reflected in the national character, demography, and economy. Czechs and Slovaks entered the modern period as peoples without a large noble class and higher social order, and subsequent developments have made them cosmopolitan, with social consciousness and a strong democratic spirit. Their prospects centre on the intensification and modernization of the national economy, but also important are the improvement of surviving backward areas and the smoothing out of regional differences.

**BIBLIOGRAPHY.** The literature on Czechoslovakia is predominantly written in Czech. Foreign sources are often out of date, but competent works with sections on Czechoslovakia include P. GEORGE and H. SMOTKINE, *Les Républiques socialistes d'Europe centrale* (1967); A.F.A. MUTTON, *Central Europe: A Regional and Human Geography*, 2nd ed. (1968); R.H. OSBORNE, *East Central Europe: A Geographical Introduction to Seven Socialist States* (1967); N.J.G. POUNDS, *Eastern Europe* (1969), and R.E.H. MELLOR, *Eastern Europe: A Geography of the Comecon Countries* (1975), all detailed works. Regional geographies include M. BLAZEK, *Ökonomische*

*Geographie der Tschechoslowakischen Republik*, in German (1959; also pub. in Russian, 1960); J. DEMEK *et al.*, *Geography of Czechoslovakia* (1971); V. HAUFLE, *Changes in the Geographical Distribution of Population in Czechoslovakia* (1966), and V. HAUFLE *et al.*, *Czechoslovakia: Land and People* (1968); population data are in *WORLD POPULATION YEAR, La Population de la Tchecoslovaquie* (1974), and detailed analysis in the official *Vývoj společnosti ČSSR*, based on the 1970 census figures; detailed information may also be found in English in the *Atlas Československé socialistické republiky* (1966); M. BLAZEK, *Ekonomická geografie ČSSR* (1964); *Průruční slovník naučný*, vol. 1, pp. 389–462 (1962), a concise encyclopaedia; and in the *Statistical Yearbook of the Czechoslovak Socialist Republic* (annual).

## Dahomey (Benin)

The Republic of Dahomey—which in 1975 was renamed the People's Republic of Benin (*République Populaire du Bénin*)—is one of the smallest independent states of West Africa. With an area of 43,500 square miles (112,600 square kilometres), it consists of a long wedge of territory extending for about 420 miles (675 kilometres) from the Niger River, which forms part of its northern frontier, to the Atlantic Ocean in the south, on which it has a 75-mile (120-kilometre) seaboard. Its population was estimated to be 3,338,200 in 1979. Benin is bounded to the west by Togo, to the northwest by Upper Volta, to the northeast by Niger, and to the east by Nigeria. The capital is Porto-Novo (population, according to the 1979 census, 132,000). Cotonou, with a population of 327,000, is the largest city and the chief port. Other important towns are Ouidah, Abomey, and Parakou.

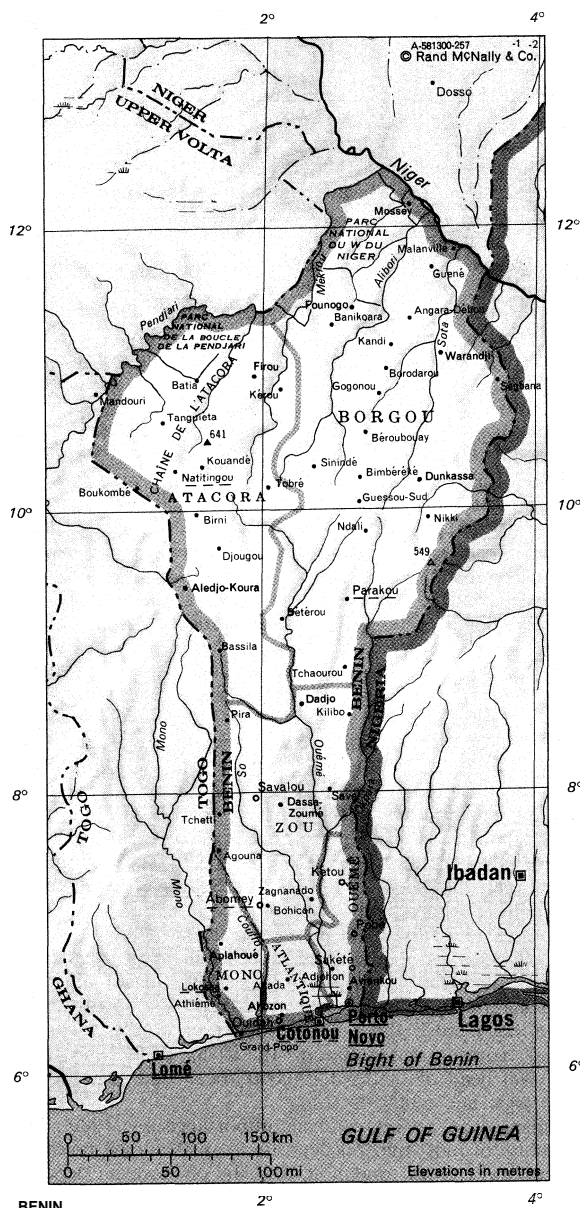

A former French colony, Dahomey became an independent republic within the French Community in 1958 and gained full independence in 1960. Thereafter, Dahomey underwent more than a decade of political instability, caused partly by its diverse ethnic composition and traditions. The majority of the people inhabiting the southern one-third of the country are related Adja peoples (including the Fon), who migrated into the region in the 13th century and later founded, among others, the Porto-Novo Kingdom and the Dahomey (or Dan-homey: "on the stomach of Dan") Kingdom. The Dahomey Kingdom—also called the Abomey Kingdom after its capital city of Abomey—conquered smaller kingdoms in the south in the 18th century and was directly involved in the transatlantic slave trade, then controlled by Portuguese settlers from the port of Ouidah. Dahomey's warriors, including the famed corps of female soldiers known as the Amazon warriors, fought heroically against, but were defeated by, French colonizers in 1893. The kingdom then lent its name to the whole country, which became a division of the federation of French West Africa (*Afrique Occidentale Française*; AOF) in 1904. Descendants of Portuguese settlers, returning slaves, and the French colonialists were instrumental in spreading Christianity and Western education in the south; by the 1950s, Dahomey was known as the "Latin Quarter" of West Africa.

Large sections of the population in the northern part of the country had migrated from the inlands of the continent to form several kingdoms or to settle in small communities. They were predominantly Muslim, and until independence they had relatively little contact with their neighbours in the south. This cleavage between the north and the south, and that in the south between Abomey and Porto-Novo, fueled conflict among political leaders. Another factor contributing to political instability was the failing economy, which was largely dependent upon the export of palm oil and palm kernels and upon external aid, primarily from France. Eleven government changes, including five military interventions, occurred during the 12 years between 1960 and 1972. The government of a three-member Presidential Council, adopted in 1970, was overthrown in 1972 by Maj. (later Lieut. Col.) Mathieu Kérékou, who has since been the president of the country. In 1975 the country was proclaimed a Marxist-Leninist state. (For further coverage of historical aspects, see WEST AFRICA, HISTORY OF.)

BENIN

**The landscape. Relief.** Benin consists of five natural regions—a coastal region, the *barre* country, the Benin plateaus, the Atacora Massif, and the Niger plains.

The coastal region is low, flat, and sandy, backed by lagoons. It forms, in effect, a long sandbar on which grow clumps of coconut palms; the lagoons are narrower in the western part of the country and wider in the east, and some are interconnected. In the west the Grand-Popo Lagoon extends into neighbouring Togo, while in the east the Porto-Novo Lagoon provides a natural waterway to the port of Lagos, Nigeria, although its use is discouraged by the political boundary. Only at Grand-Popo and at Cotonou do the lagoons have outlets to the sea.

Behind the coastal region extends the *barre* country—the word being a French adaptation of the Portuguese word *barro* ("clay"). A fertile clay plateau, the *barre* region contains the Lama Marsh, a vast swampy area stretching from Abomey to Allada. The landscape is generally flat, although occasional hills occur, rising to about 1,300 feet (400 metres).

The Benin plateaus, four in number, are to be found in the Abomey, Ketou, Aplahoué, and Zagnanado districts. The plateaus consist of clays on a crystalline base. The Abomey, Aplahoué (or Parahoué), and Zagnanado plateaus are from 300 to 750 feet high, and the Ketou plateau is up to 500 feet in height.

The Atacora Massif, in the northwest of the country, forms a continuation of the Togo mountain chain, running

southwest to northeast and reaching an altitude of 2,103 feet at its highest point. It consists of a quartzite plateau.

The Niger plains, in the northeast of Benin, slope down to the Niger River Valley. They consist of clayey sandstones.

**Drainage.** Apart from the Niger River, which, with its tributaries the Mekrou, Alibori, and Sota, drains the northeastern part of the country, the three principal rivers in Benin are the Mono, the Couffo, and the Oueme. The Mono, which rises in Togo, forms the frontier between Togo and Benin near the coast. The Couffo, near which stands Abomey, flows down from the Benin plateaus to drain into the coastal lagoons at Aheme. The Oueme rises in the Atacora Massif and flows southward for 320 miles; near its mouth it divides into two branches, one draining into Porto-Novo Lagoon and the other into Nokoue Lake. The Atacora Massif forms a watershed between the Volta and Niger basins. (For coverage of an associated physical feature, see NIGER RIVER.)

**Climate.** Two climatic zones may be distinguished—a southern and a northern. The southern zone has an equatorial type of climate with four seasons—two wet and two dry. The principal rainy season occurs between mid-March and mid-July; the shorter dry season lasts to mid-September; the shorter rainy season lasts to mid-November; and the principal dry season then lasts until the rains begin again in March. The amount of rain increases toward the east. Grand-Popo receives only about 32 inches (800 millimetres) a year, whereas Cotonou and Porto-Novo both receive approximately 50 inches. Temperatures are relatively constant, varying between 72° and 93° F (22° to 34° C).

In the northern climatic zone, there are only two seasons, one dry and one rainy. The rainy season lasts from May to September, with most of the rainfall occurring in August. Rainfall amounts to about 53 inches a year in the Atacora Massif and in central Benin; further north it diminishes to about 38 inches. In the dry season the harmattan, a hot, dry wind, blows from the northeast from December to March. Temperatures average about 80° F (27° C), but the temperature range varies considera-

Two climatic zones

The barre country

bly from day to night. In January, the hottest month, diurnal temperatures may rise to 110° F (43° C).

**Vegetation.** The original rain forest, which covered most of the southern part of the country, has now largely been cleared, except near the rivers. In its place, many oil palms and rbnier palms have been planted and food crops are cultivated. North of Abomey the vegetation is an intermixture of forest and savanna (grassy parkland), giving way further north to savanna. Apart from the oil and rbnier palms, trees include coconut palms, kapok, mahogany, and ebony.

**Animal life.** In the extreme north is the Parc national du "W" du Niger (1,938 square miles [5,020 square kilometres]), which extends into Upper Volta and Niger. Its varied animal life includes elephants, panthers, lions, antelope, monkeys, wild pigs, crocodiles, and buffalo. There are many species of snakes, including pythons and puff adders. Birds include guinea fowl, wild duck, and partridge, as well as many tropical species. The Parc national de la Pendjari (1,062 square miles) borders on Upper Volta.

**The landscape under human settlement.** The southern third of the country is by far the most densely populated region. On the coastal sandbars, coconut plantations have been established. In the lagoon region, fish are caught in wicker traps; fishing villages often consist of houses built upon stilts. The Oueme Delta region is heavily populated. The cultivation of subsistence crops, such as maize (corn), cassava, and sweet potatoes, is intensive on the outskirts of the towns. The *barre* region and the Benin plateaus are planted with oil palms, which form the cash crop, as well as with subsistence crops. To the north, the aspect of the countryside changes as savanna vegetation increases and the population diminishes; some areas are uninhabited, except by Fulani nomads. Villages, instead of being encountered frequently as in the south, become scattered.

Although some of the towns are beginning to assume a modern aspect, vestiges of former centuries are still to be seen, such as the old Danish and English forts at Ouidah, dating from the time of the slave trade. Cotonou is primarily a modern European-built city, whereas Porto-Novo, an old African-founded town, combines both African and European features. Abomey, the ancient capital, now somewhat in decline, remains an important market and is also a centre for crafts. Parakou is an important market town. (S.S.A./D.R.o.)

**The people.** About two-thirds of the people live in the southern third of Benin. Many of these are clustered about the port of Cotonou, which is the focus of the commercial and political life of the country.

**Ethnic and linguistic groups.** While French is the official language, the most widely spoken languages are Fon and Ge (Mina), both dialects of Ewe; Yoruba; Bariba; and Dendi.

The Fon are predominant in the south; they number about 700,000. They are related to other southern groups, including the Adja (22,000) and the Goun (Gun; 137,000). The 92,000 Aizo have been largely assimilated into the Fon and Adja. The Yoruba, related to the Yoruba of Nigeria and in Benin called the Nago (Nagot), number 200,000. The Yoruba include the small Holli and Ketu groups.

The Bariba, a Voltaic-speaking group numbering about 175,000, are the major ethnolinguistic group in the north. Others in the north are the Somba, who live between

Atacora and Togo, numbering about 36,000; the Pila Pila, about 24,000; the Dendi, who are associated with the Niger Valley and number about 28,000; and the nomadic Fulani (Peul), who number about 70,000.

About 5,000 Europeans, mostly French and Portuguese, also live in Benin.

**Religious groups.** Although Christian missions have been active in the coastal region since the 16th century, only about 17 percent of the total population is Christian; of the Christians, about 85 percent are Roman Catholic. The great majority of the population adheres to traditional religions. In the south, animist religions, which include fetishes (objects regarded with awe as the embodiment of a powerful spirit) for which Benin is renowned, retain their traditional strength. Islam has adherents in the north and southeast; about 15 percent of the total population is Muslim.

**Demography.** About 86 percent of the estimated population of 3,338,000 in 1979 was rural, about 14 percent urban. Life expectancy at birth was 46 years, and the fertility rate in 1978 was 6.7 for every 1,000 persons. In 1978, 51 percent of the population was of working age; of those actively engaged in the wage-earning economy, 46 percent were employed in agriculture, 15 percent in industry, and 39 percent in services. (D.R.o.)

**The national economy.** *Natural resources.* Only a few stretches of forest remain in Benin, mostly in the south and central areas; these contain mahogany, iroko, samba, and other tropical hardwoods. The rivers and lagoons are rich in fish. Known mineral deposits include iron-ore deposits in the Atacora and Kandi region; limestone deposits suitable for the manufacture of cement at Onighlo; chrome ore and a little gold in the northwest near Natitingou; about 5,000,000 tons of marble at Dadjo; an important deposit of pottery clay at Sakété; and ilmenite (a mineral source of titanium) near the coast. In addition, petroleum has been located at the Semi oil field, about 18 miles offshore from Cotonou.

*Sources of national income.* About 90 percent of the people depend on agriculture, about half of them engaged in the subsistence farming of maize (corn), cassava, yams, and sorghum. Palm oil and palm kernels constitute the main cash crop; other cash crops are peanuts (groundnuts), cotton, and tobacco. In 1978, there were also 730,000 head of cattle, 1,700,000 sheep and goats, 370,000 pigs, and 6,000 horses.

Mining was as yet of little importance by 1980. The distance of most mineral deposits from the coast rendered them uneconomic to exploit, and the offshore oil deposits remained untapped.

About 21,000 tons of fish are caught annually in the lagoons and rivers, while coastal fishing produces a further 5,000 tons. Most of the fish is exported to Nigeria or Togo. Shrimp fishing is developing, using modern vessels.

Manufacturing plants and secondary industries include several palm-oil-processing plants, in Ahozon, Avrankou, Bohicon, Cotonou, Gbada, and Pobé; several modern bakeries; a soft-drink plant; a brewery; and two shrimp-processing plants.

**Energy.** Electricity is generated by diesel engines. There are four power-generating plants, located at Bohicon-Abomey, Cotonou, Porto-Novo, and Parakou, with a combined capacity of 13,610 kilowatts. Benin's demand for electricity is met largely from Ghana's Volta River Project at Akosombo. Benin and Togo have undertaken a joint venture to construct four dams on the Mono River as part of a hydroelectric project that would have a capacity of 130,000 kilowatts.

**Foreign trade.** All governments since independence have tried to develop the agricultural sector, which consisted primarily of the cultivation of palm-oil plantations for export. Palm oil and palm kernels have usually represented two-fifths of all exports, about 380,000 tons a year. Imports are about 10 times higher than exports. The principal imports are beverages and tobacco, textiles, machinery, automobiles, and paper; the principal exports are palm oil and palm kernels, cotton, industrial diamonds, and cocoa. In the mid-1970s, France was the principal trading partner for both exports and imports, followed by

The Netherlands and Japan for exports and India and the People's Republic of China for imports.

**Management of the economy.** During the colonial period, the economy of Benin was integrated with that of former French West Africa; since independence, Benin has remained partially dependent upon France for financial aid. Economic policy from 1966 to 1970 was established in a five-year plan that sought to increase production and to stimulate economic growth.

The principal difficulty faced by successive Benin governments has been the nation's low standard of living. In 1978, the gross national product per capita was \$230. Since 1976, the revolutionary regime of Lieutenant Colonel Kérékou has gradually begun the establishment of cooperative structures, the Groupements Révolutionnaires de Vocation Co-opératif (GRVC), which are to provide a socialist base for agricultural production. Landowners are allowed to keep the titles to their lands, but they may not receive rent. Work is communal, and the workers are free to sell their produce either to the state or to private customers. Private traders and small manufacturers continue to flourish. The early results of the experiment were mixed: groundnuts production dropped, but the production of cocoa, cotton, and palm products rose.

**Transportation.** There are 4,300 miles (6,900 kilometres) of roads, of which about 450 miles are surfaced and 80 miles are urban roads. The principal roads are two: one running along the coast from the Togo border in the west via Cotonou and Porto-Novo to the Nigerian border in the east, and one running north from Cotonou to Parakou and on to the Niger frontier. The coastal route is paved for 60 miles. Road transport is usually by truck; a central truck park at Cotonou is capable of accommodating 15,000 vehicles.

There are about 360 miles of railroad track consisting of three lines. One line runs for about 20 miles from Cotonou to the Togo border, from where it continues to the Togolese port-capital of Lomé. A second line runs for about 66 miles from Cotonou via Porto-Novo to Pobé. The third line runs north from Cotonou to Parakou for about 270 miles. Following the discovery of important uranium deposits in the Republic of Niger, an extension of the Parakou line to Dosso in Niger was planned.

The lagoons, running parallel to the coast, are used as waterways by small craft. The Ouémé River is navigable for about 125 miles, the Couffo for about 80 miles, and the Mono for about 60 miles. About 2,500,000 metric tons of cargo are handled in the port of Cotonou each year. The airport at Cotonou links Benin with other West African countries and with France, the U.K., the U.S., and the Soviet Union. The government maintains a small domestic air service. (S.S.A./D.R.o.)

**Administration and social conditions.** The structure of government. The government of Mathieu Kérékou was established in a military coup during 1972. Under the constitution of 1977, Benin held its first general elections in November 1979. In those elections, 336 representatives to the unicameral legislature, the National Revolutionary Assembly, were approved by 97.9 percent of the voters. In February 1980, the legislative body confirmed Lieutenant Colonel Kérékou as president. He was the sole candidate, chosen by the Central Committee of the People's Revolutionary Party of Benin.

The government consists of the National Revolutionary Assembly (Assemblée Nationale Révolutionnaire) and a National Executive Council of 22 Cabinet ministers and the six presidents of the committees that administer the country's six provinces. Of the 22 Cabinet portfolios in the new government, 14 are held by civilians.

The six administrative provinces—Atlantique, Atakora, Borgou, Mono, Oueme, and Zou—are divided into 84 districts. In addition, there are five townships.

The People's Revolutionary Party of Benin (Parti de la Révolution Populaire du Benin; PRPB) is the only legal political party in the country. It elects a 40-member Central Committee, of whom 12 form the Political Bureau in which President Kérékou is a member.

**Justice and defense.** At the head of the judicial system is the Supreme Court. There are also a council of the

magistracy, a court of appeal at Cotonou, a tribunal of the first instance, and local tribunals that administer traditional African or Muslim law.

Defense is the responsibility of the Benin Army and the gendarmerie, which together number about 3,300. The army itself consists of three battalions with a strength of 2,100 men. There is a small air force. The president is the supreme commander of the armed forces and is also minister of defense. Internal security is the responsibility of the Ministry of Interior and Security, which supervises police services in each province.

**Education and health services.** About 30 percent of the school-age population receives a formal education. There are about 340,000 students in primary schools. About 55,000 students receive a secondary education, and another 3,000 engage in technical and higher studies. The Université Nationale du Benin was opened in 1970 in Abomey-Calavi, near Cotonou. It is estimated that in 1980 about 700 Beninois received higher education abroad, mostly in France or elsewhere in Africa.

Health services are limited by budgetary restrictions. In the late 1970s, there were about 120 physicians in the country—one for every 27,400 inhabitants. There were six hospitals, located at Cotonou, Porto-Novo, Abomey, Ouidah, Natitingou, and Parakou. In addition, there were 31 medical centres, 186 dispensaries, 65 maternity centres, and 10 leprosariums. Campaigns were waged against meningitis, leprosy, malaria, and sleeping sickness.

**Cultural life and institutions.** Examples of Benin's rich culture—carved wood masks, applique tapestry, pottery, and bronze statuettes—are sold in marketplaces and exhibited in three museums in Porto-Novo, Abomey, and Parakou. Traditional music and dance are heard in frequent village and neighbourhood compound ceremonies. Radio programs are broadcast in French, English, and 18 local languages from Cotonou and transmitted from Parakou. There is television service three times a week. The one daily newspaper, *Ehuzu*, is sponsored by the government.

**Prospects for the future.** The Kérékou government has brought unprecedented political stability to a country that for more than a decade had not had a chance to achieve it. The communalization of agricultural production is a change from traditional subsistence and private farming, but the government has imposed it gradually so as not to awaken antagonism in the population. Although Benin was still far from emerging from economic underdevelopment in 1980, its stable political situation, in comparison with its past hopelessness, projected the chance for a better future.

Attempts to improve standard of living

The armed forces

## Daigo II

Few emperors in Japan's history occupy as controversial a place as Daigo II (also known as Go-Daigo), who reigned in the 14th century. Ranked by some as one of his nation's greatest sovereigns, he is regarded by others as a ruler of limited abilities. To some he personifies courage and integrity for daring to lead a revolt against the military government in whose shadow emperors and their courts had existed for a century and a half. Others see in him a proud and inept ruler, whose clumsy efforts to restore the monarchy plunged the nation into civil war and divided the Imperial family into two rival dynasties.

Born in 1287, Daigo ascended the throne in 1318, when

Daigo II, colour on silk by an unknown artist. In the collection of Daitoku-ji, Kyōto.

the nation was in one of the more turbulent periods of its history. Politically, authority was uncertainly divided between two governments—the de jure government of the Emperor and his court in Kyoto, and the de facto government of the Shogun (the military overlord) and his court in Kamakura in eastern Japan. Neither government was stable and united, and neither Emperor nor Shogun actually wielded authority in his respective government, each having become the puppet of powerful families.

In Kyoto, political authority was still further diffused by the introduction in the 11th century of a curious practice known as *insei* ("cloistered rule"). Emperors, in their desire to recover their prerogatives, abdicated and entered a monastery, where they organized a new government and proceeded to rule from retirement. A minor would be placed on the vacated throne and would await the day he, too, could retire so that he could begin to rule. Of Daigo II's seven immediate predecessors, six were minors, one of whom acceded at the age of three and another at seven.

Adding to the political confusion in Kyoto was the practice of alternating the throne between the senior and junior branches of the Imperial family, which had been feuding over the question of succession for years. It was in accordance with the agreement forced upon the quarrelling factions by the shogunate that Daigo of the junior branch ascended the throne in 1318.

No less anomalous was the situation in Kamakura, where control of the shogunate had passed from the Minamoto to the Hōjō family. Not being eligible for the office of shogun, the Hōjō were content to rule as regents for the puppet shoguns they appointed, at first from among the younger scions of the Fujiwara family and later from the Imperial family. But by the 14th century Hōjō influence itself had declined considerably, and the regency had become the instrument of yet another family, the Nagasaki. Its ascendancy was facilitated by the youth of the regent, Hōjō Takatoki, who, at investiture, was only eight years old. As he grew to manhood, his questionable intelligence and dissolute ways—spending

much time, for example, watching dogfights—led to a widespread loss of confidence in the shogunate. Further alienation of many traditional supporters of the shogunate was caused by the favouritism to friends and relatives shown by Nagasaki Takasuke, the man who controlled the regent.

In view of these and other signs of growing discontent, Daigo, even before his enthronement, began to plot the overthrow of the shogunate and the restoration to power of the Imperial court. He continued these secret efforts after his installation and throughout the decade of the 1320s with encouraging results, but in 1331 the plot was exposed. Captured by Kamakura forces while attempting to flee from Kyōto, Daigo was sent into exile to the Oki Islands in the Sea of Japan.

But Daigo had triggered the revolt he had plotted so long. During his first year of confinement there was sporadic fighting between his supporters and shogunate forces, and in 1333 decisive events, marked by much treachery and violence, took place. The commander of some of the shogunate's forces turned and attacked Kamakura instead of the shogunate's enemies. Caught by surprise, Hōjō Takatoki and his supporters chose to take their own lives, thus bringing to an end the 150-year regime of Japan's first military government. Equally dramatic was the defection of Ashikaga Takauji, who was in command of the main armies of the shogunate. Instead of seizing Kyōto for the shogunate, he attacked the shogunate garrison there and turned the city over to Daigo, who, in the meantime, had contrived to escape from Oki.

If Daigo was grateful to the former vassals of the Hōjō for having made possible the "Kammu restoration," as this series of events is known, he failed to show it. He neither rewarded them nor brought them into his new government, except for Takauji, who was given some lands and the comparatively low rank of counsellor. Takauji expected to be designated shogun, but Daigo foolishly named his own son, Prince Morinaga, to the post. By such callous acts the sovereign alienated Takauji as well as a large segment of the warrior class at a time when their continued support would have assured the success of the restoration. In fact, historians are generally agreed that Daigo's greatest failing and the cause of many of his troubles was his inability to see that rule by a strictly civilian aristocracy was no longer feasible.

By 1335 open warfare broke out between Takauji, who proclaimed himself shogun, and Daigo, who pronounced him a rebel. Although the loyalists distinguished themselves in battle, in the end they were overpowered by the numerically superior forces of Takauji, who had gone as far as Kyushu in the southwest to raise a vast army. In 1336 Daigo, who had fled from Kyoto a number of times as the tide of battle flowed in and around the city, left the ancient capital for the last time. Takauji re-entered Kyoto and promptly elevated Kōgon of the senior Imperial line to the throne. Daigo established his own court in the Yoshino Mountains to the south of Kyoto, where he died in 1339. Thus, from 1336 until 1392, when the rival factions of the Imperial family were to be reunited, Japan witnessed the spectacle of two contending Imperial courts—the southern court of Daigo II and his descendants, whose sphere of influence was restricted to the immediate vicinity of the Yoshino Mountains, and the northern court of Kōgon and his descendants, which was under the domination of the Ashikaga family.

**BIBLIOGRAPHY.** The *Taiheiki* (Chronicle of the Grand Pacification) of unknown authorship is the most detailed primary source on Daigo II, of which there is an excellent translation by HELEN CRAIG MCCULLOUGH, *The Taiheiki: A Chronicle of Medieval Japan* (1959). For biographies of and relevant data on all 124 emperors of Japan, see RAB. PONSOMBY-FANE, *The Imperial House of Japan* (1959). The most detailed and authoritative general history in English on the subject is GEORGE SANSON, *A History of Japan*, vol. 1 and 2 (1958–61). For the views of Japanese thinkers of the Tokugawa period on the subject, see DAVID MAGAREY EARL, *Emperor and Nation in Japan: Political Thinkers of the Tokugawa Period* (1964).

(M.Sh.)

## Dairying and Dairy Products

Dairying is the production and marketing of milk, usually cows' milk, and its products; it includes the care of cows, their breeding, feeding, management, and milking. The milk must be collected, processed into dairy products, and marketed. All of these operations have been studied and improved by physiological, genetic, nutritional, chemical, microbiological, technological, economic, and marketing research and development.

**Historical development.** Cattle, goats, and sheep have been raised by humans for the production of milk throughout history. Milk and especially soured milks, butter-like products, and cheese were probably common foods of the peoples roaming the grasslands of Asia with their sheep and cattle thousands of years ago. In the biblical narratives Abel, son of Adam, was a "keeper of sheep," and Abraham served milk to the three divine beings who appeared to him at Hebron. Canaan was idealized as "a land flowing with milk and honey," and cheese is mentioned in the Book of Job. The Hindu Vedas, written before 1200 BC, mention the use of butter as food. In all these instances the mention of milk or its products implies much earlier use.

The ancient Europeans did not use butter as food but as a pharmaceutical, primarily for skin injuries and sore eyes. It was widely used as a hair oil and as fuel for lamps. Whey, the watery part left after separation of the solid curd from coagulated milk, was used widely in Europe as a medicine in the Middle Ages. Milk sugar (lactose) seems to have displaced whey as a panacea subsequent to its isolation from whey in 1628.

The Mongols in the Middle Ages prepared concentrated milks in paste, and probably in dry form, and used them as field rations while on the march. Commercial processes for making concentrated and dried milk did not appear until the 19th century. A patent for "the concentration of milk" was granted to Gail Borden of the United States in 1856, and the utility of canned concentrated milk was demonstrated by its use in army rations during the U.S. Civil War. F.S. Grimwade's British patent for producing dried milk was issued in 1855, but large-scale production of dried milks did not begin until approximately 50 years later.

The domestication and keeping of milk-producing herd animals spread from southwestern Asia to other parts of the world. At first the same animals were used for work, meat, and the production of milk. The milk was consumed at the point of production as milk or as domestically made dairy products. As urban centres developed, cows and goats were kept in larger numbers to produce milk in quantity, and transportation by wagon, rail, and tank truck became necessary.

In ancient times goats and sheep produced enough milk for each family. As the need for milk increased, the cow became a volume producer. During the Middle Ages many advances in the development of milk-producing breeds were made, and by the 18th century selective breeding was well established. Factories to process and pasteurize the milk became accepted as a safeguard for the milk supply. Large herds are now found within a few hundred miles of heavily populated areas and usually where abundant feed is available. Rapid transportation and advanced technology have brought about the rise of large, specialized dairy manufacturing plants in potentially high milk-producing areas that are distant from population centres.

The dairy industry of the world is well established, but it competes with the growing number of economical substitute foods, notably vegetable-base margarine, but including imitation creams, cheese dips, evaporated milks, and ice creams, as well as imitation milks. Many of the simulated products use skim milk or sodium caseinate as a protein source.

### Milk production

Milk for human consumption is produced primarily by the cow and the water buffalo. The goat also is an important milk producer in China, India, Egypt, and in many

Asian countries. Goat's milk is also produced in Europe and North America but, compared to cow's milk, goat's milk is relatively unimportant economically. Buffalo's milk is produced in commercial quantities in some countries, particularly India. Where it is produced, buffalo's milk is used in the same way as is cow's milk, and in some areas the community milk supply consists of a mixture of both.

### DAIRY HERDS

Dairy cows are divided into five major breeds: Ayrshire, Brown Swiss, Guernsey, Holstein-Friesian, and Jersey. There are also a number of minor breeds, among them the Red Dane, the Dutch Belted, and the Devon. There are also some dual-purpose breeds used to produce both milk and meat, notably the Milking Shorthorn and the Red Polled.

The Ayrshire breed originated in Scotland. Animals of this breed are red and white or brown and white in colour, and they are strong, vigorous, and good foragers. Ayrshire milk contains about 4.1 percent butterfat. Switzerland is the native home of the Brown Swiss. These cows are silver to dark brown in colour, with a black nose and tongue. Brown Swiss are strong and vigorous. The average fat test of the milk is 4.1 percent. The Guernsey breed originated on Guernsey Island off the coast of France. The Guernsey is fawn-coloured with clear white markings. The milk averages about 4.8 percent fat and has a deep yellow colour. The Holstein-Friesian originated in The Netherlands. It is black and white in colour and large in size. Holsteins give more milk than any other breed; the average butterfat is 3.7 percent. The Jersey breed originated on the isle of Jersey in Great Britain. Jersey cows are fawn in colour, with or without white markings. They are the smallest of the major breeds, but their milk is the richest, containing on the average 5.2 percent butterfat. The protein content of milk is highest for Guernsey (3.91 percent) and Jersey (3.92 percent) and lowest for Holstein (3.23 percent).

Breeding and herd improvement. The breeds of dairy cattle have been established by years of careful selection and mating of animals to attain desired types. Increased milk and butterfat production has been the chief objective, although the objective often has shifted to increased milk and protein production. Production per cow varies with many environmental factors, but the genetic background of the cow is extremely important. The production per cow in the 12 highest milk-producing countries is shown in Table 1.

The principles of breeding to improve production have been helpful in increasing milk production in less developed countries. Progress also has been made in India with cows and water buffalo.

Artificial breeding has developed into a worldwide practice. Bulls with the genetic capacity to transmit high milk-producing ability to their female offspring are kept in studs. Dairy-farmer cooperatives usually operate the studs, with artificial insemination generally used. Semen may be frozen for shipment to any part of the world.

Feeding dairy cattle. The dairy cow is an efficient producer of human food from roughage. This ability is due to a unique digestive system that consists of a four-compartment stomach capable of handling roughages not digested by humans and other monogastric (one-stomached) animals.

Pasture is the natural feed for dairy cattle, and an abundance of good pasture provides most of the requirements of a good dairy ration. An outstanding example of grassland dairying is found in New Zealand, where cows are on pasture all year and milk production costs are at a minimum. The farmer does not need to prepare and store feed for a long winter period. Feeding a balanced ration, however, rather than grass alone, increases milk production. By 1980 the average annual production per cow in New Zealand was 7,360 pounds (3,340 kilograms) of milk, while in the U.S., where supplemental feeding is common, it was 11,810 pounds, or 5,360 kilograms (see Table 1). Pastures of poor quality must be supplemented with other feed, such as green crops, summer silage, or hay.

Biblical  
references

Breed  
charac-  
teristics

**Disease prevention.** Disease is a major problem of the dairy farmer. It is a constant threat and may require removal of valuable animals from the herd. One study of a typical dairy herd showed that an average of 22 percent of cows were removed yearly and about a third of these were lost.

Good health herd management includes cleanliness, isolation of sick or injured animals, keeping premises free of hazards that might cause injury, and continuous protection against poisonous plants and other material. A number of diseases, such as tuberculosis, require injections. Others, such as mastitis, require constant treatment. For some diseases there is no known cure; slaughter of the animal is the only way to stop spread of the infection. Foot-and-mouth disease is a notorious example of such diseases; severe measures have been taken by most governments to exclude or control it.

### Use of milking machines

Most milking is done with machines by a carefully trained operator, usually twice a day, in stanchion barns or milking parlours. An experienced milker handles one to three machine units. The cows are first cleaned, and the teat cups put on. Pulsating vacuum draws the milk into a receiver or through piping into the farm milk tank (see Figure 1).

Milk is transported from farm to plant in a variety of ways, depending on the part of the world. In the Indian state of **Gujarāt**, for example, the milk is carried to a receiving station in jars on the heads of women who do the

PRODUCTION AND CONSUMPTION STATISTICS FOR MILK

**Table 1: Milk Production and Utilization in Specified Countries (1980)**

\* Includes butter, cheese, evaporated and sweetened condensed milk, nonfat dry milk, and ice cream.  
Sources: FAO, Production *Yearbook* (1980), and U.S. Department of Agriculture, Foreign Agricultural Service, unpublished data.

Large quantities of dairy products move in international trade. Japan, the countries of Indochina, India, Central America, and other regions bordering the Equator are in general poorly suited for dairying. Where economic conditions permit, their dairy product deficit is overcome by imports. The basic requirement for a viable dairy industry is an abundance of feed and a temperate climate for cattle. Optimum conditions exist in Australia, New Zealand, the U.S., and Europe, hence the large milk production of these areas. Per capita consumption of dairy products tends to be largest in the milk-producing countries.

Prices for milk and dairy products have not increased as rapidly during the last half century as have prices of many other products. But greater economies of milk production and product processing, together with some government price-support activity, has kept profit margins attractive in most of the dairy countries.

### Dairy products

Milk has been used by man to make many products both to increase variety and appeal and as a means of preservation. Almost half the milk produced in many countries is consumed as a fresh whole and skim-milk beverage type product. The remainder is manufactured into the more stable dairy products of commerce, principally butter and cheese, but including condensed and evaporated milks, dried milks, ice cream, and dairy by-products.

The following discussion of dairy products is based on cow's milk as the raw material because the processes so far developed have overwhelmingly used cow's milk. Similar processes are doubtless applicable to the buffalo's milk of India, China, Egypt, and the Philippines, the goat's milk of the Mediterranean region and elsewhere, to the milk of the reindeer, in northern Europe, and to the sheep's milk used in southern Europe. Special processing problems may be encountered with the milk of each of these species because of differences in composition and in the nature of the proteins. Simple pasteurization changes the flavour of goat's milk, and producers of this product often prefer to sell it unpasteurized. The fat of goat's milk is naturally homogenized and this is thought to improve its digestibility. Buffalo and goat milk when concentrated do not easily withstand sterilization for evaporated milk manufacture and so are rarely used for this purpose. A Cheddar-type cheese is made from

buffalo milk in India, but its protein-calcium complex appears different from that of cow's milk and a way has not yet been found to cure the cheese as well as cow's milk cheese. Buffalo milk is successfully dried in India to produce powder for both infant and adult use. With research, the behaviour of the milk of various species can no doubt be adapted to the manufacture of all dairy products. The basic processes have been developed around cow's milk because of its supply and the need to preserve it for future use in distant markets.

### FLUID AND CONCENTRATED MILKS

Fluid or market milk is generally considered to refer to bottled, fresh milk and its associated products, while concentrated milk refers to plain and sweetened condensed and evaporated milk.

Milk as it is secreted by the cow contains 12 to 13 percent solids. It is used in this form or it may be fermented, flavoured, or concentrated for improved utilization. It is the basic material from which all dairy products are produced. The fluid milk industry is composed of city milk plants that receive milk and process it into a variety of products, including pasteurized milk, cream, cultured buttermilk, chocolate milk, fortified skim milk, or yogurt. Specialized factories that make concentrated and dry milks, butter, cheese, and even ice cream are often located in rural heavy milk producing areas where hauling distances for the raw milk are minimal.

**Composition.** The same constituents are present in the milks of all mammals, but the proportions differ both among species and within a species (Table 2).

**Table 3: Composition of Milk Products\***

Many factors influence the composition of milk, including breed, the genetic constitution of the individual cow, and the interval between milkings. Since the last milk to be drawn at each milking is richer in fat than the rest, the completeness of milking influences the composition of the sample. The age of the cow, the stage of lactation, and certain disease conditions are among other factors affecting composition. In general, the kind of feed has slight effect on the composition of milk, but feed of poor quality and insufficient quantity causes both a low yield and a low percentage of nonfat solids.

The compositions of milk, creams, and various milk products are shown in Table 3. Those that contain high moisture and that are not artificially preserved by addition of sugar or by sterilization require refrigeration during storage and distribution. Most of these are products of the fluid milk industry, as distinguished from the concentrated and dry milks, butter, and ice cream. (The composition of cheeses is discussed later and shown in Table 4).

Milk is a good source of many of the vitamins, as shown in Table 5; however, only one milligram of vitamin C or ascorbic acid is present in each kilogram of milk and this is easily destroyed by heating. Vitamin D is formed in milk fat by ultraviolet irradiation, and beverage milk is now commonly fortified by additional vitamin D. Both vitamins A and D are fat soluble and are often added to skim milks to improve nutritive value.

**Properties of milk.** The properties of milk are important in controlling its behaviour during manufacture into various products.

The white colour of milk is caused by the fine dispersion of calcium caseinate, which is hydrated and permanently suspended in the milk. The carotenoids, largely as alpha and beta carotene (related to vitamin A) impart a natural yellow colour to the milk fat, in which they are soluble. A greenish-yellow colour in milk, noticeable particularly in whey, is caused by the presence of vitamin B<sub>2</sub> or riboflavin. The quantities of these pigments in milk are given in Table 5.

The flavour of milk is mild and bland unless it has been affected by the cow's consumption of strong flavour-producing feed such as wild garlic. Pasteurization changes flavour only slightly, but sterilization, as in the making of evaporated milk, imparts a definite cooked or heated flavour. This is caused by the liberation of volatile sulfides during heat treatment. Newer methods of sterilization using rapid ultra-high temperatures up to 300° F (149° C), attained in two or three seconds and held for one or two seconds, generate fewer sulfhydryls and less cooked flavour than older sterilization processes, with temperatures of 242° F (117° C) held for 15 minutes.

Other undesirable flavours can be developed in or absorbed by milk. Growth of bacteria and protein-splitting organisms can produce obnoxious flavours. Chemical changes take place when milk fat is oxidized or when a

product becomes stale. These changes are permanent and cannot be removed by further processing, but their development can be retarded by refrigerated storage, and oxidation of milk fat can be inhibited by absence of oxygen. Certain flavours imparted to milk by the cow's feed can be removed by heating the milk and passing it through a vacuum chamber.

Producing desirable flavours

Desirable flavours such as the clean lactic flavour of cultured buttermilk or of yogurt are developed by controlled fermentation of pure cultures. The characteristic flavours of various cheeses are produced by careful microbiological cultivation of the proper flora for each cheese variety. Many fruit flavours are produced in milk products by addition of fruit purees or juices.

**Enzymes in milk.** Milk contains many enzymes, and others are produced in milk as a result of bacterial growth. Enzymes are biologic catalysts elaborated by a living cell, in the case of milk the mammary tissue. Enzyme action in milk systems is extremely important in its effect on flavour and body of the different milk products. Lipases and other fat-splitting enzymes, oxidation catalysts, and protein-splitting proteases and starch-splitting amylases are among the more important enzymes naturally occurring in milk. These classes of enzymes and others are produced in milk by microbiological action. The proteolytic enzyme rennin, obtained from calves' stomachs, is used to coagulate milk for cheese manufacture.

**Milk fat.** Fat exists in milk as an emulsion in a water phase, that is, as finely dispersed globules that are stabilized by a milk protein membrane that permits clumping and gravity rise of the fat clumps. This is called creaming and it is expected in all pasteurized milk sold in bottles. In the United States, when paper cartons supplanted glass bottles, consumers stopped the practice of skimming cream from the top; processors then introduced homogenization by forcing the milk through a very small opening under pressure. This reduced the fat globules to a tenth their original size, and prevented their rapid gravity separation. Homogenization is used in many dairy processes to improve physical properties of products.

**Coagulation.** Coagulation of milk is an irreversible change of the milk protein from a soluble or disperse state to an agglomerated or coagulated condition. Its appearance is commonly associated with spoilage, but coagulation is a necessary step in some processing procedures. Milk may be coagulated by several agents: heat, acid, alcohol, rennet, metallic salts, certain gums, and other precipitants. Milk that naturally sours is coagulated by the lactic acid formed by the lactose-fermenting bacteria that it usually contains. When milk is pasteurized and held refrigerated for two or three weeks it will generally be spoiled if not coagulated by psychrophilic, proteolytic organisms.

Milk varies in its resistance to heat coagulation and may require many hours at 240° F (116° C) before coagulating. If the milk is concentrated, as in evaporated milk manufacture, it usually coagulates in 15 to 30 minutes at this temperature. Resistance of the concentrate against coagulation can be increased by prewarming the raw milk to a boiling temperature before concentration or by adding a minute quantity of a stabilizing salt before sterilization. Sodium phosphate is generally used for stabilization of evaporated milk.

Acidity and coagulation

Development of acid in milk by bacterial growth or addition of acid causes it to coagulate quickly during heating. Coagulation by acid is an important aid in production of special forms of milk for distribution under refrigeration in fluid markets. Cultured buttermilk is soured by controlled growth of bacteria to produce desired flavour and thick body. Yogurt is made by growing acid-forming yogurt organisms until a gellike structure is attained. Bulgarian, koumiss, and kefir cultures make the coagulated milks named for them. Milks designed to produce a soft curd in the stomach, especially for children, can be made by treatment of the milk by a proteolytic enzyme. Some cows naturally produce soft curd milk, and the homogenization of milk will give it mild soft curd characteristics.

**Processing milk. Pasteurization.** Steps in the pasteurization of milk or cream are shown in the flow chart in Figure 2. All approved pasteurization systems are equipped with a flow diversion valve to return improperly heated milk to the raw milk side of the system in case of malfunction. The liquid-vapour separator is under partial vacuum and deodorizes the milk by removing volatile off-flavours. The bottling or packaging machine fills and seals the milk in retail containers.

Milk pasteurizers were originally of the vat type that held the milk at 145° F (63° C) for 30 minutes. Modern

Drawing by D. Meighan

Figure 2: Milk pasteurization process.

pasteurizing equipment is designed for high temperature, short time, continuous operation between 162° F (72° C) for 16 seconds and up to 185° F (85° C) for no holding time. Pasteurizers are of the regenerative type, the hot pasteurized milk being cooled by the incoming raw product. Cream, skim milk, and other liquid products are pasteurized in the same equipment.

*Separation of cream.* The cream separator produces cream and skim milk, from which many dairy products are made. This machine, a high-powered centrifuge, is the successor of the gravity creaming pan. When subjected to the centrifugal force the milk-fat globules leave the plasma phase of the milk and emerge as cream from the separator bowl. Optimum separation temperature is 104° F (40° C). Efficiency is greatest when the fat globules are large, those under one micron in diameter usually remaining in the skim milk, which should contain less than 0.02 to 0.05 percent fat.

*Clarification of milk.* Milk clarifiers are centrifugal machines that remove extraneous matter from milk. They are built much like separators, but all the milk flows out of a single outlet, foreign material remaining in the bowl.

*Quality of fresh milk products.* Sanitary production and regulatory control of fresh dairy products are usually under the direction of municipal or national agencies. Inspectors regularly visit farms, plants, and distributing centres to ensure that the products are safe and nutritious.

Conditions  
of storage

Fresh milk, buttermilk, yogurt, cottage cheese, and allied products are very sensitive to conditions of handling and storage. Their storage life at 45° F (7° C) is usually considered to be about 15 days, but recent studies have shown that milk held at 33° F (1° C) has a storage life double that time. Thus the best practice is to hold dairy products at a temperature just above freezing.

Less rigid but safe requirements regulate the production of manufacturing grade milk, which is used in making all products except those in the fluid milk class.

Fat content may be considered an aspect of quality and, in most countries in which milk is an article of commerce, standards of composition of milk for retail sale are established by law or local regulations. The minimal standard for fat is usually some value between 3.0 and 3.5 percent, that for nonfat solids usually 8.5 percent.

*Packaging fluid milk products.* Milk containers in the U.S. are largely paper cartons, automatically filled and sealed by continuous machines. In countries where glass bottles are used, each bottle makes 20 to 40 trips. Returnable glass bottles are washed in automatic bottle-washing machines.

*Sweetened condensed and evaporated milk.* Sweetened condensed and evaporated milks are old forms of concentrated milks prepared and canned for consumer use. Their compositions are tabulated in Table 3. Sweetened condensed milk is a favourite product in many tropical countries, where it is made in modern recombining plants from dry skim milk and butter oil shipped in from dairy countries. Modified processes have been developed for the powder oil mixtures.

Sweetened condensed milk is usually made from fresh milk by adding sugar to the milk, prewarming and concentrating the mixture under high vacuum, cooling the sirupy milk so that the lactose crystallizes as very fine crystals, then canning the product. Although sweetened condensed milk thickens to a gel after long storage, it has excellent keeping qualities, being preserved by the sugar even after opening. The canned product is a consumer item used often where milk is scarce, refrigeration lacking, and temperatures such that unsweetened milk does not keep well.

Condensed milks without added sugar and without sterilization are made by pasteurizing fresh whole or skim milk and concentrating it under vacuum to about 30 to 40 percent solids. The products are cooled and held refrigerated until sold. Candy manufacturers, bakers, and ice cream processors are large users. The condensed products often are tailored to the specifications of the purchaser.

Production of evaporated milk involves several important steps. The raw milk is warmed to 203° F (95° C) for ten minutes to give its concentrate the stability needed to withstand sterilization in cans without coagulating. The milk is concentrated to a 2:1 solids content in a multiple-stage evaporator. The composition of evaporated milk is given in Table 3. The concentrated milk is homogenized, standardized, canned, and sterilized at 240° F (116° C) for 16 minutes in a high-capacity continuous sterilizer. Before sterilization the heat stability of the concentrate is adjusted with a stabilizing salt so that the body of the finished product is smooth and creamy. Improper stabilization can result in an unacceptable coagulated product.

New ultrahigh-temperature sterilization methods can be used to produce evaporated milk with only slightly more cooked flavour than pasteurized milk. In storage of such milk, flavour and body changes occur that reduce its consumer acceptance. More research is needed to improve the product.

Evaporated milk is usually fortified during manufacture with the addition of vitamin D; evaporated skim milk is fortified with vitamins A and D.

#### ICE CREAM AND OTHER FROZEN DAIRY PRODUCTS

Commercial production of ice cream originally grew out of the discovery that a mixture of ice and salt could produce lower temperatures than salt alone. In the late 19th century, development of mechanical refrigeration laid the basis for the modern ice cream industry.

Ice cream products are prepared for consumption in the frozen state, but many other dairy foods are frozen as a means of preservation. Frozen milk, frozen cream, frozen concentrated milk, and frozen concentrated skim milk are especially prepared for preservation by freezing and holding for future wholesale and retail use. Frozen cream and concentrated milks act as an industry balance wheel, since they are held from seasons of high production and used in seasons of scarcity.

**Composition and properties.** The compositions of ice cream, ice milk, and sherbet are shown in Table 3 and the quantities of the important vitamins in ice cream are given in Table 5. Fruit sherbet contains only 1 to 2 percent fat and 2 to 5 percent milk solids. All contain a maximum of 0.5 percent stabilizer and 0.2 percent emulsifier. The blend of milk fat and nonfat solids with sugar must result in a product of pleasing taste and one which is smooth and creamy. Composition is important but the most critical stage of ice cream manufacture is the mechanical blending, freezing and hardening of the frozen dessert. Even water ices on a stick, although quiescently frozen, must be frozen rapidly to prevent coarseness of body.

Imitation ice creams known as mellorine are made in various parts of the world where economic conditions favour them. Mellorine is cheaper than ice cream because inexpensive vegetable fats and oils are substituted for milk fat. Other than this change mellorine has approximately the same composition as ice cream. There is still no satisfactory, cheap substitute for milk protein, although some vegetable proteins, particularly soy, have been prepared with improved flavour in recent years.

**Manufacture of ice cream.** Ice cream is a complex system in which the stable mixed emulsion of a four phase system, fat–water–ice–air, must be balanced and protected from breaking or separating. The manufacture of ice cream starts with making the mix. This is composed of a combination of suitable dairy products such as cream, milk, or skim milk either concentrated or dry. At least two mixing tanks and three aging tanks are needed to feed mix continuously to the freezer. The complete mix must be homogenized, pasteurized, and aged for at least four hours to condition it for freezing. The ice cream is extruded from the freezer into packages that are conveyed to the hardening and storage rooms.

The mix is compounded and frozen in such a way that the final product is smooth, homogeneous, and free of coarse ice crystals. Emulsifiers and stabilizers are used to finely distribute the milk fat, the ice crystals, and the air

Use of  
vegetable  
fats and  
oils

bubbles of the frozen product. Sugar in the mix is essential not only to give sweetness but also to lower the freezing point. As the water freezes the syrup becomes more concentrated, and this finally creates an unfrozen syrupy vehicle to give added smoothness and palatability.

Incorporation of air in a mix during freezing (overrun) can double the volume. Hand freezers beat air into the mix as the water froze, but commercial freezers meter the air in under controlled conditions. The air must be incorporated and distributed as very fine bubbles.

Freezing is done with great rapidity and under severe agitation. Formation of the maximum amount of ice during freezer agitation produces smoothness. As ice forms the mix temperature is lowered until the heavy or molten product is discharged.

The common drawing temperature for batch freezers is 24° F (−5° C), when about 38 percent of the water in the mix is frozen. In the newer continuous freezers 54 percent of the water is frozen and the ice cream is drawn at 21° F (−6° C).

**Ice cream quality.** Quality implies a cleanly produced product of acceptable flavour, body, and texture. Defects that develop in ice cream have been a challenge to manufacturer and distributor. One scoring system for ice cream reflects the problem areas. Of 100 points, 45 are given for Aavour, 30 for body and texture, 15 for manufacturing facility, 5 for melting qualities, and 5 for packaging and colour. Flavour acceptability is governed by the quality of the flavouring ingredient used; *e.g.*, fruit, chocolate, or nuts. The basic flavour must come from high quality milk and cream. Body and texture are affected by physical characteristics such as freezing and storage conditions. Two principal defects are sandiness, caused by formation of noticeably large lactose crystals, and shrinkage of the product away from the sides of the package. Both of these develop rather slowly in hardening rooms or cabinets. An icy texture may result from partial melting and refreezing.

Grades and standards for ice cream permit it to be made to suit different tastes, weather conditions, and selling prices. Richness, reflected in fat content, affects both flavour and price. The usual fat content of ice cream is about 10 percent, but richer and more expensive products, such as French ice cream, may contain 12 or even 14 percent butterfat.

Ice milk contains between 2 and 7 percent fat. But with the use of stabilizers and rapid low-temperature freezing techniques ice milk can be made almost as smooth and creamy as ice cream.

**Frozen dairy products.** Milk and cream are sometimes frozen as a means of preserving them. The freezing point of milk is quite constant at 31.05° to 30.98° F (−0.53° to −0.58° C). A check of freezing point is a reliable method for detecting addition of water to milk. Freezing tends to destroy the fat emulsion of whole milk so that on thawing an oily fat layer forms. Homogenization before freezing almost entirely eliminates fat separation except in creams containing more than 30 percent fat. Very rapid freezing, and increase in nonfat solids, or addition of sugar also retards the amount of fat that "oils off" after thawing. Cartons of homogenized milk (not glass containers) may be quickly frozen for later use without adverse effects. Cream is frozen commercially for future use.

Fresh concentrated milk may be frozen without emulsion damage, but prolonged storage may cause the casein gradually to become insoluble.

Freezing has no observable effect on the characteristics or quality of butter and it is commonly held in cold storage at −4° F (−20° C). The freezing point of unsalted butter is 32° F (0° C) and that of salted butter −4° F (−20° C).

Because of its high sugar and lactose content sweetened condensed milk is not damaged by freezing temperatures. Its freezing point is in the vicinity of 5° F (−15° C).

The freezing points of cheeses vary from about 30° to 3° F (−1° to −16° C), depending upon moisture content. When cheese undergoes extensive freezing the body and texture become more crumbly and mealy after thaw-

ing. High-moisture cheeses such as cottage, Neufchâtel, and cream are usually seriously damaged by freezing.

#### BUTTER AND BUTTERFAT

From a quarter to a third of the world's milk production is used to make butter. Butter is a concentrate of butterfat or milk fat. Creams of various fat contents are intermediate products in butter manufacture. When the cream emulsion is broken, free milk fat is released and this is called butter oil or, if entirely dehydrated, anhydrous milk fat. Plastic cream is a milk fat concentrate containing up to 80 percent fat, the same fat content as butter, but with the emulsion unbroken. Plastic cream is produced by centrifugally concentrating milk fat, while butter requires not only concentration but also breaking of the fat emulsion. Various kinds of butter-like spreads containing some milk fat have been made but do not have wide recognition as standard products.

**Composition.** The composition of butter, butter oil, and the creams from which they are prepared is given in Table 3. Most butter contains at least 80 percent fat, not more than 16 percent water, about 2 percent added salt, and 1 percent milk curd. It is a stable mixed emulsion of fat and water but stability is lost and it oils off when the fat is melted. The fat consists largely of mixed triglycerides of fatty acids and its composition tends to vary with many factors.

Vitamins E and A and carotenoids are present in microgram quantities and these are responsible for the natural golden colour of milk fat. Vegetable colour is sometimes added in commercial production.

**Physical properties.** The physical properties of butter and the high-fat creams and spreads stem from the unusual characteristic of milk fat as it occurs in milk. Manufacturing processes are built around the physical behaviour of the individual fat globule. Most of the globules are smaller than 4 microns (1,000 microns equal one millimetre) and they seldom exceed ten microns in diameter. The globules are covered by a protective membrane that must be disrupted to obtain butter or butter oil from cream. When the globules are destabilized by churning and, at high-fat concentrations, by homogenization, the membrane is disrupted. The rising of fat globules in milk and the formation of a cream layer represent basic properties of the fat emulsion. During rising the smaller globules clump together and the aggregates rise rapidly but without disturbance to the membrane. The centrifugal separator hastens this process by producing a plasma and a cream phase rapidly and much more efficiently than older gravity systems. The separator bowl is filled with a series of disks to channel the skim milk phase to the outside of the bowl while the lighter cream phase moves toward the centre. Separator efficiency depends upon fat content and size of the globules and the temperature of the milk, which should be 104° F (40° C).

In churning, about half the fat globule membrane material is liberated into the buttermilk. During homogenization there is a fourfold to sixfold increase in new fat surface and at high-fat levels, above about 50 percent fat, there is insufficient membrane material to cover the new surface. The system becomes destabilized and may oil off. Complete destabilization occurs in creams of 70–80 percent fat, and homogenization is used under such conditions to break the emulsion as the first step in the continuous churning process.

The hardness of the butter is affected by the physical state of the fat. When secreted by the cow in milk the fat is in a liquid state. It is partly solidified for churning by a temperature adjustment and aging at about 52° F (11° C). Temperature manipulation of the cream before churning affects the consistency of the butter. If milk fat or butter is melted and gradually cooled a large number of crystalline fractions can be obtained. Melted fat cooled to room temperature (70° F or 21° C) contains about half solid and half liquid fat. A variability in hardening temperature may be used to produce a more spreadable or an excessively hard butter at refrigeration temperature. The change in hardness is subject to further change by subsequent shifts in storage temperature.

## Production of whipped butter

Whipped butter has been developed to furnish a soft, easily spread butter at refrigeration temperatures. Air or nitrogen gas is whipped into softened butter by giant whippers, the product is extruded into consumer-size cartons, tubs or serving dishes and hardened in cold storage. Volume is increased about 50 percent.

**Manufacture of butter.** Butter was first made by separating cream from milk by gravity, and then subjecting it to mechanical agitation. Invention of the cream separator made it possible to gather large amounts of cream in one place and this moved buttermaking from the home to the factory. Here the cream is churned and worked in wooden or metal churns (see Figure 3). Such butters are rela-

By courtesy of F.A.O.; photograph, Prabha Art Studio, Bombay

Figure 3: Bulk butter taken from a stainless steel butter churn (India).

tively uniform in appearance and physical characteristics. Continuous buttermaking, introduced after World War II, achieves increased manufacturing efficiencies and plant output. The early continuous processes tended to produce butters that lacked uniformity, but newer modifications of the process are succeeding in overcoming this difficulty.

Churning by either batch or continuous method must involve a destabilization of the fat emulsion by mechanical agitation. In the batch churning process small air bubbles are incorporated in the cream by agitation. The fat globules gather at the surface of the bubbles (at the fat-plasma interphase) until the foam collapses when butter granules are formed. The buttermilk is drained from the churn and the butter is worked to incorporate the correct amount of moisture. The butter is then chilled for 48 hours before grading.

Continuous buttermaking may be classed in two categories: methods involving the accelerated churning of cream of normal composition, and methods that utilize re-separated high-fat cream. In the first process, cream of about 36–40 percent fat moves in a thin layer through a churning cylinder. The violent agitation in the air-cream layer breaks the emulsion in a matter of minutes, compared with up to one and a half hours in the conventional churn. The air content of the butter and fat losses in the buttermilk have been troublesome but are being corrected. Factory capacity using this system has been increased from 500 to 5,000 kilograms (about 1,100 to 11,000 pounds) per hour.

The second continuous method appears to be less popular at present, but has been used extensively to prepare butter oil. The cream is pasteurized and concentrated from about 35 percent to 80 percent fat; it then goes to an emulsion breaker, usually a homogenizer. The oil is skimmed off to 98 percent fat in a second separator. If anhydrous milk fat is desired the oil goes to a vacuum dehydrator, which removes the last water to yield a 99.9 percent oil. If butter is desired the 98 percent fat product goes to a standardization tank where the required moisture, curd, and colour are added to ready the mixture for

the butter worker and chiller from whence it is ready for extruding into packages.

**Butter quality.** Butter should be uniformly firm, waxy, and of good spreading quality, the granules close knit to cut clean when sliced. The water droplets should be well distributed throughout the mass. Some terms for body defects are "crumbly," "leaky," "sticky," and "weak." Of lesser importance in grading are colour and salt distribution.

The yellow colour of butter reflects its carotene content. The amount varies, winter butter produced on dry feed being lower in carotene than summer butter. Vitamin A is also substantially higher in summer butter. Ninety to 100 percent of the vitamin A in the milk goes into the butter. In the U.S., a harmless yellow vegetable colour, annatto, may be added to butter to improve colour uniformity throughout the year. No other additive is permitted. Vitamin D content of butter is low.

Butter from periods of high production is often held in dry storage for later movement into consumer channels at 0° F (−18° C).

**Packaging.** A large part of the butter produced at country plants is shipped to primary receivers who "print" and package it for distribution. Printing is the term used for cutting and wrapping the butter in consumer units. Butter is usually sold at retail wrapped in tight, moisture-proof packages.

### CHEESE

An ancient legend attributes the invention of cheese to an Arabian merchant who filled his pouch made of sheep's stomach with milk and, after travelling all day, found that the milk had separated into curds and whey. The lining of the pouch contained rennet which, with the sun's warmth, caused the milk to coagulate and the whey to separate just as it does in the modern cheese vat. Some such accident may indeed have occurred; in any case, the art of cheesemaking spread from western Asia to Europe in ancient times. Special varieties developed in isolated communities in the Middle Ages, such as Gorgonzola in the Po Valley in Italy and Roquefort in the Roquefort caves of France. In the mid-19th century cheesemaking changed from a farm product to a factory industry.

**Composition and properties.** Cheese is a complex product and its composition is determined by a number of interrelated factors. The percentage of fat in the milk and the method of manufacture are most important. Moisture content, related to hardness, strongly influences keeping quality. Compositions of some common cheeses are shown in Table 4.

Part of the calcium and phosphorus of the milk is retained in the cheese. Essentially all of the fat and casein of milk goes to the cheese while the whey proteins (globulins and albumins), lactose, and soluble salts remain in the whey.

There are several hundred varieties of cheese, all with somewhat different composition and properties. Most were developed gradually over a long period as a result of accidental or intentional modifications of the cheesemaking process. Today, as cheesemaking passes from an art to a science with exact chemical and microbiological control, there is better standardization and uniformity of composition.

**Classification of cheese.** The cheese-manufacturing process is designed to produce cheese in one of four classification groups. Group 1 is very hard grating cheese ripened by bacteria, such as Parmesan, Romano, and sapsago. Group 2 is hard cheese ripened by bacteria but without eyes, as Cheddar, or with eyes, as Swiss and Gruyère. Group 3 cheeses are semisoft and of three kinds: (1) ripened by bacteria, as brick and Muenster; (2) ripened by bacteria and surface micro-organisms, as Limburger and Port du Salut; (3) ripened by mold in the interior, as Roquefort, blue, Gorgonzola, and Stilton. Group 4 is the soft cheese of two kinds, ripened, as Bel Paese, Camembert, and Neufchâtel; and unripened, as cottage, pot, cream, mysost, primost, and fresh ricotta. Examples of the manufacturing processes for one cheese in each class are given below.

Varieties of cheese

## Curds and whey

**Manufacture of cheese.** Cheese is made by coagulating milk, cutting and heating the curd to express the whey, then pressing and ripening the cheese. The process is a microbiological one in which enzymes produced by bacteria develop the desired body and flavour. The initial coagulation may be brought about by addition of rennet, by addition of bacterial starter that develops acid by fermentation of the lactose in the milk, by direct addition of acid, or by a combination of these. To hasten curd formation the milk is held quiescent and warm for a number of hours. When congealed the curd is cut and cooked by mildly heating it to release the whey. The warm curd, containing the bacterial flora needed to produce the desired cheese variety, is pressed in suitable molds, hoops, or boxes. Some varieties (e.g., cottage) are sold in the fresh state. Ripened cheeses must be held under critical temperature and moisture conditions to permit bacterial enzyme action, which creates the kind of cheese desired.

**Parmesan cheese.** Parmesan was first made in the vicinity of Parma, Italy. Milk or partly skimmed milk is warmed to 90°–98° F (32°–37° C) in copper kettles, a heat-resistant lactobacillus culture, plus rennet, is added to produce a firm curd in 20 to 30 minutes. The curd is placed in a hoop 10 inches (25 centimetres) deep and 18 inches (46 centimetres) in diameter and pressed for 20 hours. It is taken to a salting room and held at 62° F (17° C) for three days. The cheese is then removed from the hoop and held in brine for about 15 days, after which it is dried for 10 days. The first stage of curing consists of holding the cheese at 60° F (16° C) and 80–85 percent humidity for one year. The second stage is usually in the dealer's curing room at 54°–60° F (12°–16° C) and 90 percent humidity. It can now be sold, but it will keep almost indefinitely. Its most important use is for grating.

**Cheddar cheese.** Cheddar cheese was first made in the 16th century in the village of Cheddar in England. In the U.S., where almost 70 percent of the cheese made is Cheddar (often called American cheese or American Cheddar), the term "Cheddar" is used to describe both a type of cheese and a step in the manufacturing process. The most common form of the cheese is 14½ inches in diameter by 12 inches thick (37 by 30 centimetres) and weighs 75 pounds (34 kilograms).

A hard, white-to-yellow coloured cheese, Cheddar is usually made from pasteurized milk (see Figure 4). Start-

turned and piled into layers. The slabs of curd are cut in a curd mill, salted, drained, and placed in cloth-lined metal hoops for pressing. After pressing the cheeses are dressed and dried for three to four days at about 55° F (13° C) before dipping them into wax. Rindless cheese can be made by wrapping it in heat-sealing plastic film. Cheddar cheeses are usually cured at about 45° F (7° C) for several months, or sometimes as long as a year.

Much effort in the U.S., Europe, and Australia has been directed toward automation of the Cheddar-making process, but it has proved difficult to mechanize the various steps without altering the sequence of chemical and microbiological changes that must occur to produce an acceptable product. Every step of the process is critical. All must be accomplished at the proper time, temperature, and acidity. The four basic steps suitable for mechanization are: (1) coagulating the milk or forming the curd; (2) draining the whey and cheddaring the curd; (3) cutting and salting; (4) pressing and handling for ripening. Two types of equipment for steps 2 and 3 have been developed in Australia.

**Roquefort or blue-veined cheese.** The name Roquefort is limited by French regulation to cheese made in the Roquefort area from ewe's milk; much more common is a similar blue-veined cheese made in many countries from cow's or goat's milk and often called blue cheese. Blue cheese is usually made from cow's milk by setting and cutting the curd, draining the whey, and placing the cheese in hoops. Blue mold powder grown from the mold *Penicillium roqueforti* is mixed with the curd. After 24 hours, the cheeses are removed from the hoops and dry salted over a seven to ten day period at a temperature of 48° F (9° C) and 95 percent relative humidity. A week after salting, each cheese is pierced with 40 small holes to permit air to reach the interior, air being essential for mold growth. The cheese is cured for three months and scraped and cleaned every three weeks during this time. The natural caves at Roquefort provide ideal curing conditions, 48° F (9° C) and 95 percent humidity. Suitable caves exist in other countries and artificial conditions have been successful.

