## Conifer

Conifers are woody plants so named because they bear their seeds upon hard or papery scales arranged in spirals or whorls around an axis, forming a cone. Typically, they are evergreen, upright trees and shrubs, but not all members of this botanical order, Coniferales, meet that description. Some, such as various creeping junipers, never grow more than 30 centimetres tall (about one foot). Others, such as the larches and the cypress, lose their needlelike leaves annually with the approach of autumn. Even the feature of cone bearing seems to be violated by the plum-yews and podocarps, which bear seeds in olive-like "fruits" rather than in cones, and the true yews, which enclose their seeds in a fleshy cup, called an aril. **All** conifers, however, bear their pollen in smaller, thin-scaled cones, each scale bearing at least two pollen sacs.

### General features

Conifers have been of interest to man for several centuries, because many genera are of value as lumber-producing trees. They are important also as subjects for landscaping, for producing forests that hold high recreational value in many parts of the world, and for protecting soil from excessive erosion. The smaller species are of little monetary value except as garden specimens, but many of them are efficient in reducing erosion.

Early in human history, coniferous trees became objects of admiration because of their symmetrical growth and general beauty and important as sources of fuel and of material for construction of shelters. Various peoples held certain trees or groves sacred to their deities. The early inhabitants of India worshipped the deodar cedar and considered their groves the sacred abode of saints, sages, and prophets. The Aztecs venerated various large cypress trees in Mexico, and other peoples similarly regarded local conifers.

The wood of conifers is relatively soft, straight-grained, of even texture, readily worked, and strong under stress. It is, therefore, suitable for many purposes, from general construction, cabinetwork and interior finishing to the manufacture of boxes, crates, and scores of wooden items.

### DIVERSITY

Among the smallest conifers known is *Dacrydium laxifolium*, a native of the mountains of New Zealand; mature fruiting specimens of this plant have been found that were scarcely eight centimetres (three inches) tall. Many other conifers are trailing or creeping, such as some junipers, which have been selected and horticulturally developed as ground covers less than 30 centimetres tall. Some species are shrubby, with several stems arising from the root crown, and rarely exceed eight metres (26 feet) in height. Giants of the conifer forest include *Dacrydium cupressinum*, at 55 metres tall (180 feet); redwood (*Sequoia sempervirens*), many up to 90 metres tall (300 feet) with trunks up to six metres (20 feet) or more in diameter; and big tree (*Sequoiadendron giganteum*), rarely reaching 90 metres tall but with trunks up to nine metres (30 feet) in diameter.

Most coniferous trees are pyramidal or conical when young, becoming spirelike and then rounded or flat-topped in old age. Many have **columnar** trunks free of limbs for considerable heights. A few can send up new shoots from stumps after the tree is cut, but most of them

are killed and unable to sprout after logging or severe fires have cleared an area.

Massive buttresses support a few conifers; *e.g.*, the swamp cypress (*Taxodium distichum*) and some of the larger species of *Chamaecyparis* and *Cryptomeria*. Such buttressed trees may have a circumference fully three times as great at ground level as at two to three metres (seven to ten feet) higher on the same tree. Others have no apparent swelling at the base but may have radiating roots that anchor the trees against strong winds.

Young trees of the Lawson cypress (*Chamaecyparis lawsoniana*) and several other species have downwardly sweeping branches, the lower ones often resting on the ground at their tips. Most conifers, however, have spreading to ascending branches until the tree is quite old, at which time the top is flat or rounded and the branches, confined to the uppermost parts, mostly spread horizontally. Conifers growing near the timberline, along windswept coastal headlands, and on exposed ridges are often grotesquely twisted by the wind or by the weight of winter-long snow covers. Such stunted Alpine forests are known as elfinwood, or krummholz.

### DISTRIBUTION AND ABUNDANCE

Among conifers the pine family (Pinaceae) forms vast forests in the North Temperate Zone in both the Old World and the New World. The pines themselves (*Pinus*) occur mainly in a broad band along the northern, cooler part of the Northern Hemisphere. Their southern extensions occur chiefly along mountain ranges, where they grow generally at progressively higher altitudes as they approach the tropics. Lowland pine forests occur in the southeastern parts of the United States and along parts of coastal areas of the Mediterranean.

The swamp cypress grows near coasts and along rivers and lakeshores inland throughout much of the southeastern United States. In wet or swampy areas, this tree has buttresses and upward extensions from its roots called knees; its wood is remarkably resistant to decay, which accounts for the name "wood everlasting," often applied in the lumber trade.

Extensive coniferous forests occur in the Rocky Mountains and in ranges paralleling the Pacific coast. Douglas fir (*Pseudotsuga menziesii*) is a valuable timber tree of this area; from northern California well into British Columbia it forms magnificent forests and constitutes the most valuable softwood tree on the continent. This area also produces trees of high economic importance among the firs (*Abies*), larches (*Larix*), spruces (*Picea*), pines (*Pinus*), hemlocks (*Tsuga*), and junipers (*Juniperus*; commonly called cedar). A considerable extent of these forested areas in the Pacific Northwest is managed and harvested by lumber companies on a continuous-yield basis. In arid to semidesert regions flanking the Rockies are vast stands of shrubby or treelike junipers which bind the soil against erosion. Nearer the Pacific Ocean, where rainfall is higher, conifers include incense cedar (*Calocedrus*), Lawson and Nootka cypresses (*Chamaecyparis*), redwood, and white and western red cedars (*Thuja*); all are valuable timber trees and several are planted as ornamentals. The California big tree grows naturally only along the western flank of the Sierra Nevada. All groves of this tree are under government protection, and their cutting is strictly prohibited.

Conifers ranging southward into Latin America include the genera *Abies*, *Calocedrus*, *Cupressus*, *Juniperus*, *Pinus*, *Picea*, and *Pseudotsuga* from the Rocky Moun-

tains area and the ahuehuete (*Tarodium mucronatum*).

Genera of conifers now surviving only in Eurasia and northern Africa include *Cedrus* (the mountains of northwestern Africa, Asia Minor, and the Himalayas); *Cephalotaxus* (from Korea to India); *Cryptomeria* (China and Japan); *Cathaya*, *Fokienia*, *Metasequoia*, and *Pseudolarix* (China); *Sciadopitys* and *Thujiopsis* (Japan); and *Taiwania* (China and Taiwan). *Tetraclinis* is native only in the mountains of North Africa, Malta, and in a small colony in Spain. The dawn redwood (*Metasequoia*) is an especially noteworthy conifer in that it was presumed extinct and described from fossil material in the early 1940s; surprisingly, it was later found in China.

Coniferous genera common to both the Old World and the New World are *Abies*, *Calocedrus*, *Chamaecyparis*, *Cupressus*, *Juniperus*, *Larix*, *Pinus*, *Pseudotsuga*, *Thuja*, and *Tsuga*.

The *Podocarpus* genus, which has its centre of distribution and probably its origin in the New Zealand–Australia–New Caledonia region, has spread widely to Africa, East Asia, South America, Mexico, and the Caribbean. It is the coniferous genus with the largest number of species—more than 110—and with the only known parasitic conifer, *P. ustus*, a small shrub up to one metre (three feet) tall, which lives on the roots of another conifer, *Dacrydium taxoides*.

*Callitris*, confined to Tasmania and Australia, provides important timber trees and shrubs, such as *C. endlicheri*, favoured for reforestation because it grows on stony ground unfit for agriculture; even trees too small for sawlogs provide a valuable source of tannin in their bark.

Conifers are encountered less frequently in pure stands in the Southern Hemisphere. Most of them are scattered among hardwood forests or as small patches in restricted habitats. Just as *Pinus* and *Pseudotsuga* furnish a high

percentage of the timber harvested in the north, kauri (*Agathis australis*), rimu (*Dacrydium cupressinum*), and several species of *Podocarpus* furnish most of the softwood lumber in Australia, New Zealand, the South Pacific insular areas, and Africa.

Australia, New Zealand, New Caledonia, and neighbouring islands support several genera of conifers of interest because of their evolutionary significance, aesthetic value, or unusual adaptations to environmental conditions; such genera are *Acropyle*, *Actinostrobus*, *Araucaria*, *Athrotaxis*, *Callitris*, *Diselma*, *Microcachrys*, *Microstrobos*, *Neocallitropsis*, *Papuacedrus*, and *Phyllocladus*. Several of the above-mentioned genera produce timber trees, some in such rugged terrain that it is uneconomical to transport logs to sawmills.

South America and Africa are relatively poor in conifers. South America has two species of *Araucaria* and one species each of *Austrocedrus* and *Fitzroya*, both genera producing trees suitable for lumber in Argentina and Chile. Two other monotypic (or single species) genera, *Pilgerodendron* (Chile) and *Saxegothaea* (Chile and Patagonia), are valued, the first as timber trees, the second because it is a connecting link between the families *Podocarpaceae* and *Araucariaceae*.

A remarkable concentration of conifers occurs on the island of Taiwan, which has native representatives from five of the six coniferous families occurring in nearly pure stands at altitudes between 5,900 and 7,300 feet. Most of the lumber-producing trees occur on rugged mountain slopes. A species of conifer discovered on the island in 1906 was named *Taiwania*.

#### ECONOMIC IMPORTANCE

The softwood timbers provide almost 75 percent of the commercial lumber used for general construction, mine

The largest genus of conifers

Taiwan's coniferous stands

timbers, fence posts, poles, boxes and crates, and lesser articles. During an average year, Canada, for example, produces from its coniferous forests sawed lumber valued at almost \$500,000,000, pulpwood worth \$650,000,000, and paper for newsprint valued at another \$600,500,000. The United States produces considerably more cut timber but less pulpwood. Europe's production is somewhat lower. Finland, Norway, and Sweden produce large quantities of coniferous logs for pulping annually without seriously depleting their forests because of their forest-management practice of cutting trees of specified age classes on a rotating schedule.

In addition to timber used in construction, the world's nations consume huge quantities of coniferous wood as fuel and in the manufacture of cellulose products, plywood, and veneers.

Coniferous trees also are the sources of valuable resins, volatile oils, turpentine, tars, and pharmaceutical products. Many of these products are used in the manufacture of varnishes, paints, greases, and soap. *Pinus* is the chief source of raw pitch, which is treated by steam distillation to yield turpentine and resin. Kauri gum, used chiefly in fine varnishes and linoleum, is obtained from accumulations on large limbs, around the bases of the trunks of *Agathis australis*, and by digging fossil gum from beneath the soil in boggy areas (these trees are native only on New Zealand's North Island, where tapping for gum has been made illegal). A similar resin, Manila copal, comes from *A. alba*, native in the Philippines (there, too, tapping or cutting of the trees is now strictly forbidden).

## Natural history

### LIFE CYCLE

Alterna-  
tion of  
generations

The conifers, like all seed plants, exhibit an alternation of generations (see Figure 2) between an asexual phase (sporophyte) and a sexual phase (gametophyte). The familiar coniferous tree is the dominant, conspicuous sporophyte generation, which bears two kinds of cones, both kinds on the same tree (and thus is termed **monoecious**) in most conifers, on separate trees (dioecious) in a few. The smaller of the cones produces the pollen grains, technically called the male gametophytes, or **microgametophytes**. The larger, often woody cones bear female gametophytes, or megagametophytes, on the upper side of the cone scales. The nucleus of each living cell in a sporophyte contains a double set of **chromosomes**—the bodies that transmit genetic characteristics from parent to offspring—and the sporophytes are thus known as the diploid ( $2n$ ) generation in the life cycle. Cells called spore mother cells—in pollen sacs on the male, or staminate, cones and in ovules on the female, or ovulate, cones—undergo a special cell division called meiosis, whereby two successive divisions of a spore mother cell produce four nuclei, each with half as many chromosomes as the spore-mother-cell nucleus, the haploid ( $n$ ) number. Thus, the spore mother cell is the last diploid member of the sporophyte phase in the alternation of generations, and the microspores and megaspores are the first cells of the alternate, or gametophyte, phase.

In the staminate cone the microspores separate, each developing a spore coat consisting of an outer (exine) and an inner (intine) layer. In many conifers the exine balloons out to form two or three hollow wings, which increase the buoyancy of the pollen grain (**microgametophyte**) and facilitate transportation by air currents. Simultaneously with the formation of the wings, a series of divisions begins, which sooner or later produces two male gametes, or sex cells, ready to fertilize the egg nucleus when the latter is receptive. When the pollen is shed, each grain is usually made up of two or more prothallial cells (flattened cells with degenerate nuclei, the only remaining vegetative cells of the male **gametophyte** generation), a tube nucleus, and a generative nucleus. In some genera no prothallial cells form, and tube and generative nuclei develop after the pollen grain lodges in the opening (micropyle) of an ovule. Pollen grains usually are released in the spring and float long distances on air currents. Only a minute fraction of them

lodge between the scales of ovulate cones; those that do may germinate and ultimately fertilize the egg nucleus. In *Pinus* and other genera that require two years from appearance of young ovulate cones to produce ripe seeds, the pollen lodges on the ovulate scales one spring, and the pollen tube grows part way toward the egg nucleus, then remains quiescent through the winter; it fertilizes the egg nucleus in the spring of the following year. In those that produce seed in one year, the processes are telescoped, and all stages from pollination to ripe seed occur in one spring–summer–autumn period.

The female strobilus (ovule-bearing structure) is an obvious cone in all members of the families Araucariaceae, Cupressaceae, Pinaceae, and Taxodiaceae, in spite of the different appearances among them. The nature of the ovule-bearing structures in *Cephalotaxus* and in the family Podocarpaceae is less apparent, but they are greatly reduced cones that have lost most of their scales and undergone fusion of remaining parts.

The ovule is that part of the ovulate cone that produces the female gametophyte (megagametophyte). The number of ovules per scale varies; a single functional one appears on each fertile scale in the Araucariaceae, *Cephalotaxaceae*, and Podocarpaceae. Two ovules occur on each scale in the Pinaceae, and from two to nine are found among the Cupressaceae and Taxodiaceae.

In the early stages of development, an ovule consists of a spherical or ellipsoidal mass of cells on the upper face of a cone scale. This mass is made up of food-storage tissue (nucellus) that occupies the bulk of the ovule and is surrounded by a coat, or integument, two to several cells thick. The integument is free from but lies closely against the nucellus, except at the apex, where a small opening (the micropyle) leads to the ovule.

Conifers  
with less  
obvious  
cones

Drawing by M. Pahl based on (A, B, C, D, E, H) B. Lloyd. Handbook of Botanical Diagrams (1962), University of London Press Ltd.; and (F, G) Harold C. Bold. The Plant Kingdom, 2nd ed., © 1964, reprinted by permission of Prentice-Hall, Inc., Englewood Cliffs, N.J.

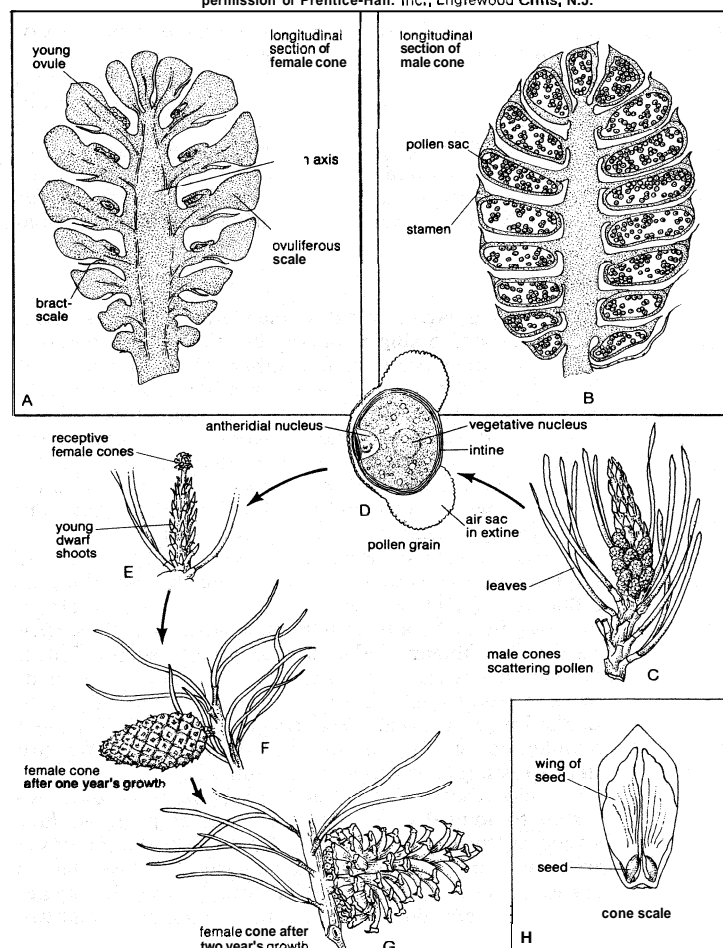

Figure 2: Reproductive structures and events in male and female cones.

Ovulate cones begin to develop in the fall, remain quiescent during winter, and have ovules ready for pollination in late spring. At this time the ovulate cones spread the tips of their scales apart, allowing pollen grains wafting on the breeze to sift among them. The ovules often have a small drop of liquid at the mouth of the micropyle at this time; pollen grains entrapped in the droplet are drawn toward the top of the **nucellus** as the liquid evaporates. The pollen tube then digests its way through the **nucellus** toward the archegonium, a flask-shaped structure in which the egg cell is developing. The pollen tube forces its way into the archegonium and extrudes its contents into the egg cell. A **male-gamete** nucleus soon fuses with the egg nucleus. The fusion of the male and female gametes is a complex process that produces two diploid nuclei in the earliest stage of the embryo. The two nuclei constitute the first cell generation of the next sporophyte generation in the alternation cycle.

#### SEED DEVELOPMENT

The rate of development accelerates markedly after fusion of the gamete nuclei. A complicated set of events follows, and several embryos are established. This condition, called **polyembryony**, is universal among conifers, but competition among the several to numerous embryos generally results in elimination of all but one; only rarely do two or more viable embryos develop in a single seed. The seed may be shed soon after maturity or, in **closed-cone** pines, may remain inside the cones on the tree from several to many years (as long as 30 years in *Pinus radiata*, *P. attenuata*, and *P. muricata*). Most conifers shed their seed at the end of the summer in which fertilization occurred.

Seeds that are shed in the fall lie dormant through the winter, and only about 20 percent of an average seed crop germinates with the arrival of spring.

Seedling mortality is high among conifers—approaching 100 percent for some species. Although thousands of seedlings often appear in early summer on land recently burned-over or cleared in construction projects, only a minute percentage of them live through the first summer. The greatest loss is attributable to drought during early growth stages, to excessive heating when in full sun, to the depredations of browsing animals, and to attacks from insect and fungus pests. Competition for space eliminates others, particularly when the early stand is dense.

#### ECOLOGY

As indicated earlier, conifers may often occur as extensive forests of a single species, but they are also found in ecological associations with other conifers or in a mixture of conifers and deciduous, broad-leaved hardwoods. Some occupy arid slopes, as do the **piñon** pines (*Pinus edulis*, *P. monophylla*, and *P. quadrifolia*); others grow in dense swamps or boggy land, as do the swamp cypress and the black spruce (*Picea mariana*). *Dacrydium araucarioides*, which grows only in New Caledonia, generally occupies dry situations on serpentine rocks.