**Cottage cheese.** Cottage is sometimes called pot or Dutch cheese, or schmierkase. It is soft, uncured, high in moisture, and perishable. Cottage cheese is made from pasteurized skim milk to which rennet and bacterial starter are added to coagulate the milk and produce flavour. The curd is cut when firm and whey is expelled from it by heat. The whey is drained from the firmed curd particles, which are then salted, creamed, and packed in 50-pound (23-kilogram) tubs or consumer-size cartons.

**Process cheese.** Process cheese is made by grinding fine and mixing together by heating and stirring one or more cheeses of the same kind, or two or more varieties. Soft cheeses such as cottage, cream, or skim-milk cheeses are not used. Vinegar, other organic acids, colour, spices, and flavouring may be added. Emulsifying agents help to reduce the mixture to a homogeneous mass which is then stirred and cooked at about 155° F (68° C). When ready to be packaged it is extruded into cartons lined with a transparent film that acts as a sealer to exclude air. The packaged cheese is then cooled and held under refrigeration. As made and packaged, process cheese is practically sterile and does not ripen further. Fruits, vegetables, or meats, or mixtures of these, may be added to process cheese.

**Quality of cheese.** Cheese is a product of fermentation except for certain fresh curd varieties made by direct addition of acid to coagulate the milk. This is a new procedure and is not yet acceptable in many areas. Fermentations constantly undergo changes that affect cheese flavour, body, texture, and colour. These are influenced by the quality of the milk, the techniques of manufacture, and the temperature and time of curing. To manufacture cheese of uniformly good quality, it is essential to use good quality milk, sanitary and adequate equipment, uniformly active starter, a standardized and proven manufacturing procedure, and controlled temperature and length of curing time.

Microbiological control to suppress unwanted bacterial

er, rennet, and colour are added to the milk, which sets to a firm curd in about 30 minutes. The curd is cut into small cubes and stirred continuously with warming to 100° F (38° C). About 2½ hours after the rennet is added the whey is drained and the cubes of curd are piled along the sides of the vat, where they fuse together. When the curd is firm enough to be turned without breaking, it is "cheddared" or matted; that is, cut into slabs to be

Micro-  
biological  
control

and mold growth during cheese ripening is important in production of any specific variety. The making and ripening processes have been developed to encourage favourable chemical and physical changes of fermentation, proteolysis, and slight fat breakdown, and to discourage growth of organisms that produce objectionable characteristics.

#### DRIED MILKS

Skim milk, whole milk, and certain other milk products are dried to reduce weight and shipping charges, to provide a means of handling surpluses, to prolong keeping quality, and to reduce the products to a more useful form. Besides skim milk and whole milk, dairy products or by-products that are dried include buttermilk, malted milk, sweet or sour cream, ice cream mix, whey, coffee creamers, cheese mixtures, chocolate milks, skim milk-vegetable fat mixtures, and sodium or calcium caseinates. Lactose is always prepared in dry form. Skim milk, whole milk, malted milk, and buttermilk are major dry products; the others may be considered as by-products for which there are many special uses.

**Composition and properties.** Composition of dry whole, dry skim, dry malted milk, and dry cream are shown in Table 3. Composition, especially fat content, may be varied over a wide range to suit special uses in food manufacture. The content of vitamin A and the water-soluble B vitamins are not seriously changed by processing into dry form. The objective of drying is to produce a dry product without seriously impairing the solubility, colour, or flavour of the original material. This can be done to a remarkable degree and a freshly dried product when remixed with water cannot usually be distinguished from its fresh pasteurized counterpart.

**Manufacture of dried milks.** Two general types of milk dryers are used today. The simplest and cheapest is the drum or roller dryer. A common form consists of two large metal drums that turn toward each other and are heated from the inside by steam. The concentrated liquid is applied to the hot drum in a thin sheet which is dried during one revolution of the drum then scraped off by a steel blade. The process produces a flake-like powder particle that is easily dispersed in water but that dissolves poorly. It is used in food manufacture or for animal feed.

The spray dryer is widely used to dry liquid materials by spraying them in finely atomized form into a stream of hot air. The large droplet surface causes rapid evaporation of moisture and provides a highly soluble powder. The drying chamber may be conical, rectangular, or silo-shaped. The dry powder passes from this chamber through a series of cyclone collectors for separation from the drying air. About three pounds of steam are required to evaporate each pound of water. The product to be dried is heated, condensed to 45 to 50 percent solids, sprayed into the dryer, and collected as powder. The process may include foam-spray drying. This is a new modification and involves injection of gas, usually air, into the high-pressure line before the spray. The gas expands the droplet and causes it to dry easily into a light low-density particle.

Spray-dried milk is difficult to mix with water, and to improve its dispersibility a process called agglomeration or instantizing has been developed. This consists of quickly moistening the fine powder particles and causing them to stick together. The instantizing process produces only limited improvement in dispersibility of fat-containing dairy products, and it is not used for dry whole milk. Most powders can be made to dissolve readily when they contain sugar, particularly if they are dry-blended with sugar.

Buttermilk is either spray- or roller-dried. Malted milk consists of approximately half milk solids and half solids from a mash prepared from barley malt and wheat flour. It is usually made by evaporating the mixture to dryness under a vacuum.

Whey is roller- or spray-dried, but, because of its high lactose content, it presents special drying problems. The milk sugar is best crystallized after concentration and before drying since its presence in the dry powder in a non-

crystalline condition is conducive to moisture pickup and caking of the powder.

**Quality of dried milks.** Unusual sanitary precautions are taken to avoid contamination of the powder with salmonella organisms. All skim-milk powders are examined and must be free of these organisms. Whey is a perfect growth medium as it is drained warm from the cheese curd and for food use must be pasteurized and cooled at once, after which it can be held for condensing and drying.

**Packaging, marketing, and distribution.** Dried milks must be packaged to preserve flavour and physical characteristics. When packaged and distributed under favourable conditions dried whole milk and buttermilk will keep six months, while the skim milks and malted milks may be held up to 18 months. Stored milk fat in any form is subject to flavour changes caused by oxidation. Dried whole milk is packed in tins in an oxygen-free atmosphere and should be stored in a cool place, preferably under 45° F (7° C). Dried buttermilk contains traces of an unstable fat fraction and is best handled like whole milk. It is used in wholesale food preparation.

The dried milks and wheys readily absorb moisture, and packaging and storage must ensure against water pickup. The products contain about 3 percent moisture as made but readily absorb water to 5 or 6 percent, which causes rapid deterioration of flavour, caking, and lowered solubility of the milk proteins. Instant dried nonfat milk is packed in tight paper boxes or envelopes; it may be quickly dispersed in water with little or no stirring or shaking, and there should be no settling of insoluble protein on refrigerated storage. Once mixed with water the milk must be held under refrigeration.

Malted milk contains a natural antioxidant, and chocolate malted milk, especially, will keep in a dry environment at room temperatures for at least 18 months.

#### DAIRY BY-PRODUCTS

Skim milk, buttermilk, casein, whey, and whey components including lactose or milk sugar, are by-products of the dairy industry. They have high nutritive value and are used for human and animal food and to a lesser extent for industrial purposes. Most of the price paid for milk is for the fat and thus by-product prices are relatively low, the major items contributing to their cost being transportation, manufacture, distribution, and selling. Early in the 20th century farmers were separating their milk, selling the cream, and feeding the skim milk to farm animals. Today skim milk is valued as an important human food supplement and as a source of casein and lactose, which are prepared from it. Whey is a by-product of cheese and casein manufacture and is an important source of whey protein and lactose. Buttermilk is a by-product of the churning of cream. In the past the cream often was sour, leaving a buttermilk fit only for animal food. Today, most butter is made from sweet cream and the buttermilk has become a valuable food component.

**Composition.** The composition of skim milk, buttermilk, and whey are shown in Table 3. Extra grade casein contains 95 percent protein, a maximum of 10 percent moisture, 1.5 percent fat, and 2.2 percent ash. Lactose or milk sugar is the carbohydrate obtained from whey, and it should be at least 99 percent pure. Casein and whey protein are sometimes prepared by a single precipitation, and the composition of the coprecipitate may be 83 percent protein, 1 percent lactose, 1.5 percent fat, 10.5 percent ash, and 4.0 percent moisture.

**Physical properties.** The physical properties of the by-products differ greatly, depending upon their composition. The state of the protein and lactose is of major interest to the food manufacturer and the consumer since this affects the physical properties of the food. The casein of skim milk is uniformly dispersed but it can be flocculated or coagulated by acid, enzymes, or heat. Coagulation is accompanied by an uptake of water, which causes thickening and the building of body or structure in the food. The coagulum is unstable and syneresis or wheying off will occur with time or heating, similar to the whey separation in cheesemaking. Casein is coagulated to re-

Keeping  
character-  
isticsSpray  
dryingCasein of  
skim milk

move it from the milk. To make it redispersable for use as food it is prepared as sodium caseinate, which will reabsorb water and rebuild a structure. Whey protein differs from casein in that it is acid soluble but very sensitive to heat, coagulating at temperatures below the boiling point of water.

Lactose, which makes up half the solids of skim milk and three fourths of the solids of whey, is much less soluble than most other sugars. At room temperature lactose is saturated in water at a 17 percent concentration. On a scale of sweetness on which sugar is 100, lactose is only about 20. If lactose crystals form in a food such as ice cream or sweetened condensed milk they are kept to a very small size to avoid giving a sandy texture.

**Manufacture of by-products.** Manufacture of skim milk, whey, and sweet cream buttermilk for food use follows conventional lines of vacuum concentration and drying. Sometimes these products are used in condensed form and the lactose is crystallized with stirring to produce fine crystals. Drying may be either by the spray or roller methods, the spray system producing the higher quality product. Buttermilk as a by-product of butter-making is not to be confused with cultured buttermilk, which is sold fresh, never in the dried form. Cultured buttermilk, once dried, will not reabsorb water. Dried sour-cream buttermilk is suitable only for animal feed.

Processing of whey presents a special problem because small cheese factories cannot afford concentrating and drying equipment, and whey cannot economically be hauled over long distances. Reverse osmosis or membrane filtration to concentrate whey to 25 percent solids, thus reducing hauling costs, is being advanced as a solution. In any processing scheme for whey the extreme perishability of the product must be considered.

Casein is made by precipitating it from skim milk by the addition of an acid, usually hydrochloric. The precipitated casein is washed, dried, and ground. Skim milk can be naturally soured, and the lactic acid thus formed acts as the acidulant.

Lactose is produced from whey by heat coagulating and removing the whey protein, concentrating the clear whey, then crystallizing the lactose and removing it by centrifugal separation. A pure sugar is obtained by redissolving the sugar, clarifying, decolorizing, and concentrating the syrup, then centrifuging it.

**Quality of by-products.** The world shortage of food and a realization of the high nutritional value of milk components have led to the development of rigid quality standards for the sanitary production of milk by-products. Rigid bacteriological control is necessary since skim milk, buttermilk, and whey all contain 90 percent or more water and are excellent media for bacteria growth. By-products are usually packaged in multiwall paper bags, often with a moisture-tight lining.

#### DAIRY PRODUCTS IN HUMAN NUTRITION

Milk and dairy products are accepted in many countries as basic foods, some of which persons of all ages should have every day. The precise role of the milk components—protein, fat, lactose or carbohydrate, and minerals—in human nutrition is still incompletely understood. But these essential elements of a balanced diet are combined in the proportions and amounts needed for the growth of infants and children and for the dietary well-being of an adult. Indeed, the milk of each species is a complete food for its young. One pint of summer milk contributes about 90 percent of the calcium, 30 to 40 percent of the riboflavin, 25 to 30 percent of the protein, 10 to 20 percent of the calories and vitamins A and B, and up to 10 percent of the iron and vitamin D needed by an adult. Although milk supplies a higher proportion of the daily needs of a five-year-old child for calories, protein, vitamins A, B<sub>1</sub>, and B<sub>2</sub>, the contribution of the calcium needs is reduced to about 70 percent because of the higher calcium requirements of a child.

Milk protein is of high nutritional value, since it contains all the essential amino acids; *i.e.*, those that cannot be synthesized in quantity. Eighty-two percent of milk protein is casein and 18 percent whey protein. The nutri-

tional response to casein or to whey protein is quite uniform, and these proteins, especially casein, are used as a protein reference standard in feeding experiments. Because cow's milk contains proportionally more casein and less lactose than human milk, it is usually recommended that, for babies' formulas, water and lactose be added to cow's milk.

The nutritional value of milk fat is still unclear. It is the most complex of the natural fats, containing at least 142 fatty acids. Its composition varies widely, depending upon such factors as the cow's intake of unsaturated fatty acids and the levels of dietary fat, protein, and roughage eaten. Considerable research has been done on the possible involvement of milk fat in cardiovascular disease in man but no conclusions can yet be drawn as to what effects this or other fats may have on this ailment.

Lactose, or milk sugar, is a product of mammalian metabolism secreted in milk for nourishment of the young. Its exact nutritional function is not known, but its role in a number of metabolic processes has been studied. Lactose is hydrolyzed in the body to glucose and galactose. Glucose is absorbed directly. Galactose is considered a dietary essential because of its occurrence in cerebrosides and mucopolysaccharides. A deficiency of these is thought possibly to lead to diseases of structural and nervous tissue in later life. There is increasing evidence that a lactose intolerance produces mild or even severe digestive disturbances and diarrhea. Symptoms have been produced in individuals, most often of non-Caucasian races, by feeding 50 grams of lactose in water or even in milk or whey. It is not known whether the intolerance is genetic or whether it has been acquired by long omission of milk from the diet. Intolerance appears to be caused by the absence of the enzyme lactase in the intestine.

There are interrelationships between milk minerals and other food nutrients that are still not clear. Many minerals are involved in maintaining the balance of mineral ions in body fluids, in regulating the metabolism of enzymes, in keeping an acid-base balance, and in facilitating membrane transfer of essential compounds. The mineral content of milk includes calcium and phosphorus adequate for normal skeletal development. The dietary essential minerals that occur in major amounts in milk are, in grams per quart: potassium 1.31, calcium 1.18, chlorine 0.97, phosphorus 0.91, sulfur 0.28, and magnesium 0.11.

The nutritionally essential elements that occur in milk in minor amounts, in milligrams per quart, are: zinc 3.6, iron 0.95, copper 0.28, iodine 0.20, fluorine 0.15, manganese 0.019, molybdenum 0.069, cobalt 0.0006. Other minerals in milk occur only in trace amounts.

Milk contains all of the vitamins known to be required by man. The quantities of water soluble vitamins in a quart of milk are shown in Table 6. Milk contains the

fat-soluble vitamin A and carotene, its precursor, but the amount varies considerably with the food of the lactating animal. Since green food is the main source of this vita-

min in the diet of cows, summer milk usually has more than winter milk. Some commercial producers have fortified milk with the addition of vitamins and sometimes of iron.

#### DAIRY INDUSTRY ORGANIZATIONS

Types of  
organiza-  
tions

The dairy industry is organized in rural and urban areas on a local, national, and international basis. Organizations within the industry represent farmers, processors, distributors, suppliers, engineers, educators, and industrial and research scientists.

The International Dairy Federation, with its headquarters in Brussels, was established in 1903 and consists of 32 member countries throughout the world. It sponsors an International Dairy Congress at four-year intervals; the 20th such congress was held in Paris in 1978. The 21st congress was scheduled for Moscow in 1982. The congresses include reviews of research and industrial progress and exhibits of dairy industry equipment.

The United Nations Food and Agriculture Organization (FAO) and United Nations Children's Fund (UNICEF) have made important contributions to international dairying. Their attention has been directed especially toward increasing the production and utilization of milk in the less developed countries. FAO has sponsored studies in production, processing, and distribution of milk and its products. UNICEF has been the motivating force for establishing a dairy industry in many of the underdeveloped countries. One of these is India, where large, modern processing plants have been set up to process locally produced milk or to reconstitute milk from donated or purchased milk fat and powder. Domestic milk production has increased in India, and part of the pasteurized milk is provided free to children in the larger cities through the auspices of UNICEF.

An outstanding example of a UNICEF-aided activity in India is the Bombay Milk Scheme, which furnishes pasteurized milk for the residents of Bombay. Two hundred miles (about 300 kilometres) north of Bombay at Anand is Amul Dairy, a milk-processing cooperative that has developed a daily milk intake of 132,000 gallons (500,000 litres) milked from water buffalo. Under agreement with UNICEF 52,800 gallons (200,000 litres) of this milk is shipped to Worly Dairy in Bombay for distribution in the city milk stations, and the remainder is processed into powder, concentrated milks, and cheese. Amul Dairy operates a feed mill and offers complete veterinary services for its members. A successful example of a complete food-producing unit, Amul Dairy has been duplicated in other parts of India with assistance from UNICEF, the Indian government, and some of the large milk-producing countries of the world. These organizations have sponsored the Indian Dairy Development Board (Anand) and the Indian Dairy Corporation (Baroda), which derive support from the sale of milk from donated butter oil and milk powder.

The kind of national and local dairy organizations within a country vary widely. They are sponsored by governments, farmer cooperative groups, industrial processors, suppliers, or marketers, and institutional research and development organizations.

The first cooperative artificial breeding association was organized in Denmark in 1936. There are now many such associations, which use a few highly selected bulls to breed large numbers of cows.

Regulatory agencies operate in all developed countries, supported by either local or national governments. The dairy industry has always been strictly regulated because it is concerned with a basic but highly perishable food in which contaminating organisms can grow quickly to dangerous numbers. Most municipalities require inspection of the cattle, farms, trucks, and factories.

## Dakar

Dakar, the capital of Senegal, is situated near the westernmost point of Africa. Due to its strategic and impressive site and the importance of its port and airport, Dakar is one of the major cities in Africa. It was once the capital of French West Africa, from 1904 to 1959, and of the Mali Federation, from 1939 to 1961. The name comes from *dakhar*, a Wolof name for the tamarind tree, as well as the name of a coastal Lebu village that was located south of what is now the first pier. The population of the city is more than 1,000,000.

**History.** European settlement in the Dakar area began when the Dutch bought the islet of Goree, near Dakar Point, in 1617; it was captured by the French in 1677. In Anglo-French wars Goree was taken by the British five times; in peacetime it was a calling point for French East Indian ships, a centre of the slave trade, and a base for the suppression of the slave trade.

The mainland was occupied by France in 1857. A pier was built on Dakar Point, and in 1866 French steamships serving South America began to call there to take on coal. The next impetus to development came with the opening in 1885 of West Africa's first railway, from Saint-Louis to Dakar. The object was to replace Saint-Louis, the port for the then important Senegal Valley, with the better port of Dakar. The railway achieved this, but unexpectedly did far more for Dakar and Senegal by stimulating the cultivation of peanuts (groundnuts) in the vicinity of its track. The increase in trade led to an extension of the jetty in 1892 and to the building of the port's first breakwater.

Anglo-French rivalries in Africa and British troubles in South Africa brought about the establishment in 1898 of a French naval base at Dakar. As a result, a northern breakwater was built to enclose a large deepwater harbour. The southern jetty was again extended, and a dry dock was provided. In 1904 Dakar replaced Gorée as the federal capital of French West Africa. Two more southern piers were built between 1904 and 1910, and other facilities were improved. By 1914 Dakar was a well-equipped port and a pleasantly planned town, with a population of almost 24,000.

World War I brought an increase in the tonnage of shipping using the port; this increase was partly maintained after the war by the opening in 1924 of the Dakar-Bamako-Koulikoro railway line to the French Sudan (now Mali). The railway brought new transit trade to the port, and peanut cultivation was again stimulated in both countries. Between 1926 and 1933 two piers were added near the landward end of the northern breakwater especially for peanut export, supplemented in the later 1930s by the installation of pipelines for the export of peanut oil. These improvements destroyed the port of Rufisque, about 17 miles (27 kilometres) to the east, as a peanut-shipping competitor to Dakar. A fuelling pier was also built on Dakar's northern breakwater. Just before World War II the original pier on the southern jetty was further improved, and the breakwater was equipped to discharge oil tankers and refuel other vessels. By 1936 the town's population was almost 93,000.

During World War II Dakar, like all of French West Africa, recognized the authority of the Vichy administration of France in 1940, and the efforts of the Free French, under the leadership of General Charles de Gaulle, to

French  
occupation

Presidential Palace, the main government building of Dakar, facing the Baie of Gorée.

Harold M. Lambert Studios

secure the town in the same year failed badly. Further development of Dakar was delayed until French West Africa rallied to the Allies in 1943. Yof Airport was then constructed with American aid, and has since become of intercontinental significance. Another pier for peanut exports was added on the northwestern side of the harbour, the northern jetty and the westernmost southern pier were extended, and a cold-storage plant was provided. The storage plant encouraged Japanese and other tuna fleets to call at Dakar and led to a local fleet being established. It also made possible the import of more varied foodstuffs from temperate climates.

World War II gave a great impetus to peanut-oil refining because of local and North African needs for vegetable oil, previously refined mostly in France. Industries manufacturing cigarettes, textiles, shoes, soft drinks, and other consumer products began to be established to supply the entire French West African market. When, from 1959 to 1961, French West Africa split into eight independent states, each seeking its own industries, markets were reduced. The threat to Dakar's industries was less than feared, however, because the local market increased through the continued presence of about 28,000 French residents, by the relative prosperity of the port at times when the Suez Canal was closed, by the advent of cruise liners, and, finally, by increasing air traffic.

The years after World War II saw the greatest urban expansion, in the course of which the area of Dakar doubled. New quarters were built in the 1950s to the north and northwest of Dakar beyond the Médina, at Fann, Point E (with the campuses of the university and of the Fann Hospital Centre between them), Mermoz, and in the 1960s at many estates of Grand Dakar in the north. The first of these new quarters were originally European, but are no longer exclusively so. The northward spread of Dakar is also the consequence of an expansion in both industry and transport, including an increase in ownership of small French cars. The islet of Gorée has become a charming tourist centre, as well as a retreat for the diplomatic and richer commercial communities.

**The contemporary city.** *The site.* The narrow, westward-tapering Cape Verde Peninsula is in part a tombolo or former island that has been joined to the land by coastal drift and windblown sand on the north and by backwash on the south. Cape Manuel to the south and the offshore islets are Miocene basalts (from 7,000,000 to 26,000,000 years old). The centre of the town is built on Cretaceous or Eocene limestone (from 38,000,000 to

136,000,000 years old) on some of which there is laterite (red, leached, ferruginous soil and rock), while to the northwest are the two conical Pleistocene hills (from 10,000 to 2,500,000 years old) called Les Mamelles (breasts), the westerly and higher being Cape Verde itself. Basalts from these form the Almadies Point, Africa's western extremity. All these rocks provide building stone, and compose the low cliffs from the harbour to Capes Manuel, Verde, the Almadies, and Yof. To the northeast there is sand, on which the harbour and the industrial and northern housing estates have been built. The urban area extends about three miles, the limit of Dakar proper coinciding with the transverse avenue El Hadji Malik Si. Beyond are the peripheral arrondissements (quarters). Dakar Commune includes Dakar proper, the peripheral arrondissements, and the suburbs of Rufisque, Bargny, and Sebikhotane.

*Climate and soils.* The climate, although humid, is usually pleasant because northern winds and sea breezes sweep across the narrow peninsula, helped by the street alignments. Mean maximum temperatures vary from 79° F (26° C) in January to 89° F (32° C) in September to October, and the mean minimum temperatures from 63° F (17° C) in February to 76° F (24° C) from July to October. Annual rainfall is 23 inches, falling between late June and early October. Originally, the volcanic areas, such as the island of Gorée, were devoid of surface water, while the sandy areas were often marshy.

*The city plan.* The shape of the peninsula, its geology, history, colonial and other policies, such as subsidiary houses for civil servants, have created contrasted districts. In the southern district are public buildings, hospitals, the Pasteur Institute, and embassies. North is the business district, which is focussed on the central Place de l'Indépendance. North and east lie the quarters associated with the port, such as the port proper, the naval arsenal, the fishing harbour, and the peanut export sector. Near the latter, and close to the railway, are the older peanut-crushing plants and other factories, and further north is the industrial estate of Hann. The central business district and its northwestern fringes were until 1939 bordered by open space. Industry, markets, and sports stadiums later occupied this area, to the north of which lies the Médina, the first out-of-town Senegalese quarter, designed by the French in 1916. Beyond are the quarters built since World War II.

*Transport.* Roads are generally adequate for traffic needs; a motorway leads north and a good road north-

Postwar  
develop-  
ment

The city's  
districts

east. Buses serve the main areas, and both buses and the railway provide limited suburban service.

The port is fully sheltered, and always easy for ships to enter. There are five miles of quays, with depths of up to 36 feet; about 30 vessels can be accommodated. The port facility is equipped for repairs, refuelling, and the provision of water and victuals. In 1969 more than 5,300 vessels entered Dakar; goods exported totalled 1,559,000 tons (of which 1,048,000 tons were phosphates), and imports amounted to almost 1,973,000 tons (of which hydrocarbons to fuel shipping and generate electricity accounted for 1,001,000 tons). The modern airport is important for European-South American, American-African, European-African, and local services. In 1969 more than 8,000 commercial aircraft were handled.

**Demography.** The last sample census, in 1960–61, put the population of Dakar and Gorée at about 266,000 Africans and about 32,000 non-Africans. In 1968 the population of Dakar proper was estimated as more than 550,000. In addition, there are the peripheral arrondissements, which had about 65,000 Africans and about 3,000 non-Africans in 1961. As to tribal affiliation, the 1960–61 census revealed that the Wolof comprised 46 percent of the Africans, the Tukulor 11 percent, the Lebu 8 percent, and the Serer 6 percent. The total metropolitan area population was estimated at 661,000 in 1968. The annual growth of Dakar proper is about 6 percent, an increase that is now more by natural growth than by immigration. In religion the Africans are mostly Islamic, while the non-Africans are mostly Catholic Christians.

**Housing.** Types of housing range from ultraluxurious mansions or apartments in the south and in the Fann area to shacks made of flattened containers or boxes in the north-central quarters near the motorway. The northern estates have been built by commercial housing societies. Public buildings are imposing, and include the Presidential Palace, the Administrative Building, the National Assembly, and the buildings around Place de l'Indépendance and at the university.

**Economic life.** Dakar is one of tropical Africa's leading industrial and service centres. Industries not already cited include fish canning, flour milling, brewing, truck assembly, and oil refining. Commercial activities are usually prosperous and international in their range.

**Services and institutions.** Public services, by the standards of tropical Africa, are good—especially the educational and medical services. Dakar has several newspapers and many cinemas. There are excellent museums of the sea and of history on Gorée, and of ethnography and archaeology in Dakar; there is also a village of working craftsmen. There is, however, no permanent theatre nor are there any significant public libraries. There is a radio station and one government-sponsored educational television station. The only park and the zoo are at Hann; other open spaces are few. The corniche road (cut into the cliff) round Cape Manuel affords fine views of the harbour and the islands. On this road is a large swimming pool, and there are some good beaches.

Dakar is neither purely Senegalese nor typically West African; rather it is southern French in character and international in function.

## Dalhousie, James Ramsay, 1st marquess of

Governor general of India from 1847 to 1856, James Andrew Broun Ramsay, 1st marquess of Dalhousie, added to the territories under British administration by many conquests and annexations. At the time, confidence in British rule and its benefits was at its peak, and Dalhousie, who fully shared this confidence, accelerated the pace of westernization. So radical were the resulting changes and so widespread the resentment they caused that his policies were frequently held responsible for the Indian Mutiny in 1857, one year after his retirement.

By courtesy of the National Portrait Gallery, London

Dalhousie, oil painting by Sir John Watson-Gordon, 1847. In the National Portrait Gallery, London.

He was born on April 22, 1812, the third son of George Ramsay, the 9th earl of Dalhousie, at Dalhousie Castle, Midlothian, Scotland. His family had traditions of military and public service but, by the standards of the day, had not accumulated great wealth, and, consequently, Dalhousie was often troubled by financial worries. Small in stature, he also suffered from a number of physical infirmities. Throughout his life he derived energy and satisfaction from the thought that he was achieving public success in spite of private handicaps.

After an undistinguished career as an undergraduate at Christ Church, Oxford, he married Lady Susan Hay in 1836 and entered Parliament the following year. From 1843 he served as vice president, and from 1845 as president, of the Board of Trade in the Tory (conservative) ministry of Sir Robert Peel. In that office he handled a number of railroad problems and gained a reputation for administrative efficiency. He lost his post when Peel resigned in 1846. In the following year he accepted the new Whig ministry's offer of the governor generalship of India, becoming the youngest man ever appointed to that post.

When Dalhousie arrived in India in January 1848, the country seemed peaceful. Only two years earlier, however, the army of the Punjab, an independent state founded by the religious and military sect of the Sikhs, had precipitated a war that the British had won only with great difficulty. The discipline and economy enforced by the new Sikh regime, sponsored by the British, aroused discontent, and in April 1848 a local rebellion broke out at Multan. This was the first serious problem faced by Dalhousie. Local officers urged immediate action, but he delayed, and Sikh disaffection spread

Role in the Punjab rebellion of 1848

throughout the Punjab. In November 1848, Dalhousie dispatched British troops; and, after several British victories, the Punjab was annexed in 1849.

Dalhousie's critics maintained that he had allowed a local rebellion to grow into a national uprising so that he could annex the Punjab. But the commander in chief of the British army had warned him against precipitate action. Certainly, the steps Dalhousie eventually took were somewhat irregular; the uprising at Multān had been directed not against the British but against policies of the Sikh government. In any event, he was created marquess for his efforts.

In 1852, commercial disputes in Rangoon prompted new hostilities between the British and the Burmese, rival powers in the area for almost a century, prompting the Second Burmese War. It was settled within the year with little loss of life and with the British annexation of Rangoon and the rest of the Pegu province. Dalhousie was again criticized for aggressive diplomacy, but Britain profited from the installation of a new Burmese government that was less aggressive abroad and less oppressive at home. Another advantage was that Rangoon, Britain's most valuable acquisition from the war, became one of the biggest ports in Asia.

Dalhousie also took advantage of every opportunity to acquire territory by peaceful means. The East India Company (no longer an independent corporation but largely under the control of the British government) was rapidly becoming the predominant power in India. It had concluded alliances with Indian rulers, promising to support them and their heirs in return for various concessions, including the right to keep a British resident and a military force within the state. Although this type of agreement gave the British an effective influence over general policy, Dalhousie sought to acquire even more power. It was customary for a ruler without a natural heir to ask the British government whether he could adopt a son to succeed him. Dalhousie concluded that if such permission were refused, the state would "lapse" and thereby become part of the British possessions. On these grounds, Sātāra was annexed in 1848 and Jhānsi and Nāgpur in 1854. Dalhousie maintained that there was a difference in principle between the right to inherit private property and the right to govern, but his main argument was his own belief in the moral and material benefits of British rule.

His annexation of Oudh in 1856, however, entailed grave political danger. Here there was no question of lack of heirs; the Nawab (ruler) was simply accused of misgovernment, and the state was annexed against his will. The transfer of power over the Nawab's protests offended the Muslim elite. More dangerous was the effect on the British army's Indian troops, many of whom came from Oudh, where they had occupied a privileged position before its annexation. Under the British government, however, they were treated as equals with the rest of the population, which represented a loss of prestige. Moreover, after Dalhousie's departure in 1856, the landed aristocracy of Oudh lost many of its privileges. In these various ways, the annexation of Oudh contributed to the mutiny and rebellion of the following year.

Dalhousie's energy extended beyond the mere acquisition of territories. His greatest achievement was the molding of these provinces into a modern centralized state. His confidence in Western institutions and his ability as an administrator immediately led him to attend to the development of a communication and transportation system. He gave much attention to the planning of the first railways. Drawing on the knowledge he had acquired in London at the Board of Trade, he laid the foundation of future railway development, outlining the basic concept of trunk and branch lines and making provisions to safeguard both the railway workers and the property owners affected by railway construction. He planned and instituted a network of electric telegraph lines, promoted the completion of the Grand Trunk Road between Calcutta and Delhi and its extension into the Punjab, and instituted a centralized postal system, based on a low uniform rate paid in advance by the purchase of stamps, thus

replacing a variety of methods characterized by uncertainty of delivery and high rates. His social reforms included strong support for the suppression of female infanticide in the Punjab and in the northwest generally and the suppression of human sacrifice among the hill tribes of Orissa. Besides encouraging the use of the vernacular languages in schools, he gave particular encouragement to the education of girls.

He left India in 1856, and the controversies aroused by his policy of annexation, which were widely—and justly—criticized as contributory factors to the mutiny and rebellion of 1857, overshadowed his achievements in modernization. Vexed by such arguments and exhausted by his years of overwork and ill health in India, he died on December 19, 1860, at Dalhousie Castle.

## Dalton, John

John Dalton was a self-tutored English chemist and physicist who crystallized modern scientific thought about the nature of matter with his development of the atomic theory, one of the basic theories of all sciences and the one that marked the establishment of chemistry as a true science.

By courtesy of the trustees of the British Museum; photograph, J.R. Freeman & Co. Ltd.

Dalton, engraving by W. Worthington, after a portrait by William Allen, 1814.

Dalton was born in the village of Eaglesfield, in the North of England, on Sept. 6, 1766, the son of a Quaker weaver. When only 12 he took charge of a Quaker school in Cumberland and two years later taught with his brother at a school in Kendal where he was to remain for 12 years until he became a teacher of mathematics and natural philosophy at New College in Manchester, a college established by the Presbyterians to give a first class education to both laymen and candidates for the ministry, the doors of Cambridge and Oxford being open at that time only to members of the Church of England. He resigned this position in 1800 to become secretary of the Manchester Literary and Philosophical Society and served as a public and private teacher of mathematics and chemistry. In 1817 he became president of the Philo-

Policy of  
"lapse"  
and  
annexation

Early  
scientific  
research

sophical Society, an honorary office that he held until his death in 1844.

In the early days of his teaching, his way of life was influenced by a wealthy Quaker, a capable meteorologist and instrument maker, who interested him in the problems of mathematics and meteorology. His first scientific work, which he began in 1787 and continued until the end of his life, was to keep a diary—which was ultimately to contain 200,000 entries—of meteorological observations recording the changeable climate of the lake district in which he lived. In 1793 he published *Meteorological Observations and Essays*. He then became interested in preparing collections of botanical and insect species. Stimulated by a spectacular aurora display in 1787, he began observations about aurora phenomena—luminous, sometimes coloured displays in the sky caused by electrical disturbances in the atmosphere. His writings on the aurora borealis reveal independent thinking unhampered by the conclusions of others. As he notes, "Having been in my progress so often misled by taking for granted the results of others, I have determined to write as little as possible but what I can attest by my own experience." In his work on the aurora he concluded that some relationship must exist between the aurora beams and the earth's magnetism: "Now, from the conclusions in the preceding sections, we are under the necessity of considering the beams of the aurora borealis of a ferruginous (iron-like) nature, because nothing else is known to be magnetic, and consequently, that there exists in the higher regions of the atmosphere an elastic fluid partaking of the properties of iron, or rather of magnetic steel, and that this fluid, doubtless from its magnetic property, assumes the form of cylindric beams." Some of his studies in meteorology led him to conclusions about the origin of trade winds involving the earth's rotation and variation in temperature—but he may not have been aware that this theory had already been proposed in 1735 by George Hadley. These are only some of the subjects on which he wrote essays that he read before the Philosophical Society: others included such topics as the barometer, thermometer, hygrometer, rainfall, the formation of clouds, evaporation and distribution and character of atmospheric moisture, including the concept of the dew point. He was the first to confirm the theory that rain is caused not by any alteration in atmospheric pressure but by a diminution of temperature. In his studies with water he determined the point of the maximum density of water to be 42.5° F (later shown to be 39.16° F). Along with his other researches he also became interested in the theory of colour blindness, a condition that both he and his brother shared. The results of this work were published under the title "Extraordinary Facts Relating to the Vision of Colours."

Dalton had a gift for recognizing many unsolved scientific problems around him as well as a tremendous capacity to organize research on a wide variety of problems. An indefatigable investigator or researcher, he had an unusual talent for formulating a theory from a variety of data. The mental capacity of the man is illustrated by his major work that was to begin at the turn of the century—his work in chemistry. Although he taught chemistry for six years at New College, he had no experience in chemical research. He embarked on this study with the same intuitiveness, independence of mind, dedication, and genius for creative synthesis of a theory from the available facts that he had demonstrated in his other work. His early studies on gases led to development of the law of partial pressures (known as Dalton's law), which states that the total pressure of a mixture of gases equals the sum of the pressures of the gases in the mixture, each gas acting independently. These experiments also resulted in his theory according to which gas expands as it rises in temperature (the so-called Charles' law, which should really be credited to Dalton). On the strength of the data gained in these studies he devised other experiments that proved the solubility of gases in water and the rate of diffusion of gases. His analysis of the atmosphere showed it to be constant in composition

to 15,000 feet. He devised a system of chemical symbols and, having ascertained the relative weights of atoms (particles of matter), in 1803 he arranged them into a table. In addition, he formulated the theory that a chemical combination of different elements occurs in simple numerical ratios by weight, which led to the development of the laws of definite and multiple proportions. Dalton discovered butylene and determined the composition of ether, finding its correct formula. Finally, he developed his masterpiece of synthesis—the atomic theory, the thesis that all elements are composed of tiny, indestructible particles called atoms that are all alike and have the same atomic weight.

All of Dalton's studies and writings, many included in his *New System of Chemical Philosophy* (part I, 1808; part II, 1810), cast light on the man—dedicated to scientific research, independent in his approach, often diffident in seeking help in scientific papers that would aid him, or misguide him as he often thought—a genius in synthesizing facts and ideas. Almost a recluse, with few friends, and unmarried, he was deeply dedicated to a search for the answer to scientific problems. His home-made equipment was crude, his data not usually exact, but good enough to give his alert and creative mind clues to the probable answer. A scientist exclusively dedicated to the pursuit of new knowledge, Dalton remained a man of simple wants and uniform habits; his dress and manners were consistent with his Quaker faith. He died at Manchester on July 27, 1844.

Dalton's record keeping, although remarkable for quantity, often lacked exactness in dating, probably because he revised his manuscripts as secretary of the Philosophical Society between the time of the oral presentation and the publication. The exact date of some of his work, especially the atomic theory, is still in doubt because he had the opportunity to revise it before publication. His documents were destroyed during the bombings of England in World War II. A fellow of the Royal Society, from whom he received the Gold Medal in 1826, and a corresponding member of the French Academy of Sciences, John Dalton was also cofounder of the British Association for the Advancement of Science. A giant among early scientists and at the same time a quiet, modest man, he was highly revered and respected by his countrymen as well as by scientists who benefitted from his discoveries.

**BIBLIOGRAPHY.** H.E. RosCOE, *John Dalton and the Rise of Modern Chemistry* (1895), the most authoritative biography, and with A. HARDEN, *A New View of the Origin of Dalton's Atomic Theory* (1896), original material on Dalton's research; D.S.L. CARDWELL (ed.), *John Dalton and the Progress of Science* (1968), J.B. CONANT, and L.K. NASH (eds.), *Harvard Case Histories in Experimental Science*, vol. 1 (1957), probably the most critical recent analysis of Dalton's work; FRANK GREENAWAY, *John Dalton and the Atom* (1966).

## Dam

A dam is a structure built across a stream, river, or estuary to retain water. Its purposes are to meet demands for water for human consumption, irrigation, or industry; to reduce peak discharge of floodwater; to increase available water stored for generating hydroelectric power; or to increase the depth of water in a river so as to improve navigation. An incidental purpose can be to provide a lake for recreation.

Auxiliary works at a dam may include spillways, gates, or valves to control the discharge of surplus water downstream from the dam; an intake structure conducting water to a power station or to canals, tunnels, or pipelines for more distant use; provision for evacuating silt carried into the reservoir; and means for permitting ships or fish to pass the dam. A dam therefore is the central structure in a multipurpose scheme aiming at the conservation of water resources. The multipurpose dam holds special importance in the underdeveloped countries, where a small nation may reap enormous benefits in agriculture and industry from a single dam.

Dams fall into several distinct classes, by profile and by building material. The decision as to which type of dam to build depends largely on the foundation conditions in the valley and the construction materials available. Broadly, the choice of materials now lies between concrete, soils, and rockfill. Though a number of dams were built in the past of jointed masonry, this practice is now largely obsolete. The monolithic form of concrete dams permits greater variations in profile, according to the extent water pressure is resisted by the deadweight of the structure, is transferred laterally to buttresses, or is carried by horizontal arching across the valley to abutments formed by the sides of the valley.

## HISTORY

**Ancient dams.** The earliest recorded dam is believed to have been on the Nile River at Kosheish where a 15-metre-high (49-foot) masonry structure was built about 2900 BC to supply water to King Menes' capital at Memphis. Evidence exists of a masonry-faced earth dam built about 2700 BC at Sadd-el-Kafara, about 30 kilometres (19 miles) south of Cairo; this dam failed shortly after completion when, in the absence of a spillway, it was overtopped by a flood. The oldest dam in use is a rockfill structure about six metres (20 feet) high on the Orontes (Nahr al-'Āṣī) in Syria, built about 1300 BC.

The Assyrians, Babylonians, and Persians built dams between 700 and 250 BC for water supply and irrigation. Contemporary with these was the earthen Sudd-al-Arim Dam, built near Marib in the Yemen, 14 metres high and nearly 600 metres long. Flanked by spillways, this dam delivered water to a system of irrigation canals for more than 1,000 years. Other dams were built in this period in Ceylon (modern Sri Lanka), India, and China.

**The Romans.** Despite their undoubted skill as civil engineers, especially in the field of water supply, the Romans' role in the evolution of dams is not remarkable for quantity or for advances in height. Their skill lay in the comprehensive collection and storage of water and in its transport and distribution by aqueducts. Remarkably, at least two Roman dams in southwestern Spain, Proserpina and Cornalbo, are still in use, although a third, the Alcantarilla Dam, has overturned, and the reservoirs of some others have filled with silt. The Proserpina Dam, 12 metres (40 feet) high, has a masonry-faced core wall of concrete backed by earth; it may be regarded there-

**Early dams in the Orient.** Quite independently, dam construction evolved in the East. In 240 BC a stone crib was built across the Gukow River in China; this structure was 30 metres (98.4 feet) high and about 300 metres (984 feet) long. Many earth dams of moderate height (in some cases, of great length) were built by the Sinhalese in Ceylon after the 5th century BC to form reservoirs or tanks for extensive irrigation works. The Kalabalala Tank (formed by an earth dam 24 metres [79 feet] high and nearly six kilometres [3.7 miles] in length) had a perimeter of 60 kilometres (37 miles) and helped store monsoon rainfall for irrigating the country around the ancient capital of Anuradhapura. Many of these tanks in Ceylon are still in use today.

The  
Kalabalala  
Tank

In Japan the Diamonike Dam reached a height of 32 metres (105 feet) in AD 1128. Numerous dams were also constructed in India and Pakistan. In India a design employing hewn stone to face the steeply sloping sides of earth dams evolved, reaching a climax in the 16-kilometre-long (ten-mile) Veeranam Dam, Tamil Nadu, built from AD 1011 to 1037.

In Iran the Kebar, a pioneer arch dam, was built early in the 14th century (Figure 1B). Spanning a narrow limestone gorge, it reached 26 metres (86 feet) high with a thickness of less than five metres (16 feet). The central curved portion, 38 metres (124.6 feet) in length and radius, was supported on two straight abutments.

**Fifteenth to 18th century.** In the 15th and 16th centuries dam construction resumed in Italy and, on a larger scale, in Spain, where Roman and Moorish influence was still felt. Of these dams, the Tibi (1579–89) was an arch-gravity structure 42 metres (137.8 feet) high; this height was not surpassed in western Europe until the building of the Gouffre d'Enfer Dam in France, almost three centuries later. Almanza Dam in Spain is illustrated in Figure 1C. An attempt to build a dam 52 metres (170.6 feet) high near Lorca, Spain, at the end of the 18th century failed disastrously in 1802, when earth and gravel below the piled structure washed out. In Europe, where rainfall is ample and well distributed throughout the year, dam construction before the Industrial Revolution was on only a modest scale and was restricted to forming water reservoirs for towns, driving water mills, and making up water losses in navigation canals. An exception was the 36-metre-high (115.2-foot) earth dam built in 1675 at St. Ferréol, near Toulouse, France, to supply the Canal du Midi; for more than 150 years it was the highest earth dam in existence.

**Nineteenth century.** Up to the middle of the 19th century, dam design was entirely empirical. Knowledge of the properties of materials and structural theory had been accumulating for 250 years; Galileo, Newton, Leibniz, Hooke, Daniel, Bernoulli, Euler, de la Hire, and Coulomb had made outstanding contributions. In the 1850s W.J.M. Rankine, professor of civil engineering at Glasgow University, successfully demonstrated how applied science could help the practical engineer. Rankine's work on the stability of loose earth for example, provided a better understanding of the principles of dam design and performance of structures. This led in turn to improved construction techniques and larger dams. Furthermore, in certain countries, Rankine's work encouraged acceptance of civil engineering as a subject for university study and added to the status of civil engineers. Much remained to be learned of soils and natural rocks in the 100 years after Rankine. Many scientists and engineers made, and continue to make, noteworthy contributions.

Rankine's  
contribu-  
tions

Proserpina  
Dam

Figure 1: Cross sections of early dams. (A) Proserpina, built by the Romans in southwestern Spain about AD 100. (B) Kebar, in Iran, constructed about AD 1300. (C) Almanza, in Spain, completed about AD 1586.

fore as a forerunner of the modern earth dam. The Proserpina is strengthened on the upstream face by buttresses (Figure 1A). Of similar construction, 14 metres (46 feet) high and 550 metres (1,804 feet) in length, Alcantarilla Dam was supported by a great weight of earth, which eventually caused failure of the wall. Cornalbo represented a further advance in design; the masonry wall was constructed of cells, which were filled with stones or clay, and faced with mortar. It differs from Proserpina and Alcantarilla in having a sloping upstream face and in being straight in plan. Proserpina and Alcantarilla were polygonal in plan. The merit of curving a dam upstream was not apparently fully appreciated by the Romans until such a curved structure, the forerunner of the modern "arch-gravity" dam, was built in AD 550 at Dâra on the present Turkish-Syrian border by Byzantine engineers.

**Development of modern structural theory.** Concrete dam design is based on conventional structural theory. In this relationship two phases may be recognized. The first, extending from 1853 until about 1910 and represented by the contributions of a number of French and British engineers, was actively concerned with the precise profile of gravity dams in which the horizontal thrust of water in a reservoir was resisted by the weight of the dam itself and the inclined reaction of the dam's foundation. Starting about 1910, however, engineers began to recognize that concrete dams were monolithic three-dimensional structures in which the distribution of stress and the deflec-

tions of individual points depended on stresses and deflections of many other points in the structure. Movements at one point had to be compatible with movements at all others. Owing to the complexity of the stress pattern, model techniques were gradually employed. Models were built in plasticine, rubber, plaster, and finely graded concrete. In recent years the digital computer has facilitated use of the analytical method of finite elements, by which a monolithic structure is divided into an assembly of separate blocks. Study of both physical and digital models permits deflections of a dam's foundations and structure to be taken into account.

During the 100 years up to the end of World War II, experience in design and construction of dams advanced in many directions. In the first decade of this century many large dams were built in the U.S. and western Europe. In succeeding decades, particularly during the war years, many impressive structures were built in the U.S. by federal government agencies and private power companies. Hoover Dam, built in 1936, is an outstanding example of an arch-gravity dam built in a narrow gorge across a major river and employing advanced design principles. It has a height of 221 metres (726 feet) from its foundations, a crest length of 379 metres (1,243 feet), and reservoir capacity of  $37 \times 10^9$  cubic metres.

Among earth dams, Fort Peck Dam, completed in 1940, contained the greatest volume of fill, 96,000,000 cubic metres. This volume will not be exceeded until the completion in 1975 of Tarbela Dam in Pakistan (145,000,000 cubic metres). The table lists the greatest dams in the world.

#### BASIC PROBLEMS IN DAM DESIGN

Most modern dams continue to be of two basic types: masonry (concrete) and embankment (earthfill). Masonry dams are typically used to block streams running through narrow gorges, as in mountainous terrain; though such dams may be very high, the total amount of material required is limited. Embankment dams are preferred to control broad streams, where only a very large barrier, requiring a great volume of material, will suffice. The choice of masonry or embankment and the precise design depend on the geology and configuration of the site, the functions of the dam, and cost factors.

**Site investigation and testing.** Investigation of a site for a dam includes sinking trial borings to determine the strata. The borings are supplemented by shafts and tunnels which, because of their cost, must be used as sparingly as possible. In the shafts and tunnels, tests can be made to measure strength, elasticity, permeability, and prevailing stresses in strata, with particular attention given to the properties of thin partings, or walls, between the more massive beds. The presence in groundwater of chemical solutions harmful to the materials to be used in the construction of the dam must be assessed. Sources of construction materials need exploration. As dams continue to increase in height, the study of foundation conditions becomes increasingly critical.

Model tests play a major part in the structural, seismic, and hydraulic design of dams. Structural models are particularly useful in analysis of arch dams and in verifying analytical stress calculations. Various materials have been used for model tests; on some early tests for Hoover Dam, rubber was employed. The need for accurate reproduction of stress patterns in complex models is met by using material of low elasticity. In a sense, dams themselves are models for future design. The instruments built into them to record movements under load, strains within materials after construction, temperature and pressure changes, and other factors are installed primarily to study the performance of the structure and to warn of possible emergencies, but their value in confirming design assumptions is important.

The digital computer has permitted considerable advance in analytical methods of design. Its ability to handle a great volume of data and to solve large sets of simultaneous equations containing many variables has made practicable the method of Finite Element Analysis.

In this method a complicated structure is divided into a number of separate equilibrium conditions, and strains are rendered compatible, thus leading to a complete analysis of stress and strain distribution throughout the structure.

**Problems of materials.** Each of the two basic dam materials, concrete and earth or rock fill, has a weakness that must be overcome by the proper design of the dam.

**Weaknesses of concrete.** Concrete is weak in tensile strength; that is, it can be pulled apart easily. Concrete dams must therefore be designed to place minimum tensile strain on the dam and to make use of concrete's great compressive strength, or ability to support vertical loads. The chief constituent of concrete, cement, shrinks as it sets and hardens, due to water absorption in the crystalline structure, to evaporation of water to the atmosphere, and to cooling from the higher temperatures reached when the chemical reactions in the cement are in progress during hydration. Because of the large volume of concrete in a dam, shrinkage presents a serious cracking hazard.

Various expedients are used to overcome the problem. Concrete is usually cast in separate blocks of limited height. Gaps may be left to permit heat losses and filled in later. Low-heat cements may be used; these are specially blended so that rates of heat evolution are retarded. Cement content can be safely reduced in the interior concrete in the dam, in which strength and resistance to climatic and chemical deterioration are less important. The cement content, and therefore the heat caused by hydrating, can also be reduced by using aggregate (the other major constituent of concrete) of larger stones. Another expedient is to use other fine-grained materials, such as fly ash (pulverized fuel), as filler, reducing the total cement volume in the concrete. Another is to use certain additives, surface-active agents, and air-entraining agents that permit using a lower water-to-cement ratio in mixing the concrete. Techniques used to speed the cooling process include replacing some of the water in the mix by ice, circulating water through pipes laid in the concrete, and extracting excess water from surfaces by vacuum.

**Weaknesses of earth and rock fill.** Soils and rock fragments lack the strength of concrete, are much more permeable, and possess less resistance to deterioration and disturbance by flowing water. These disadvantages are compensated for by a much lower cost and by the ability of earth fill to adapt to deformation caused by movements in the dam foundation. This assumes, of course, sufficient usable soil available close to the dam site. In bare mountain country it may be necessary to quarry rock and construct a rockfill rather than an earthfill dam. Earth fill is of course more economical, and often a suitable borrow area can be found close to the site.

Soil consists of solid particles with water and air in between. When the soil is compressed by loading, as occurs in dam construction, some drainage of air and water takes place, causing an increase in pressures between the solid particles. When there is a high rate of seepage, the soil tends to develop differential pressures and reach a condition called quick, in which it behaves as a fluid. Even if it does not reach this condition, there is often some weakening of its structure, and steps must be taken to counter this.

**The earthquake problem.** Many large dams have been built in the seismically active regions of the world, including Japan, the western United States, New Zealand, the Himalayas, and the Middle East. In 1968 the Tokachi earthquake damaged 93 dams in Honshu, the main Japanese island; all were embankment dams of relatively small height.

Despite a great deal of work on the distribution of seismic activity, the measurement of strong ground motions, and the response of dams to such motions, earthquake design of dams remains imprecise. The characteristics of strong ground motions at a given site cannot be predicted, and all types of dams possess some degree of freedom, imperfect elasticity, and imprecise damping. Never-

†A concrete gravity dam of different size, referred to in text, also forms part of the Bratsk complex.

theless, the digital computer and model testing have given promise of considerable progress. It is now possible to calculate the response of a concrete dam to any specified ground motion; this has been done for the Tang-e Soleyman Dam in Iran and the Hendrik Verwoerd Dam in South Africa.

There has also been considerable advance in the theoretical estimation of the effects of ground motion on embankment dams.

#### THE MODERN CONCRETE DAM

**Concrete gravity dams.** Concrete gravity dams share certain features with all types of concrete dams. Running in virtually a straight line across a broad valley, they resist the horizontal thrust of the retained water entirely by their own weight; at each level in their height the water's thrust is deflected down toward the foundation by the weight of the concrete. In this action their purpose resembles that of the abutment of an arched bridge or the buttresses and pinnacles of a church. A gravity dam is a right-angled triangle; its hypotenuse forms the sloping downstream face. The base width is approximately three-quarters the height of the dam.

The three main forces acting on a gravity dam are the thrust of the water, the weight of the dam, and the pressure, or reaction exerted by the foundation, which is necessarily inclined in respect to the superstructure. It is also essential to consider the thrust exerted on the upstream face by silt deposited in the reservoir or by ice on the water surface, the inertia forces that can be caused by seismic action, and, in particular, the buoyant uplift force of water seeping under the dam or into the horizontal joints.

Uplift due to seepage has caused sustained discussion among engineers. It calls for the greatest of care in design and construction. Where a dam is founded on solid rock, a simple downward projection of concrete into the rock will generally suffice to cut off seepage and eliminate uplift pressures. Usually, however, the rock foundation is permeable, sometimes to considerable depths, so construction of an absolutely reliable cutoff is either difficult or impossible. Reliance must then be placed on an extensive system of grouting the fissured rock and on relieving uplift pressures by means of drainage. Many dams possess both cutoffs and underdrainage.

A relatively new development in the construction of gravity dams is incorporation of post-tensioned steel into the structure. This helped reduce the cross section of Allt Na Lairige Dam in Scotland to only 60 percent of that of a conventional gravity dam of the same height. A series of vertical steel rods near the upstream water face, stressed by jacks and securely anchored into the rock foundation, resists the overturning tendency of this more slender section. This system has also been used to raise existing gravity dams to a higher crest level, economically increasing the storage capacity of a reservoir.

Of special interest are three concrete gravity dams all of which feature a straight sloping downstream face. Bratsk, built across the Angara River at Irkutsk, in the Russian S.F.S.R., and completed in 1964, stands 125 metres (410 feet) above foundation level and, excluding the earth side dams, is nearly 1,525 metres (5,000 feet) in length; it contains 4,500,000 cubic metres (159,000,000 cubic feet) of concrete. Grand Coulee Dam, completed in 1942 across the Columbia River, Washington, is 168 metres high, 1,280 metres in length and contains 8,100,000 cubic metres of concrete. Grande Dixence Dam in Switzerland, completed in 1962 across the narrower valley of the Dixence, has a crest length of 700 metres and contains approximately 5,957,000 cubic metres of concrete; at 285 metres (935 feet) it was the highest dam in the world until the Nurek was completed. By comparison, the Pyramid of Khufu contains 2,600,000 cubic metres (92,000,000 cubic feet) of masonry.

**Concrete buttress and multiple-arch dams.** Unlike gravity dams, buttress dams do not rely entirely upon their own weight to resist the thrust of the water. Their upstream face, therefore, is not vertical but inclines about 25–45 degrees, so the thrust of the water on the upstream face inclines toward the foundation. Embryonic buttresses existed in some Roman dams built in Spain, among them the Proserpina. As technology advanced, dams with thin buttresses of reinforced concrete supporting inclined panels of similar construction were built. In today's buttress dams, less account is taken of effecting maximum economy in the use of concrete. The trend is to reduce the area of costly formwork necessary and to avoid use of steel reinforcement.

With greater heights, modern buttress dams are inevitably less slender.

Post-tension construction

Uplift pressure

Several variations are possible in the design of the junction between each buttress at the water face. Where no relative movement in the buttress foundations is anticipated, the design can link individual buttress heads rigidly, by means of arches, to form a multiple-arch dam. A recent Canadian example of this type is the 214-metre-high (703-foot) multiple-arch Daniel Johnson Dam on the Manicouagan River, Quebec. The dam has a total of 14 buttresses used in its crest length of 1,310 metres (4,297 feet); two very much larger buttresses support the structure over the original riverbed.

Where buttress foundations might yield, the design must allow some freedom of movement between the heads of the buttresses. This is normally achieved by enlarging the heads until they are almost in contact, then joining them with flexible seals. Thus joined, they present a solid face to the water. Such a design was used in the construction in the Farahnaz Pahlavi Dam in Iran. Built for the Tehrān Regional Water Board, this dam has a maximum height of 107 metres (351 feet) and a crest length of nearly 360 metres (1,181 feet).

A comparison between the Daniel Johnson multiple-arch dam and the Farahnaz Pahlavi buttress dam shows that the buttresses have to be placed much closer together than is necessary with a multiple-arch dam. This allows each buttress to be more slender, however, and spreads the load more easily over the foundation. The detailed design at the bottom of the Farahnaz Pahlavi buttresses was necessitated by weak foundation conditions at the site and by the need to limit the length of each buttress to reduce its response to seismic action. By contrast, the Daniel Johnson buttresses could be founded individually, exploiting fully an important advantage of buttress dams over gravity dams, that of smaller uplift forces.

**Arch dams.** The advantages of building a dam curved in plan, utilizing the water pressure to keep the joints in the masonry closed, was appreciated as early as Roman times. An arch dam is a structure curving upstream, where the water thrust is transferred either directly to the valley sides or, indirectly, through concrete abutments. Theoretically, the ideal constant angle arch in a V-shaped valley has a central angle of 133 degrees of curvature. This leads to the development of the cupola (or variable radius) arch dam with the crest portion overhanging downstream (Figure 2). The constant radius arch dam generally has a vertical upstream face. There are many other factors, however, to take into account, including fixity at the abutments at the upper levels and the vertical cantilever effect of the arch at the riverbed level.

Figure 2: Plan view of an arch dam showing double curvature.

An arch dam is therefore a shell structure, admittedly sometimes of significant thickness, that owes its strength essentially to its curved profile but that is supported at the riverbed and up the valley sides by constraints that cause both flexure and shear on the membrane. Dependent for its strength upon effective support at its abutments, its very strength and rigidity make it sensitive to movements at the abutments. Only favourable sites providing sound rock are suitable for arch dams.

The great reserves of strength inherent in an arch dam were dramatically displayed in 1963 when the reservoir

behind Vaiont Dam in Italy was virtually destroyed by a landslide. Vaiont, at that time the second highest dam in the world, was built across a narrow gorge on limestone foundations so that the crest 262 metres (858 feet) above the valley bottom was only 190 metres (623 feet) in length. Some large-scale instability in the mountainside above the reservoir had been observed earlier by the engineers during filling; they were allowed to proceed very slowly and three years later on October 9, 1963, with filling still incomplete, about 240,000,000 cubic metres of soil and rock slid down into the reservoir, sending a tremendous volume of water to a height of 260 metres (853 feet) on the opposite side of the valley. The flood overtopped the dam to a depth of 100 metres (328 feet) and surged down the valley, causing a major tragedy, the destruction of several villages with a large loss of life. Yet only superficial damage was caused to the dam, which, at its crest, is about 3.4 metres (11.2 feet) thick.

Dam  
disaster

#### EMBANKMENT DAMS

**General characteristics.** Earlier embankments were undoubtedly built as simple homogeneous structures, with the same material used throughout. No effort was made at first to subdivide the dam into separate zones with the best suited material in each zone. The homogeneous dam nicely illustrates the general behaviour of an embankment dam and demonstrates the reasons for the rather baffling pattern of heterogeneous dam profiles employed.

Like a concrete gravity dam, the weight of an embankment dam deflects the horizontal thrust of the water pressure down to the foundation. The resultant pressures on the foundation must not cause excessive deformation or collapse.

Unlike concrete, embankment dam materials possess only limited resistance to water penetration. The rate of penetration depends on the pressures exerted by the water in the reservoir, the length of seepage paths through the dam, and the permeability of the material of construction. Soils and rock range from substantially impermeable clays, through silts and sands, to coarse-graded gravels and rock fragments that possess little resistance to the movement of water. The range is extremely wide; the seepage rate through clean gravel is 10,000 times that through sand, 10,000,000 times that through silt, and 100,000,000 times that through dense clay.

An embankment dam must be stable in itself. Its side slopes must not slip or slide; liquefaction of the soils must not occur; erosion of the soils, as the result of water overtopping the crest, by wave action on the upstream face, or by seepage washing out the fine material through the coarser, must be avoided. As with a concrete dam, seepage of water from the reservoir through the foundation and under the actual embankment also must be controlled.

Water  
penetra-  
tion

Figure 3: Paths of seepage through embankment dams. (A) Homogeneous dam. (B) Dam with a drainage blanket.

**Potential weakness.** There are three parts of a dam where weakening of the soil structure and liquefactions can occur. In Figure 3A the pattern of seepage through a homogeneously filled dam is shown. Near the downstream toe the gradient of the pore-water pressures is

steep and constraints holding the soil structure together are low; this is one area of weakness in an embankment dam. One solution is to introduce drainage as indicated in Figure 3B where the area of steep seepage gradients has been moved to where the soil is constrained near the centre of the dam. Seepage gradients at the vulnerable downstream toe are eliminated.

A second area of potential weakness is the upstream face when the water in the reservoir is rapidly drawn down. If the pore-water pressures cannot adjust themselves fast enough to this change in the free-water surface in the reservoir, severe seepage gradients begin; these can cause failure. A zone of freely draining fill of coarser grading can be placed on the upstream face to counter this.

Water seepage from the reservoir through the foundations under the dam is another potential weakness. Owing to their great widths, embankment dams can be constructed on unfavourable sites, such as open-joined rock or weaker and possibly locally permeable clay. It is necessary, however, either to check or to drain away harmlessly the seepage water that would otherwise weaken the downstream parts of the dam, in extreme cases causing it to fail. Several countermeasures, possibly in combination, can be employed: the foundation can be grouted or a cutoff trench excavated and backfilled with an impermeable material; a drainage blanket can be constructed at the base of the downstream part of the dam, or individual drainage wells or galleries can be excavated; the length of the seepage paths under the dam can be extended by means of an impermeable blanket laid on the upstream side of the dam, or additional free-draining fill can be placed at the downstream toe of the dam.

**Construction techniques.** Use of *cores*. Today, all large embankment dams have a core of lower permeability built near their centre. Suitable materials, such as a plastic clay, are weaker than more permeable soil. The width of the core is restricted to that necessary to lower sufficiently the pore pressures in the downstream part of the dam. Though the top of the core must be at the crest of the dam, the core itself need not be vertical. On some rockfill dams the core can slope forward to an extreme position where it lies on the upstream face. Usually a sloping core occupies an intermediate position so it can be constructed on a sloping face of a partially built dam.

Where seepage is inevitable, the use of finely graded core material in proximity to coarser material is avoided. Bands of intermediately graded material must be inserted to prevent the finely graded material from leaching through the coarse zones. Filter zones are graded so each band is four to five times coarser than the preceding band.

Figure 4A shows a typical section of the Aswān High Dam, an embankment 111 metres (365 feet) high, built of dune sand and rock fill on a very permeable foundation of deep alluvium. Here, the central clay core is vertical; this barrier to seepage is extended to the original riverbed as grouted sand and below the riverbed to a depth of 225 metres (740 feet) as a grout curtain. A corrugated blanket of clay extends upstream within the dam from the base of the core. Within the upstream and downstream cofferdams, partly of rock fill, much of the filling is of compacted sand. Filter layers separate the cofferdam filler from the outer layers of freely draining rock fill. Drainage wells will be observed below the downstream toe. The early stages of construction were carried out under deep water; hence the grouted coarse sand between the clay core and the grout curtain.

The rather simpler section of Oroville Dam, in California, is shown in Figure 4B. Until the 317-metre-high (1,040-foot) Nurek Dam in the Soviet Union was completed, Oroville (236 metres) was the highest embankment dam in the world. Unlike the Aswān High Dam, Oroville was not built on deep permeable alluvium, nor was it necessary to place part of the fill under water. Unusual is the concrete block at the base of the sloping core designed to fill in the incised gorge of the Feather River Canyon. The grout curtain, compared with that of

Figure 4: Sections of (A) the Aswān High Dam, Egypt, and (B) Oroville Dam, California.

From (A) 9th International Congress on Large Dams; (B) *Civil Engineering*, A.S.C.E. (June 1969)

the Aswān High Dam, is of nominal depth. On each side of the sloping core, transition zones separate the core from the main mass of more pervious filling. The downstream transition zone is backed by a curtain drain of selected pervious material connected to a drainage blanket on the downstream side. The upstream face of the dam is protected against wave action by a one-metre layer of broken stone (riprap).

**Placing and compacting materials.** Efficient compacting of soils requires maximum density of dry particles consistent with an economic number of passes of the compacting plant. The process of compacting a soil by kneading it involves expelling as much of the air as practicable; water content is not normally much reduced. The optimum water content for maximum dry density—which results in maximum strength—can be achieved for a given amount of work done on the soil in compaction. In arid climates water must often be added to excavated soils. In temperate climates, however, water content is usually too high except in deeply excavated and well-drained soils.

Normally, soils are placed in embankment dams in thin layers individually compacted by rolling. Finer soils, such as those used in cores, may be harrowed before rolling. Coarser soils, including rock fragments, are compacted by vibration and rolled. Coarse rock fragments (rock fill) are compacted to a limited extent by impact on being dumped from the construction plant; compaction of smaller fragments is assisted by sluicing with water.

In the process of hydraulic filling, sands are dredged from borrow pits, transported in water by pipelines to the filling area, and deposited there by draining off the surplus water. Hydraulic filling is widely practiced in maritime works, if sand is the only construction material available. It has also been used in the construction of embankment dams, although on some inland sites too much water would be required to transport the material. The practice has tended to fall out of favour for dams, but renewed interest in hydraulic filling has been taken in the Soviet Union.

#### AUXILIARY STRUCTURES

**Spillways.** Serious consequences follow if a dam is overtopped. Disaster is likely in the case of an embankment dam not designed to permit uncontrolled flow of water on its downstream slope. In March 1960 the partially completed embankment dam at Orós, Brazil, was accidentally overtopped during a period of unexpectedly heavy rainfall. Despite heroic efforts to avert disaster, the

Aswān  
High  
Dam

Hydraulic  
filling

water level rose nearly one metre above crest level, eroded about half the fill in the dam, and cut a deep breach about 200 metres (660 feet) wide in the structure. Although there was time to evacuate 100,000 people living downstream, half were subsequently rendered homeless and about 50 perished. Spilling over a concrete gravity dam is also serious since the floodwater would erode the foundations at the downstream toe. Arch dams possess greater resistance to failure after overtopping.

Flood hydrology is a difficult subject. Much effort is being made to establish relationships between rainfall and river discharge, both in quantity and in time lag. Such statistical methods cannot estimate the maximum possible flood. At best they indicate only the probability of a specified flow being exceeded in a particular period. In constructing the Kariba Dam on the Zambezi, analyses of the available records of river discharge yielded the estimate that a flood of 7,600 cubic metres per second should be expected once in four years. During the first year of construction on the riverbed a flood of 8,500 cubic metres per second was experienced, and in the second year the Zambezi discharged 16,200 cubic metres per second.

In these circumstances civil engineers attach much importance to the design of spillways on dams. Inadequate spillway capacity caused failure of many older earth dams built before modern flood data became available.

Four general aspects of spillways should be emphasized. First, the uncontrolled discharge of surplus water past the dam should be automatic and, like a safety valve on a steam boiler, not under human control. Second, the spillway intake should be wide enough so that the largest floods can pass without increasing the water level in the reservoir enough to cause a nuisance to riparian inhabitants and property upstream. Third, the rate of floodwater discharge should not increase much above that experienced before the construction of the dam. An increase creates a flood nuisance downstream. A dam usually reduces the peak discharge rate due to the lag effect caused by a flood passing through the reservoir. Fourth, floodwater discharged over the height of a dam can be destructive to the dam structure itself and to the riverbed unless its energy is controlled and dissipated in harmless turbulence.

With embankment dams, a separate spillway structure is normally constructed to one side of the dam itself. With concrete gravity dams the sloping downstream face of the structure serves as the spillway. The water travels at very high speeds (about 160 kilometres [100 miles] per hour in the case of a dam 100 metres [328 feet] high), forms a standing wave where it enters the riverbed and proceeds downstream at lower mean velocity, but in a highly turbulent state. Grand Coulee Dam utilizes a spillway of this type. An obstruction known as a kicker, placed at the toe of the dam to project the water slightly upward, can move further downstream the area in which erosion of the riverbed is most intense. With higher dams, it is possible to deflect the jet of spilling water from a level above the base of the dam; this is known as a ski-jump spillway.

Ski-jump  
spillway

Spillways need not be open to the atmosphere. Shaft and tunnel spillways can destroy the energy of the water at a predetermined point downstream of the dam. At the upstream end, the intake can be self-priming siphons or bell-mouthed drop shafts; the latter are also known as morning-glory spillways.

With arch dams it is convenient to construct gated openings in the shell structure at some distance below the crest of the dam, ensuring that the discharging jets fall well clear downstream. A line of six such gates is used in the design of Kariba Dam.

Spillways constructed to one side of earth dams are featured in the design of Oroville Dam, California, and of Mangla in Pakistan. The spillway at Mangla discharges 28,000 cubic metres of water per second; the upper stilling basin has the dimensions of an Olympic Games stadium with its grandstands.

Rockfill dams, specially designed to be overtopped in times of flooding, are a new development. The first such

permanent dams have been constructed in Australia. For temporary works the technique has been used on the Blue Nile.

**Gates, sluices, and outlets.** In addition to spillways, openings through dams are also required for drawing off water for irrigation and water supply, for ensuring a minimum flow in the river for riparian interests downstream, for generating power, and for evacuating water and silt from the reservoir. These gated openings normally are fitted with coarse screens at the upstream ends to prevent entry of floating and submerged debris. Provision for cleaning these screens is essential.

Several forms of gates have been developed. The simplest and oldest form is a vertical-lift gate that, sliding or rolling against guides, can be raised to allow water to flow underneath. Radial or tainter gates are similar in principle but are curved in vertical section better to resist water pressure. Tilting gates consist of flaps held by hinges along their lower edges that permit water to flow over the top when they are lowered.

Drum gates can control the reservoir level upstream to precise levels, automatically, and without assistance of mechanical power. One drum gate design consists of a shaped steel caisson held in position by hinges mounted on the crest of the dam and supported in a flotation chamber constructed immediately downstream of the crest. Water pressure in the reservoir and buoyancy of the caisson in the flotation chamber hold the caisson in rotational equilibrium. Raising or lowering the water level in the flotation chamber causes the caisson to rotate in the same direction, thus reducing or increasing flow from the reservoir over the gate. This action can be linked to and operated automatically by a float control device in the reservoir. Two drum gates are installed at Pitlochry Dam in Scotland.

**Reservoirs.** Modern engineers have learned the value of giving attention early to potential problems in reservoir maintenance. Sediment in rivers seriously influences the effective life of a reservoir and therefore the financing of a dam. Some modern dams have been rendered useless for storing water because the reservoir has filled with silt. In many others effective storage capacity has been seriously reduced. At the Nile barrages, the heavy silt-laden floodwater is allowed to pass through the sluices and only the cleaner water at the end of the flood season is stored.

**Fish passes.** For many years hydroelectric dam design has taken into account the need to conserve certain species of migratory fish. Success has been achieved with salmon in Scotland and on certain rivers in the U.S. and Canada. Notable examples of conservation measures are to be found at Bonneville, Priest Rapids, and Wanapum dams and at many dams in Scotland.

Adult salmon striving to reach their spawning grounds upstream must be prevented by screens from entering the turbine tailraces at power stations, and induced instead to enter a fish pass that allows them to surmount the dam. Similarly, young salmon must be allowed to pass a dam safely on their journey downstream to feeding grounds in the ocean. Young salmon are remarkably insensitive to sudden changes of pressure and have been known to pass safely through turbines operating at heads of up to 50 metres (160 feet). Nevertheless, it is preferable to induce them to use the fish passes.

Fish passes usually take the form of fish ladders and fish locks. A fish ladder is utilized at Pitlochry Dam in Scotland; it consists of a series of stepped pools, through which water is continuously discharged during the migratory seasons. The individual pools may be separated by a series of low weirs or linked by short inclined underwater pipes to provide the necessary steps of 0.3 to 0.6 metres in water levels. Sometimes both weirs and pipes are provided.

Fish  
ladder

The Borland fish lock was developed in Scotland as an alternative to fish ladders. It operates on the same intermittent principle as a ship lock but is constructed as a closed conduit. Intermittent closure of the gates at the bottom causes the continuous flow through the lock to

fill the conduit at intervals, and thus allows fish waiting in the bottom chamber to be raised through the height of the dam. The lock also serves at other seasons to flush young salmon down past the dam.

(1963, updated to December 1968), a register listing basic statistical data about large dams in countries that are members of the commission; U.S. COMMITTEE OF THE INTERNATIONAL COMMISSION ON LARGE DAMS, *Register of Dams in the United States* (1963), basic statistical details of dams in the U.S., with some photographs; CANADIAN NATIONAL COMMITTEE OF THE INTERNATIONAL COMMISSION ON LARGE DAMS, *Register of Dams in Canada* (1964), basic statistical details of Canadian dams, with some photographs and a useful bibliography; ACADEMY OF SCIENCES OF THE GEORGIAN SSR, INSTITUTE OF POWER ENGINEERING, *The High Dams of the World* (Eng. trans. 1967), basic statistical details of world dams, with an extensive bibliography; NORMAN SMITH, *A History of Dams* (1971), an outstanding detailed record of ancient dams.

(J.G.B.)

## Damascus

Damascus (in Arabic, formally Dimashq, colloquially ash-Shām), the capital of Syria, is one of its two largest cities, the other being Aleppo. Situated at the base of Jabal Qāsiyūn (Qāsiyūn Mountain), among the orchards of al-Ghiifāh oasis, it has been called "the pearl of the east," "the city of many pillars," and "the gate of Mecca." It is probably the oldest city in the world.

**History.** The historical origins of Damascus are unknown, but excavations in the court of the Umayyad Mosque have unearthed potteries belonging to the 3rd millennium BC. The earliest historical reference to it is found in the hieroglyphic tablets of Tell el-Amarna in Egypt, where "Dimashqa" is listed as one of the cities that were conquered during the 15th century BC by Thutmose III, who subdued all Syria after defeating its Aramaean kings. The Aramaeans had established a number of kingdoms in Syria, of which Damascus was the most famous and powerful. Damascus had many conquerors, including King David of Israel, the Assyrians under Tiglath-pileser III (732 BC), and the Chaldeans under Nebuchadrezzar II (around 604 BC). The Persians conquered it around 530 BC under Cambyses; the kings of Damascus continued to reign under the protection of the Persian Empire until 333 BC, when Syria was conquered by Alexander the Great.

The year 333 BC marked the beginning of the Hellenistic Age, during which Damascus came under the rule of the Seleucids, the Romans, and the Byzantines, in succession. Around 90 BC many Greeks came to live in it, thus beginning an important cultural contact between the Aramaean and the Hellenistic civilizations. The native population assimilated the language, arts, and beliefs of the Greek community. A Greek city eventually sprang up close to Aramaean Damascus, and remains of it still exist in the form of a porched street east of the Umay-

yad Mosque and an agora that used to occupy the centre of the city. Greek influence began to dwindle in 85 BC, when the city was occupied by the Nabataeans under Aretas III. The Nabataeans established themselves in a quarter of their own, east of the Greek. Western influence made a second return to Damascus in 64 BC, when it was captured by the Romans, who declared Syria a Roman province. The Nabataeans were allowed to re-occupy the city in 37 AD, and they remained there until 54 AD. It was during this period that Saul of Tarsus came to Damascus in pursuit of Christians and was miraculously converted to become St. Paul the Apostle. A chapel relating to his visit, known as Ananias' Chapel, is still in good preservation.

Damascus profited considerably from the Pax Romana. Under the emperor Diocletian it became an important military centre for the armies of the empire in their wars with the Persians. It was given the status of a metropolis under Hadrian (2nd century) and became a Roman colony under Alexander Severus (222-235). The advancement of the city allowed it to play an active role in Roman life. Its celebrated architect Apollodorus of Damascus built the famous stone bridge over the Danube, the Trajan Forum in Rome, and many public buildings, baths, and triumphal arches. Damascus flourished as a trade centre on the desert caravan routes. The Romans took special care to fortify the city, enclosing it with a rectangular-shaped wall, of which some of the remains have been preserved. At the northwest corner was a castle that has since been restored and is known as the Citadel. Some of the Roman aqueducts were in use until the early years of the 20th century.

With the division of the Roman Empire toward the end of the 4th century, Damascus became an important military outpost of the Byzantine Empire. Most of the population adopted Christianity. The Temple of Jupiter was turned into a cathedral dedicated to St. John the Baptist, whose head is said to lie in a crypt within the Umayyad Mosque.

In 635 Damascus fell to the Arabs, and from 661 to 750 it was the capital of the Islāmic empire. During this period, the city began to spread outside its walls. The Christian cathedral was purchased by the caliphate and turned into a mosque, which was restored in the 11th, 15th, and 19th centuries and is now known as the Umayyad Mosque. With the fall of the Umayyad dynasty in 750, insurgent armies ravaged the city and destroyed all within it that they considered to stand for Umayyad dynasticism: buildings, palaces, fortifications, and even cemeteries. The new 'Abbāsīd dynasty removed the seat of the empire from Damascus to Baghdad. As the unity of the caliphate dissolved and local dynasties arose, Damascus changed hands often; but for most of the 200 years after the middle of the 9th century it was held by those who ruled Egypt. According to the 12th-century historian 'Abd ar-Rahmān ibn al-Jawzi, the population of Damascus was reduced to 5,000 in the year 1075. Only two bakeries were left out of 240, the marketplaces were empty, and a house that normally cost 3,000 dinars failed to find a buyer willing to pay 10 for it.

In 1076 Damascus was occupied by the Seljuq Turks. It became the capital of a province extending eastward to the Euphrates, westward to Tiberias, and northward to Homs. During the Second Crusade it was besieged unsuccessfully in 1148 by Conrad III of Germany and Louis VII of France. It was finally taken by Nureddin (Niir ad-Din), the Egyptian general, who entered it in 1154 and united Syria and Egypt in 1168. By this time the city plan of Damascus had become chaotic. The Muslims had the western part of the city around the citadel, as well as the Umayyad Mosque, the Christians had the northeastern, and the Jews, the southeastern parts. Under Nureddin, Damascus regained its status as a capital. His successor, Saladin, reunited Syria with Egypt. Many remains in Damascus date back to this period, among them Bāb-al-Faraj in the northern part of the city wall, and the Šālihiyah quarter at the foot of Jabal Qāsiyūn (started in 1161). After a brief occupation by the Mongols, Damascus was included in the Mamliik

Damascus  
under  
Islām

The  
ancient  
city

state of Egypt and Syria in 1260. This period saw a good measure of progress in the sciences, arts, and industries. Damascene goods acquired a world reputation, attracting merchants from Venice and Genoa. The sultans regarded Damascus as their second capital, had palaces built for them, and occasionally lived there. The administrative province of the city extended to the Euphrates in the east, to the Mediterranean in the west, and to the river Rastan in the north. The Mamlūk period was interrupted by a tragic interlude when the Mongols under Timur levelled Damascus and deported its scholars and artisans to their capital in Samarkand. The Mamlūks returned the following year and set out to reconstruct the city.

In 1516 Damascus was captured by the Ottoman sultan Selim I and remained the capital of a Turkish province for 400 years. Religion apart, there was little in common between the Arabs and their Ottoman rulers. Damascus was reduced to the status of a small *paşalık* within an immense empire run by a powerful central authority. The governors of the city succeeded one another at such a rate that there were 133 of them between 1517 and 1697. Economic life suffered under their exactions, and trade was further diminished by the discovery of an alternative commercial route between Europe and the east toward the end of the 15th century. But Damascus still traded with the rest of Syria and with neighbouring countries, such as Iraq, Anatolia, Persia, and Hejaz; and French and Venetian commercial agents brought their silks, woollens, sugar, and gold in exchange for raw materials and spices. Damascus also became the point of departure of the pilgrim caravan to Mecca under the governor's protection and patronage. A new quarter grew up on the pilgrimage route in the south of Damascus, called as-Siniiniyah after the Turkish governor Sinān Pasha.

Entry of  
the West

One of the most important events in the 19th century was the coming to power in Egypt of Muhammad 'Alī Pasha and the incorporation of Syria in his empire. During the Egyptian period (1831–40) Damascus once again became the capital of Syria. After 1878 its population grew to 150,000. Europeans came in increasing numbers—consuls, merchants, and tourists. The imperialistic ventures of the great powers in the Middle East opened the door wider to European cultural and economic influence.

In 1878 an enlightened Turkish governor, Midhat Paşa, was appointed for Damascus. He succeeded in improving its sanitary conditions and its system of transport. He dug new roads in the Old City and widened some of its dark alleys, such as that connecting Siiq al-Hamidiyah with the Great Umayyad Mosque. New government buildings rose up west of the Old City around al-Marjah Square (the Meadow), which has become the city centre. In 1894 Damascus was linked by railway to Beirut and Hawriin and in 1908 to Medina in the Hejaz.

Two new quarters of Damascus were added as Muslim immigrants arrived from Crete, settling on the slopes of Jabal Qūsiyūn in what has come to be known as al-Muhijirīn, the immigrants' quarter, and as Kurds coming in from the north found space just to the east of al-Muhājirīn in al-Akrad, the Kurds' quarter. New buildings were put up near Bāb Tiimah (Thomas' Gate) for European consuls, merchants, and missionaries.

In World War I Damascus was the headquarters of Turkish–German forces. The Arab Legion entered Damascus in October 1918, followed by the Allies. The first Syrian government was set up in 1919, with Damascus as its capital. But the French, having obtained a mandate from the League of Nations, occupied the city in July 1920. The French presence (1920–45) encountered much resistance in the form of strikes, riots, and uprisings, the most serious of which occurred in October 1925 and was not suppressed before the French had twice bombarded the city.

The period of the French mandate was one of great urban development, often at the expense of the orchards on the left bank of the Barādī River. The new quarters of al-Jisr, al-'Arnūs, and ash-Shuhadā' accommodated various elements of the population without any apparent

segregation. Northeast of the city the quarter of Qaṣṣā' sprang up adjacent to Bāb Tiimah and the eastern city wall. Wide, tree-lined avenues were laid out, and the city was provided with a modern water supply.

During World War II Allied troops entered the city in June 1941, driving out the Vichy French, who were pro-German. After four years of tension over the issue of independence, British and French troops were evacuated in April 1946, and Syria became an independent country with Damascus as its capital.

**The city and its environment.** The early site of Damascus was a terrace on the right bank of the Barādā River at the point where it emerges from its canyon before losing itself in the desert. The terrace, consisting of compact gravels, has an elevation of about 2,250 feet above sea level. The growth of the city has forced it up the slopes of Jabal Qāsiyūn, northwest of the original terrace, to an elevation of almost 3,000 feet. The main expansion of the city, however, has been to the northeast and south, where the terrain is gentler and the elevation does not exceed 2,300 feet.

Topog-  
raphy

Damascus is open in all directions except the west, which is blocked by Jabal Qāsiyūn. The fertile alluvial plain extending 12 miles eastward supplies the city with vegetables, fruit, timber, and some cereals. The principal cereal requirements are met from the plains of Hawrān to the south.

Greater Damascus covers an area of about 39 square miles (100 square kilometres), including all of Jabal Qāsiyūn, Mt. Mazzah, and the townships of Dummar, Barzah, al-Qābūn, Jawbar, al-Qadam, al-Mazzah, and Kafr Siisah; *i.e.*, about five times the area of the city proper, which is eight or nine square miles. The city has sent out tentacles in all directions except the west. The most important of these elongations is that extending along the slopes of Jabal Qāsiyūn to the villages of Barzah in the northeast and al-Mazzah in the southwest; a second extends northeast to Jawbar and al-Qābūn; the third and oldest has already swallowed up the village of al-Qadam. Al-Mazzah, al-Qābūn, and Barzah are considered suburban areas because they are still separated from Damascus by green areas that the municipal government is anxious to preserve.

**Climate.** Although Damascus is only 50 miles from the sea, the Lebanon and Anti-Lebanon mountain ranges cut off the moisture-laden winds and make the climate a subdesert one. The mean annual precipitation is 6.89 inches, as compared with a mean of 33.15 inches in Beirut, Lebanon, on the other side of the mountains. Most of the precipitation is in November, December, January, and February. In the dry months, desert winds blow from the south and east, bringing dust with them. Variations of temperature are sudden and capricious. The January average is often about 45° F (7° C) but may occasionally fall to 18° F (−8° C) and rise to 72° F (22° C). August is the hottest month in Damascus, with an average of 81° F (27° C), but the temperature often rises to 99° F (37° C) and may reach 111° F (44° C). Summer is the longest season. Spring lasts a few weeks between the second half of March and the first half of April, while autumn may not come until November. Variations in rainfall are extreme. In some years it may reach as much as 13 or 14 inches, which is sufficient for dry farming, while in others it may fall below six inches or even as low as two inches or less, as it did in 1931–33 and 1959–60.

**Plant and animal life.** The desert surrounding the oasis has a variety of dry and thorny shrubs, thistles, and herbs. The Ghūṭah, however, has a temperate and sub-tropical vegetation, including such trees and plants as the mulberry, apricot, olive, vine, apple, peach, and nut; aspens and poplars grow thickly near the streams. Truck gardening is intensive, and the fringes of the Ghūṭah contain cereals such as wheat, barley, and lentils grown in the shade of olive trees.

Animals have been driven out by man. Gazelles, wolves, and hares have disappeared. The drying up of marshes has eliminated many migratory birds, such as ducks, water hens, and storks. Cows, goats, and sheep are bred

The Citadel of Damascus, with Jabal Qāsiyūn in the background.  
Carl Frank

in increasing numbers to meet the milk and meat requirements of the city, while transport animals—horses, mules, and donkeys—are rapidly decreasing.

*City plan.* A modern city plan was laid out for Damascus in 1929 by a French expert, providing for its orderly growth. A number of wide streets and avenues were built subsequently, notably in the modern residential quarter of Abū Rummānah, which sprang up at the expense of the old village of Nayrab. This quarter, which has many embassies, has continued to extend westward and northward, threatening to engulf all the orchards in the northwestern parts of the city. Other residential quarters have also sprung up north of Baghdad Street, spreading toward the al-Akrad quarter on the slopes of Jabal Qāsiyūn. The city's accelerated growth since World War II has required modifications in the plan, which were made by a Japanese planner in 1964.

Most of the streets in Damascus are straight, and they cross at right angles. There are some diagonals. Widening operations have been carried out in the Old City to give it better ventilation and open it to modern transport, but its most prominent features remain. A typical house in the Old City opens onto a yard lined with trees and containing a water fountain in the centre. Damascus is zoned into residential, commercial, and industrial areas, the latter being located to the east of the city. Governmental ministries and departments are scattered about in various locations west of the Old City. Many are concentrated at Marjah Square, the area of banks and fashionable shops.

Streetcar lines were built in Damascus in 1906, but between 1963 and 1970 they were discontinued. Intracity transport is provided by buses and taxis. Traffic lights have been introduced since 1966. The total number of motor vehicles in 1970 was about 20,000, including motorcycles. Damascus has an international airport about 19 miles east of the city.

*Demography.* The city's population in 1971 was more than 1,000,000, as compared with 130,000 in 1922 and 529,963 in 1960. The present figure includes 50,000

refugees from Palestine since 1948, and 75,000 from the Golan Heights since June 1967. Muslims constituted more than 91.2 percent of the population, Christians 8.4 percent, and Jews 0.04 percent. The natural increase was estimated at the very high rate of 28 per thousand in 1968, with a birth rate of 40 per thousand and a death rate of 12 per thousand. Those below 15 years of age comprised 42.8 percent of the population; only 11.2 percent were over 50. There were 313 families with 10 children or more, and some had as many as 17.

The traditional Damascene house with its patio and water fountain is no longer being built. Cement, which was not introduced as a building material until 1918, has brought an architectural revolution that has completely transformed the city. European design has become the rule, usually in the French and Italian Mediterranean style. Reinforced concrete is the principal material of residential buildings. Their upper stories are often uninhabitable in the heat of summer.

*Economic and cultural life.* Damascus is a centre of government and light industry. Once celebrated for its fine silken textiles and ornamental fabrics, as well as for steel and swords, it still has a fairly active and prospering group of handicraft industries. Notable among their products are mother-of-pearl mosaics, silk brocades, copper goods, blown glass, and cabinetry. The more modern industries include furniture, clothing, shoes, textiles, food, leather, and printing. These industries started to emerge in 1929 when the first wool-cloth factory was built, followed by a cement factory in 1930 and a food-preserving factory in 1935. The cotton textile industry began in 1946, although factories using imported yarns date back to 1937. Damascus now has 80 textile establishments with more than 1,800 modern looms. The first glass factory was completed in 1945. Most of the major factories are now state owned.

Damascus plays an important role in transit trade between Beirut, Amman, Baghdad, Kuwait, and the countries of the Arabian Peninsula. It is also a distributor of imported goods to various parts of central and southern

The  
changing  
city

Major  
industries

Syria. Wholesale trade is now largely a state monopoly. An international trade fair is held at the river every autumn. The fair is visited by about 1,500,000 people. Damascus has an excessive number of retail shops and small tradesmen, attributable to a lack of regular employment in other fields. There is a surplus of manpower because of heavy migration to the city from the countryside.

**Public utilities.** Damascus draws its water supply from the Baradft River's source at 'Ayn al-Fījah through underground canals. The system, initiated by the Turkish governor Nāẓim Pasha in 1908, was completed in 1932. Electric power consumption in 1968 was 206,109,000 kilowatt-hours, of which one-fourth went to industry and over one-half to illumination. Sewage is discharged into the lower Baradft River or into the Yazid and Tawrfit streams that issue from the Baradā.

**Public health.** In 1969 Damascus had 10 state hospitals and sanatoria, with 2,676 beds, and 17 private hospitals, with 403 beds, affording one bed for every 421 people. There were 61 state and private outpatient clinics, 13 maternal and child-welfare centres, one centre for tuberculosis control and another for malaria eradication, two schools of nursing and midwifery, and 700 physicians—45 percent of all the country's doctors. Endemic diseases are generally absent from Damascus with the exception of tuberculosis, which attacks the poor.

**Education.** Damascus had 385 public elementary schools in 1968 (150 for boys, 120 for girls, and 115 mixed) along with 80 private schools and 50 schools run by the United Nations for Palestine refugees. The number of teachers in all these was about 4,000. Preparatory and secondary education was provided by 60 state, 55 private, and 18 United Nations' schools employing about 2,000 teachers. There were four industrial schools with 3,745 pupils, a domestic science school with 267 girls, two commerce schools, and one agricultural school. The University of Damascus had about 31,000 students, about half of whom were registered in the faculty of literature. Illiteracy among persons over the age of 15 was about 20 percent.

**Culture and recreation.** Most formal cultural activities in Damascus are directed and controlled by the Ministry of Culture. The National Museum, founded in 1921, superintends the excavations carried out by foreign archaeological missions (Italian, French, American, Danish, and Polish) in various parts of the country. The Qaṣr al-'Azm Museum, close to the Great Umayyad Mosque, specializes in the history of folklore and popular arts. The Arab Academy, founded in 1919 by the scholar Muhammad Kurd 'Alī, contains the az-Zāhiriyyah national library, with 40,000 manuscripts and 100,000 publications.

All mass media are controlled by the Ministry of Information. Syria's two national daily newspapers, *al-Baṭh* and *ath-Thawrah*, are published in Damascus, as well as two weeklies—one for workers and the other for farmers and peasants. The Damascus radio broadcasts 14 hours daily in Arabic, English, French, Turkish, Russian, German, Hebrew, Armenian, and Spanish. There are also daily television broadcasts.

The cinema is one of the most popular amusements among Damascenes, who are presented with a choice of films from Arab countries, the United States, Europe, India, and Pakistan. The first cinema theatre in Damascus was built in 1925; in 1971 there were 13 of them. Damascus has night clubs and numerous discotheques. The annual international fair, held August 25 to September 20, offers a great variety of recreation and entertainment.

There are some public gardens and parks, most of them fairly small. The great orchards of the Ghūṭah are open to the public, but there is no zoological garden.

The most popular sport in Damascus is association football, followed by basketball and swimming. The main stadium accommodates 50,000 spectators. Damascus also has a number of excellent swimming pools in its suburbs. Other sports are wrestling, boxing, and tennis.

## Dana, James Dwight

A versatile naturalist and an eminent student of the Earth, James Dwight Dana shaped his country's geological thought for over half a century. Explorer, investigator, writer, editor, and teacher, Dana's productive career spanned 60 years, from his first publication in 1835, a study of Vesuvius, to the 4th edition of his *Manual of Geology* in 1895. A brilliant synthesizer and leading theorist of geology, he also made permanent contributions to the subjects of mineralogy and zoology.

By courtesy of the Yale University Library

Dana.

Born in Utica, New York, February 12, 1813, Dana attended Charles Bartlett's Academy, then entered Yale College as a sophomore in 1830. On graduation from Yale in 1833 he instructed midshipmen in mathematics on a United States Navy cruise to the Mediterranean; he returned to New Haven in 1836 as an assistant to his former teacher, Benjamin Silliman, professor of chemistry and mineralogy at Yale. Evidence of Dana's great productive energy came at age 24 with the publication in 1837 of *A System of Mineralogy*, a work of 580 pages that has persisted through numerous editions and remains the standard manual in its field. In 1838 Dana joined a United States exploring expedition to the South Seas under Charles Wilkes; he served four years as a geologist and also was responsible for much of the zoological work.

In 1844, two years after his return from the expedition headed by Charles Wilkes, Dana married Henrietta Silliman, the daughter of his mentor at Yale, and settled in New Haven. Dana spent his intense energy largely on science. From 1844 to 1854, his most productive years, he published about 7,000 printed pages in addition to hundreds of plates, most of which he drew. His writings on the Wilkes expedition include four illustrated quarto volumes, each over 700 pages—the *Zoophytes* (1846) describing the coral-forming animals and a two-volume work, *Crustacea* (1852–54) and the report on the *Geology* in 1849. Numerous short papers treated other aspects of his work with the expedition. The zoological work alone, in which he described more than 800 species of marine animals, was monumental and made Dana an authority on the groups.

The main thrust of Dana's effort was geological. Among

his many publications were the text *Manual of Mineralogy* (1848) and three editions of *A System of Mineralogy* (1st edition, 1837), including a complete revision in which he founded a classification of minerals based on mathematics, physics, and chemistry. More significant to Dana's impact on American geology during this decade was the start of his long association with the *American Journal of Science*, a leading organ of scientific inquiry founded by Benjamin Silliman. As an editor and contributor of critical reviews, original papers, and perceptive syntheses, Dana exerted a vitalizing influence on American geology. One of the best informed men of science in his day, his concern with the physical processes that produced geologic phenomena led to brilliant generalizations on such fundamental questions concerning the formation of the physical features of the Earth as the origin and structure of continents and ocean basins, the nature of mountain building, and volcanic activity. From his own studies and his mastery of the works of other American and foreign geologists, Dana constructed a view of the Earth as a geological unity developing through time. Adopting the theory of a contracting Earth cooling from a molten condition, he argued that the present continents mark areas that cooled first; subsequent contractions caused the intervening oceanic areas to subside. As settling oceanic crusts adapted periodically to a shrinking interior, pressure was exerted against continental margins causing upheaval of great mountain chains such as the Appalachians, Rockies, and Andes. Dana stressed the progressive change of the Earth's physical features but at first was reluctant to accept the idea of the evolution of living things.

By the early 1850s Dana had attained international recognition and was corresponding with other outstanding scientists of his day, among them Asa Gray, noted American botanist; Louis Agassiz, Swiss-born naturalist and teacher at Harvard; and Charles Darwin. All had measurable influence on his thinking. Spurred by tentative proposals from Harvard for Dana's services, friends at Yale established the Silliman Professorship of Natural History, which Dana accepted in 1856. But in 1859, the strain of his self-imposed overwork resulted in a physical breakdown from which he never fully recovered. During his remaining 35 years he was forced to live a secluded existence, largely withdrawn from the public. For a less modest man this would have been difficult, for many academic honours came to him during this period. Recognition included the presidencies of the American Association for the Advancement of Science and the Geological Society of America; he was also a founding member of the National Academy of Sciences.

Despite ill health Dana continued to publish: in 1862 his influential textbook, *Manual of Geology* (4 eds.); in 1864, *A Text-book of Geology*, a more elementary work; and in 1872 *Corals and Coral Islands*, which was the climax to his notable studies of coral reefs, begun on the Wilkes expedition. Dana investigated coral islands in greater detail than anyone before him, substantiating Darwin's observation that atolls were evidence of subsidence of the ocean bottom. Reef-building corals, Dana independently concluded, lived only in shallow, tropical waters on hard substrates, commonly forming fringing reefs about volcanic islands. Coral rock found at some depth on island flanks and atolls made only of reef rock indicated that extensive volcanic lands had disappeared beneath the Pacific leaving clusters of atolls to mark their former existence.

During his later years he wrestled with the challenge of organic evolution proposed by Darwin. Always a deeply religious man, Dana believed in the special creation of species, yet he was keenly aware of the intricate relationships between species and their environment. Darwin's impressive argument, coupled with Dana's own zoological knowledge, was persuasive in the end, however, and he adopted evolution theory in the last edition of his *Manual*. For Dana the natural and the divine had to be inseparable—all nature and the design of continual improvement of life that he read into it were a manifestation of the divine.

During Dana's lifetime, and largely under his leadership, American geology grew from a collection and classification of unrelated facts into a mature science.

Actively at work until the last, Dana died on April 14, 1895, in New Haven at the age of 82.

## Dance, Art of

The art of dancing is the art of moving the body in a rhythmical way, usually to music, to express an emotion or idea, to narrate a story, or simply to take delight in the movement itself. The dance impulse seems, so far as is known—for there is no concrete evidence—to date from the very beginning of man's existence on Earth and to begin with his own life. Dance may even have been the first means of communication; children today, even in sophisticated societies, will dance with delight before they know how to express their feelings in words.

Dance as an art, as distinct from a natural activity, can be traced from the moment when it was harnessed to a rhythm, probably the stamping of feet and clapping of hands. It is, however, an intangible art, existing in the bodies of the performers and dying with them. Only in recent years has it been possible to preserve on film or in precise notation the actions of the dancers.

There is evidence, throughout recorded history, of men dancing, but the evidence is static—in drawings, paintings, or sculpture. It is only possible to guess how the dancers portrayed may have moved from one pose to another. Not until the 15th century is there any written description of actual dances, and, although scholars have attempted to reconstruct the social dances of the 13th and 14th centuries, they are still reluctant to say more than "they may have danced in this manner." Yet, it is possible to trace in broad outline the origins and functions of dancing, its components, and its development in various ways of life and also to describe the kinds of dancing that can be seen today.

Since this article comprises a general survey of all forms of dancing, other articles should be consulted for greater detail on some of the major forms: *e.g.*, BALLET; FOLK DANCE; MODERN DANCE; and POPULAR DANCE. Various kinds of interaction between dance and drama are covered in such articles as KABUKI THEATRE; MUSIC, THEATRICAL; NO THEATRE; and POPULAR THEATRE. The article DANCE, WESTERN covers the history of dance in the West, but, for information on the character and the history of dance in non-Western cultures, see DANCE AND THEATRE, EAST ASIAN, as well as sections on dance or the performing arts in such articles as AMERICAN INDIAN PEOPLES, ARTS OF; CENTRAL ASIAN PEOPLES, ARTS OF; SOUTH ASIAN PEOPLES, ARTS OF; ISLAMIC PEOPLES, ARTS OF; JEWISH PEOPLES, ARTS OF; and OCEANIAN PEOPLES, ARTS OF.

### ORIGINS AND FUNCTIONS OF THE DANCE

**Primitive beginnings.** It is not known how primitive man danced, but it can be deduced from the behaviour of primitive tribes surviving today that the rhythms that spurred on the dancers came mostly from the beat sustained through the stamping of feet upon the ground. Footwork probably would not have been intricate, and rhythms would have been simple—a regular recurrence of beat or shouts as the dancers roused themselves to a frenzy of activity. The earliest dances may have been simple expressions of pleasure or acts related to courtship, a theory supported by the fact that birds and animals, even spiders, dance to attract and impress a mate. Soon, however, dance was used for purposes affecting a whole tribe, which would, so far as can be deduced, dance and enact beforehand the results they wished to achieve on some expedition—be it a hunting dance to

depict the capture of prey or a warlike dance to show the defeat of an enemy.

There were surely dances of thanksgiving for harvest, for good weather, and for wanted rain. Rain dances have survived in parts of the world until today, and belief in "the rainmaker" persisted in parts of North America into the 20th century.

**Emergence of religious motivations for dance** Supplication to the gods in early times was the beginning of the religious aspect of dancing. It has been used throughout history not only for glorification but also, before written books, as a means of communication between religious leaders and the people. Dances of worship continue today in every part of the world. In the East, temple dancers preserve something of the style and traditions of ancient cultures. In the West, the most sophisticated of professional dancers put their art at the service of religion, taking part in services of celebration in great cathedrals or humble churches.

Ritual dances of considerable complexity and beauty are believed to have been developed during the ancient civilizations of Egypt and Peru. Bas-reliefs of royal processions and religious ceremonies suggest a highly stylized kind of movement. Indeed, so far as anthropologists can establish, dancing has played an important role in the social life of all civilizations.

**From antiquity to the Renaissance.** It is certain that the Greeks considered the art of dancing an essential element in their ideal of creating a sound mind in a sound body. Plato demanded a place for the dance in his ideal republic, saying it would help toward acquiring "noble, harmonious and graceful attitudes." Such a statement implies that dance was already appreciated for its own sake as an expression of beauty of movement. This aspect of dance, as well as more grotesque and comical performances, was incorporated into the Greek theatre, which reached its highest achievement c. 500 BC. From that period the beginning of theatrical dance can be dated, but how the dancers performed can only be speculated upon: the attempts to revive the Greek dance by the U.S. dancer Isadora Duncan and by the British dancer Ruby Ginner are based on such conjecture.

**Development of dancing as a social grace** The Romans, it is believed, developed earthier and more grotesque kinds of dancing in their plays and spectacles, bringing the theatrical form into disrepute. The social accomplishment of dancing, however, was recognized, and daughters of the nobility received dancing lessons. (There is no evidence of couples dancing together, however; that was to happen much later, probably in Provence in the 12th century.) The Romans also developed the art of mime, which was to lead, by the 16th century, to the improvised mime plays of the Italian *commedia dell'arte*.

**The East.** Whereas in the West various kinds of religious, social, and theatrical dance evolved slowly into the dances of today, quite different styles of movement were being perfected in the East. In general, Western dance techniques are based mostly on footwork, whereas Eastern forms of art dance, depending upon footwork to sustain the rhythm, derive their greatest beauty and subtle meanings from the infinite variety of delicate movements of the upper part of the body, especially the hands, neck, and head.

In the East as in the West, dance was indigenous to religious ceremony, was used for court entertainments, and, in a debased form, was practiced by courtesans. This debasing of the art has happened in all countries and all centuries. Because of its physical appeal, dance lends itself to erotic purposes and has been practiced to these ends by both sexes. It has, therefore, frequently incurred the displeasure of various ecclesiastical authorities who, though using dance for disseminating their own views, have condemned indulgence by the people.

**The Renaissance.** The domination of the Roman Catholic Church in Europe, after the fall of Rome, virtually extinguished theatrical dance, but it was reborn, together with the other arts, in Renaissance Italy. Emerging from the restrictions of the Middle Ages and intoxicated with a love of beauty and knowledge, the Italians, encouraged by their great princes, incorporated dance into their lavish spectacles and court entertainments. The earliest

book from which scholars can endeavour to re-create their dances was appropriately called *De arte saltandi et choreas ducendi* ("On the Art of Dancing and Conducting Dances") by Domenico da Piacenza, written in the early 1400s. From Domenico's manuscript and from the published works of his successors can be traced, albeit with much conjecture, the dance forms of Europe that were to spread throughout the Western world.

**Post-Renaissance developments.** The art of dancing in modern times stems from these Italian dancing masters. The dances of the people, the folk dances, often yielded characteristics that were incorporated into the more formal measures of the nobility. The court dances were used in the court entertainments until the end of the 18th century, by which time professional dancers took over as the entertainers and techniques began to diverge. The courtiers, who loved dancing for the honoured guests, maintained the noble style, whereas the professionals, at first following the court's example, eventually developed a technique of their own that was eventually to be codified by the 19th-century Italian teacher and theoretician Carlo Blasis as the classical ballet. But, once the courtiers had handed over responsibility for staging and dancing to the professionals, the audience changed, for the ballets were mounted in the new public theatres, and the common people could watch as well as the nobility.

Social dances—as distinct from folk dances—became the ballroom dances of the upper classes, so, though class distinctions gradually were eroded, especially in the 20th century, such dances became popular among all classes. Dances with a prescribed technique were performed at formal occasions. The popularity of different dances changed with the discovery of new rhythms for which new steps were invented. Queen Elizabeth I of England delighted in a dance called the volta, which contained some rather daring "lifts" and doubtless horrified her churchmen. In the 19th century the waltz was a "crazy" dance and was considered shocking; today, it is sedate yet charming. The 20th century has seen other temporarily fashionable dances—the Charleston boom of the 1920s, rock and roll in the 1950s. Common to all such forms of dance has been their reflection of the social structure and the "spirit of the time."

#### COMPONENTS OF THE DANCE

**The dancer.** It is through the body of the dancer that the art of dancing is portrayed, and the physical, emotional, and national characteristics of the dancer determine the quality and the nature of the dance. For example, women tend to be more supple than men, but they do not usually have equal strength and stamina. The way in which dancers perform depends greatly on the land of their origin, the dance styles, the national dress, even the climate. The dances of northern countries tend to be vigorous and those of southern lands more languid. Eskimos, bundled up in warm clothing, obviously will not attempt dainty movements. The small-boned, delicately built peoples of Southeast Asia, in their beautiful traditional costumes, perform dances that are exquisitely subtle. Conquest and occupation of a country by various invaders may alter and enrich dance styles. The Philippines, having been occupied by many races, have a dance culture that has borrowed from all of them.

Temperament, a difficult word and idea to define, also affects the style of the dancer. Slavic peoples have a reputation for fiery manners, and the proud dignity of the Spaniard is reflected in his dances. Italian gaiety produced the lively tarantella. The dances of North American Indians and other tribally organized peoples are nearly all associated with matters of group concern.

Dance styles throughout the world are different for men and women. In most national dances the men demonstrate their strength and virility, the women their charm and femininity—characteristics that are well illustrated in Russian folk dances. In ballet, women's steps sometimes are performed by men for burlesque purposes, whereas some women have mastered dance styles that are really a male preserve. The great 20th-century Gypsy dancer Carmen Amaya could rival any man in the tem-

Court dance and its descendants

Cultural and sexual dichotomies in dance

pestuous speed of her flamenco dancing. In India, Shanta Rao specialized in the *kathākali* style, which is usually associated with men.

The dancer's instrument is the human body, and the ways in which it can be used depend almost entirely on how it has—or has not—been trained. It is possible to devise very beautiful and striking ensemble works with dancers who have had virtually no training but who can look and move well. A clever choreographer can manipulate them into sculptural poses or groups. Many Nativity plays, for example, have used untrained dancers to very good effect.

The trained body is, however, nearly always more eloquent and permits a much greater variety of steps, jumps, turns, lifts, and almost acrobatic feats. The classical ballet dancer (who must start training from about the age of 11 to achieve full technical mastery) has a remarkable range of movement that cannot be attempted by ordinary mortals. Similarly, the highly trained dancers of Bali and the men and women who have mastered the complex language of Indian dancing can use their bodies far more expressively than can the untrained.

The degree of movement of which the human body is capable depends on the flexibility and strength of the muscles and on the length of the bone-connecting ligaments. These tissues are not flexible, like muscles, but they can be lengthened by special training at an early age, before they have had time to harden. This is one reason why the professional dancer must start training young. In classical ballet, it is always possible to spot a "late starter" because the body—and especially the feet and legs—will not have the strength and flexibility of the dancer who has started young. The training of a dancer, in any style, is based on daily practice of exercises carefully planned and perfected over centuries, to give the greatest strength and awareness to every part of the body.

The least flexible part of the body is the skeleton, the bony frame. The structure of bones and joints governs the amount of bodily movement in any one direction. The ribs and chest can easily be bent to each side and forward but will not bend backward. The ball and socket structure of the shoulder and hip joints permits a small degree of movement. Movement from the hip is easier in a forward direction; it is more difficult to swing the leg up to the side or the back than in front of the body. The ballet dancer must practice until his legs can be raised high in all directions without loss of balance or control. A fundamental of dancing is the control of distribution of weight.

Although the ballet dancer trains each part of the body, performing exercises to acquire harmonious movements of the arms and changes of direction with the shoulders (*Cpaulement*), special care is given to the feet and legs. The hours of working in the classroom, at the barre or in the centre of the room, are designed to help the dancer to leap high in the air, to perform intricate beating movements of the feet (*batterie*), and also to alight softly and surely and with sufficient control to go straight into a fast series of multiple turns (*pirouettes*).

The Hindu dancer of India, performing barefoot and not attempting the virtuoso footwork of the ballet or other Western dancers, cultivates an equally complex technique. The *Bhārata Nāṭya-śāstra*, the 2,000-year-old manual of Hindu dance, lays down movements for all parts of the body, but it has been calculated that there are at least 4,000 *mudrās* (picture patterns of the hands), so each finger must be eloquent. To the initiated, these *mudrās* alone can tell detailed myths and stories. The 20th century has seen a revival of Indian dancing, and pioneers such as Uday Shankar and Ram Gopal have helped Western audiences understand their art.

Because the trained dancer has brought his body to a high state of flexibility, control, and alertness, he will always be a better and more expressive dancer than the untrained one. His body is probably more beautiful and his carriage more erect, so he can achieve the harmony of movement that is the essence of the art of dance.

The age at which a dancer retires depends entirely on the style of dancing and the amount of physical effort

required. If the dance style can be adapted and refined down to a minimum of movement, then the dancer can continue until death. In nations in which age is revered, tribal elders will preside over dances until their deaths. In the West, the U.S. dancer Ruth St. Denis was still touring and appearing in some of her simple solo dances when over 80. The career of a classical ballerina, however, usually ends at 50, and male dancers tend to lose their virtuosity by their mid-40s. Character dancers in ballet can, of course, continue until old age. A man may lead a mazurka or czardas with authority until well into his 60s, while mime roles can be played by even older dancers. Ballroom dancing can be enjoyed so long as a man or woman is active, though perhaps without complicated variations.

**The choreographer.** The choreographer, the arranger of dances either for a soloist or a group, is the most important figure in dance history. His is the creative mind that invents the order and combination of steps, the patterns of group dances, the communication of narrative through dance, and the extension of dance techniques by using familiar actions in new and more complex ways.

A choreographer, given trained bodies, can set them in motion in an almost unlimited number of ways. It is possible to construct "story ballets," grave or gay, in which the action is unfolded through dance and mime. Different combinations of steps can express different emotions. A quick, light, darting solo, for instance, may suggest the happiness of first love; heavier, earthbound, and slower dances may convey grief. Dance can be highly stylized or simple, almost naturalistic. Choreographers draw inspiration from many kinds of dancing, and each kind influences the others.

Unfortunately, nothing at all is known of the work of the first choreographers. Someone must have suggested the shapes of the traditional folk and group dances, but only the work of those who have tried to revive and preserve them can be studied.

Attempts have been made to write down dance patterns—social and theatrical—from the time of the first books about dancing. Western dance can be reconstructed from various systems of notation ever since Thoinot Arbeau, a canon of Langres in France, published his *Orchésographie* in 1588. The systems, however, although they can be deciphered by experts today, leave much open to conjecture. The most comprehensive system invented is that of Rudolf Laban, clearly set out in the textbook *Labanotation or Kinetography Laban* (1971) by Ann Hutchinson. Used in conjunction with film, this method records any kind of movement.

Lacking such aids, choreographers have relied in the past on their works being preserved and handed down by generations of dancers, but inevitably changes will occur constantly. No producer can resist adding his personal stamp to a restaging of even the most cherished classic of the ballet repertory. It is possible to study the history of ballet, for example, from fragments of choreography surviving from as early as 1786, when the Italian ballet master Vincenzo Galeotti staged his *Whims of Cupid and the Ballet Master* for the Royal Danish Ballet in Copenhagen. The Danes have been great traditionalists in ballet, and their version of *La Sylphide*, originally staged in 1836, preserves most purely the Romantic style of ballet. In it can be found all characteristics of that period—the toe dancing of the supernatural Sylphide, the setting in a foreign country (Scotland), and the brilliant footwork for the male dancer that was derived from the example and teaching of Auguste Vestris, star performer of the French ballet in the late 18th and early 19th centuries.

In Russia, where technique was being enriched by teachers from France, Italy, and Scandinavia, the Romantic ballets were injected with the new virtuosity, and it is from Russia, through the Stepanov system of dance notation, that most of the ballets of the Romantic era have been restaged in the West. The 19th-century Frenchman Marius Petipa was the architect of the pure classical ballet as used in such works as *The Sleeping Beauty*, *La Bayadère*, and the more brilliant parts of *Swan Lake*.

Longevity

skills

Methods  
of  
preserving  
choreo-  
graphic  
works

In the 20th century the influential choreographers have been the Russian reformer Michel Fokine, who returned to the landmark principles of unity of construction and expression articulated by the innovative dancer-choreographer Jean-Georges Noverre in 1760; the Russian dancer Vaslav Nijinsky, who in a short, tragic career created three works (none of which survives) that are considered of capital importance because of his novel uses of dance; the Russian *Léonide Massine*, who worked in the 1920s with Cubist and Constructivist painters and used every medium of theatre art; Nijinsky's sister, Bronisława Nijinska, who brought ritual and sculptural groupings to the ballet stage in *Les Noces* (1923; still danced by Britain's Royal Ballet); George Balanchine, who has shaped the development of classical dance in the United States; Sir Frederick Ashton, architect of the English, lyrical style of classical dancing; the Englishman Antony Tudor, who found new "psychological" undertones that could be expressed through movement; and the American Jerome Robbins, who has united nearly all forms of dance, writing with genius for classic ballet, musical comedy and drama, or motion picture. Some of their works have been recorded, but many have already been lost.

**Accompaniments to the dance.** Dance can be and has been accompanied by every conceivable kind of sound. On the other hand, it may need no sound, for the dancer, blessed with conscious rhythm, can perform highly complex and stylized movements in silence. It is reasonable to believe that the first accompaniments were stamping, clapping, and chanting and then possibly drumming. Song has also played an important part: at the time of the opera-ballets of the 17th and 18th centuries in western Europe, the arts of music, dance, and song were inseparably linked. Once divorced, theatre dance found its own composers, and the status of ballet has been almost entirely governed by the quality of its music. Dance is not dependent upon music, but it is usually enhanced by it; a gavotte danced to the music of Gluck is likely to be a more highly refined form of social dancing than a fox-trot done to a dance band.

The musical instruments used to play for dancing are almost invariably those of the country of the dance's origin—for example, the gamelan orchestra that accompanies the dances of Java and Bali. Sometimes, however, unusual juxtapositions can be effectively used in the theatre. Contemporary modern dancers in the West have found inspiration in Indian music. Music specifically written for the concert hall has often been used—with varying degrees of success—by choreographers working in the theatre or other mediums.

The spoken word can also be used as an effective accompaniment to dance. It may be written for the purpose, or a dancer may choose to "interpret" a poem through movement while it is being spoken on stage. Sometimes both the musicians and dancers will improvise, almost in competition with each other.

**Theatrical effects.** When dance is a spectacle, every device of costume, makeup, and theatrical effect can be used. The makeup and costumes for the ancient dances of Japan, China, and India are astounding in their complexity and the significance that each part of costume and the painting of the face plays in the dance-dramas. Kabuki, the popular Japanese dance theatre, places great emphasis on costume, and the personality of the dancer is molded, virtually extinguished, by the theatrical trappings. The spectacular Kathākali dancers of India spend up to four hours being made up for a performance. The makeup entirely transforms the human face to enable the dancer to play the superhuman characters of their dance-dramas.

Even in the more realistic performances of the West, costume and decor play an important part. The entertainments of the Renaissance were of surpassing beauty, both in the costumes and in the scenic effects. Costume is nearly always influenced, in the theatre, by fashion. Dance techniques are encumbered or liberated by costume. Not until the invention of tights (French *maillot*) was the female ballet dancer free to leap high and throw

her legs into the air. In recent years tights and leotards covering most of the body have given complete freedom of movement to both sexes.

The theatrical effects of the ballets staged in the 18th-century court theatres were elaborate. Gods would ascend or descend on chariots or clouds, and the stage machinery was remarkably effective. (A perfect survival is the court theatre at Drottningholm, Sweden, still used for the performance of 18th-century operas and reconstructions of the old ballets.)

Ballet design in the 18th and 19th centuries was usually entrusted to a resident designer, attached to the theatre. Diaghilev revolutionized this practice by bringing easel painters of such calibre as Pablo Picasso and Henri Matisse to design ballets.

Today, choreographers use every kind of lighting and mixed media in their productions. Film projections have long been used. The dance, especially among the modern dancers of the United States, and above all in the work of Merce Cunningham, keeps pace with every element of the theatre—and sometimes is ahead. The Alwin Nikolais Dance Company has probably had more influence on the theatre and television than on dance.

**Narrative methods and materials.** There are many things that can be said in dance, others that cannot be said. Passage of time in years can be suggested by aging the characters; lighting can indicate different times of day. Certain relationships cannot, however, be conveyed in dance or mime. It is easy to establish a love relationship through dancing, but it is quite impossible without program notes to convey blood relationships.

The dancer communicates with the audience in two distinct ways, either through an outpouring of emotion through the body as well as the face or by a complex language of mime and gesture that can be fully understood only by spectators who know the "language."

The best known of these sign languages is the traditional mime of the classical ballet (now almost lost) and the *mudrās*—symbolic hand gestures—of Indian dancing. The classical ballet gestures are sometimes obvious to the point of naïveté—hand on heart means love; pointing to the fourth finger of the left hand means marriage, but these may be no more understood by the layman than the fact that a powerful downward movement of crossing the arms means death or that a circling of the arms above the head means to dance.

The classical dancing of India uses an enormous amount of hand gestures that, to the initiated, can describe anything from a tortoise to a fish to a lotus flower. Although Indian dancing may be enjoyed by Westerners simply for its technical expertise and for the gorgeous costumes, a study of the basic *mudrās* is rewarding. In Kathākali alone there are several hundred, built up from a basic 24. Good dancers are expected to have a vocabulary of 500.

The early ballets in the West were mostly based on stories from classical mythology, and, by the time ballet had reached the court of the 17th-century French king Louis XIV, it was being used for political purposes. The King himself danced only the most important roles, thus impressing upon the spectators his supremacy in his kingdom. (It was after he appeared as the Sun in the Ballet de la nuit, 1653, that he acquired the title Le Roi Soleil.)

A choreographer of genius can create works that are almost as eloquent in their storytelling as a play, and there have been examples of plays being translated into dance form and retaining much of their impact. The American Martha Graham has translated Greek tragedy into terms of contemporary dance, producing even a full-length version of Clytemnestra (1958). In England, the choreographer Sir Frederick Ashton used Shakespeare's *Midsummer Night's Dream* for his ballet *The Dream* (1964), contrasting the delicate dancing of the fairies with the rural frolics of the rustics and the comedy of manners of the lovers' quarrels. Quite different was Sir Robert Helpmann's version of *Hamlet* (1942), presented as a tormented and distorted flashback of events in the mind of the dying prince.

Such works, of course, presuppose a knowledge of the

Diversity of musical and natural sounds

Dance as language and the languages of dance

The enhancement of visual effects

Expressive variety of Indian dance movement

Narrative and non-narrative usages

play. Other narratives, such as *La Fille mal gardée*, exist only on the stage. First produced in Bordeaux in 1789, this charming pastorate—of a girl who escapes her mother's attempts to marry her to a rich simpleton and subsequently wins the young farmer she loves—has been, in varying styles of production, an enormous success. A narrative work gives pleasure from characterization and mime as well as from dance. Non-narrative works, such as Balanchine's *Jewels* and Ashton's *Monotones I and II*, rely upon pure dance images to make their effects.

#### KINDS OF DANCE

There are as many kinds of dancing as of any other human activity. The art of dancing stretches from the simplest forms of pure dance expression, performed by an individual for his or her own satisfaction, through the complexities and subtleties of Eastern dance, to the most sophisticated, modern, and large-scale productions in which dance is the dominant factor. The definitions must therefore be broad, and they must encompass both general ways of dancing as well as the recognized genres of the dance.

**Natural, or untutored, dance.** Being a natural impulse, dance can be enjoyed both by the trained and the untrained dancer. The untrained may derive the greatest personal pleasure, having to obey no rules, but will be restricted by the lack of a technique, a vocabulary of movement. Nearly every man and woman must at some time have danced for pure pleasure, spontaneously leaping and running to release an intoxication of high spirits. "Creative dance" is now encouraged in some schools that frown upon what they call the unnatural and rigid disciplines of formal dance training. Children are encouraged to "express themselves" in movement. In doing so, they simply release the natural instinct and, by giving it some semblance of "meaning," are veering toward the art of dancing.

This activity may have therapeutic value, but it is arguable that it has any educational value, since the children submit to no discipline and are required to obey no laws of movement. From time to time, however, a great artist emerges who, through sheer force of personality and without formal training, can devise a form of dancing that may, in its own right, be described as true art. In the 20th century the supreme example is Isadora Duncan, but it is significant that her art died with her and that it was dependent to a great degree on the great music to which she danced.

A trained body is obviously a more articulate instrument than an untrained one, but these strictures apply mainly to the performing artist. For the individual to take part in group or couple dances, it is necessary to learn only a few basic steps.

**Solo and group dance.** Solo dance is usually performed for a specific purpose. Among primitive peoples, the incantations and frenzied movements of the shaman or witch doctor were designed to contact the spirits of nature and to drive out evil ones. Among sophisticated peoples, the solo dancers are usually those who perform in public recitals to demonstrate a particular technique or style of dancing in a program of their own devising. "Concert dancers" flourished in Germany in the 1920s and 1930s and among the modern dance pioneers in the United States. In all kinds of dancing, "stars" or virtuoso performers usually have a favourite dance of their own that they may perform within the context of a company. For example, the 19th-century Romantic ballerina Fanny Elssler was internationally celebrated for her *cachucha* dance, a Spanish dance accompanied by castanets. Anna Pavlova, a great Russian classical ballerina, is mostly remembered for her famous solo *The Dying Swan*. The supreme Spanish dancer of this century, Antonio, will be remembered for his solo *zapateado*, a flamenco dance of dazzling and intricate heel work, rather than for his lavish stage spectacles.

Group dances fall into several categories. Folk dance is almost always performed by groups with perhaps a leader to begin the dance. Ballroom dancing is likewise a group activity, with many couples taking the floor

together and sometimes changing partners in the course of a dance. In classical ballet the *corps de ballet*, or chorus, functions essentially to sustain the action and to provide a framework for the principal dancers. Modern or contemporary dancers usually have their own groups for whom they choreograph, although they often take major parts themselves.

**Ethnic dance.** The concept of ethnic dance probably embraces the largest variety of dances, since it applies to all dance that is indigenous to a certain race or country. It applies to the primitive tribal dances, with their built-in purpose of religious supplication or thanksgiving, and it applies to the most highly trained court dancers used in religious ceremony, especially in the East. Ethnic dance includes the traditional styles of dancing developed all over the world, and excludes theatrical or spectator dance as well as folk dance.

**Folk dance.** The folk dances of the world are, as the name suggests, the dances of the peoples of all parts of the world that they have devised for their own pleasure. Essentially, they are for the enjoyment of the performers, and they are not spectator dances—although pleasure may be derived from watching them, and they have been, in recent times, artificially preserved and performed in places far from the village green or jungle clearing of their origin.

In the linked, or chain, dances from which most European folk dance derives, it is easy for a dancer to learn the rudimentary steps. Only in the 20th century have folk-dance groups been trained in the kind of virtuosity that makes them exciting theatre for sophisticated audiences. The English folk dances have been artificially preserved by scholars and enthusiasts and are enjoyed by thousands of amateurs, but they are no longer danced by country people. They are, of course, simple in technique and require no special training.

**Court dance.** The court dances of the Western world were social accomplishments, polished from material usually found among folk dances. The root dance in the West was the *carole* of the early Middle Ages. From its two forms—the *brarles*, which gave the first known rhythms and steps, and the *farandole*, which gave figures or floor patterns—all court dances developed.

In 12th-century Provence, courtly dancing began to emerge in a dance form called *estampies*, which may have been processional but is now believed to be the beginning of the *danses a deux*, or couple dances. In 15th-century Italy a distinction is made for the first time between a *danza* and a *ballo*. A *danza* had a uniform rhythm throughout, a *ballo* had varied rhythms.

By the 16th century in the courts of France and England, figure dances with a distinct floor pattern were common. Such dances as the *pavane*, *galliard*, and *courante* were popular and were being described by dancing masters to the court. Intricate steps and rhythms led, during the 17th and 18th centuries, to such dances as the *sarabande*, *gavotte*, *minuet*, and *hornpipe*.

The French Revolution and the Napoleonic Wars put an end to court dances as spectator dances performed by and for the nobility. Dancing remained a social accomplishment for the upper classes, but the dance forms of Western civilization now divide into those of the ballroom and those of the theatre.

**Ballroom dance.** Ballroom dancing, sometimes called social or popular dance, is nearly always now performed by couples, dancing prescribed steps for their own pleasure either at private functions or in public dance halls. Between 1820 and 1910 the popular dances were the waltz, quadrille, and polka. The Russian and eastern European nobility before the Revolution also danced adaptations of such national dances as *mazurkas* and *czardas*. Immediately before World War I the rhythms of Negro and South American dances reached Europe, and the tango and then the rumba became the rage. They were the first of the popular Latin American dances.

The popular teen-age dances of the mid-20th century have no set "steps"; the dancers respond spontaneously to the beat of the musicians. The degree of satisfaction attained by young people "twisting" or "shaking" to the

## Ballroom dance contests

blare of amplified music in dance halls, further enlivened by psychedelic lighting, is different from the pleasure derived by their elders waltzing to *The Blue Danube*—but it is only a difference of age and time. Fundamentally, both age groups are enjoying the pleasure of dancing in their own way and at their own pace. Once, it was scandalous for a man to put his arm around a woman as they danced. By the 1950s young dancers once again were dancing without touching their partners, apparently oblivious to “coupleness.” The end product is doubtless the same—physical pleasure in the activity of dancing and sexual awareness of a partner, whether embraced or half-consciously observed.

International contests in ballroom dancing gained favour early in the 20th century. In the 1920s in London, dance teachers codified the basic steps of such dances as the waltz, tango, and fox-trot and encouraged dancers to learn the steps, practice them to professional standards, and enter competitions or championships. The championship type of ballroom dancing now bears little relation to what is danced in society, the steps having become so intricate and artificial that only people who have time for constant practice can accomplish them. Championships continue, nonetheless, to attract thousands of spectators in various countries.

**Theatrical dance.** When Louis XIV of France in 1671 (the date of the first performance at the Paris Opéra) handed over to the professional dancers the entertainments that had been performed by the court, he laid the foundations of classical ballet as it is known today. His dancing masters, drawing on the earlier work of the Italians, gradually codified the basic principles of the five positions of the feet, the directions of the body, the use of arms, head, and shoulders, and the seven movements in classical dancing: to bend, to stretch, to raise, to slide, to jump, to dart, and to turn. Since the first textbooks were written in French and since France reigned supreme in ballet until the Revolution in 1789, classical technique is still described in French.

Classical ballet is the most highly trained and physically the most eloquent form of theatrical dance. It has been criticized—perhaps inevitably—by many for its seeming artificiality, and many innovators in the 20th century have looked for other forms of expression through dance. In Germany, Mary Wigman became the founder of modern dance in Europe, performing her own dances and teaching generations of others. In the U.S., where the pioneer work of Isadora Duncan was largely ignored during her lifetime, modern dance was brought to its highest achievements by such artists as Hanya Holm (a pupil of Wigman), Doris Humphrey, Martha Graham, and their students. The modern dancer usually performs barefoot but has a demanding technique.

Dance can be used to heighten the effect of dramatic productions, and it has been used with skill in films and on television. The best known of film dancers was the American Fred Astaire, who used tap dancing as the high point of the many film musicals in which he starred. Stage dancing translates badly to film or television. The best work in these media has been created especially for the screen, notably, by the American Gene Kelly, in such films as *Singin' in the Rain* (1952).

Dance has always been part of the musical theatre, sometimes a mere interlude, sometimes an essential part of the production. Agnes deMille used a dance sequence in *Oklahoma!* (1943) to further the plot, and, since that time, dance has occupied an increasingly important role in Broadway musicals. Jerome Robbins achieved an unusual synthesis in his *West Side Story* (1957).

**BIBLIOGRAPHY.** The earliest surviving manuscript about the art of dancing was written by DOMENICO DA PIACENZA, early in 1400; in it he describes the dances of his day and the dances he himself arranged. This work was written before the invention of printing, but books by Domenico's pupils were printed and survive in the great dance-book collections of the world. Most of them are available on microfilm or in paperback form. The *Livre des basses danses* (c. 1450), called *The Golden Manuscript*, is a valuable source of information about medieval dances in western Europe, which has been reissued in facsimile (1912). The Italian dancing master

FABRITIO CAROSO in *Il ballarino* (1581) describes and illustrates the dances of his day. The Italian dancing master BALTHAZAR DE BEAUJOYEULX's grand spectacle staged for Catherine de Medici in France, the *Ballet comique de la reine* (1581), was described in an elaborately illustrated publication (1582) that was distributed throughout the courts of Europe. THOINOT ARBEAU, *Orchésographie* (1588), was translated by the British ballet critic and historian CYRIL BEAUMONT in 1925. It contains dance descriptions, musical examples, and some small drawings. Written partly in dialogue form, it is subtitled *Whereby all manner of persons may easily acquire and practise the honourable exercise of dancing*. In 1604 the Italian dancing master CESARE NEGRI published his treatise on dancing, *Nuove inventioni di balli*, which is richly illustrated. In 1651 the English musician JOHN PLAYFORD published a collection of dances and their tunes called *The English Dancing-Master*, which is proof that the art of dancing was still popular during the Puritan regime of Cromwell's Commonwealth. In 1682 CLAUDE-FRANÇOIS MENESTRIER, a French Jesuit, wrote his *Des Ballets anciens et modernes*, the first printed history of the ballet. In 1701 came the French dancer and choreographer RAOUL FEUILLET, *Chorégraphie ou l'art de décrire la danse*; Feuillet was one of the first to invent a system of dance notation, showing the floor patterns of the dances. He wrote a number of other works on the dance and greatly influenced the English dancing master JOHN WEAVER, who translated Feuillet's book (*Orchesography, or the Art of Dancing*, 1706) and himself wrote in 1712 *An Essay Towards the History of Dancing*. In 1725 came the French dancing master PIERRE RAMEAU, *Le Maître à danser* (1725; Eng. trans., *The Dancing Master*, 1931), a well-illustrated book that sets down the rules of dancing and deportment at that time. NOVERRE'S *Lettres sur la danse, et sur les ballets* (1760) stated the principles of this fiery, reforming ballet master, which are still valid. By 1820 the technique of classical ballet as it is still known had been codified by the Italian dancer-choreographer-teacher CARLO BLASIS in his *Traité élémentaire thchorique, et pratique de l'art de la danse* (*An Elementary Treatise upon the Theory and Practice of the Art of Dancing*, 1944), a technical manual. The *Manual of the Theory and Practice of Classical Theatrical Dancing*, by CYRIL BEAUMONT and Polish dancer STANISLAS IDZIKOWSKI (1922), records the method of the great Italian teacher Enrico Cecchetti. *Osnovy klassicheskogo tantso* (1934; Eng. trans., *Fundamentals of the Classic Dance*, 1948, reprinted 1969), by the Russian ballerina and teacher AGRIPPINA VAGANOVA, describes the school of Soviet ballet; it has been reissued and updated several times.

Among 20th-century scholars who have contributed important books toward an understanding of the art of dancing are the Austrian researcher CURT SACHS, *Eine Weltgeschichte des Tances* (1933; Eng. trans., *World History of the Dance*, 1937, reprinted 1963); CYRIL BEAUMONT, author of innumerable, invaluable works; the U.S. musician and ballet writer LOUIS HORST, *Preclassic Dance Forms* (1937), indispensable to the study of early dances; the U.S. writer and ballet patron LINCOLN KIRSTEIN, *Dance* (1935), probably the best single survey of the art, and *Movement and Metaphor: Four Centuries of Ballet* (1970), a brilliant analysis of the component parts of ballet followed by descriptions of 50 seminal works illustrating the development of ballet from 1573 to 1968; and LILLIAN MOORE and IVOR GUEST, historians of the ballet. The art of ballroom dancing is surveyed by the British writer and ballet patron P.J.S. RICHARDSON in his *History of English Ballroom Dancing* (1946) and *Social Dances of the Nineteenth Century in England* (1960); and by the ballet writer ARTHUR H. FRANKS in *Social Dance: A Short History* (1963). In England, CECIL SHARP, founder of the English Folk Dance and Song Society, sought out the national dances and the songs and music that accompanied them and left a legacy that this society not only preserves but constantly seeks to enrich. In North America, TED SHAWN studied the dances of the American Indian. IGOR MOISEYEV rescued Russian national dances and also choreographed them for presentation on theatre stages and in public arenas. On Indian dance, see BERYL DE ZOETE, *The Other Mind: A Study of Dance in South India* (1953); and RINA SINGHA and REGINALD MASSEY, *Indian Dances: Their History and Growth* (1967), a lucid guide to the complexities of Indian dancing, accurate and well illustrated.