Certain species of *Podocarpus* grow only in Alpine habitats in the Southern Hemisphere at elevations of 5,000 feet (1,500 metres) or more above sea level: *P. andinus* in the South American Andes and *P. macrophyllus* in Yunnan, China, are adapted to such habitats. Others occupy rain-drenched slopes and canyons at moderate levels, while a few grow near sea level only. One of the lowland species, *Podocarpus dacrydioides*, is well adapted to swampy ground and holds promise for use in reforesting New Zealand swamplands.

The closed-cone pines listed earlier have become adjusted to long dry periods and irregularly spaced fires sweeping through the forests. Under such conditions a tree may die following a particularly hot fire, but its seeds, protected from excessive heat by the closely appressed, woody cone scales, remain unscathed and are released in large numbers a few weeks after the fire, thereby reseeding the ash-enriched terrain.

Other conifers are tolerant of very low temperatures.

Those that grow at timberline and near the Arctic Circle are undamaged by temperatures that drop to about  $-45^{\circ}\text{C}$  ( $-49^{\circ}\text{F}$ ). In contrast, many conifers in the Southern Hemisphere—e.g., tender species of *Araucaria*, *Dacrydium*, and *Podocarpus*—cannot survive even light frosts.

Coniferous trees, like other trees, suffer from violent storms, destructive fires, and man-caused disturbances such as stream diversion, dam building, wasteful logging, and ill-advised agricultural exploitation. In recent years serious injuries have been inflicted by air pollution, in many areas bringing about the death of pure stands of such conifers as white pine. Smelter fumes are particularly injurious and have caused denudation of large areas of conifer forest. Areas cleared to provide agricultural land sometimes result in excessive soil erosion, so the land as well as the forest is destroyed.

Numerous insects and fungi may be extremely destructive of conifers. The white-pine blister rust is a serious menace in North America, and attempts to control it by eradicating the alternate hosts, the gooseberry and currant bushes (*Ribes* species generally), have been only partly successful. Bud-boring insects damage shoots, and other insects attack needles, the bark, and the wood. Under constant, often virulent attacks, conifer forests—especially pure stands, because of the ease with which disease and insects spread through such stands—have suffered greatly.

#### Form and function

##### THE ROOT

Many conifer seedlings develop a strong taproot after germination and retain it throughout the life of the tree. Others, especially trees growing in waterlogged soil, send out shallow lateral roots, the taproot dying shortly after the spreading roots are established. All conifers develop short roots from their main laterals or taproots. These short roots, which branch profusely, are the absorptive organs; they are abundantly supplied with mycorrhiza, fungi in a biological relationship with the root cells, which assist in absorbing dissolved minerals.

The internal anatomy of conifer roots is fairly uniform. No bark-forming tissue is apparent in the young roots of conifers. A cross section a short distance back of the tip of a young root shows an epidermis one cell thick, from some cells of which stubby root hairs grow outward. Interior to the epidermis is a layer of cortex, several cells thick, with many of the cells containing **mycorrhiza**, while others may contain starch grains, oil droplets, and other food reserves. A central strand of tissue comprises the vascular elements of the root, and its outermost sheath of cells, the endodermis, separates the vascular bundles from the cortex. Resin ducts are often seen in the roots.

Soon after the initial tissues become established—that is, the phloem, the tissue that functions in transporting foods manufactured in photosynthetic regions to other parts of the plant, and xylem, the woody parts of the water vascular system—arcs of cambium (dividing) cells become differentiated in the general ground tissue (parenchyma) and add secondary xylem cells to the woody part of the root and new phloem cells exterior to the cambial arcs. This activity soon fills the regions between the arms of protoxylem and produces a **rodlike** body of xylem consisting mostly of tracheids—long, slender cells with pointed ends and with perforations (bordered pits) in their thickened walls. The tracheids soon become empty conducting elements, having lost their contents during the deposition of thickenings on their walls. These empty elements serve two functions: mechanical strength and transportation of water with its dissolved mineral salts upward from the roots.

Vascular rays, present in roots in which secondary xylem has been deposited, consist of cells usually arranged in thin plates or bands one cell thick and several to many cells high that **run** radially from the xylem outward through the phloem. In many conifers the rays consist of thin-walled parenchyma cells only. In other conifers some rays have modified tracheids along the upper and

Hazards  
to conifers

Seedling  
mortality

Functions  
of the  
tracheids

lower margin, with the parenchyma cells constituting the central part of the strip. The number of rays increases as the stem or root grows in diameter.

#### THE SHOOT

The seedling shoot (hypocotyl) has the vascular tissues arranged in the same manner as in a root at its lower end, then has a transition region in which parenchyma cells come to occupy the centre of the vascular complex and above which the vascular elements are arranged as in stems. Stomates ("breathing holes") occur in the epidermis of the hypocotyl but are fewer than on leaves.

The growing tip of a conifer stem differs from that of its root in lacking a protective cap, lacking root hairs, and in possessing cells that are potential buds a short distance back of the apex.

A cross-section slice of a two-year-old stem shows an epidermis, usually ruptured at intervals by slit openings called lenticels, which permit the exchange of gases between the interior and the air outside. The centre of a cross section of a young stem consists of thin-walled unspecialized cells, the pith, with patches of xylem (usually three to five) constituting the primary xylem. Exterior to the outermost xylem elements is secondary xylem, which at first consists of discrete bundles but very shortly forms a cylinder of tracheids interrupted only by the medullary rays—rays that run from the pith outward. New vascular rays develop as the stem grows in diameter. Outside the ring of xylem is the cambium, which functions exactly as in roots, cutting off xylem elements to the interior and phloem elements to the exterior.

Scattered through the xylem in several conifer genera, particularly in *Agathis*, *Larix*, *Picea*, *Pinus*, and *Pseudotsuga*, are resin ducts running longitudinally in the secondary xylem, each surrounded by small, thin-walled cells that exude resin (pitch) into the duct; it is these ducts that supply resin when the tree is tapped or the bark injured. Also present in the xylem of many conifers are scattered parenchyma cells that retain their contents for some time after the adjacent tracheid elements are empty. Parenchyma cells are much shorter than tracheids, have blunt ends, and have simpler perforations in their walls. The vascular and medullary rays in conifers are usually one cell wide and a few cells high (when viewing them in tangential sections of the stem). All conifers that normally have resin ducts in their xylem have occasional fusiform rays; *i.e.*, rays that are spindle shaped in tangential view, several cells wide and three to six times as high as wide. Running longitudinally through the central part of many fusiform rays is a resin duct similar to those parallel to the tracheids. As in roots, the vascular and medullary rays in many conifers are composed of parenchyma cells only. A few, such as *Sequoia*, at times develop ray tracheids along the upper or lower margins or in both positions. Some conifers that normally lack resin ducts—*e.g.*, *Abies*—may develop some in the vicinity of injuries.

#### LEAVES

Most conifer leaves are relatively narrow (several times longer than wide), usually have stomates arranged in longitudinal rows along either side of the single vein, or vascular bundle, and have a protective waxy cuticle. The vein, in all except a few genera, consists of one or two centrally located strands of vascular cells surrounded by a few parenchyma cells, outside of which is the endodermis. Between the endodermis and the epidermis are parenchyma cells, special transport cells (forming transfusion tissue) along the flanks of the strand, and, exterior to these latter cells, the palisade cells packed with the green-pigment bodies, or chloroplasts, that carry on photosynthesis. Some conifers have cylindrical palisade cells; others, as in *Pinus*, have almost spherical ones with deep folds in their walls, thus increasing the surface through which exchange of gases takes place. Immediately under the epidermis are strands of varying size and thickness composed of rigid, thick-walled cells; the strands constitute the hypodermis, a tissue that adds mechanical strength and stiffness to the leaf. Resin ducts,

usually numbering from one to five in most species, vary in length and location, depending upon the species.

The leaves of many conifers—especially pines, firs, and spruces—are long and stiff and hence are called needles. Leaves of others—cypresses, cedars, *Calocedrus*, *Chamaecyparis*, and *Cryptomeria*, for example—are smaller and scalelike and have much of their length attached firmly to the twig, with only their tips free. Scale leaves are arranged along the branch in pairs or threes, with alternate sets at right angles to each other so as to form four to six distinct longitudinal rows. In some species the scale leaves take two forms: a longer pair set in one plane and a shorter pair, less spreading and appressed to the twig, set in the other plane, an arrangement that often results in fanlike, flattened branchlets, as in the cedars. In contrast, species with scale leaves all of similar size usually have leafy twigs that are circular in cross section.

*Pinus* bears two kinds of needles: simple, solitary ones set spirally on the branch of very young seedlings and longer, stiffer ones borne in bundles of two to five on a short stub, or spur branch, with each such bundle ensheathed at its base by papery scales. Each bundle persists from two to 20 years, depending on the species; then the entire spur branch falls, carrying the needles with it.

One conifer, *Phyllocladus*, carries on photosynthesis in leaflike flattened branchlets, its true leaves being minute scales that fall soon after they appear. *Sciadopitys* has two anatomically identical leaves united side by side and borne at the tip of a minute spur that is formed in the angle of a temporary scale leaf and the twig.

Leaves of most species of *Podocarpus*, those of *Cephalotaxus* and *Cunninghamia*, and some species of *Araucaria* are intermediate between needles and scale leaves. They usually are oblong to broadly linear, stiff and leathery, and often have sharp ends. They are spirally arranged, but some of them have twisted bases so that they appear to grow on opposite sides of the twig. Some have several veins running from base to apex rather than a single, middle vein. Several genera in the family *Taxodiaceae* bear leaves on lateral branchlets that function through one to several seasons, then shed the entire branchlet. *Taxodium* and *Metasequoia* shed such branchlets annually, leaving the trees bare during the dormant season; while *Sequoia* and *Sequoiadendron* retain the branchlets several years and are evergreen.

In some conifers, stomates are confined to the lower surface of the leaves, but in others they may occur on all surfaces with a concentration on the undersurface.

#### GROWTH AND BIOLOGICAL PRODUCTION

Conifers require a much lower concentration of mineral nutrients than is needed by food crops. Minute quantities of iron are essential, and traces of zinc and several other minerals are needed. (Zinc deficiency caused considerable loss among plantations of Monterey pine [*Pinus radiata*] during the early phases of reforestation in Australia.) Potassium-deficiency symptoms appear in young conifers only when concentration of that mineral falls below four parts per million, and calcium deficiency occurs only when that mineral drops below three parts per million. Mineral deficiencies sometimes produce no apparent symptoms other than reduction in rate of growth, but changes in colour are often indicative of a low level of vital nutrients. Nitrogen deficiency—as might occur in low wetlands—stunts seedlings and causes their leaves to turn yellow; phosphorus-deficient plants turn purple; and potassium and iron deficiencies cause loss of chlorophyll in conifer leaves.

Nearly 50 species of fungi enter into symbiotic relationships with the roots of conifers as mycorrhiza. Mycorrhiza may afford some protection against pathogenic fungi, and they definitely assist the conifer host in drawing up certain minerals and increase the rate of absorption of water from relatively dry soils.

Most conifers are able to carry on photosynthesis in low light intensity; thus, young plants can survive under rather shady conditions and in light near the blue end

Needle-like  
and scale-  
like leaves

Resin  
ducts

Conditions  
for  
maximum  
growth

of the spectrum. Many conifers carry on photosynthesis more efficiently than broad-leaved hardwoods because their needles have a relatively higher concentration of chlorophyll. Conifers in cool areas continue photosynthetic processes at temperatures as low as  $-6^{\circ}\text{C}$  (about  $21^{\circ}\text{F}$ ); few flowering plants can approach such a performance. Conifer seedlings grow at maximum efficiency under long-day photoperiods—light for 15–20 hours daily—but cease growing when the 10-hour days of autumn begin. Of course, different photoperiod reactions occur, depending upon the latitude and on species adaptation to environmental factors normal to their respective habitats. Furthermore, growth of conifers is most rapid under conditions of warm days and cool nights, with the greatest growth occurring among those subjected to the greatest differences, within their tolerances, between day and night temperatures.

Not only is there an annual growth rhythm, resulting in annual growth rings, but there is also a strong daily rhythm, with more shoot elongation occurring at night than during daylight hours. In semi-arid regions, where precipitation during the growing season often is in the form of brief but violent rainstorms, several growth rings may form in a conifer during a single summer. Such alternate growth surges and low activity are directly correlated with the intermittent rains but lag appreciably behind the actual occurrence of the storms. Where the water supply is uniformly high and the temperatures uniformly warm, however, conifers produce almost no visible growth rings, since growth is fairly uniform.

Physiological factors associated with the initiation of cone production are puzzling, but genetic factors are definitely involved. The average age of first cone formation of 60 conifer species is 5.2 years. A few species produce some ovulate cones at two years of age; others, such as the sugar pine (*Pinus lambertiana*), bear no cones until 25 years old. A number of species have a nonproductive period of several years between the first crop of cones and the next. Among many conifers seasons of high seed production alternate with seasons of low production.

Longevity and senescence are equally difficult to understand. The ability to root from cuttings appears to decline with age. The terminal shoot of a tree four or five years old roots easily when cut and placed in a rooting medium. In contrast, a cutting from the top of a pine tree 200 years old will not root, even if treated with potent growth-promoting substances. The conifers with the longest life-span discovered to date—and the oldest plants in existence—are the bristlecone pines (*Pinus aristata*), growing at 11,000 feet (3,400 metres) above sea level in the White Mountains of California and similar areas in Nevada, Utah, Colorado, and northern Arizona and New Mexico. Ages of almost 5,000 years have been determined by counting growth rings in borings taken from the thick trunks of these gnarled and twisted trees. Conifers that produce tall, sturdy trunks rarely attain ages one-half as great.

Seeds of conifers vary greatly in viability (ability to germinate) and in longevity. The seeds of pines in the subgenus *Haploxylon*—typified by white pines—lose their viability very rapidly if stored at room temperature, much faster than do those of the subgenus *Diploxylo-* *lon*, or yellow pines, under similar conditions. Seeds of all conifers that grow in temperate climates or in sub-Arctic areas retain their viability best if stored at a temperature of about  $5^{\circ}\text{C}$  ( $41^{\circ}\text{F}$ ). Seeds of closed-cone pines have remained viable up to 30 years when contained within the cones held on the trees; they deteriorate rapidly, however, after they are released from the protective cones. Some conifer seeds germinate more rapidly when subjected to at least a short period of illumination, others do best if left in light throughout each day, and a few react favourably to short periods of illumination with red light.

#### CHEMICAL COMPOSITION

The chemistry of pines is more thoroughly known than that of any other conifer because of the great amount of

investigation conducted by industries that utilize pine products.

Cellulose is a component of cell walls in all higher plants, including conifers; lignin occurs in xylem, or wood, and is more complex in its structure. Coniferous lignin differs from the lignin of broad-leaved angiospermous trees in giving no reaction to a test for the chemical syringaldehyde.

The hemicellulose present in conifers can be made to yield such sugars as xylose, mannose, arabinose, galactose, glucose, and rhamnose and the urinelike uronic acids. Conifer wood yields only 15 to 20 percent of hemicelluloses, compared with 20 to 30 percent in angiosperm wood.

The sugar pine exudes a sugary substance that the American Indians used as food and medicine. First named pinite, later pinitol, it has been found in the wood of six species of pines in the subgenus *Haploxylon* but not in the wood of any of the pines of *Diplorylon*.

Polyphenolic compounds occur in the wood of many conifers, but percentages of separate phenols vary greatly from sample to sample. Some polyphenols are abundantly present in the heartwood, or nonliving core, of conifers, with only minimal fractions of them in the sapwood, bark, needles, cones, and pollen grains.

As much as 50 percent of the weight of conifer seeds is fat, which constitutes the main food reserve for the embryo; the fats are mainly triglycerides of unsaturated fatty acids such as oleic, linoleic, and linolenic, predominantly the second. Seeds of pines growing in northern areas contain somewhat higher percentages of unsaturated fats than do those of trees from southern, warmer areas.

Waxes present in the bark, on needles and twigs, and in the pollen of some conifers often impart a whitish or bluish "bloom." These waxes generally are classified as estolides and are made up of long chains of polyesters of hydroxy acids.

Volatile oils occur in the leaves, twigs, wood, and to a lesser degree in the bark of conifers. They usually constitute only about 0.5 percent of the fresh weight of the material processed. The chemical composition and relative volatility of these oils vary greatly, that obtained from needles being different from that from the twigs and older stem wood in the same tree.

Tall oil, a mixture of substances obtained as a by-product of paper-pulp manufacture, is used chiefly in the manufacture of soaps and greases.

Oleo-resins present in many conifers form the basis of the naval-stores industry in several parts of the world. Droplets of oleo-resins occur chiefly in cells surrounding the resin ducts in the sapwood. When the resin canals are severed or ruptured, the pitch seeps through the wound and may be collected in a suitable receptacle. Raw oleo-resin can be separated into two main components, turpentine and rosin, the relative percentages of which vary considerably among the pitch-producing pines and other conifers. Oleo-resins also collect in pockets in the bark of several species of *Abies*, although the wood of this genus lacks resin ducts. Each "blister" must be tapped individually, and the product, Canada balsam, is produced in small quantities and has limited uses.

Venetian turpentine, used mainly in artwork, is an oleo-resin taken from the heartwood of the European larch (*Larix decidua*) by boring a hole in the lower trunk, allowing the pitch to accumulate, and collecting it periodically. The annual production is very low, usually not over two ounces of pitch per tree per year.

Oleo-resins obtained from stumps and collected by tapping living trees yield rosin generally composed of about 90 percent diterpene resin and acids and up to 10 percent of nonacid compounds. The steam-volatile fraction of oleo-resins from pines, called turpentine, is a complex of about 30 chemical constituents.

#### Evolution and paleontology

##### ANCESTRAL CONIFERS

The geological history of the conifers began in the Carboniferous period (about 345,000,000 years ago). The

The oldest  
plants

Volatile  
oils

"Form genera" of the Voltziaceae

earliest conifers represented in the fossil record have been lumped, for convenience, in the family Voltziaceae, of uncertain relationship to still earlier groups of plants (see Figure 3). Within the Voltziaceae several "form genera" (those based on a general type of organ, such as a leaf, a twig, unidentifiable beyond these general lines) have been included in a newly proposed genus, *Lebachia*, and one older genus, *Walchia*, the latter retained to include all leaf-bearing twigs in which stomatal characters cannot be determined.

*Lebachia*, a straight, upright tree with a slender trunk of unknown height, appeared first in the late Carboniferous time (about 300,000,000 years ago) and became commoner and more widespread later. Both staminate and ovulate cones of *Lebachia* were cylindrical and were borne singly at the tips of twigs on the same tree.

In the Permian Period (from 225,000,000 to 280,000,000 years ago) occurred *Ernestiodendron filiciforme*, vegetatively similar to *Lebachia* but evolutionarily advanced over *Lebachia*. A further evolutionary advance is shown by *Pseudovoltzia liebeana*. It had two kinds of leaves, spirally arranged, those at the ends of the younger branches being long, linear, and flattened, while those on the older branches were shorter, more slender, and incurved. Scales of the ovuliferous cones were arranged spirally but had a flattened, five-lobed appendage axillary to each bract except the basal two or three. These appendages have been interpreted as having arisen by fusion of five ovuliferous scales such as those in *Lebachia*, their terminal parts still free, and a loss of the ovule from at least two of the five scales. Continued reduction, or fusion, through a greater part of the scales, plus loss of one more ovule, could have resulted in an ovulate cone scale similar to those now possessed by many modern conifers.

The foregoing series of fossils presents a clear line of development from ancestral forms to the immediate predecessors of modern conifers. This evolutionary line apparently developed rapidly during the Mesozoic Era (from 65,000,000 to 225,000,000 years ago), but few fossils of that age are adequately preserved, so it is difficult to follow advances in later differentiation.

Figure 3: Conifer dendrogram.

#### FOSSILS OF CONTEMPORARY CONIFERS

It is difficult to identify any modern coniferous genera with fossils older than those from the Cretaceous Period (from 65,000,000 to 136,000,000 years ago).

Early in the 20th century, some botanists argued that the family Pinaceae represented the most primitive stock of the coniferous evolutionary sequence and were followed by the family Araucariaceae. The general opinion has become that both families are descendants of an ancient stock—possibly going back to the Pityeae—that they represent two lines that became differentiated in the Middle and Late Mesozoic and that the present segregation of the two—and other families of the Coniferales—is chiefly the result of the extinction of intermediate, Mesozoic types. The conifers as a group reached their zenith in the Middle Cretaceous and have been declining ever since. The angiosperms have been more successful in the never-ending competition among organisms and have come to dominate the floristic scene.

The decline of the conifers

The diagram in Figure 3 of the theoretical lines of descent among the gymnosperms shows the presumed general routes of evolution followed by the different branches of the groups in geologic time.

The oldest fossil referred to the family Araucariaceae with reasonable assurance is *Araucarites delafondii* from the Permian of France. It consists only of triangular cone scales that had separated from the cone axis, with each scale bearing a single seed on its undersurface.

Extensive deposits containing *Araucarioxylon* and *Woodworthia* wood occur in North America, the most famous being those in the Petrified Forest National Park in Arizona. No cones are attached to the petrified logs, but the tracheids have pit characteristics of Araucaria, and there is no doubt about the relationship. Several species of *Araucarites* occur in Cretaceous sediments in Alabama, New Jersey, North Carolina, South Dakota, and Wyoming.

Excellent fossil cones of *Proaraucaria mirabilis* came to light in volcanic ash, probably Eocene in age (from 38,000,000 to 54,000,000 years ago), in Patagonia. These cones differ from modern *Araucaria* cones in having a deep cleft between the tips of the bract and the ovuliferous scale, a condition similar to that found in modern members of the Pinaceae. Only one seed appears on a scale, and the structures of both scale and seed strongly resemble those in the *Eutacta* section of *Araucaria*.

Cone scales of *Agathis* are fairly common in Cretaceous and Tertiary sediments. The first specimens found were *A. borealis* from Arctic deposits, but subsequently others were found in Cretaceous rocks along the North American Atlantic coastal plain. Cones of *Protodammara speciosa*, of similar age but slightly smaller than *Agathis borealis*, were obtained in New York.

The plum-yew family (Cephalotaxaceae) is represented by fossils of foliage and seeds that resemble those of *Cephalotaxus*, in Lower Cretaceous beds in Alaska, South Dakota, and Virginia.

A fairly recent family, the cypresses (Cupressaceae), is represented by undisputed fossil specimens of several genera in Upper Cretaceous and Tertiary sediments, including *Callitris*, *Thujopsis*, *Thuja*, *Juniperus*, and *Chamaecyparis*.

Fossils of the pine family (Pinaceae) may extend back into early Mesozoic times, but definite relationships of the genera are hard to establish. *Prepinus*, consisting of needlelike leaves on short shoots, were found in Lower Cretaceous formations in New York. Internal structure of these leaves suggests that *Prepinus* is an ancestral form of *Pinus*, possibly linking the pines, true cedars, and larches. Some undisputed *Pinus* cones and seeds are known from Cretaceous rocks of Greenland, Maryland, South Dakota, Virginia, and western Canada, and cones were found in Lower Cretaceous deposits in Europe. Fossils of various pine structures, including pollen, first appear in Eocene rocks and become abundant in Miocene (about 7,000,000 to 26,000,000 years ago) and Pliocene (from 2,500,000 to 7,000,000 years ago) formations from widely scattered localities.

Fossil remains belonging to *Abies*, *Cedrus*, *Keteleeria*, *Pseudotsuga*, and *Tsuga* have been found in Miocene and Pliocene beds. *Picea* occurred in the Lower Cretaceous of Belgium but did not appear in North American fossil floras until Miocene time, and *Larix* seems not to have appeared in the fossil record until the Pleistocene Epoch, about 2,500,000 years ago. Leafy shoots that might have been precursors of either *Cedrus* or *Larix* came from Jurassic rocks (of 136,000,000 to 190,000,000 years ago) and were called *Pitycladus*.

Three different types of wood with characteristics of the Pinaceae, but without attached cones or leaves, have been found in abundance and now are generally assigned to three form genera—*Cedaroxylon*, *Piceoxylon*, or *Pinuxylon*—which replace earlier names. Altogether, about 200 different "species" presumed by their authors to belong to the Pinaceae have been described.

The earliest known representative of the family Podocarpaceae was found in the Lower Jurassic (about 190,000,000 years ago) of New Zealand and in India. The

The  
earliest  
known  
podocarps

Podocarpaceae and Araucariaceae competed for dominance in the Southern Hemisphere at this time, and fossils belonging to *Dacrydium* and *Podocarpus* lines have been found in Middle Jurassic rocks of Antarctica. Other fossil representatives of these genera occurred throughout Cretaceous and Tertiary times in Argentina, Chile, South Africa, India, Australia, and Tasmania. *Phyllocladus asplenioides*, found in Eocene deposits in New South Wales, and other fossils resembling *Phyllocladus* have been found in Cretaceous rocks in Nebraska, New York, and Greenland.

Some Mesozoic fossils named *Elatides* were first placed in the Pinaceae but now are considered closer to the family Taxodiaceae. *Elatides williamsonis*, from Middle Jurassic strata in Yorkshire, is the most ancient of the unquestioned Taxodiaceae. Its staminate cones had scales with pronounced stalks and broadened, triangular terminal expansions set almost at right angles to the stalk. The ovulate cone scales bore two to five small ovules near the juncture of the stalk and the expanded terminal part. This fossil probably was closely related to *Cunninghamia*, or it might have been intermediate between *Cryptomeria* and *Sequoiadendron*.

The fossil predecessors of *Sciadopitys* go back to Lower Jurassic beds of New Jersey and Norway, to the Lower Jurassic of Sweden, and from Jurassic to Cretaceous in Greenland.

Fossils of *Sequoia*, *Metasequoia*, and *Taxodium* have been hard to differentiate when cones were not among the leaves and twigs. Much of the *Sequoia* and *Taxodium* material of Eocene age is now known to be *Metasequoia*. It is possible that some petrified tree trunks still standing in the Yellowstone National Park may be those of *Metasequoia*.

Genuine *Taxodium* fossils are abundant in Tertiary deposits of North America, Europe, and Asia; fossils uncertainly referred to as *Glyptostrobus* occur in the Lower Cretaceous of Greenland, and more positively determined ones come from Eocene rocks in North Dakota, the Miocene of Oregon, and from several other Tertiary localities; *Cryptomeria* has been found in Tertiary beds in Great Britain and from Upper Cretaceous strata in Japan; *Athrotaxis* has been recorded from the Lower Cretaceous of Patagonia and questionably from Czechoslovakia; *Cunninghamia* has come from the Upper Cretaceous of Japan, and pollen grains of this genus were found in the Green River shales of Eocene age in Colorado and Utah.

## Classification

### DISTINGUISHING TAXONOMIC FEATURES

The foremost identifying feature of the conifers is the cone, which has already been discussed in earlier sections. Another equally important character resides in the chromosomes. Not only the number but also some of the structural characteristics of conifer chromosomes are remarkably stable and may serve as taxonomic guides. Three basic series of chromosome number occur among the conifers: an 11 series in the Cupressaceae and Taxodiaceae, a 12 series in the Cephalotaxaceae and Pinaceae, and a 13 series in the Araucariaceae. The Podocarpaceae, obviously more evolutionarily versatile than the other families, has no fewer than four basic numbers in its various genera: 12, 13, 19, and 20 having been determined. (The last two numbers in this diverse series probably arose through the fusion of one or two chromosomes, followed by duplication of the entire set.) The chemical characteristics of various resins, turpentine, and other substances are important factors in the classification of conifers. It is already known that terpenoid characteristics of the heartwood of the Cupressaceae are quite different from those of the Pinaceae and that those of the Araucariaceae and Podocarpaceae have distinctive chemical divergences. Phenolic compounds in the haploxyton pines are markedly different from those of the diploxyton pines.

Arrangement of families, genera, and species according to morphological, anatomical, chemical, and ecological characteristics is not too difficult. But construction of a

phylogenetic classification that shows lines of evolutionary derivation is a far more difficult task because of the incomplete nature of the fossil record.

### ANNOTATED CLASSIFICATION

The taxonomic scheme given below is based upon characters, mostly visible, that are used in formulating what is called a key, or horizontal, rather than phylogenetic, classification.

#### ORDER CONIFERALES

Creeping shrubs to giant trees, all of which bear staminate, or pollen-producing, cones and most of which bear ovulate, or seed-producing, cones (exceptions: Cephalotaxaceae and Podocarpaceae). The largest order of gymnosperms, with about 50 genera and more than 500 species, found in all parts of the world.

##### Family Araucariaceae

Shrubs and trees with cone scales flattened, overlapping, and usually numerous and bearing bracts, at least in young cones. A single seed on each ovulate scale. Leaves are mostly leathery or their bases leathery and the free part curved.

The Araucariaceae consist of 2 genera only, *Agathis*, with 21 species, and *Araucaria*, containing 14 species distributed among 3 sections of that genus, based on characters of leaves, cones, seeds, and methods of germination. Section *Colymbea* has broad, flattened, rigid leaves, large cones about 20 cm long, seeds with only 2 cotyledons, and hypogeal germination (*i.e.*, the seed and cotyledons remain under the soil throughout germination and establishment of the seedlings). Section *Eutacta* has awl-shaped, less rigid, smaller, curved leaves, smaller cones (usually less than 10 cm long), seeds with 2 to 4 cotyledons, and epigeal germination (*i.e.*, the cotyledons are pushed above the surface of the soil upon germination). Section *Intermedia* has awl-shaped, only slightly rigid juvenile leaves but broad, flat, rigid adult leaves, cones intermediate in size, 2 to 4 cotyledons, and epigeal germination. The family is completely limited to the Southern Hemisphere in its natural distribution.

##### Family Cupressaceae (cypresses)

Prostrate to upright shrubs and trees with cone scales usually expanded at their tips and meeting at their edges (not overlapping), numbering usually 3 to 12 per cone; bracts not visible externally. Ovules, containing the seeds, are borne erect. Leaves are scalelike, in pairs or threes; they may be spirally arranged in juvenile forms of certain species.

The cypress family consists of 18 genera and 130 species: *Juniperus* leads with about 60 species, distributed widely in the Northern Hemisphere, *Cupressus* is second with 21 species likewise widely distributed, and the rest of the genera contain from 1 to 13 species each and range less widely.

##### Family Cephalotaxaceae (plum-yews)

Shrubs or small trees having single seeds borne at the tips of dwarf branches. No cone scales normally visible (one or two sterile ones may appear at base of the seed). Staminate cones are globular or ovoid, pollen sacs 3 to 9 per scale, and the pollen grains are winged.

The Cephalotaxaceae family has 1 genus and 7 species confined to eastern Asia from Assam to Korea and Japan. They have no economic value except as ornamentals.

##### Family Pinaceae (pines, firs, spruces, etc.)

Shrubs to tall trees with cone scales flattened, overlapping, usually numerous, and bracts evident. Two seeds on each ovulate scale. Leaves are needlelike.

The Pinaceae is the most diverse of all the living coniferous families: it includes 10 genera and more than 200 species; *Pinus* alone has about 100 species (some botanists recognize only about 80) divided between 2 subgenera, *Haploxyton* and *Diploxyton*. *Haploxyton* pines, in which each needle has only 1 vascular bundle and usually 5 needles on a dwarf shoot, are called white pines; their wood is usually softer than that of the other subgenus. *Diploxyton* pines, whose needles have 2 vascular strands side by side within the endodermal sheath and mostly in bundles of 3 (3 on a dwarf shoot), have wood that contains more resin than does that of the white pines and is harder, the heartwood being slightly yellowish, hence the common name yellow pines. Many pines bear large, edible seeds that have high nutritive value and are used commercially. The smaller edible seeds of other pines are consumed by animals in large quantities.

Among the other genera of the Pinaceae, *Abies* has almost 50 species, widely distributed in the Northern Hemisphere. *Cedrus*, with 4 species in the Atlas Mountains of North Africa, Asia Minor, and the Himalayas, and *Cathaya* and *Keteleeria*, with 2 each, are both native in China. *Larix* has 10 species in the Northern Hemisphere. *Pseudolarix* contains 1 species, in eastern China. *Pseudotsuga*, with 5 species and an additional

variety, occurs in western North America, Japan, and China. *Tsuga* has about 10 species, in the Northern Hemisphere. *Pinus*, with 31 species, is widely distributed in temperate regions of the Northern Hemisphere.

#### Family Podocarpaceae

Prostrate shrubs to tall trees having single olive-like seeds borne at the tips of dwarf branches. No cone scales normally visible. Staminate cones cylindrical, with two pollen sacs per scale, and the pollen grains not winged.

This predominantly Southern Hemisphere family consists of 7 genera collectively possessing approximately 150 species. *Podocarpus* surpasses *Pinus*, having more than 110 species distributed throughout the greater part of the Southern Hemisphere and extending well into the Northern Hemisphere in Asia and as far north as Mexico and the Caribbean in North America. *Dacrydium* is second in the family, with about 20 species, centred in the New Zealand-New Caledonia area but extending to Chile, the Philippines, and Malaysia. Two genera, *Microcachrys* and *Saxegothaea*, each consists of a single species of limited range; the former native in Tasmania and the latter native in southern Chile and western Patagonia. The other 3 genera are: *Acmopyle*, with 3 species in New Caledonia and Fiji; *Microstrobus*, with 2 species confined to New South Wales and Tasmania; and *Phyllocladus*, with 6 species in New Zealand, New Guinea, Tasmania, Borneo, and the Philippines.

#### Family Taxodiaceae

Shrubs and tall trees with cone scales usually expanded at their tips and meeting at their edges (not overlapping), numbering usually 3 to 12 per cone; bracts not visible externally. The ovules are inverted (in contrast to the condition in the Cupressaceae). Leaves are linear to awl-shaped (scalelike on adult branches of *Sequoia* and *Sequoia*) and spirally arranged on branchlets.

The Taxodiaceae include 10 genera, 6 of which have only one species. *Taxodium* and *Athrotaxis* consist of 3 species each, and *Cunninghamia* and *Taiwania* each have 2. It would seem probable that the 6 monotypic genera are approaching extinction. They are *Cryptomeria* (Japan); *Glyptostrobus* (south China); *Metasequoia* (interior China); *Sciadopitys* (Japan); *Sequoia* (western coastal United States); and *Sequoia* (western flanks of the Sierra Nevada in California).

#### CRITICAL APPRAISAL

Classification of the conifers has been debated vigorously for more than a hundred years and is still being studied critically. Significant advances have been made in the understanding of the lines of descent and the familial relationships among the conifers. One of the most important of these advances was that made by the Swedish botanist, Rudolf Florin, who, in 1951, clarified the line of descent from *Cordaites*, a gymnosperm that has been extinct since about the end of the Permian, to *Lebachia*, thence through *Ernestiodendron*, *Pseudovoltzia*, and *Ulmannia* to the earliest genera of the conifers, and who detected the homologies between Cordaitan inflorescences and the ovulate strobili of modern conifers. As a result, it is no longer doubted that the one-seeded structures of *Cephalotaxaceae* and *Podocarpaceae* are homologous with the apparently vastly different woody cones of *Araucaria* and *Pinus*.

A particularly vexing problem is the proper disposition of the yews (family Taxaceae). Earlier they were considered, along with the pines (Pinaceae), as the only two groups within the order of conifers. Later investigations, however, have led to the separation of the yews as a distinct order, Taxales, equivalent in rank to the Coniferales (see GYMNOSPERM).

The problems encountered in aligning, relating, and separating the genera and species included within the six families of conifers are extremely complex. Such details can be found only by consulting a fairly large number of research papers and books. Such a task would require using interdisciplinary approaches, data derived from microscopic as well as macroscopic features, and the consultation of chemical, physiological, and ecological sources. The brief bibliography below holds clues to more extensive literature dealing with such specialized and divergent subjects.

BIBLIOGRAPHY. L.H. BAILEY, *The Cultivated Conifers in North America, Comprising the Pine Family and the Taxads* (1933), descriptions of native and introduced conifers, with data on habitats, range, cultural needs (U.S. and Canada),

pests, and uses; C.R. HARRISON, *Ornamental Conifers* (1975), a guide to ornamental uses of a wide range of genera and species, with descriptive notes, some history, hardness zones (U.S.), and extensive colour illustrations; W. DALLIMORE and A.B. JACKSON, *A Handbook of Coniferae and Ginkgoaceae*, 4th ed., rev. by S.G. HARRISON (1966), a manual covering conifers, with descriptive text, lists of cultivated forms, ranges of native habitats, and data on distribution, suitability for planting (England), and some indication of uses, with a list of important references consulted; R. FLORIN, "Evolution in Cordaites and Conifers," *Acta Horti Bergiani*, 15:285-388 (1951), a technical paper reviewing the work of earlier and contemporary botanists, with concise coverage of nearly 30 years of research by the author, including a comprehensive bibliography; HUI LIN-LI, "Present Distribution and Habitats of Conifers and Taxads," *Evoluton*, 7:245-261 (1953), a review of distribution of these groups, with selected references; N.T. MIROV, *The Genus Pinus* (1967), an outstanding treatment of the pines of the world.

(I.L.W.)

## Connecticut

One of the six New England states, Connecticut is located in the northeastern corner of the United States. In area it is the third smallest state in the nation, with 5,009 square miles (12,973 square kilometres), and ranks among the most densely populated. It lies athwart the great urban-industrial complex along the Atlantic Coast, with Massachusetts to the north, Rhode Island to the east, Long Island Sound (an arm of the Atlantic Ocean) to the south, and New York to the west.

Connecticut, with its many beaches and harbours, its forest-clad hills, and its village greens that are often surrounded by houses that date from the 17th and 18th centuries, represents a special blend of modern urban life, rustic landscape, and historic sites. It is a highly industrial and service-oriented state, and its per capita income and value added by manufacture are among the highest in the nation. The strength of its economy lies in a skilled working force, much of it fabricating products that have been manufactured in Connecticut since the products were invented.

As might be expected, the population of more than 3,000,000 residents is heavily urban. The state has no single large city, however, and the intense crowding characteristic of many urban areas is not found in Connecticut. On a national scale, it continues its long tradition of being a prosperous state, with in-migration attracted by the good employment opportunities, excellent educational facilities, and pleasant living conditions for the majority of its people. (For related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; and NORTH AMERICA.)

#### THE HISTORY OF CONNECTICUT

**Colonization.** In contrast to many of the other New England areas, relations between Indians and the early settlers in Connecticut were good. Trading posts were established along the Connecticut River by the Dutch from New Amsterdam and by the English from the Plymouth Colony, but the first permanent European settlers in the state came from the Massachusetts Bay Colony to the middle Connecticut Valley during 1633-35 and to the Saybrook-New Haven coastal strip during 1635-38. In 1665 the Connecticut River settlements and the New Haven Colony were united, and the general outline of the state emerged, although its borders were not finally demarcated until 1881, more than 200 years later. The New Haven Colony was unsuccessful in an attempt to settle Delaware Bay, and the united Connecticut Colony, despite its charter provisions, lost its claim to a strip of land extending to the Pacific. Following the American Revolution settlers from Connecticut, with claims in the Midwest, were among the first to move into an area that became known as the Western Reserve, now northeastern Ohio.