Governments throughout the world have begun to realize the export potential of their national dances, and many are financing research into their origins so that they can be shown overseas with some degree of authenticity. The libraries and museums of most of the European opera houses have a wealth of material about the art of theatrical dancing. The museum of the Paris Opéra and the collection of the Bibliothèque Nationale are probably the richest. In London, the Victoria and Albert Museum has many treasures. The Library of the Royal Academy of Dancing contains the priceless collection of rare

dance books assembled by P.J.S. RICHARDSON (of which a bibliographical description was published in 1954 and all of which is on microfilm). The Royal Ballet School also has a valuable archive. The dance collection of the New York Public Library is one of the greatest in the world. Harvard University also has an important dance collection, and many other U.S. university libraries are now buying dance materials. In Stockholm, BENGT HAGER has assembled a superb dance museum that incorporates most of the Rolf de Maré collection, the Archives Internationales de la Danse. The greatest private collection of dance books is undoubtedly that of the Hungarian dancer and teacher DERRA DE MORODA in Salzburg, Austria.

ANATOLE CHUJOY and P.W. MANCHESTER (eds.), *The Dance Encyclopedia*, rev. ed., with an introduction by LINCOLN KIRSTEIN (1967), with nearly 5,000 entries and 274 photographs, is a standard reference work that contains illuminating articles about all forms of dancing.

(M.Cl.)

## Dance, Western

The peoples of the West—of Europe and of the countries followed through permanent European settlement elsewhere—have a history of dance characterized by great diversity and rapid change. Whereas most dancers of the East repeated highly refined forms that had remained virtually unchanged for centuries or millennia, Western dancers showed a constant readiness, even eagerness, to accept new vehicles for their dancing. From the earliest records, it appears that Western dance has always embraced an enormous variety of communal or ritual dances, of socializing dances at different levels of society, and of skilled theatrical dances that followed distinct but often overlapping lines of development.

The West cannot always be clearly distinguished from the non-West, especially in such countries as Russia, where some dances are Asian and others European in origin and character. This article focuses on the dance of Western peoples, noting where appropriate the influence of other cultures.

The articles BALLET; POLK DANCE; MODERN DANCE; and POPULAR DANCE cover in greater detail the unique nature, techniques, forms, and functions, and the historical developments of each of these kinds of Western dance. In addition, the article DANCE, ART OF, covers the aesthetics and the varieties of dance, both Western and non-Western. Aspects of Eastern dance are detailed in the article DANCE AND THEATRE, EAST ASIAN.

### From antiquity through the Renaissance

Before men left written records, a vast span of time elapsed about which scholars can only speculate. Pictorial records in cave paintings in Spain and France showing dancelike formations have led to the conjecture that religious rites and attempts to influence events through magic were central motivations of prehistoric dance. Such speculations have been reinforced by observation of dances of primitive peoples in the contemporary world, though the connection between ancient and modern "primitives" is by no means accepted by many scholars. If the dances recorded in early written records represented a continuity from prehistoric dances, there may have been prehistoric work dances, war dances, and erotic couple and group dances as well. One couple dance surviving in the 20th century, the Bavarian-Austrian *Schuhplattler*, is considered by historians to be of Neolithic origin, from before 3000 BC.

#### DANCE IN THE ANCIENT WORLD

In the civilizations of Egypt, Greece and its neighbouring islands, and Rome, written records supplement the many pictorial remains. There are still conjectures, but there is far more concrete evidence.

**Ancient Egyptian dance.** With its highly organized forms of community life, Egypt practiced formalized ritual and ceremonial dances in which the dancing priest-king represented the person of a god or the servant and regenerator of his people. These dances, culminating in ceremonies representing the death and rebirth of the god Osiris, became more and more complex, and ultimately they could be executed only by specially trained dancers.

Egyptian dancing, detail from a tomb painting from Shaykh 'Abd al-Qurnah, Egyptian, c. 1400 BC. In the British Museum.

By courtesy of the trustees of the British Museum

From Egypt also come the earliest written documentations of the dance. These records speak of a class of professional dancers, originally imported from the interior of Africa, to satisfy the wealthy and powerful during hours of leisure. These dancers were considered highly valuable possessions, especially the pygmy dancers who became famous for their artistry. One of the pharaohs prayed to become a "dance dwarf of god" after his death, and King Neferkare (3rd millennium BC) admonished one of his marshals to rush such a "dance dwarf from the Land of Spirits" to his court.

African  
origins

There is considerable agreement that the belly dance, now performed by dancers from the Near East, is of African origin. A report of the 4th century BC from Memphis in Egypt described in detail the performance of an apparently rumba-like couple dance with an unquestionably erotic character. The Egyptians also knew acrobatic exhibition dances akin to the present-day adagio dances. They definitely were aware of the sensual allure of the sparsely clad body in graceful movement. A tomb painting from Shaykh 'Abd al-Qurnah, now in the British Museum, shows dancers dressed with only rings and belts, apparently designed to heighten the appeal of their nudity. These figures probably were intended to entertain the dead as they had been entertained in life.

Egypt, then, presented a dancing scene that was already varied and sophisticated. In addition to their own danced temple rituals and the pygmy dancers imported from the headwaters of the Nile, there were Hindu dancing girls from conquered countries to the east. This new dance had none of the long masculine strides or the stiff, angular postures seen in so many Egyptian stone reliefs. Lines of movement undulated softly, nowhere bending sharply or breaking. These Asiatic girls brought a true feminine style to Egyptian dance.

**Dance in classical Greece.** Many Egyptian influences can be found in the Greek dance. Some came by way of Crete, others through the Greek philosophers who went to Egypt to study. The philosopher Plato (c. 428–348/47 BC) was among them, and he became an influential dance theoretician. He distinguished dances that enhance the beauty of the body from awkward movements that imitate the convulsions of ugliness. The initiation rites of Egypt had their equivalent in the Cretan bull dance of about 1400 BC. It inspired the labyrinthine dances that, according to legends, Theseus brought to Athens on his return with the liberated youths and maidens.

Another dance form that originated in Crete and flourished in Greece was the *pyrrhichē*, a weapon dance. Practiced in Sparta as part of military training, it was a basis for the claim of the philosopher Socrates that the best dancer is also the best warrior. Other choral dances that came to Athens from Crete include two dedicated to Apollo and one in which naked boys simulated wrestling matches. Female characteristics were stressed in a stately

Kordax dance, Greek vase painting, 5th century BC. In the Museo Nazionale Tarquiniese, Italy.  
SCALA

and devout round dance in honour of the gods, performed by choruses of virgins.

#### Dionysian dances

Numerous vase paintings and sculptural reliefs offer ample proof of a wild and ecstatic dance connected with the cult of Dionysus. It was celebrated with a "sacred madness" at the time of the autumnal grape harvest. In his drama *Bacchae*, Euripides (c. 480–406 BC) described the frenzy of Greek women, called *bacchantes* or *maenads*. In their dance for generation and regeneration, they frantically stamped the ground and whirled themselves about in rhythmic convulsions. Such dances were manifestations of demoniacal possession characteristic of many primitive dances.

It was the Dionysian cult that brought about Greek drama. After the women danced, the men followed in the disguise of lecherous satyrs and *sileni*. Gradually the priest, singing of the life, death, and return of Dionysus while his acolytes represented his words in dance and mime, became an actor. The scope of the dance slowly widened to incorporate subjects and heroes taken from the Homeric legends. A second actor and a chorus were added. In the lyric interludes between plays, dancers recreated the dramatic themes in movements and steps adopted from the earlier ritual and bacchic dances. In the comedies, they danced the very popular *kordax*, a mask dance of uninhibited lasciviousness.

These dances and plays were executed by skilled amateurs. At the end of the 5th century BC, however, there came into being a special class of show dancers, acrobats, and jugglers, the female members of which were evidently *hetaerae*, members of a class of courtesans. No doubt influenced by Egyptian examples, they entertained guests at lavish banquets. The historian Xenophon (c. 430–c. 355 BC) in his *Symposium* tells of the praise Socrates lavished on a female dancer and a dancing boy at one such occasion, finally himself emulating their beautiful movements. Elsewhere, Xenophon describes a dance representing the union of the legendary heroine Ariadne with Dionysus, an early example of narrative dance.

SCALA

Funeral dance, Etruscan fresco from a tomb cover, 5th century BC. In the Museo e Gallerie Nazionali di Capodimonte.

**Ancient Roman dance.** There was a striking difference between the Etruscan and the Roman peoples in their approach to the dance. Little is known about the Etruscans, who populated the area north of Rome up to Florence and flourished between the 7th and 5th century BC. But it is apparent from their lavish tomb painting that dance played an important part in their enjoyment of life. Women apparently had a prominent role in these couple dances. They were performed without masks in public places and showed a distinct courting character.

In Rome, a basic antagonism to dance seems to reflect the sober rationalism and realism of the Roman people. Nonetheless, Rome did not entirely evade the temptations of dance. Before about 200 BC, dances were evidently in the form of choral processions only. There were seed-sowing processions in spring, headed by priests, and heavy and majestic weapon dances of the *Salli*, a congregation of the priests of Mars who walked around in a circle while rhythmically beating their shields.

Later, Greek and Etruscan influences began to spread, though people who danced were considered suspicious, effeminate, and even dangerous by the Roman nobility. One public official did not believe his eyes when he watched dozens of the daughters and sons of well-respected Roman patricians and citizens enjoying themselves in a dancing school. About 150 BC all dancing schools were ordered closed, but the trend could not be stopped. And though dance may have been alien to the Roman's inner nature, dancers and dancing teachers were increasingly brought from abroad in the following years. The statesman and scholar Cicero (106–43 BC) summed up the general opinion of the Romans when he stated that no man danced unless he was insane.

A form of dance that enjoyed great popularity with the Romans under the emperor Augustus (63 BC–AD 14) was the wordless, spectacular pantomime that rendered dramatic stories by means of stylized gestures. The performers, known as *pantomimi*, were at first considered more or less as interpreters of a foreign language, since they came from Greece. They refined their art until the two dancer-mimes Bathyllus and Pylades became the star performers of Augustan Rome. In contrast to the acrobatic dancers who performed with the jugglers, these *pantomimi* were taken quite seriously by the Romans.

#### CHRISTIANITY AND THE MIDDLE AGES

Dancing was traditional also to the tribes of barbarians to the north, as attested by the writings of the Christian missionaries. Wherever they went, they found the same fertility-rite dances—if in different guise—the same charm dances to induce good and ward off evil, the same warrior and weapon dances to bolster fighting morale, and the same uncontrolled expressions of the joy of life, which the missionaries attributed to the devil.

Erotic dancing was not the exclusive property of heathen societies. In Byzantium, the Christian emperor Justinian I (483–565) married the notorious Theodora, a dancer who had appeared in the nude in theatrical performances. About 500, St. Caesarius of Arles reported a sacrificial banquet ending in some demoniacal dancing rites performed to the accompaniment of lewd songs. The Anglo-Saxons had little girls performing dances at Easter in which a phallus was carried in front of them.

**Ecclesiastical attitudes and practices.** The attitude of the Christian Church toward dance was by no means unanimous. On the one side there was the ascetic rejection of all manifestations of lust and ecstasy, and dance was seen as one of the strongest persuasions to sexual permissiveness. On the other side, some early Church Fathers tried to find functions for pagan dances in Christian worship. Thus St. Basil of Caesarea in 350 called dancing the most noble activity of the angels, a theory later endorsed by the Italian poet Dante (1265–1321). St. Augustine (354–430) was strictly against dancing of any kind, but despite his great influence in the medieval church, dancing in churches continued for centuries.

Charlemagne, the Holy Roman emperor at the beginning of the 9th century, officially prohibited all kinds of dancing, but the ban was not observed. The Teutonic

Antagonism of the Romans

Ambivalence of the church

peoples were accustomed to dancing as part of their religious rites. On Christian feast days, which coincided with their ancient rites of expelling the winter, of celebrating the arrival of spring, and of rejoicing that the days grew longer again, they revived their old dances, though they were camouflaged with new names and executed to different purpose. In this manner the dances became more and more secularized. After such secularization, two lines of development were open: the social dance or the assimilation of dance into theatrical spectacle by the *joculators*, travelling comedians who combined the arts of dancer, juggler, acrobat, singer, actor, mime, and musician in one person.

**Dance ecstasies.** There were two kinds of dance peculiar to the Middle Ages, the dance of death, or dance macabre, and the dancing mania known as St. Vitus' dance. Both originally were ecstatic mass dances, dating from the 11th and 12th centuries. People congregated at churchyards to sing and dance while the representatives of the church tried in vain to stop them. In the 14th century another form of the dance of death emerged in Germany, the *Totentanz*, a danced drama with the character of Death seizing people one after the other without distinctions of class or privilege. The German painter Hans Holbein the Younger (1497/98–1543) made a famous series of engravings of this dance.

The dance  
of death

The St. Vitus' dance became a real public menace, seizing hundreds of people, spreading from city to city, mainly in the Low Countries, in Germany, and in Italy during the 14th and 15th centuries. It was a kind of mass hysteria, a wild leaping dance in which the people screamed and foamed with fury, with the appearance of persons possessed. In these convulsive, frantic, and jerky dances, religious, medical, and social influences probably interacted in response to such things as the epilepsy-like seizures of persons suffering from the Black Death. Italy was afflicted with tarantism, an epidemic presumably caused by the bite of venomous spiders. Its effects had to be counteracted by distributing the poison over the whole body and "sweating it out," which was accomplished by dancing to a special kind of music, the tarantella.

**Dance and social class.** In western Europe by the 12th century, society had developed into three classes, the no-

bility, the peasantry, and the clergy. This separation contributed to the development of the social dance. The knights created their own worldly and spiritual ideals, exemplified in tournaments and courtly entertainments that were praised in song and poetry by the troubadours and minnesingers. The couple dances of the knights expressed the polished and aristocratic notions of courtly love. The round dances of the peasants were executed by circles or lines of people, often singing and holding each other by their hands. The rustic choral round had strong pantomimic leanings and unpolished expressions of joy and passion. And while the choral rounds almost always were executed to the singing of the participants, the court dances of the knights generally were accompanied by instrumental playing, especially of fiddles, and when there was singing, it emerged from the spectators rather than the performers.

Courtly  
couples  
and rustic  
rounds

From the late Middle Ages, graphic artists frequently recorded what dancing looked like in all its different manifestations. How dancing adapted to the idealism of knightly love is shown in manuscript illuminations and tapestries. Paintings of the Flemish painter Pieter Bruegel the Elder (c. 1525/30–69) leave no doubt that the peasants enjoyed their uninhibited stamping and cavorting.

#### THE RENAISSANCE WORLD AND THE ART DANCE

France had set the fashion in court dance during the late Middle Ages; with the Renaissance, however, Italy became the centre of the new developments in dance. The Renaissance brought greater mixing of social classes, new fortunes and personal wealth, and greater indulgence in worldly pleasures and in the appreciation of the human body. The period emerged as one of the most dance-conscious ages in history.

**Court dances and spectacles.** Celebrations and festivities proliferated. The itinerant jugglers of the Middle Ages became highly respected and much sought after as dancing masters. They quickly assumed the function of instructing the nobility not only in the steps but also on posture, bearing, and etiquette. They became responsible for the planning and realization of the spectacular festivities. The social prestige of this newly developing profession grew constantly.

### The rise of the dancing master

Some of these dancing masters were highly learned men, and their treatises leave no doubt about their scholarly ambitions. Many of them were Jewish, descended from the Klesmorim, a group of medieval Jewish entertainers. The first dancing master known by name was Domenico da Piacenza, who in 1416 published the first European dance manual, *De arte saltandi et choreas du-cendi* ("On the Art of Dancing and Directing Choruses"). His disciple, Antonio Cornazano, a nobleman by birth, became an immensely respected minister, educator of princes, court poet, and dancing master to the Sforza family of Milan, where about 1460 he published his *Libro dell'arte del danzare* ("Book of the Art of the Dance"). Such books record little about the actual steps and the melodies to which they were performed, but they are eloquent in the description of the balli—works that were invented by the dancing masters themselves. Adapting steps from the various social dances, they used them in a kind of dance pantomime.

In France, numerous forms developed from the branle, a round dance of peasant origin that became fashionable in the courts. One of the most frequently mentioned of all the dances of the 15th century was the *morisca*, or *moresque*, a romanticized version of dances from Moorish Spain. These were first mentioned in 1446 by a Bohemian traveller who visited Burgos, Spain. Later, in Portugal, he encountered similar forms. Sometimes religious motifs of the legendary fight between Charlemagne and the Turkic invader Timur entered the *morisca*, but usually it was performed as a double-file choral dance. It had nothing to do, as was long believed, with the English masked Morris dance, now considered to be a survival from a primitive religious cult.

From such choral dances the ballet emerged. At the court entertainments throughout Savoy and northern Italy, sumptuous spectacles with mythological, symbolical, or allegorical content became increasingly popular. At these early stages, however, pantomime and dance are not easily distinguished. Famous examples of these spectacles are the presentation of the story of Jason and the Golden Fleece at the marriage of Philip the Good of Burgundy in 1430, and the dinner ballet on the same, though widely enlarged, subject staged for the wedding of the Duke of Milan in 1489.

Tudor England of the early 16th century had similar pageants, with the participants disguising "after the manner of Italie." Like the Italian *balli*, the English masque offered an almost unlimited choice of performing variations, from a simple dance in masks to the most elaborate

spectacle interspersed with songs, speeches, and pantomimes. As for the actual dances, Robert Copland's *Maner of Dauncynge of Bace Daunces after the Use of Fraunce*, published in 1521 as an appendix to a French grammar, leaves no doubt that the English upper class of that period was thoroughly familiar with continental dance. But whereas the nobility preferred dances of slow, measured, and dignified stature, stylishly performed and modelled upon the standards of the French court, the peasants continued their boisterous dancing, in England as elsewhere, very much as they had for centuries.

In England in the late 16th century, Queen Elizabeth I gave dancing a further boost. She was a skilled practitioner of the galliard and the volta, with its tight embraces by high-leaping couples. She enjoyed watching the English country dances—the chain, ring, and round dances of ancient origin and constantly new invention. These dances apparently provided a continuous infusion of new vitality into court dances. The nobles vied with one another in the execution of the jig, a sprightly and swift dance of "the folk" accompanied by songs. Dancing schools flourished everywhere in London, giving public displays and contributing considerably to the reputation of "the dancing English." Another extremely important contribution to dance was provided by Spain, which in the late 16th and early 17th centuries enjoyed a cultural renaissance. It was the "golden age" of Cervantes in literature, of Lope de Vega and Pedro Calderón de la Barca in the theatre, of El Greco and Diego Velázquez in painting. With the growth of Spain's empire in the Americas, dances of Afro-American origin found their way back to Europe. The sarabande and the chaconne were brought from Central America before 1600. Both were considered outspokenly obscene in their suggestions of sexual encounters. They became extremely popular in the harbours of Andalusia, where they were polished and their pantomimic literalness somewhat moderated. From there they crossed the Pyrenees and were integrated into the canon of the French court dance.

Other dances from abroad played major roles in the shaping of Spain's national dances. The *canarie* of African origin certainly sired the Aragonese jota, while the sarabande brought forth the seguidilla. The Afro-Cuban *chica* lived on in the fandango, and the flamenco dances of the Andalusian Gypsies retained their Moorish heritage into the 20th century. It can be presumed that this exchange of dances was not a one-way traffic, that the European conquerors and colonists similarly influenced the dancing habits of the people in other lands.

Spread of Spanish dance

**Ballet  
comique  
de la reine**

**The birth of ballet.** Meanwhile, dance became the subject of serious studies in France. A group of writers calling themselves La Pldiade aimed for a revival of the theatre of the ancient Greeks with its music, song, and dance. In Catherine de Médicis (1519–89), the Florentine wife of Henry II, the Italian dancing masters found an influential sponsor in Paris. She called to Paris the Italian musician and dancing master Baltazarini di Belgioioso, who changed his name to Balthazar de Beaujoyeulx (early 16th century to 1587). There had been previous fetes in both France and Italy that offered masquerades, pantomimes, and dances with allegorical and symbolical subjects, but none of them compared to the splendours of the *Ballet comique de la reine* that Beaujoyeulx staged in 1581 for Catherine.

This "ballet" told the story of the legendary sorceress Circe and her evil deeds. Spoken texts alternated with dances amid magnificently decorative settings. The performers, recruited from the nobility, moved on the floor more like animated costumes than individual dancers. They came together in strikingly designed groups, and they set up geometrical floor patterns that had highly symbolic meanings. (To audiences of the period, for example, three concentric circles represented Perfect Truth, and two equilateral triangles within a circle stood for Supreme Power.) The ballet, which ended in an act of homage to the royal majesties present, had a distinct political moral. Circe had to render her might to the absolutist power of the king of France as the supreme symbol of a peaceful and harmonious world.

The *Ballet comique* launched the species known as *ballet de cour*, in which the monarchs themselves participated. The idealized dances represented the supreme order that France itself, suffering from internal wars, lacked so badly. The steps were those of the social dances of the times, but scholars became aware of how these native materials might be used to propagate the Greek revival. They thoroughly analyzed and systematized the dances, and in 1588 the priest Jehan Tabourot, writing under the pen name Thoinot Arbeau, published his *Orchésographie*, which he subtitled "a treatise in dialogue form by which everyone can easily learn and practice the honest exercise of the dance." This was the first book containing reliable descriptions of how, and to what kind of music, the *basse danse*, pavane, galliard, volta, courante, allemande, gavotte, *canarie*, *bouffon*, *moresque*, and 23 different variations of the branle were performed.

**During the 17th, 18th, and 19th centuries**

Under kings Louis XIV and Louis XV, France led western Europe into the age of the Rococo in the arts. The Rococo began as a movement toward simplicity and naturalness, a reaction against the stilted mannerisms and preciousness to which the earlier Baroque art was considered to have degenerated. It was a great age of and for dancing, with the minuet the symbol of its emphasis on civilized movement. This formal dance, the perfect execution of which was almost a science in itself, reflected the Rococo idea of naturalness. The statement that "the dance has now come to the highest point of its perfection" by the composer Jean-Philippe Rameau (1683–1764) suggested how conscious the French were of the great strides dance had made. That this was particularly the case in France was confirmed by the English poet and essayist Soame Jenyns (1704–87) in his lines "None will sure presume to rival France, / Whether she forms or executes the dance." None, however, excelled the estimation of his profession by the dancing master in Molikre's *Le Bourgeois Gentilhomme* (1670):

There is nothing so necessary to human beings as the dance . . . Without the dance, a man would not be able to do anything. . . . All the misfortunes of man, all the baleful reverses with which histories are filled, the blunders of politicians and the failures of great leaders, all of this is the result of not knowing how to dance.

**THE MATURING OF BALLET**

Dance was finally deemed ready for an academy of its own. In 1661, 13 dancing masters who had been mem-

bers of a professional guild of medieval origin, together with some musicians, composers, and the makers of instruments, were granted a charter by Louis XIV for the Académie Royale de Danse.

**Technical codifications and dance scholarship.** The academicians were charged with setting up objective standards for perfecting of their arts, with unifying the rules of dance training, and with issuing licenses to dancing instructors. Though the nobility continued for some time to participate in the *ballets de cour*, and Louis himself danced in them until 1669, the dance became more and more the province of highly trained specialists.

After 1700 ballet and social dance took separate paths. But while the ballet continued to absorb new ideas from the folk and social dance, its practitioners and theoreticians looked down on those more common forms. A profusion of books on dance began to appear—treatises, instructions, and analyses as well as the first attempts to record dances by means of written notation. The first history of dance was Claude-François Menestrier's *Des ballets anciens et modernes* ("On Dances Ancient and Modern"; 1682). The second major work of European dance literature, after Arbeau's *Orchésographie*, was Raoul Feuillet's *Chorégraphie, ou l'art de de'crire la danse* ("Choreography, or the Art of Describing the Dance"; 1701). It became the standard grammar for the dances practiced at the turn of the century, describing them in minute detail and notating them by a system devised by Feuillet. This gave the position of the feet and directions, combinations, and floor patterns of the steps and leaps. It was unable, however, to register the movements of the upper parts of the body. Feuillet provided as well a complete definition of the principles of the dance first described by the Académie in the 1660s. These included the *en dehors* (i.e., the turnout of the body and its limbs), the five classical positions of the feet, the *port de bras* (i.e., the positions and movements of the arms), and the leaps to the *grar'ze e'levation*, the aerial movements of the dance.

In 1706 Feuillet's book was translated into English by John Weaver (1673–1760), a dancer, choreographer, and teacher who worked mainly at the Drury Lane Theatre, London. In 1717 he produced one of the first serious ballets without words, *The Loves of Mars and Venus*. Weaver was the first dance teacher to insist that dance instructors should have a thorough knowledge of anatomy. In 1721 he published his *Anatomical and Mechanical Lectures upon Dancing*, which became a standard work of international importance. Germany also was represented in the field of dance scholarship, most notably by Leipzig Gottfried Tauber in *Der rechtschaffene Tanzlehrer* ("The Correctly Working Dance Teacher"; 1717). These books strongly emphasized the contributions of dance to general education and manners. In this period dance was considered the basis of all education, and well-to-do parents went to great pains to have their children properly instructed.

**Varieties of the ballet.** As the technical demands of performance became greater and the amateurs gave way to the professionals, the ballet moved from the dance floor onto the stage. There it gradually shed its declamations and its songs and concentrated on telling a story through dance and mime alone. But this purifying process took time. For decades different forms of mixed-media spectacles were seen, from the *comédie ballets* of Molikre (1622–73) and the composer Jean-Baptiste Lully (1632–87) to the *ope'ra-ballets* of André Campra (1660–1744) and Rameau, which were successions of songs and dances on a common theme. The first ballet without the diversions of speech or song was *Le Triomphe de l'amour* (*The Triumph of Love*; 1681), choreographed by Charles-Louis Beauchamp (1636–c. 1719) to Lully's music. Originally a *ballet de cour*, it was revived for the stage with a professional cast. Its star, Mlle Lafontaine, became ballet's first *première danseuse* exactly 100 years after the *Ballet comique* had been produced.

An even more dramatic form known as *ballet d'action* came into being in 1708, when two professional dancers presented an entire scene from the tragedy *Horace* by

Early  
works  
about  
ballet

Pierre Corneille (1606–84) in dance and mime. Weaver's silent ballets, whose expressive dance much impressed English audiences, also encouraged Marie Sallé, a highly ambitious dramatic dancer. Despairing of the *opéra-ballets* of Paris, she went to London, where she performed in pantomimes and produced a miniature dance-drama of her own, *Pygmalion* (1734). In it she appeared in a

flimsy muslim dress and loose, flowing hair rather than the heavy costumes and elaborate wigs usually worn by ballerinas. Thus lightened, the dancer was able to move with much greater freedom.

**Early virtuosos of the dance.** The era of the great dancer was at hand. Marie Sallé (1707–56) was the greatest dancer-mime and an important innovator of her day. Her popularity was rivalled by the Brussels-born Marie Camargo (1710–70), who excelled Sallé in lightness and sparkle. She used the *entrechat*, a series of rapid crossings of the legs that previously had been used only by male dancers. To show off properly her *entrechats* and other lithe footwork, she shortened her skirt by several inches, thereby contributing to costume reform. Both ballerinas were depicted by Nicolas Lancret (1690–1743), a painter known for his festive scenes, and both were praised by the writer and philosopher Voltaire (1694–1778), who carefully compared their respective virtues. Both, however, were surpassed by the Italian dancer Barberina Campanini (1721–99), whose fame is less adequately recorded in dance history. By 1739, she had taken Paris by storm, demonstrating jumps and turns executed with a speed and brilliance hitherto unknown. She offered ample proof that the Italian school of dance teaching had by no means died out with the earlier exodus of so many of its best practitioners to the French courts. Despite the great public acclaim that these ballerinas attracted, they were overshadowed by Louis Dupré (1697–1744), known as "The Great Dupré" and "the god of the dance." In grace, majesty, and allure, he was unsurpassed, giving the male dancer a prominence he held for a century. Dupré was also the first of a direct line of great dance teachers that was unbroken in the late 20th century.

#### THE REIGN OF THE MINUET

In the realm of the social dance, the years between 1650 and 1750 were called "the age of the minuet" by the dance and music historian Curt Sachs.

**The French dance suite.** At the great balls of the French court at Versailles, the minuet was the high point of the festivities, which culminated in a suite of dances. The opening branle, led by the king and his es-

cort, was a measured circling around, one couple after another. Next came the *courante*, which had been toned down from its earlier rather capricious figurations. It assumed a continuously greater dignity until it was danced with such gravity and sobriety that it was termed the "doctor dance." It went quickly out of fashion, however, after 1700. Following it in the succession was the *gavotte*, which opened in the form of a round dance. A couple separated to perform a short solo, then returned to the original circle. Sometimes the suite was extended through an *allemande* (French: "German"), an old dance form that was introduced into France from the heavily German-speaking province of Alsace in the 1680s. This dance, with its turning couples, the lady on the arm of the gentleman, was a relative of the German *landler* and a precursor of the waltz.

**Form of the minuet.** But the unrivalled king of the social dances was the minuet, named from the *pas menu* ("small step"), a term used at least as early as the 15th century. The earliest surviving specimen was composed by Lully in 1663. Mozart composed a series of twelve minuets as late as 1789. It originated as a folk dance in Poitou, but as a court dance it took its form from the *courante*. Though today it looks mannered, even artificial, in its time it was looked upon as the most beautiful and harmonious of dances, and to execute it perfectly required prolonged and careful study:

The *minuet* was performed in open couples; spectators and partners were saluted with ceremonial bows. With dainty little steps and glides, to the right and to the left, forward and backward, in quarter turns, approaching and retreating hand in hand, searching and evading, now side by side, now facing, now gliding past one another, the ancient dance play of courtship appears here in a last and almost unrecognizable stylization and refinement. (Curt Sachs, *World History of the Dance*, trans. Bessie Schonberg, W.W. Norton & Co., Inc., 1937.)

In spite of the great popularity of the minuet before the French Revolution, it was the object of much barbed commentary in the late 18th century. Voltaire compared the metaphysical philosophers of his time with the dancers of the minuet, who, in their elegant attire, bow and mince daintily across the room showing off their charms, move without progressing a single step, and end up at the very spot from which they began.

#### ENGLISH SOCIAL DANCE

England thoroughly democratized the dance. Though the English Puritanism of the 17th century stigmatized dance as one of man's most sinful occupations, even Oliver Cromwell, lord protector of England under the Puritan rule in the 1650s, could not prevent the appearance of *The English Dancing-Master* (1651), by the bookseller and publisher John Playford (1623–c. 1686). This was a collection of English traditional dances and tunes. It had 18 editions in 80 years, each one adding to the repertoire. Its 900 choral dances of rustic origin, which formerly had been danced in the open air but were now usually performed indoors, included an enormous variety of forms and patterns. It was written in straightforward, matter-of-fact language, with no discrimination of dances by social class. Its instructions could be understood and its dances performed by anyone. People could enjoy dancing as a playful, sportive activity rather than as an exercise of courtly etiquette.

These "country dances" could as well be city dances, as is suggested by such names as "Mayden Lane" and "Hide Park" from London locales. Others were named for persons—"Parson's Farewell" and "My Lady Foster's Delight"—and that there were foreign influences can be surmised from "The Spanish Jeepsie" and "A la Mode de France." At the same time, native jigs and hornpipes continued to flourish. The English were particularly fond of the Morris dance. This dance may have received its name from the blackened faces of some of its participants, suggestive of the African Moors, but its origins were in the ancient ritual dances. It was a vigorous male dance, in the form of a dance procession through town streets. Its participants, in the disguises

of such popular characters as the fool or the Queen of May, wore jingling bells around their ankles and sometimes galloped about on hobby horses. Other dancers wore antlers, tails, and similar animal masking.

About 1700 the English country dances began to appear on the Continent, where they were somewhat formalized and sometimes substantially altered. In France they were named *contredanses*. The longways, dances with double lines of dancers facing one another, became *contredanses anglaises*; the rounds became the *contredanses françaises*, which were also known as cotillions and quadrilles. These figure dances, which quickly spread to Spain, Germany, Poland, and other countries, were the dances of the rising middle class. By no means revolutionary in their content, they were nonetheless a distinct declaration of rationality and common sense in dance, a counterbalance to the artificialities and mannerisms of the aristocratic court dances. The orthodox dance teachers might bemoan the decline from the standards that were epitomized in the minuet, but the townspeople and peasants, unconcerned with such niceties, continued in their uncomplicated knowledge that dancing could be fun.

#### DANCE IN COLONIAL AMERICA

**Attitudes.** The English colonists in America had mixed opinions about dance. There was the complete disapproval of those who saw only its inherent licentiousness, but from others came at least a tacit toleration of the obviously irrepressible urge to dance. The South, more heavily populated by colonists with aristocratic backgrounds, was generally more inclined to dance than the North, where religious fervour had motivated much of the migration from England. But what was allowed and even encouraged in Connecticut was strictly forbidden in Massachusetts. The general consensus was apparently that dancing in itself was not bad, but that no punishment could be severe enough for what was regarded as lascivious dancing. The Quakers, mainly in Pennsylvania, were very much against dancing, and in 1706 they complained bitterly about a dancing and fencing school being tolerated in Philadelphia, fearing it would tend to corrupt their children.

**External and internal influences.** Nonetheless, Playford's *The English Dancing-Master* was by no means unknown in America. There were also dancing masters and dancing mistresses to instruct in and lead the dances that had been brought from the Old World. There were society balls in the cities along the coast, and on the inland frontiers the settlers of the widely scattered farmsteads often came together for exuberant feasting and social dancing. Here dancing was considered a socializing virtue expressed in this anonymous observation:

I really know among us of no custom which is so useful and tends so much to establish the union and the little society which subsists among us. Poor as we are, if we have not the gorgeous balls, the harmonious concerts, the shrill horn of Europe, yet we delight our hearts as well with the simple negro fiddle.

What the colonists saw of American Indian dancing they found very strange and primitive, and there was virtually no exchange of dancing customs between the groups. The situation differed, however, with regard to the Negro slaves, who in the 17th century had brought their own songs and dances from their native lands in Africa.

Slave dances

Religious holidays in New Amsterdam saw dancing in the streets, accompanied by three-stringed fiddles and drums constructed from eel pots and covered with sheepskins. Dutch families joined in the festivities, dancing with the Negroes. When New Amsterdam became New York, however, the English discouraged dancing between whites and blacks; the Negro went on to develop the characteristic dance style that would so deeply affect social dancing in the 19th and 20th centuries.

Early in the 18th century, rather rough theatrical entertainments, acts of acrobatic skill or pantomimes in which dances played an increasing role, began to spread through the American colonies. These often amateurish showings

got a mighty boost when the first professional companies came from Europe, about the middle of the century, to perform plays and harlequinades with incidental dances.

#### THE RISE OF THE WALTZ

The age of the minuet was followed by that of the waltz. As the French Revolution approached, the minuet, a form that exuded the essence of earlier decades, died a natural death. The English country dances, expressing the self-satisfaction of the bourgeoisie, fared little better.

**The Romantic movement in dance.** The young people, whose preferences led the way in creating new forms, had lived through the revolutionary events of the 1780s and '90s. They now looked to dance as a way to unleash deeper emotion, to satisfy the needs of body and soul, and to mobilize more vital and dynamic expression than that permitted by the sober and decorous rules of the dancing masters. The overflow of feeling and the striving for horizons broader than those understood by the traditional canons of French Rationalism were among the factors that generated the Romantic movement in the arts of Europe. This new direction was clearly expressed in the waltz, a dance filled with the Dionysian spirit.

Like much of the spirit of the Romantic movement, the waltz was of German origin. It paralleled the Sturm und Drang movement in German literature, which featured the new forms of prose and poetry by Johann von Goethe and Friedrich Schiller. One of the most glowing advocates of the waltz was Goethe, who time and again praised it, nowhere more than in his novel *Die Leiden des Jungen Werthers* (1774; *The Sorrows of Werther*, 1779): "Never have I moved so lightly. I was no longer a human being. To hold the most adorable creature in one's arms and fly around with her like the wind, so that everything around us fades away." Even the aristocrats who formed the Congress of Vienna in 1815, which sought to restore law and order to Europe following the upheavals brought on by Napoleon, delighted in performing this earliest of all nonnristocratic ballroom dances.

**Spread of the waltz.** The waltz started as a turning dance of couples. It was especially popular in south Germany and Austria, where it was known under such different names as *Dreher*, *landler*, and *Deutscher*. More than any other dance it appeared to represent some of the abstract values of the new era, the ideals of freedom, character, passion, and expressiveness. This may explain somewhat its eruption into the limelight of international popularity. This popularity was scaled in 1787 when it was brought to operatic stage. Vienna became the city of the waltz, for there it surpassed everything in wild fury. It swept over national frontiers, and in 1804 the French were reported to be passionately in love with this light, gliding dance. "A waltz, another waltz" was the common cry from the ballroom floor, for the French could not get enough of the dance.

Some guardians of the public morality disapproved of the "mad whirling" of the waltz and it did not arrive in England until 1812. At the Prussian court in Berlin it was forbidden until 1818, though Queen Luise had danced it while still a princess in 1794. The guardians could do no more than delay its total victory, and it conquered the world without sanction of courts, of dancing masters, or of other powers. After many centuries of leadership, France no longer set the fashions. In 1819 Carl Maria von Weber's *Invitation to the Dance* represented the declaration of love of classical music to the waltz. Shortly thereafter began the age of the Viennese waltz kings, most notably expressed by the Strauss family.

**Offspring and rivals.** The waltz sired a great variety of offspring throughout Europe. Germany developed such variations of the waltz as the *schottisch*, with turns like those of the waltz. France had its airy *balance valse*, and the Americans later on had their Boston waltz, a slower, gliding variant. About 1840 a serious rival to the waltz emerged in the polka, a Bohemian dance that took its name from the Czech word *půlka*, "half step." It was full of fiery vigour. Another Bohemian folk dance find-

Waltzers in "Le Bal à Bougival," oil painting by Pierre Renoir, 1883. In the Museum of Fine Arts, Boston.

By courtesy of the Museum of Fine Arts, Boston

ing favour in the dance halls was the *rej dovák* or redowa, while Poland's mazurka and krakowiak enjoyed great popularity. No ball could be concluded without a galop, in which couples galloped through the hall with accelerated polka steps, an exhausting exercise that required considerable reserves of stamina.

#### FOUNDATIONS OF MODERN BALLET

The ideals of naturalness, character, soul, passion, and expressiveness came to govern the ballet.

**Noverre and his contemporaries.** The French dancer-choreographer-teacher Jean-Georges Noverre (1727–1810), who became known as the "Shakespeare of the dance," was the first major reformer of ballet. He defined his artistic positions in *Lettres sur la danse, et sur le ballet* (*Letters on Dancing and Ballets*), published in 1760 and continuously reprinted ever since. He worked in Paris, London, Stuttgart, and Vienna, and his influence spread as far as St. Petersburg. He preached the dignity of the ballet and tried to purge it of its excessive artificialities and conventions. He choreographed subjects of mythology and history in highly dramatic narrative forms. He collaborated with some of the major composers of the period, including Mozart, on his ballets.

Noverre was not alone, and the others around him were full of the same zest to give a new meaning to ballet. In Vienna he had a feud with the Italian choreographer Gasparo Angiolini (1731–1803) over Noverre's reforms of the *ballet d'action*. Angiolini claimed these for his teacher, the Austrian choreographer Franz Hilverding (1710–68). In Bordeaux, Noverre's pupil Jean Dauberval premiered in 1789 *La Fille mal gardée* (*The Ill-Guarded Maiden*), usually called *Vain Precautions* in English, which became the first durable ballet comedy. It introduced the *demi-caractère* dance, which featured what were considered to be "true-to-life" characters. In London, still another pupil, Charles Didelot, created in 1796 *Flore et Zéphyre*. This was the first attempt to bestow on the individual dances within the ballet a certain

The influence of Noverre

Dionysius revived

period and local coloration, and to break the uniformity of step and movement of the corps de ballet by assigning individual tasks to its various members. Later, Didelot thoroughly reformed the ballet school in St. Petersburg, which had existed since 1738. There he also created the first ballets of the Russian national repertory. Among these were the first ballets to be based on the works of the Russian writer Alexandr Pushkin (1799–1837), whose stories continued to be used as ballet libretti for many decades.

In Milan, Salvatore Viganò, who had worked under Dauberval and Didelot and who had choreographed in 1801 the first performance of Beethoven's *Creatures of Prometheus*, was praised by the French writer Stendhal for his thrilling ballets based, among other subjects, on Shakespeare's *Othello* and *Coriolanus*. He was followed by Carlo Blasis, who was more noted as a teacher and theoretician. His *Traité élémentaire, théorique, et pratique de l'art de la danse* (1820; *Elementary Treatise upon the Theory and Practice of the Art of Dancing*) became the standard work of ballet teaching for the 19th century. In 1837 he founded the Imperial Ballet Academy, through which Milan became, with Paris and St. Petersburg, a third ballet centre of world renown.

**The Romantic ballet.** During the 1830s and '40s the Romantic movement flooded ballet stages with nature spirits, fairies, and sylphids. The cult of the ballerina replaced that of the male dancer, whose last and greatest representative had been the Italian dancer Gaetano Vestris (1729–1808). The techniques of female dancing were greatly improved. Skirts were shortened further, and blocked shoes permitted toe dancing. Choreographers strove for a more expressive vocabulary and to highlight the individual qualities of their dancers.

*La Sylphide* (1836) stated a main subject of the Romantic ballet, the fight between the real world and the spiritual world. This theme was enhanced and expanded in *Giselle* (1841) and *Ondine* (1843). Paris and London were the taste setters, and it was London that in 1845 witnessed the *Pas de quatre*, for which the French choreographer Jules Perrot brought together, for four performances, four of the greatest ballerinas of the day, the Italians Marie Taglioni (1804–84), Carlotta Grisi (1819–99), and Fanny Cerrito (1817–1909), and Lucile Grahn (1819–1907). After this the decline of Romantic ballet was rapid, at least in these cities. It continued to flourish into the early 1860s, however, in Copenhagen under the choreographer Auguste Bournonville, whose repertoire was kept alive by the Royal Danish Ballet into the second half of the 20th century. Russia, under the French-born Marius Petipa (1819–1910) and his Russian aide Lev Ivanov (1834–1901), built a world-famous ballet culture of its own. Linked at first with Paris, it gradually developed its own balletic idiom from native as well as imported sources. The high point of the classical ballet under the tsars was reached with the St. Petersburg productions of *The Sleeping Beauty* (1890), *The Nutcracker* (1892), and *Swan Lake* (1895), all with music composed by Peter Tchaikovsky, and *Raymonda* (1898), composed by Aleksandr Glazunov (1865–1936). While the ballet prospered in St. Petersburg and Moscow, it waned in Paris. Its ballerinas even appeared in male roles, as in *Coppélia* (1870). In Milan the extravaganzas of Luigi Manzotti (1838–1905) offered anything but dancing while glorifying the progress of mankind through material discoveries and inventions. The 19th century also saw an unprecedented increase in travel and in cross-cultural influences. Many seemingly exotic dance styles arrived on the Western scene. Troupes from as far as India and Japan appeared at expositions in Paris and London, starting a lively interest in folk and ethnic dancing. Ballerinas of the Romantic ballet travelled from one European city to another, from Milan to London to Moscow. The Austrian dancer Fanny Elssler toured the Americas in the early 1840s for two years, visiting Havana twice. The great choreographers, too, went from city to city. The language of dance became a medium of international communication without regard for difference in geography or spoken language,

#### THEATRE AND BALLROOM DANCE

Other dance entertainments of a lighter kind gained immense popularity during the 19th century. In Paris the all-female cancan became the rage. Its electrifying high kicks were shockingly exhibitionistic and titillating. After

Giraudon

Cancan with "Jane Avril Dancing," oil on cardboard by H. Toulouse-Lautrec, 1892. in the Louvre. Paris.

1844 it became a feature of the music halls, of revues, and of operetta. It was raised to musical prominence by operetta composer Jacques Offenbach (1819–80) and vividly depicted by the painter Henri de Toulouse-Lautrec (1864–1901). London enjoyed the Alhambra and Empire ballets, which were mostly classical ballets with spectacular productions. But it was America that provided the widest variety. There were patriotic spectacles, popular after the Revolutionary War, such as *The Patriot, or Liberty Asserted*, in which dance figured prominently.

More important and of longer range results were the minstrel shows, extravaganzas, burlesques, and vaudevilles. These represented a confluence of a wide assortment of dance and theatrical influences, especially from the Negro culture. White men affected black faces and black dances, and black men affected the faces and dances of the white. Dances were tap and soft-shoe, the buck-and-wing, and similar routines. Theatrical productions offered all kinds of dance, from European-imported ballets through entirely native exhibitions of female beauty verging on the striptease. American dancers began to establish reputations both in America and Europe. The ballerina Augusta Maywood (1825–76?) was the first American dancer to perform at the Paris Opéra.

During the 19th century there was also an enormous increase in the number of public ballrooms and other dancing establishments in the fast-growing cities of the West. Here were first encountered American imports such as the barn dance, then called the military schottische; the Washington Post, a very rapid two-step in march formation; and the cakewalk, which contorted the body to degrees previously unknown. For the first time Europe found in the New World a new infusion of blood

Russian  
rise,  
Western  
decline

for its dancing veins. The tempo of the dances quickened, reflecting perhaps the quickening pace of life and the great social changes of the century.

### The 20th century

Two trends were evident during the first years of the 20th century, before World War I. As if aware of some impending catastrophe, the wealthy society of Europe and the Americas indulged itself to the full in quicker waltzes and faster galops. At the same time, it tried to revive the minuet, gavotte, and pavane, producing only pale and lifeless evocations. There had hardly ever been such a frantic search for new forms, such radical questioning of values previously taken for granted, such a craze among the youth of all nations for individual expression and a more dynamic way of life. All the arts were deeply influenced by the rapid accumulation of discoveries in the physical and social sciences and an increasing awareness of social problems.

New  
directions  
in the  
dance

Overall, it was an incredibly lively time for the dance, which never before had generated so many new ideas or attracted so many people. The ballet was completely rejuvenated under the leadership of Russian impresario Sergey Diaghilev (1872–1929). It inspired some of the foremost composers and painters of the day, becoming the primary theatre platform for the most up-to-date work in the arts. Proponents of another reform movement, "modern dance," took their cue from the American dancer Isadora Duncan to strike in another way at the artificialities that Romantic ballet had generated. It took vigorous roots in Germany, where its expressionistic forms earned it the name *Ausdruckstanz* ("expressionistic dance"). The ballroom dances were thoroughly revolutionized through infusions of new vitality from South American, Creole, and Negro sources. With the overwhelming popularity of Afro-American jazz, the entire spirit and style of social dancing altered radically, becoming vastly more free, relaxed, and intimate through the following decades.

There was also a renewal of interest in the folk dances that had been the expressions of the common people in past centuries. This was fostered partly through special folk-dance societies, partly through various youth movements that saw that these dances might assist in shaping new community feelings. Theatrical dance of all kinds, from the highly stylized, centuries-old dances of the Orient to exhibitions of naked female flesh, reached new heights of popularity.

### DIAGHILEV AND HIS ACHIEVEMENTS

The artistic consequences of Diaghilev's Ballets Russes were enormous. Diaghilev's interest in dance began while he was a member of a small circle of intellectuals in St. Petersburg who fought to bring Russia's arts onto the wider European scene. The painters Alexandre Benois and Léon Bakst were his earliest collaborators.

**The Ballets Russes.** The Russian ballet troupe that Diaghilev brought to Paris in 1909 boasted some of the best dancers from the imperial theatres in St. Petersburg and Moscow. They set all Paris ablaze. No living person could remember ballets of such quality. For the next 20 years the Ballets Russes, which never appeared in Russia, became the foremost ballet company in the West. Diaghilev, who never choreographed a ballet himself, possessed a singular flair for bringing the right people together. He became the focus of the ballet world, striving for the integration of dance, music, visual design, and libretto into a "total work of art" in which no one element dominated the others.

Between 1909 and 1929, the contributions of many of the finest dancers and choreographers and of some of the most avant-garde, style-setting painters and composers made the Diaghilev company the centre of creative artistic activity. The group became a haven for Russian dancers who emigrated after the 1917 Revolution. It was the first large, permanently travelling company that operated on a private basis and catered to a cosmopolitan Western clientele.

Michel Fokine (1880–1942) was the first choreographer

to put Diaghilev's ideas into practice. He worked with contemporary composers, notably the Russian Igor Stravinsky (1882–1971) and the Frenchman Maurice Ravel (1875–1937). He drew also upon many eminent composers of the past, such as the Russians Aleksandr Borodin (1833–87) and Nicolay Rimsky-Korsakov (1844–1908), and the Pole Frédéric Chopin (1810–49). His major scenic artists were Benois and Bakst, whose contributions to theatrical design had influences beyond the sphere of ballet. Among his dancers were the Russians Anna Pavlova (1881–1931), who left after the 1909 season to dance with her own company throughout the West as well as the Orient, and Vaslav Nijinsky (1890–1950), who succeeded Fokine as the company's choreographer. A classic dancer, Nijinsky was an anticlastic choreographer, specializing in turned-in body movements and in unusual footwork. His composers included Stravinsky and the French Impressionist Claude Debussy (1862–1918).

The work  
of Fokine

After Nijinsky's career was cut short by his insanity, the dancer Léonide Massine (1896– ) assumed the role of choreographer. He quickly became noted for his wit and the precisely characterizing gestures of his dancers. His musical collaborators included Stravinsky; Manuel de Falla (1876–1946), whose work was full of the flavour of his native Spain; Ottorino Respighi (1879–1936), noted for his musical evocations of Italian landscapes; and Erik Satie (1866–1925), a Frenchman known for his originality and eccentricity. Massine's designers included leading painters of the School of Paris such as André Derain (1880–1954) and Pablo Picasso (1881–1973). Following Diaghilev's death, Massine created a furor in the 1930s with his ballets based on symphonies by Tchaikovsky and Johannes Brahms.

Another of Diaghilev's choreographers was Nijinsky's sister, Bronislawa Nijinska (1891–1972), who became famous for her massive ensemble groupings and her talent for depicting the follies of contemporary society. Diaghilev's last choreographic discovery was the Russian-trained George Balanchine (1904– ). Balanchine's *Apolon Musagète* (1928) began his long association with Stravinsky and led the way to the final enthronement of neoclassicism as the dominant choreographic style of the following decades.

**The continuing tradition.** When Diaghilev died his was no longer the only ballet company touring the world. Anna Pavlova's company visited places in Europe, the Americas, Australia, and the Orient that had never heard of, let alone seen, ballet. A troupe assembled by Ida Rubinstein (1885–1960) had Nijinska as a choreographer and Stravinsky and Ravel as composers. The Ballets Suédois featured, from 1920 to 1925, another group of avant-garde, largely French and Italian composers, painters, and writers. New dancers came from the schools in Paris, London, and Berlin that were directed by self-exiled Russian teachers. Important developments took place in London, where Dame Marie Rambert (1888– ), a Diaghilev dancer, founded the Ballet Rambert, and Ninette de Valois (1898– ) founded the company that became in 1956 the Royal Ballet. In New York, Balanchine set up the School of American Ballet in 1934. From it he drew the dancers for the several companies that led ultimately the founding of the New York City Ballet in 1948.

**The Soviet ballet.** Although Diaghilev's achievements were ignored there, the Soviet Union in the 1920s abounded with the daring choreographic experiments of Fyodor Lopukhov (1886–1973) and others. Despite the official imposition of "socialist realism" as the criterion of artistic acceptability in 1932, ballet gained enormous popularity with the Soviet people. They loved their dancers, who were superbly trained by generations of teachers under the leadership of Agrippina Vaganova (1879–1951).

### MODERN DANCE

Despite the recovery of ballet from its sterility in the late 19th century, other dancers questioned the validity of an art form so inescapably bound to tradition by its relative-

ly limited vocabulary. They wished to change radically the culture concept of expressive stage dancing. In a period of women's emancipation, women stepped to the front as propagandists for the new dance and toppled the conventions of the academic dance. They advocated a dance that arose from the dancer's innermost impulses to express himself or herself in movement. They took their cues from music or such other sources as ancient Greek vase paintings and the dances of Oriental and American Indian cultures.

The pioneers of this new dance were Isadora Duncan (1877-1927), who stormed across European stages in her loosely flying tunic, inspiring a host of disciples and imitators, and Ruth St. Denis (1877-1968), who surprised American and European audiences with her Oriental-style dances. With her partner Ted Shawn (1891-1972) she founded (1915) Denishawn, which, as a school and performing company, became the cradle of America's early protagonists of modern dance; notable among them were Martha Graham, Doris Humphrey, and Charles Weidman (1901-75).

In the German Ausdruckstanz the central figure was Rudolf Laban (1879-1958), who was more a theoretician and teacher than a choreographer. His researches into the physiological impulses to movement and rhythm crystallized in a formidable system of physical expression. His system of dance notation, known most widely as Labanotation, provided the first means for writing down and copyrighting choreographies. His most prolific disciples were Mary Wigman (1886-1973) and Kurt Jooss. Jooss became known—for his dances containing strong elements of social commentary. When Wigman toured America in the 1930s, Americans became aware that they were not alone in their search for new forms of expressive dance. She left behind one of her closest collaborators, Hanya Holm, who became another major figure on the American scene.

Across America schools opened, producing small groups of dancers who performed on college campuses and on small stages in the cities. Each choreographer and company brought different materials, artistic points of view, and performing styles to the dance. Perhaps the single element common to all of the many facets of modern dance was the search for new and valid forms of artistic expression.

#### NEW RHYTHMS, NEW FORMS

The changes in the social climate that were evident in the new century had a notable influence on the ballrooms.

**Latin-American and jazz dances.** The younger generation in Europe eagerly took up the more vivacious, dynamic, and passionate social dances from the New World. The turning dances of the 19th century gave way to such walking dances as the two-step, the one-step, or turkey trot, the fox-trot, and the quickstep, performed to the new jagged rhythms. These rhythms were African in origin, whether from the Latin-American tangos and rumbas or from the American Negro jazz. It is impossible to say how far this music was reduced in intensity from its original forms, but its influence was enormous in shaping the ragtime popular before 1918, the syncopated rhythms and mellow swing that followed it, the acrobatic jitterbug of the 1930s and 1940s, and the rock and roll of the next decades.

**Dance contests and codes.** After 1912, when the tango became the rage of the dancing world, even elegant hotels invited their clientele to their "tango teas." In fashionable restaurants professional dance couples demonstrated the new styles. In 1892 New York saw one of the first cakewalk competitions, and in 1907 Nice advertised the first tango contest. After the first world dance competition in 1909, in Paris, this became an annual event, which in 1913 lasted for two weeks. But it was England that acted as arbiter of taste for the new movements in social dance. There the first dance clubs, like the Keen Dancers' Society (later the Boston Club), were founded in 1903. In 1904 the Imperial Society of Teachers of Dancing was established, and in 1910 the periodical *Dancing Times* made its bow. After World War I the English version of the fox-trot was acknowledged as the essence of the

Charleston from the cover of *Life*, designed by John Held, Jr., 1926.

Culver Pictures

internationally acclaimed "English style." Victor Silvester's *Modern Ballroom Dancing* (1928) became the handbook of the dancing world until it was succeeded by Alex Moore's *Ballroom Dancing* (1936). The English style involved strict definitions for the five standard dances—quickstep, waltz, fox-trot, tango, and blues—to which were added after 1945 the Latin-American rumba, samba, calypso, and cha-cha-cha. What was left of the social barriers existing in 1900 between the exclusive and the popular dancing establishments was swept away.

Many observers were indignant about the changes taking place. Even so liberal a historian as Curt Sachs could not refrain from stating:

Since the Brazilian *maxixe* of 1890 and the *cakewalk* of 1903 broke up the pattern of turns and glides that dominated the European round dances, our generation has adopted with disquieting rapidity a succession of Central American dances, in an effort to replace what has been lost to modern Europe: multiplicity, power, and expressiveness of movement to the point of grotesque distortion of the entire body. . . . All [of these dances are] compressed into even movement, all emphasizing strongly the erotic element, and all in that glittering rhythm of syncopated four-four measures classified as *ragtime*. (From Curt Sachs, *op. cit.*, pp. 444-445.)

Sachs went on to note the rapid rise and fall in popularity of individual dances and suggested an impermanence to the entire movement.

**Effect on folk dancing.** As social dancing spread with the advent of the radio and the phonograph, the regions where genuine folk dancing was practiced became fewer. It continued least corrupted by the new forms in those countries outside the mainstream of Western urbanization and industrialization. Spain maintained its vigorous tradition of flamenco dancing, and in Hungary the composers Béla Bartók (1881-1945) and Zoltan Kodaly (1882-1967) collected the remnants of a wealth of folk song and dance folklore. Minority groups such as the Basques in Spain did likewise to maintain their identity against the overpowering influences of their neighbours.

Folk dancing remained a vital reality in the Soviet Union, especially in those European and Asiatic provinces that had distinctive ethnic populations and were far removed from Moscow, Leningrad, and other centres with Western contacts. In the industrial nations of Europe and the Americas, special nationwide councils and

societies were founded to preserve the traditional folk dance that was under threat of extinction.

Experiments. Technological progress itself became the subject of dance and dancing. In the Soviet Union, there were experiments during the 1920s with dances created to express the whirl of the urban sidewalk and of rushing autos, the accuracy of machine work, and the grandeur of skyscrapers. In Germany, the painter Oskar Schlemmer (1888–1943) realized his vision of a dance of pure, geometrically shaped form in the *Triadisches Ballet* performed in Stuttgart in 1922. In 1926 a sound vision of the technological ages, *Ballet mécanique* (*Mechanical Ballet*), by the American composer George Antheil (1900–59), was scored for mechanical pianos, automobile horns, electric bells, and airplane propellers. It was written not for the live dancer but for an animated film.

#### THE DANCE SINCE 1945

Dance of all kinds emerged from World War II, more vital and more expansive than before.

Social dance. In the realm of social dancing, motion pictures and television helped to spread such rock and roll dances as the "twist" more rapidly and widely than dances had travelled before. A characteristic of this new generation of jazz-based dances was the lack of bodily contact between the participants, who vibrated their legs, gesticulated with their hands, swung their shoulders, and twitched their heads. Many observers attempted to draw social implications of all kinds from these dances, which began to spread also among the youth of the Communist nations of Eastern Europe and Asia. Among the more interesting interpretations was that of Frances Rust:

... this type of dancing can be thought of as "progression" rather than "regression." Historically speaking, country-dancing of a communal or group nature gives way, with the break up of communities, to partnered-up ballroom dancing with a concentration on couples rather than groups. This, in turn, is now replaced amongst young people by partner-less dancing, which, although individualistic, seems none-the-less, to be rooted in a striving for community feeling and group solidarity (from *Dance in Society*; Routledge and Kegan Paul, 1969).

Dance in the theatre. On the postwar ballet scene there were no revolutionary developments such as those of Diaghilev earlier in the century. The classical ballet style reigned supreme throughout the West and in the Soviet Union. The popularity of ballet and the establishment of many apparently permanent companies made inevitable, however, wide variations in style and content. International tours were resumed on a large scale. There was also considerable interaction in terms of style and personnel between ballet and modern dance. The musical theatre, an inheritor of the techniques of these theatrical forms, became more artistically conscious and mature.

Companies presenting dances from India, Ceylon, Bali, and Thailand were no longer considered exotic on Western stages, and their influences contributed to both ballet

and modern dance. Numerous ensembles sprang up, their repertoires based on traditional national dances adapted for the stage. Many were modelled on the Soviet Moiseyev folk-dance company, which attracted large audiences during its frequent European and American tours. Similar companies existed in several eastern European countries, in Israel, and in some new African nations, as well as in Brazil, Mexico, and the Philippines.

Dance and the film. Both the cinema and television played important roles in making some of the best and most interesting dance performances accessible to millions of persons. Film served also as a means to preserve the work of major dancers and choreographers for future audiences. Aside from these distributive and preservative functions, however, the dance probably made more contributions to the film than the film made to the dance. In the 1930s and 1940s, Hollywood developed a kind of spectacular choreography featuring glittering chorines or stylish couples and soloists, a mode adapted by television. Movies centred on ballet and ballets commissioned for television had little critical approval except in Sweden, where Birgit Cullberg (1908– ) choreographed some notable productions for television.

From the beginning of the 20th century the dance scene became extremely multifaceted and colourful. If some of its manifestations appeared contradictory, that could be regarded as proof of its vitality. No other century granted dance so prominent a role among its social activities. Indications of this prominence included a vast increase in dance research and writing, the opening of colleges and universities in America to special dance faculties, and establishment in the Soviet Union of institutes for the study of choreography. And dance notation promised great advances in recording specific choreographies and as a basic linguistic tool in dance education.

**BIBLIOGRAPHY.** CURT SACHS, *Eine Weltgeschichte des Tanzes* (1933; Eng. trans., *A World History of the Dance*, 1937, reprinted 1963), the most comprehensive, systematic, and factual history of dance in all its epochs and forms, with special emphasis on its earliest beginnings and close attention to dance accompaniment; W.F. RAFFE, *Dictionary of the Dance* (1965), detailed descriptions of the particular dances, their background, and history; ANATOLE CHUJOY and P.W. MANCHESTER (eds.), *The Dance Encyclopedia*, rev. ed. (1967), the most comprehensive ballet dictionary available, including entries on specific productions, artistic biographies, and histories of ballet in various countries; LINCOLN KIRSTEIN, *Dance: A Short History of Classic Theatrical Dancing* (1942, reprinted 1969), a very thorough book on the pre-balletic forms of dance as well as classic theatrical dance; WALTER SORELL, *The Dance Through the Ages* (1967), a general, readable survey of the worldwide dance scene from prehistoric times through today, with superb pictures of ancient and modern dance; A.H. FRANKS, *Social Dance: A Short History* (1963), the first attempt at relating the origins and developments of the most important social dance forms to their social environment; FRANCES RUST, *Dance in Society* (1969), a study giving even more documentary evidence of the social dances and their relationships to the changing structures of society, with emphasis on the English scene and the teen-age explosion in dance during the 1960s.

(H.Ko.)

## Dance and Theatre, East Asian

From ancient times the performing arts have played a vital role in the civilizations of East Asia—in China, Korea, and Japan. Their origin in Japan is explained by a myth that relates dance and theatre to the gods who created earth and life. Amaterasu, the Great Heavenly Shining Goddess, retired to a cave in anger, thus depriving the world of light. In order to lure her out, another goddess mounted an overturned tub, bared her body, and danced vigorously as the audience of gods sang and beat time. Intrigued by the laughter and shouting, Amaterasu came out and joined them, thus ending her self-imposed exile. The gods, having discovered the pleasure of performing and watching dance, passed their accomplishment on to man.

In early times the performances of plays and of dances were closely tied to religious beliefs and customs. In China, records from around 1000 BC describe magnifi-

Origin of  
dance and  
theatre in  
religious  
customs

cently costumed male and female shamans who sang and danced to musical accompaniment, drawing the heavenly spirits down to earth through their performance. Impersonation of other characters through makeup and costume was occurring at least by the 6th century BC. Many masked dances in Korea have a religious function. Performances invoking Buddha's protection are especially popular and numerous in Japan and Korea. Throughout East Asia the descendants of magico-religious performances can be seen in a variety of guises. Whether designed to pray for longevity or for a rich harvest or to ward off disease and evil, the rituals of impersonation of supernatural beings through masks and costumes and the repetition of rhythmic music and patterns of movement perform the function of linking man to the spiritual world beyond. Hence, from the earliest times in East Asia, dance, music, and dramatic mimesis have been naturally fused by their religious function.

In East Asia the easy intermingling of dance and theatre, with music as a necessary and inseparable accompanying art, also derives from aesthetic and philosophic principles. In the West, by contrast, concert music, spoken drama, and ballet have evolved as separate performing arts. Confucian philosophy holds that a harmonious condition in society can be produced by the proper actions of man, including the playing of music and the performance of dances that are appropriate and conducive to moderation. Throughout China's history, poems were written to be sung; songs were danced. Dancing, while it might be pure dance without meaning, could just as easily be used to enact a story in the theatre. Zeami Motokiyo (died 1443), the most influential performer and theoretician of Nō drama in Japan, described his art as a totality, encompassing mimesis, dance, dialogue, narration, music, staging, and the reactions of the audience as well. Without arbitrary divisions separating the arts, there has developed in East Asia exceptionally complex artistic forms that produce on their audience an impact of extraordinary richness and subtlety.

Dance may be dramatic or nondramatic; in all traditional theatre forms, some elements of dance will be found. Puppets, masks, highly stylized makeup, and costuming are common adjuncts of both dance and theatre. Dialogue drama (without music) is rare but does exist. The major dance and theatre forms performed today in East Asia can be described as follows: unmasked dances (folk and art dances in each country), masked dances (Korean masked dances and *bugaku* and folk dances in Japan), masked dance theatre (Nō in Japan and *sandae* in Korea), danced processions (*gyōdō* in Japan), dance opera (Peking and other forms of Chinese opera), puppet theatre (*khoktugaksi* in Korea and *burzaku* in Japan), shadow theatre (in China only), dialogue plays with traditional music and dance (Kabuki in Japan), dialogue plays with dance (*kyōgen* in Japan), and straight dialogue plays introduced into China, Korea, and Japan from the West in the 19th century.

### Characteristics of East Asian dance and theatre, and their social milieu

#### COMMON TRADITIONS

China, Korea, and Japan have been historically close for centuries, thus accounting for many common artistic traditions. From pre-Christian times, until the 8th and 9th century AD, the great trade routes crossed from the Middle East through Central Asia into China. Hinduism, Buddhism, some knowledge of ancient Greek, and much knowledge of Indian arts entered into China, and thence in time into Korea and Japan. Perhaps before Christ, the Central Asian art of manipulating hand puppets was carried to China. For more than 700 years, until 668, in the kingdom of Koguryō, embracing northern Korea and Manchuria, court music and dances from Central Asia, from Han China, from Manchuria, and from Korea, called *chisō* and *kajisō*, were performed. Many of the dances were masked; all were stately as befit serious court art. They were taken to the Japanese court in Nara around the 7th century. Called *bugaku* in Japan, they have been preserved for 12 centuries and can still be seen

performed at the Imperial Palace in Tokyo, though they have long since died out in China and Korea. In Koguryō's neighbouring kingdom of Paekche, a form of Buddhist masked dance play was performed at court and, in the 7th century, it too was taken to the Japanese court at Nara by a Korean performer, Mimaji, who had learned the dances while staying at the southern Chinese court of Wu. Called *kiak* in Korea and *gigaku* in Japan, the Aryan features of some of its masks clearly indicate Indian (or Central Asian) influence. Such complicated genealogies are common in East Asian performing arts.