**Political, economic, and social maturation.** The political development of the colony began with the Fundamental Orders of Connecticut (1639), a civil covenant by the settlers establishing the system by which the river towns of Windsor, Hartford (now the capital), and Wethersfield

An overview of the state

Land claims

Advances in knowledge of conifer relationships

agreed to govern themselves. The orders created an annual assembly of legislators and provided for the election of a governor. This was superseded by the royal charter of 1662, a liberal document that provided for virtual self-government by the propertied men of orthodox faith in the colony. It served Connecticut well until it was replaced by the state constitution adopted in 1818, a document that after being amended many times was replaced by a new constitution that was adopted in 1965, reflecting the more complex needs of contemporary government. The Congregational Church was disestablished by the constitution of 1818.

Connecticut remained an agricultural region of farms with a few small urban areas—Hartford, New Haven, New London, and Middletown—until the early 19th century. The economy began to change, however, after 1800 when textile factories were established, and by 1850 employment in manufacturing outnumbered that in agriculture. The shift to manufacturing had been aided by the inventive genius of a number of Connecticut residents. Eli Whitney, well known for his invention of the cotton gin, developed the idea of machine-made parts for guns. An order for muskets from the federal government enabled him to build a musket factory in **Hamden**. The principle of interchangeable parts, adapted to clock manufacturing by Eli Terry of Plymouth in 1802, rapidly became basic to all manufacturing.

The economic, social, and political innovations that emerged in the 19th and 20th centuries were often resisted at first, but eventually they were accepted. Slavery, first attacked by legislation in 1784, was not abolished completely until 1848. The constitution of 1818 granted suffrage to men with certain property qualifications, but women's suffrage came only through federal enactment in 1920.

#### THE NATURAL AND HUMAN LANDSCAPE

The natural environment. **Surface features.** Essentially a rectangle in shape, 100 miles (160 kilometres) west to east and 50 miles north to south, Connecticut covers the southern portion of the New England Upland. It contains three major regions: the Western Upland, the Central Lowland (Connecticut Valley), and the Eastern Upland. The northern part of the Western Upland, often called the Berkshire Hills, contains the highest elevations in the state, about 2,300 feet (700 metres) in the northwest corner. It is drained by one major river, the Housatonic, and numerous tributaries.

The Central Lowland is different in character, being a downfaulted block of land, approximately 20 miles wide at the Massachusetts border and narrowing as one progresses toward the sea, which it meets at New Haven. It is filled with sandstone and shale. Periodic volcanic activity pushed immense quantities of molten rock to the surface and produced the igneous deposits of the central valley. These layers of sandstones and traprock have been faulted, broken, and tipped so that there are numerous small ridges, some reaching as high as 1,000 feet above their valleys. Within the lowland, the Connecticut and other rivers have eroded the soft sandstones into broad valleys.

The Eastern Upland resembles the Western in being a hilly region drained by numerous rivers. Their valleys come together to form the Thames River, which reaches Long Island Sound at New London. Elevations in this area rarely reach above 1,300 feet. In both uplands the hilltops tend to be level and have been cleared for agriculture.

**Climate.** In Connecticut's moderate climate, winters usually average slightly below the freezing level (32° F, or 0° C) and the state receives from three to five feet of snow each year. Snow may remain on the ground until March, but more commonly mild spells and rains that occur during the winter melt it so that the ground is bare. Summers average between 70° and 75° F (21° to 24° C), with occasional heat waves driving the daytime temperatures above 90° F (32° C). Precipitation, averaging from three to four inches (75 to 100 millimetres) per month, is quite evenly distributed. The coastal portions have some-

what warmer winters and cooler summers than does the interior, while the northwestern uplands are high enough to have cooler and longer winters with heavier falls of snow. Perhaps the most marked characteristic of Connecticut's weather is its changeability. Cold waves and heat waves, storms and fine weather can alternate with each other weekly or even daily. The statement of Hartford resident Mark Twain "If you don't like Connecticut weather, wait a minute" has become a widely appropriated and adapted proposition.

**Vegetation and animal life.** Originally, Connecticut was a forested region. The few Indian clearings, the swampy flood plains, and the tidal marshes accounted for about 5 percent of the total area. It is part of the mixed deciduous and coniferous forest of the eastern United States. The southern two-thirds is largely an oak forest. The northern border belongs to the northern hardwood region of birch, beech, maple, and hemlock. A few higher elevations and some sandy sections support a coniferous forest. Virtually all of the primeval forest has been cut, and the current woodland that covers two-thirds of the state is a mixed forest.

The animal life when the first settlers arrived included deer, bear, wolves, foxes, and numerous smaller species, such as raccoon, muskrat, porcupines, weasels, and beaver. Deer are still found in the less densely settled regions, but in general the larger animals have been severely decimated. Most birds are migratory, but chickadees, blue jays, and the immigrant English sparrows are year-round residents.

Patterns of human use. Most regions in Connecticut are not clearly defined, although Fairfield County in the southwest section is uniquely oriented toward New York City, serving as a major "bedroom suburb" for many commuters. With two of the state's largest cities, Stamford and Bridgeport, the region is the fastest growing area of the state. The northwestern and northeastern quarters are less densely populated areas. They have some agriculture, but most residents there, as elsewhere in the state, work in the manufacturing cities and towns along the rivers.

Connecticut's small towns represent a territorial concept that is equivalent to a township in other parts of the country. Within each town, a town centre is surrounded by the town hall, schools, churches, usually a village green, a number of houses, and often a tiny business district with several stores. Elsewhere within the town, other hamlets may contain similar communal gatherings. If the hamlet is on a stream, the houses often cluster around a red brick factory that was erected in the 19th century to run its machinery from a waterwheel in the river. Such mill villages are to be found throughout the state, although many of the factories have been abandoned. Farmsteads and cultivated fields once lay between such small population nodes, but the roads connecting these villages have become sparsely lined with rural, nonfarm homes.

City status in Connecticut is determined not by population but by vote of the residents to change their governmental system from a town meeting to a city form. By 1980 there were six towns in Connecticut with more than 50,000 people and one city with fewer than 10,000. All of the larger towns and cities are manufacturing centres, some of which originated as mill towns and grew with their factories. The power source changed from water to steam and later to electricity, and often the products manufactured have changed to fill the needs of a new economic and social structure, but each city and town prides itself on the uniqueness that often is associated with its products.

#### THE PEOPLE OF CONNECTICUT

The ethnic mix. The Algonkin Indians, the original occupants of Connecticut, comprised about 16 separate tribes with some 5,000 to 7,000 members. The first European settlers were English, coming directly from England or by way of the Massachusetts Bay Colony. During the 17th and 18th centuries population growth occurred primarily through an excess of births over deaths; immi-

Physiographic regions

Rural and urban settlement

grants, mainly from the British Isles, arrived at a rather slow rate. At the time of the first U.S. census, in 1790, Connecticut had a homogeneous population, about 90 percent of which was of English ancestry. Blacks were a minor element in the population, accounting for about 2 percent in 1790.

Patterns of  
immigration

The immigration of the Irish, beginning in the 1840s, and of French Canadians after the Civil War, continued throughout the 19th century. Later in the 19th century the primary sources of foreign immigration shifted to southern and eastern Europe—Italy, Poland, the Austro-Hungarian Empire, and Russia. Each immigrant group tended to congregate in certain parts of the state. Thus New Haven and its suburbs are populated largely by descendants of Italian immigrants; Poles are concentrated in the Naugatuck Valley, and the French Canadians live in the northeast. The immigration of blacks into Connecticut after World War II showed the same tendency. By 1980 blacks comprised almost 7 percent of the state's population, with more than two-thirds of them living in the five largest cities. New Haven and Hartford were more than 30 percent black. Puerto Ricans have moved to Connecticut from New York City, especially into Stamford and Bridgeport.

**Demography.** From 1790 to 1840 the state's growth rate hovered between 4 and 8 percent per decade. Connecticut was—considering its small size and its limited agricultural resources—quite adequately filled. During the 19th century thousands of Connecticut residents, especially the young, migrated to better agricultural lands in the western part of the country; their places were taken by newcomers from Europe. The state's population growth passed the national rate in 1900 and did not fall below it until the 1970s.

For more than 300 years the distribution of Connecticut's people has reflected the region's changing economy and resources of the land. Settlement began in the middle Connecticut Valley, where the soils were good, and on the coast, where maritime activities, trading, and fishing supplemented the living that the settlers were able to derive from the land. The upland areas were not fully occupied until the late 18th century, yet by 1790 the population was fairly evenly distributed across the state. Towns with better agricultural lands or with other resources—marine or mineral—had denser populations. During the 19th century the rise of waterpowered manufacturing attracted young people from the agricultural upland towns to the growing mill towns, and virtually all of the upland towns lost population. Towns with better assets for manufacturing grew rapidly.

The movement of people and industry into the cities dominated the population movements until 1920. Since then Bridgeport, Hartford, and New Haven, the three largest cities, have had a general movement of population to the suburbs and to the former agricultural hill towns.

#### THE STATE'S ECONOMY

**Sources of income.** The foundation of Connecticut's economy is manufacturing, which employs about one-third of the state's work force. In addition to such military products as helicopters, submarines, aircraft engines, guns, and ammunition, it makes thousands of items that are sold on a worldwide basis. Among the items that have been manufactured in Connecticut by long tradition are pins, clocks, silverware, sewing machines, Winchester rifles, and many brass products. Historically, mining was important; but the last iron mines closed early in the 20th century, and the state's high ranking in value added by manufacture is due mainly to the import of nearly all raw materials. Only sand, gravel, and stone are still produced within the state.

Since 1870, agriculture has declined in importance, and it is a relatively minor element in the economy. The precipitous decline in the number of farms resulted in the enactment of a farmland preservation program. Connecticut's farms produce substantial quantities of milk, eggs, poultry, and vegetables for local consumption and one important export crop, shade-grown tobacco, used mainly for cigar wrappers.

An  
economic  
overview

Except for the oyster industry and the historically important whaling industry, commercial fishing has never been very important in the state. The oyster industry has been attempting a comeback from the devastation that was caused by natural elements and pollution of the coastal waters.

Connecticut often is referred to as the nation's insurance centre and Hartford as The Insurance City. Marine insurance was the first concern of Connecticut companies, and eventually the coverages that they offered expanded to many forms of casualty insurance. Some of the largest insurance companies of the United States are based in Connecticut.

**Economic management.** To correct abuses in the free enterprise system, Connecticut has had to enact numerous regulations. The first child labour law was passed in 1842, but it was ineffectual; for 30 years after its passage hundreds of children continued to work long hours in the textile mills. A labour department was set up by the state government in 1873, and since then hundreds of laws and regulations have been enacted to control working conditions. The length of the working day, minimum wage rates, equal pay for equal work, and similar protective regulations have been passed. State departments supervise banks, insurance companies, and the public utilities, and in 1959 the Department of Consumer Protection was organized to consolidate several existing agencies. Labour unions are strong and may be given partial credit for the high wages and good working conditions characteristic of most factories. There is also an active association of manufacturers.

Labour  
legislation

**Transportation.** Connecticut's railroad network is a basic link in the Boston-New York City transportation pattern. The first railroads were constructed to bring the produce of the agricultural interior to Connecticut ports. Each of the larger river valleys—the Housatonic, Naugatuck, Connecticut, Willimantic, and Quinebaug—supported its own railroad. The line along the shore was completed in 1852. Until 1930 the railroads flourished with the expanding Connecticut economy, but highway competition for passengers and products reduced railroad traffic severely. Most of the river lines have dropped passenger service; freight service continues on some, but on others it has been abandoned. Service on the New York-New Haven Line has deteriorated despite its heavy use as a commuter facility between southern Connecticut and New York City. Limited-access highways crisscross the state, but they are concentrated in the densely settled coastal and Connecticut Valley regions. Connecticut pioneered this new type of road. The first section of the Merritt Parkway, from New York to near Milford, opened in 1938 and often is acclaimed as one of the most scenic and best designed of these highways.

Bradley International Airport, north of Hartford, is the major airport, but there are many other airports throughout the state that offer regional services. The port of New Haven is one of the largest in New England, and the U.S. Coast Guard Academy is located in New London.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**Structure of government.** *State* level. Connecticut's state government is headed by a strong governor who is elected for a four-year term. The governor initiates legislation, prepares the state budget, appoints department heads, and can veto individual items of an appropriation bill.

Connecticut's General Assembly met biennially until the adoption of a constitutional amendment in 1970 provided for annual legislative sessions. The 187 members are elected for two-year terms. The 36 senatorial districts are approximately equal in population. The House of Representatives was originally based on towns, with each town, regardless of size, having at least one representative. The 1965 constitution reapportioned the lower branch so that it also is based upon population.

The state's judiciary is headed by the Supreme Court. Superior courts were formed in 1978 by a merger of the courts of common pleas and the juvenile courts. The justices of the Supreme Court and of the superior courts are

The  
judicial  
system

nominated by the governor and appointed by the General Assembly for eight-year terms. Probate judges are elected on partisan ballots for four-year terms.

**Local government and politics.** Below the state government are 169 local units called towns. Legally, they are creations of the state, with their rights and responsibilities set out in state statutes. There is, nonetheless, a long-standing and intense tradition of local autonomy. These local governments maintain roads and provide elementary and secondary education and police and fire protection. Larger municipalities also provide water and sewage facilities and other services. The original form of government was based on the town meeting, at which the citizens elected selectmen to run the town between the annual meetings. As populations increased and problems of administration became more complex, other systems were substituted. Most larger communities have opted for a city form with an elected mayor and council. Some smaller communities have elected mayors; some have town or city managers. Many towns have retained the town meeting or have substituted the representative town meeting.

**The social milieu.** **Education.** From the earliest days, every town has been required to maintain public elementary schools and, as the town grew in size, secondary schools as well. Connecticut is renowned for its private schools and colleges. Yale University, in New Haven, is regarded as one of the world's great universities; and other institutions, such as Wesleyan University in Middletown, have national recognition. Public higher education has expanded considerably. The community college system, founded in 1965, had 12 colleges by 1980. Also under the control of the state are five technical colleges, four state colleges, and the University of Connecticut, with its main campus in Storrs.

**Health and welfare.** The community and the state have become increasingly involved in health and medical care. Most people live within 10 miles of hospital services, and doctors and other medical personnel are numerous. There are many community health clinics in addition to the advanced medical centres of the University of Connecticut at Farmington and of the Yale-New Haven Hospital. In relation to most states, Connecticut provides generous welfare benefits. Departments for the aged and for children and youth services have been established to meet the special needs of communities.

**Urban redevelopment.** Despite inner-city blight and abandoned housing, progress has been made by urban redevelopment programs in Connecticut's larger cities. Urban renewal programs in New Haven during the 1950s and 1960s became a prototype for the nation. Much work in rehabilitating urban areas remains to be done, however, especially in residential neighbourhoods.

**Government involvement.** The state government has provided increasing funds to local governments for the many social programs that are operated. Although Connecticut has an income tax, the government relies to a great extent on high sales and business taxes for revenue. In 1977 the state government was reorganized, consolidating authority in 20 executive and two administrative departments in order to make these departments and the many unaffiliated agencies more accountable to public officials.

#### CULTURAL LIFE AND INSTITUTIONS

**Preservations.** Connecticut provides a variety of landscapes: rocky headlands, beaches, forested hills, and, perhaps most attractive, the small towns around their tree-dotted village greens. Throughout the towns, hundreds of houses dating from the 17th and 18th centuries are preserved by more than 100 local or national historical societies.

Numerous sites important in Connecticut's past or associated with illustrious individuals are maintained by state or private organizations. These include the Putnam Wolf Den in Pomfret, Mt. Riga Furnace in Salisbury, Ft. Griswold State Park in Groton, Old New-Gate Prison and Copper Mine in East Granby, the Mark Twain Memorial home in Hartford, the Tapping Reeve House and Law School in Litchfield, and the (William) Gillette Castle

State Park in East Haddam. Perhaps the best known is Mystic Seaport in Mystic, where a small New England seaport has been recreated with all its ships and shops. The outdoorsman can tramp the many miles of trails and camp in one of the 30 state forests, covering more than 130,000 acres (52,500 hectares), or in one of 88 state parks, comprising some 30,000 acres.

**The arts.** Recreation in another form is provided in the fine arts. Art exhibitions are held annually in many cities, a number of which have art galleries and museums. The best known are the Yale University Art Gallery, the Wadsworth Atheneum in Hartford, and the New Britain Museum of American Art. Symphony concerts and concerts by smaller groups are presented regularly in the larger communities. Several educational institutions have public concerts throughout the year. Repertory companies operating in or near resort areas in the summer include Westport County Playhouse in Westport and the Oakdale Musical Theatre in Wallingford. The American Shakespeare theatre in Stratford, the Long Wharf Theatre in New Haven, and the Goodspeed Opera House in East Haddam are well known. The Yale School of Drama was, at its founding in 1925, the first such school at an institution of higher learning. Southwestern Connecticut is also within easy reach of the vast artistic resources of New York City.

**Communications.** There are about 25 daily newspapers in the state, including two university papers. By 1980 few cities had both morning and evening papers, but almost 60 towns supported weekly papers. There are 75 AM and FM radio stations and nine television stations. Most of the state's residents also can receive television broadcasts originating in New York, Massachusetts, or Rhode Island; and Boston and New York City newspapers are widely distributed.

**Prospects.** Vigorous efforts have been made to improve living conditions throughout the state. Many citizens and groups have given attention to preservation of the state's natural landscape, and laws controlling air and water pollution have been passed by the legislature. Plans for development and conservation have been made to provide a framework for the state's future.

**BIBLIOGRAPHY.** *Connecticut: A Guide to Its Roads, Lore, and People* (1938), one of the "American Guide Series" describing all parts of the state; CHARLES M. ANDREWS, *The Colonial Period of American History: The Settlements*, vol. 2 (1934, reprinted 1964), the most authoritative account of early Connecticut history; JOHN W. BARBER, *Connecticut Historical Collections* (1836), a town-by-town description by an investigator who travelled and knew the state personally in the 1830s; CONNECTICUT DEPARTMENT OF COMMERCE, *Connecticut Market Data* (annual), statistics on population and economy, and *Your Connecticut Guide* (annual), a comprehensive guide to tourist attractions in the state; *The Physical Geography of Connecticut* (1963), one of a valuable series including other economic, political, and social areas; CONNECTICUT, SECRETARY OF THE STATE, *State Register and Manual* (annual), compendium of facts about Connecticut state and local governments; FLORENCE S.M. CROFUT, *Guide to the History and the Historic Sites of Connecticut*, 2 vol. (1937), the definitive work on this topic; JOHN W. DE FOREST, *History of the Indians of Connecticut from the Earliest Known Period to 1850* (1851, reprinted 1970), the basic reference on Connecticut's Indians; JOSEPH B HOYT, *The Connecticut Story* (1961), a children's history, well illustrated and with geographical insights; ARTHUR H. HUGHES and MORSE S. ALLEN, *Connecticut Place Names* (1976), an exhaustive list of place-names that includes a wealth of information on the history of the state; LEAGUE OF WOMEN VOTERS OF CONNECTICUT, *Connecticut in Focus* (1974, revised periodically), a description of Connecticut government; ODELL SHEPARD, *Connecticut, Past and Present* (1939), well-written essays about the appearance as well as the history of Connecticut; CHARD POWERS SMITH, *The Housatonic, Puritan River* (1946), a work on one of the most important rivers of New England; WAYNE R. SWONSON, *Lawmaking in Connecticut* (1978), a good survey and analysis of the General Assembly; ALBERT E. VAN DUSEN, *Connecticut* (1961), a history of Connecticut that is weighted on political developments but is rather weak on geographical and economic aspects of the state; LAWRENCE F. WILLARD and A.V. SIZER, *Pictorial Connecticut* (1962), a collection of excellent photographs by an able photographer, with descriptive text.