Very likely by the 7th century, gypsy-like puppeteers, who originally had been nomads from Central Asia and had taken up abode in northern Korea, migrated to Japan. The men continued to be both herdsman and puppet manipulators in their new homeland, while the women performed dances and sang as popular entertainers. (There may have been a native puppet tradition in Japan as well.) In time the art of puppet manipulation joined with that of epic storytelling to produce the famous *bunraku* puppet theatre. Musical accompaniment for *bunraku* and for other popular plays in Japan, such as Kabuki, was provided primarily by the *samisen*, a three-stringed lute, borrowed from China by way of Okinawa. The lion dance, originally from China, is performed in a score of versions in Korea and Japan as well as in China, India, Ceylon, and Bali. Certain myths are dramatized in common as well. The story of the angel or nymph who flies down to earth and arouses the love of a mortal man is known in many parts of the world. It is dramatized in Southeast Asia (especially in Burma and Thailand, as the play *Manora*), in Chinese opera, and in both Nō and Kabuki theatre in Japan (as the "Feather Robe"). The legend of the one-horned wizard who traps the dragon gods of rain and causes a searing drought originated in India and was later transmitted to Japan by the Chinese, where it is dramatized in Nō ("The One-Horned Wizard") and in Kabuki ("Saint Narukami").

The direction of artistic exchange was reversed in the last century. As part of Japanese national policy following the Meiji Restoration (1868), artists studied Western performing arts. Chinese and Korean actors, dancers, and playwrights studying in Japan took back to their countries Western theory and practice in ballet, modern dance, and theatre. In time, Western theatre and dance directly influenced Chinese and Korean performing arts. Perhaps most influential in all three countries was the Western dramatic theory of realism. It diametrically opposed the traditional intermingling of music and dance with drama, and it eschewed the stylization and symbolism that lay at the heart of East Asian performing arts for more than 2,000 years. A conflict between traditional and Western performing arts came into being that continues to the present.

As has been noted, dance and theatre are accompanied by music in all except the most unusual cases. Music may be instrumental or vocal. The music is especially composed for each *bunraku* puppet play in Japan and for most dance plays and court dances. Fixed melodies accompany most folk performances. In Chinese opera and in Japanese Kabuki, melodies appropriate to scene, action, character, or mood being portrayed are selected from a standard musical repertory of several hundred tunes. The knowledgeable spectator easily identifies scenes by the music that accompanies them (a similar system is found in Southeast Asian theatre). The close linking of music with dance and theatre can be seen in the Korean drum dance, in which the dancer also is a musician who plays the drum, and in a number of Japanese Kabuki and puppet plays that show characters expressing their deepest feelings by playing a musical instrument. Equally important, the performer demonstrates to the audience his skill in yet another refined accomplishment.

The performing arts of India are closely linked to sculpture and painting by the unusual phenomenon that bodily positions in all these arts are regulated by similar, indeed almost identical, codes. The code of hand gestures, for example, for the dancer and the actor set forth in the *Nāṭya-śāstra* ("Principles of Dramatic Art"), a 6th-cen-

Western  
influences

Current  
dance and  
theatre  
forms

Aesthetic parallels of visual arts and performing arts

tury-BC treatise on dramaturgy, is identical with that for Buddhist temple sculpture, or painting. Although these hand positions (*mudrā*) from India are also seen in Chinese, Korean, and Japanese statues of the Buddha, they have never been adopted by performing artists (as, by way of contrast, they were by dancers and actors in Cambodia, Thailand, Burma, Java, and Bali). In three notable instances, however, the performing arts in China and in Japan can be seen to be closely related to the visual arts. During the Sung dynasty (960–1279) in China, Northern and Southern schools of painting evolved that were totally different in style; the former used bold outline and brilliantly contrasting colors of deep green, blue, and gold, while the latter emphasized delicate, monochrome ink painting of misty landscapes. Northern and Southern schools of opera at the time reflected the same contrasting characteristics: the former dynamic, vigorous, and filled with action, the latter emphasizing wistful emotions and soft, gentle singing. Zen Buddhism was a common source of inspiration in the 15th and 16th century in Japan for *Nō* dance drama, for the tea ceremony, for ink painting, and for the art of rock-and-sand gardens. Sparseness of form, discipline, and suggestion rather than explicit statement are Zen attributes found in these and other arts cultivated by the military ruling class (*samurai*) of the time. In 18th-century Japan, a lively and faddish urban culture produced both *Ukiyo-e* woodblock prints and Kabuki. In fact, *Ukiyo-e* artists, such as Sharaku, established their fame by portraying famous Kabuki actors as their subjects. Eroticism, verve, brilliant colouring, and an intense interest in the passing moment characterize equally both Kabuki theatre and *Ukiyo-e* visual art.

Although dances were often performed to sung poems and plays were either written in verse form or contained references to classic poems, the performing arts traditionally are seen as distinct from literature in East Asia. A century and a half passed in Kabuki before the first complete play script was preserved, and in China, where a tradition of written literature goes back to 1400 BC, no play text was considered worth committing to paper until late Sung, around the 13th century. With few exceptions, playwrights have rarely been accorded the same status as writers of poetry, novels, or criticism. As a result, the performing arts in East Asia succeeded by and large in escaping the stultifying grip that literature came to hold on Indian Sanskrit drama and some would say, still, at least in part, holds on drama in the West.

Artistic borrowings among East Asian countries

The general outlines of artistic borrowings among East Asian countries can be traced from historical records. But borrowing tells only half of the story. No matter how strong the initial outside influence, in time, assimilation of the foreign art took place. Older native performing traditions reasserted themselves, and new creativity altered the borrowed elements. This can be seen even in *bugaku* dances in Japan; although they are believed to preserve ancient Chinese and Korean forms to a very remarkable extent, native Japanese qualities are also present. Local styles predominate even more in the popular arts. Japanese *bunraku* puppet plays and Kabuki theatre show almost no observable signs of foreign influence. In spite of certain general cultural similarities, then, the dance and theatre of China, Korea, or Japan exhibit definite local characteristics not shared by the arts of their neighbouring countries.

In China singing became highly developed, and the most important theatre performances are built around song (hence the term Chinese opera). Dance as a separate art has a weak tradition there, and, at least in the 20th century, is tied very closely to the theatre. The shadow theatre, known from Morocco through Egypt and Greece, in India, Indonesia, Malaysia, Thailand, and Cambodia, is found in East Asia only in China. In Korea, dance predominates over drama. There are scores of Korean court and folk dances and danced plays, but no sophisticated dramatic forms evolved until this century. Masked dances especially are characteristic of Korea. In Japan, from an early tradition of imported pure dance and from folk dance, complex theatrical forms evolved that include dance drama, epic narrative performed as a puppet play,

and dialogue dramas either accompanied or unaccompanied by music.

The aesthetic principles that govern dance and theatre in East Asia are radically different from those of the West. The dancer in the West attempts to free himself from the pull of the earth; he tries to leap and soar in the air. The dancer in China, Korea, or Japan stands firmly on the dance floor, often scarcely raising his feet in the air, and moves in relatively slow and often geometric patterns. Arms and hand movements are important and varied while in Western dance the hands are little used. Whether movement is dance or not, it is always stylized. Speech is stylized as well, whether it is dialogue or narration, chanted or sung. The intent may be to portray archetypes, human or mythological, especially in shadow and puppet theatre and in masked dances and plays. There is great emphasis on form, both for its ritual value and because audiences are trained to recognize the beauty implicit in form. There may be a purposeful contradiction between artistic ends and means: children were moved as human puppets in China, and adults acted before lighted screens to make a living shadow play; in Japan, puppets execute realistic daily actions, while live Kabuki actors refrain from duplicating daily life. The East Asian audience is prepared to respond in quick succession to a sequence of different stimuli—physical characterization, human speech, song, narrative commentary, visual composition, formal movement patterns—over long periods of time; for eight hours in *Nō* or up to twelve hours in Kabuki. This differs from the West, where the spectator expects to be exposed to a clearly focussed theatrical image for only two or three hours. The East Asian experience is more diverse, more extended, more conventional than the Western experience in the theatre.

Aesthetic principles

A further important characteristic of dance and theatre in China, Korea, and Japan is that performing arts developed very largely within an oral tradition. By and large the performers themselves created the forms; only gradually did specialists in choreography, musical composition, or playwrighting take their places in performing groups. Even after forms reached maturity, traditions of dance, acting, and music were passed on orally to the next generation. A major exception is that play scripts in China and Japan came to be written in full.

#### SOCIAL CONDITIONS

It is notable that although some dance and theatre forms were highly regarded in China, Korea, and Japan, performers were usually looked down upon. Wandering performers especially were despised in the agrarian societies, where attachment to the land was valued and Confucian teaching, strong throughout East Asia, stressed veneration of one's parents, which included tending their graves and making offerings for their welfare in the spirit world. The place of drama or of dance in these societies depended in part upon their audiences, whether they were court nobles, villagers, or town merchants.

Social position of the performer

Chinese emperors, Korean kings, and Japanese emperors and military rulers all supported performers at their courts. During the T'ang dynasty, the 8th-century Chinese emperor Ming Huang established schools in the palace city of Ch'ang-an for music, dancing, and acting. The latter school was set up in a pear garden; ever since, actors in China have been called "children of the pear garden" (*li yüan tzu ti*). Over a thousand young people from all ranks of society drew government salaries while studying and performing at lavish state banquets and for official ceremonies. Acting or dancing might be a permanent job (at least until old age made one less attractive) at the Chinese court, but, in Korea, performers at the court held other positions in the government and were mobilized from around the country only for rehearsal and performance. In Japan, dancers and musicians have been attached to the imperial household from the 7th century until the present time. First *gigaku* and then *bugaku* dances were official performing arts, while shrine dances (*kagura*) were also partly under imperial patronage. The military rulers of Japan (*shogun*) incorporated into their retinues *Nō* actors and musicians beginning in the 15th

century, and, in time, provincial lords also began to follow this practice.

Court  
patronage

Court support resulted in high artistic levels in all countries. Performers were relieved of financial problems and could devote themselves, often full time through their entire lives, to their art. Audiences were educated and for the most part discerning. The importance attached to official performances undoubtedly spurred the artists to extend themselves to their utmost. In time, however, such forms as Japanese *Nō* and *bugaku* and Chinese *k'un-ch'ü* opera became so rarefied that they could be appreciated only by a small elite group.

At the Chinese and Korean courts young female dancers were part of the ruler's personal retinue (often his concubines); they were not allowed to mix with men of the court, so that some courts' arts were performed solely by men and others solely by women. This custom and the consequent artistic practice of male and female impersonation is also found in court theatre of Cambodia and Thailand. In Japan, women seldom performed at court and the major dance and theatre forms have been the province of male performers. Since it was unusual for rulers or courtiers themselves to take part in performance (they often did in Java, Bali, and Thailand), the court artist was usually a middle-level civil servant.

Folk and  
popular  
theatre  
and dance

Folk performers, on the other hand, are local villagers who, like the *sandae* masked dancers of Korea or the girls who perform festive *ayakomai* dances in Japan, are amateurs who do not live by their art. The midsummer Bon dance for spirits of the dead or early spring rice-planting dances in many areas of Japan or various auspicious dances held at the New Year in Korea and China were performed only once a year, and hence a high level of artistry was not usually achieved. Because many folk performances were held as part of religiously sanctioned rituals (Korean mask plays ensuring harvest, dances and dance plays of many varieties in Japan dedicated to local *Shintō* deities), performers achieved considerable status in the local community by their participation in these essential communal rites.

Performers of popular dance and theatre in East Asia live as do commercial artists everywhere—by their ability to draw audiences who are willing to pay money for a seat at a show. The shadow and puppet performers of China, Peking opera actors and musicians, and Kabuki and *bunraku* puppet performers in Japan are popular artists. Neither a part of village culture nor patronized by the court, they have always been held suspect by their rulers. Kabuki, in particular, was faced with repressive government action throughout its history. Popular theatre grew in importance in China and in Japan concurrently with the growth of large urban centres and a moneyed, mercantile economy, especially since the 16th century. (An important urban popular theatre, however, has not developed in Korea.) Troupes perform nightly through the year, when it is possible, and consequently, in popular theatre, large repertoires of standard plays are created (some 350 in Kabuki and more than 200 in Chinese opera). Popular theatre forms in China and Japan are intensely theatrical, though they lack literary qualities which would recommend them to the intelligentsia. Indeed, Kabuki in Japan and Peking opera in China have had little official status until recent years in spite of their immense audience popularity and their obvious excellence as performing arts. Travelling troupes that perform shadow or puppet plays, do acrobatics and juggling, dance and sing, and perform versions of court or popular entertainments have long been a feature of Chinese and Korean village and provincial town life. Artistically the forms are related to folk performing arts; socially the performers are considered outcasts, wandering entertainers of no status who belong to the popular tradition of performing arts.

### The development of dance and theatre in the East Asian nations

#### CHINA

**Formative period.** Singing and dancing were performed at the Chinese court as early as the Chou dynasty (c.

1122–221 BC). An anecdote describes a case of realistic acting in 402 BC, when the chief jester of the court impersonated mannerisms of a recently deceased prime minister so faithfully that the emperor was convinced the minister had been restored to life. Drama was not yet developed, but large-scale masques (a short allegorical performance with masked players) in which dancing maidens and young boys dressed as gods and as various animals were popular. Sword-swallowing, fire-eating, juggling, acrobatics, ropewalking, tumbling and similar stage tricks had come from the nomads of Central Asia by the 2nd century BC and were called the "hundred entertainments." During the Han dynasty (206 BC–AD 220) palace singers acted out warriors' stories, the forerunners of military plays in later Chinese opera, and by the time of the Three Kingdoms (AD 220–264) clay puppets were used to enact plays. These evolved into glove and stick puppets in later years.

**T'ang period.** The emperor Ming Huang showed interest in the performing arts, stimulating many advances in stage arts during the T'ang dynasty (618–907). More than a thousand pupils were enrolled in music, dance, and acting schools. Spectacular masked court dances and masked Buddhist dance processions that soon were learned by Korean and Japanese performers were part of court life. Three types of play are recorded as having been popular. "False Face" was about Prince Lan Ling, who covered his gentle face with a horrifying mask to frighten his enemies when he went into battle. Some suggest the colourful painted faces of warriors in today's Chinese opera derive from this play. "The Swinging Wife" was a farcical domestic play, in which a weaving and sobbing wife bitterly complained about her brutal husband, who then appeared and, singing and dancing, abused his wife even more. The embezzling rascal hero of "The Military Counselor" became a stock character in later plays. Thus, by T'ang times, three basic types of drama were known: military play, domestic play, and satire of officialdom.

**Sung period.** A form of play called the variety play (*tsa-ch'ü*) was created by writers and performers in North China during the Northern Sung dynasty (960–1126). None of the scripts has survived, but something of their nature can be deduced from the 280 titles which remain and from court records. A play consisted of three parts: a low-comedy prologue, the main play in one of two scenes (consisting of extended sequences of songs, dancing, and perhaps dialogue), and a musical epilogue. Two, three, or four variety plays would be included in a program along with a sampling from the "hundred entertainments." In the following Southern Sung dynasty (1126–1279), northern writers continued composing plays of this general type under the name professional scripts (*yüan-pen*). None of the 690 professional scripts of which the titles are known has survived. Concurrently a new form of drama, southern drama (*nan-hsi*), emerged in the area around Hangchow in southern China. Originally the creation of folk authors, it soon became an appealing and polished dramatic form. A southern drama tells a sustained story in colloquial language; flexible verses (*ch'ü*) were set to popular music, making both music and poetry accessible to the ordinary spectator. Professional playwrights belonging to Hangchow's book guilds (*shu-hui*) wrote large numbers of southern dramas for local troupes. Of these, 113 titles and three play texts remain, preserved in an imperial collection of the 15th century. "Chang Hsieh, the Doctor of Letters" (probably the oldest of the three) dramatizes the story of a young student who aspires to success, earns a degree and position, but callously turns his back on the girl who faithfully loves him.

Professional theatre districts became established during the Sung dynasty. Major cities contained several districts (17 in Hangchow), with as many as 50 playhouses in a district. Plays performed by puppets and mechanical dolls were extremely popular.

A legend attributes the origin of shadow theatre in China to an incident said to have occurred around 100 BC: a priest, claiming to have brought to life the Emper-

Chinese shadow play.

oured shadows on the screen. In this respect they were unlike Javanese shadow puppets, which, though brilliantly coloured, are opaque and cast a colourless shadow. Shadow plays are still occasionally seen in China. Singers, dancers, actors, acrobats, and other performers were all employed at the professional theatres of the districts. Troupes were as small as possible for economic reasons, containing as few as five or six performers. They would tour the countryside if they had no work in the large cities, thus spreading throughout the vast region of China urban styles of performing arts.

**Yüan period.** Scholars turned to writing drama in the Yuan period (1279–1368) when they were removed from their positions in the government by China's new Mongol rulers, descendants of Genghis Khan. They developed the earlier northern style of *tsa-ch'ü* into a four-act dramatic form, in which songs (in the same mode in one act) alternated with dialogue. Singing was restricted to a single character in each play. Melodies were those of the Peking region. The beauty of poetic lyrics was highly valued, while plot incidents were of lesser importance. About 200 plays survive, from thousands of romances, religious plays, histories, domestic, bandit, and lawsuit plays that were composed. *Hsi hsiang chi* ("Romance of the Western Chamber"), by Wang Shih-fu, is a 13th-century adaptation of an epic romance of the 12th century. The student Chang and his beautiful sweetheart Ying Ying are models of the tender and melancholy young lovers who figure prominently in Chinese drama. Loyalty is the theme of the history play "The Orphan of Chao," written in the second half of the 13th century. In it the hero sacrifices his son to save the life of young Chao so that Chao can later avenge the death of his family (a situation developed into a major dramatic type in 18th-century popular Japanese drama). "The Chalk Circle," demonstrating the cleverness of a famous judge, Pao, is well known in the West, having been translated into English and adapted (1948) by the German playwright Bertolt Brecht in *The Caucasian Chalk Circle*. The class of bandit dramas are mostly based on the novel "The Water Margin" and its 108 bandit heroes, who live by their wits doing constant battle against corrupt and avaricious officials. The life of the common man is portrayed with considerable reality in Yuan drama, though within a highly formalized artistic frame. The lasting worth of Yüan plays is attested to by the fact that they have been adapted constantly to new musical styles over the years so that Yuan masterpieces make up a large part of the traditional opera repertory.

**Ming period.** Plays of the 'Yüan period were widely popular with the people. When under the native Chinese Ming rulers (1368–1644) Mongol influence was eradicated, drama was, for a time, forbidden. Revived in the south, it increasingly became a literary form for a scholarly elite. The best known Ming play is "Lute Song," written in 42 scenes, by the scholar Kao Ming in the 14th

century. Its heroine, Ts'ai Yung, sets a perfect example of Confucian filial piety and marital fidelity, caring for her husband's parents until their tragic death and then playing the lute to eke out a living as she patiently searches for her husband.

In the early 16th century, a musician, Wei Liang-fu, of Soochow, devoted ten years to creating a new style of music called *k'un ch'ü*, based on southern folk and popular melodies. At first it was used in short plays. Liang Ch'en-yü, poet of the 16th century, adapted it to full-length opera in time, and it quickly spread to all parts of China, where it held the stage until the advent of Peking opera, two centuries later. Important *k'un ch'ü* dramatists were T'ang Hsien-tsu (died 1616), famed for the delicate sensitivity of his poetry, Shen Ching (died 1610), who excelled in versification, and the creator of effective theatrical pieces, Li Yu (born 1611). A large-scale performance of *k'un ch'ü* for the emperor Ch'ien-lung in 1784 marked its high point in Chinese culture. *K'un ch'ü* had begun as a genuinely popular opera form; it was welcomed by audiences in Peking in the 1600s, but within decades it had become a theatre of the literati, its poetic forms too esoteric and its music too refined for the common audience. In 1853 Soochow was captured by the Taiping rebels, and thereafter *k'un ch'ü* was without a strong base of support and declined rapidly.

**Ch'ing and Manchu periods.** Peking opera, or *ching hsi*, came into being over a period of several decades at the end of the 18th century, during the Ch'ing dynasty (1644–1911). In the wake of the Taiping Rebellion, *k'un ch'ü* troupes resident in Peking returned to their homes in the south. Their places in Peking's theatres were quickly taken by opera troupes from the surrounding provinces, especially Anhwei, Hupeh, Kansu, and Shansi. Anhwei opera had been performed on the occasion of the emperor Ch'ien-lung's birthday in 1790. Peking opera was born of an amalgamation of elements from several sources: rhythmic beating of clappers to mark time for movements (from Shansi and Kansu), singing in the two modes of *hsi p'i* and *erh huang* (from Anhwei), and increased use of acrobatics in fighting scenes. Undoubtedly, court support for Peking opera from Tz'u-hsi (1835–1908), the Empress Dowager, contributed to its rise, but it was also very widely patronized by local audiences. It became the custom to rehearse in public teahouses, and in time these became regular performances providing troupes with much of their financial support.

Essentially, *ching hsi* was a continuation of northern-style drama, while *k'un ch'ü* marked the culmination of southern-style drama. Musically they are very different: the former uses loud clappers and cymbals for scenes of action and the penetrating sound of fiddles accompanies singing; in the latter, the flute is the major instrument, and strings and clanging cymbals are absent. A limited number of melodies are repeated many times in Peking opera (set to different lyrics), while in *k'un ch'ü* the melodic range is much wider. Peking opera lyrics are in colloquial language (they are often criticized as lacking in literary merit). Overall, the newer opera form is highly theatrical and vigorous, while the older form is restrained, gentle, and elegant. Some Peking operas are Yuan plays or *k'un ch'ü* operas adapted to the new northern musical system. Many plays first staged as Peking opera are dramatizations of the war novel *Romance of the Three Kingdoms*, written in the 14th century by Lo Kuan-chung. Mei Lan-fang, the most famous performer of *ching hsi* female roles in the 20th century, introduced a number of these highly active military plays into the repertory. *K'un ch'ü* dramas told a long and involved story in great detail, often in 40 or 50 consecutive scenes. It became the custom in Peking opera to perform a bill of a number of acts or scenes from several plays, like a Western concert program.

Concurrent with the national forms of drama mentioned before, local opera is found in every area of China (the different forms have been estimated at 300). They are performed according to local musical styles and in regional languages. General characteristics of most forms of Chinese opera are similar, however. Action occurs on

a stage bare of scenery except for a backdrop and side-pieces. A table and several chairs indicate throne, wall, mountain, or other location. (More elaborate scenery is used in Canton and Shanghai, influenced by Western drama and motion pictures.) Actors enter through a door right and exit through a door left. Costumes, headgear, and makeup identify standard character types. Actors play a single role type as a rule: male (*sheng*), female (*tan*), painted-face warrior (*ching*), or clown (*ch'ou*). Each role type can be subdivided into several role subtypes. Actors undergo seven years of training as children, during which time their appropriate role type is determined. Singing is essential for *sheng* and *tan* roles; minor actors and actors of clown roles must be skilled in acrobatics that enliven battle scenes. Singing is accompanied by a large number of conventionalized movements and gestures. For example, the long "flowing water" sleeves that are attached to the costumes of dignified characters can be manipulated in 107 movements. Pantomime is highly developed and several scenes have become famous for being enacted without dialogue: in "The White Snake" a boatman rows his lovely daughter across a swirling river; in "The Crossroads" two men duel in the dark; in "The Flower" a maiden threads an imaginary needle and sews. Symbolism is highly developed. Walking in a circle indicates a journey. Circling the stage while holding a horizontal whip suggests riding a horse. Riding in a carriage is represented by a stage assistant holding flags painted with a wheel design on either side of the actor. Four banners indicate an army. A black flag whisked across the stage means a storm, a light blue one a breeze

Manchu dynasty ended. Troupes, however, continued to perform for private patrons and in public at teahouses and in theatres. Following the liberal ideals of the time, attempts were made to write in colloquial language (rather than in classical Chinese, as previously) and old plays considered undemocratic were dropped from the repertory. A school for Peking opera acting, modelled on Western pedagogical methods, was established in 1930, actresses being admitted for the first time in three centuries. The basic style of opera remained unchanged, however.

Western drama was first introduced by Chinese students who had studied in Japan and there learned of Western plays. In 1907 a Chinese adaptation of *Uncle Tom's Cabin* was successfully staged in Shanghai by students, marking the beginning of a proliferation of amateur study groups devoted to reading and staging Western plays. Originally aimed only at a small group of Western-educated intelligentsia, spoken drama's appeal was broadened to the middle class by the China Traveling Dramatic Troupe, which toured many cities from its home in Shanghai. In 1936 it performed "Thunderstorm," a four-act tragedy by Ts'ao Yü. An extremely successful playwright in the Western style, by 1941 Ts'ao Yu wrote six important plays, including "Peking Man"; heavily influenced by O'Neill and Ibsen, he portrayed dissolute members of the old gentry class and new rising entrepreneur class.

Nationalism, the upheaval of World War II, and changes of government in China, Korea, and Japan between 1945 and 1949 are reflected in contemporary theatre and dance in East Asia. In China an estimated 60,000 performers were mobilized into some 2,500 propaganda troupes during the Sino-Japanese War beginning in 1937 under the direction of the well-known playwright T'ien Han. Hundreds of thousands of ordinary Chinese in the army were exposed to modern forms of drama for the first time, and, equally significant, artists discovered regional folk legends, songs, and dances, which they then incorporated into their work. The creation of new flexible forms blending local and Western theatrical elements that is characteristic of contemporary Chinese theatre owes much to this wartime experience. Yang-ko folk dances of Hopeh province were developed into a propaganda dance play by the Communist Eighth Route Army and performed in areas under their control during the war, culminating in the creation of "The White-Haired Girl," a play originally done in *yang-ko* style and subsequently adapted to opera and into ballet using Western orchestra. The heroine, an escaped concubine of a cruel landlord, symbolized all the people victimized by oppressive governments and social systems.

In 1942 Mao Tse-tung stressed that art was a means of "uniting and educating the people." This philosophy has been carried out in the People's Republic of China since its establishment in 1949, with two chief results: dance and theatre are highly valued and strongly supported by the government; and content and form of dance and of drama are decided by appropriate government organs. Since 1949, folk dances of the many regions of China have been encouraged. Regional language opera has flourished. Amateur groups as well as professional are extremely numerous.

Under Communism there have been far-reaching reforms in the performing arts. Traditional opera was supported by placing performers on government salaries and by establishing opera schools in most provinces. But because traditional opera had been created by a feudal class, the new government strove to reshape it into an art form more accessible to a mass audience. Some reforms were technical (abolishing the stage assistant and using act curtains) and were designed to modernize staging. Also, antidemocratic, superstitious, erotic, or feudal sentiments were proscribed. Through 1953 most changes in the repertory consisted of rewriting offending passages or scenes. Beginning in 1964, operas with contemporary themes, with soldiers and workers as heroes costumed in ordinary dress, using realistic scenery and lighting, and acted in mixed real and conventional style were en-

or the ocean. Chinese opera is one of the most conventionalized forms of theatre in the world. It has been suggested that the poverty of troupes and the need to travel with few properties and little scenery led to the development of many of these conventions.

Confucian morality underlies traditional Chinese drama. Duty to parents and husband, loyalty to one's master and elder brother or sister, were virtues inculcated in play after play. Spiritualism and magical powers, derived from Taoism, are themes of some dramas, but by and large, Chinese drama is ethical rather than religious in direction. Plays were intended to uphold virtuous conduct and to point out the dire consequences of evil. The Western tragic view, which holds that man cannot understand or control the unseen forces of the universe, has no place in Chinese drama; the typical play concludes on a note of poetic justice with virtue rewarded and evil punished, thus showing the proper way of human conduct in a social world.

**20th century.** With the establishment of the Republic of China in 1911, court support for Peking opera by the

couraged. Traditional music was largely retained. During the period of the Great Proletarian Cultural Revolution (1966–1969) most traditional operas ceased to be performed in favour of new works, realistic in style and content, and using, paradoxically, Western musical instrumentation.

The Nationalist government has supported Peking opera on Taiwan since establishing the headquarters of the Republic of China on that island. Troupes of the Air Force and the Army are active, and a private school, Foo Hsing, trains children in Peking opera performance. Local opera, sung in the Taiwanese dialect, is extremely popular in commercial theatres, and approximately 200 itinerant Taiwanese troupes tour glove-puppet plays to towns and villages.

#### KOREA

In addition to folk dances, the main theatrical forms that developed in Korea are ritual court dances, masked dances, and puppet plays. Of these, masked dances and masked-dance plays have perhaps the oldest and richest traditions. Archaeological evidence suggests that masks were used at least by the 3rd century AD to impersonate animal spirits and thereby placate them. Various kinds of masks—demon masks, medicine masks, spirit masks—were worn by shamans as they danced to draw into themselves the spirit being addressed, in order to cure an illness or otherwise affect daily life. Magical properties continued to be associated with masks even after performances ceased to have religious or magical functions and became merely entertainment.

**Three Kingdoms period.** Lack of records makes it impossible to describe accurately dances and dance plays of Korea prior to the period of the Three Kingdoms (c. 57 BC–AD 668). Chinese, Japanese, and Korean accounts beginning in the 7th century give some indication of court arts in the Three Kingdoms of Koguryŏ, Paekche, and Silla. In Koguryŏ, encompassing what is now Manchuria and northern Korea, Central Asian music and dances were combined with local styles of music and dance. Twelve of 24 pieces in the repertory were mask dances. So highly regarded were the arts of Koguryŏ that they made up a separate Korean component of the Nine Departments of Musical Art and Dance at the T'ang court in China (25 musical and dance items were identified as Korean), and from the 7th century they were introduced into Japan, where they became the basis of *bugaku* (court masked dance). The strongly Buddhist state of Paekche in the southwest had been in contact with both China and Japan from early in the Christian Era. Typical of Paekche was a Buddhist masked-dance procession (*kiak*), originating in southern China and taken to Japan in 612 by a resident of Paekche, Mimaji. No Korean account of *kiak* survives, but Japanese accounts make clear that it was performed as a Buddhist ceremonial for evangelical purposes.

**Great Silla period.** The third kingdom, Silla, absorbed Koguryŏ and Paekche in the 7th century, and during the Great or Unified Silla period (668–935) the folk and court performing arts of all parts of Korea intermingled. Several major types of masked dance are mentioned in Silla records. The spirit of a noble youth who died to save his father's throne was memorialized in a masked sword dance (before this time, palace dancing girls had performed sword dances, but always unmasked). Masked dances called "The Five Displays" are mentioned in a Silla poetic composition of the 9th century. They included acrobatics, ball juggling, farcical pantomime (some of it unmasked), shamanistic masked dances, and the lion dance. The similarity of several to Japanese *bugaku* dances has been noted. Others believe "The Five Displays" derive from the "hundred entertainments" of China. Finally, an important dance play honouring Ozoyong, the son of the Dragon God of the Eastern Sea, dates from this period. Ozoyong showed such generosity toward the spirit of plagues that henceforth the spirit promised never to enter a household where a portrait of Ozoyong was hung. Originally derived from animistic beliefs, the dance was modified by Buddhism and was de-

veloped in the Yi dynasty (1392–1910) into a spectacular dance play, performed by a cast of five masked dancers, 16 unmasked dancing girls, and accompanied by an ensemble of 37 musicians.

**Koryŏ period.** The two major court festivals at which performances were held during the Koryŏ period (935–1392) were Buddha's birthday, or the Feast of Lanterns, in the second lunar month, and the midwinter ceremony honouring spirits of local gods. Dances and masked plays from Silla times were carefully preserved and performed on these occasions in a specially decorated and candle-lit ceremonial room. New masked plays memorializing loyal warriors who had died in battle were added from the 10th century. Buddha was offered gifts of wine and food, and performance was dedicated to maintaining a reign of peace and harmony. From the time of King Mun Jong (1047–83), T'ang style dances and sung dramas were performed on other occasions; modified by Korean forms, they became part of Korean court dance in centuries following. Folk dances and plays undoubtedly go back many centuries before this; in the Koryŏ period, professional troupes also became part of urban life. The practice of court performers holding civil-service jobs in the major cities and in provincial towns probably accounts for the fact that knowledge of court performing arts began to reach beyond the confines of the court during this time. Popular troupes began the process of secularizing religious masked dances (such as the *narye*, which formerly was performed to exorcise evil). They performed acrobatics and shows of skill and at least by the 12th century were staging satirical dialogue plays (masked and unmasked), which held officialdom up to ridicule. (The development of social satire is found in many Asian drama forms: the Vidusaka jester in Sanskrit drama, the god-clown-servants of Indonesian *wayang* shadow plays, and the servants of *kyōgen* comedies in Japan are major roles in these forms.)

**Yi and modern periods.** Buddhism was rejected as a state religion by the Yi dynasty (1392–1910), with the result that court entertainments were no longer scheduled according to Buddhist days of worship but at any time court entertainment was required. A Chinese envoy to the Yi court in 1488 described court performances that included: the *ozoyong* dragon-god dance play, children's

Satirical theatre

The dance play honouring Ozoyong

dancing, acrobats, ropewalking, and displays of animal puppets. Following invasions by the Japanese (1592) and by the Manchus (1636), court support declined. Former palace performers formed professional troupes, in the process adapting court forms to popular tastes. These performers included all the miscellaneous stage arts in their repertory and created from the various court dances and masked plays a type of folk masked play usually termed *sandae togam kūk*. A prominent feature was the satirical treatment of depraved Buddhist monks and of grasping officials (naturally, favourite themes for a popular audience). Satirical plays were occasionally performed at court as well, but the banishment in 1504 of an actor for ridiculing the institution of kingship in a court play suggests satire was not welcomed.

In addition to professional groups, villagers in different areas of the country formed folk groups to perform their own local versions of the *sandae* masked play and dances. Today, the *sandae* masked play is performed by villagers in Yangju, in Pongsan in northern Korea, and in South

Kyōngsang. Performers are males. Masks cover either the whole head or the face and are made from paper or gourds or, occasionally, are carved from wood. They are simply, even crudely, painted to represent the stock characters of the play: monks, shaman, noblemen, young dancing girl, and others. There may be 20 or 30 masks used; often they are burned and made anew each year to insure their ritual purity. Performance encompasses singing, dancing, pantomime, and dialogue. The stories enacted vary with the village, but common scenes include offerings to the gods, criticism of venial Buddhist priests, exposure of corruption by gentry and officials, flirtation, and a funeral service that brings absolution. Performances may be given as a rainmaking rite.

The origin of puppet plays in Korea has not been determined; however, in the Koryō period puppet plays were widely performed and very popular among the people. Several types of puppet play developed in Korea. The folk puppet play "Khoktu Khaksi," named after the wife of the main character, is still performed in the summer months in southern Korea by farmers in troupes of six or seven players and musicians. Twelve or 15 puppets make a set (compared to more than a hundred in Indonesian or Japanese puppet theatre); they are simply made glove and stick figures that can be manipulated by a single puppeteer. One play, with variations, is performed. It consists of eight relatively independent scenes that satirize a figure of the gentry who is the major character. Scenes satirizing depraved monks and insulting the gentry, a domestic triangle, and Buddhist prayers for the dead appear to be adapted from masked plays.

*Gu gug* (literally "old plays") became popular around the middle of the 19th century. They were dramatic songs, danced to gestures and simple group movements. Troupes played throughout the countryside and in the new National Theatre, built in Seoul by the government in 1902. Until the 1930s, variety programs of *gu gug* and female court dances were popular entertainments at commercial theatres in the city. Sentimental melodramas, called "new school," or *shimpa*, plays (the same name as in Japan), were performed by a dozen troupes that formed and disbanded between 1908 and around 1930. The new school movement was begun by the novelist In-zig Yi. Other major figures had learned the style while studying in Japan. In 1931 the actor He-seng Hong and others organized the first drama and cinema exhibition in Korea; the following year its organizers formed the Society for Research in Dramatic Art, which studied and staged translations of modern European plays. Its members were primarily teachers and students of foreign languages and literature concerned with bringing Western *sin gug* ("new drama") into Korea. By 1940 about 100 amateur new drama groups had come into being.

**Since World War II.** In Korea, after 1940, all dramatic groups were obliged to belong to the Japanese-organized Dramatic Association of Korea. Many groups survived the war with Japan by touring small towns and villages. Performances lagged immediately after World War II because of unsettled conditions. A National Theatre was established in Seoul just before the Korean War began; national support included subsidies for performances. The destruction of the war has never been wholly repaired in the performing arts, for although the National Theatre was reinstituted in 1953, its operation has not grown as originally planned.

In addition to the National Theatre established by the South Korean government, a Drama Center devoted to training in modern drama was founded in Seoul in 1962 with private support. During the 1960s historical plays derived from "old plays" and girls' operetta, using traditional music and dance styles, were performed to large audiences in Seoul. Folk dances and puppet plays are declining in number in Korean villages, as a result of rapid urbanization and the spread of motion pictures. In Seoul, motion pictures and television had largely replaced dance plays in the theatres by 1970.

Like the Chinese Communists, the North Koreans have made an effort to encourage and support ideologically desirable dance and theatre forms, especially folk forms.

#### JAPAN

Among the most varied and technically complex theatre arts in Asia are those of Japan. While dance remained predominant over drama in Korea and singing is perhaps the most important single element of Chinese performance, in Japan music and dance gradually evolved into highly developed dramatic and theatrical forms, the most important of which are Nō dance drama, popular Kabuki theatre, and *bunraku* puppet drama.

**Formative period.** From prehistoric times, dances have served as an intermediary between man and the gods in Japan. *Kagura* dances dedicated to native deities and performed at the imperial court or in villages before local Shinto shrines are in essence a symbolic re-enactment of the propitiatory dance that lured the Sun Goddess from the cave in ancient myth. Though *kagura* dance has been influenced by later more sophisticated dance forms, it is still performed much as it was 1,500 years ago, to religious chants accompanied by drums, brass gongs, and flutes. At the same time, villagers had their rice-planting dances, performed either at New Year's as a prayer for good planting or during the planting season in early summer. These lively dances were later, in the 14th century, brought to the cities and performed as court entertainment and called *dengaku* ("field music").

**7th to 16th centuries.** A massive influx into Japan of Chinese and Korean arts and culture occurred between the 6th and the 10th centuries. It has been noted that a Korean performer, *Mimaji* (Mimashi in Japanese),

The *gigaku* processional dance play

brought the Buddhist *gigaku* processional dance play to the Japanese court in 612. The current regent to the throne, Prince Shōtoku, was a devout Buddhist who gave Mimashi a place at the court so that he could establish an official school to train Japanese dancers and musicians in *gigaku*. Other Korean and Chinese performers from Paekche and Koguryō were invited in following years. *Gigaku* masks cover the entire head (as do Korean folk masks today). Carved of wood and painted with lacquer, the 223 masks that remain (most in the Shōsō-in, or imperial storehouse, in Nara) date back as early as the 7th century. They are superb examples of the art of mask making. Strong featured and beautifully conceived. From a description of a 13th-century performance, *gigaku* apparently consisted of a succession of scenes enacted as characters passed by. Masks characterized an Aryan-featured dignitary called Baramon (or Brahman, indicating Indian origin), a fierce wrestler, a Buddhist monk, a princess of the state of Wu in China, a bully, a wistful old man, and others. Some scenes were serious, others were earthy slapstick.

*Bugaku* court dances introduced from Korea were also patronized by Prince Shōtoku. They supplanted *gigaku* as official court entertainment, and *gigaku* disappeared as a performing art by the 12th century. It was the custom to have performers of *bugaku* enter from dressing rooms to the right and the left of the raised platform stage: "right" dances, costumed in orange or red, were those from India, Central Asia, or China proper; "left" dances, costumed in blue-green, were those from Korea and Manchuria. *Bugaku* is performed by groups of four, six, or eight male dancers who move in deliberate, stately steps, repeating movements in the four cardinal direc-

Performance of *bugaku* court dances

tions. Musical accompaniment is by drums, bells, flute, and *shō* (panpipe). A composition consists of three sections, introduction, development, and conclusion or "scattering" (*jo-ha-kyū*). Japanese performers and courtiers created new compositions within the old style in the 10th and 11th centuries. Still, *bugaku* represents a remarkable preservation of ancient Chinese, Indian, and Korean music and dance that has long since disappeared in their country of origin. *Bugaku* has been performed by musicians attached to the imperial court and to major Shinto shrines from the 7th century without break to the present day.

Juggling, acrobatics, ropewalking, buffoonery, and puppetry—the "hundred entertainments" of China and called *sangaku*, "variety arts," in Japan—became widely popular as well. During the Heian period (794–1185) professional troupes, ostensibly attached to temples and shrines to draw crowds for festival days, combined these lively stage arts, now called *sarugaku*, with dancing to drums from *dengaku*, and began to perform short plays consisting of alternate sections of dialogue, mimicry, singing, and dancing. Sometime in the 14th century a *sarugaku* actor from Nara named Kan-ami Kiyotsugu

incorporated in his plays a chanted dance (*kuse-mai* or *kdwaka-mai*), for the first time creating the possibility of dramatic dance that could carry forward a story. This fusion of dance, drama, and song, which soon came to be known as *sarugaku* Nd, or simply *Nō*, marked a revolutionary advance in Japanese theatrical art. Kan-ami's son, Zeami Motokiyo, refined the style of performance, composed 50 or more of the finest *Nō* plays in the repertory, and wrote treatises on the art of acting and drama—turg that have not been surpassed in his country.

When Zeami was 11, the military ruler of Japan, the shogun Yoshimitsu, saw him perform, became enamoured of the boy's beauty, and took him into his residence in Kyōto as a companion. For most of his life, Zeami benefitted from the patronage and the refined audiences that stemmed from this circumstance. The *sarugaku* troupe that Kan-ami and later, Zeami, headed was one of four in Nara; the others soon adopted the changes in performing style and the plays created by father and son. Through Zeami's lifetime, *dengaku* troupes continued to be potent rivals for patronage of the warrior class (indeed for a time, Zeami lost favour at court to the *dengaku* actor Zoami). The artistic superiority of *Nō* was such, however, that by Zeami's death *dengaku* had ceased to be important and gradually died out.

The borrowings of *Nō* from other arts are many. The exquisite masks for which *Nō* theatre is famous have a quality of serenity, a neutrality of expression that places them in a rank perhaps unmatched in the world. Yet, historically there is no doubt that they are derived from earlier *bugaku* and *gigaku* masks and hence are related, if distantly, to the masks of Korea, China, and India. One evidence of the special development of *Nō* masks is that they are smaller than previous masks; they cover only the face proper. From *bugaku* music, Zeami took the three-part structure of the *Nō* drama. Each individual play, therefore, is divided into three sections. A normal *Nō* program consists of five plays, which are grouped into three dramatic units: the introduction, the development, and the conclusion. The first play, a "god" play, comprises the introduction; the development section includes three plays—the second drama or "warrior" play is the introduction of the development; the third, or "woman," play is the development of the development; the fourth, or "living person," play is the conclusion of the development; and the fifth, or "demon," play is the conclusion. Drums and flute were taken over from earlier musical forms, and *Nō* chanting is based on the style of Buddhist prayer chants. The songs' poetic meter of alternating phrases of seven and five syllables had come from China six centuries earlier and was the standard Japanese poetic form. On the other hand the *Nō* stage represents an advance on the simple square platform of *bugaku*. A sharply peaked roof over the stage is supported by four pillars—to help the performer orient himself as he looks out through tiny eye holes in the mask—and a long ramp, *hashigakari*, emphasizes the appearance and the departure of major characters.

Typical of a number of *Nō* plays that are dramatizations of Chinese history and legends is the 15th-century *Yōkihi*, by Komparu Zenchiku, based on an ancient narrative poem ("The Song of Everlasting Sorrow") by Po Chū-i. The original describes Emperor Ming Huang's love for Yang Kuei-fei (Yōkihi in Japanese), which led to the eventual destruction of his realm; the *Nō* play emphasizes the Buddhist sentiment of the evanescence of mortal life and the inevitability of pain and sadness. In the major scene of the play the ghost of Yang Kuei-fei returns to mourn her parting from the Emperor. Every *Nō* play contains Chinese poems, quoted verbatim or paraphrased so as to appeal to the educated spectator. It was a first principle of dramatic writing, said Zeami, to base a play on a well-known incident the central character of which the audience would find readily familiar. Zeami's plays emphasized the quality of restrained beauty (*yūgen*), a concept derived in part from Zen Buddhism. Later plays, especially those by Kanze Nobumitsu (died 1516), such as "The Maple Viewing" and "The Ataka Barrier," emphasize action and spectacle (*fūryū*).

*Nō* theatre

### The kyōgen farce comedy

On the usual Nō program, each play was followed by a kyōgen farce comedy, performed not by the chief (*shite*) or supporting (*waki*) actors of Nō but by kyōgen actors who also acted the roles of villagers or fishermen in Nō plays. The antecedents of *kyōgen* cannot be described with certainty, but it is probable that *kyōgen's* short sketches of master-servant quarrels, husband and wife arguments, animal fables, and scenes of rustic life derive from early *sangaku* entertainments. A few kyōgen plays are accompanied by the drums and flute of Nō. The ritual play *ōkina*, performed as an auspicious prayer for longevity at the beginning of a Nō-*kyōgen* program, is in both repertoires, and some suggest that the kyōgen version is the older. The style of *kyōgen* music (*komai*) is distinct from that of Nō music; it is derived directly from popular songs. *Kyōgen* plays with music are, however, a rarity. The usual play is a straight dialogue drama, making it perhaps the oldest developed form of nonmusical play in East Asia. Dialogue is composed in colloquial language of the 15th century, in short phrases suitable for comedy. Movement is highly stylized, again for comic effect. Masks may be worn for the roles of animals and demons, but most roles are played unmasked. *Kyōgen* texts do not seem to have been committed to writing until the 16th century, suggesting that actors traditionally ad-libbed their parts. Today, kyōgen actors commit lines to memory.

**Momoyama period.** Nō and kyōgen were dance and theatre forms that had come to express the gravity and decorum of a rigidly formal samurai ruling class by the end of the Momoyama period (1568–1600). Artistically severe and highly disciplined, Nō was imbued with the sternly pessimistic philosophy of Buddhism. In content, Nō plays taught the folly of worldly power and position, that time destroys all living things. The heroes of play after play pray for Amida Buddha's divine intercession in order that they, tormented ghosts of dead warriors and court ladies, may break free of earthly attachments to achieve salvation. In contrast to this, commoners of the cities in the late 16th century began to perform their own radically different dances and plays that were up-to-date, lively, exciting, and at times morally licentious. They were intended to appeal to literate townsmen, well-to-do wives of merchants, workers, and the fops and wits and dandies of the burgeoning cities.

**Edo period.** During the Edo period (1603–1867) Nō was assiduously cultivated by warriors (samurai) as a refined accomplishment. Following the shogun's example, Nō troupes were patronized by provincial lords throughout the country. Actors received minor samurai status.

*Sarugaku* had been a popular art in its beginning, an entertainment for townsmen and villagers at temple and shrine festivals. Even after Zeami had become a court favourite, Kan-ami continued to tour small temples in the countryside with his troupe. But, during the Edo period, commoners were forbidden by law to study Nō and were excluded from performances except on special "subscription" occasions, when any person, high or low in rank, could see Nō performed outdoors in a large enclosure. Nō became the exclusive theatre art of the warrior class, while *bugaku* continued as the chief performing art of the imperial court.

The earliest important urban entertainments of the commoner in Japan were secularized forms of Buddhist dance plays (*ennen*) and folk dances (*yayako odori* and *kaka odori*) that came to be called *fūryū* ("drifting on the wind") dances. They were enormously popular. In 1604 in the capital city of Kyoto, five teams of 100 dancers each participated in a mass *fūryū* dance commemorating the death of the ruler. The frenzied *fūryū* dancing of

Origin of  
Kabuki

100 men and 150 women earlier in 1567 had broken the boards of the dance platform.

In 1603 several kinds of urban dances were arranged into a new dance, called Kabuki, by a young woman named Okuni. Other troupes of female performers, actually prostitute-performers, adopted the sensuous and popular style of Okuni's Kabuki dance. A scroll of the period shows Okuni as a young, fashionably dressed samurai, indolently leaning on a sword, dallying with a teahouse girl. Around her neck hangs a Christian crucifix, not as a religious article but as an exotic decoration recently introduced by "southern barbarian" Portuguese merchants. Other pictures of the time show young women playing the three-stringed samisen as they recline sensuously on tiger skins, dancing girls circling about them. Audiences of monks, warriors, young lovers, and townsmen gaze raptly at this appealing and even bizarre sight. The original sensuous appeal of women's Kabuki continued long after women were banned from the stage in 1629. From around Okuni's time until 1652 troupes of young boys, actually professional sodomites, performed graceful Kabuki dances to samisen music to attract customers. The appearance of professional women and boy performers in Kabuki was a phenomenon of urban society. In the past, men alone had performed *gigaku*, *bugaku*, *Nd*, and *kyōgen*. Court nobles and samurai lords had always been able to take mistresses in any number they wished; now the commoner and townsman could, with his new wealth, purchase the favour of a newly risen class of women whose role was to cater to their desires. In the same way, taking young boys as sexual companions, which was common practice among the Buddhist clergy and the warrior class (Zeami, for example, was the shōgun's catamite), becomes a feature of Japanese urban life now as well.

Only in 1653, when the authorities required Kabuki to be performed by adult males, did Kabuki begin to develop as a serious art. During the Genroku era (1688–c. 1703), most of Kabuki's essential characteristics became established. Large, commercial theatre buildings holding several thousand spectators were constructed in the three major cities—Edo (Tokyo), Kyōto, and Osaka. The stage, which previously had been simply a copy of the Nō stage, became wider, deeper, and was equipped with a draw curtain to separate acts; and in the early 1700s a ramp (*hanamichi*) was constructed from the rear of the auditorium to the stage for actors' entrances and exits. The idea of the rampway came from the Nō *hashigakari*, but in typical Kabuki fashion, it was transformed into an infinitely more theatrical device. From the puppet theatre Kabuki borrowed the use of fairly elaborate scenery, the revolving stage (100 years before its use in Europe), traps, and lifts. To the old Nō drums and flute were added the new samisen, a large drum, a dozen bells, cymbals, gongs, and two types of wooden clappers, making the resulting music flexible and varied.

Nō and *kyōgen* plays were often performed as Kabuki in the early decades. A print of approximately 1670 shows Kabuki actors performing "The Sumida River," with costumes and properties modelled closely on the Nō original. But it was not considered proper for "beggars of the riverbed," as Kabuki actors were called, to stage the art which had become the exclusive privilege of the warrior class. By Genroku times, new Kabuki dramatic styles had emerged. The actor Sakata Tōjūrō (died 1709) developed a relatively realistic, gentle style of acting (*wagoto*) for erotic love stories in Kyōto, while in Edo, a stylized, bravura style of acting (*aragoto*) was created at almost the same time by the actor Ichikawa Danjūrō I (died 1704) for bombastic fighting plays. In the play "Sukeroku: Flower of Edo" written by Tsūuchi Jihē in 1713, the two styles are blended most successfully. The hero, Sukeroku, is a swaggering young dandy and lover acted largely in the Edo style, while Sukeroku's brother, Shinbei, is a meek, gently comic foil in the Kyōto style. Genroku period Kabuki plays are lusty and active and contain much verbal and physical humour.

Kabuki theatres were required to be built in special entertainment quarters (similar to and often near licensed

quarters for prostitution ordered established by the government at about the same time). Side by side in these entertainment quarters were puppet theatres. Puppets, imported from Korea centuries earlier, were fused with epic storytelling and the resulting narrated play accompanied by samisen music sometime before 1600. The earliest tales were about the Princess Jōruri (hence, *jōruri* as another name for puppet plays). This and other legends were in the nature of Buddhist miracle stories, the obligatory scene being one in which Buddha sacrifices himself or otherwise brings to life one of the main characters. Simple doll puppets, held overhead by one man, animated these blood and thunder *kojōruri* ("old *jōruri*") puppet plays.

A new style of puppet play was created in 1686 by the writer Chikamatsu Monzaemon (died 1724) and the chanter Takemoto Gidayū at the Takemoto Puppet Theatre in Osaka, the city which was and continued to be the home of puppet theatre in Japan. Chikamatsu went on to become Japan's most famous playwright. Although he is best known for his puppet plays, he wrote Kabuki plays as well, most of them for Sakata Tōjūrō. From Tōjūrō, Chikamatsu learned the soft style of Kabuki performance and the situation that is so unique to early Kabuki, in which a comic lover visits a courtesan in the licensed quarter and quarrels with her. Between "Love Suicides at Sonezaki," written in 1703, and "Love Suicides at Amijima," written in 1721 three years before his death, Chikamatsu composed a dozen domestic tragedies handling the theme of lovers' suicide. As early as 1678 Kabuki plays were dramatizing current city scandals, lovers' suicides, murders, and tragic deaths. One of the most characteristic features of Kabuki was its contemporaneous dramatic subject matter; puppet drama was much changed when Chikamatsu brought this quality from Kabuki into his puppet plays.

In the 1720s and 1730s puppet plays gradually became more dramatic and less narrative under the influence of Kabuki. A revolutionary three-man puppet was created in which mouth, eyes, eyebrows, and fingers could move, encouraging writers to compose dramatic plays calling for complex emotional expression. A theatre manager and writer, Takeda Izumo (died 1756), collaborated with several other authors on all-day history plays, the so-called "Three Great Masterpieces" of puppet drama: "The House of Sugawara," "Yoshitsune and the Thousand Cherry Trees," and "Chushingara: The Treasury of Loyal Retainers." "Chushingara," the best loved and most often performed drama ever written in Japan, typifies mature puppet drama. It is based on an actual event that occurred in 1703: 47 retainers killed the enemy of their lord and were then sentenced to commit suicide by disembowelment (*seppuku*, or less properly, *harakiri*). The first four acts of the 11-act play dramatize the events leading up to the death of their lord; in the remaining acts the unswerving loyalty of a number of retainers is shown, which culminates in the 11th-act nighttime vendetta. The major scenes of Hangan's and Kampei's suicides are intensely emotional scenes of self-sacrifice. These scenes normally occur as the final section of the third act in a five-act history play and are called *sewa* ("family") scenes because, although the figures are samurai, tearful family separation is the emphasis of the scene. "Chronicle of the Battle of Ichinotani" contains a *migawari* ("child substitution") scene, typical of puppet history plays, which is, if anything, even more tear provoking: in response to the wishes of his lord Yoshitsune, General Kumagai slays his own son, so that the son's head may be substituted for that of a prince who has been condemned to die. Although the emotionalism and lack of humour of these puppet plays were foreign to Kabuki, they were so popular with audiences that they were adopted with little change to Kabuki. Today, the best puppet plays are equally a part of the Kabuki and puppet theatre repertoires.

Few new puppet plays were added to the repertory after 1800 and in Osaka and Kyōto few Kabuki plays were being written. During the 19th century the most important Kabuki dramas were written in Edo, by Tsuruya

plays

Bunraku, a scene from the comedy "Fishing for a Wife," a puppet performance of a Kabuki dance version of the kyōgen original play. Chief puppeteers wear conventional dress, minor puppeteers wear black. Pine-and-plank scenery indicates the Nō-kyōgen origin of the play.  
Hirosh Kaneko

Namboku and Kawatake Mokuami. They wrote all the standard types of Kabuki play—*sewantono* (domestic), *jidaïmono* (history), and *shosagoto* (dance plays)—in large numbers; each wrote between 150 and 200 plays in his professional career. They were wholly products of Edo's urban culture. They spent their lives in the Kabuki theatre as writers. Although neither was formally educated, their plays reflect with great discernment the desperate social conditions that prevailed as the feudal system in Japan neared its collapse. Thieves, whores, murderers, pimps, and ruthless masterless samurai are major figures in a new type of play, *kizewamono*, or the raw domestic play, which Namboku created and Mokuami developed. They wrote for the talents of star actors: Namboku wrote for the finest *onnagata* (female impersonator) of his time, Iwai Hanshirō V, and Mokuami wrote for Ichikawa Danjūrō VII and a remarkable actor of gangster roles, Ichikawa Kodanji IV. Each was a master of Kabuki art, and between them they added new dimensions to Kabuki's stylized form. Namboku created rhythmic dialogue composed in phrases of seven and five syllables; Mokuami used puppet-style music to heighten the pathos of certain scenes and wrote elaborately conceived major speeches which required exceptional elocutionary skill on the part of the actor.

**Meiji period.** Nō, puppet theatre, and Kabuki were affected in differing degrees by the abolition of feudalism in 1867. At a stroke, the samurai class was eliminated and Nō lost its base of economic support. Important actors retired to the country to eke out a living as menial workers. For several years Nō was not performed at all, except that Umewaka Minoru, a minor actor, gave public performances in his home and elsewhere between 1868 and 1876. In 1881 a public stage was built in Shiba Park, Tokyo, for performances sponsored by the newly formed Nō Society and by its successor, the Nō Association. The most influential supporter of Nō during the Meiji period (1868–1912) was the aristocrat Iwakura Tomomi. The study of Nō came to be a highly regarded activity among the middle classes, and in time each of the five Nō schools (Kanze, Hōshō, Komparu, Kongō, and Kita) became financially stable, sponsoring their own performances and building their own theatres in the major cities.

The end of feudal society forced Nō to seek and cultivate a new audience; the popular audience of Kabuki and the puppet theatre, however, continued with little change during the Meiji period. Kabuki audiences remained large and loyal, but audiences for puppet plays continued to decline as they had for the previous hundred years. There was a brief revival of interest in Osaka puppet drama in the 1870s under the impetus of the theatre manager Bunrakuken (the popular term for puppet drama, *bunraku*, dates from this time). Learning to chant puppet texts became a vogue during the late Meiji period.

Still, commercial theatres did not prosper. In 1909 the Shōchiku theatrical combine supported performances at the Bunraku Puppet Theatre in Osaka, but by 1914 this was the only commercial puppet house remaining.

As they always had, Kabuki writers and actors of the Meiji period tried to place current events on the stage. Thus, the actor Onoe Kikugorō V began acting in a series of contemporary plays, dressed in daily kimono or Western clothes and with his hair cut Western fashion (the origin of *zangirimono*, or the so-called "cropped-hair plays"), in the last decades of the 19th century. Western influence was also seen in theatre construction, with the first European style theatre built for Kabuki in Tokyo in 1878. Released from previous government restrictions, Kabuki artists created dance dramas from the Nō plays "The Ataka Barrier," "The Maple Viewing," and others, in which the elevated tone of the Nō original was purposely retained. Kabuki attendance was more than a million spectators yearly. But in spite of prosperity and seeming adaptation to new conditions, by the early decades of the 20th century, new artistic creation in Kabuki reached an end, and henceforth Kabuki would be restricted almost as much as *bunraku* and Nō to a classic repertory of plays.

Scholars and artists, learning of Western drama, organized successive groups designed to reform Kabuki—that is, to eliminate excessive stylization and to press for a more realistic manner of performance. The actor Ichikawa Danjūrō IX acted in historically accurate (and reportedly dull) *katsureki* geki ("living history" plays) written by the journalist Fukuchi Ōchi. Three *shin* Kabuki ("new Kabuki" plays) written by the scholar Tsubouchi Shōyō were influenced by Shakespeare, whose plays Tsubouchi was then translating. In 1908 a young actor, Ichikawa Sadanji II, returned from a year's study and observation in Europe. These and other influences produced few long-lasting changes in Kabuki, but they did set the stage for the creation of new kinds of drama that would depart radically from traditional forms.

The first plays in Japan consciously based on Western models were those arranged and acted in by Kawakami Otojirō. Kawakami's first plays were political and nationalistic in intent. After performing in Europe and America (1899 and 1902), he introduced to Japan productions of Shakespeare, Maurice Maeterlinck, and Victorien Sardou. Most of these "new school," or *shimpa* plays, however, were little more than crude melodramas. Actresses performing in *shimpa* marked the first time women had appeared on the professional stage since Okuni's time. One *shimpa* troupe continues to perform today, in a style which retains turn-of-the-century sentiment and mannerisms.

In 1906 the Literary Society was established by Tsubouchi Shōyō to train young actors in Western realistic acting, thus beginning the serious study of Western drama.

Contributions of Kawakami

Among the "new drama," or *shingeki*, groups devoted to studying and performing the works of such 19th-century European playwrights as Henrik Ibsen, George Bernard Shaw, Anton Chekhov, Leo Tolstoy, and Gerhart Hauptmann, were: the Art Theatre, founded by a Tsubouchi disciple, Shimamura Hdgetsu; The Free Theatre, modelled by Osanai Kaoru on the various Free Theatres of Europe; and The Stage Association. By the 1920s these groups had dissolved and others had taken their places. The major *shingeki* group after World War I was the Tsukiji Little Theatre. The members of *shingeki* troupes were earnest amateurs working for the day their efforts might raise their troupe to a level of professional excellence and financial independence.

**Since World War II.** In Japan during World War II Nō continued to be performed occasionally, Kabuki was limited to short daytime programs, while the majority of modern drama groups, pacifist or leftist, were forced to cease performing or to abandon politics. During the first three years of the American occupation (1945–1948) traditional theatre was censored; important Kabuki and *bunraku* classics, such as "The Subscription List" and "Chushingura," were banned. Modern drama, on the other hand, was encouraged as being democratic in spirit. The disillusionment of Japanese youth with wartime policies that had led to their country's defeat and occupation found fervent expression in postwar *shingeki* drama. Old groups were revitalized and scores of new groups sprang up. The Min-gei-za, or People's Art Theatre, staged plays strongly attacking militarism, including American action during the Korean War. The Bungaku-za, or Art Theatre, continued its prewar policy of producing translations of Western classics and new Japanese plays. The Haiyu-za, or Actors' Theatre, built its own theatre and established a dramatic school that became a training ground for a new generation of actors, directors, and writers. The resurgence of modern spoken drama peaked in the early 1960s.

Avant-garde theatre groups have sprung up since the 1960s that perform happenings, multimedia presentations, and extemporaneous living theatre in any type of situation, from tiny cabaret rooms to travelling tent shows. The plays of established *shingeki* playwrights (Tanaka Chikao, Kinoshita Junji, Morimoto Kaoru, Iizawa Tadasu) are criticized by these young groups as being too Western-influenced and excessively literary. In another direction, highly acclaimed novelists Mishima Yukio and Ariyoshi Sawako have written plays consciously designed to appeal to an audience wider than the small group of intelligentsia traditionally associated with *shingeki*. Western ballet, modern dance, and opera may be seen in the same theatres that stage, at other times, popular sword-fighting plays (*shinkokugeki*), domestic comedies (*shinkigeki*), or all-girl operettas and revues (best known as *takarazuka*). Theatre plants are among the best equipped in the world.

The effects of modernization on performing arts in 20th-century Japan have been great. In the 1950s the country's motion-picture industry became the second largest in the world. Yet, in a decade it was being displaced by television, which soon reached the most isolated hamlets. The largest audiences today are those of the mass media; live dance and theatre, though still widespread, have seen their audiences decline.

In the traditional performing arts, professional Kabuki troupes perform under commercial Shdchiku sponsorship, and at the new National Theatre of Japan in Tokyo (since 1966); a single *bunraku* puppet troupe subsidized by the government performs to small audiences in major cities; Nō is avidly studied by thousands of amateurs, and frequent performances (in the form of recitals) can be seen in major cities; numerous schools teach Kabuki dance (*nihon buyō*) as an artistic accomplishment; musicians and dancers of the imperial *bugaku* group now give public performances each year at the National Theatre of Japan.

## Dandolo, Enrico

Enrico Dandolo, who was doge of the Republic of Venice from 1192 to 1205 and whose long and active life covered almost the whole of the 12th century, is remembered chiefly for his promotion of the Fourth Crusade, which led to the overthrow of the Greek Byzantine Empire and the aggrandizement of Venice.

Dandolo was born in Venice, probably in 1107. His father, Vitale, had held important public positions. During Enrico Dandolo's public life he was sent on many important missions for the Venetian government. He accompanied the doge Vitale II Michiel on an expedition to Constantinople in 1171. The following year, with the Byzantine ambassador, he went again to Constantinople, where, according to one account, he was so assiduous in defending the interests of the Venetians that the Emperor had him blinded. Later he was to be known as the blind doge. But the chronicler Geoffroi de Villehardouin, who wrote the history of the Fourth Crusade and knew Enrico Dandolo personally, stated merely that he did not see well because of an injury to his head. After his diplomatic mission to Constantinople, Dandolo went as ambassador to the King of Sicily (1174) and then to Ferrara (1191). When the doge Orto Mastropiero retired to a monastery, Dandolo was elected doge on June 1, 1192, at the age of 85.

In one of his first actions as doge, he swore the "ducal promise," spelling out the rights and duties of the office of doge. Dandolo also revised the penal code and published the first collection of civil statutes, setting the customary law of Venice on a firm juridical basis. He also revised the coinage, issuing a silver coin called the *grosso*, or *matapan*. This began a wide-ranging economic policy intended to promote trade with the East. Dandolo's image appears on the *grosso* coin; he is wearing a cloak and holding the "ducal promise" in his left hand and the gonfalon (banner) of St. Mark's in his right.

His constitutional and legal reforms

He also concluded treaties with Verona and Treviso (1192), with the Patriarch of Aquileia (1200), with the King of Armenia (1201), and with the Byzantine Empire (1199) and the Holy Roman Emperor (1201). He fought a victorious war against the Pisans in 1199.

But the prominent place Enrico Dandolo occupies in history must be attributed to the part he played in the Fourth Crusade: the arrangements made with the French barons for the transportation of their army; his provision of funds in exchange for their assistance in conquering Zara (Zadar), a Christian town on the Dalmatian coast then held by the King of Hungary; and his success in persuading the crusaders to help the Venetians conquer Constantinople. The personality of the doge stands out vividly in the accounts of the chroniclers. Although quite old, he was always found in the front line. At the assault of Constantinople he stood in the bow of his galley, completely armed and with the gonfalon of St. Mark's in front of him, encouraging his men as they made their landing.

Expansion  
of the  
Venetian  
Empire

After the capture of Constantinople, Dandolo took for himself and the doges of Venice the title "lord of the fourth part and a half of the whole empire of Romania." The title corresponded exactly to that part of the territories of the Byzantine Empire apportioned to the Venetians in the division of spoils among the crusaders. Since he had been one of the most powerful leaders of the expedition, Dandolo remained in Constantinople to direct all the operations there and also to look out for the interests of Venice. It is said that he had some valuable marble shipped to his son Renier for the construction of the great palace of the Dandolos on the Grand Canal. Ruins of a building in Moorish style and an ancient column of green marble were discovered in an excavation performed during the 19th century in the San Luca section of Venice, where the Dandolo palace had been located.

Dandolo died in Constantinople in 1205, at the end of May or the beginning of June. He was buried in the vestibule of the church of Santa Sophia in a marble tomb, on top of which was sculptured the doge's cap and the coat of arms of St. Mark's. The tomb was probably destroyed when Santa Sophia was converted to a mosque after the conquest by the Turks in 1453.

When Dandolo became doge, the Venetian republic faced considerable problems both internally and abroad. He resolved the internal problems by giving Venice an advanced civil code and constitutional system. In his pursuit of Venetian interests in the Adriatic and in the East, he was able, through shrewd commercial transactions, to acquire large territorial possessions. His burial at Constantinople was symbolic of that city's importance in the rise of Venice to wealth and power.

## Dante

The greatest poet of Italy, generally acclaimed with Shakespeare and Goethe as one of the three universal geniuses of western European literature, Dante Alighieri was also a prose writer, rhetorician, theorist of his own Italian vernacular literature, moral philosopher, and political thinker, with an immense variety of literary output. The loftiness of his art and the breadth and depth of his interests make him one of the most important figures of medieval and Romance literature. By writing his masterpiece *La divina commedia*, or *The Divine Comedy*, in Italian rather than in Latin he influenced decisively the evolution of European literature away from its origins in Latin culture and toward the expression of a new civilization. The poem itself is the greatest Christian poem. It is a profound vision of the medieval Christian world in terms of the principal problems with which it was most interested: man's moral "obligation to be"; the relationship between reason and faith; the value of learning and poetry as the means of understanding the supernatural; the reaching of the metaphysical through analysis of reality; and the understanding of the Christian revelation through theological study. But the choice of the vernacular Italian language, as opposed to Latin, as the means of

communication and the wide range of styles employed mark a precise turning point in Italian literature in its earliest development. In addition to *The Divine Comedy*, the remaining works of Dante hold an important place in the history of Italian literature and make their essential contribution to the formation of a literary awareness and tradition, establishing new literary forms and new aims of thought and influencing his successors the poet Petrarch and the prose writer Boccaccio in the 14th century.

Alinari—Mansell

"Dante and His Work" by Domenico di Michelino, 1465. In Florence Cathedral.

**Family and early years.** Along with his early biographers and a few surviving documents, Dante, or Durante, Alighieri himself is the source of much biographical data about his noble ancestry and its origins and about the circumstances of his own birth and its date, which fell under the constellation of Gemini (between May 15 and June 15), 1265, in Florence; this biographical fact and many of those which follow are given, in particular, in passages in *The Divine Comedy*, in *La vita nuova*, and in *Il convivio*. He was the great-great-grandson of Cacciaguida, who was born at the end of the 11th century, within the "ancient boundaries" of Florence, was knighted by Conrad III, and died in the Second Crusade of 1147. In the *Paradiso* Dante traced his ancestry as far back as the legendary Roman origins of his city. His was a family of ancient urban nobility. His kin were not wealthy country landowners, although they did possess a few modest properties in the immediate outskirts of Florence. They were active instead in the economic life of the Florentine commune, or community—which was founded on trade and industry. Bellincione, Dante's grandfather, was a moneylender in Florence and in nearby Prato. Alighiero di Bellincione d'Alighiero, Dante's father, continued Bellincione's practice until the time of his death, which occurred before 1283. Dante seldom mentions these close relatives in his works; he may not have been proud of their activities. During the long struggle between the Guelph (papal) and the Ghibelline (imperial) parties for supremacy in the city, Dante's family's participation in the political life of Guelph Florence was of only minor importance. Bellincione and Alighiero do not appear among the names of those suffering hardship (as Guelph supporters) under the Ghibellines in their period of power between 1260 and 1266; moreover, Dante's father, after the Guelph defeat of Montaperti (1260), seems not to have been sent into exile by the Ghibellines. "The great town on the fair river of the Arno" was, by the time of the poet's birth, already devoting its energies to territorial and economic expansion, and he deemed this to be the principal cause of the internal discord afflicting the commune from 1216 onward. He described, in an episode of the *Paradiso* relating to Cacciaguida, how the steady infiltration of the feudal nobility into the city's economic

His  
family's  
economic  
activity

and political life had been a root cause of the great divisions and dislocations that shook medieval Florence. It had caused the magnates themselves to split into Guelph and Ghibelline factions, provoked the rich Guelph bourgeoisie's struggle against the magnates (with the former emerging powerful between 1250 and 1260); and had finally resulted in Guelph dominance after 1266, when Charles I of Anjou defeated and slew Manfred the imperial claimant at the Battle of Benevento. From then on Florence remained within the sphere of Angevin and papal influence but not without fierce social strife, resulting from the antimagnate politics of the Guelph commune. Unrest was further aggravated by external conflicts caused by campaigns of territorial conquest. Such was the background of events known to the young Dante that in their later development were to provoke active participation by the mature poet. Dante grew up—after the death of his mother, Bella (probably of the Abati family), and the remarriage of his father to Lapa di Chiarissimo Cialuffi—in the company of an older sister and a half brother, Francesco, and half sister, Gaetana, from his father's second marriage.

**Early studies and first writings.** Dante's precocious studies of grammar and rhetoric brought him into contact with the Latin authors; but it was also the stimulation of Florence's cultural environment that fostered a natural inclination toward poetry while he was still a youth. Florence in those years was the meeting place of many literary currents. For Dante, in the years of his literary apprenticeship, two masters stood out above all the others: Brunetto Latini and Guido Cavalcanti. Dante himself confesses that it was Brunetto who taught him "how man becomes eternal," that is, how he leaves a lasting trace of himself through his literary works. But beyond the poet's own important admission, it is easy to grasp the extent of the influence; Latini, who had returned to Florence from exile in France in 1266 and, after having regained important public appointments in the commune, died in about 1294, almost certainly furnished Alighieri with the first documents of *Ars dictandi*—that is to say, of the art of letter writing—and so of writing ornate Latin prose; also, active as a rhymier in vernacular Italian and as a philosophical prose writer, he undoubtedly represented a model which Dante kept before him from the beginning of his apprenticeship as poet. Brunetto's rhetorical and literary instruction is evident in the numerous adaptations from his texts, present in Dante's major and minor works, both in Latin and in Italian, and particularly in two early poetic exercises, forcefully executed and not far apart from each other—the *Detto d'amore* and the *Fiore* (adaptations in Italian verse of the widely known French poem, the *Roman de la rose*). These works show the rhetorical technique and popularizing style dear to Latini and yet give evidence of a spirited freshness.

Besides the "paternal image" of Brunetto, Dante was influenced by the circle of Florentine poets who worked in the wake of the Sicilian school and of Guittone d'Arezzo. It was the poetry and friendship of Guido Cavalcanti, however, that most influenced the concrete development of Dante's art. Having reached his majority (at the age of 18, being fatherless) and being about to take Gemma Donati as his wife (he had been betrothed to her since 1277) in about 1285, Dante sent Cavalcanti a sonnet, "To Every Captive Soul and Gentle Heart." It was the sonnet that reappeared nearly ten years later in the opening of the *Vita nuova* ("The New Life"), which was dedicated to Cavalcanti. Dante's first poetic experience thus grew out of schemes set forth by the Sicilian school and by Guittone. And then, under Cavalcanti's influence, accents of acute distress and tormented love appeared beside the light, graceful tones of certain *ballate* (ballades), in new, more dramatic forms. Dante's poetry later acquired a marked individuality, and in the so-called rhymes of praise for Beatrice, his ideal lady, the poet distinguishes his own style from the models of traditional love poetry, fully developing the lesson of Guido Guinizzelli (the master of his own masters) and transcending it with the *canzone*, or lyric ("Ladies Who Have Understanding of

Love"). This *canzone* was a true poetic manifesto of the *stil nuovo*, the "new style." Under the stimulus of new ideas and that of the rhymes of praise, Dante became the champion of a kind of love poetry connected with his discovery of the value of the beauty of Beatrice as a mystic analogue and revelation of the divine. (This cultural attitude toward woman as a means of metaphysical knowledge of the divine sustains the masterly poetry of the third book of the *Divine Comedy*, the *Paradise*.) And he persuaded himself of the need to renounce every hope of and desire for concrete amorous recompense. These achievements foreshadowed the beginnings of Dante's ideological clash (later expressed in literary and political terms) with Guido Cavalcanti and resulted in their separation.

#### **The "Vita nuova," as literary form and autobiography.**

The death of Beatrice Portinari, on June 8, 1290, was succeeded, for Dante, by a period of intense study. The texts of such authors as Boethius, Cicero, St. Augustine, Aristotle, and other philosophers read during this period were a certain source for many changes in his works. The *Vita nuova* (c. 1293) represented a crystallization of these innovations. This work is a collection of 31 lyric poems, composed between 1283 and 1291, arranged within a prose framework with a conceptual plot. Ideally a "book of the memory," the work is based on the experiences of Dante in relation to his adolescent love for Beatrice. The lyric poems, upon their insertion into the prose framework, underwent stylistic changes. The prose that orders these verses and explains their literary and spiritual meaning takes on the form of an autobiographical novel and commentary and describes what has been well defined as a "*legenda sanctae Beatricis*" ("legend of Beatrice sanctified"). The autobiographical material covers about 18 years, beginning with Dante's first meeting with Beatrice, at the age of nine. After their second meeting, nine years later, the beatific experience of her gentle salutation invokes, for the poet, in a "dream-vision," a presentiment of her imminent death, seen as a culmination of the ultimate perfection of nature. The work narrates the events of about ten years more. Dante, wishing to conceal his intense love for Beatrice, which had totally engrossed him, pretended amorous sentiments for two other women, writing for them "certain trifles in verse." These were interpreted by many as "beyond the limits of courtesy," and Beatrice herself refused to greet him. So Dante, deprived of his only bliss, addressed himself to Beatrice, declaring in verse the nobility and loftiness of his love, asking nothing and hoping for nothing but content uncompensated to praise her spiritual beauty. The praise itself becomes joy and reward. The verses of praise and the *canzone* "Ladies Who Have Understanding of Love" mark the beginnings of a new style in Dante's poetry, that of the New Verse, which later became the exemplar of the *stil nuovo*; and these poems in the *Vita nuova* mark the beginnings also of the theme (which later underlies the poetry of the *Paradise*) of the parallel relationship between Beatrice the lovely creature and God the Creator, leading to the notion of the identity of love and a gentle heart—*i.e.*, of the metaphysical cause and its effect. During an illness, Dante had a second vision of the imminent death of Beatrice, which provoked a period of sorrowful meditation. Upon her actual death, in 1290, he was comforted by the certainty that Beatrice had soared "to heaven on high, to the kingdom where the angels have peace." After the first anniversary of her departure, Dante was moved by the compassion of a "fair lady, young and quite lovely," so that for a short while he withdrew from his sorrow. But if the heart gives in to a natural need for comfort, reason keeps watch and imposes victory over "evil desire"; the image of Beatrice returned with greater force, provoking shame and remorse. Thus Dante reached the final, supreme "wonderful vision" of Beatrice in the glory of the empyrean, probably foreshadowing her glorification in the *Paradise* "upon the throne her merits have assigned her." Following this vision, the poet proposed "to say no more about his blessed lady until he could do so in a way more

worthy of her" and say "what hath not before been written of any woman." This was his promise of a full, new, and eminently poetic glorification from which, about 15 years later, the *Divine Comedy* derived its origin and force. But already, in the *Vita nuova*, Beatrice appears, in life and death, as the first of the great inspiring muses of modern poetry, comparable in importance to Laura, the inspiration of Petrarch, half a century later.

**Political life and exile in 1302.** The death of Beatrice marked a precise turning point in the poet's life. For about 30 months (as he said in the *Convivio*) he attended "the schools of the religious and the disputations of the philosophers" and in deep study prepared the ground for the great works of his maturity. He became acquainted with such classical authors as Virgil, Ovid, Lucan, and Statius. Through his reading of St. Thomas Aquinas' commentary he came to know the works of Aristotle, especially *Ethics* and *Politics*; and he read medieval authors such as Albertus Magnus, St. Bonaventure, and Averroes. These studies gave a new dimension to his poetry, extending its limits beyond the themes of love, as is reflected in the allegorical canzoni in praise of philosophy and his doctrinal verses. To the same period belong four *rime petrose* (December 1296) written for Pietra, a lady who had rashly rejected his love; they too give evidence of mature experiment in metre and style, modelled on that of a Provençal troubadour, Arnaut Daniel, and look forward to the style of the *Divine Comedy*. The philosophical canzoni, with their judgment of current ideas and modes of life, are the fruit of meditation on daily experience of the class prejudices that underlay the violence of the magnates, a theme that was to recur in the eighth canto of the *Inferno* with the episode of Filippo Argenti. Dante already adhered firmly to the democratic ideals of the Gueff commune. In the meantime he had taken part as a cavalryman in the Battle of Campaldino (June 11, 1289) against Ghibelline Arezzo and in the military operations two months later against the Pisan castle of Caprona. Following the overthrow of Giano della Bella in 1295, and the subsequent reform of his *Ordinamenti di Giustizia* (Ordinances of Justice) of 1293, which had severely limited the power of the nobility, the poet enrolled himself in the Guild of Doctors and Pharmacists (for his philosophical studies) and became politically active. Between November 1295 and April 1296, he was a member of the special Council to the Captain of the People (upholder of popular authority in parallel with the podesta, or supreme authority), although he never took the floor and in fact five times had to justify his absence from meetings. Between May and September 1296 he belonged to the general Council of the Hundred (citizens' parliament) and supported legislation against the magnates. The moral and democratic leanings displayed in these stands was also expressed by Dante in the above mentioned canzoni celebrating the moral virtues of nobility and loveliness.

Little is known about the poet's activity in the immediately succeeding years, and there is no documentation of Dante's official position regarding the events of 1297, when Pope Boniface VIII proclaimed the crusade against the powerful, anti-papal Roman Colonna family and sent Cardinal Matteo d'Acquasparta to Florence to solicit help. But an episode about Guido da Montefeltro in the *Inferno* clearly expressed the poet's opinion about the "arrogant fever" of Boniface's thirst for power, which led to the stirring up of open conflict between the two Gueff factions of the city, the Black Gueffs (headed by the Donati family, of magnate ancestry) and the more moderate White Gueffs (headed by the Cerchi, a family of bankers and merchants). Donati support of the Pope transformed what had until then been a struggle between municipal parties into a conflict between the commune and the papacy. The *signoria* of the White Gueff party struck hard against the Blacks, sending them into exile. Boniface sent Cardinal Matteo d'Acquasparta to Florence a second time, in 1300, ostensibly to reconcile the parties but secretly to favour the Blacks. On May 7 Dante was nominated ambassador to San Gimignano to consolidate the Gueff League, then supporting the Pope

in a war against the Aldobrandeschi family of Santa Fiora. He was elected one of the six priors, or presidents, of the guilds for the period June 15–August 14, 1300, during which time he and his colleagues gave proof of their impartiality, exiling the heads of both parties; among the latter was Guido Cavalcanti, his "first friend," exiled to Sarzana. But events followed close one upon another: during the succeeding priorate (to which Dante no longer belonged) the *signoria* government under the Whites recalled their followers from exile, while the Blacks assembled in the spring of 1301 in the church of Sta. Trinità to make another bid to recover power. These were the last months of Dante's political and civic activity: surviving documents present him as the leader of a large group of Whites; and the role that he played in Florentine events between 1300 and 1301, especially after his priorship, cannot be minimized. On September 13, 1301, and then again on the 20th and 28th of the same month, he urged that full powers be given to the priorate, in view of the dangers threatening the city. In fact, on October 4, Charles of Valois, brother of the French king, Philip IV the Fair, in concert with the Pope, arrived at Castel della Pieve, the Black Gueffs' headquarters on the boundary of Florence. The White party controlling the *signoria* attempted once more to reach a compromise, sending an embassy of three citizens with four Bolognese doctors of law to the Pope. Dante Alighieri, one of the three ambassadors, left Florence at the end of October, never again to return. On November 1, 1301, Charles entered the city and soon won the support of the more extreme Blacks. As the struggle between the parties degenerated into fierce political persecution with the victory of the Blacks, trials of Whites, accused of Ghibellinism (pro-imperialism) and public embezzlement, were instituted. Dante was among the first and most severely stricken, being condemned for barratry (poor administration of the public funds) on January 27, 1302, and sentenced to pay 5,000 small florins, an enormous sum in those days, within three days and to remain outside Tuscany for two years. With his colleagues, Dante was also accused of opposing the Pope and Charles of Valois, as well as of having favoured the scission of parties in Pistoia that had damaged the Blacks. The poet, journeying from Rome, was not present to pay the fine, and so on March 10, he and his 14 co-defendants were by default condemned to death.

**Life in exile.** The poet reacted strongly and united with the other White and Ghibelline (pro-imperial) exiles to seek military aid from other pro-Ghibelline families—the Ubaldini in Mugello, Scarpetta Ordelfaffi in Forlì, and Bartolomeo della Scala in Verona—in an attempt to re-enter Florence by force. Dante participated as an ambassador at those negotiations, and on June 8, 1302, in the church of S. Godenzo, with 16 other Florentines he undertook to compensate the Ubaldini in the event of damages resulting from military operations against Florence. When Pope Benedict XI succeeded to the papacy (October 1303), the exiles saw better prospects for peace. In March 1304, Benedict sent Cardinal Nicolò da Prato to Florence to mediate between the parties. On this occasion Dante composed Epistle I, on behalf of the exiles gathered in Arezzo; the letter accepting his mediation was sent to the Cardinal, but the Blacks succeeded in wrecking the negotiations and forced the Cardinal to leave the city after he had issued an interdict. On the death of Benedict in July 1304, the Whites and Ghibellines took up arms again. Their defeat at La Lastra above Florence (July 20, 1304) ended all hope for the exiles. Dante had already expressed his dissent regarding the decision taken: supporting a policy of reconciliation, he had long since refused to take up arms against his native city and made "a party by himself." Evidence of this attitude can be found in his other works of these first years of exile—in the envoy of the canzone "Three Women Have Come Round My Heart" (1304), in a moving reference to Florence in *De vulgari eloquentin* ("Of Eloquence in the Vulgar Tongue") and in the *Convivio* ("The Banquet"); later, this attitude developed into an expressive pathos that

Election to the priorate

Political persecution of the White party

Political activity

animates the episode of Farinata degli Uberti in *Inferno*, X, representing the exaltation of magnanimous patriotic love.

*The De vulgari eloquentia and the Convivio.* Forced to wander about Italy alone in poverty (he went to Forlì and Verona in 1303), seeking protection and friendship, Dante's only comforts were study and poetry. Between 1304 and 1306 he was taken in by Bologna, a favourable environment for studies in philosophy, law, and rhetoric. Two of his major works were begun here: *Il convivio* and the *De vulgari eloquentia*, which were written to console himself for his painful solitude and also to show himself to Florence and the world as a man of culture, a philosopher and a poet, whose perspectives of thought and art were enlarging far beyond the "municipal" dimensions of his early years. These two works, both of them unfinished, were permeated by a deep nostalgia for his distant native city. They are both written with a concise, almost effortless rhythm and with the enthusiasm of mature insight. They differ, however, in outlook and in purpose.

Originally planned in four books but interrupted at chapter xiv of Book II, the *De vulgari eloquentia* (1304–05) was written in Latin, and it reveals in its interior biography of Dante his linguistic, philosophical, and rhetorico-artistic preoccupations. It is a clear literary manifesto directing poets to establish norms that can be widely understood. In Book I, Dante set up an opposition between *locutio vulgaris* (language as means of communication, variable in time and space) and *grammatica* (literary language, stable in being fixed by rules). The basic and yet paradoxical aim of the work was to give rules (thus artificial stability) to the Italian vernacular. The poet delineated the historic evolution of language from the first human tongue (that of Adam, preserved in the Hebrew language). He went on to examine in particular the three vernaculars (of Provence, France, and Italy) belonging to the southwestern nucleus, and then concentrated his attention on the Italian, selecting one of its many dialects for elevation to the status of a literary language. Having examined them all, Dante found evidence of this language (defined as the "illustrious vulgar tongue") only in examples of the work of those poets (the Sicilians, the Bolognese school, and the Florentines of the *stil nuovo*, including Dante himself) who could detach themselves from their local manner of speech. The highest of the styles recognized by the rhetoricians—the tragic, with its elevated themes of arms, love, and virtue—was appropriate to this vulgar tongue.

The *De vulgari eloquentia* remained unfinished. On October 2, 1306, the commune of Bologna expelled the Florentine exiles. The *Convivio* was continued, in spite of Dante's renewed wanderings, until the end of 1307 or the beginning of 1308. It was interrupted, however, by the election in November 1308 of Henry of Luxembourg as Henry VII, king of the Romans, an event that the poet had earlier anticipated in the work. A no less important cause of the interruption was the burning conception and vast design of *The Divine Comedy*.

First planned as a work of 15 treatises, the *Convivio* gives its readers a portrait of Dante as a vigorous and mature though sometimes eclectic thinker and as a man passionately interested in science. His encyclopaedic and didactic intention, as well as choice of material, link him with his old teacher Brunetto Latini. Latini, in his encyclopaedic *Trésor*, had written in French in order to break away from the traditional use of Latin in scientific works. Dante, instead, employed his own native vernacular and so set down the foundations for Italian literary prose. In the first treatise he stated his intention to set out material for 14 moral and philosophical canzoni. In the second book, he referred again to the episode of the "fair lady" in the *Vita nuova* and interpreted it as a conflict between his love of Beatrice and his love of philosophy. The third book was dedicated to the glorification of philosophy, and the fourth expounded the nobility of man, which is not tied to hereditary privilege or to wealth but to the goodness of individual human nature and the possession of moral and intellectual virtues. The *Convivio*

contains themes and conclusions which were later developed more fully: for example, the digression on the four senses of the Scriptures (sacred and profane); on the two kinds of allegory; and on the authority of the emperor and the necessity of the empire for the well-being of humanity.

On October 6, 1306, Dante, expelled from Bologna, had concluded peace at Sarzana between Marchese Franceschino Malaspina and the Bishop of Luni. In 1308 he was probably in Lucca, where the presence in that year of his eldest son, Giovanni, is confirmed by a reference to Gentucca, a girl of Lucca, in *Purgatory*, XXIV, the second part of the *Divine Comedy*. Having returned to the Casentino (the country north of Arezzo), he sent shortly afterward to Moroello Malaspina, a Guelph leader, the canzone "Love, Since After All I Am Forced to Grieve" with an explanatory Epistle IV. He was probably in the Casentino when he learned of the election of Henry of Luxembourg as German king (1308). In exile he had long meditated the events that had overtaken him and had become convinced that those events and the ensuing disorder had occurred only because there was no Holy Roman emperor. The heart of the exile exulted, therefore, while the deliverer prepared to come to Italy. And when Clement V agreed to crown the new emperor in Rome, the poet made himself the sounding board of the general expectation and delight, in Epistle V ("*Universis et singulis*," 1310), urging the princes and peoples of Italy to rejoice at the coming of the *Rex pacificus*. Only Florence, allied to Robert of Naples, opposed the emperor; and the poet expressed his indignation in Epistle VI (March 31, 1311) against the "most wicked Florentines." He then turned to Henry, to whom homage had already been paid in Milan, and urged him to crush the head of the viper that attempts to bite its mother (Epistle VII, April 17, 1311). For this plea, Dante was excluded from an amnesty granted by Florence to other exiles on September 2, 1311, as Henry was approaching the city to besiege it. Out of reverence for his native city, which he described in *Paradise* as an "evil stepmother," he did not appear among the exiles who encamped with the imperial troops on the plain of San Salvi, and his name is missing from a list of the condemned published by the commune in March 1313.

*The Monarchia and later minor works.* The treatise of political philosophy, composed in Latin and arranged in three books, is definitely later than the *Convivio*, the arguments and themes of the fourth book of which it develops. It was composed in the years immediately following the arrival of Henry VII in Italy. The first two books of the *Monarchia* treated again the *Convivio's* theme that the empire was necessary to the well-being of the world, while the third and last book considered whether the emperor depended directly upon God or derived his power through the pope, vicar of God. For Dante, imperial authority, as that of the pope, issued directly from God, so that direct power in temporal things was denied to the church, the spiritual organ. The treatise adumbrated the two ends assigned by God to all humanity, one of which is attainable in time, the other in eternity: earthly happiness is attainable with the guidance of the emperor; and the supreme happiness of celestial paradise is attained only with the guidance of the pope. The emperor, as devoted son of the father, must thus give reverence to the pope.

A rift that soon opened between Henry and Clement V and the sudden death of the Emperor dashed the poet's hopes; after staying for some time in Tuscany he returned about 1316 to Verona, where Cangrande della Scala (imperial vicar nominated by Henry VII in 1312) was founding a powerful Ghibelline state in northern Italy. To these years belong the last three letters now known: Epistle XI (June 1314; urging the Italian cardinals in conclave after the death of Clement V to elect an Italian pope who would bring the seat of the papacy back to Rome from Avignon); Epistle XII (May 1315; to a Florentine friend, refusing an amnesty because its conditions are regarded as humiliating); and

Epistle XIII (c. 1316; dedicating *Paradise*, which he had just begun, to Cangrande, and setting down the beginning of a commentary on it together with the general framework of the *Commedia* and an explanation of its literal and allegorical meanings). This began the final stage in the life of Dante: he left Verona about 1318 and went to Ravenna as guest of the poet Guido da Polenta. In the tranquility of Ravenna, his surviving children gathered round him: Pietro, Iacopo, and Antonia (who after the death of her father was to become a nun, taking the name of Sister Beatrice). He composed two Latin eclogues there in reply to Giovanni del Virgilio (a Bolognese grammarian), who had urged him to write a poem in Latin verse on a historical theme and had invited him to Bologna, promising him the poetic laurel. He may have stayed briefly at Verona. On his return to Ravenna from Venice, where he had been sent on a difficult embassy by Guido da Polenta, Dante, who had only very recently finished *Paradise*, was struck down by malaria and died during the night of September 13–14, 1321. But he left to Italy and to the world the *Commedia*, which posterity judged to be divine.

**"The Divine Comedy."** Dante began working on the *Commedia* in about 1308, after leaving off the *Convivio* and *De vulgari eloquentia*. On a vast fresco depicting his sorrows and hopes, his fierce hatreds and his cherished beliefs, he reaffirmed in poetic terms his ethical and political conception of the world and of the ends and duties of man within the twofold order of nature and grace. A poet above all, he felt that only in poetry would he be able to express fully his dream of a spiritual and civilized renewal of the whole of humanity. The poem, though unique, (1) is closely related to the tradition of medieval allegorical poetry, at the same time, (2) is modelled on Virgil's *Aeneid* (considered in the Middle Ages to be an allegorical work), and (3) is inspired by the poetry of the Bible and by the Christian wisdom of the Holy Scriptures. Divided into three books, or *cantiche* (treating of Hell, Purgatory, and Paradise—the first composed by 1312, the second by 1315, the third between 1316 and 1321), it is written in Italian vernacular and is composed of 14,233 hendecasyllables in terza rima (a rhyme scheme aba, bcb, cdc, and so on), arranged in 100 cantos (one being a prologue to the entire work, and each *cantica* having 33 cantos). Thus the number 3, a symbol of the Trinity, is always present in every part of the work, with its multiples and in its unity. The title, with its medieval meaning, is *Commedia* because the subject, horrible in the *Inferno*, becomes desirable and pleasing in the other two *cantiche*, *Purgatory* and *Paradise*. The literal subject of the work is the journey Dante makes through the world beyond the grave, repeating by divine grace the experience of Aeneas in his descent to Avernus. At the age of 35, on the evening of Good Friday, 1300, the poet finds himself wandering astray in a dark wood. After a night of anguish, he sets out toward a hill illuminated by the sun, but three wild beasts—a female ounce (a species of leopard), a lion, and a wolf: symbols of lust, pride, and avarice—bar his path and force him back toward the darkness of the wood. Virgil, however, sent by the Virgin Mary, St. Lucy, and Beatrice, appears to help him. He guides Dante through the infernal realm and the mountain of Purgatory, at the summit of which the Roman poet is replaced by Beatrice, who then conducts Dante (raising him from heaven to heaven by the brilliant and loving power of her glance, which is that of a blessed soul contemplating God) as far as the empyrean, where the poet enjoys for a brief moment the supreme vision of the divinity.

Time has confirmed the *Commedia* to be a sublime work of poetry, for its greatness of conception and construction, for the concreteness of its imagery, for its characters—prismatically reflected within the framework of the imaginary journey—and for its artistic mastery and impassioned moral power. For many readers it is equalled only by the great poems of classical antiquity and the sublime poetry of the Bible. Dante intended the poem to have, in addition to its purely literary sense, an allegorical meaning that is not superimposed from out-

side but is the conceptual nucleus around which the poetic images flower; happiness on this earth (represented by the terrestrial paradise) and blessedness not on earth but in eternity (found in the vision of God in paradise) are the ends assigned by Providence to all humanity and are attainable with the help of the two guides—emperor and pope—assigned by God to man. Earthly happiness, Dante held, is acquired through the practice of the moral and intellectual virtues; celestial happiness by living this life according to the Christian virtues of faith, hope, and charity. Dante's progressive liberation from the slavery of passion corresponds—in the progressive spiritual probing that guides the poet—with his every judgment of men and events, of the passions and inclinations of troubled humanity, and corresponds, too—at the poem's structural level—with his overcoming, in the course of his journey, a particular sin or reaching a particular level of blessedness. The poet proceeds in continual ascent from the "dark wood" (symbol of the uncultivated life, without reason or virtue) to the possession of God as infinite good, which becomes the reward for the soul that contemplates it in the luminous darkness of faith. The poetic experience of the *Commedia* is allegorically the history of Dante's own soul, the journey of his mind to God, serving as a prime example for every reader and helping him to rediscover the "straight way" of a moral life that leads to perfection. Dante wanted readers of the *Commedia* to find in it, as in a great, sacred allegory, an exemplum, a picture, that would lead them to meditate on the evil of the tragic contemporary scene and that would also indicate the solutions: the empire as the sole remedy and bridle for human avarice and the necessity for a return on the part of the church to purity and evangelical poverty. In this sense, taken with Epistle XIII to Cangrande, the purpose of the *Commedia* can be said to be to "remove those living in this life from the state of misery and lead them to the state of felicity," because Dante's exceptional poetic experience could be repeated at the level of ordinary life by anyone who wished to move with equal resolve toward the same spiritual goal.

#### MAJOR WORKS

POETRY: *La vita nuova* (c. 1293; trans. by B. Reynolds, 1969); *Commedia*, consisting of *cantiche* I, *Inferno*; *cantiche* II, *Purgatorio*; *cantiche* III, *Paradiso* (composed c. 1310–21; *The Divine Comedy*, trans. by W.F. Ennis, 1965); *The Comedy of Dante Alighieri*, verse trans. by D.L. Sayers and B. Reynolds, 3 pt. (1949–62).

OTHER WORKS: *De vulgari eloquentia* (1304–05; Eng. trans., *Dante's Treatise "De Vulgari Eloquentia,"* trans. by A.G. Ferraers Howell, 1890); *Il convivio* (c. 1304–07; *Dante's Convivio*, trans. by W.W. Jackson, 1909).

**BIBLIOGRAPHY.** PAUL COLUMB DE BATINES, *Bibliografia dantesca* (1845–46) (1888); CORNELL UNIVERSITY LIBRARY, *Catalogue of the Dante Collection . . .*, 2 vol. (1898–1900) and *Additions*, 1898–1920 (1921); GIULIANO MAMBELLI, *Gli annali delle edizioni dantesche* (1931). For post-World War II studies: ALDO VALLONE, *Gli studi danteschi dal 1940 al 1949* (1950); ENZO ESPOSITO, *Gli studi danteschi dal 1950 al 1964* (1965). Annual bibliographies of Dante studies published in America are printed in *Dante Studies*, published by the Dante Society of America. Bodies specializing in Dante studies have been established in many countries. Apart from the Società dantesca italiana (founded 1888), of special interest to English-speaking readers are the Oxford Dante Society (founded 1876) and the Dante Society of America (founded 1881).

*Collected editions:* Complete critical editions of Dante's work include MICHELE BARBI *et al.* (eds.), *Le Opere di Dante. Testo critico della Società dantesca italiana*, 2 vol. (1921–22; 2nd ed., 1960); EDWARD MOORE (ed.), *Le Opere di Dante* (The Oxford Dante; 4th ed. rev. by PAGET TOYNBEE, 1924). Invaluable for textual scholarship, the National Edition of the Società dantesca italiana is in course of preparation (1932–).

*Commentaries:* For extracts from early commentaries, see GUIDO BIAGI *et al.*, *La Divina Commedia nella figurazione artistica e nel secolare commento* (1921–40), and its useful bibliography. Modern commentaries include those by GIUSEPPE VANDELLI, 16th ed. (1955); CARLO GRABHER, 26th ed., 3 vol. (1966); MANFREDI PORENA, new ed., 3 vol. (1954–55); ATTILIO MOMIGLIANO, 3 vol. (1964); and NATALINO SAPEGNO, 3 vol. (1957). See also FRANCESCO MAZZONI, *Saggio di un nuovo commento alla Divina Commedia* (1967). For English-

speaking readers, the commentary of CHARLES H. GRANDGENT, *La Divina Commedia di Dante Alighieri*, rev. ed. (1933), is excellent; as is CHARLES S. SINGLETON, *The Divine Comedy* (1970- ).

*Aids and introductory works:* Of the general works available to English-speaking readers, see especially ERNEST H. WILKINS and THOMAS G. BERGIN, *A Concordance to the Divine Comedy of Dante Alighieri* (1965). EDWARD S. SHELDON and ALAIN C. WHITE, *Concordanza delle opere italiane in prosa e del Canzoniere di Dante Alighieri* to the minor Italian works (1905); and EDWARD K. RAND and ERNEST H. WILKINS, *Dantis Alagherii operum latinorum concordantiae* to the Latin works (1912), are also useful. PAGET TOYNBEE, *A Dictionary of Proper Names and Notable Matters in the Works of Dante* (1898; rev. by CHARLES S. SINGLETON, 1968), is invaluable. Excellent introductions to Dante include UMBERTO COSMO, *Guida a Dante* (1947; Eng. trans., *A Handbook to Dante Studies*, 1950); MICHELE BARELLI, *Dante: vita, opere e fortuna* (1940; Eng. trans., *Life of Dante*, 1954); THOMAS G. BERGIN, *Dante* (1965). Also useful are JEFFERSON B. FLETCHER, *Dante* (1965); FRANCIS HERGUSON, *Dante* (1966); THOMAS C. CHUBB, *Dante and His World* (1966); and ALDO VALLONE, *Dante* (1971).

*General studies:* EDWARD MOORE, *Studies in Dante* (1896-1917, reprinted 1968); PAGET TOYNBEE, *Dante Studies* (1921); BENEDETTO CROCE, *La poesia di Dante*, 3rd ed. rev. (1922; Eng. trans., *The Poetry of Dante*, 1922); T.S. ELIOT, *Dante* (1929; reprinted in *Selected Essays, 1917-1932*, 3rd ed., 1951); JOHN FRECCERO (ed.), *Dante: A Collection of Critical Essays* (1965); UBERTO LIMENTANI (ed.), *The Mind of Dante* (1965); the OXFORD DANTE SOCIETY, *Centenary Essays on Dante* (1965); WILLIAM J. DE SUA and GINO RIZZO, *A Dante Symposium* (1965); FRANCESCO MAZZONI, *Contributi di filologia dantesca* (1966).

*Specialized studies:* On the *Vita Nuova*, see CHARLES S. SINGLETON, *An Essay on the Vita Nuova* (1949); on the *Canzoniere*, PATRICK BOYDE, *Dante's Style in His Lyric Poetry* (1971); on Dante's philosophical thought, ETIENNE GILSON, *Dante et la philosophie* (1939; Eng. trans., *Dante the Philosopher*, 1948); on Dante's political thought, ALESSANDRO PASSERIN D'ENTREVES, *Dante As a Political Thinker* (1952); EWART K. LEWIS, *Medieval Political Ideas* (1954); CHARLES T. DAVIS, *Dante and the Idea of Rome* (1957); on the *Commedia*, W.H.V. READE, *The Moral System of Dante's Inferno* (1909, reprinted 1969); KARL VOSSLER, *Die gottliche Komodie*, 4 pt. (1907-10; Eng. trans., *Medieval Culture: An Introduction to Dante and His Times*, 2 vol., 1929, reprinted 1958); ERNST R. CURTIUS, *European Literature and the Latin Middle Ages* (1963); FRANCIS HERGUSON, *Dante's Drama of the Mind* (1953); CHARLES S. SINGLETON, *Dante Studies*: vol. 1, *Commedia: Elements of Structure* (1954) and vol. 2, *Journey to Beatrice* (1958); JOHAN CHYDENIUS, *The Typological Problem in Dante* (1958); JOSEPH A. MAZZEO, *Structure and Thought in the Paradiso* (1958) and *Medieval Cultural Tradition in Dante's Comedy* (1960); IRMA BRANDEIS, *The Ladder of Vision: A Study of Dante's Comedy* (1960); HELEN F. DUNBAR, *Symbolism in Medieval Thought and Its Consummation in the Divine Comedy* (1961); THOMAS G. BERGIN, *Perspectives on the Divine Comedy* (1967) and *The Diversity of Dante* (1969).

(F.Ma.)

## Danton, Georges

Few leaders of the French Revolution have left so deep an impression on the collective memory of the French people as Georges-Jacques Danton. Almost 200 years after his death, Danton still evokes instinctive sympathy—for his energy, enthusiasm, and audacity. He is one of the most complex and controversial statesmen of the Revolutionary period.

A powerful orator who initially championed the extreme left and contributed to the fall of the monarchy, he was executed once his insistent calls for moderation seemed to threaten the extreme policies of the Revolutionary government headed by Maximilien de Robespierre. A compassionate defender of the rights of the oppressed, he was also an opportunist who did not scruple to enrich himself by selling the power of his office.

**The tribune of the people (1789-92).** Danton was born at Arcis-sur-Aube, in Champagne, on October 26, 1759, the son of Jacques Danton, an attorney, and his second wife, Marie-Madeleine Camus. After attending school in Champagne, Danton was from 1773 educated by the Oratorians at Troyes. After obtaining his law de-

Danton, portrait by Mme Constance-Marie Charpentier (1767-1849). In the Musée Carnavalet, Paris.  
J.E. Bulloz

gree in 1784 at Reims, he went to Paris to practice and in 1787 bought the office of advocate in the *Conseil du roi* (council with legislative and judicial functions). He then married Antoinette Charpentier.

At the outbreak of the Revolution in July 1789, Danton enrolled in the *garde bourgeoise* (civic guard) of the Cordeliers district and was elected president of the district in October. In the spring of 1790, with some militants from his district, he founded the popular association that was to become famous as the Club of the Cordeliers. So far, however, Danton's fame had been merely local. Elected a member of the provisional Paris Commune (city council) in January 1790, he was excluded from the council in its final form in September. Although elected administrator of the *département* of Paris in January 1791, he actually exercised no influence on that body.

Meanwhile, however, Danton shone at the Club of the Cordeliers and at another political association, the Club of the Jacobins, before both of which he frequently made speeches during 1791. During the crisis following Louis XVI's attempt to leave the country in June, he became increasingly prominent in the Revolutionary movement. His signature, however, does not appear on the famous petition of the Cordeliers demanding the abdication of Louis XVI, which, on July 17, resulted in the massacre of some of the petitioners by the national guard. During the repression following these events, Danton took refuge in London.

He returned to Paris to take part in the elections to the Legislative Assembly as elector for the *Théâtre Français* section, and in December 1791 he was elected second assistant to the *procureur* (public prosecutor) of the Paris Commune.

During the national crisis in the spring of 1792 (war was declared on Austria and Prussia on April 20), Danton resumed his role of tribune of the people. On June 18 he attacked the Marquis de Lafayette, an adviser of the King and a general, for using his position to play politics. Yet he took no part in the demonstrations before the royal palace of the Tuileries on June 20. Although his part in the overthrow of the monarchy by the insurrection of August 10, 1792, remains obscure, he was largely credited with its success.

Speaking before the Revolutionary Tribunal, Danton boasted that he had "been responsible for" the events of August 10; that insurrection, however, was not the result of the efforts of Danton or any other man but, rather, the collective act of obscure militants from all over the city. However small a part he played in removing the King, he was elected minister of justice by the Legislative Assembly. Though not officially its president, in the new government Danton dominated his colleagues by his

monarchy

strength of character, the aura of his Revolutionary past, and his ability to make swift decisions. When the news arrived that Longwy had been taken by the invading allies on August 25, 1792, and Jean-Marie Roland, minister of the interior, proposed that the government should move from Paris to Blois, Danton objected vigorously. The proclamation he then caused the Executive Council to adopt bears his stamp: it was a summons to battle. On the morning of September 2, when it was learned in Paris that Verdun was besieged and while the populace broke into the prisons to search for suspects and traitors, Danton, in the Legislative Assembly, delivered the most famous of his speeches: "To conquer the enemies of the fatherland, we need daring, more daring, daring now and always, and France is saved!"

While Danton was delivering this speech, the prison massacres began for which the Girondins, the moderate wing of the Revolution, charged Danton with responsibility. There is no proof, however, that the massacres were organized by him or by anyone else, though it is certain that he did nothing to stop them. Just as in the case of the August insurrection, the September massacre was not the act of one man but of the people of Paris.

On September 6 Danton was elected deputy for Paris to the National Convention. He immediately made every effort to end all the disputes between the Revolutionary parties, but his policy of conciliation was thwarted by the Gironde, which demanded that he render an accounting when he left his post as minister of justice. Danton could not justify 200,000 livres of secret expenditures. He emerged from this conflict embittered and with his political prestige diminished.

Sent on a mission to Belgium, Danton took no part in the opening of Louis XVI's trial in the Convention. He was present, however, on January 15, 1793, and voted for death without reprieve. Although absent from the trial, Danton had played a part in it since the autumn of 1792. According to the *Mémoires* of Théodore, comte de Lamath, a former Revolutionary, Danton wanted to spare the King. It seems that having failed, despite strenuous efforts, to gain the support of the Girondins, Danton plotted with Gen. Charles-François du Périer Dumouriez to obtain the intervention of the English government by bribery. Only when the plan miscarried did he vote for the death of the King.

Danton remained in the mainstream of the Revolution, not without often engaging in intrigue. His dealings with Dumouriez, who commanded the army of Belgium, have never been clarified. After the defeat of Neerwinden (March 18, 1793), when Dumouriez went over to the Austrians, the Gironde accused Danton of complicity with the General. Boldly turning the tables, Danton made the same accusation against the Girondins. The break was irreparable.

**Danton's Committee of Public Safety.** On April 7, 1793, Danton became a member of the first Committee of Public Safety, which, created the previous day, became the executive organ of the Revolutionary government. For three months Danton was effectively the head of the government, charged especially with the conduct of foreign affairs and military matters. During this second period in the government he pursued a policy of compromise and negotiation. He tried in every direction to enter into diplomatic conversations with the enemy. No doubt he could in all honesty think it useful to negotiate in an attempt to dissolve the allied coalition or even to obtain a general peace. By the spring of 1793, however, a policy of negotiation was no longer conceivable: it was useless to try to disarm the enemy by concessions when he was victorious. On July 10, when the Committee of Public Safety's term expired, the Convention elected a new committee without Danton.

**Leader of the moderate opposition.** From that time Danton's political conduct became more complex. On various occasions he supported the policy of the Committee of Public Safety though at the same time refusing to play a part in it—which would have stabilized the political situation. Danton still reappeared from time to time as the tribune of the people, voicing the demands of

the masses. He quickly showed, however, that he sought to stabilize the Revolutionary movement; very soon—whether he wanted it or not—he appeared as the leader of the Indulgents—the moderate faction that had risen out of the Cordeliers.

During the great Parisian popular demonstrations of September 4 and 5, 1793, Danton spoke eloquently in favour of all the popular demands. Yet at the same time he tried to set bounds to the movement and keep it under control. He demanded, for instance, that the meetings of the hitherto permanent sectional assemblies be reduced to two per week.

Danton's moderate position became more marked in the autumn of 1793. He did not, however, intervene personally but left it to his friends to criticize the policy of the government. His disapproval of the terrorist repression had become so strong that he withdrew from political life, alleging reasons of health or of family. Of the Girondins, he is reported to have said to a friend at the beginning of October 1793, "I shall not be able to save them," and to have burst into tears. On October 12 he obtained leave from the Convention and left for his native town. He returned on November 21, although the reasons for his return remain ambiguous.

Danton at once resumed political activity. He vigorously supported the Committee of Public Safety against excesses of the anti-Christian movement and later opposed the abolition of the salaries of constitutional priests and hence the separation of church and state. Danton's support of the governmental policy of stabilization was doubtless not without ulterior motives, both personal and political; he was determined to save friends of his who had been arrested or who were in danger of arrest. But he also wanted to slow the Revolutionary drive of the government. The Dantonist policy was opposed in all points to the program of popular extremism supported by Jacques Hébert and his Cordeliers friends: extreme terror, war to the hilt.

Danton defined his moderate political line on December 1, 1793, when he informed the Revolutionary radicals that their role was ended. From then on, whether he wanted it or not, he was looked upon as the leader of the moderate opposition. At the beginning of 1794, Danton and his friends took an even more critical attitude, the Revolutionary journalist Camille Desmoulins, of *Le Vieux Cordelier*, serving as their spokesman. They were challenging not only the system of the terror of Robespierre but the whole policy of the Revolutionary government, while awakening the hopes of the opponents of the regime.

Once the government realized it could not allow itself to be overwhelmed from the right, however, the tide turned abruptly. When Fabre d'Églantine, the dramatist and zealous Revolutionary, compromised in the affair of the Compagnie des Indes, was arrested in January 1794, Danton tried to defend him obliquely by demanding that the arrested deputies should be judged before the people. "Woe unto him who sat beside Fabre and who is still his dupe!" cried a deputy, clearly threatening Danton himself.

The incident signalled more than the defeat of the offensive of the Indulgents, for, already compromised, they were themselves soon threatened by the counter-offensive of their adversaries, Hébert's ultra-left faction, the Exagérés, or Enragés. When the crisis, however, became more acute and the Exagéré opposition hardened its position, the government lost its patience: in March 1794, Hébert and the principal Cordeliers leaders were arrested. Sentenced to death, they were executed on March 24. The Indulgents, believing that their hour had come, increased their pressure. The government, however, had no intention of letting itself be overwhelmed by the moderate opposition of the right. Warned several times of the threats that hung over him, Danton remained unafraid: "They will not dare!" Finally, during the night of March 29–30, 1794, he and his friends were arrested. Before the Revolutionary tribunal, Danton boldly spoke his mind. To silence him, the Convention decreed that a suspect on trial who insulted national justice be excluded from the

Trial of Danton

The massacres of September 1792

debate. "I will no longer defend myself," Danton cried. "Let me be led to death, I shall go to sleep in glory." Danton was guillotined with his friends on April 5, 1794. "Show my head to the people," he said to the executioner. "It is worth the trouble."

**Assessment.** Denigrated during the first half of the 19th century, Danton was rehabilitated under the Second Empire and enshrined as a hero under the Third Republic. A chief controversy about him is the problem of his wealth and hence of his venality. To his contemporaries, Danton's venality was obvious, even though, for lack of documentation, it was not proved during his lifetime. Scholarly opinion in the 20th century was originally divided between two views: that Danton was a sincere democrat and sound patriot or that he was an unscrupulous politician capable of betraying the Revolution and selling himself to the court. It has become generally accepted that Danton was used as an informer by the court and that in return he received payments from the funds of the Civil List. At the same time, however, his attachment to the nation and to the Revolutionary cause is beyond doubt. The historian Georges Lefebvre, in stressing Danton's complexity, has tried to account for his behaviour:

Interested flexibility, wily prudence, venality...; but sometimes also the genuine realism of a statesman; then indomitable furies, careless neglects, sudden renunciations, due to a violent temperament which no moral or intellectual discipline ever tried to master;... too avid for pleasure to tolerate the somber reflections of suspicion and hatred.

Danton was a leader of men. More than any other Revolutionary leader, he could enter into communion with the sansculottes—the Revolutionary have-nots—to share their passions. He pleased the people by his generosity, his indulgence, his verve. All these were characteristics that won him the sympathy of the people and that, during the crisis of the summer of 1792, enabled him to serve the Revolution well.

**BIBLIOGRAPHY.** There is no reliable critical edition of Danton's addresses and speeches and no up-to-date biography. The best collection is ANDRÉ FRIBOURG, *Discours de Danton* (1910). For its historical interest the edition of the *Oeuvres de Danton* by AUGUSTE VERMOREL (1866) may be mentioned. The first important works on Danton appeared in the mid-19th century. The earliest well-documented study is ALFRED BOUGEART, *Danton: Documents authentiques pour servir à l'histoire de la Révolution française* (1865). Many more studies of Danton appeared under the Third Republic. Of special interest are JEAN ROBINET, *Danton, homme d'État* (1889); and the numerous writings of A. AULARD, favourable to Danton, published in the periodical *La Révolution Française* (see, for example, the year 1893). A more recent apologetic biography is JEAN LOUIS BARTHO, *Danton* (1932), in French. ALBERT MATHIEZ answered AULARD's articles with studies critical of Danton in his journal, *Les Annales révolutionnaires* (such as, "La Fortune de Danton," 1912, and "Les Comptes de Danton," 1913). Mathiez's attacks centred on Danton's corruption; he collected his basic arguments in two volumes: *Danton et la paix* (1919) and *Autour de Danton* (1926). Most modern historians agree on a middle position, as adopted by LOUIS MADELIN in *Danton* (1914), in French; and in the fine biography by HERMANN WENDEL, *Danton* (1930, in German; French trans., 1932). See also GEORGES LEFEBVRE, "Sur Danton," in *Annales historiques de la Révolution française* (1932), reprinted in *Études sur la Révolution française* 2nd ed. (1963). (A.L.S.)

## Danube River

The Danube is the second longest river of Europe after the Volga. It rises in the Black Forest mountains of West Germany and flows for approximately 1,770 miles (2,850 kilometres) to its mouth on the Black Sea. Along its course, it passes through eight countries under six variations of its name. In West Germany and Austria it is known as the Donau, in Czechoslovakia as the Dunaj, in Hungary as the Duna, in Yugoslavia and Bulgaria as the Dunav, in Romania as the Dunărea, and in the Soviet Union as the Dunay.

The Danube played a vital role in the settlement and political evolution of central and southeastern Europe. Its banks, lined with castles and fortresses, formed the boundary between great empires, and its waters served as

a vital commercial highway between nations. The river's majesty has long been celebrated in music. The famous waltz *An der schönen, blauen Donau* (*The Blue Danube*), by Johann Strauss the Younger, became the symbol of imperial Vienna. In the 20th century the river has continued its role as an important trade artery. It has been harnessed for hydroelectric power, particularly along the upper courses, and the cities along its banks—including the national capitals of Vienna, Budapest, and Belgrade—have depended upon it for their economic growth. Unfortunately, the Danube has been used as a disposal for urban, industrial, and agricultural waste and has joined the ranks of other rivers polluted by man.

**History.** During the 7th century BC, Greek sailors reached the lower Danube and sailed upstream, conducting a brisk trade. They were familiar with the whole of the river's lower course and named it the Ister. The Danube later served as the northern boundary of the vast Roman Empire and was called the Danuvius. A Roman fleet patrolled its waters, and the strongholds along its shores were the centres of settlements, among them Vindobona (later Vienna), Aquincum (later Budapest), Singidunum (later Belgrade), and Sextantaprista (later Ruse).

During the Middle Ages the old fortresses continued to play an important role, and new castles such as Werfenstein, built by Charlemagne, the 9th century Holy Roman emperor, were erected. When the Ottoman Empire spread from southeastern Europe to central Europe in the 15th century, the Turks relied upon the string of fortresses along the river for defense. The Habsburg dynasty recognized the navigational potential of the Danube. Maria Theresa, queen of Hungary and Bohemia from 1740 to 1780, founded a Department for River Navigation, and in 1830 a riverboat made a first trip from Vienna to Budapest, possibly for trading purposes. This trip marked the end of the river's importance as a line of defense and the beginning of its use as a channel of trade.

Regulated navigation on the Danube has been the subject of a number of international agreements. In 1616 an Austro-Turkish treaty was signed in Belgrade under which the Austrians were granted the right to navigate the Middle and Lower Danube. In 1774, under the Treaty of Küçük Kaynarca, Russia was allowed to use the Lower Danube. The Anglo-Austrian and the Russo-Austrian conventions of 1838 and 1840 promoted free navigation along the entire river, a principle that was more precisely formulated in the Paris Treaty of 1856, which also set up the first Danubian Commission with the aim of supervising the river as an international waterway. In 1921 and 1923 final approval of the Danube River Statute was granted by Austria, Germany, Yugoslavia, Bulgaria, Romania, Great Britain, Italy, Belgium, Czechoslovakia, Hungary, and Greece. The international Danube Commission was thus established as an authoritative institution with wide powers, including its own flag, the right to levy taxes, and diplomatic immunity for its members. It controlled navigation from the town of Ulm to the Black Sea and kept navigational equipment in good repair.

During World War II free international navigation was interrupted, and a consensus concerning its resumption was not reached until the Danubian Convention of 1948. Based on Soviet proposals, it allowed only the Danubian countries to participate in the new Danube Commission. Britain, France, and the United States refused to sign the convention.

**The river's course.** The Danube's vast drainage of 315,000 square miles (816,000 square kilometres) includes a variety of natural conditions that affect the origins and the regimes of its watercourses. They favour the formation of a branching, dense, deepwater river network that includes some 300 tributaries, 34 of which are navigable. The river basin expands unevenly along its length. It covers about 18,000 square miles at the Inn confluence, 81,000 square miles after joining with the Drava, and 228,000 square miles below the confluences of its most affluent tributaries, the Sava and the Tisza. In the lower course the basin's rate of growth decreases; at the estuary the drainage area includes 315,000 square miles. About 56 percent of the entire Danube Basin is drained by its right-

Ancient  
settlement

International  
control

bank tributaries, which collect their waters from the Alps and other mountain areas and contribute up to 66 percent of the total river runoff or outfall.

Three sections are discernible in the river's basin. The upper course stretches from its source to the gorge in the Austrian Alps and the Western Carpathian Mountains called the Hungarian Gates. The middle course runs from the Hungarian Gates to the Iron Gate Gorge in the Southern Romanian Carpathians. The lower course flows from the Iron Gate to the delta-like estuary at the Black Sea.

**The upper course.** The Upper Danube springs as two small streams—the Breg and Brigach—from the eastern slopes of the Black Forest (Schwarzwald) mountains of West Germany, which partially consist of limestone. The headstreams lose some of their water because it leaks through the rock to the adjoining Rhine Basin. From Donaueschingen, where the headstreams unite, the Danube flows northeastward in a narrow, rocky bed. To the left of the valley rise the wooded slopes of the Swabian and the Franconian mountains. Between Ingolstadt and Regensburg the river cuts across them and forms a scenic canyon-like valley. To the right of the river course stretches the large Bavarian Plateau, covered with thick layers of river deposits from the numerous Alpine tributaries. The bank is low and uniform, composed mainly of fields, peat, and marshland.

At Regensburg the Danube reaches its northernmost point. From there the river veers south and crosses wide, fertile, and level country. Shortly before it reaches Passau on the Austrian border, the river narrows and its bottom abounds with reefs and shoals. The Danube then flows through Austrian territory, where it cuts into the slopes of the Bohemian Forest (Bohmer Wald) and forms a narrow valley. In order to improve navigation, dams and protecting dikes have been built near Passau, Linz, and Ardagger. The Upper Danube, some 600 miles long, has a considerable average inclination of the riverbed (0.93 percent) and a rapid current of 2.2 to five miles per hour. Depths vary from 3 to 26 feet (1 to 8 metres). The Danube swells substantially at Passau where the Inn River, its tributary, carries more water than the main river. Other major tributaries in the Upper Danube course include the Iller,

Lech, Isar, Traun, Enns, and Morava rivers.

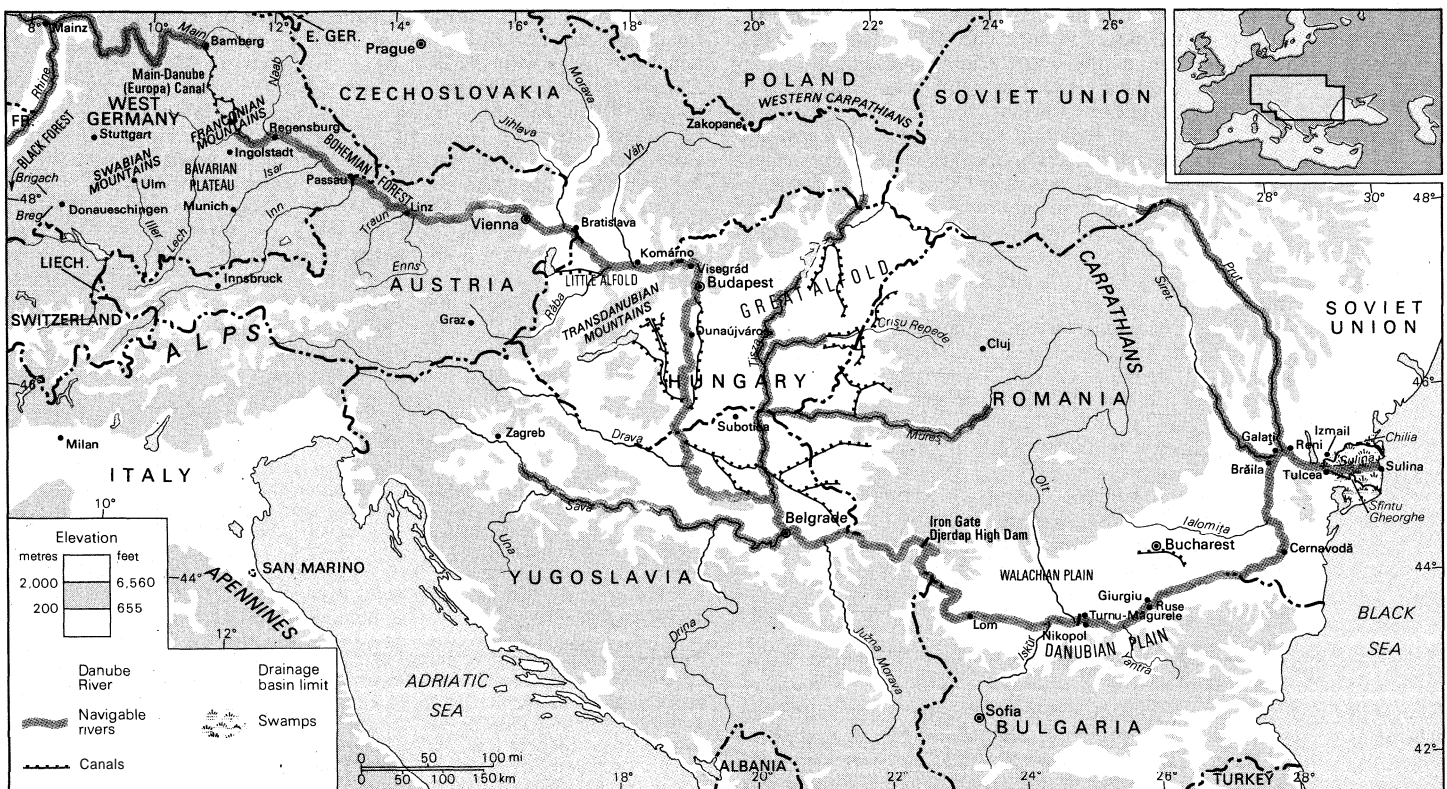

**The middle course.** In its middle course the Danube looks more like a flatland river, with low banks and a bed that reaches a width of more than one mile. Only in two sectors—at Visegrád (Hungary) and the Iron Gate—does the river flow through narrow, canyon-like gorges. The basin of the Middle Danube exhibits two main features—the flatland of the Little Alfold and the Great Alfold plains, and the low peaks of the Western Carpathians and the Transdanubian mountains.

The Danube enters the Little Alfold plain immediately after emerging from the Hungarian Gates Gorge near Bratislava, Czechoslovakia. There the river stream slows down abruptly and loses its transporting capacity, so that gravel and sand settle on the bottom. Between Bratislava and Komárno 785,000 cubic yards (600,000 cubic metres) of silt are deposited annually. A principal result of this deposition has been the formation of Great and Little Schiitt (Velký Žitný Ostrov and Szigetkoz) Islands, an area of 734 square miles that supports some 190,000 inhabitants in more than 100 settlements. The silting hampers navigation and occasionally divides the river into two or more channels. East of Komarno the Danube enters the Visegrád Gorge, squeezed between the foothills of the Western Carpathian and the Hungarian Transdanubian mountains. The steep right bank is crowned with fortresses, castles, and cathedrals of the Hungarian Árpád dynasty of the 10th to the 15th centuries.

The Danube then flows past Budapest and across the vast Hungarian Plain until it reaches the Iron Gate Gorge. The riverbed is shallow and marshy, and low terraces stretch along both banks. River accumulation has built a large number of islands, including those of Margitsziget and Csepelsziget near Budapest. In this long stretch the river takes on the waters of its major tributaries—the Drava, the Tisza, and the Sava—which create substantial changes in the river's regime. The average runoff increases from 3,074 to 7,639 cubic yards per second at the Iron Gate. The river valley looks most imposing there. Depths vary between five and 177 feet, and the current velocity ranges between 2.2 and 11.2 miles per hour. The rapids and reefs made the river unnavigable until a lateral navigation channel and a parallel railway

The river's northernmost point

The Iron Gate

The Danube River Basin and its drainage network

allowed rivercraft to be towed upstream against the strong current.

**The lower course.** Beyond the Iron Gate the Lower Danube flows across a wide plain. To the right, above steep banks, stretches the tableland of the Danubian Plain of Bulgaria. To the left lies the low Walachian Plain, which is separated from the main stream by a strip of lakes and swamps. The tributaries in this section are comparatively small and account for an increase in the total runoff of only 1,086 cubic yards per second. They include the Olt, the Siret, and the Prut. The width of the riverbed varies between 132 and 3,960 feet, the depth ranges between five and 30 feet, and the current speed is between one and 2.5 miles per hour.

The river is again obstructed by a number of islands. At Cernavodh, the Danube heads northward until it reaches Galați, where it veers abruptly eastward. Near Tulcea, some 50 miles from the sea, the river begins to spread out into its delta.

**The delta.** The river splits into three channels—the Chilia, which carries 67 percent of the total runoff; the Sulina, which accounts for 9 percent; and the Sfintu Gheorghe (St. George), which carries 24 percent. Navigation is possible only along the 39-mile-long Sulina Channel, which has been straightened and dredged to a depth of 23 feet. Between the channels, a maze of smaller creeks and lakes are separated by oblong strips of land called *grinduri*. Most *grinduri* are arable and cultivated, and some are overgrown with tall oak forests. A large quantity of reeds that grow in the shallow water tracts are used in the manufacture of paper and textile fibres. The Danube Delta (Delta Dunării) covers an area of 1,660 square miles and is a comparatively young formation. About 6,500 years ago the delta site was a shallow cove of the Black Sea coast, but it was gradually filled as the river deposited 80,000,000 tons of silt a year. The delta continues to grow seaward at the rate of 80 to 100 feet annually.

**The river regime.** The different physical features of the river basin affect the amount of water runoff in its three sections. In the Upper Danube the runoff corresponds to that of the Alpine tributaries, where the maximum occurs in June when melting of snow and ice in the Alps is the most intensive. Runoff drops to its lowest point during the winter months.

In the middle basin the phases last up to four months, with two runoff peaks in June and April. The June peak stems from that of the upper course, reaching its maximum 10 to 15 days later. The April peak is local. It is caused by the addition of waters from the melting snow in the plains and from the early spring rains of the lowland and the low mountains of the area. Rainfall is important; the period of low water begins in October and reflects the dry spells of summer and autumn that are characteristic of the low plains. In the lower basin all Alpine traits disappear completely from the river regime. The runoff maximum occurs in April, and the low point extends to September and October.

The river carries considerable quantities of solid particles, some 95 percent of which are quartz grains. The constant shift of deposits in different parts of the riverbed forms shoals. In the stretches between Bratislava and Komárno and in the Sulina Channel (Brațul Sulina), draglines are constantly at work to maintain the depth needed for navigation.

The temperature of the river waters depends on the climate of the various parts of the basin. In the upper course, where the summer waters derive from the Alpine snow and glaciers, the water temperature is low. In the middle and lower reaches summer temperatures vary between 71° and 75° F (22° and 24° C), while winter temperatures near the banks and on the surface drop below freezing. Upstream from Linz the Danube never freezes entirely because the current is turbulent. The middle and lower courses, however, become icebound during severe winters. Between December and March periods of ice drift combine with the spring thaw, causing floating ice blocks to accumulate at the river islands, jamming the river's course, and often creating major floods.

The winter freeze

The natural regime of river runoff changes constantly as a result of the introduction of stream-regulating equipment, including dams and dikes. The chemical content also changes as city sewerage, fertilizers, and industrial wastes are dumped into the river.

**Pollution.** The mineral content of the river is greater during the winter than the summer. The content of organic matter is relatively low, but pollution increases as the waters flow past industrial areas.

**Economic development.** **Navigation.** Eight countries—the Soviet Union, Romania, Yugoslavia, Hungary, Bulgaria, Czechoslovakia, Austria, and West Germany—use the river for freight transport. The major river ports include Izmail and Reni, Soviet Union; Galați, Brăila, and Giurgiu, Romania; Ruse and Lom, Bulgaria; Belgrade, Yugoslavia; Dunaujvaros and Budapest, Hungary; Komarno and Bratislava, Czechoslovakia; Vienna and Linz, Austria; and Regensburg, West Germany.

**Power generation.** The Danube has been tapped for power in a rudimentary fashion, mainly in its upper course. The process, however, is spreading downstream. The largest hydroelectric project—the Djerdap High Dam and the Iron Gate power station—was built jointly by Yugoslavia and Romania. The project has a 2,300,000-kilowatt capacity and an annual output of 11,000,000,000 kilowatt-hours. Another hydroelectric project by Yugoslavia and Romania, the Iron Gate II power station, was under construction in the early 1980s. Czechoslovakia and Hungary were building a hydroelectric station on the upper reaches of the river, and Romania and Bulgaria were constructing a station on the lower reaches. There are irrigated areas along the river in Czechoslovakia, Hungary, Yugoslavia, and Bulgaria. Industrial use of Danube waters is made at Vienna, Budapest, Belgrade, and Ruse.

**Fishing.** Until the late 1960s the Danube was a rich fishing ground. The most important fish varieties included the sturgeon, wels, pike, beluga, and Black Sea herring. Because of industrial pollution, however, animal life in the Danube has diminished, and some of the fish have moved to side lakes and swamps. Some 70 species of fish remain in the Danube.

There have long been plans to make the Danube part of a navigational system that would permit traffic between the North and the Black seas. In 1921 the central German government signed an agreement with the state of Bavaria for the construction of a 106-mile canal to link the Rhine and Main rivers with the Danube. Progress on the Main-Danube (Europa) Canal has been slow over the years, but by the 1970s it had been completed between the Main river and the town of Nürnberg, a distance of 44 miles. Construction then began on the more difficult segment of the canal south of Nürnberg, where the waterway would drop about 300 feet in 60 miles to Regensburg on the Danube. During the early 1980s, however, the West German government delayed completion of the canal because of the cost.

A canal linking the Danube, Oder, and Elbe rivers was also planned during the 1970s. Beginning at Bratislava, it would link up with the east-west navigable waterway of the Mittelland-Vistula-Bug-Dnepr rivers and push further north to bring Danubian freight to the North and Baltic seas.