## Connective Tissue, Human

The connective tissues are a heterogeneous group of tissues derived from the mesenchyme, a meshwork of stellate cells that develop in the middle layer of the early embryo. They have the general function of maintaining the structural integrity of organs and providing cohesion and internal support for the body as a whole. The connective tissues include several types of fibrous tissue that vary only in their density and cellularity, as well as more specialized variants ranging from adipose tissue through cartilage to bone. The cells that are responsible for the specific functions of an organ are referred to as its parenchyma, while the delicate fibrous meshwork that binds the cells together into functional units, the fibrous partitions or septa that enclose aggregations of functional units, and the dense fibrous capsule that encloses the whole organ, collectively make up its connective-tissue framework, or stroma. Blood vessels, both large and small, course through connective tissue, which is therefore closely associated with the nourishment of tissues and organs throughout the body. All nutrient materials and waste products exchanged between the organs and the blood must traverse perivascular spaces occupied by connective tissue. One of the important functions of the connective-tissue cells is to maintain conditions in the extracellular spaces that favour this exchange.

Some organs are suspended from the wall of a body cavity by thin sheets of connective tissue called mesenteries; others are embedded in adipose tissue, a form of connective tissue in which the cells are specialized for the synthesis and storage of energy-rich reserves of fat, or lipid. The entire body is supported from within by a skeleton composed of bone, a type of connective tissue endowed with great resistance to stress owing to its highly ordered, laminated structure and to its hardness, which results from deposition of mineral salts in its fibres and amorphous matrix. The individual bones of the skeleton are held firmly together by ligaments, and muscles are attached to bone by tendons, both of which are examples of dense connective tissue in which many fibre bundles are associated in parallel array to provide great tensile strength. At joints, the articular surfaces of the bones are covered with cartilage, a connective tissue with an abundant intercellular substance that gives it a firm consistency well adapted to permit smooth gliding movements between the apposed surfaces. The synovial membrane, which lines the margins of the joint cavity and lubricates and nourishes the joint surfaces, is also a form of connective tissue.

### COMPONENTS OF CONNECTIVE TISSUE

All forms of connective tissue are composed of (1) cells, (2) extracellular fibres, and (3) an amorphous matrix, called ground substance. The proportions of these components vary from one part of the body to another depending on the local structural requirements. In some areas, the connective tissue is loosely organized and highly cellular, in others its fibrous components predominate, and in still others, the ground substance may be its most conspicuous feature. The anatomical classification of the various types of connective tissue is based largely upon the relative abundance and arrangement of these components.

The fibrous components are of three kinds, collagenous, elastic, and reticular fibres. Most abundant are the fibres composed of the protein collagen. The fibrous components of loose areolar connective tissue when viewed with the light microscope appear as colourless strands of varying diameter running in all directions, and, if not under tension, these have a slightly undulant course (see photo). At high magnification, the larger strands are seen to be made up of bundles of smaller fibres. And the smallest fibres visible with the light microscope can be shown with the electron microscope to be composed of multiple fibrils up to 1000 Å in diameter. These unit fibrils are cross-striated with transverse bands repeating every 640 Å along their length.

Collagenous and reticular fibres

(Top) Electron micrograph of four collagen fibrils shadowed with metal to increase their contrast and reveal their periodic 640-Å cross striation. (Bottom) In a more highly magnified electron micrograph of a collagen fibril stained with phosphotungstate, the cross striation can be resolved into several distinct bands which depend upon the arrangement of the tropocollagen molecules within the fibre.

By courtesy of (top) J. Gross, (bottom) B.R. Olsen

**Extracellular fibres.** Collagen is of commercial as well as medical interest because leather is the dense collagen of the dermis of animal skins preserved and toughened by the process called tanning. Fresh collagen dissolves in hot water, and the product is gelatin. Under appropriate conditions, collagen can be brought into solution without chemical change. The fundamental units in such solutions are slender tropocollagen molecules about 14 Å wide and 2800 Å long. Collagen appears to be secreted in this form by the connective-tissue cells called fibroblasts, and the tropocollagen molecules assemble extracellularly to form striated collagen fibrils. By an alteration of the physicochemical conditions, tropocollagen in solution can be induced to polymerize with the formation of cross-striated fibrils identical to native collagen, thus simulating in the test tube the process of assembly that is believed to take place during fibrogenesis in the living organism. Analysis of the structure of collagen by X-ray diffraction has shown that the tropocollagen molecule consists of three side-by-side polypeptide chains—linear combinations of a number of amino acids, which are subunits of proteins—each in the form of a left-handed helix. These three left-handed helices are further twisted around one another to form a major right-handed helix. Upon chemical analysis, the amino-acid composition of collagen is found to be unique in its extremely high proline content (22 percent) and in the fact that one-third of the amino acid residues are glycine. It is the only naturally occurring protein known to contain hydroxyproline and hydroxylysine. Two of the three polypeptide chains comprising the tropocollagen molecule are similar in amino-acid composition, while the third is distinctly different. In the tissues, the collagen fibrils are believed to be held together by a polysaccharide component that has not been fully characterized.

Reticular fibres are distinguished by their tendency to form fine-meshed networks around cells and cell groups, and by virtue of their property of staining black because of adsorption of metallic silver when they are treated with alkaline solutions of reducible silver salts.

Photomicrographs of connective tissue components.  
 (Top left) Long fusiform fibroblasts growing in tissue culture (magnified about 520 X).  
 (Top right) Randomly oriented collagenous fibres of varying size in a thin spread of loose areolar connective tissue (magnified about 370 X). (Centre left) Four macrophages in cell culture (magnified about 825 X). Their irregular outline is associated with amoeboid migration. (Bottom left) Metachromatic granules fill the cytoplasm of these mast cells, which have centrally located nuclei (magnified about 750 X). (Bottom right) Selectively stained network of thin elastic fibres in a thin sheet of areolar connective tissue (magnified about 390 X).

They were formerly believed to be composed of a distinct protein, reticulin, but electron microscopy has revealed that reticular fibres are small fascicles of typical collagen fibrils interwoven to form a network. It is now apparent that reticular fibres are simply a form of collagen and that their distinctive staining depends upon the mode of association of the fibrils and possibly upon subtle differences in their relation to the polysaccharide material that binds them together.

Elastic fibres are composed of the protein elastin and differ from collagenous fibres in dimensions, pattern, and chemical composition. They do not have uniform subunits comparable to the unit fibrils of collagen. They present a variable appearance in electron micrographs; sometimes they appear to have an amorphous core surrounded by minute fibrils, while in other sites they appear to consist exclusively of dense amorphous material. Whether there are in fact two components or whether these are differing forms of the same substance is not yet clear. At the light-microscope level, the fibres vary in diameter and often branch and reunite to form extensive networks in loose connective tissue. When present in high concentration, they impart a yellow colour to the tissue. In elastic ligaments, the fibres are very coarse and are arranged in parallel bundles. In the walls of arteries, elastin is present in the form of sheets or membranes perforated by openings of varying size. Elastic fibres are ex-

tremely resistant to hot water, to strong alkali, and even to digestion with the proteolytic enzyme trypsin. They can be digested, however, by a specific enzyme, elastase, present in the pancreas. Upon chemical analysis, elastin, like collagen, is found to be rich in glycine and proline, but it differs in its high content of valine and in the presence of an unusual amino acid, desmosine. As their name implies, elastic fibres are highly distensible and, when broken, recoil like rubber bands. Changes in this property and diminution in their numbers are thought to be, in part, responsible for the loss of elasticity of the skin and of the blood-vessel walls in old age.

**Ground substance.** The amorphous ground substance of connective tissue is a transparent material with the properties of a viscous solution or a highly hydrated thin gel. Its principal constituents are large carbohydrate molecules or complexes of protein and carbohydrate, often called mucopolysaccharides. One of these carbohydrates is hyaluronic acid, composed of glucuronic acid and an amino sugar, N-acetyl glucosamine. Other carbohydrates of the connective tissue are chondroitin-4-sulfate (chondroitin sulfate **A**) and chondroitin-6-sulfate (chondroitin sulfate **C**). The sugars of the sulfates are galactosamine and glucuronate. Multiple chains of chondroitin sulfate seem to be bound to protein. These substances in solution are viscous. All substances passing to and from cells must pass through the ground substance.

Variations in its composition and its viscosity may therefore have an important influence on the exchange of materials between tissue cells and the blood. Its physical consistency also constitutes a barrier to the spread of particulates introduced into the tissues. It is interesting, in this relation, that some bacteria produce an enzyme, **hyaluronidase**, which breaks up hyaluronic acid into subunits and alters the viscosity of ground substance. The ability of these bacteria to produce this enzyme is probably responsible for their invasiveness in the tissues.

**Cells of connective tissue.** The cells of connective tissue include three types that are relatively stationary, fibroblasts, macrophages, and adipose cells, and several types of motile, migrating cells—mast cells, monocytes, lymphocytes, plasma cells, and eosinophils. The ubiquitous fibroblasts are the principal cells of connective tissue, occurring as long spindle-shaped cells stretched along bundles of collagen fibrils. Their function is to secrete tropocollagen and constituents of the ground substance and to maintain these extracellular tissue components. When organs are injured, the fibroblasts of the stroma are stimulated to proliferate; they migrate into the defect and deposit an abundance of new collagen, which forms a fibrous scar. The macrophages or histiocytes are also important for tissue repair and for defense against bacterial invasion. Like fibroblasts, they are normally fusiform or stellate and are deployed along the collagen fibre bundles, but, if there is tissue damage or bacterial invasion, they withdraw the projections by which they are anchored and migrate by active amoeboid movements into the affected area. They have a great capacity for phagocytosis—the process by which cells engulf cellular debris, bacteria, or other foreign matter, and break them down by intracellular digestion. Thus they represent an important force of mobile scavenger cells.

Adipose cells are connective-tissue cells that are specialized for synthesis and storage of reserve nutrients. They receive glucose and fatty acids from the blood and convert them to lipid, which accumulates in the body of the cell as a large oil droplet. This distends the cell and imposes upon it a spherical form. The nucleus is displaced to the periphery, and other metabolically active constituents of the cell are confined to a thin rim of cytoplasm around the large, central droplet of lipid. Adipose cells may occur in small numbers anywhere in connective tissue, but they tend to develop preferentially along the course of small blood vessels. Where they accumulate in such large numbers that they become the predominant cellular element, they constitute the fat or adipose tissue of the body.

All the cells of connective tissue develop during embryonic life from the mesenchyme, a network of primitive stellate cells that have the potentiality for differentiating along several different lines depending upon local conditions. In addition to the specialized cell types of adult connective tissue described above, it is believed that small numbers of mesenchymal cells persist into postnatal life in the walls of small blood vessels and elsewhere and that these retain the capacity to differentiate into fibroblasts, adipose cells, or histiocytes as the need arises.

Mast cells

In addition to the relatively fixed cell types just described, there are free cells that reside in the interstices of loose connective tissue. These vary in their abundance and are free to migrate through the extracellular spaces. Among these wandering cells are the mast cells; these have a cell body filled with coarse granules that exhibit a characteristic metachromatic staining reaction. The function of these cells is still poorly understood, but they are known to produce and store in their granules two biologically active substances, histamine and heparin. **Histamine** affects vascular permeability, and heparin, when added to blood, delays or prevents its clotting. Mast cells respond to mechanical or chemical irritation by discharging varying numbers of their granules. Histamine released from them causes fluid to escape from **neighbouring** capillaries or venules; this results in local swelling, as seen in the welt that appears around an insect bite.

Tissue eosinophils are a type of white blood cell or

leukocyte. Some of these migrate through the walls of capillaries and take up residence in the connective tissues. They have polymorphous nuclei and, in the cell substance outside the nuclei, coarse granules that stain with eosin and other acid dyes. In electron micrographs, the granules contain conspicuous crystals. The granules have been isolated and shown to contain a variety of hydrolytic enzymes. Eosinophils are normally widespread in connective tissues of the body, but they are especially abundant in persons suffering from allergic diseases. The cells are believed to phagocytose and break down antigen-antibody complexes.

Eosinophils

Plasma cells, which are present in limited numbers in loose connective tissues and in larger numbers in lymphoid tissue, are essential to the body's immunological defenses. They are specialized for synthesis and release of those specific immune globulins, called antibodies, that combine with and neutralize foreign proteins introduced into the body. Lymphocytes are among the normal cellular elements of the blood, but they may also leave the blood and migrate in the connective tissues. They are small round cells with a thin rim of cytoplasm and only limited synthetic activity. They appear to be able to recognize foreign protein and to respond to its presence by enlargement, proliferation, and transformation into plasma cells. They thus constitute an important reserve of relatively undifferentiated cells capable of sustaining an immunological response. They are the subject of intensive study because of their important role in defense against disease and because they participate in the rejection reaction that often frustrates the surgeon's efforts to transplant organs from one individual to another.

Another of the leukocytes that enter the connective tissues from the blood is the monocyte, a mononuclear cell larger than the lymphocyte and with different potentialities. These migratory cells can divide and, when appropriately stimulated, can transform into highly phagocytic macrophages. Thus at sites of bacterial invasion, when the resident population of fixed **macrophages** or histiocytes cannot cope with the situation, the monocytes of the connective tissues are reserves that can be mobilized at the focus of infection and can be continually reinforced by emigration of additional **monocytes** from the blood. This reaction of the blood and connective-tissue cells to injury is called inflammation and is usually accompanied by local heat, swelling, redness, and pain. Under these conditions, the neutrophilic leukocytes (white blood cells called neutrophilic because of their neutral staining characteristics with certain dyes), which are not normally present in connective tissue in significant numbers, may also migrate through the capillary walls in astronomical numbers and join the macrophages in the work of ingesting and destroying bacteria. Voraciously phagocytic, the neutrophils have a short life-span; having accomplished their mission, they die in great numbers. Pus, which may accumulate at sites of acute inflammation, is composed largely of dead and dying neutrophilic leukocytes.

Monocyte and neutrophilic leukocyte

#### TYPES OF CONNECTIVE TISSUE

The description presented thus far applies to the widely distributed loose areolar connective tissue, which is relatively unspecialized and can therefore be considered **prototypic**. In the more specialized forms of connective tissues, one component or another may predominate over all the others, depending upon the local structural or metabolic requirements.

Adipose tissue, for example, is a variant of loose areolar tissue in which large numbers of adipose cells make up the bulk of the tissue.

Dense fibrous connective tissue is composed of closely packed bundles of collagen and their associated fibroblasts, but there are relatively few elastic fibres and little ground substance. The term irregular dense fibrous tissue is applied to sites where the collagen bundles are randomly oriented and interwoven, as in the dermis of the skin and the capsules of joints. Regular dense fibrous tissue is the term used to describe tendons, ligaments, and

Three types of connective tissue.

(Left) Photomicrograph of hyaline cartilage from the trachea. The chondrocytes are enclosed in lacunae distributed in groups in an abundant matrix (magnified 250 X). (Centre) Electron micrograph of a small area of connective tissue illustrating the intimate association of cells and fibres. In the centre is a portion of a fibroblast, and on either side are two collagen fibres. The collagen fibre on the left is cut transversely, showing round cross sections of the unit fibrils. The collagen fibre on the right has been cut nearly parallel to its long axis and shows extensive segments of the cross-striated fibrils (magnified about 6,625 X). (Right) Photomicrograph of a ground section of bone showing a haversian system, or osteon, in cross section, and adjacent interstitial lamellae. The osteocytes occupy flat lacunae, which appear black in this preparation. Slender **canaliculi** connect neighbouring canaliculi (magnified about 125 X).

aponeuroses (fibrous sheets that form attachments for muscles), where the collagen fibres are precisely oriented in parallel bundles.

Synovial membrane lining joint capsules is composed of loose vascular connective tissue but has cells specialized for secretion of the viscous synovial fluid, which is rich in hyaluronic acid. This fluid serves as a lubricant and nutrient for the avascular joint surfaces. Similar tissue forms sheaths around tendons where they pass over bony prominences.

#### Cartilage

Cartilage is a form of connective tissue in which the ground substance is abundant and of a firmly gelled consistency that endows this tissue with unusual rigidity and resistance to compression. The cells of cartilage, called chondrocytes, are isolated in small lacunae within the matrix. Although cartilage is avascular, gaseous metabolites and nutrients can diffuse through the aqueous phase of the gel-like matrix to reach the cells. Cartilage is enclosed by the perichondrium, a dense fibrous layer lined by cells that have the capacity to secrete hyaline matrix. Cartilage grows by formation of additional matrix and incorporation of new cells from the inner chondrogenic layer of the perichondrium. In addition, the young chondrocytes retain the capacity to divide even after they become isolated in lacunae within the matrix. The daughter cells of these divisions secrete new matrix between them and move apart in separate lacunae. The capacity of cartilage for both appositional and interstitial growth makes it a favourable material for the skeleton of the rapidly growing embryo. The cartilaginous skeletal elements present in fetal life are subsequently replaced by bone.

Hyaline cartilage, the most widely distributed form, has a pearl-gray semitranslucent matrix containing randomly oriented collagen fibrils, but relatively little elastin. In elastic cartilage, on the other hand, the matrix has a pale yellow appearance owing to the abundance of elastic fibres embedded in its substance. This variant of cartilage is more flexible than hyaline cartilage and is found principally in the external ear and in the larynx and epiglottis. The third type, called fibrocartilage, has a large proportion of dense collagen bundles oriented parallel. Its cells occupy lacunae that are often arranged in rows between the coarse bundles of collagen. It is found in intervertebral disks, at sites of attachment of tendons to bone, and in the articular disks of certain joints.

**Bone.** Like other connective tissues, bone consists of cells, fibres, and ground substance, but, in addition, the

extracellular components are impregnated with minute crystals of calcium phosphate in the form of the mineral hydroxyapatite. The mineralization of the matrix is responsible for the hardness of bone. It also provides a large reserve of calcium that can be drawn upon to meet unusual needs for this element elsewhere in the body. The structural organization of bone is admirably adapted to give maximal strength for its weight-bearing function with minimum weight. There are bones strong enough to support the weight of an elephant and others light enough to give internal support and leverage for the wings of birds.