**BIBLIOGRAPHY.** Though old, the ADMIRALTY NAVAL STAFF, NAVAL INTELLIGENCE DIVISION, *A Handbook of the River Danube*, 2 pt. (1915-19), is detailed on geographical and hydrological features, including a section on diseases and itineraries. STEPHEN GOROVE, *Law and Politics of the Danube* (1964); COMMISSION EUROPÉENNE DU DANUBE, *Un Siècle de coopération internationale sur le Danube, 1856-1956* (1956); and ÖSTERREICHISCHES OST- UND SÜDOSTEUROPA INSTITUT, *Atlas of the Danubian Countries* (1970- ), examine the river's international importance. A useful article is GUSTAV HOLZMANN, "Die Zukunft der Donauschifffahrt," *Z. Wirt Geogr.*, 8:18-25 (1964); while the river's importance at specific stages of its economic development is analyzed by ANTONIN BASCH in *The Danube Basin and the German Economic Sphere* (1944). Historical works include EMIL LENGYEL, *The Danube* (1940); and JOSEPH WECHSBERG, *The Danube: 2,000 Years of History, Myth, and Legend* (1979). A good travel account is LOVETT F. EDWARDS, *Danube Stream* (1940). JOHN LEHMANN, *Down River: A*

Dams and irrigation

*Danubian Study* (1939); JOHN R. COLVILLE, *Fools' Pleasure: A Leisurely Journey down the Danube to the Black Sea, the Greek Islands and Dalmatia* (1935); and J.E.P. HUGHES, *Through Many Lands by Water: 1780 Miles down the Danube* (1930), are useful. An older, straightforward guide to places of interest along the river is *The Danube from Passau to the Black Sea*, a trans. from the German by MAY O'CALLAGHAN (1913); there are two portraits of the Danube in a more leisurely age by JOHN P. SIMPSON, *Letters from the Danube*, 2 vol. (1847); and ROBERT SNOW, *Journal of a Steam Voyage down the Danube to Constantinople* (1842). *The Danube Delta*, issued by the Foreign Languages Publishing House in Bucharest (1956), is a book of photographs.

## Darius I the Great, of Persia

One of the greatest of the Achaemenid kings of Persia (Iran), Darius I unified the administration of the Achaemenid Empire and began the Persian attempt to penetrate Europe. Darius, who reigned from 522 to 486 BC, was the son of Hystaspes, the satrap (provincial governor) of Parthia. The principal contemporary sources for his history are his own inscriptions, especially the great trilingual inscription on the Bīsītūn (Behistun) rock at the village of the same name, in which he tells how he gained the throne. The accounts of his accession given by the Greek historians Herodotus and Ctesias are in many points obviously derived from this official version but are interwoven with legends; e.g., that Darius and his fellow conspirators left the question as to which of them should become king to the decision of their horses and that Darius won the crown by a trick of his groom.

Darius I, seated before two incense burners, giving audience to a dignitary; detail of a bas-relief of the north courtyard in the Treasury at Persepolis, late 6th–early 5th century BC. In the Archaeological Museum, Tehrān.

According to Herodotus, Darius, when a youth, was suspected by Cyrus II the Great (who ruled from 559 to 529 BC) of plotting against the throne. Later, he was in Egypt with Cambyses II, the son of Cyrus and heir to his kingdom, as a member of the royal bodyguard. After the death of Cambyses in the summer of 522 BC, Darius hastened to Media, where, in September, with the help of six Persian nobles, he killed Bardiya (Smerdis), another son of Cyrus, who had usurped the throne the previous March. In the Bīsītūn inscription Darius defended this deed and his own assumption of kingship on the grounds that the usurper was actually Gaumata, a Magian, who had impersonated Bardiya after Bardiya had been murdered secretly by Cambyses. Darius therefore claimed that he was restoring the kingship to the rightful Achaemenid house. He himself, however, belonged to a collateral branch of the royal family, and as his father and grandfather were alive at his accession, it is unlikely that he was next in line to the throne. Some modern scholars consider that he invented the story of Gaumata in order to justify his actions and that the murdered king was indeed the son of Cyrus.

Darius did not at first gain general recognition but had to impose his rule by force. His assassination of Bardiya was followed, particularly in the eastern provinces, by widespread revolts, which threatened to disrupt the empire. In Susiana, Babylonia, Media, Sagartia, and Margiana, independent governments were set up, most of them by men who claimed to belong to the former ruling families. Babylonia rebelled twice and Susiana three times. In Persia itself a certain Vahyazdata, who pretended to be Bardiya, gained considerable support. These risings, however, were spontaneous and uncoordinated, and, notwithstanding the small size of his army, Darius and his generals were able to suppress them one by one. In the Bīsītūn inscription he records that in 19 battles he defeated nine rebel leaders, who appear as his captives on the accompanying relief. By 519 BC, when the third rising in Susiana was put down, he had established his authority in the east. In 518 Darius visited Egypt, which he lists as a rebel country, perhaps because of the insubordination of its satrap, Aryandes, whom he put to death. He also removed Oroetes, the disloyal satrap of Sardis.

Having restored internal order in the empire, Darius undertook a number of campaigns for the purpose of strengthening his frontiers and checking the incursions of nomadic tribes. In 519 BC he attacked the Scythians east of the Caspian Sea and a few years later conquered the Indus Valley. In 513, after subduing eastern Thrace and the Getae, he crossed the Danube into European Scythia, but the Scythian nomads devastated the country as they retreated from him, and he was forced, for lack of supplies, to abandon the campaign. The satraps of Asia Minor completed the subjugation of Thrace, secured the submission of Macedonia, and captured the Aegean islands of Lemnos and Imbros. Thus, the approaches to Greece were in Persian hands, as was control of the Black Sea grain trade through the straits, of major importance to the Greek economy. The conquest of Greece was a logical step to protect Persian rule over the Asiatic Greeks from interference by their European kinsmen. According to Herodotus, Darius, before the Scythian campaign, had sent ships to explore the Greek coasts, but he took no military action until 499 BC, when Athens and Eretria supported an Ionian revolt against Persian rule. After the suppression of this rebellion, Mardonius, Darius' son-in-law, was given charge of an expedition against Athens and Eretria, but the loss of his fleet in a storm off Mt. Athos (492 BC) forced him to abandon the operation. In 490 BC another force under Datis, a Mede, destroyed Eretria and enslaved its inhabitants but was defeated by the Athenians at Marathon. Preparations for a third expedition were delayed by an insurrection in Egypt, and Darius died in 486 BC before they were completed.

Although Darius consolidated and added to the conquests of his predecessors, it was as an administrator that he made his greatest contribution to Persian history. He completed the organization of the empire into satrapies, initiated by Cyrus the Great, and fixed the annual tribute due from each province. During his reign, ambitious and far-sighted projects were undertaken to promote imperial trade and commerce. Coinage, weights, and measures were standardized and land and sea routes developed. An expedition led by Scylax of Caryanda sailed down the Indus River and explored the sea route from its mouth to Egypt; and a canal from the Nile to the Red Sea, probably begun by the chief of the Egyptian delta lords, Necho I (7th century BC), was repaired and completed.

While measures were thus taken to unite the diverse peoples of the empire by a uniform administration, Darius followed the example of Cyrus in respecting native religious institutions. In Egypt he assumed an Egyptian titulary and gave active support to the cult. He built a temple to the god Amon in the Kharga oasis, endowed the temple at Edfu, and carried out restoration work in other sanctuaries. He empowered the Egyptian Udjahorresne, who had served under Cambyses, to re-establish the medical school of the temple of Šais, and he ordered

Fortification of the empire

Darius as an administrator

Ascension to monarchy

his satrap to codify the Egyptian laws in consultation with the native priests. In the Egyptian traditions he was considered as one of the great lawgivers and benefactors of the country. In 519 BC he authorized the Jews to rebuild the temple at Jerusalem, in accordance with the earlier decree of Cyrus. He also continued the privileges granted by Cyrus to the Greek sanctuaries: a Persian official was reprimanded for exacting tribute and forced labour from the priests of the temple of Apollo near Magnesia on the Maeander River. In the opinion of some authorities, the religious beliefs of Darius himself, as reflected in his inscriptions, show the influence of the teachings of Zoroaster, and the introduction of Zoroastrianism as the state religion of Persia is probably to be attributed to him.

Darius was the greatest royal architect of his dynasty, and during his reign Persian architecture assumed a style that remained unchanged until the end of the empire. In 521 BC he made Susa his administrative capital, where he restored the fortifications, built an audience hall (apadana), and a residential palace. The foundation inscriptions of his palace describe how he brought materials and craftsmen for the work from all quarters of the empire. At Persepolis, in his native country of Fars (Persis), he founded a new royal residence to replace the earlier capital at Pasargadae. The fortifications, apadana, council hall, treasury, and a residential palace are to be attributed to him, although not completed in his lifetime. He also built at Ecbatana and Babylon.

## Darwin, Charles

Charles Robert Darwin, the English naturalist whose demonstration of organic evolution and its operating principle, natural selection, revolutionized human knowledge, was born on Feb. 12, 1809, at Shrewsbury. He was the son of Robert Waring Darwin and Susannah, daughter of Josiah Wedgwood I, the famous potter. His grandfather Erasmus Darwin was the polymath physician, poet, philosopher, and inventor who, by his second marriage, was also the grandfather of Francis Galton, founder of the science of eugenics.

By courtesy of the National Portrait Gallery, London

Darwin, oil painting by John Collier (1850–1934). In the National Portrait Gallery, London.

Youth and education. Darwin's mother died when he was eight years old, and he was brought up by his eldest

sister, Caroline, to whom he was always grateful for instilling in him a humanitarian spirit. The boy developed very slowly: he was given, when small, to inventing gratuitous fibs and to daydreaming; and he was passionately fond of collecting seals, franks (equivalents of postage stamps), pebbles, and minerals—an important trait in his future as a naturalist.

In 1818 he entered Shrewsbury School. Later he complained that he was taught only classics, never realizing his debt to them for providing a sound basis for his education. He was a poor student, and in 1825 his father reproached him, saying, "You care for nothing but shooting, dogs, and rat-catching, and you will be a disgrace to yourself and all your family." He was then sent to Edinburgh University to study medicine, but that also was a failure: the lectures disgusted him with science, witnessing an operation nauseated him; and he only enjoyed collecting marine animals in tidal pools, accompanying fishermen trawling for oysters, and learning to skin and stuff birds from a Negro who had accompanied a naturalist in South America.

As there was no future for Darwin in medicine, he left Edinburgh in 1827 and was sent to Cambridge to prepare for Holy Orders in the Church of England. At Christ's College he paid little attention to his official studies and fell in with a set of sporting young men as keen on shooting, riding, and hunting as he was. But he also got to know some distinguished scientists—in particular, John Stevens Henslow, professor of botany, who influenced Darwin profoundly by stimulating his interest in natural history and by giving him confidence in himself.

Career. In 1831 the Admiralty asked for a naturalist to accompany Capt. Robert Fitzroy of the Royal Navy on a voyage in HMS "Beagle" to survey the coasts of Patagonia, Tierra del Fuego, Chile, and Peru, to visit some Pacific islands, and to establish a chain of chronometrical stations around the world. Henslow recommended Darwin, who wanted to accept, but whose father objected that it would only be another interruption in his checkered education. His uncle Josiah Wedgwood II, however, persuaded Robert Darwin that his objections were unsound and he withdrew them. Darwin sailed from Devonport in the "Beagle" on Dec. 27, 1831. He was to be away five years.

The Cape Verde Islands provided him with his first object lesson of a volcano, on which he was able to test for himself the validity of Charles Lyell's *Principles of Geology*, which Henslow had advised him to take with him, but on no account to believe. Darwin did believe the results of his own observations, however, and these confirmed him in his acceptance of Lyell's doctrine of uniformitarianism (i.e., natural laws apply uniformly throughout time) and laid the foundations of his future as a scientist. In Brazil he saw his first tropical forest; in Argentina he found his first fossils—sloths, mastodons, and horses. In Tierra del Fuego he saw a race of men so savage, so devoid of any beliefs (and even occasionally cannibalistic) that they hardly seemed human. Three of them had been taken to England three years previously by Captain Fitzroy "to teach them the elements of Christianity and the use of tools," and they were now being repatriated. Darwin was astonished that "three years had been sufficient to change savages into as far as habits go complete and voluntary Europeans." But they soon reverted to savagery.

In Chile Darwin witnessed an earthquake and observed both its effects in raising the level of the land and its connection with volcanic eruption. Repeatedly when ashore he went on long, arduous, and dangerous expeditions on horseback, collecting and shooting, which showed that his addiction to sport had not been useless. On more than one occasion he saved the situation for his companions: once by running far and fast enough to save their boat from being destroyed by the wave raised by a glacier fall (they would all have been doomed had he failed) and another time by going on to get help when his captain and companions were exhausted and incapable of walking a step farther. Wherever he saw a mountain he

of the  
"Beagle"

HMS "Beagle" in Straits of Magellan, engraving by unknown artist. Mount Sarmiento is in the distance.  
The Bettmann Archive

climbed it, and on one journey from Chile to Argentina over high passes of the Andes, he was bitten massively by bugs. From the Galápagos Islands the "Beagle" sailed to Tahiti, New Zealand, Australia, Cocos Keeling Atoll, Mauritius, South Africa, St. Helena, Ascension Island, Brazil again (to check chronometers), and then home. Darwin landed at Falmouth on Oct. 2, 1836.

All Darwin's work stemmed directly from the observations and collections that he made during the voyage of the "Beagle." As shown in the title of his book *Journal of Researches into the Geology and Natural History of the Various Countries Visited by H.M.S. Beagle, 1832-36* (1839), his main interests were at first geological (although natural history took precedence over geology in the second edition of his *Journal*, 1845), and his observations resulted in three further books: *Structure and Distribution of Coral Reefs* (1842), *Geological Observations on Volcanic Islands* (1844), and *Geological Observations on South America* (1846). In the eyes of posterity, these works were so eclipsed by Darwin's bombshell on evolution that they have been neglected, but they were fundamental to his later work.

Starting from the fact that coral polyps can live only in clear salt water less than 20 fathoms deep, at temperatures not less than 68° F, and that coral atolls and barrier reefs are all at about sea level, Darwin argued that such atolls and reefs could only have resulted from subsidence of the sea floor, the corals growing upward as their bases dropped. Darwin's view has since been confirmed by deep borings of coral reefs revealing at depths of nearly 5,000 feet dead corals that once lived within 120 feet of the surface.

Another kind of reef, which Darwin called the fringing reef, occurs above sea level and results from elevation of the sea floor. Plotting on the map the distribution of atolls and barrier reefs on the one hand and of fringing reefs on the other, he saw that great areas of the ocean bottom had undergone subsidence, and others elevation, and that all active volcanoes are in the latter. This agreed with the correlation that he had observed in South America between volcanic action and elevation of the ground. That such changes of level could be substantial he saw from his discovery in the Andes—at an altitude of 7,000 feet—of a fossil forest overlain by thousands of feet of sedimentary deposits laid down by the sea, thus proving the occurrence of earlier earth movements of the order of 10,000 feet vertical height.

In petrology his comparison of volcanic lavas with plutonic rocks showed that they were closely related. The minerals in crystalline granites and in glasslike lavas were similar. His studies of the direction of the strike and the angle of dip of strata showed that planes of cleavage and of foliation were constant over very wide areas, parallel to the direction of great axes along which elevation

of land had taken place over hundreds of miles. Furthermore, these planes of cleavage and foliation had no relation to the planes of stratification of sedimentary deposits and had been superimposed on strata by pressure and recrystallization. This was the origin of the "deformation" theory of metamorphic rocks.

The collection of animals that he made was described by a team of specialists under Darwin's editorship and published in *The Zoology of the Voyage of the Beagle* (1840-43). But Darwin's biological contribution to science was of a different nature. When he started on the voyage, like everyone else he did not question the immutability of species. But several questions set him thinking: Why do so many similar animals exist so far apart geographically? Why does the South American rhea, for example, resemble so closely the African ostrich? On the other hand, why were adjacent areas populated by similar though not identical species? Why, for instance, were the birds and tortoises of each Galápagos island different, although the physical conditions of the islands seemed identical?

After his return Darwin saw, in 1837, that these questions and many more—in comparative anatomy, embryology, classification, geographical distribution, and palaeontology—could be satisfactorily explained if species were not immutable but had evolved into other species, many with a common ancestor. The evolutionary view of descent with modification from ancestral species, exhibited by descendant species, provides a complete explanation of all these questions, which otherwise remain inexplicable and without a common determining principle. Further details of the huge mass of evidence supporting this view from all branches of biology are given in the article on EVOLUTION.

Darwin realized that it would be useless, in the state of opinion of his day, to try to convince anybody of the truth of evolution unless he could also explain how it was brought about. In searching for this cause he knew that the key to man's success in producing change in cultivated plants and domestic animals was careful selection of parents from which to breed the desired qualities, and he felt sure that selection must somehow also be operative in nature's creation of species. He knew that all individuals in a species were not identical but showed variation, and he realized that some individuals, well adapted to the places they occupied in the economy of nature (in the mid-20th century called ecological niches), would flourish, while others, less adapted, would perish. This was the principle of natural selection that he had grasped as early as 1837, but he still required to know how nature enforced it. On Sept. 28, 1838, he read Malthus' *Essay on the Principle of Population* in which the author tried to show that, as the rate of increase of human population was in a geometrical ratio, while that of increase in human food supply was only in arithmetical ratio, the result must be misery and death for the poor, unless population growth was checked. Malthus' argument was unsound because it has never been determined to what extent human food supply could be artificially increased if it were given sufficient priority and finance. But Darwin saw at once that this fallacious argument could be applied correctly to plants and animals, which are unable to increase their food supply artificially. He saw, too, that in these organisms mortality must be very high, thereby automatically enforcing the mechanism of selection of parents of successive generations. The note in telegraphic style which Darwin entered that day in his "Notebook on Transmutation of Species" is worth quoting:

On an average every species must have same number killed year with year by hawks, by cold, & c.—even one species of hawk decreasing in number must affect instantaneously all the rest. The final cause of all this wedging must be to sort out proper structure. . . . One may say there is a force like a hundred thousand wedges trying to force every kind of adapted structure into the gaps in the oeconomy of nature, or rather forming gaps by thrusting out weaker ones.

In these words Darwin showed that he had solved the problem of the origin and improvement of adaptation as

Darwin's evolutionary concept

The principle of natural selection

Geological writings

a result of selection pressure, and that modification during descent (*i.e.*, evolution) does not take place in a vacuum but is strongly related to the ecological niches occupied by the species. Darwin is therefore included among the founding fathers of the science of ecology.

Evolution had been advocated before, by some French speculative philosophers (Montesquieu, Maupertuis, Diderot), by Darwin's grandfather Erasmus Darwin, and by Lamarck, who was the first to draw up an evolutionary tree from unicellular organisms to man. But Lamarck's neglecting to provide evidence for evolution and his attempt to explain its cause by appealing to an "inner feeling"—the supposed existence of a tendency to perfection—and to his equally fanciful belief in the satisfaction of the needs of the organisms, led other scientists to reject his evolutionary theory. Darwin was the first to provide adequate evidence for evolution and to explain how the process of natural selection produces adaptation.

After having discovered the greatest general principle in biology, Darwin kept it to himself. In 1842 he pencilled a "Sketch" of his results, which he expanded in an "Essay" in 1844, but he showed it only to his botanist friend Joseph Dalton Hooker. From 1846 to 1854 he devoted his attention and energies to a study of the different species of living and fossil barnacles, for the purpose of classifying them. This tedious work provided him with firsthand experience of the amount of variation found in species and of the problems of classification, essential for the study of how species originate. These researches were published between 1851 and 1854 in four specialized monographs on stalked and sessile, living and fossil Cirripedia.

In 1856 Darwin started to put on paper his discoveries about evolution and natural selection, adding all the time to his evidence by studies on the problem of divergence (*i.e.*, the greater variability of species belonging to wide-ranging genera containing many species), on geographical distribution and the function of sea and wind in disseminating the population of oceanic islands, and by discussions with his friends Lyell, Hooker, and Thomas Henry Huxley. The work went steadily on until, on June 18, 1858, out of the blue, Darwin received from Alfred Russel Wallace, a naturalist then in the Malay Archipelago, a succinct but complete statement of his own conclusions on evolution and natural selection. Darwin's shock at the danger of being forestalled in work on which he had been engaged for 20 years was great, but the situation was saved by Lyell and Hooker who insisted that a joint paper by Darwin and Wallace should be read before the Linnean Society of London on July 1, 1858. Darwin then started what he called an "abstract" of the full work on which he was engaged. This abstract was the *Origin of Species*, which was published on November 24, 1859, and sold out immediately. By 1872 the work had run through six editions.

With this book Darwin brought down on himself enemies of two kinds. The first were old-fashioned scientists, some like Adam Sedgwick who refused to admit Darwin's method of using hypothesis as acceptable in science, and another like Richard Owen who had until then enjoyed the (very undeserved) reputation of being the leading English biologist and who, mad with jealousy and devoid of all scruple, realized that his former friend Darwin might eclipse him altogether and must, at any cost, be discredited. The other class of enemies were the upholders of orthodox religious beliefs, to whom Darwin administered two shocks: if evolution was true, the account of the Creation in the Book of Genesis was false or, at least, not literally true, and if evolution worked automatically by natural selection, there was no room for divine guidance and design in the production of living plants and animals, including man, on earth. The battle was joined at the Oxford meeting of the British Association for the Advancement of Science on June 30, 1860. Owen had carefully coached Samuel Wilberforce, bishop of Oxford, who attacked Huxley in a patronizing and contemptuous manner over Darwin's views. Huxley

tore the bishop to pieces in his brilliant reply, and the Church of England never again formally attempted to cross swords with science.

Darwin published three more books as extensions and amplifications of the principles expressed in the *Origin of Species*. These were *The Variation of Animals and Plants Under Domestication* (1868), which was a detailed inquiry into the origins and varieties of cultivated plants and domestic animals; *The Descent of Man and Selection in Relation to Sex* (1871), which applied the principle of evolution to man, including his moral sense, and introduced the notion of sexual selection as complementary to natural selection; and *The Expression of the Emotions in Man and Animals* (1872), which was the culmination of an interest that Darwin had already shown in 1837 when he wrote "Seeing a dog, horse and man yawn, makes one feel how all animals are built on one structure." The latter book was a notable contribution to psychology and the foundation of the science of ethology.

Darwin's remaining books dealt with plants, but all had running through them the theme of adaptation, its origins and improvements, and the survival value that it conferred. This is clearly seen in *On the Various Contrivances by Which British and Foreign Orchids are Fertilised by Insects* (1862), in which he showed that the flowers have a shape adapted to the landing on them of insects, which thrust their proboscises into the flower in search of nectar, and that the pollen sacs then become detached from the flower and attached to the insect, which flies away and pollinates other flowers. There are a number of fascinating points involved here: Darwin showed that all flowers that depart from radial symmetry are adapted to the reception of insects, whose role in pollinating flowers explains why flowering plants and insects both evolved rapidly in the Jurassic Period, when insects first appeared, and also why no plant that is pollinated by wind has coloured flowers, the function of which is to attract insects.

Having observed cross-pollination by insects and assuming that it provided a selective advantage, Darwin proceeded to investigate it. He raised two large beds of plants from cross-pollinated and self-pollinated seeds obtained from the same parent plant and found that the former were larger, more vigorous, and more fertile than the latter. The reasons for this are now well understood from Mendelian genetics. Darwin's results were published in *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom* (1876). He had found the reason why there are two sexes in the plant and animal kingdoms, for they are adaptations to ensure cross-fertilization and, as was learned later, interchange of genes.

In *Climbing Plants* (1875) Darwin studied not only the mechanism of twining, which he found to be a circular sweeping movement of growth by the apex of stems, but also the significance of this ability to twine and climb, which enables the plant to reach in one season a height where its leaves are more exposed to sunlight and air, without having to develop a thick woody trunk. Twining is therefore an adaptation, which is improved in some species by the conversion of leaves into tendrils and even further in others where the tips of the tendrils when they strike a solid surface are converted into adhesive disks, as in Virginia creeper. This Darwin viewed as a progressive series of adaptive improvements.

These observations led Darwin to experiment on the factors that cause growing tips of shoots and roots to bend; *i.e.*, to grow faster on one side than on the other. His great discovery here was that the growing tip of a shoot is sensitive to light, and that the tip turns toward the light because the stem grows on the side of the shoot away from the light; but this growth occurs at a place some distance down the stem, even if it is screened from light. Therefore, there is "some matter in the upper part which is acted upon by light, and which transmits its effects to the lower part." Similarly, in roots it is the tip that is sensitive to gravity and to contact with solid objects and that brings about differential growth further up the root as well as bending. From these experiments

tion of  
*Origin of  
Species*

Botanical  
writings

sprang the whole science of growth hormones in plants. In *Insectivorous Plants* (1875) Darwin described the most remarkable adaptations. In the sundew (*Drosera rotundifolia*) the upper surface of each leaf bears some hundred tentacles ending in a gland that secretes a viscid substance. When a fly touches these glands it becomes stuck, and neighbouring tentacles bend toward it and their glands fix on the fly. Raw meat, ammonia, and other solutions, Darwin found, have the same effect as a fly. The secretion of the glands dissolves (digests) albumin, muscle, connective, and other tissues. The bending of the tentacles is due to the transmission of excitation through the cells of the leaf. The sensitivity of the glands is such that a tiny piece of hair weighing 0.0008 milligrams is sufficient to cause bending. The most extraordinary thing of all is that after a fly has been caught and the glands have secreted their digestive juice onto it the products of the digested insect are then absorbed by the glands into the plant. This fantastic state of affairs led Darwin to write jokingly to Hooker (Dec. 4, 1860), "By Jove, I sometimes think *Drosera* is a disguised animal." That it is adaptive was shown by Darwin's son Francis who grew *Drosera* plants "fed" on meat and compared them with "unfed" plants under the same conditions. The former were larger, had more leaves and more seed capsules. Later it became clear that *Drosera* can grow on very poor soil and has few roots because it supplements its nitrogen supply with animal food.

The *Formation of Vegetable Mould Through the Action of Worms* (1881) was a pioneer study in quantitative ecology. The amount of soil, ground fine, brought up to the surface from the depth of a foot by earthworms, Darwin calculated (by weighing wormcastings) to amount to 18 tons per acre per year. The mold thus formed is not only aerated and most suitable for plant growth, but the wormholes make it easier for the rootlets to grow. The importance of this work was stressed in the mid-20th century by the fact that the chemical manures and pesticides that came to be used in agriculture kill the unpaid army of worms and reduce fertility.

**Personality.** The development of Darwin's mind and personality presents a number of problems. A few weeks before he served on the "Beagle" he did not even know what science was, until the Rev. Adam Sedgwick showed him that if a certain fossil shell of a tropical mollusk had really been found in a certain glacial deposit, it would overthrow all that was known of geology in England, for science is a consistent and organized body of knowledge. It was therefore no experienced scientist who sailed on the "Beagle" but an undistinguished candidate for Holy Orders equipped mainly with courage and horse sense. The man who returned, however, was the hardest headed biologist of the century. Part of this mental metamorphosis was due to his reading Lyell's *Principles of Geology* and applying them in the field to the facts that he observed. Another factor was his conviction from what he saw that the account of the Creation in the Bible was demonstrably false. He had learned to apply critical judgment.

At the same time he was astonishingly naïve in such general matters as methodology. In his day science was supposed to make progress only by inductive methods. Darwin wrote, "I worked on true Baconian principles and without any theory collected facts on a wholesale scale." This was invalidated by Darwin himself when he wrote to Lyell (June 1, 1860): "Without the making of theories, I am convinced there would be no observations." Thus he recognized that there are no such things as purely inductive observations, for if the observer had not already in his head an idea of what he was looking for, derived from deduction, he would not observe anything at all.

Darwin's method was to spin a hypothesis about anything that struck his attention (*i.e.*, anything that he was predisposed by ideas to see), and then to deduce from it consequences that should follow and could be refuted or verified. This "hypothetic-deductive" method, as Sir Peter Medawar has called it, is illustrated in Darwin's

letter to F.W. Hutton (April 20, 1861): "I am actually weary of telling people that I do not pretend to adduce direct evidence of one species changing into another, but I believe that this view is in the main correct, because so many phenomena can thus be grouped and explained."

As he went on and realized the enormous importance of his demonstration of evolution by natural selection, he began to concentrate more and more deeply on this field. He wrote to Hooker (Oct. 13, 1858): "It is an accursed evil to a man to become so absorbed in any subject as I am in mine." All his mental energy was focussed on "his subject," and that was why poetry, pictures, and music ceased in his mature life to afford him the pleasure that they had given him in his earlier days. As he himself said, his mind had become "a kind of machine for grinding general laws out of large collections of facts."

His technique for collecting facts, in addition to those that he observed for himself, was illustrative of his tenacity. Whenever he found any man whose practical experience in a field of study had made him expert, Darwin bombarded him unremittently with questions and clung to him like a leech. He always gilded the pill of his questions with disarmingly sweet phrases: "if it would not cause you too much trouble" or "pray add to your kindness"; and he realized what a burden he must be to his correspondents, as he admitted to J. Jenner Weir (March 6, 1868), "If any man wants to gain a good opinion of his fellow men, he ought to do what I am doing, pester them with letters."

It is remarkable that, though in physical appearance he aged very markedly, he retained the most endearing childlike traits. On Jan. 20, 1839, he wrote to his fiancée, his first cousin Emma Wedgwood, nine days before their wedding, "I take so much pleasure in the [new] house, I declare I am just like a great overgrown child with a new toy; but then not like a real child, I long to have a co-partner and possessor." He remained a great overgrown child all his life, and this accounts for his ever-present sense of fun, often expressed at his own expense, as when he accepted Jenner Weir's invitation to become a Patron of the Cat Show (Sept. 18, 1872), and added, "People may refuse to go and admire a lot of atheistical cats." His description of a good novel was that it must have in it some character that one can thoroughly love, and if a pretty woman, all the better. When he lost a game of cards he exploded in mock anger. He was also fond of teasing friends.

This childlike mentality was responsible for some astonishingly naïve views that he held. To Huxley he wrote (Jan. 9, 1860), "The history of error is quite unimportant." He had no historical or political sense whatever, as may be seen in what he wrote to the Austrian explorer Karl von Scherzer, (Dec. 26, 1869): "What a foolish idea seems to prevail in Germany on the connexion between Socialism and Evolution through Natural Selection." He was not unaware of Karl Marx, for when the latter asked permission to dedicate the English edition of *Das Kapital* to him, Darwin refused because he did not wish to be associated with attacks on religion. This needs explanation.

The former candidate for Holy Orders had come to see that the Old Testament, "from its manifestly false history of the earth, . . . and from its attributing to God the feelings of a revengeful tyrant, was no more to be trusted than the sacred books of the Hindoos, or the beliefs of any barbarian." The New Testament did not fare any better, and he could "indeed hardly see how anyone ought to wish Christianity to be true; for if so, the plain language of the text seems to show that the men who do not believe, and this would include my Father, Brother and almost all my best friends, will be everlastingly punished. And this is a damnable doctrine." The key to understanding Darwin's thinking is his horror of the imposition of suffering—on slaves by their masters, on animals by men, and by "the clumsy, wasteful, blundering, low, and horribly cruel works of nature," as seen in the suffering caused by parasites and in the delight in cruelty

Method  
of work

Darwin  
as an  
ecologist

Darwin's  
agnosticism

shown by some predators when catching and playing with their prey. If God is as almighty, omniscient, and possessed of inexhaustible compassion as he is painted, "it revolts our understanding to suppose that his benevolence is not unbounded." So Darwin became a reverent agnostic.

As a young man he was passionately fond of shooting, but after he discovered a bird that had been maimed but not killed on a previous shoot, he never shot again. But he did not give way to sentimentalism, as may be seen in the letter that he wrote to *The Times* (London) on June 23, 1876, about the controversy then (and since) raging over vivisection: "Women, who from the tenderness of their hearts and from their profound ignorance are the most vehement opponents of all such experiments, will I hope pause when they learn that a few such experiments performed under the influence of an anaesthetic, have saved and will save through all future time thousands of women from a dreadful and lingering death."

The young man who, during all the hardships and dangers of the voyage of the "Beagle" and his numerous hazardous journeys ashore, enjoyed stout health and great physical stamina, within a few months of his return began to show increasingly frequent symptoms of illness that reduced him to a state of semi-invalidism. These were great lassitude, painful intestinal discomfort with much flatulence, frequent vomiting, and sleeplessness. His doctors were quite unable to find any organic cause for his condition, in which he settled down to a daily routine of four hours' work, walks in the garden, and rests on a sofa smoking a cigarette while being read to. Frequently he was unable to work at all. On several occasions he went to take the water cure at a spa, but without lasting benefit.

Recently, psychiatrists have claimed to account for Darwin's condition by advancing diverse (and contradictory) explanations: that he had "poor nervous heredity on both sides," or "depressive obsessional anxiety and hysterical symptoms" due to "a distorted expression of aggression, hate, and resentment felt at an unconscious level by Darwin towards his tyrannical father"; that his work on evolution had killed the Heavenly Father and given him an Oedipus complex; and that his shunning of social life and acceptance of his wife's ministering care was evidence of his being a neurotic. All this specious and special pleading is unnecessary since S. Adler drew attention to the massive attack that Darwin suffered in 1835 from the bites of a bug, *Triatoma infestans*, the most important carrier of the trypanosome of Chagas' disease. This trypanosome, not discovered until 1909, is found in the blood even many years after infection; it causes lassitude and heart block and prevents normal functioning of the intestines. The case histories of patients with Chagas' disease and Darwin's symptoms fit like a glove: he suffered a heart attack in 1873 and died of another in 1882.

It is against this background of suffering that Darwin's scientific work was achieved and that his family life was lived. His home was an oasis of loving-kindness, as all visitors to Down House found, after the family had moved there in 1842 from London, where the strain of social life tired Darwin too much. Ten children were born, of whom two died in infancy. One, Anne, died at the age of ten under very tragic circumstances, and when Darwin had recovered somewhat from his grief he composed a little ode on her, the most beautiful thing that he ever wrote.

Of his other children, George, Francis, and Horace made such important contributions to science in astronomy, botany, and civil engineering, respectively, that they were knighted; Leonard was an economist and eugenicist. Subsequent generations have also shown great distinction, a tribute alike to Darwin and Wedgwood genes and to the family circles in which they grew up.

Darwin died at Down on April 19, 1882. Twenty members of Parliament petitioned the dean of Westminster for him to be buried in the Abbey. Agreement was reached immediately and the funeral took place on April

26. Among the pallbearers were Hooker and Huxley, as well as a great number of foreign dignitaries.

#### MAJOR WORKS

*Journal of Researches into the Geology and Natural History of the Various Countries Visited by H.M.S. Beagle, 1832-36*, popular title, *The Voyage of the Beagle* (1839); *The Structure and Distribution of Coral Reefs* (1842); *On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life* (1859); *The Various Contrivances by Which Orchids are Fertilised by Insects* (1862); *The Movements and Habits of Climbing Plants* (1865); *The Variation of Animals and Plants Under Domestication* (1868); *The Descent of Man, and Selection in Relation to Sex*, 2 vol. (1871); *The Expression of the Emotions in Man and Animals* (1872); *The Insectivorous Plants* (1875); *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom* (1876); *The Different Forms of Flowers on Plants of the Same Species* (1877); *The Power of Movement in Plants* (1880); *The Formation of Vegetable Mould Through the Action of Worms* (1881).

**BIBLIOGRAPHY.** FRANCIS DARWIN (ed.), *Life and Letters of Charles Darwin*, 3 vol. (1887), is the standard life by Darwin's son. It contains most of the personal information about Darwin but was written at a time when the full significance of evolution of natural selection was not understood, and when the practice of transcribing and publishing letters was imperfect. *More Letters: Letters of Charles Darwin*, 2 vol., ed. by FRANCIS DARWIN and A.C. SEWARD (1903), is also a collection of essential documents but again suffers from inadequate methods of publication.

Works edited by SIR GAVIN DE BEER include: *Darwin and Huxley: Autobiographies* (1971), an edition collated from the original manuscript that represents the only accurate text; "Darwin's Sketch of 1842" and "Essay of 1844," in *Evolution by Natural Selection* (1958), contain Darwin's earliest exposition of his discoveries, first published by Francis Darwin in 1909 and long out of print; "Darwin's Notebooks on Transmutation of Species," *Buil. Br. Mus. (Nat. Hist.)*, Historical Series, vol. 2 (1960) and vol. 3 (1967), contain the evidence of the progress of Darwin's thoughts from 1837 to 1839. The only work to take into account Darwin's notebooks on transmutation of species and Mendel's attitude toward Darwin is *Charles Darwin* by SIR GAVIN DE BEER (1963).

The Cambridge University Library is the receptacle of most Darwin manuscripts, but an important collection is in the American Philosophical Society Library in Philadelphia, containing Darwin's letters to Sir Charles Lyell and a "Critical Chronology of Darwin's Life" on index cards.

(G.de B.)

## Dating, Relative and Absolute

Dating is placing events in time—a necessary pursuit to understanding the ebb and flow of the past. In the context of dating, numbers such as AD 1492, when Columbus came to the New World, or AD 1066, the Battle of Hastings, come to mind. This kind of dating is called absolute dating, and a specific number of years is always given. Dating also can be done with relation to notable events or periods of history, without any numerical citation; this is described as relative dating. Examples are Renaissance literature and Colonial architecture, where the adjectives Renaissance and Colonial relate the nouns to past intervals that are noted more for what happened than for when it happened.

Ideally, it would be desirable to date a given event both absolutely and in a relative sense. When the extraordinary events and periods of history are absolutely dated, it becomes possible in many instances to date them relatively as well. If a certain English poem were known to have been written in AD 1580, for example, it would be—in relative terms—Elizabethan, because England's Queen Elizabeth I reigned from 1558 to 1603.

Unfortunately, the converse of the above principle does not always follow. That is, an event relatively dated is not necessarily dated absolutely. Two situations will demonstrate why the converse is not always so. First, the date of an event may be known only as having occurred before or after another event, with no knowledge of how long before or after. The discovery of fire, for example, is dated relatively as having occurred in prehistoric time—that is, before about 6,000 years ago. How much before is uncertain at present.

Distinction between absolute and relative dating

Darwin's illness

A second situation in which relative dating is possible without knowledge of absolute age occurs when the sequence of notable happenings to which dating is related has not been defined absolutely. In geology and in prehistoric archaeology, this situation existed for many decades before the application of radiometric dating. Such relative terms as Paleozoic and Neolithic originated when sequences of important events had been deciphered from layered deposits but without knowledge of the absolute dates of the events comprising each sequence.

This article treats dating outside the traditional field of history, which relies upon written records. Its focus instead is on human remains and artifacts that predate traditional history and on the geological rock record that reflects even more remote events. The dating of these events and these objects is of major concern here. This article also covers the several methods of dating and their application within the following format:

- I. Relative dating
  - Application to geological problems
    - The rock cycle
    - Determination of sequence
    - Correlation
    - The geological time scale
  - Application to archaeological problems
    - Archaeological sites
    - Correlation
    - The archaeological time scale
- II. Absolute dating
  - General considerations
    - Meaning of absolute age
    - Dating requirements

### I. Relative dating

Historically, determination of relative-age relationships preceded methods for absolute-age measurement. Such an order was not rationally predetermined; it simply reflects the fact that it is usually easier to decipher which of two events came first than to determine how many years ago either one happened.

The determination of the particular events that have happened came before their relative dating. This task generally depends on the existence of tangible things that are indicative of past events. In the field of archaeology, the tangible record consists of artifacts, skeletal remains, and structures such as buildings. In geology the documents of past events are rocks and the surface and subsurface features comprised of rocks. Because of the practical value of geological knowledge, systematic efforts at deciphering the geological past came before extensive archaeological endeavour. This gave rise to the principles of relative dating basic to both fields.

#### APPLICATION TO GEOLOGICAL PROBLEMS

**The rock cycle.** A concise description of crustal changes and rock origins is communicated through what is called the rock cycle. In interpreting the rock record, geologists observe the processes that are shaping the Earth

today and assume that rocks came into being through similar processes in the past. More accurately, what is assumed rigorously is the temporal uniformity of the physical and chemical behaviour of matter. But applied practically, this usually means leaning very heavily on present processes while being fully aware that their intensity and scope may have been highly variable in the past.

Although all rocks are derived from pre-existing matter in some form, igneous rocks, those crystallizing from silicate melts, are the closest approximation to primordial earth material. Thus, an examination of the rock cycle—the idealized path traversed from molten material through various rock types and, ultimately, back to the bowels of the Earth—generally begins with magma, the molten material that cools on or within the Earth to give rise to igneous rocks.

The fate of almost any rock in extended contact with the atmosphere is to undergo change. When igneous rocks such as granite and basalt interact with atmospheric constituents—mainly oxygen, moisture, and carbon dioxide—the rocks are chemically altered and reduced in particle size. At some size, ranging from atoms to great blocks, particles are transported by water, winds, or glaciers and are deposited elsewhere when the transporting power diminishes. In certain favourable areas, deposition is extensive enough and of sufficient duration to result in the conversion of sediments into rock. Compaction and natural cementing, generally by precipitation of mineral matter from solution in pore spaces, are the main processes responsible for this change, called lithification. If stream sorting of particles has resulted in deposition of a bed of sand-size grains, for example, the rock formed by lithification will be a sandstone whose grains are bound by a mineral cement.

Sedimentary rocks commonly are deposited in great troughs in the Earth's crust that are loci of subsequent mountain building. Mountain-building conditions involve both crustal deformation and the action of deep-seated igneous processes, and any rock present at depth may be altered; it is then called a metamorphic rock. Marble, a derivative of sedimentary limestone, is an example of such alteration. Under the high pressure and temperature of the metamorphic environment, changes of different sorts occur: the development of new minerals, enlargement of pre-existing crystals, and the rearrangement of crystals into more orderly patterns. If the temperature of metamorphism exceeds the rock melting point, partial or total melting will occur, and a new magma will be formed. Thus, the rock cycle may begin all over again.

Not every rock on Earth has run the gamut of changes included in the rock cycle. The cycle is merely a systematic representation of the sorts of changes, both observed and inferred, that have happened throughout most of Earth history. These are the changes that must be placed in proper sequence—that is, relatively dated in geological problems.

**Determination of sequence.** Relative geological dating focusses principally on sedimentary rocks. These rocks cover about three-quarters of the area of the continents, and unconsolidated sediments blanket most of the ocean floor. They provide evidence of former surface conditions and the life-forms then present. The sequence of a layered sedimentary series is easily defined because deposition always proceeds from the bottom to the top. This principle would seem self-evident, but its first enunciation more than 300 years ago represented an enormous advance in understanding. It is called the principle of superposition and means that in a series of sedimentary layers or superposed lava flows the oldest layer is at the bottom, and layers from there upward become progressively younger.

On occasion, however, deformation may have caused tilting of the rocks of the Earth's crust, perhaps to the point of overturning them. And, if erosion has blurred the record by removing considerable portions of the deformed sedimentary rocks, it may not be at all clear which edge of a given layer is the original top and which the original bottom.

Formation  
of sedi-  
mentary  
rocks

Problems  
caused by  
tilting

Identifying top and bottom is clearly important in sequence determination—so important, in fact, that a considerable literature has grown up centring on this question alone. Many of the criteria of top–bottom determination are based on asymmetry in depositional features. Oscillation ripple marks, for example, are produced in sediments by water sloshing back and forth. When such marks are preserved in sedimentary rocks, they define the original top and bottom by their asymmetric pattern. Certain fossils also accumulate in a distinctive pattern or position that serves to define the top-side.

Another factor which causes complications in sequence determination is the action of thrust faulting, which slides older rocks on top of younger ones. Although each layer in a sedimentary series may continue to be oriented with its top side up and bottom side down, their relative ages will no longer accord with the principle of superposition. This occurrence has taken place in many of the world's mountain ranges. In Glacier Park, Montana, for example, a block of sedimentary layers 1,000,000,000 years old has been thrust over layers only one-tenth as old.

Cross-cutting relationships

The principle of crosscutting relationships is another important criterion in sequence determination. It states that, if rock feature *A* cuts across rock feature *B*, then *A* is younger than *B*. Commonly, *B* is a rock mass, whereas *A* is generally a quasi-planar feature, such as a dike (tabular body of igneous rock) or a fault or an unconformity (interruption of the sequence by erosion or nondeposition). Thus, a fault that offsets the stratification of a sedimentary sequence occurred after the layers were deposited. And a dike running up the face of a limestone quarry was injected as magma along a crack in the limestone after the limestone was deposited as sediment. Similarly, an unconformity that terminates a series of inclined layers is a buried erosion surface created after the layers were tilted.

A rock mass encasing a relatively small fragment of different rock type must be younger than the fragment it contains, and this provides another tool for deciphering the rock record. If a conglomerate, for example, consists of pebbles of a distinctive granite, then the conglomerate formed as a rock unit after the parent granite mass solidified from magma. Another example concerns the relative age of a sill formed of magma forced between adjacent layers of sedimentary rock. In the magma injection, chunks of overlying sedimentary materials often break loose and are trapped within the upper part of the sill magma, perhaps later to be seen in a cliff exposing a cross section of the layered series. The fact that the sill is younger than the overlying sedimentary layer becomes clear from the sedimentary fragments encased in the upper sill rock. Without the fragments, other criteria—often more subtle—would be needed to distinguish the sill from a lava flow that had been subsequently buried by younger sedimentary material.

On the basis of the foregoing principles, the proper sequence of the layers exposed in any particular outcrop—be it as extensive as the Grand Canyon or as limited as a small road cut—can be determined. A hypothetical outcrop in which these principles are applied is shown in Figure 1.

Figure 1: Hypothetical outcrop to which sequence-determining techniques can be applied. The correct sequence, from oldest to youngest, is: *D, E, N, X, S, G, M, F, Z, B, T*.

As the only tangible record of a certain past interval at a certain place, every sedimentary outcrop is essentially the sole source of whatever is to be learned about that interval in that place. Geologic deduction must then extract from the rock at hand as much information about past conditions as is possible—such information as the regional climate, the depositional environment, the nature of the source area that provided sediment grains, and the living forms then extant.

Unfortunately, when the geologist finishes interpreting a single sedimentary outcrop, he has only the story of an unknown time interval from somewhere in the vastness of the past. Beneath the lowermost layer in the outcrop, rocks that would extend that time interval may be present, but they are out of sight. In addition, erosion may have removed overlying rocks and the record that they contain. It is even possible that within a given outcrop there may not be a continuous record of deposition. Whatever the situation, it is clear that a single outcrop falls far short and is inadequate for representing all of the past. The solution is found in the technique called correlation.

**Correlation.** Correlation is the technique of piecing together the information content of separated outcrops. When two outcrops are pieced together, the time interval they represent is probably greater than that of each alone. Presumably, if all the world's outcrops were integrated, sediments representing all of geological time would be available for examination. This optimistic hope, however, must be tempered by the realization that much of the Precambrian (older than 570,000,000 years) record is missing. Correlating two separated outcrops means establishing that the two share certain characteristics that imply their formation at the same time. The most useful indication of time equivalence is similar fossil content. The basis for assuming that similar fossils indicate contemporary formation is called faunal succession.

Unlike the principles of superposition and crosscutting, faunal succession is a secondary principle. That is, it depends on other sequence-determining principles for establishing its validity. Suppose there exist a number of fossil-bearing outcrops each composed of sedimentary layers that can be arranged in relative order, primarily based on superposition. Suppose, too, that all the layers contain a good representation of the animal life existing at the time of deposition. From an examination of such outcrops with special focus on the sequence of animal forms comes the empirical generalization known as faunal succession—that the faunas of the past have followed a specific order of succession, so that the relative age of a fossiliferous rock is indicated by the types of fossils it contains.

William Smith, an English geologist and engineer, first noticed around 1800 that the different rock layers he encountered in his work were characterized by different fossil assemblages. Using fossils simply for identification purposes, Smith constructed a map of the various surface rocks outcropping throughout England, Wales, and southern Scotland. Smith's geologic map was extremely crude, but in its effect on Earth study it was a milestone.

Following Smith's pioneering work, subsequent generations of geologists have confirmed that similar and even more extensive fossil sequences exist elsewhere. To this day, fossils are useful as correlation tools to geologists specializing in stratigraphy. In dating the past, the primary value of fossils lies within the principle of faunal succession: each interval of geologic history had a unique fauna that associates a given fossiliferous rock with that particular interval.

The basic conceptual tool for correlation by fossils is the index, or guide, fossil. Ideally, an index fossil should be such as to guarantee that its presence in two separated rocks indicates their synchronicity. This requires that the life-span of the fossil species was but a moment of time relative to the immensity of geological history. In other words, the fossil species must have had a short temporal range. On the practical side, an index fossil should be distinctive in appearance so as to prevent misidentifica-

Index fossils

tion, it should be cosmopolitan both as to geography and as to rock type, and its fossilized population should be sufficiently abundant for discovery to be highly probable. Such an array of attributes represents an ideal, and many problems of stratigraphic geology are rendered difficult because of departure of the natural fossil assemblage from this ideal. Nevertheless, there is no greater testimony to the validity of fossil-based stratigraphic geology than that provided by absolute dates made possible through radioactive measurements. Almost without exception, the relative order of strata defined by fossils has been confirmed by radiometric ages.

Correlation based on the physical features of the rock record has also been used with some success, but it is restricted to small areas that generally extend no more than several hundred miles. The first step is determining whether similar beds in separated outcrops can actually be traced laterally until they are seen to be part of the same original layer. Failing that, the repetition of a certain layered sequence (*e.g.*, a black shale sandwiched between a red sandstone and a white limestone) lends confidence to physical correlation. Finally, the measurement of a host of rock properties may well be the ultimate key to correlation of separated outcrops. The more ways in which two rocks are physically alike, the more likely it is that the two formed at the same time.

Only a partial listing of physical characteristics is necessary to indicate the breadth of approach in this area. Such features as colour, ripple marks, mud cracks, raindrop imprints, and slump structures are directly observable in the field. Properties derived from laboratory study include (1) size, shape, surface appearance, and degree of sorting of mineral grains; (2) specific mineral types present and their abundances; (3) elemental composition of the rock as a whole and of individual mineral components; (4) type and abundance of cementing agent; and (5) density, radioactivity, and electrical-magnetic-optical properties of the rock as a whole.

With the development of miniaturized analytical equipment, evaluation of rock properties down a small drill hole has become possible. The technique, called well logging, involves lowering a small instrument down a drill hole on the end of a wire and making measurements continuously as the wire is played out in measured lengths. By this technique it is possible to detect depth variations in electrical resistivity, self-potential, and gamma-ray emission rate and to interpret such data in terms of continuity of the layering between holes. Subsurface structures can thus be defined by the correlation of such properties.

Field geologists always prize a layer that is so distinctive in appearance that a series of tests need not be made to establish its identity. Such a layer is called a key bed. In a large number of cases, key beds originated as volcanic ash. Besides being distinctive, a volcanic-ash layer has four other advantages for purposes of correlation: it was laid down in an instant of geological time; it settles out over tremendous areas; it permits physical correlation between contrasting sedimentary environments; and unaltered mineral crystals that permit radiometric measurements of absolute age often are present.

Correlation may be difficult or erroneous if several different ash eruptions occurred, and a layer deposited in one is correlated with that from another. Even then, the correlation may be justified if the two ash deposits represent the same volcanic episode. Much work is currently under way to characterize ash layers both physically and chemically and so avoid incorrect correlations.

The **geological time scale**. The end product of correlation is a mental abstraction called the geological column. It is the result of integrating all the world's individual rock sequences into a single sequence. In order to communicate the fine structure of the geological column, it has been subdivided into smaller units. Lines are drawn on the basis of either significant changes in fossil forms or discontinuities in the rock record (*i.e.*, unconformities); the basic subdivisions of rock are called systems, and the corresponding time intervals are called periods. In the upper part of the geological column, where

fossils abound, these rock systems and geological periods are the basic units of rock and time. Lumping of periods results in eras, and splitting gives rise to epochs. In both cases, a threefold division into early-middle-late is often used, although those specific words are not always applied. For example, the three eras with abundant life have prefixes paleo ("old"), meso ("middle"), and ceno ("recent"). Similarly, many periods are split into three epochs. Names assigned to individual epochs follow no single worldwide standard except for the seven epochs comprising the last two periods (Figure 2).

	Precambrian		4030	4600	
	formation of Earth's crust			4600	

Figure 2: Geological time scale.

Over the interval from the Paleozoic to the present, about 35 epochs are recognized in North America. This interval is represented by approximately 250 formations, discrete layers thick enough and distinctive enough in lithology to merit delineation as units of the geological column. Also employed in subdivision is the zone concept, in which it is the fossils in the rocks rather than the lithologic character that defines minor stratigraphic boundaries. The basis of zone definition varies among geologists, some considering a zone to be all rocks containing a certain species (usually an invertebrate), whereas others focus on special fossil assemblages.

The lower part of the geological column, where fossils are almost absent, was at one time viewed in the context of two eras of time, but subsequent mapping has shown the provincial bias in such a scheme. Consequently, the entire lower column is now considered a single unit, the Precambrian. Hopefully, the results of radiometric dating will someday provide finer Precambrian subdivisions that have worldwide applicability.

The geological column and the relative geological time scale are sufficiently defined to fulfill the use originally envisioned for them—providing a framework within which to tell the story of Earth history. Just as human history has its interweaving plots of warfare, cultural development, and technological advance, so the Earth's rocks tell another story of intertwined sequences of events. Mountains have been built and eroded away, seas have advanced and retreated, a myriad of life-forms have inhabited land and sea. In all these happenings the geological column and its associated time scale spell the difference between an unordered series of isolated events and the unfolding story of a changing Earth.

Rock properties determined in the laboratory

Divisions of the geological column

APPLICATION TO ARCHAEOLOGICAL PROBLEMS

The fields of archaeology and geology are significantly different in subject matter. To the archaeologist, man is the central figure, his cultural and skeletal remains are the materials for study, and knowledge of his developing culture is the goal. By contrast, man is a minor character in the geological drama. He appeared almost at the end of the story, when the topography and continental outlines had achieved essentially their present configurations and life on Earth was much like that existing today. In methodology, however, geological and archaeological investigations have many similarities. Both focus on a record within the Earth and exhume objects for laboratory study; more importantly, both depend on superposition and correlation to introduce chronological order among widely scattered remains of ancient events.

**Archaeological sites.** Although archaeological sites do not display the almost perfect layering characteristic of most sedimentary outcrops, they often show enough layering to permit application of the principle of superposition for sequence determination. Much of the layering is the result of natural sedimentary processes that take place at the sites of human occupation. Dust and volcanic ash settle from the air, flood deposits cover living sites adjacent to rivers, and cave floors accumulate ceiling rocks, dripstone coatings, or animal excrement. The growth of vegetation may make a significant contribution.

In towns occupied for long intervals, streets gradually rise by serving as rubbish receptacles, while degenerating houses collapse alongside them. Every so often, fire or earthquake or invader strikes with destruction, forcing residents to rebuild from scratch on freshly smoothed-out rubble. Such events have raised the multilayered tells of the Middle East as much as 100 feet (30 metres) above their surrounding plains.

Man, of course, is as likely to stir up layers as he is to form them. In burying his departed brethren or the day's garbage, he may be forcing relatively young objects into levels of far greater antiquity. Failure to recognize such intrusions may lead to erroneous sequences and stand in the way of reconstructing a realistic history.

In its ideal configuration, an archaeological site is a series of layers that must be stripped away one at a time. The artifacts or structures in each layer are separated from the sedimentary matrix, after which their locations in three-dimensional space are recorded. Hopefully, such locations in the horizontal time plane have cultural significance rather than merely reflecting random scattering.

Because no site is ideally layered, one or more trenches are often dug in order to see the stratigraphy in cross section. Trenches indicate the approximate thickness of culture-bearing deposits and provide some idea whether the site is worth the digging required to examine it.

**Correlation.** Artifacts are to archaeological correlation what fossils are to rock correlation. As correlation tools, both artifacts and fossils are undergirded by the principle of superposition for defining their order of appearance. Both include special types that are valuable because their temporal range is very short. Both have successions of forms that developed over time. And the limitations and problems that beset one are like those that plague the other.

Chief among the artifacts useful in archaeological correlation are tools, hand weapons, and pottery fragments (potsherds). Generally made of durable materials, such objects can perform their intended function through a multitude of designs. Like fossils, there are no a priori grounds on which to predict the evolution in design of a pot or a spear point or even whether change in style necessarily occurred.

The geographical spread of an ancient pottery style depended on the degree to which trade homogenized a region. To the extent that individual groups were isolated from other societies by natural and cultural barriers, their artifacts would almost certainly develop along different lines. Isolation, then, clearly limits the distance of

correlation and introduces an undesirable element of provincialism in archaeological study.

As a way to overcome the spatial limitations imposed by correlating with artifacts, there has been a concerted effort by archaeologists to search out climatic indicators associated with cultural material—such features as characteristic sediments, distinctive weathering patterns, and climate-sensitive plants and animals. The goal is to match various archaeological sequences with the climate chronology that has been determined for the Ice Age and subsequent time (see Figure 3). It follows that two widely

From William Lee Stokes, *Essentials of Earth History: An Introduction to Historical Geology*, 2nd ed. (© 1966); Prentice-Hall, Inc.

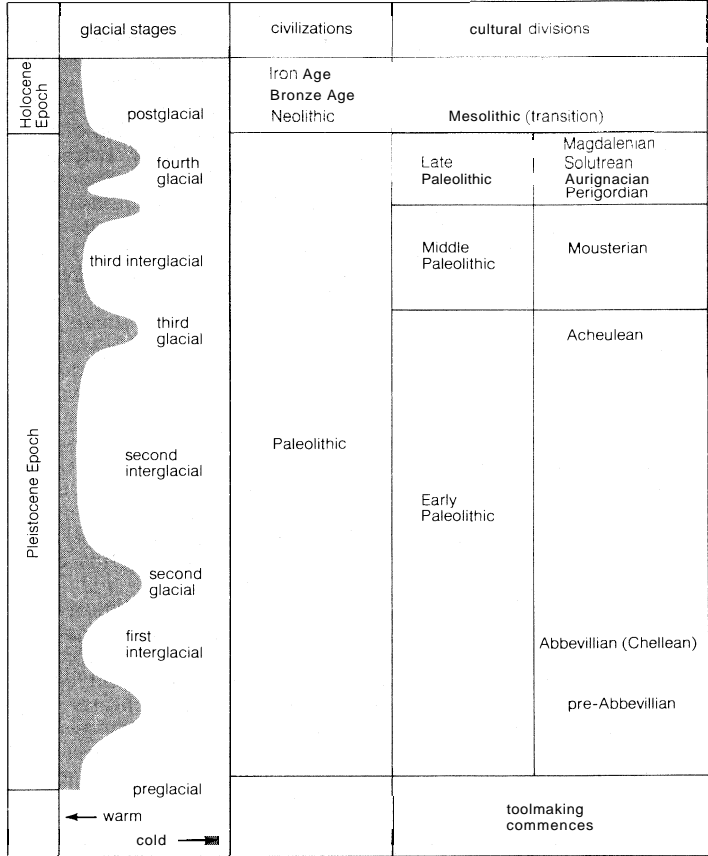

Figure 3: Archaeological time scale.

separated archaeological layers would be correlated if they fitted identically into the standard relative chronology of climatic change.

Associated fossils are a further aid in correlation, provided they are of extinct organisms. In fact, it was the association of man-made implements with the bones of such extinct mammals as the mammoth and rhinoceros that was instrumental in winning the day for those propounding the great antiquity of man. The crowning evidence came in 1864 with the discovery in a French cave of a mammoth's portrait engraved on a mammoth tusk.

Despite a century of developing principles and methods, archaeological correlation in 1950 clearly needed a new technique with sufficient versatility to integrate hundreds of isolated sites. It was then that carbon-14 dating first became feasible, evoking an overwhelmingly positive response from archaeologists. In carbon-14 dating they were offered an absolute dating technique spanning the last 50,000 years and applicable to the sorts of organic material often plentiful in culture layers. If its numerical ages were correct, then worldwide correlation and sequence determination of separated sites was possible, as well as the unscrambling of stratigraphically complex deposits.

On the basis of more than 20 years of experience, it is now safe to say that carbon-14 dating is indeed the Rosetta Stone of prehistoric archaeology. A measure of chronological order has been introduced where previ-

Importance of carbon-14 dating

Layering in archaeological sites

Major artifacts used in archaeological correlation

ously there was often chaos. Furthermore, it has provided the yardstick necessary to establish and calibrate additional chronometers based on time-dependent physical properties such as thickness of obsidian rinds and magnetic intensity. Only with fossil men, whose ages are measured in hundreds of thousands of years, does carbon-14 dating fail to provide insights. And here potassium-argon dating gives evidence of picking up where carbon-14 leaves off. In combination, potassium-argon and carbon-14 hold out the promise of understanding mankind's history to a degree undreamed of before their introduction. Hopefully, the sharp distinction between history and prehistory will be blurred by this new chronologic light on man's ancient past. Details concerning the two techniques are discussed under *Radio-metric dating: Major dating methods*.

**The archaeological time scale.** Like its geological counterpart, the archaeological time scale (Figure 3) is a product of Western intellectual thought that crystallized chiefly within the 19th century. Parallels between the two time scales are remarkable in many ways. First, there were ideological barriers to overcome. This meant at the outset that stone artifacts had to be properly recognized as products of man rather than freaks of nature or the works of elves and fairies. That accomplished, a more formidable task remained—convincing Western man that the history of his ancestors was far longer than that allowed for in Archbishop Ussher's pronouncement that creation occurred in 4004 BC.

The foundation of an archaeological time scale can be ascribed chiefly to C.J. Thomsen of Denmark. While working in his family's shipping business, Thomsen spent one day a week as the unpaid secretary of the Royal Commission for the Preservation of Danish Antiquities. His job was to put some order to the correspondence and specimens that had accumulated for several years. As a rank amateur, Thomsen carried out his task unfettered by any presuppositions on how best to classify material. The artifacts themselves formed the basis of his system. Specifically, they were placed in broad categories according to construction material (stone, metal, and pottery). Further subdivisions were made on the basis of use intended, such as tools, weapons, containers, and cult objects. When his museum was opened for public view some three years later, Thomsen displayed selected specimens in three cabinets housing, respectively, objects of stone, bronze, and iron.

At the grand opening Thomsen probably had not reached the conclusion that material type indicated relative age. But an extensive correspondence with archaeologists in the coming years brought a conviction that prehistory could be divided chronologically into Stone Age, Bronze Age, and Iron Age. Twenty years after taking over as commission secretary, Thomsen published his classic account entitled *Guide to Scandinavian Antiquities*, in which he not only presented his three-age hypothesis but even provided such details as criteria to discern objects of bronze made in the Iron Age. Undergirding Thomsen's chronology were observations on the artifacts that occurred together and, in some cases, stratigraphic relationships. There was even an awareness that certain artifact types suggested evolution of form.

The three ages of stone, bronze, and iron formed only the superstructure of prehistory, however. As expected, closer scrutiny of the physical record brought an avalanche of evidence pointing toward greater complexity. First came the recognition in France that the Stone Age needed subdivision into an old period (Paleolithic) and a new period (Neolithic); this conclusion was based on the recognition that chipped stones antedated polished ones. Further excavations suggested that the Paleolithic-Neolithic boundary corresponded to the termination of the Ice Age and the onset of postglacial conditions. Later, the Mesolithic, or Middle Stone, Age was introduced in the early 20th century to correct a misconception that there had been a hiatus in European human history during the transition from glacial to nonglacial conditions.

In the late 1800s prehistorians reached the high point in their preoccupation with chronological classification.

It was then that a whole series of French archaeological sites gave rise to new subdivisions or cultural traditions within the Paleolithic. Such adjectives as Abbevillian (formerly called Chellean), Acheulean, Mousterian, and Aurignacian were introduced, each derived from a different location in France where an important find had been made.

So long as the world of archaeology lay totally in Europe and the Middle East, there was almost an implicit faith that the three-age time scale had a universality to it in both space and time. The pace and course of cultural development have clearly been different in different places, however, and today different time scales are being developed in different parts of the world, each with its own set of period names. In North America, for example, the major time divisions of prehistory bear the names Paleo-Indian, Meso-Indian, and Neo-Indian, and cultural traditions within these broad intervals have been given such names as Clovis and Hopewellian. Multiplying terminology is clearly a danger if it obscures similar sequences of events in different places. Yet it is an obvious necessity if geographical barriers have resulted in many totally unique lines of development. The hope is that recently developed absolute-dating schemes will soon unify global prehistory to the point where the jargon explosion will be curbed. In the meantime, the archaeological time scale of Figure 3 will continue to be the standard for some time to come.

## II. Absolute dating

### GENERAL CONSIDERATIONS

**Meaning of absolute age.** Absolute age, the elapsed time since a past event occurred, must be clearly understood in terms of that event. For people, age is almost universally measured from birth, but in some cultures it is conceivable that age might be reckoned from the time of puberty rites. That is, what is implicit in one context may not be so in another. Similarly, when absolute ages are given for an object of geological or archaeological significance, a knowledge of what happened at time zero is of the utmost importance. Failure to be specific in this regard may introduce misunderstanding.

In most cases, the age of a rock is the number of years that have elapsed since it reached its present condition. To say that a rock is 1,000,000,000 years old means that it underwent crystallization, deposition, or its last metamorphism 1,000,000,000 years ago—depending on whether it is an igneous, sedimentary, or metamorphic rock. On the other hand, if the rock is a granite pebble that has been fashioned into an axhead, the most significant age is the time since the tool was made, not the interval since the granite crystallized. Similar comments apply to a piece of wood used for an ax handle; photosynthesis and shaping occurred at different times. In more subtle situations, this sort of distinction may be crucial to understanding or application.

**Dating requirements.** Essential to dating is a physical record of time. Beginning with such a record, all schemes of absolute dating are comprised of three elements: (1) a discernible starting point that defines the meaning of absolute age, (2) a discernible termination point, and (3) a known rate for spanning the two. A freshly cut tree that exposes a record of time in its cross section of concentric rings provides a good example. The starting point is the inner ring and the termination point the outer ring; the two are spanned at a rate of one ring per year. Hence, 100 rings indicate a tree that grew continuously from a time 100 years ago until recent cutting. The tree is said to be 100 years old, even though all rings but the inner one are younger than this age.

For 100 years to be the correct age, however, two premises that were tacitly assumed must be true. First, there must be a physical record for every year—in other words, the tree is presumed to have deposited rings continuously. Second, the rate of ring addition is assumed to be exactly one per year. How valid these two premises are depends on a detailed examination of the growth patterns of many trees representing different species and different environments. It has been deter-

Essential elements in absolute dating schemes

Thomsen's efforts to create a time scale

mined that the two premises are generally true, although exceptions have been noted. A small uncertainty is therefore associated with the 100-year age, its magnitude being determined by species of tree and growth environment. Implicit in this discussion is the assumption that tree growth during observation is typical of that in previous years.

Another assumption involves the date of the start of growth. If a tree stump is produced not by cutting but, rather, by natural causes—such as felling by a heavy wind in the unknown past—a counting of rings would establish only the age of the tree when it was killed, not the time when the tree began to grow. The record of ring widths provides a 100-year chronology of climatic variation in either case, but the **chronology** obtained from the man-made stump is fixed, whereas that from the wind-created stump is without an anchor in time. It is said to be floating. Floating chronologies are usually far less valuable than those that are fixed.

Questions asked in evaluating dating methods

The foregoing example points to five questions that must be posed in evaluating any method proposed for determining absolute ages: (1) what physical record of time is available? (2) is the record complete? (3) are the end points of the record clearly discernible? (4) what point in time corresponds to the terminal point of the record? and (5) is the rate of buildup or accumulation of the record determinable and, if so, how reliably?

**Rate of record accumulation.** The physical records used in absolute time measurement leave much to be desired in the way of completeness and clarity. But the crucial problem in absolute dating is generally the rate at which the record accumulated. The usual procedure is to measure the present rate and assume that this has prevailed throughout the period of record accumulation. If there were good theoretical and practical reasons for constancy of rate, this procedure would be satisfactory, but there exist in nature many changing conditions that can alter process rates. It is for this reason that radiometric dating claims such a supreme position; there seems to be no possible way for environmental change to cause a change in the rate of radioactive decay.