The shaft of a typical long bone of the skeleton has a central medullary or marrow cavity surrounded by a cortex of compact bone. Toward either end, the compact bone is gradually reduced to a thin peripheral layer and the interior is occupied by cancellous or spongy bone consisting of a tridimensional lattice of branching and anastomosing trabeculae. Compact bone is penetrated by blood vessels that course longitudinally within its substance. The bone tissue is arranged in concentric layers or lamellae around these vascular channels. The concentric lamellar units so formed are called osteons or haversian systems. The intercellular substance of the bony lamellae is largely collagen whose parallel fibres are arranged helically within each concentric layer of the osteon. The pitch of the helix changes from one lamella to the next. The longitudinal channel in the centre of each osteon is referred to as a haversian canal. The angular areas between the cylindrical osteons of compact bone are filled in with interstitial lamellae that are parallel but have no particular orientation with respect to the vascular channels. Similarly in the trabeculae of spongy bone, which are avascular, the lamellae are not arranged in osteons but appear as a mosaic of angular units each composed of parallel lamellae. The laminated construction of bone and the internal reinforcement of its matrix with oriented bundles of collagen, and with crystals of mineral within the collagen fibrils, all contribute to its remarkable properties as a strong but relatively light-weight skeletal material.

The cells of bone are of four kinds, osteocytes, osteoblasts, osteoclasts, and osteoprogenitor cells. Osteocytes, the principal cells of bone, are lodged in flattened lacunae located within or between the successive lamellae. Radiating from these lacunae are many slender channels (canaliculi) that join them to neighbouring lacunae. Compared to cartilage matrix, the heavily mineralized matrix of bone is relatively impermeable. The sys-

Bone cells

tem of intercommunicating canaliculi between lacunae is therefore thought to be essential to permit diffusion of nutrients from blood vessels in the haversian canals to the osteocytes in lacunae some distance away. These cells are metabolically active and are believed to play a significant role in the maintenance of the surrounding matrix.

Bone is constantly being resorbed and renewed. Large multinucleate cells, the osteoclasts, often occupy shallow excavations in the surface of bone and are believed to be the active agents of bone resorption. The sizable resorption cavities that they produce are then filled in by osteoblasts, the formative cells of bone that line the cavities and secrete amorphous matrix and collagen precursors that are deposited layer upon layer to fill in the cylindrical cavity with a new osteon. In this process, some of the osteoblasts become incarcerated in the newly formed matrix and are buried in the continued deposition of matrix by osteoblasts that remain on the surface. Thus osteoblasts gradually diminish in number as they become isolated in lacunae and transform into osteocytes. The marrow cavity and the haversian canals are lined by a tenuous cellular layer called the endosteum, and the outside of a bone is invested by a dense connective-tissue layer called the periosteum. Cells of the endosteum and of the inner aspect of the periosteum constitute a population of relatively undifferentiated osteoprogenitor cells. When stimulated they have the capacity to develop into osteoblasts and initiate bone deposition, as in the healing of fractures. In other circumstances, they can coalesce and give rise to osteoclasts that are active in removing excess bone callus after fracture repair, or form resorption cavities in the continual internal remodelling of bone.

The common impression that bone is a hard, unyielding, inert material is erroneous. It is a living, actively metabolizing tissue, constantly being renewed. Its structure is responsive not only to changing patterns of external stress but also to the nutritional state and the internal endocrine environment of the body.

## Connective Tissue Diseases

Connective tissue is the collective designation for the tissues that provide the supportive framework and protective covering of the body and of its internal organs. It includes bone and periosteum—i.e., the membranous covering of the bones; cartilage, tendon, and ligament (cartilage is translucent elastic tissue that forms much of the temporary skeleton of the embryo and persists in such locations as in the nose, in the external ear, and in joints; tendons are the fibrous cords by which muscles are attached to bones; ligaments are bands of tissue that support organs or connect bones); fascia—sheets or layers that ensheath muscles and viscera and are continuous with other connective tissue structures; and the dermis, the inner or true skin. In addition, connective tissue is a major component of the arteries and veins. The connective tissues serve as the site for the transport of essential nutrients and the collection of metabolic wastes, as well as the arena for immunologic and inflammatory reactions that protect the body from invasion by micro-organisms (see CONNECTIVE TISSUE, HUMAN).

### CLASSIFICATION AND GENERAL CHARACTERISTICS AND THEORIES OF CAUSATION

Classification. Diseases of the connective tissue can be divided into (1) a group of relatively uncommon, genetically determined disorders that affect the primary structure of this tissue, and (2) a number of acquired maladies in which the connective tissues constitute the site of several more or less distinctive immunologic and inflammatory reactions. The latter conditions formerly were called collagen diseases because the connective

tissues, which were found to show similar changes, were once known as the collagen or collagen-vascular system. The term collagen is now restricted to a specific fibrous protein, and there is little or no evidence in the majority of these disorders of any fundamental abnormality in the structure or metabolism of collagen; consequently, the designation collagen disease should be discontinued. The connective tissue diseases are now generally taken to include, besides certain heritable diseases, the following acquired diseases: rheumatoid arthritis, systemic lupus erythematosus, progressive systemic sclerosis (scleroderma), polymyositis (dermatomyositis), necrotizing vasculitides, Sjogren's syndrome (sicca syndrome), rheumatic fever, amyloidosis, thrombotic thrombocytopenic purpura, and relapsing polychondritis.

General characteristics. The above acquired diseases, which will be touched upon in later sections, display certain common clinical features, including inflammation of the joints (polyarthralgia and arthritis), serous (fluid-exuding) membranes (pleurisy, pericarditis), and small blood vessels (vasculitis), and a high frequency of involvement of various internal organs that are particularly rich in connective tissue (e.g., the lungs). The walls of inflamed blood vessels, portions of which may become necrotic (i.e., may die), are often found to contain characteristic deposits of hyaline (translucent) material. This is called fibrinoid because staining with dyes (e.g., eosin) reveals tinctorial properties similar to fibrin (a fibrous protein that forms the lattice of blood clots). It was the demonstration of such hyaline deposits in various organs that was responsible, in large part, for the original grouping of these disorders as collagen diseases. Fibrinoid is not uniform in composition, however, but varies from one condition to another, and the similarity of structural changes in the connective tissues does not necessarily imply a common pathogenesis (disease origin).

Theories of causation. A number of observations suggest that acquired connective tissue diseases are autoimmune diseases—i.e., diseases that result from reactions against components of the body as if they were foreign substances. In general terms these observations are that: (1) there are abnormally high levels of immunoglobulins in the blood; the immunoglobulins, also called gamma globulins, consist wholly or chiefly of antibodies; (2) these antibodies include several directed against particular serum proteins and other components of the affected person's own tissues; (3) there are complexes (combinations) of these antibodies and their antigens at the sites of tissue damage; (4) at the sites of tissue damage there are also aggregations of the cells (plasma cells and lymphocytes) that are responsible for the production of antibodies; (5) there is a favourable response to treatment with substances, such as corticosteroid hormones, known or believed to inhibit the production of antibodies; (6) connective tissue diseases are associated with other disorders known or suspected to be the result of an aberrant immune reaction.

The nature of the bodily components that serve to excite the production of antibodies in connective tissue diseases is the subject of continuing investigation.

An account of the effects of the interactions between antibodies and antigens may be found in the article ALLERGY AND ANAPHYLACTIC SHOCK. The effects include the damaging of cells to which antibodies have become attached so that the cells release substances that act upon the blood vessels and bring about such symptoms as those encountered in asthma or hay fever (allergic rhinitis) or in certain instances of drug allergy. The interactions may result in the destruction of red or white blood cells or platelets or may inactivate circulating hormones or enzymes. The antibody-antigen complexes may be deposited in the walls of blood vessels and there combine with a substance in the blood called complement, with a variety of injurious effects, including those seen in serum sickness, rheumatoid arthritis, and the kidney damage seen in systemic lupus erythematosus (see below). Last, the interaction may result in a complex reaction known as cellular immunity, which is thought to play an important role in certain auto-immune disorders that in-

**Antibody-  
antigen  
inter-  
actions**

volve solid organs, as well as in such processes as transplant rejection and cancer immunity.

#### HERITABLE DISORDERS OF CONNECTIVE TISSUE

Heritable disorders of connective tissue are a heterogeneous group of generalized, single-gene-determined disorders that affect one or another of the primary elements of the connective tissues (collagen, elastin, or ground substance [mucopolysaccharide]). Many cause skeletal and joint abnormalities that may interfere seriously with normal growth and development. All of these conditions are uncommon or rare when compared to the acquired connective tissue diseases.

**Marfan's syndrome.** Also called arachnodactyly (spider fingers), Marfan's syndrome is the least uncommon of the heritable disorders of connective tissue, having an estimated prevalence of about 15 cases per 1,000,000. The main skeletal characteristic is excessive length of the extremities. Weakness of joint capsules, ligaments, tendons, and fasciae is responsible for such manifestations as hyperextensible joints (double-jointedness), recurrent dislocations, spinal deformities, flat feet, hernias, and dislocation of the lens of the eye (ectopia lentis). The latter is present in at least three-quarters of the cases and usually occurs in both eyes. Cardiovascular abnormalities, which result from degenerative changes in the media (middle coat) of the great vessels, include insufficiency of the aortic valve and aneurysm (weakening of the wall and consequent bulging) of the ascending segment of the aorta.

Marfan's syndrome is inherited as an autosomal dominant trait; in other words, the gene involved is not a sex gene (all the genes that are not sex genes are autosomal). No more than 15 percent of cases occur as an isolated instance in a family and may be attributable to a new mutation. Death is usually due to heart failure or an aneurysm of the aorta. A normal life span is possible.

Although the basic abnormality of some unidentified component of connective tissue cannot be remedied, wound-healing occurs normally, and surgical correction of some of the defects is practicable.

**Homocystinuria.** Homocystinuria, so called because of the presence of homocystine in the urine, may closely resemble Marfan's syndrome. Distinctive from the latter, however, is the frequent occurrence of progressive mental deterioration, a fine skin with a tendency to flushing, osteoporosis (thinning of the bones), which may result in fractures, and thrombosis (blood clotting) of the coronary blood vessels and the peripheral blood vessels of medium size. The joints tend to have restricted mobility rather than hyperextensibility. Death from vascular occlusion is common during childhood, but persons with the disorder have survived into their 50s.

Homocystinuria is inherited as an autosomal recessive trait (it is not manifested unless inherited from both parents). Affected persons have a deficiency of an enzyme (cystathionine synthetase) required for the conversion of the amino acid cystathionine to cysteine. Treatment of affected infants with a diet low in methionine and high in cystine shows some promise, as does the regular administration of large amounts of pyridoxine, a component of the vitamin B complex.

**Ehlers-Danlos syndrome.** The Ehlers-Danlos symptom complex is manifested particularly by an abnormal skin elasticity and fragility and by loose-jointedness. Some persons with this syndrome perform as contortionists. The skin, peculiarly stretchable even in early childhood, gradually loses its elasticity. Minor injury can cause lacerations that tend to bleed severely and to extend. In addition to the fragility of blood vessels in the skin, large vessels may develop aneurysms, varicosities, intervascular fistulas, or free rupture. Varicosities are enlargements of vessels over considerable lengths; they usually occur in superficial veins. Intersvascular fistulas are openings between the walls of adjacent vessels. **Scoliosis** (lateral curvature of the spine), recurrent dislocations of joints, and hernias of the abdominal wall or the diaphragm (the muscular partition between the chest and the abdomen) are seen as in the Marfan syndrome, and

there may be blue sclerae (the "whites" of the eye), such as occur in osteogenesis imperfecta (see the subsection below).

The underlying defect has not been defined. It is likely that it consists of the abnormal organization of collagen bundles, the individual fibres of which are normal. Some investigators have also detected an excess of elastin fibres. (Collagen and elastin are two of the fibrous proteins in connective tissue.) It is now clear that there are several distinct varieties of the Ehlers-Danlos syndrome. The disease is most commonly inherited as an autosomal dominant trait. Death from rupture of a major blood vessel may occur in childhood, but most affected persons live at least to middle age. Surgical repair of cutaneous, vascular, or other lesions is difficult because of the fragility of the tissues, which retain sutures poorly.

**Osteogenesis imperfecta.** Osteogenesis imperfecta is a general disorder of connective tissue that involves bone, sclera, inner ear, ligamentous structures, and skin. Several syndromes have been described, but they probably represent different degrees of expression of the same heritable disorder. The principal variants are **osteogenesis imperfecta congenita**, **osteogenesis imperfecta tarda**, and the **van der Hoeve syndrome**. In osteogenesis imperfecta congenita, stillbirth is common, or fractures are evident at birth; severe crippling occurs as a result of numerous fractures, and survival to adulthood is uncommon. In osteogenesis imperfecta tarda, the infant is normal at birth, but, depending on the severity of disease, few or many fractures occur over the following years, usually as a result of trivial mishaps. The frequency of fractures tends to diminish after puberty. The van der Hoeve syndrome consists of osteogenesis imperfecta tarda, with bluish sclerae and deafness. The peculiar colour of the sclera is due to its abnormal thinness, which permits the pigmentation of the choroid (the middle coat of the eyeball) to show. Hearing loss may be due to deformities of the bones of the inner ear as well as pressure on the auditory nerve because of deformity of its canal in the skull. Hyperextensibility of joints-double-jointedness—and abnormally thin skin are also characteristic.

The fundamental defect in this disorder, which is usually inherited as an autosomal dominant trait, appears to involve the collagen fibres. Treatment is limited to surgical fixation of fractures.

**Alkaptonuria.** Alkaptonuria is a rare, inherited (recessive) disorder in which absence of the enzyme **homogentisic acid oxidase** results in an abnormal accumulation of homogentisic acid, which is a normal intermediate in the metabolism of the amino acid tyrosine. A portion of the homogentisic acid is excreted in the urine, to which, upon alkalization and oxidation, it imparts a black colour. The remainder is deposited in cartilage and, to a lesser degree, in the skin and sclerae. The resultant darkening, or blackening, of these tissues by this pigment is termed **ochronosis**.

The pigment is bound particularly to collagen fibres in the deeper layers of joint cartilage and intervertebral disks (the fibrous pads between adjacent bones of the spine) and causes these tissues to lose their normal resiliency and become brittle. The erosion of the abnormal cartilages leads to a progressive degenerative disease of the joints, which usually becomes manifest by the fourth decade of life. Usually, the intervertebral disks become thinned and calcified first, and later the knees, shoulders, and hips are affected.

Alkaptonuria is compatible with normal life expectancy. Whether the arteriosclerosis (hardening of the arteries) that has been described in some cases is a **manifestation** of the disease or coincidental is uncertain. No effective treatment is available for the underlying metabolic disorder.

**Pseudoxanthoma elasticum.** Pseudoxanthoma elasticum, also known as the **Grönblad-Strandberg syndrome**, has its principal effects on the skin, the eyes, and the blood vessels. The word pseudoxanthoma refers to the yellowish papules (pimple-like protuberances) that occur most commonly in the fold of the skin of the neck, armpits, and groin. The colour results from degenerative

Charac-  
teristics of  
Ehlers-  
Danlos  
syndrome

Van der  
Hoeve  
syndrome

Angioid streaks in the eye

changes in the elastic fibres in the deep layers of the skin. Calcium deposition may occur in the skin, and premature arteriosclerosis is common. The characteristic eye lesion is that of angioid streaks (streaks resembling blood vessels) of the retina, which are found in at least 80 percent of the cases. Through the ophthalmoscope (an instrument for viewing the interior of the eye), the angioid streaks can be seen as brown or brownish-black bands that resemble the normal retinal vessels but are generally much wider. These streaks are produced by breaks in the elastin-rich internal membrane of the choroid, which permits the choroidal pigment to be seen. Deterioration of vision may occur because of bleeding or degenerative changes. Bleeding in the stomach is also fairly common. The basic lesion appears to be a premature deterioration of elastic fibres of connective tissue. Pseudoxanthoma elasticum is inherited as an autosomal recessive disorder. No specific treatment is available.

**Cutis laxa.** Cutis laxa is a rare disorder in which the skin hangs loosely in folds. In this disorder, unlike the Ehlers-Danlos syndrome, with which it is often confused, the skin is neither abnormally elastic nor unduly fragile, and the joints are not affected. There are several forms of the disorder, which are separable into inherited and acquired varieties. In the inherited variety there may be a characteristically hooked nose, with nostrils opening outward, and a long upper lip. Included among the complications are diverticula (abnormal pouches or pockets in the walls) of the gastrointestinal tract and bladder, hernias of the diaphragm or the abdominal wall, and rectal and vaginal prolapse (falling from a normal position). Present evidence indicates that cutis laxa is a disease of elastin, the collagen of the skin being normal.

**Mucopolysaccharidoses.** The mucopolysaccharidoses include six or more separate varieties of a disorder that, in varying degrees, affects the skeleton, brain, eyes, heart, and liver. Biochemically, the varieties have in common the abnormal production, storage, and excessive excretion of one or more mucopolysaccharides. (The mucopolysaccharides, which are complex, high molecular weight carbohydrates, form the chief constituent of the ground substance that fills the space between the connective tissue cells and fibres.)

Hurler's syndrome

Hurler's syndrome, or mucopolysaccharidosis 1, is the least rare and most rapidly fatal. Few children afflicted with it reach the age of ten. Abnormalities begin to appear when the infant is a few months old. The lower vertebrae develop abnormally, resulting in hunchback; the neck is usually short, and the head becomes large and misshapen. This is in part due to intrinsic maldevelopment of the skull, and in part results from hydrocephalus (the accumulation of abnormal amounts of fluid in the brain). Cerebral function deteriorates gradually. Various deformities of the extremities develop, accentuated by stiffness of the joints. The corneas become clouded. The liver and spleen enlarge because of deposition of mucopolysaccharides. Death most often results from heart failure, which is attributable to infiltration of heart muscle and coronary vessels with mucopolysaccharides.

The facial deformities and dwarfed, deformed bodies that occur characteristically in Hurler's syndrome and in mucopolysaccharidosis 2 (Hunter's syndrome) are referred to as *gargoylism*. Individuals with a mucopolysaccharidosis other than Hurler's syndrome commonly live to adulthood, but a normal life-span is unusual.

These diseases may be identified biochemically according to the type of mucopolysaccharide excreted excessively in the urine.

The mode of inheritance is autosomal recessive in all the types except mucopolysaccharidosis 2, which is sex-linked recessive (only males show the disease). Symptoms can be alleviated, but no cure is available.

**Myositis ossificans progressiva.** In myositis ossificans progressiva bone develops in tendons, fasciae, and striated (striped or voluntary) muscle. Skeletal growth is normal, although certain abnormalities occur in the majority of cases, particularly shortening of the thumbs or the great toes, or both. Symptoms usually begin in

childhood and progress irregularly until the third decade. Lesions may begin abruptly with local tenderness, swelling, and fever, or develop very gradually, with increasing stiffness and firmness as the only symptoms. Involvement of the chewing muscles may make eating impossible. Death most often results from an infection.

Why certain connective tissues become sites for the aberrant formation of bone is completely unknown.

#### ACQUIRED CONNECTIVE TISSUE DISEASES

**Rheumatoid arthritis.** Rheumatoid arthritis is a chronic disease in which a predominant nonsuppurative inflammation (an inflammation that does not discharge pus) of the peripheral joints is frequently combined with a variety of manifestations not directly associated with the joints. The most prominent of these latter ones are inflammation of tendons and their sheaths and **granulomatous** nodules that occur in the connective tissue beneath the skin and beneath the periosteum. This, the most common of the inflammatory arthritides, occurs in individuals of all ages, including young children, and with particular frequency in young and middle-aged women; it is approximately three times as common in women as in men.

According to epidemiological surveys conducted in many different parts of the world, rheumatoid arthritis affects at least 1–2 percent of the population. It is estimated that there are, in the United States, 3,000,000–5,000,000 individuals with the disease, approximately 30 percent of whom are less than 55 years of age. A high rate of serious interference with joint function, combined with the tendency for the disease to occur among the young and middle-aged, makes rheumatoid arthritis the leading cause of occupational disability among the rheumatic diseases.