Support for the constancy of radioactive change comes from both nuclear theory and experiment. In the laboratory, for example, it is impossible to alter the rate of radioactive decay by any combination of pressure and temperature known to exist within the Earth's crust. The same is true with respect to gravitational, magnetic, and electric fields as well as the chemical state in which a given radioactive element is found. In short, the process of radioactive decay is immutable under all conditions significant to geology and archaeology.

#### RADIOMETRIC DATING

**Radioactivity and radioactive decay.** The word radioactivity almost defines itself, indicating a sustained process in which radiation is continuously emitted from certain types of matter. An examination of radioactivity at the atomic level, however, shows that the outward appearance of continuity is merely the combined result of many random atomic events called disintegrations, or decays. When an individual radioactive atom disintegrates, two things happen: (1) one or more particles are ejected from the nucleus of the atom, contributing to the total sample radiation; and (2) the nucleus changes character as a result of particle ejection, becoming a new kind of matter in most cases.

The two results of atomic disintegration

It is impossible to predict the instant when any given radioactive atom will disintegrate. But, when enough radioactive atoms of a certain type are placed together, observation shows that the number of disintegrations per unit time is proportional to the number of radioactive atoms present. The situation is analogous to the death rate among the human population insured by an insurance company. Although it is impossible to predict when a given policy holder will die, the company can count on paying off a certain fraction of beneficiaries every month.

The foregoing behaviour of radioactive atoms can be expressed mathematically as follows:

$$\begin{array}{ccccc} R & \alpha & N & & \\ \text{rate of disintegration} & \text{is proportional to} & \text{number of radioactive atoms.} & & (1) \end{array}$$

Converting this proportion to an equation incorporates the additional observation that different radioisotopes have different disintegration rates even when the same number of atoms are observed undergoing decay. In other words, each radioisotope has its own decay constant, abbreviated  $k$  ( $\lambda$ ), which provides a measure of its intrinsic rapidity of decay. Proportion (1) becomes:

$$R = \lambda N. \quad (2)$$

Stated in words, this equation says that the rate at which a certain radioisotope disintegrates depends not only on how many atoms of that isotope are present but also on an intrinsic property of that isotope represented by  $\lambda$  ( $\lambda$ ), the so-called decay constant. Values of  $\lambda$  vary widely—from  $10^{20}$  reciprocal seconds (*i.e.*, the unit of 1/second) for a rapidly disintegrating isotope such as helium-5 to less than  $10^{-25}$  reciprocal seconds for slowly decaying cerium-142.

In the calculus, the rate of decay  $R$  in equation (2) above is written as the derivative  $dN/dt$ , in which  $dN$  represents the small number of atoms that decay in an infinitesimally short time interval  $dt$ . Replacing  $R$  by its equivalent  $dN/dt$  results in the differential equation

$$\frac{dN}{dt} = -\lambda N. \quad (3)$$

Solution of this equation by techniques of the calculus yields one form of the fundamental equation for radiometric age determination,

$$\frac{N}{N_0} = e^{-\lambda t}, \quad (4)$$

in which  $N_0$  is the number of radioactive atoms present in a sample at time zero,  $N$  is the number of radioactive atoms present in the sample today,  $e$  is the base of natural logarithms (equal to about 2.72),  $\lambda$  is the decay constant of the radioisotope being considered, and  $t$  is the time elapsed since time zero.

Two alterations are generally made to equation (4) in order to obtain the form most useful for radiometric dating. In the first place, since the unknown term in radiometric dating is obviously  $t$ , it is desirable to rearrange equation (4) so that it is explicitly solved for  $t$ . Second, the more common way to express the intrinsic decay rate of a radioisotope is through its half-life (abbreviated  $t_{1/2}$ ) rather than through the decay constant  $\lambda$ . Half-life is defined as the time period that must elapse in order to halve the initial number of radioactive atoms. The half-life and the decay constant are inversely proportional, because rapidly decaying radioisotopes have a high decay constant but a short half-life. With  $t$  made explicit and half-life introduced, equation (4) is converted to the following form, in which the symbols have the same meaning:

Definition of half-life

$$t = \frac{t_{1/2}}{0.693} \times \log_e \left( \frac{N_0}{N} \right) \quad (5)$$

**Principles of radiometric dating.** Among the 103 known chemical elements, there exist approximately 1,650 different species of atoms known as isotopes. Of this total, about 335 are naturally occurring (as opposed to man-made), and more than 1,350 are radioactive (as opposed to stable). In nature there are about 65 radioactive isotopes. Those most useful in dating are listed in Table 1.

In radiometric dating as currently practiced, the dominant cumulative effect that is measured is the amount of daughter isotope present (the daughter is the isotope produced by decay of some original, long-lived isotope called the parent). Figure 4 summarizes pictorially the four modifications of the basic decay principle central to radiometric dating. The simple hourglass (Figure 4A), which includes the majority of rock-dating methods, is readily related to equation (5) above. Because the half-life

**Table 1: Natural Radioactive Isotopes of Possible Use in Absolute Dating**

radioisotope	mode of origin*	half-life (years)	particle emitted	daughter
Aluminum-26 ( $^{26}\text{Al}$ )	cosmogenic	$7.4 \times 10^5$	beta-plus	magnesium-26 ( $^{26}\text{Mg}$ )
Argon-39 ( $^{39}\text{Ar}$ )	cosmogenic	269	beta-minus	potassium-39 ( $^{39}\text{K}$ )
Beryllium-10 ( $^{10}\text{Be}$ )	cosmogenic	$2.7 \times 10^6$	beta-minus	boron-10 ( $^{10}\text{B}$ )
Carbon-14 ( $^{14}\text{C}$ )	cosmogenic	5,730†	beta-minus	nitrogen-14 ( $^{14}\text{N}$ )
Chlorine-36 ( $^{36}\text{Cl}$ )	cosmogenic	$3.07 \times 10^5$	beta-minus	argon-36 ( $^{36}\text{Ar}$ )
Hydrogen-3 ( $^3\text{H}$ )	cosmogenic	12.3	beta-minus	helium-3 ( $^3\text{He}$ )
Iodine-129 ( $^{129}\text{I}$ )	primordial	$16 \times 10^6$	beta-minus	xenon-129 ( $^{129}\text{Xe}$ )
Lead-210 ( $^{210}\text{Pb}$ )	radiogenic	22	beta-minus	bismuth-210: ( $^{210}\text{Bi}$ ); ultimately to lead-206
Lutetium-176 ( $^{176}\text{Lu}$ )	primordial	$36 \times 10^9$ (?)	beta-minus	hafnium-176 ( $^{176}\text{Hf}$ )
Potassium-40 ( $^{40}\text{K}$ )	primordial	$1.28 \times 10^9$	electron capture beta-minus	calcium-40 ( $^{40}\text{Ca}$ ) and argon-40 ( $^{40}\text{Ar}$ )
Protactinium-231 ( $^{231}\text{Pa}$ )	radiogenic	$3.24 \times 10^4$	alpha	actinium-227 ( $^{227}\text{Ac}$ )
Rhenium-187 ( $^{187}\text{Re}$ )	primordial	$43 \times 10^9$ (?)	beta-minus	osmium-187 ( $^{187}\text{Os}$ )
Rubidium-87 ( $^{87}\text{Rb}$ )	primordial	$50 \times 10^9$	beta-minus	strontium-87 ( $^{87}\text{Sr}$ )
Silicon-32 ( $^{32}\text{Si}$ )	cosmogenic	650	beta-minus	phosphorus-32: ( $^{32}\text{P}$ ); ultimately to sulfur-32
Sodium-22 ( $^{22}\text{Na}$ )	cosmogenic	2.6	beta-minus	neon-22 ( $^{22}\text{Ne}$ )
Strontium-90 ( $^{90}\text{Sr}$ )	man-made	28.9	beta-minus	yttrium-90: ( $^{90}\text{Y}$ ); ultimately to zirconium-90
Thorium-230 ( $^{230}\text{Th}$ )	radiogenic	$7.8 \times 10^4$	alpha	radium-226 ( $^{226}\text{Ra}$ )
Thorium-232 ( $^{232}\text{Th}$ )	primordial	$14.1 \times 10^9$	alpha	radium-228: ( $^{228}\text{Ra}$ ); ultimately to lead-208
Uranium-234 ( $^{234}\text{U}$ )	radiogenic	$2.47 \times 10^5$	alpha	thorium-230: ( $^{230}\text{Th}$ )
Uranium-235 ( $^{235}\text{U}$ )	primordial	$0.71 \times 10^9$	alpha	thorium-231: ( $^{231}\text{Th}$ ); ultimately to lead-207
Uranium-238 ( $^{238}\text{U}$ )	primordial	$4.5 \times 10^9$	alpha	thorium-234: ( $^{234}\text{Th}$ ); ultimately to lead-206
Uranium-238 ( $^{238}\text{U}$ )	primordial	$1.0 \times 10^{16}$	spontaneous fission	many fission fragments‡ plus 2–3 neutrons

\*Primordial isotopes have existed as long as the Earth; radiogenic isotopes are the products of radioactive decay; cosmogenic isotopes result from cosmic rays impinging on matter; and man-made isotopes are mainly produced during nuclear bomb testing. †See text for variation. ‡Radioactive.

is constant for any particular radioisotope being considered and is known from physical measurement, dating laboratories focus on measurements of the ratio  $N_0/N$ , the reciprocal of which is merely the fraction of radioactive atoms still remaining in the sample being dated. When the numerical value of  $N_0/N$  is inserted into equation (5) along with the appropriate half-life, the age  $t$  is readily calculated.

Although the number (N) of radioactive atoms present in a sample is directly measurable, the comparable number at time zero ( $N_0$ ) must be arrived at indirectly. In the simple hourglass (Figure 4A), the initial number of radioactive atoms is just the sum of the stable daughter atoms and the radioactive parent atoms now in the sample. This means that analyses for two different

sample isotopes are required. As an example, suppose a uranium sample is shown to contain four trillion ( $4 \times 10^{12}$ ) atoms of uranium-238 and one trillion stable lead-206 atoms. It follows that there were five trillion uranium-238 atoms at time zero and that the ratio ( $N_0/N$ ) is 5:4, or 1.25. Insertion of 1.25 into equation (5) along with a half-life of 4.5 billion ( $4.5 \times 10^9$ ) years results in an age of 1.45 billion years.

In Figure 4B the so-called bottomless hourglass, equation (5), is again used, but here there is no possibility of analyzing for stable daughter atoms. The reason is simply that these atoms are swallowed up in a sea of primordial isotopes of the same type. Consider the most important example of B, namely, radiocarbon dating, in which carbon-14 decays to nitrogen-14, the dominant isotope of nitrogen. Because nitrogen is quite common and is always present in natural situations in which carbon-14 is disintegrating, nitrogen-14 produced by decay is immediately mixed in with environmental nitrogen-14 and completely dwarfed by it. There is no possibility whatsoever of distinguishing identical isotopes of different origin. What must be done in the case of the bottomless hourglass is to look about for other systems involving the same radioisotope but having essentially zero age. Hopefully, there will be good reason to believe that the sample of unknown age began its life with a similar level of radioactivity. In radiocarbon dating, for example, the carbon-14 level in living material is presumed to represent the time-zero level of older wood and charcoal samples submitted for dating. Such an assumption and others like it are clearly not made without first marshalling evidence that they have a high probability of being valid. Failure of the assumption may introduce a significant error.

In Figure 4C is a third radiometric dating method, one in which a radioisotope is being added to a sample as fast as it is departing by decay. The experience of using a funnel to pour liquid through a small opening is a common one and readily demonstrates that any given equilibrium level in the funnel has a corresponding rate of addition. If that rate increases, the level rises until the outgoing rate also increases enough to balance inflow, thus establishing a new and higher equilibrium level.

In the natural situation, radioactive atoms are added

Figure 4: Principles of various radioactive dating methods: (A) Simple hourglass. (B) Bottomless hourglass. (C) Funnel at equilibrium. (D) Cascade series returning to equilibrium (two options).

to a sample through cosmic radiation. Generally, the material being irradiated is meteoritic matter in interplanetary space or rocks from the lunar surface. Mainly composed of high-energy protons, cosmic rays bombard the nuclei of sample atoms with such high intensity that a whole series of so-called spallation reactions occurs. These involve nuclear fragmentation and the creation of over 30 different, brand-new stable and radioactive isotopes. The abundance of each radioisotope builds up to an equilibrium level at which it decays as fast as it forms. From the outset of irradiation, stable daughter products of the various radioisotopes steadily accumulate.

When a meteorite falls or a lunar sample is brought back to Earth, the sample is removed from its radiation environment, and radioisotope synthesis ceases. But if the decay rates of its several radioisotopes are measured immediately, they approximate both the production and decay rates in space. Such rates in combination with a quantitative measurement of the accumulated stable daughter isotopes permit a calculation of age. For example, the age of a sample would be  $10^{15}$  seconds (about 30,000,000 years) if it contained  $10^{15}$  stable daughter atoms built up through a disintegration rate of one per second.

Exposure  
age of a  
meteorite

The age described here is a so-called **exposure age**—how long the sample spent being irradiated in space. Implicit in exposure ages of meteorites is this view of their history: they are fragments of even larger objects broken up by space collisions long ago; at that time, they took on essentially their present configuration and were laid bare to a cosmic-ray flux that has remained constant ever since. Clearly, then, meteorite exposure ages are also breakup ages. For lunar samples, exposure ages presuppose a time when rocks were placed on the Moon's surface in a certain position so as to expose an upper surface to an invariant cosmic-ray flux.

The fourth variation of radiometric dating—Figure 4D—is more subtle and mathematically more complex than the first three cases. This situation is restricted to natural decay chains with several intermediate radioactive daughters—specifically, the chains headed by uranium-238 and uranium-235. In uranium deposits that have been in place for at least several million years, the decay chains exist in what is called secular equilibrium. This may be likened to a cascade series in which water flows at constant rate out the bottom of one tank into the next one and so on down through a number of tanks. Under equilibrium conditions, with water flowing into each tank as fast as it leaves through the bottom, any variation in the size of a drain hole from one tank to another must be compensated for by differences in height of water in the various tanks. The bottom pan will be exceedingly large and without a bottom hole, so that with time it becomes more full.

The water in each tank represents the relative number of atoms of an isotope in the decay chain, the passage of water from tank to tank corresponds to radioactive decay down the chain, the size of hole in each tank is analogous to an individual decay constant or half-life, and the final large tank without a hole represents the steady accumulation of stable daughter atoms. A constant water supply being fed into the cascade parallels the uranium parent's insertion of decay products into the chain.

In the natural situation there is obviously no flow of material. A more appropriate image would have uranium atoms as red balls fixed in a crystal lattice; their successive transitions to different isotopes down the decay chain would then be visualized as a sequence of intermittent colour changes, finally ending with a green ball, symbolic of stable lead.

So long as the equilibrium situation just pictured prevails, there is no chronometer apart from the disappearance of uranium and the accumulation of lead. This is simply the case shown in Figure 4A. The basis of case D, however, is an upset in the equilibrium by some natural process and a subsequent period of return to equilibrium. If the extent of upset is known, how far the

system has progressed back to equilibrium is an indication of the time since the upsetting conditions occurred.

The two options of case D show two different ways of upsetting equilibrium. On the left is the situation in which the level in one of the tanks down the cascade is somehow made higher than the equilibrium height. The effect on the tank involved is to make it drain faster than it was draining at equilibrium. Because the inlet rate remains constant, the net result is a gradual drop in the tank level until equilibrium height is restored. In the right-hand option, water is removed from a tank lower down, so that the tank then gains water from above faster than it drains. With time, the level rises to the previous equilibrium position. In either case it is assumed that both the initial displacement from equilibrium and the rate of return to equilibrium are known. Thus, the level at any moment is a key to the time since equilibrium was disturbed.

Time zero in radiometric dating. Although the time-zero events of significance in radiometric dating appear quite diverse, they share one common factor: they all involve the assemblage of a group of atoms into a configuration, which, with the exception of nuclear disintegration effects, is ideally retained to this day. In most cases, the atomic assemblages of interest exist in the solid state, into which they were assembled by such processes as crystallization, surface adsorption, photosynthesis, and animal metabolism. Among these, crystallization is of greatest importance geologically and encompasses such specific mechanisms as the cooling of magma to become igneous rock, metamorphism of pre-existing rock material, and organic or inorganic precipitation of matter previously dissolved in different aqueous environments (*e.g.*, lakes, groundwater, or the oceans). In a few situations involving short-lived radioisotopes such as carbon-14 and hydrogen-3 (tritium), the sample material is liquid—specifically, water. At time zero such water was removed from intimate contact with the atmosphere, which was the source of its radioactive components. Table 2 lists the time-zero events for different sample types dated by radioactivity.

Sources of error. If a certain radiometric age proves to be wrong, the error stems from one of three sources: the measurement, interpretation, or assumptions made.

Measurement errors can be made in many ways. Most of the daughter isotopes of importance are present in exceedingly small amounts—for example, often at microgram levels—and the problem of contamination from dust in the air or impurities dissolved in laboratory reagents can be a very significant one. Human or instrumental error is a constant problem, made even more significant by the low concentrations involved. Contamination and human fallibility are handled not only by taking certain procedural and environmental precautions arrived at through a priori reasoning but also by making duplicate measurements that serve to point up accidental errors. In order to discern systematic errors, interlaboratory comparisons and employment of different dating methods are two possible approaches.

The real value of a radiometric age generally resides in its being a key to the time of a past event. In exploiting this value, however, there exists a danger that what is actually dated and what is thought to have been dated may be two different things. As an illustration of error resulting from interpretation, imagine an ancient group of people who collected driftwood and burned it in their fires. Thousands of years later, an archaeologist collects the charred wood remaining and has it dated by radiocarbon. In the published account of his work he quotes the radiocarbon age as the time when the tribe resided at the site, not the time when the wood was photosynthesized. Although the author may have been unaware of what a radiocarbon age represents, it is more likely that he made a certain assumption without stating it—that the interval between photosynthesis of driftwood and its conversion to charcoal was negligible compared to the measurement error inherent in the radiocarbon age. If in reality the driftwood were 500 years old when burned, he would unknowingly be wrong by

Measure-  
ment  
errors

Errors of  
interpreta-  
tion

**Table 2: Tie-Zero Events for Different Sample Types Dated by Radioactivity**

sample type	time-zero event	qualifying remarks
Igneous rock	time of crystallization from magma	actually, time zero is the moment the rock cooled to the point at which it became a closed system; although the rock body dated did not experience its time-zero event simultaneously in all parts, the interval is almost always negligible in relation to subsequent time
Metamorphic rock	time of metamorphism	same remarks as for igneous rock
Sedimentary rock	time of sedimentation	repeat of the second remark under igneous rock; those sediment grains derived without alteration from igneous or metamorphic rocks date the time of crystallization or metamorphism, not the time of sedimentary accumulation
Meteorite	time of first exposure to cosmic-ray flux	because meteorites are almost certainly igneous, they also have a crystallization age that must exceed exposure age
Organic material (wood, shell, etc.)	time of plant photosynthesis or animal metabolism	the rate of turnover of different biochemical components of organisms is highly variable; organism lifetime, however, is usually so short as to be essentially a point event relative to time since death (exception: inner rings in large, old trees)
Deep-sea sediment (inorganic fraction)	time of settling through water during which dissolved radionuclides were removed by adsorption on grain surfaces	the organic fraction of deep-sea sediment has the usual time zero of organisms; a primary volcanic ash component in deep-sea sediment has a crystallization time zero essentially identical to that defined by settling
Groundwater, ocean water, and glacier ice	time when water or ice ceased to have contact with atmospheric CO <sub>2</sub>	flow patterns of water and ice must be known for time zero to have much meaning

500 years. The error would be solely one of interpretation, having nothing to do with the measurement made or the assumptions upon which the radiocarbon method rests. Similar examples could be cited for other dating methods.

Most of the effort that has gone into making radiometric dating a reliable enterprise focusses on overcoming errors of assumption. Of all the assumptions, none is so significant as the one that presupposes a closed system—*i.e.*, that a sample has remained as it was originally assembled except for changes produced by radioactive decay. This is a reasonable premise, but it may not hold for all natural samples.

A second important assumption is that a sample began its life free of daughter atoms. If this were not so, there would be the appearance of a certain age even at time zero. At a later time such a "built-in" age would be the error inherent in a measured age. This second assumption is never valid in the strictest sense, and there are some cases in which it is not even valid practically. A simple chemical formula such as NaCl (symbolizing sodium chloride, common table salt), for example, implies that a search of all salt crystals would uncover atoms of just two elements, sodium and chlorine. But, in the real world of crystals, the substitution of foreign atoms for a few of the dominant ones is the rule rather than the exception. This is particularly true when the medium out of which crystals are forming (*e.g.*, magma or seawater) has great compositional diversity. Of course, crystalline substances vary greatly in their inherent power of excluding foreign atoms during their formation, but no substance forms absolutely pure. In samples used for dating, an isotope present at the time of crystallization becomes significant only when it dwarfs or is comparable in amount to the same isotope accumulated by radioactive decay.

As applied to materials used in radiometric dating, any daughter element present at time zero is labelled with the adjective common. For instance, the lead crystalliz-

ing along with uranium in the same mineral would be called common lead. Without corrections, common lead would cause a radiometric age to be too great; its presence must be recognized and corrected for.

Laboratories that measure radiometric ages do not generally measure half-lives. Instead, dating laboratories simply insert into their age calculations whatever half-life is currently held in highest esteem among the physicists who specialize in measuring absolute decay rates. This involves the tacit assumption that the half-life values are correct. In all probability, future physical measurements will not change half-lives beyond the percentages noted in Table 3.

**Major dating methods.** The decay schemes of concern and the specific material types and ranges appropriate to each major method of radiometric dating are listed in Table 3. The principle behind each method has been discussed earlier (see Figure 4).

**Uranium–thorium to helium–lead.** Methods that focus on uranium and thorium as geochronometers have been pushed into the background today by the potassium–argon and rubidium–strontium techniques. The reasons for this involve limited applicability and questionable reliability. Uranium and thorium have low average abundances in the Earth's crust—about two parts per million for uranium and seven parts per million for thorium. Although natural processes of enrichment provide higher levels in some rocks, it is only in rare bodies such as pegmatite (very coarse crystalline rocks) and vein deposits that actual igneous minerals of uranium and thorium are found. In common igneous rocks, the two elements exist primarily as substitutes for other atoms in minor minerals such as zircon (ZrSiO<sub>4</sub>). The net effect of this overall distribution is to limit severely the number of rock types to which uranium–thorium geochronometers can be applied. Nonetheless, the method offers considerable reward, because the occurrence of two uranium isotopes, each providing an independent age, makes available an internal check on reliability. Unfortunately, such checks have

**Table 3: Major Methods of Radiometric Dating**

parent isotope	daughter isotope	parent half-life (in years)	half-life uncertainty (percentage)	dating principle	approximate dating range (years)	applicable material types*
<sup>238</sup> U	<sup>206</sup> Pb	4.51 × 10 <sup>9</sup>	1	A	10 <sup>7</sup> –age of Earth	igneous and metamorphic rocks containing such minerals as zircon, uraninite, monazite, pitchblende, xenotime, samarskite, thorianite, thorite†
<sup>235</sup> U	<sup>207</sup> Pb	0.71 × 10 <sup>9</sup>	2	A	10 <sup>7</sup> –age of Earth	
<sup>232</sup> Th	<sup>208</sup> Pb	14.1 × 10 <sup>9</sup>	1	A	10 <sup>7</sup> –age of Earth	
U, Th	4He	(as above)	—	A	10 <sup>5</sup> –age of Earth	magnetite in igneous and metamorphic rock; shells of mollusks and coral (maximum range of 10 <sup>7</sup> years)
<sup>40</sup> K	<sup>40</sup> Ar	1.28 × 10 <sup>9</sup>	3	A	10 <sup>5</sup> –age of Earth	igneous and metamorphic rocks containing muscovite, biotite, phlogopite, lepidolite, sanidine, hornblende†; sedimentary rocks containing glauconite and sylvite
<sup>87</sup> Rb	<sup>87</sup> Sr	50 × 10 <sup>9</sup>	5	A	10 <sup>7</sup> –age of Earth	igneous and metamorphic rocks containing muscovite, biotite, lepidolite microcline†; sedimentary rocks containing glauconite

\*Inclusion of a material type means that some successful applications are known, not that success is the general rule. †Minerals in moderately coarse-grained rocks are usually isolated by special techniques following rock crushing. Fine-grained rocks such as rhyolite, basalt, tuff, slate, and phyllite are generally handled whole with no attempt to separate discrete mineral fractions.

Errors of assumption

The problem of discordance in atomic ages

painted a generally gloomy picture for those seeking a chronometric tool—albeit a most revealing picture for those interested in geochemical processes. The gloom arises from the general discordance among isotopic ages based not only on uranium-235 and uranium-238 but also on thorium-232. The last radioisotope usually accompanies uranium because of its similar ionic charge and radius.

Experience shows that, with the exception of results from the mineral uraninite, the three uranium–thorium–lead ages are almost always different. Why this should be so is the subject of many scientific papers and much experimental work. Clearly, discordance is not usually due to common lead. The presence of such lead is revealed through its nonradiogenic isotope lead-204 and is corrected for by calculations involving its isotopic composition; the latter is usually obtainable from cogenetic lead minerals (e.g., galena) found in physical association with the uranium mineral being dated.

Where discordance generally seems to lie is in the failure of uranium-bearing minerals to be closed systems. This situation appears to prevail whether uranium is the dominant metal in the mineral or is merely a trace constituent. Whatever invalidates the closed-system assumption is beyond direct observation and must be inferred from analytical data on natural and laboratory-treated samples. It seems probable that lead loss is the most significant mechanism causing discordance. Of less certainty is the chronology of lead loss—specifically, whether it involved continuous diffusion beginning at the time of crystallization or was a relatively short-term process active only during a metamorphic event.

The escape of helium is also significant. Derived from alpha particles, helium accumulates within a uranium mineral in a time-dependent manner similar to lead buildup. The main difference is that for every atom of uranium or thorium decaying there are six, seven, or eight helium atoms produced, depending on whether the parent atom is thorium-232, uranium-235, or uranium-238. The escape of some helium is predictable on the basis of its small mass and incompatibility with its environment in a crystal lattice. Furthermore, there is no isotopic way to recognize common helium, for it is also alpha-particle derived. As a consequence, uranium–helium dating has received far less attention than the various lead methods. At the present time, its application to the mineral magnetite seems reliable, provided that acid leaching first removes surficial material not held within the tight magnetite lattice. Increasingly significant is the application of uranium–helium dating to the shells of marine organisms that incorporate small numbers of uranium atoms into their calcium carbonate lattices.

**Potassium-40 to argon-40.** Unlike uranium and thorium, the element potassium is of high average crustal abundance (about 2.5 percent) and occurs widely at concentrations where analysis is relatively easy. The fact that potassium is radioactive was recognized as early as 1905. Over 30 years went by, however, before potassium-40 was revealed as the radioactive isotope and another 20 years before its half-life was accurately determined. Because two decay modes are possible for potassium-40, one yielding stable argon-40 and the other stable calcium-40, potassium minerals accumulate two daughter elements. These build up in the ratio of eight calcium-40 atoms to one argon-40 atom. Clearly, once the production ratio of the two daughters has been accurately determined, both need not be measured in a radiometric-dating analysis. For example, the detection of eight trillion calcium-40 atoms in a sample implies the presence of one trillion argon-40 atoms and therefore the decay of nine trillion potassium-40 atoms over the life of the sample.

Despite the relatively greater abundance of calcium-40, it is argon-40 that is almost always measured. The reason is simply that the calcium-40 isotope in common calcium is almost always so abundant that it overwhelms radiogenic calcium-40. Only a few potassium-bearing minerals, such as lepidolite and sylvite, form under conditions where the common calcium level is low enough not to mask radiogenic calcium-40.

The two main problems that plague potassium–argon dating are like those of the uranium–lead method—common argon (sometimes called excess, or extraneous, argon) and argon leakage. Because of its inert chemical behaviour, argon tends to be almost totally excluded from most potassium-bearing minerals at the time they crystallize. Even so, minute amounts may enter the lattice and form a significant fraction of the argon-40 in samples younger than 100,000 years. Furthermore, there is no isotopic way to recognize the common argon, for it is pure argon-40 held in the crust since its formation by even earlier potassium-40 decay.

Still another source of argon contamination is an atmospheric contribution adsorbed on surfaces at the time samples come in contact with air. A significant part of this is removable by heating in a vacuum at a temperature low enough to suppress the escape of radiogenic argon-40. Through measurements of nonradiogenic argon-38 and argon-36, what is left of the atmospheric portion can be recognized and corrected for.

Far more serious than argon contamination is argon leakage. As was the case with the uranium–thorium methods, recognition is the first problem. It centres on age comparisons involving different decay schemes applied to the same rock samples. Specifically, search is made for potassium-bearing minerals associated with uraninite specimens that have shown concordant uranium–thorium–lead ages. The ubiquitous association of rubidium and potassium offers a second comparison of radiometric chronometers. As a result of such comparisons, supplemented by laboratory and field studies on leakage rates, potassium minerals have been evaluated with respect to the seriousness of argon loss. The results are much more encouraging than is true for uranium methods. Micas (biotite, muscovite, phlogopite) are especially good in retaining argon despite a priori arguments to the contrary. Hornblende is even better; potassium feldspar is poorer. Elevated temperatures—in excess of 300°C (about 600°F)—can change the rankings and ultimately cause intolerable leakage in all potassium minerals. It follows that the thermal history of a dated sample is very significant in determining how valid its potassium–argon age is.

**Rubidium-87 to strontium-87.** The geochemical similarity of rubidium to potassium is most fortunate for radiometric geochronometry. The two elements occur not only in the same rock types but also in the same minerals. Moreover, from silicate meteorites to the various common types of terrestrial igneous rocks, the atomic ratio of potassium to rubidium remains more or less constant at about 600 (about 0.25 if just the two radioisotopes are considered). Consequently, almost every potassium-bearing sample carries two geochronometers within it—one involving the decay of potassium-40, the other based on the decay of rubidium-87. The age comparisons made possible are of incomparable value.

The rubidium–strontium method is not without its problems—specifically, loss of the radiogenic daughter (strontium-87), presence of common strontium, and uncertainty about the half-life. Very little experimental work is available on which to judge strontium-87 retention by minerals. Experience in dating samples by different methods suggests the following order of decreasing retentivity, however: potassium feldspar > muscovite > biotite. Ages that are based on analyses of whole rocks show them to have the highest retention of all, an indication that those strontium atoms that do escape their parent mineral grains do not wander far.

Common strontium is the rule rather than the exception. It is recognized through its nonradiogenic isotope strontium-86 and defined isotopically by measurements of associated rubidium-free minerals such as plagioclase feldspar and apatite. Calculation then suffices to remove the nonradiogenic strontium-87 contribution from the total strontium-87 content of a sample.

The half-life of rubidium-87 has been a thorny problem that is still not fully resolved. The uncertainty centres on the difficulty of detecting every disintegration in a sample of rubidium-87. At a time when physicists were quot-

Problems in the potassium–argon method

Half-life of rubidium-87

ing 60 billion years as the half-life, geochronologists were arguing that a 50-billion-year value was needed to make rubidium-87 ages agree with those from the potassium-40 and uranium methods. Recent physical measurements suggest that the geological half-life is closer to the truth, and 50 billion years is now quoted in the chart of nuclides prepared by the U.S. Atomic Energy Commission.

At the present time, applying the rubidium-strontium method to igneous and metamorphic rocks generally involves treating a number of sample analyses in the context of a so-called isochron diagram (Figure 5). This dia-

Figure 5: Rubidium-strontium isochron diagram. The four solid circles represent four different rubidium-bearing minerals separated from the same rock and analyzed for the two atomic ratios shown on the axial coordinates. Arrows for each mineral show how subsequent decay of rubidium-87 to strontium-87 changed the ratios from their initial values (open circles) to their final values.

gram is the graphical expression of the basic dating equation (5) after certain modifications are made. In order to use the isochron diagram, it is necessary first to isolate different potassium minerals from a rock and then to measure each mineral for two ratios: strontium-87/strontium-86 and rubidium-87/strontium-86. Each pair of ratios defines a point on the diagram; if measurements are correct and each mineral has been a closed system, the several points should define a straight line. From the inclination of the line, rock age can be determined; rock age  $t$  is related to the inclination angle  $A$  by the equation  $\tan A = e^{\lambda t} - 1$ . The point of intersection of the line with the vertical axis defines the isotopic ratio of common strontium.

An age determined from an isochron diagram represents the most recent time when all of the strontium in the rock was of the same isotopic composition. Since that time, different rock minerals have changed that composition by decay of their contained rubidium. The greater the rubidium content, the greater the isotopic change of strontium in each mineral. The process responsible for homogenizing the strontium initially was either metamorphism or melting. Without data such as field evidence, however, the exact cause of homogenization may be unknown.

**Carbon-14.** Radioactive-carbon dating stands in marked contrast to the previously described rock-dating methods. Application of carbon-14 dating is mainly to material synthesized by organisms within the past 50,000 years, and the principle of carbon-14 dating is that of the bottomless hourglass rather than the simple hourglass (see Figure 4).

The discovery of natural carbon-14 by the U.S. scientist Willard Libby began with his recognition that a process that had produced radiocarbon in the laboratory was also going on in the Earth's upper atmosphere—namely, the bombardment of nitrogen by free neutrons. Once created in the atmosphere, newly created carbon-14 atoms were presumed to react with atmospheric oxygen to form carbon dioxide ( $\text{CO}_2$ ) molecules. Radioactive carbon thus was visualized as gaining entrance wherever atmospheric carbon dioxide enters—into land plants by photosynthesis, into animals that feed on the plants, into marine waters and freshwaters as a dissolved component,

\*Error on ages is between one and three percent.

and from there into aquatic plants and animals. In short, all parts of the carbon cycle were seen to be invaded by the isotope carbon-14.

Invasion is probably not the proper word for a component that Libby calculated should be present only to the extent of about one atom in a trillion stable carbon atoms. So low is such a carbon-14 level that no one had detected natural carbon-14 until Libby, guided by his own predictions, set out specifically to measure it. His success initiated a series of measurements designed to answer two questions: is the concentration of carbon-14 uniform throughout the plant and animal kingdoms? And, if so, has today's uniform level prevailed throughout the recent past?

After showing the essential uniformity of carbon-14 in living material, Libby sought to answer the second question by measuring the radiocarbon level in organic samples dated historically—materials as old as 5,000 years from sources such as Egyptian tombs. With correction for radioactive decay during the intervening years, such old samples hopefully would show the same starting carbon-14 level as exists today. This was just what Libby's measurements showed. His conclusion was that over the past 5,000 years the carbon-14 level in living materials has remained constant within the 5 percent precision of measurement. A dating method was thus available, subject only to confirmation by actual application to specific chronologic problems.

Since Libby's foundational studies, tens of thousands of carbon-14 measurements of natural materials have been made. Expressed as a fraction of the contemporary level, they have been mathematically converted to ages through equation (5). Archaeology has been the chief beneficiary of radioactive-carbon dating, but late glacial and post-glacial chronological studies in geology have also been aided greatly.

With improvements in accuracy of measurement and ever-mounting experience in applying carbon-14 dating, superior and more voluminous data are accumulating to provide better answers to Libby's original questions. It is now clear that carbon-14 is not homogeneously distributed among today's plant and animal kingdoms. The occasional exceptions all involve nonatmospheric contributions of carbon-14-depleted carbon dioxide to organic synthesis. Specifically, volcanic carbon dioxide is known to depress the carbon-14 level of nearby vegetation; dissolved limestone carbonate occasionally has a similar effect on freshwater mollusks, as does upwelling of deep ocean water on marine mollusks. In every case, the living material affected gives the appearance of built-in age.

In addition to spatial variations of carbon-14 level, the question of temporal variation has received much study. A 2 to 3 percent depression of the atmospheric radioactive-carbon level since 1900 was noted soon after Libby's pioneering work, almost certainly the result of the dump-

Variations of the carbon-14 level in nature

ing of huge volumes of carbon-14-free carbon dioxide into the air through smokestacks. Of more recent date is the overcompensating effect of man-made carbon-14 injected into the atmosphere during nuclear-bomb testing. The result has been to raise the atmospheric carbon-14 level by over 50 percent. Fortunately, neither effect is significant in the case of older samples submitted for carbon-14 dating, but there is a clear warning to investigate the past for comparable natural effects. Libby hoped to do just that in his original work on historically dated samples as old as 5,000 years.

Since then, precision of measurement has improved, and tree rings as old as 8,200 years have become available for analysis. The results reveal that the atmospheric radiocarbon level prior to 1000 BC deviates measurably from the contemporary level. In the year 6200 BC it was 8 percent above today's level. In the context of carbon-14 dating, this departure from the present level means that samples with a true age of 8,200 years will be dated by carbon-14 as 7,500 years old. The situation between 5500 BC and 9000 BC is currently being investigated through comparison with varved sediments (sharply defined sedimentary layers deposited in special environments at the rate of two per year). Comparable modes of checking times even more remote than 9000 BC are currently a hope rather than a reality.

The ultimate cause of carbon-14 variations with time has generally been attributed to temporal fluctuations in the cosmic rays that bombard the upper atmosphere and create terrestrial carbon-14. Whatever the cause, however, it is clear that carbon-14 dates lack the accuracy that traditional historians would like to have. Hopefully, there will come a time when all carbon-14 ages rest on firmer knowledge of the sample's original carbon-14 level than is now available. Until then, the inherent error from this uncertainty must be recognized.

**Carbon-14 contamination** A final problem of importance in carbon-14 dating is the matter of sample contamination. If a sample of buried wood is impregnated with modern rootlets or a piece of porous bone has recent calcium carbonate precipitated in its pores, failure to remove the contamination will result in a carbon-14 age between that of the sample and that of its contaminant. Consequently, numerous techniques for contaminant removal have been developed. Among them are the removal of humic acids from charcoal and the isolation of cellulose from wood and collagen from bone. Today, contamination as a source of error in samples younger than 25,000 years is extremely rare. Beyond that age, however, the fraction of contaminant needed to have measurable effect is quite small, and, therefore, undetected or unremoved contamination may occasionally be of significance.

**Uranium-series disequilibrium.** Uranium disequilibrium methods offer the tantalizing prospect of checking carbon-14 dating within its range and then extending this range by an additional 200,000 years. The underlying principle was described earlier in terms of a cascade series returning to equilibrium (see Figure 4D). Currently there are only two series of practical importance, those started by the two major isotopes of the element uranium. The important transitions involve the decay paths of  $^{238}\text{U}$  (uranium-238) to  $^{206}\text{Pb}$  (lead-206) and  $^{235}\text{U}$  (uranium-235) to  $^{207}\text{Pb}$  (lead-207), which are (with half-lives in years bracketed):

Within uranium-bearing minerals of the Earth's crust a stable condition called secular equilibrium is established within the first few million years after mineral formation. Such a state involves the maintenance of a constant number of atoms of each radioactive member of the two chains shown above, a situation made possible when the decay of each radioisotope is just balanced by formation from its radioactive precursor. In terminology used previously, there exist two cascade series at equilibrium.

By disrupting this equilibrium the dating potential is introduced. What occurs is a two-step sequence that culminates in a solid sample having either a deficiency or a superabundance of uranium relative to other radioactive elements in the chain. Disequilibrium then prevails in the newly formed solid.

The first step in the creation of datable samples is the breakdown of uranium-bearing rocks by chemical weathering, thereby permitting rainfall to move the two uranium decay series into freshwater or ocean water. Step two is the reassembly of solid samples within these water bodies by one of two mechanisms that create disequilibrium: (1) preferential incorporation of dissolved uranium-238 and uranium-235 into a calcium carbonate solid such as coral, at the same time excluding protactinium-231 and thorium-230 (the latter is sometimes called ionium), or (2) preferential adsorption of protactinium-231 and thorium-230 on suspended clay particles while excluding uranium isotopes. In most cases the radioisotopes are present at levels of one to ten parts per million.

With time the uranium isotopes in calcium carbonate decay into thorium-230 and protactinium-231 and build up these two daughters toward their equilibrium amounts. Before this steady state is reached, the nearness to equilibrium is time-dependent and thus an indicator of carbonate age.

In the case of clay particles, their fate is to settle out on the floor of an ocean or a lake and to undergo decay of adsorbed thorium-230 and protactinium-231. Based on a constant rate of clay sedimentation, the amounts of these two radioisotopes per gram of clay decrease downward because of increasing age. If a zero age is ascribed to surface material, the age of material farther down is obtainable by comparing concentrations of thorium-230 and protactinium-231 within a sample core to those in surface sediment.

The foregoing account describes the uranium-series methods as one would wish them to be rather than as they are. Four assumptions are involved, each of which is generally or frequently invalid: (1) carbonates and clay sediments are completely closed systems, (2) clay sedimentation rates are uniform in each sediment column, (3) all radioactive elements incorporated in clay grains are adsorbed during settling, and (4) there is total exclusion of uranium from clay sediments and of thorium-230 and protactinium-231 from calcium carbonate solids. In addition, a further complicating factor has been ignored, namely, the discovery that uranium-238 and its daughter uranium-234 are usually not at secular equilibrium within natural aqueous solutions or in the precipitates derived from them.

Taken together, these complications explain the great amount of experimental work currently under way in uranium-series dating. The goals are, first, to determine whether there are compensating steps that will get around failures in the above assumptions and, second, to identify those materials and situations that offer the greatest promise of successful dating.

At present, uranium in carbonates looks very favorable for corals, unfavorable for mollusk shells, and promising for oolites, inorganic marls, and speleothems (*i.e.*, layers in stalagmites). The chief problem centres on the closed-system assumption. Evidence suggesting that a carbonate sample has been a closed system includes: (1) age agreement between the uranium-234–thorium-230 and uranium-235–protactinium-231 clocks as well as with related carbon-14 and potassium–argon dates; (2) uranium-series ages consistent with stratigraphic relationships; and (3) no evidence of calcium carbonate recrystallization that has turned aragonite into calcite.

In the case of clay-sediment ages, a measure of success has come in dating marine sediments from deep-sea cores. Almost total failure, however, has resulted from strict adherence to the assumed constancy in clay sedimentation rate. As an alternative, it is often assumed that radiogenic thorium-230 and the main thorium isotope thorium-232 are adsorbed from seawater in a constant ratio. Because thorium-232 has such a long half-life (14,000,000,000 years), its decay with depth in a

Steps in the creation of datable uranium-bearing rock samples

Uranium in carbonates

sediment core is negligible. Consequently, an index of sediment age is derived from the extent to which the surface value of thorium-230–thorium-232 has decreased with depth. A somewhat better approach has been to focus on how the ratio protactinium-231–thorium-230 changes down a core. Using this ratio for dating marine sediments requires the fewest and the most probable assumptions concerning temporal constancy of adsorption variables. The greatest dating success has thus been obtained through protactinium-231–thorium-230 ratios, subject mainly to uncertainties in how closely marine sediments approximate closed systems.

An unsuspected disequilibrium in the uranium series was discovered in the early 1960s. Natural waters and precipitated solids derived from them were shown to have an excessive amount of uranium-234 relative to the parent uranium-238. In contemporary ocean water as well as marine carbonates, this excess is uniformly 15 percent, whereas much greater values have been found in waters and precipitates of the continents. The mechanism responsible for disequilibrium is preferential leaching of uranium-234 by groundwater acting upon uranium-bearing surface rocks. Such rocks have the two uranium decay chains at equilibrium. When a uranium-238 atom ejects an alpha particle to produce what soon becomes a uranium-234 atom, however, there is a recoil that loosens the uranium-234 atom in its lattice position and makes it more susceptible to being leached away.

Although the excess of uranium-234 has introduced a complication in uranium-series methods, it has simultaneously offered another possibility of dating carbonates. Dating hinges on a firm knowledge of the percent of excess at time zero, for it is from the time-zero value that uranium-234 drops toward equilibrium (that is, toward no excess). At present, the 15 percent excess shown by all ocean-water samples gives hope for dating marine carbonates. It is not at all certain, however, whether this uniformity in space is matched by uniformity in time. In other words, today's oceanic value of 15 percent excess uranium-234 may not have prevailed in the past. This uncertainty is typical of the uranium-series methods; they all require comparisons at many points in order to provide confidence in the ages obtained.

**Spontaneous-fission tracks.** In place of simple radioactive decay, a small fraction of uranium-238 atoms undergo a process known as spontaneous fission. The effect of a single fission event is to create a minute region of crystal disruption called a track. The density of spontaneous-fission tracks in uranium-bearing samples is dependent on the concentration of uranium and the duration of fission. It follows, then, that measurements of track density and uranium content permit calculation of sample age. Because uranium-235 fissions readily when bombarded with slow neutrons in a nuclear reactor, the track density so induced is a measure of uranium content for any particular neutron dose. Consequently, a complete fission-track age measurement requires just two track-density determinations combined with a measured neutron dose.

The actual procedure of fission-track dating begins with preparation of a smooth sample through either polishing or mineral cleavage. Immersion in an etching solution follows, resulting in enlargement of spontaneous-fission tracks to the point of microscopic visibility. Because of chemical variation from sample to sample, a number of acids and alkalis find use in etching. Hydrofluoric acid is used for most silicates, although strong potassium and sodium hydroxides are occasionally employed. The mineral apatite is etched with nitric acid, calcite with hydrochloric acid. Trial and error determine the optimum etching conditions of time (seconds to hours), temperature (ambient to several hundred degrees), and solution strength (usually concentrated).

In order to count tracks, a high-powered microscope is required. This means magnifications of from 250 to 1,800. How much sample area must be examined for tracks depends on their abundance. The fewer the tracks, the more area must be counted in order to obtain a statistically reliable track density.

After a count of tracks made by spontaneous fission, the sample is placed in a nuclear reactor for a period of hours or days until from  $10^{16}$  to  $10^{18}$  slow neutrons per square centimetre have passed through it. Etching is repeated, followed by counting of the new tracks that formed by the induced fission of uranium-235. Values of the two track densities and the neutron dose are inserted into the following equation in order to obtain sample age:  $\text{age (in years)} = 6 \times 10^{-8} \times N \times (Ds/Di)$ , in which  $N$  is the total neutron dose expressed as neutrons per square centimetre,  $Ds$  is the track density for spontaneous fission of uranium-238, and  $Di$  is the track density for induced fission of uranium-235.

Many minerals and rocks are datable by fission-track counting. These include the common silicate minerals of igneous rocks (different micas, feldspar, and hornblende) as well as accessory minerals such as zircon and apatite. Natural glasses such as obsidian, tektites, and basaltic glass also have been used successfully. Even man-made glasses have been dated, especially those in which uranium minerals were added to give colour. Satisfactory results on meteorites have also been obtained.

The dating range of fission-track dating is governed mainly by the uranium content of samples. At a uranium level of one part per million, for example, samples as young as 300,000 years can be measured by track counting for just one hour. This can be lowered to 8,000 years if the investigator is willing to invest a 40-hour week in counting. Most natural glasses contain uranium in parts-per-million amounts, while zircon and apatite may go as high as 100–1,000 parts per million. Man-made glasses coloured with 10 percent uranium are easily dated even when they are as young as 30 years. At the other end of the range, rock ages of 1,000,000,000 years have been obtained.

The major drawback to fission-track dating lies in the tendency of tracks to fade away when elevated temperatures are maintained for long periods. One-hour experiments in the laboratory show that different materials have different critical temperatures at which tracks quickly disappear. The temperature extremes vary from 60° C (140° F) for the uranium mineral autunite up to 1,050° C (1,920° F) for quartz. Held at 20° C (68° F) for its complete lifetime, any substance with a critical temperature exceeding 400° C (750° F) should be able to preserve fission tracks for periods comparable to the age of the Earth. The most promising rocks, therefore, are those that have always been at or near the Earth's surface—that is, volcanic rocks. By contrast, rocks originating in the hotter interior, such as granite and metamorphic rocks, almost universally show smaller fission-track ages than those obtained through rubidium–strontium and potassium–argon methods. Confined to its proper niche, however, fission-track dating has made and will continue to make important contributions to chronologic studies.

**Thermoluminescence dating.** Hope rather than accomplishment mainly characterizes the status of thermoluminescence dating at the present time. The phenomenon of thermoluminescence is the emission of light from heated crystals previously exposed to radiation. The longer the time allowed for radiation to build up an inventory of trapped electrons, the greater the light energy released when the crystals are heated and electrons return to their normal positions. In theory, it is possible to date the onset of radiation by measuring the amount of light released, the total radiation dose, and the rate at which that dose was applied.

In applying thermoluminescence dating to such materials as pottery, bones, and minerals, the sample material is first ground to a powder. A gram or less is then spread out thinly over an electric heating plate. Next, the sample is heated at 20° C (36° F) per second within a nitrogen atmosphere, during which time the light emitted is measured by a photomultiplier tube. The final record is a graph of light intensity plotted against sample temperature. Total glow is usually taken as the light emitted between 350° and 450° C (650° and 850° F). Finally, radioactive impurities responsible for the glow are mea-

Problems in fission-track dating

Steps in fission-track dating

# Assump- tions of thermo- lumi- nescence dating

sured by standard radiochemical techniques applied to another portion of the sample.

Three assumptions are basic to thermoluminescence dating. The first is that the glow recorded is an accurate measure of age. This requires that no light be lost previous to laboratory heating and that nothing but sample radiation is responsible for the glow recorded. Here the thermal, chemical, and physical histories of the sample are of central importance. If the sample spent a significant part of its past at depths exceeding several thousand feet, the elevated temperature might have caused a slow drain of light. Sample recrystallization would cause a similar effect. Furthermore, luminescence from both chemical reactions and sample grinding may occasionally augment the glow of radiation-induced thermoluminescence.

The second assumption is that the laboratory radiation dose simulates the natural dose in all ways except rate, which is patently false. Natural radiation is a mixture of alpha, beta, and gamma radiation from impurities within the sample, whereas the artificial source is outside the sample and generally consists of cobalt-60 gamma rays or strontium-90 beta rays. Despite these differences, there often are ways to adjust for them and thus secure acceptable ages.

Only the total radiation dose is considered to be an influence on sample glow. The rate of radiation is supposedly immaterial. Although almost certainly not true in a rigid sense, this assumption cannot be far from the truth for those ages that receive independent confirmation.

Where thermoluminescence dating appears to have the greatest potential is in dating pottery, fossil bones, and teeth. Young deposits of volcanic ash also show promise, provided that small quartz and feldspar crystals (about one millimetre in diameter) can be isolated. To date, a number of potsherds as old as 8,000 years have given reliable ages when checked by associated carbon-14 dates. Dating of bones and teeth is just beginning but may one day be of great value. Unfortunately, bone samples younger than 100,000 years are currently out of reach because of chemiluminescence originating from residual organic matter. Successful extraction of the organic fraction might lower the dating limit to a point at which checks with carbon-14 dating become possible.

Minor dating methods. As analytical instrumentation becomes more sophisticated and scientific understanding improves, putting the label minor on a particular dating

method may ultimately be shown quite presumptuous. Any review, therefore, must be considered as a status report prefaced with the qualifying words "as things now stand."

Table 5 contains a brief summary of a number of radiometric dating methods that thus far have had only limited application. Some of the reasons for such limitations are as follows: (1) uncertain half-life; (2) low concentrations resulting in difficult analysis and large errors; (3) theoretical uncertainties in the specific geochemical pathways followed by parent or daughter isotopes; and (4) haphazard contributions of man-made isotopes to the atmosphere and hydrosphere.

Three additional notes are in order. First, there is nothing minor about the importance of estimating the interval between synthesis of the chemical elements and their incorporation into crystallizing meteorites. The fact that Table 5 includes the methods behind such estimates merely reflects their limited application and their order-of-magnitude results. Secondly, the isotopes used in estimating meteorite exposure ages are so numerous that almost all have been excluded from Table 5. Several such isotopes are listed in Table 1, however (e.g., <sup>22</sup>Na [sodium-22], <sup>26</sup>Al [aluminum-26], <sup>36</sup>Cl [chlorine-36]). Finally, although man-made fission products such as cesium-137 and strontium-90 have been useful in defining motions and rates within the atmosphere and oceans, none has been included in Table 5.

## NONRADIOMETRIC DATING

In addition to radioactive decay, many other processes have been investigated for their potential usefulness in absolute dating. Unfortunately, they all occur at rates that lack the universal consistency of radioactive decay. Sometimes human observation can be maintained long enough to measure present rates of change, but it is not at all certain on a priori grounds whether such rates are representative of the past. This is where radioactive methods frequently supply information that may serve to calibrate nonradioactive processes so that they become useful chronometers. Nonradioactive absolute chronometers may conveniently be classified in terms of the broad areas in which changes occur—namely, geological and biological processes, which will be treated here.

Geological processes as absolute chronometers. *Weathering processes.* During the first third of the 20th

\*The lead-210 in this method is derived from the radioactive decay of the gas radon-222, which escapes into the atmosphere from uranium-bearing surface rocks and within a few days becomes lead-210.

century, several presently obsolete weathering chronometers were explored. Most famous was the attempt to estimate the duration of Pleistocene interglacial intervals through depths of soil development. In the American Middle West, thicknesses of gumbotil and carbonate-leached zones were measured in the glacial deposits (tills) laid down during each of the four glacial stages (see Figure 3). Based on a direct proportion between thickness and time, the three interglacial intervals were determined to be longer than postglacial time by factors of 3, 6, and 8. To convert these relative factors into absolute ages required an estimate in years of the length of postglacial time. When certain evidence suggested 25,000 years to be an appropriate figure, factors became years—namely, 75,000, 200,000, and 150,000 years. And, if glacial time and nonglacial time are assumed approximately equal, the Pleistocene Epoch lasted about 1,000,000 years (the presently accepted duration of the Pleistocene is from 2,500,000 to 10,000 years ago, approximately).

Obsidian  
hydration

Only one weathering chronometer is employed widely at the present time. Its record of time is the thin hydration layer at the surface of obsidian artifacts. Although no hydration layer appears on artifacts of the more common flint and chalcedony, obsidian is sufficiently widespread that the method has broad application.

In a specific environment the process of obsidian hydration is theoretically described by the equation  $D = Kt^{1/2}$ , in which  $D$  is thickness of the hydration rim,  $K$  is a constant characteristic of the environment, and  $t$  is the time since the surface examined was freshly exposed. This relationship is confirmed both by laboratory experiments at 100° C (212° F) and by rim measurements on obsidian artifacts found in carbon-14 dated sequences. Practical experience indicates that the constant  $K$  is almost totally dependent on temperature and that humidity is apparently of no significance. Whether in a dry Egyptian tomb or buried in wet tropical soil, a piece of obsidian seemingly has a surface that is saturated with a molecular film of water. Consequently, the key to absolute dating of obsidian is to evaluate  $K$  for different temperatures. Ages follow from the above equation provided there is accurate knowledge of a sample's temperature history. Even without such knowledge, hydration rims are useful for relative dating within a region of uniform climate.

Like most absolute chronometers, obsidian dating has its problems and limitations. Specimens that have been exposed to fire or severe abrasion must be avoided. Furthermore, artifacts re-used repeatedly do not give ages corresponding to the culture layer in which they were found but instead to an earlier time, when they were fashioned. Finally, there is the problem that layers may flake off beyond 40 microns (0.002 inch) of thickness—that is, over 50,000 years in age. Measuring several slices from the same specimen is wise in this regard, and such a procedure is recommended regardless of age.

**Erosional processes.** It is beyond the scope of this article to describe the reasoning and results of quantitative geomorphology, that branch of geology directed toward estimating the pace at which landforms develop and continental surfaces are lowered by erosion. One example will suffice to illustrate the dating possibilities inherent in processes of erosion, however. That case is the cutting of a deep gorge by recession of the lip of Niagara Falls.

Over the past 100 years of observation, the falls have retreated at a rate of several feet per year. The entire gorge, therefore, represents 25,000 years' worth of erosion, provided that today's rate has always prevailed. If the onset of cutting occurred very shortly after departure of the most recent ice sheet, postglacial time has lasted for 25 millennia.

This period of time was the key to assigning absolute durations to interglacial ages. But all of this reasoning has been shown wrong by carbon-14 dating, which places the departure of the most recent glacier at around 11,000 years ago at this latitude. Either today's rate of falls retreat is unusually low, or part of the gorge was cut before postglacial time began (see further **WATERFALLS**).

**Accumulational processes.** Sediment in former or present water bodies, salt dissolved in the ocean, and

fluorine in bones are three kinds of natural accumulations and possible time indicators. To serve as **geochronometers**, the records must be complete and the accumulation rates known.

The fossiliferous part of the geologic column includes perhaps 400,000 feet of sedimentary rock, if maximum thicknesses are selected from throughout the world. In the late 1800s, attempts were made to estimate the time over which it formed by assuming an average rate of sedimentation. Because there was great diversity among the rates assumed, the range of estimates was also large—from a high of 2,400,000,000 years to a low of 3,000,000 years. Despite this tremendous spread, most geologists felt that time in the hundreds of millions of years was necessary to explain the sedimentary record.

If the geological column were made up entirely of annual layers, its duration would be easy to determine. Limited sedimentary deposits did accumulate in this way, and they are said to be **varved**; one year's worth of sediment is called a **varve**, and, in general, it includes two laminae per year.

Varves arise in response to seasonal changes. New Mexico's Castile Formation, for example, consists of alternating layers of gypsum and calcite that may reflect an annual temperature cycle in the hypersaline water from which the minerals precipitated. In moist, temperate climates, lake sediments collecting in the summer are richer in organic matter than those that settle during winter. This feature is beautifully seen in the seasonal progression of plant microfossils found in shales at **Oensingen**, Switzerland. In the thick oil shales of Wyoming and Colorado, the flora is not so well defined, but layers alternating in organic richness seem to communicate the same seasonal cycle. These so-called Green River Shales also contain abundant freshwater-fish fossils that confirm deposition in a lake. At their thickest, they span 2,600 vertical feet. Because the average thickness of a varve is about 1/2,000 of a foot, the lake is thought to have existed for more than 5,000,000 years.

Each of the examples cited above is of a floating chronology—that is, a decipherable record of time that was terminated long ago. In Sweden, in contrast, it has been possible to tie a glacial varve chronology to present time and so create a truly absolute dating technique. Where comparisons with radiocarbon dating are possible, there is general agreement (see further **VARVED DEPOSITS**).

As early as 1844, an English chemist named Middleton claimed that fossil bones contain fluorine in proportion to their antiquity. This idea is sound in principle, provided that all the other natural variables remain constant. Soil permeability, rainfall, temperature, and the concentration of fluorine in groundwater all vary with time and location, however. Fluorine dating is therefore not the simple procedure that Middleton envisioned.

Still, the idea that hydroxyapatite in buried bone undergoes gradual change to fluorapatite is a correct one. In a restricted locality where there is uniformity of climate and soil, the extent of fluorine addition is at least a measure of relative age and has been so used with notable success in dating certain hominid remains. Both the **Pilt-down** hoax, for example, and the intrusive burial of the Galley Hill skeleton were exposed in part by fluorine measurements. Supplementing them were analyses of uranium, which resembles fluorine in its increase with time, and nitrogen, which decreases as bone protein decays away.

Fluorine changes could conceivably be calibrated if bone samples were found in a radiometrically dated sequence. But conditions governing fluorine uptake are so variable even over short distances that it is risky to use fluorine content as an absolute chronometer much beyond the calibration site itself. In short, fluorine dating is not now and probably never will be an absolute chronometer. Even when used in relative dating, many fluorine analyses on diverse samples are needed, and these must be supplemented by uranium and nitrogen measurements to establish confidence in the chronological conclusions.

dating

Archaeo-  
magnetic  
dating

**Geomagnetic variations.** Based on three centuries of direct measurement, the Earth's magnetic field is known to be varying slowly in both its intensity and direction. In fact, change seems to have been the rule throughout all of the Earth's past. Magnetic minerals in rocks and in articles of fired clay provide the record of ancient change, for they took on the magnetic field existing at the time of their creation or emplacement.

The technique called archaeomagnetic dating rests on a carbon-14 calibration of secular variations that have been determined from fired clay objects. In certain areas tree-ring dating and historic records also provide calibration ages. Material from ancient kilns and fire pits is the best source of data, because these are stationary and thus preserve the directional character of the magnetic field existing at the time they were last heated up. Measurements on several samples are averaged to obtain the necessary magnetic values indicative of time. At present, much work remains in calibrating curves for the many areas in which dating is desired. The goal is a dating method useful as far back as the Neolithic Period (about 10,000 years ago).

Polar reversals were originally discovered in lava rocks and since have been noted in deep-sea cores. In both cases the time dimension is added through radiometric methods applied to the same materials that show the reversals. Potassium-argon is the commonest chronometer used. A so-called paleomagnetic time scale has been proposed along the line of the geologic time scale; time divisions are called intervals, or epochs (see further ROCK MAGNETISM).

**Biological processes as absolute chronometers.** *Tree-ring growth.* In the early 1900s an Arizona astronomer named Andrew E. Douglass went looking for terrestrial records of past sunspot cycles and not only found what he sought but discovered a useful dating method in the process. The focus of his attention was on 'the growth rings in trees—living trees, dead trees, beams in ancient structures, and even large lumps of charcoal.

The key documents for tree-ring dating (or *dendrochronology*, as it is more formally called) are those trees that grow or grew where roots receive water in direct proportion to precipitation. Under such a situation, the annual tree rings vary in width as a direct reflection of the moisture supplied. What is important in tree-ring dating is the sequence in which rings vary. Suppose, for example, that a 100-year-old tree is cut down and its ring widths are measured. The results can be expressed graphically, and, if a similar graph were made from a small stump found near the 100-year-old tree, the two graphs could be compared until a match of the curves was obtained. The time when the small stump was made would thereby be determined from the position of its outer ring alongside the 100-year record.

Not every tree species nor even every specimen of a suitable species can be used. In the American Southwest, success has been achieved with yellow pine, Douglas fir, and even sagebrush. Unfortunately, the giant sequoia of California does not live in a sufficiently sensitive environment to provide a useful record. The even older bristlecone pine in California's White Mountains does have a climate-sensitive record, but its area of growth is so limited and so inaccessible that no bristlecone specimens have so far appeared in archaeological sites. Despite this shortcoming, dead bristlecone pine trees are presently providing rings as old as 8,200 years for dating by carbon-14. The purpose is to check the carbon-14 method.

**Coral growth.** Certain fossil corals have long been used to date rocks relatively, but only recently has it been shown that corals may also serve as absolute *geochronometers*. They may do so by preserving a record of how many days there were in a year at the time they were growing. The number of days per year has decreased through time because the rate of rotation of the earth has decreased; geophysical evidence suggests that days are currently lengthening at the rate of 20 seconds per million years. If this were typical of the slowdown during the past, a year consisted of 423 days about 600,000,000 years ago.

It is thought that horn corals indicate the number of days per year by means of their exceedingly fine external ridges of calcium carbonate, each of which is thought to represent a day's growth. Several hundred of the fine ridges also seem to cluster as a unit that presumably corresponds to one year. In certain modern West Indian corals the number of fine ridges in a presumed annual increment is approximately 360, suggesting that coral patterns are being properly interpreted.

Not many fossil corals are in a state of preservation that permits the counting of ridges. But those that are give encouragement that an absolute chronometer may be in the offing. Several Middle Devonian corals indicate between 385 and 410 ridges, with an average of about 400. It remains to be seen whether this method of dating, so elegant in concept and so simple in application, will blossom or wither away in the years to come.

#### APPLICATIONS OF ABSOLUTE DATING

**The geological time scale.** At the time radioactivity was discovered in 1896, the relative geologic time scale was essentially in the form shown in Figure 2—minus the numbers, of course. The problem was to obtain those numbers. Because the relative time scale is based on the geologic column, the obvious first approach is to sample the column at intervals and date the material using radiometric techniques. Unfortunately, this approach is limited, because the geologic column is almost totally composed of sedimentary rocks, and ironically these are least amenable to radiometric dating.

The picture is not totally bleak, however. In the first place, there is promise in the mineral glauconite, a green potassium-bearing component in a number of fossiliferous sandstones with ages ranging from Cambrian (500,000,000 to 570,000,000 years ago) to the present. Thought to precipitate from seawater, glauconite gives radiometric ages that presumably measure the time of sedimentation. Clouding the picture, however, is evidence that some glauconite samples gradually lose radiogenic argon. This means that their ages are suspect and define only minimum values.

Of more importance than glauconites are volcanic rocks that interrupt the sedimentary column. Once they were ash-falls or lava flows, now they are layers of tuff or rhyolite interbedded with sedimentary rocks. Because they are well defined stratigraphically and generally provide reliable radiometric ages, they constitute some of the best reference points in the whole time scale. The main problem is that they are rare.

In the absence of interlayered datable rocks, the procedure changes to setting maximum or minimum ages on fossil-bearing sediments that have a clear-cut age relationship with igneous bodies. If a dike cross-cutting a Middle Cambrian shale has a potassium-argon age of 400,000,000 years, the shale is at least 400,000,000 years old. Elsewhere the shale may be eroded so as to reveal the granite on which it was originally deposited. If the granite is 800,000,000 years old, the shale age is then bracketed between 400,000,000 and 800,000,000 years. Pinpointing the age further may require dating a multitude of samples until finally an approximate numerical age can be assigned to the Middle Cambrian.

The age data shown on the geological time scale will probably change only in minor detail in the future. Where major change will occur through future radiometric dating is in the vast reaches of Precambrian time, now in desperate need of a time framework like that given by fossils to the last half-billion years.

**The age of the Earth.** The age of the Earth is a single point in the absolute geological time scale but one so important philosophically as to merit special consideration. First, it is possible to set upper and lower limits on the Earth's age. The minimum value is obviously the age of the oldest rock on Earth, about 3,500,000,000 years. For a maximum age, a more theoretical approach is taken; it is based on the belief that at the time of element synthesis prior to the existence of the Earth as a discrete planet, the two uranium isotopes were approximately equal in abundance. Because uranium-235 decays faster

than uranium-238, the ratio is now one to 137.7 rather than the original one-to-one. Calculation shows that 6,000,000,000 years are necessary to bring about the change. Hence, an earth age in the range 3,500,000,000 to 6,000,000,000 years is indicated.

If meteorites and the Earth had similar beginnings—and all evidence is consistent with that assumption—then the age of meteorites is relevant here. On the basis of many measurements using several radiometric methods, meteorite ages fall very close to 4,500,000,000 years. This value almost splits the range given above.

Finally, the isotopic composition of terrestrial lead provides valuable evidence. Of the four lead isotopes, only lead-204 has no radioactive precursor; the other three are produced, in part, by the radioactive decay of uranium-235, uranium-238, and thorium-232. Over time the isotopic composition of lead has therefore changed appreciably. To go from primordial lead (represented by that in iron meteorites) to modern lead (represented by that in recent deep-sea sediments) requires 4,500,000,000 years of decay by the uranium and thorium in the crust.

The conclusion, then, from several lines of evidence is that the age of the Earth—that is, the time since it differentiated into layers of core, mantle, and crust—is about 4,500,000,000 years.

**Sea-floor spreading.** Although the idea of drifting continents has been debated for decades, discoveries at sea since 1960 appear to have supplied the long-missing element, a mechanism that would raft land masses about. That mechanism is called sea-floor spreading.