Incidence of rheumatoid arthritis

In the majority of cases the onset of rheumatoid arthritis is insidious, with generalized weakness, feeling of ill health, and aching and stiffness, often poorly localized to joints. This is followed by the gradual appearance of frank joint inflammation in the form of pain, swelling, redness, warmth, and tenderness. The symptoms usually originate in the small joints of the hands and feet but in most cases spread to other parts, especially the wrists, elbows, hips, knees, and subtalar joints (the subtalar, or talocalcaneal, joint is in the ankle); in severe cases, virtually all of the peripheral junctures may be affected, as well as a number of other joints, including the jaw, the intervertebral joints, and even such fine structures as the cricoarytenoid joints of the larynx.

The many manifestations of rheumatoid arthritis not associated with the joints include evidence of **blood-vessel** inflammation in the form of tiny areas of necrosis in the fingertips; chronic leg ulcers and lesions in the peripheral nerves; inflammation of the pericardium, the **sac-enclosing** the heart, and of the sclerae; inflammation and nodule formation in the lungs and pleura (tissue covering the lungs); anemia; enlargement of the lymph nodes; and Sjogren's, or sicca, syndrome (see below). Enlargement of the spleen occurs in approximately 5 percent of affected persons.

The disease process within the joints begins as an inflammation of the synovium (joint-lining tissue). In most cases there is an increase, often considerable, in the amount of synovial (joint) fluid.

The course of the disease varies greatly from person to person and is characterized by a striking tendency toward spontaneous remission (temporary recovery) and exacerbation. With continuing inflammation of the joints, there is destruction of the joint cartilage. The degree of articular (joint) disability present in rheumatoid arthritis depends in large measure upon the amount of damage done to this cartilage. If the injury is severe, large areas of bone may be denuded of cartilage, so that adhesions form between the articular surfaces. Subsequent transformation of these adhesions into mature fibrous or bony connective tissue leads to firm union between the bony surfaces (ankylosis), which interferes with motion of the joint and may render it totally immobile. In other instances, the loss of cartilage and bone, coupled with

Causation  
of rheuma-  
toid  
arthritis

weakening of tendons, ligaments, and other supporting structures, results in instability and partial dislocation of the joint. In a small minority of cases, the disease pursues a rapidly progressive course marked by relentless joint destruction and evidence of diffuse vasculitis (inflammation of blood vessels).

There is now convincing evidence that immunologic reactions play an important role in the causation of the processes just listed. Suspicion of this originated with the observation that the serum of approximately 80–90 percent of persons with rheumatoid arthritis contains an immunoglobulin (called rheumatoid factor) that behaves as an antibody and reacts with another class of immunoglobulin. This immunoglobulin is produced by cells (plasma cells) that are present in sites of tissue injury. At this time the nature of the agent (antigen) responsible for the initiation of the rheumatoid inflammatory reaction is not clear. There is evidence to suggest that this agent may be one or more viruses or viral antigens that persist in the joint tissues.

**Systemic lupus erythematosus.** Systemic lupus erythematosus is a chronic inflammatory disease that affects, either singly or in combination, the skin, joints, kidneys, nervous system, serous membranes lining body cavities, and often other organs as well. The disease is characterized by a striking tendency toward remissions and exacerbations and by the presence of a multitude of immunologic abnormalities, including antibodies that react with various components of cell nuclei, as well as antibodies directed against circulating proteins, blood cells, and solid organs. The disease may develop at any period of life but appears with highest frequency during the second to fourth decades. The majority of affected persons are women.

Systemic lupus erythematosus exists in many forms, from the very mild to severe and rapidly fatal, and is far more common than once recognized. The annual incidence of the disease has been estimated to be at least three to six cases per 100,000 population.

This disorder, like many others, was first recognized by a characteristic rash, and the term lupus erythematosus (literally "red wolf") is based on the early confusion of this rash with certain disorders that commonly ended in ragged ulcerations of the skin and the erosion of underlying parts in a manner similar to the destruction wrought by a hungry animal.

Systemic and discoid lupus erythematosus must be distinguished. The latter is a localized disorder of the skin and is usually confined to a facial rash, which may be similar in appearance to that which occurs in the systemic disease. Only a small minority of persons with discoid lupus erythematosus (probably less than 5 percent) develop evidence of involvement of organs and structures other than the skin.

Character-  
istics of  
systemic  
lupus ery-  
thematosus

The identification of systemic lupus erythematosus is based primarily on certain clinical findings, the most specific and frequent of which include the following: (1) facial erythema (reddening), which often takes the form of a butterfly-shaped rash over the bridge of the nose and the cheeks; this rash occurs in only a minority of adults with the disease; (2) discoid lupus—an erythematous raised patchy eruption that heals with scarring and atrophy of the skin and may be found anywhere on the body; (3) Raynaud's phenomenon (see below); (4) photosensitivity, manifested by unusual skin reaction after exposure to sunlight; (5) nondeforming arthritis; (6) inflammation of the kidneys (glomerulonephritis); (7) pleurisy or pericarditis or both (inflammation of the chest lining or the membranous sac enclosing the heart); and (8) evidence of involvement of the central nervous system, in the form of psychosis or convulsions. In addition to this evidence of specific organ involvement, the affected persons also have constitutional symptoms—including fever, weakness, fatigability, and weight loss—that are often the first manifestation of illness.

Some degree of anemia (effects of deficiency of red blood cells or hemoglobin) is found in the majority of persons with the disease; in a number of cases, this is the result of an increased rate of red cell destruction attrib-

utable to antibodies that coat the cell and damage its membrane. Low white blood cell counts (leukopenia) and platelet counts (thrombocytopenia) are also characteristic; these, too, can often be traced to the presence of specific auto-antibodies. Abnormal bleeding may result from thrombocytopenia or from an antibody that combines with and inactivates certain plasma proteins (clotting factors) involved in blood coagulation. False positive serological tests for syphilis are found in up to 20 percent of patients; in a significant number of cases this, or other isolated serologic abnormalities, may be the first evidence of systemic lupus erythematosus and may antedate other developments by a period as long as several years. Rheumatoid factor (see the subsection above on rheumatoid arthritis) occurs in about 25 percent of cases. Most important from the standpoint of diagnosis are the antibodies that combine with various components of cell nuclei. One or more of these antinuclear antibodies are present in virtually 100 percent of persons with active disease. The first of these antibodies to be recognized was the lupus erythematosus cell factor, discovery of which permitted detection of many previously obscure and unrecognized forms of systemic lupus erythematosus and greatly expanded knowledge of the clinical spectrum of this disorder.

The compound thus formed is avidly ingested by certain phagocytic (particle-engulfing) white blood cells, neutrophilic leukocytes, and these cells, distended by the compound of antibody and of lymphocyte-nucleus component, are the characteristic lupus erythematosus cells. Other antibodies fairly characteristic of lupus erythematosus include two that react specifically with deoxyribonucleic acid (DNA) and double-stranded ribonucleic acid (RNA) of cell nuclei. The presence of these two antibodies is associated with clinically active disease, and in particular with inflammation of the kidney, and with skin and brain lesions.

Recent evidence strongly suggests the possibility that one or more viruses may be the ultimate source of the antigenic stimulation responsible for the development of these auto-antibodies.

The treatment of systemic lupus erythematosus is designed to reduce or control inflammation and to limit the damage done to vital organs. Salicylates (aspirin) are used to relieve pain, particularly when joints are involved, and to reduce fever. In most cases, however, it is necessary to employ corticosteroid hormone to reduce inflammation in acute crises of the disease. Certain antimalarial drugs, such as chloroquine and hydroxychloroquine, have been found to exert an anti-inflammatory effect on skin and joint lesions and are widely used for the treatment of milder forms of the disease.

The course of systemic lupus erythematosus is highly variable. Acute episodes occur, but more commonly the disease gives rise to a subacute or chronic illness that smoulders on for many months or years, subject to spontaneous remissions and exacerbations. There may be long intervals (up to 20 years or more) in which the affected person is entirely free of symptoms, with little or no evidence of the disease aside from serologic abnormalities, which tend to persist indefinitely. In most cases the prospects of survival are determined by the degree of kidney involvement and its responsiveness to treatment with corticosteroids and other measures. Persons with severe and persistent thrombocytopenia (deficiency of blood platelets) and hemolytic anemia or with central-nervous-system disease fare poorly compared to those whose illness mainly involves the joints.

There are a number of drugs that have been found to be responsible for the induction of a lupus-like disease. Typically, this state is manifested by the appearance of fever, joint pain, pleurisy, deficiency of white blood cells, and the development of various antinuclear antibodies (antibodies that interact with cell nuclei). The clinical features thus resemble closely those of natural lupus, with the exception that evidence of kidney involvement is notably rare and the fact that the symptoms generally disappear upon discontinuation of the offending drug. Drugs that have had this effect include hydralazine (used

Drug-  
induced  
lupus

in the treatment of arterial hypertension), procainamide (used for the control of irregular heart rhythms), various anticonvulsants, isoniazid (an antituberculous agent), the antibiotic penicillin, and penicillamine. In one study, these or other drugs were found to account for 3 to 12 percent of all the cases identified as lupus. Only a small proportion of persons who receive these drugs present evidence of a lupus-like disease, although, in the instance of procainamide, it appears that a much larger number develop antinuclear antibodies without (other) signs of illness.

**Progressive systemic sclerosis.** Progressive systemic sclerosis, or scleroderma, is a generalized disorder of connective tissue of uncertain causation characterized by inflammatory, fibrotic (increase of fibrous tissue), and degenerative changes in the skin, joints, muscles, and certain internal organs. The term scleroderma refers to the thickening and tightening of skin, by which the disease was first recognized. The disease affects women approximately twice as often as men. The initial symptoms, which usually appear in the third to fifth decade of life, include painless swelling or thickening of the skin of the hands and fingers, pain and stiffness of the joints (**polyarthralgia**)—often mistaken for rheumatoid arthritis—and paroxysmal blanching and cyanosis (becoming blue) of the fingers induced by exposure to cold (Raynaud's phenomenon). The skin changes may be restricted to the fingers (sclerodactyly) and face but often spread. The disease may remain confined to the skin for many months or years, but in most cases there is insidious involvement of the esophagus (gullet), intestinal tract, heart, and lungs. A number of affected persons develop changes in the vessels of the kidneys or lungs accompanied by severe systemic arterial and pulmonary hypertension (high blood pressure), respectively. The diagnosis is based on the typical clinical features, particularly the findings in the skin, and X-ray evidence indicative of a disturbance in esophageal or intestinal motility, or both, and otherwise unexplained pulmonary fibrosis. (The motility involved is the waves of contractions, or peristaltic movements, by which the esophageal and intestinal contents are moved along.) Confirmation is often sought by means of examination of specimens of skin, which discloses an increase in skin thickness because of deposition of compact collagen in the dermis, or true skin.

Although there may be spontaneous improvement in the condition of the skin, those persons with more diffuse scleroderma tend to lose the ability to straighten their fingers. In general, the outlook is poor in cases marked by rapid progression of dermal changes, intestinal malabsorption, or heart failure, and is particularly serious in those patients who have kidney involvement and the grave type of high blood pressure known as malignant hypertension. In many cases, however, the disease progresses extremely slowly. There is no drug that is generally accepted as effecting a cure. The use of corticosteroids has proved disappointing, although these agents may help in those persons in whom there is inflammation of the muscles (myositis).

**Polymyositis.** Polymyositis is characterized by inflammation and degeneration of skeletal muscle, especially the muscles of the shoulder and pelvic girdles. In dermatomyositis, a closely related disorder, polymyositis is accompanied by an inflammation of the skin. Polymyositis occurs in all ages and is slightly more common in women. The muscle disease is manifested primarily by weakness and later by atrophy and contractures. Involvement of the muscles of the esophagus and the larynx causes difficulty in swallowing and in uttering sounds. Heart muscle may be affected. The skin changes, which occur in approximately half the persons affected and are highly variable, include a characteristic puffiness around the eyes with lavender discoloration of the upper eyelids and sharply demarcated reddened patches overlying the small joints of the fingers, which heal with atrophy and whitening of the skin. Calcium deposits under the skin, around the joints, and in the muscles are a common sequel to the inflammation in skin and muscle; when extensive, the condition is called calcinosis universalis. Other less com-

mon features of the disease include Raynaud's phenomenon, polyarthritis, and interstitial fibrosis (formation of fibrous tissue between the air sacs) of the lung. In at least 15 percent of affected adults, especially those with reddening of the skin, cancers are present.

The diagnosis is supported by an increase in the serum levels of certain enzymes that are released into the bloodstream when there is active destruction of muscle fibres and is confirmed by microscopic examination of affected muscle. There is evidence to suggest that the injury of muscle is produced by a toxic substance produced by sensitized lymphocytes. Certain structures that appear to be viruses have been observed by electron microscopy in muscle cells from several cases of chronic polymyositis. It is not yet clear, however, whether such virus infection is primarily responsible for polymyositis or represents a secondary invasion of injured tissue.

The course of the disease is highly variable. Children with dermatomyositis usually react more favourably to corticosteroids than do adults. It has recently been reported that persons with corticosteroid-resistant polymyositis may respond to the drug methotrexate. Significantly fewer adults than children with the disease survive.

**Necrotizing vasculitides.** The symptom complexes included in this category are characterized by inflammation of segments of blood vessels, chiefly small and medium-sized arteries. Clinical manifestations depend upon the site and severity of the arterial involvement and are therefore highly variable.

No single cause or disease mechanism has been identified. In some cases the lesions are similar to those encountered in human serum sickness and in animals given large amounts of foreign protein, in which conditions there is convincing evidence to link the disease to the deposition of immune (antigen-antibody) complexes in the walls of small blood vessels. An antigen (Australia antigen) associated with viral hepatitis (liver inflammation) has recently been found in the serum of several persons with polyarteritis nodosa, raising the possibility that some cases of polyarteritis may result from the deposition in blood vessels of immune complexes of viral antigen and antibody.

In polyarteritis nodosa, formerly known as periarteritis nodosa, inflammation and necrosis of small and medium-calibre arteries leads to local dilation and the formation of small aneurysms. The kidneys are the most frequently involved organs, and the disease is often first manifested by hypertension or other evidence of nephritis (kidney inflammation). Unexplained fever is common, as well as various combinations of abdominal pain, gastrointestinal bleeding, heart failure, disease of the peripheral nerves, asthma, or pneumonia. The diagnosis is established by the finding of characteristic inflammation of the blood vessels on examination of tissue specimens and sometimes by the X-ray demonstration of aneurysms of the renal arteries. Corticosteroids are the principal form of treatment, although this may aggravate the hypertension. Survival for more than one year after the onset of multiple-system manifestations is uncommon.

Hypersensitivity angiitis tends to involve smaller blood vessels than those affected in polyarteritis nodosa. Frequently, the affected person seems to have experienced hypersensitivity to various drugs, particularly penicillin, sulfonamides, and iodides. Treatment is with corticosteroids, and the outlook tends to be somewhat better than in polyarteritis nodosa.

Wegener's granulomatosis is a disorder marked by the combination of granulomatous lesions of the upper air passages and lower respiratory tract; destructive inflammation of blood vessels, both arteries and veins, especially in the lungs; and localized kidney disease. The disease affects adults of either sex. Corticosteroid therapy is often ineffective, and, in the past, most affected persons succumbed of kidney failure or lung infection within a year. Recently, complete, long-lasting recovery following treatment with various immunosuppressive agents has been reported.

aorta, involves principally the thoracic (chest portion of the) aorta and the adjacent segments of its large branches. Symptoms and signs, including obliteration of the pulses in the arms, are related to narrowing and obstruction of these vessels. Most reported cases have occurred in young Oriental women. The diagnosis and extent of vascular involvement can be established by means of angiography (X-ray observation of the blood vessels). Corticosteroids administered early during the course of illness have a beneficial effect, accompanied on occasion by return of pulses. Anticoagulants may prevent thrombosis (formation of blood clots).

Giant-cell or temporal arteritis occurs chiefly in older people and is manifested by severe temporal or occipital headache (headache in the temples or at the back of the head), mental aberrations, visual difficulties, unexplained fever, anemia, aching pains and weakness in the muscles of shoulder and pelvic girdles (polymyalgia **rheumatica**), and—in a minority of cases—tenderness and nodularity of the temporal artery. This vessel is the site of an inflammation that is characterized by the presence of numerous giant cells. Treatment with small doses of corticosteroids usually leads to dramatic relief of symptoms.

**Sjogren's syndrome.** Sjogren's syndrome, or sicca syndrome, is a chronic inflammatory disorder characterized by severe dryness of the eyes and mouth that results from a diminution in secretion of tears and saliva. Dryness may also involve the nose, pharynx, larynx, and tracheobronchial tree. Approximately half the persons affected also have rheumatoid arthritis, or, less commonly, some other connective tissue disease, such as **scleroderma**, **polymyositis**, or **systemic lupus erythematosus**. The great majority of the persons affected are women.

Features of  
Sjogren's  
syndrome

Infiltration (gradual assemblage) of lymphocytes and plasma cells leads to enlargement of the parotid or other salivary glands in half the patients. There may also be enlargement of the spleen, diminution in white blood cell numbers. **Ravnaud's phenomenon**, vasculitis (inflammation of vessels) with **chronic leg ulcers**, a disease of the peripheral or trigeminal nerves, nonthrombocytopenic purpura (purpura is the presence in the skin of a number of red spots from the escape of blood into the tissues from small blood vessels; if it is nonthrombocytopenic, it is not due to deficiency of blood platelets), chronic (Hashimoto's) thyroiditis (inflammation of the thyroid), enlargement of the liver, and inflammation of the pancreas. A number of persons with sicca syndrome of long duration have developed neoplasms of the type called reticulum cell sarcoma, or primary macroglobulinemia (the presence in the blood of globulins of high molecular weight). The frequent occurrence of elevated levels of immunoglobulin in the serum and of various antibodies, including antisalivary duct antibody, antinuclear antibody, and antiglobulin antibody (rheumatoid factor) has strengthened suspicion that Sjogren's syndrome is an autoimmune disorder. Treatment is directed toward relief of symptoms. The ocular dryness may be relieved by the use of artificial tears. Corticosteroids or immunosuppressive drugs have been employed with some success for the more serious manifestations.

**Rheumatic fever.** Rheumatic fever is an **inflammatory** disease that represents a delayed sequel to infection with the group A hemolytic streptococcus and predominantly affects children between the ages of five and 15 years. Although its name is based upon involvement of the joints, rheumatic fever owes its importance to its tendency to damage the heart. The attack rate of rheumatic fever ranges as high as 3 percent in cases in which streptococcal infection is associated with sore throat and pharyngeal exudate (oozing from the throat surfaces). The occurrence of the disease does not confer immunity to second attacks, and persons who have had it are more susceptible to recurrences than the general population is to an initial attack.

Rheumatic fever may be gradual and unnoticed in onset, or it may develop rapidly. Typically, clinical evidence of the disease appears after a symptom-free latent interval of a few days to several weeks after the inciting streptococcal infection. The major indications of its pres-

ence in children include inflammation of the heart (especially the valves, manifested by heart murmurs), arthritis, chorea (a nervous disorder involving unceasing, involuntary movements), subcutaneous nodules, and skin rashes, the most characteristic of which is erythema marginatum (reddening of the skin in disk-shaped areas with elevated edges). **Fever** is common, but not invariably present. Symptoms in adults are usually confined to the heart, the joints, or both. Antibiotics, especially penicillin, are employed during the attack to eradicate the streptococci, whereas aspirin and corticosteroids are used to treat the acute symptoms. Both decrease discomfort but neither shortens the course of illness. Occasionally, death occurs from an overwhelming inflammation of the heart, but, unless there is damage to heart valves, recovery usually is complete. Scarring and deformity of the valves may lead to their narrowing or failure to close properly, and this may eventually lead to the development of heart failure when the heart muscle is unable to keep up with the extra work load imposed by the abnormal functioning of the valves. The prophylactic use of antibiotics (chiefly penicillin) has led to a dramatic reduction in the frequency of streptococcal infections and resultant recurrences of rheumatic fever.

Several antibodies against the streptococcus develop in response to infection. These are directed against various constituents of the micro-organism or its products. The mechanisms whereby streptococcal infection initiates the process of rheumatic fever appear to be immunological in nature and to be based in large measure on antigenic cross-reactive relationships between a protein constituent of the streptococcal cell walls and human heart tissue and between other fractions of the streptococcus and a component of joint cartilage. **Immunoglobulins** produced in response to these bacterial antigens may act as **auto-antibodies** and be responsible for the inflammation of the heart and joints.

**Amyloidosis.** Amyloidosis is a disorder characterized by the accumulation of the substance amyloid in the connective tissue. Amyloid's name was originally assigned it in the mistaken belief that this material is akin to starch. Amyloid consists of a filamentous protein that is derived from immunoglobulins. The deposition of this substance may be widespread, with involvement of major organs leading to serious clinical consequences, or it may be very limited in extent with little effect on health. Amyloidosis has been separated into a primary form, unrelated to any other disease, and a secondary form, which is associated with chronic infections and inflammatory disorders. In addition, it appears that amyloid is related to the phenomenon of aging in that deposits are found with increasing frequency in the heart and brain of individuals past the age of 70. Included in the category of primary amyloidosis are a number of heritable forms, which have been reported from many different parts of the world. As seen by electron microscopy, all the types of amyloid examined consist chiefly of fine fibrils (minute fibres).

Because any organ may be involved, the clinical manifestations of amyloidosis are varied. Accumulation of amyloid in and about peripheral nerves and the skin, tongue, joints, and heart is particularly common in the primary forms, whereas in secondary amyloidosis the liver, spleen, and kidney are the sites chiefly involved. The diagnosis is established by means of examination of tissue specimens. Correction of the underlying infection or inflammation may prove helpful in the amelioration of secondary amyloidosis, but the primary types remain untreatable.

**Osteoarthritis.** Osteoarthritis, also called degenerative joint disease, is a ubiquitous noninflammatory disease of joints; the weight-bearing joints are particularly affected, including the knees and the hips. The disease is characterized by the progressive deterioration of joint cartilage and by the reactive formation of dense bone and of bony projections at the margins of the joint. Although **osteoarthritis** remains the most popular name for this condition, the term is inaccurate because its suffix, "**-itis**," implies the existence of a basically inflammatory disorder.

Osteoarthritic changes have been noted in skeletal re-

Complica-  
tions of  
rheumatic  
fever

Mani-  
festations  
and  
diagnosis  
of amy-  
loidosis

mains of Neanderthal man (40,000 BC) and in a wide variety of animal species, both large and small, including fossil dinosaur skeletons. Some erosion of joint cartilage is virtually universal in the elderly and, indeed, appears to be an inherent part of the aging process. Recent surveys in the United States and Great Britain are the basis of estimates that 40–50 percent of the adult population have X-ray visible changes of osteoarthritis in the hands or feet and that approximately 5,000,000–10,000,000 Americans have symptoms as a result of these changes; thus, osteoarthritis is by far the most common form of joint disease.

In addition to the aging process, there are a variety of predisposing conditions as well as local joint factors that influence the site and severity of degeneration of joint cartilage. These include excessive wear and tear related to occupation, injury, developmental structural abnormalities, and obesity; certain metabolic disorders that affect articular cartilage directly; repeated bleeding in a joint, such as occurs in hemophilia; and impaired proprioception (reception of sensory stimuli from within the body) of the joints, such as occurs in joint disorders resulting from nervous-system diseases (Charcot joints).

Heberden's  
nodes

Finally, it appears that for some forms of osteoarthritis —e.g., so-called Heberden's nodes— there exists a genetically determined predisposition. Heberden's nodes are bony protuberances (osteophytes), which are found at the margins and on the dorsal surface of the terminal joints of the fingers. The nodes develop more frequently in women, tend to occur in families, and are often associated with degenerative change in other joints.

Osteoarthritis is considered more at length in JOINT DISEASES AND INJURIES.

**Thrombotic thrombocytopenic purpura.** Thrombotic thrombocytopenic purpura is a rare disorder that has been included with the connective tissue diseases chiefly because of certain clinical similarities to systemic lupus erythematosus. The main features of this disorder, which usually appears suddenly and intensely in young women, include thrombocytopenic purpura (presence in the skin of red spots from the escape of blood into the tissues as a result of scarcity of blood platelets), hemolytic anemia (anemia resulting from destruction of red cells), changing neurological manifestations, fever, and kidney failure. The principal lesion is that of widespread blockage of small blood vessels — arterioles, venules, and capillaries— by material consisting principally of fibrin, the principal constituent of blood clots. The heart, kidneys, and brain are particularly affected. Corticosteroids remain the principal agent in treatment. Few persons survive longer than a month after onset of the disease.

**Relapsing polychondritis.** Relapsing polychondritis is an uncommon inflammatory disease that primarily affects cartilages. It begins usually in the fourth or fifth decade and is marked by recurrent periods of inflammation of various cartilages, lasting several weeks to months. The external ear and nose are affected most frequently and are eventually disfigured ("cauliflower ear") in a high percentage of cases. Involvement of joint cartilages produces pain and swelling of the joints, and the destruction of these cartilages results in a degenerative joint disease that may be disabling. Most serious is involvement of the trachea (windpipe), which may lead to respiratory obstruction or recurrent pneumonia. Hearing may be impaired when the inner ear is involved. About half of the affected persons have inflammation of the eyes. The aorta and the ring of the aortic valve may be involved. The acute manifestations of the disease can usually be suppressed with corticosteroid therapy, but the changes in the cartilages are permanent.

**BIBLIOGRAPHY.** Detailed accounts of the connective tissue diseases and of the rheumatic disorders in general may be found in JOSEPH L. HOLLANDER (ed.), *Arthritis and Allied Conditions*, 8th ed. (1972); W.S.C. COPEMAN (ed.), *Textbook of the Rheumatic Diseases*, 4th ed. (1969); and JAMES A. BOYLE and W. WATSON BUCHANAN, *Clinical Rheumatology* (1971). VICTOR A. MCKUSICK, *Heritable Disorders of Connective Tissue*, 3rd ed. (1966), is the most complete and authoritative text dealing with the genetically transmitted connective

tissue diseases. IAN R. MACKAY and F. MACFARLANE BURNET, *Autoimmune Diseases* (1963), was one of the first to clearly formulate and champion the role of autoimmunity in the connective tissue diseases and a number of other maladies of obscure etiology. MAX SAMTER (ed.), *Immunological Diseases*, 2nd ed., 2 vol. (1971), describes the mechanisms whereby aberrant immunity leads to tissue damage. Briefer, clinically oriented accounts may be found in MICHAEL MASON and HARRY L.F. CURREY (eds.), *An Introduction to Clinical Rheumatology* (1970), and the *Primer on the Rheumatic Diseases*, 7th ed. (1972). LEON SOKOLOFF, *The Biology of Degenerative Joint Disease* (1969), considers the comparative pathology of this ubiquitous arthropathy and reviews recent important experimental studies. EDMUND L. DUBOIS (ed.), *Lupus Erythematosus* (1966), provides an exhaustive summary of the condition that has been influential in the development of the modern concept of connective tissue disease.

(G.P.R./T.G.B.)

## Conodonts

The conodonts, toothlike microfossils consisting of calcium phosphate, are among the most frequently occurring fossils in marine sedimentary rocks of Paleozoic age. The organisms to which the conodonts belonged are unknown and probably have been extinct since the middle or late Mesozoic Era (65,000,000 to 225,000,000 years ago).

Conodonts were first found and described in 1856 in Lower Ordovician greensand in the East Baltic area. They were at first thought to be the teeth of primitive fish, and several authors since then have endorsed the fish hypothesis. Others, however, have pointed out the similarity between certain conodonts and the jaws of the worm group polychaetes (see ANNELIDA). The polychaete, or annelid, hypothesis became particularly attractive after the discovery (1934) that several kinds of conodonts must have functioned together in individual animals as a kind of mechanism resembling the jaw apparatus of polychaetes.

The conodonts also have been regarded as internal, skeletal structures set within soft tissue. At least one worker has assumed that they supported the food-gathering organ (consisting of a lophophore or braccia appendage) of a free-swimming lophophorate animal, surrounding the mouth and extending into the mouth cavity. They have also been compared with the radular teeth (muscular food-tearing mechanism) of gastropods, with parts of crustaceans, and with the copulatory structures (spicules) of nematodes. It has even been claimed that they do not belong to the animal kingdom at all but are algal structures.

Conodonts occur in all kinds of sedimentary rocks that have their origin in the sea, and have been found at practically all stratigraphic levels of their historical range. Because they permit precise and accurate correlation of rock sequences over great distances, they are of considerable practical importance, particularly in defining stratigraphic boundaries for petroleum exploration.

This article treats the morphology and physical properties of conodonts, describes their classification, geological occurrence, and stratigraphic use, and presents the several theories of origin of conodonts. For further information on the relationship between conodonts and other fossils, see FOSSIL RECORD. See also STRATIGRAPHIC BOUNDARIES for a discussion of the types of problems in which correlation by conodonts is useful.

### THE NATURE OF CONODONTS

Among the well-known hard parts of fossil or living animals, those that bear the greatest resemblance to conodonts are those elements of the polychaete jaw apparatus known as scolecodonts (worm mandibles) and the teeth of fish. Scolecodonts and conodonts are distinguished from each other because the former consist of acid-resistant organic material, whereas the conodonts, phosphatic, are soluble in hydrochloric acid. In rocks that have not undergone high-temperature alteration, the conodonts are light yellow to yellowish brown and at least partially translucent, whereas scolecodonts are dark brown to black and are opaque.

Initial  
discovery

Figure 1: Simple and compound elements and conodont nomenclature.

There are also differences in outer shape between conodonts and scolecodonts. The denticles (small spinelike teeth) that rise from the base of conodonts may be long and slender and occur either in branches or in several parallel rows, whereas denticles of the scolecodonts are relatively short and occur in a single row. Platform conodonts may have a tuberculate or pitted surface, whereas scolecodonts have a smooth one.

Fish teeth and conodonts are similar in composition. The outer resemblance between certain stout and simply constructed conodonts and teeth may be great. Fish teeth, however, do not have the thin and strongly recurved denticles and the long, narrow denticulate processes found in many conodonts. The most important distinguishing characters lie, however, in the inner structure. Only moderate magnification is sufficient to show that well-preserved conodonts consist of thin concentric lamellae, without a trace of the bony tissue and blood-vessel canals that occur in teeth.

Arthropods and certain brachiopods may yield fragments that are mistaken for conodonts, but the former are nonphosphatic or, if phosphatized, lack the finely layered structure of conodonts. Phosphatic brachiopod shells may carry denticulate structures resembling conodonts. With respect to certain primitive, conical fossils which place within the classification of animals is still open.

Chemical composition and internal structure. The chemical composition of conodont phosphate contains no hydroxyl groups and approaches that of the phosphate mineral apatite. Minor amounts of organic compounds are also present; amino acids from Devonian conodonts were identified in 1966. Leucine, phenylalanine, and lysine have been found to be particularly important constituents of the conodonts. Fossil bone and teeth differ significantly in this respect. Because the environments of the material studied were rather special, it is possible that different results may be obtained in the future.

Though it has been customary to make a structural distinction between lamellar and fibrous conodonts, the distinction may be a false one. One argument favouring a structural distinction is the fact that in fracturing, lamellar conodonts break straight across the denticles, whereas in fibrous forms the fractured denticles may give lengthwise splinters, like wood. Another argument is that lamellar conodonts have opaque parts consisting of white matter, and in well-preserved specimens the entire fibrous conodont is more or less translucent. Certain well-defined genera contain only translucent elements, which break in the fibrous way. Working against the validity of a structural distinction is the fact that fibrous conodonts actually have a concentric lamellar structure similar to that of the main lamellar group, and typically lamellar conodonts have a lengthwise fibrous structure within the lamellae.

The lamellae, usually a few microns thick, may be separated by narrow interlamellar spaces and consist of columnar phosphate crystallites with dimensions considerably less than one micron. Judging from microscopic observation, the crystallites are probably arranged at right angles to the lamellar surfaces.

Whereas the base of well-preserved specimens is translucent, the denticles may contain white matter that does

not let light through. The lamellar structure probably continues through the white matter, although this cannot easily be ascertained. Electron-microscopic studies indicate that the white matter owes its aspect to closely set empty spaces, the diameters of which may be about one micron. The hollow spaces are known to cut discordantly through the fabric of crystallites, and it has been suggested that this might indicate that they were formed by resorption.

Morphology and nomenclature. Distinctive forms of conodonts are called elements. An element normally consists of a base that carries one or several denticles (Figure 1). Conventionally, the denticles are oriented upward. On the lower side of the base many conodonts, including the most primitive, have a conical basal cavity. The oldest part of the element is at the tip of the basal cavity. This part is usually somewhat curved. The convex side is said to be anterior (forward), the concave side posterior (backward). This terminology is conventional and arbitrary, because the orientation in the animal is not known. As a rule the denticles also curve toward the posterior. The lamellae about this oldest part of the element are concentric. They are interrupted by the basal cavity, the interior of which shows the free margins of successive lamellae. In certain platform conodonts the basal cavity is replaced by a flat or slightly convex area, the attachment surface, or escutcheon, on which the lamellae appear as concentric striations. Even these elements originate with a basal cavity that remains as a small pit at the centre of the escutcheon.

The basal cavity or the escutcheon serves as an attachment surface of the basal filling. In simple and compound conodonts, this may be a hollow cone (basal funnel) inserted in the basal cavity. Platform conodonts may have a padlike basal filling. The basal filling is lamellar and phosphatic, but with somewhat less phosphate and more organic matter than the conodont. The crystallites are smaller than in the conodont. In most specimens the basal filling has been lost.

The three principal kinds of conodont elements are simple, compound, and platform. The distinction depends on the development of the base and the number and arrangement of the denticles.

The simple conodonts consist of a main denticle (cusp), base, and basal cavity. In certain genera they are patterned, for instance, with lengthwise ridges and furrows.

In compound elements, the base carries more than one denticle. The main denticle, or cusp, originates at the tip of the basal cavity. The base develops branches (processes or bars), and denticles are aligned on the upper, or outer, side of the processes. This side is called oral, which suggests orientation in a mouth. The term is, however, due to historical usage and gives no indication of place or function. The basal cavity (escutcheon) continues along the lower (aboral) side of the processes.

Compound elements with one, two, three, or four processes, bilaterally symmetrical or asymmetrical, may belong to a single species that normally contained all these kinds of elements, as well as transitions between them (symmetry transitions).

Platform conodonts are compound forms in which the oral surface is widened to the sides and carries some kind of ornamentation, usually crests, rows of denticles, or

Chemical  
and  
structural  
distinctive-  
ness

Conodont  
elements

tubercles, as well as a finely reticulate pattern. In some of the most important groups of platform conodonts, there is a main row of denticles with the oldest part near the centre. In the anterior part the denticles may be fused so as to form a high blade. The platform usually occupies the posterior part of the unit, though the superfamilies Prioniodontacea and Bryantodontacea have platforms anteriorly as well as posteriorly, and the Gondolellacea have the platform practically restricted to the anterior process. On the platform, the main denticle row is low and may be fused into a ridge, or carina.

The platform may develop in either of two ways. The sides of the processes may thicken into ledges and develop platforms by further sideward thickening, as occurs in the polygnathids. On the aboral side the basal cavity is transformed into an escutcheon with central pit. The other possibility, represented by the idiognathodontids, is that the whole base expands, including the basal cavity. The oral surface of the expanded posterior part of the basal cavity then provides the space for platform ornamentation.

**Conodont assemblages.** Conodonts are collected as separate elements. Until 1934 it was the general belief, expressed in classification, that a conodont-carrying animal had only one kind of element. The discovery of natural assemblages on shale surfaces of Pennsylvanian (Upper Carboniferous) age, made independently in North America and Europe, showed that elements that were until then regarded as different genera could belong to a single individual. The composition of the most frequently occurring Pennsylvanian assemblages has been found to be fairly constant: a pair of platform elements, right and left; a pair of bladelike compound elements classified as Ozarkodina; a pair of pick-shaped compound elements (*Neoprioniodus* or Synprioniodina); and four or five pairs of long, barlike compound elements (Hindeodella). Assemblages have been found in different shales of Pennsylvanian and Mississippian age, recently also in Upper Devonian Kellwasser Limestone in West Germany. The elements of the assemblages may be arranged in a more or less orderly fashion. Amorphous organic material may be concentrated around the assemblages. Otherwise, no recognizable organic structure other than the conodonts occurs.

Because the elements occur in constant proportions, it should be possible to reconstruct assemblages from series of samples of isolated elements. This method has been successfully applied to samples from Ordovician-age rocks. Probable assemblages have also been outlined for the Silurian. Most of the reconstructed assemblages are comparable to the classical assemblages found in the Pennsylvanian.

In order to avoid confusion with the taxonomic nomenclature, conodonts found in assemblage are referred to by adding an ending to the name of the genus to which they would have been referred in the old taxonomy (thus, polygnathiform, ozarkodiniiform, or neoprioniodiiform elements, etc.).

#### THE CLASSIFICATION OF CONODONTS

A taxonomy founded on isolated elements persisted after the discovery of assemblages, though researchers became increasingly aware that it was artificial. Efforts to stabilize the traditional taxonomy as a form taxonomy (based on similarity between species and genera only in form) were frustrated in 1958 by the International Congress of Zoology. Since then, a taxonomy based on isolated elements, in reality though not by right a form taxonomy, has been further elaborated, while at the same time a taxonomy based on natural assemblages (in which several conodont elements occur in the same species or genera) gradually has taken its place. The decision of the International Congress of Zoology means that the same genus and species names must be used in both classifications until the form-taxonomic approach has been completely abandoned.

Taxonomic units above the level of the genus cannot be more securely founded than the genera themselves. A classification in the Treatise on Invertebrate Paleontology

recognizes seven families (Distacodontidae, Belodontidae, Coleodontidae, Prioniodontidae, Prioniodontidae, Polygnathidae, and Idiognathodontidae), all of which are defined as utilitarian. These families are too heterogeneous to be useful. Most conodont publications therefore leave the question of suprageneric classification aside.

In 1944 a classification that appears to indicate some basic relationships was proposed. In this scheme, the order Conodontophorida, of uncertain affinity, comprises the two suborders Neurodontiformes and Conodontiformes. Neurodontiformes, fit conodonts, contains 11 families Chirognathidae, Idiognathodontidae, and Tru-cherognathidae. Conodontiformes, or lamellar conodonts, is divided into the families Distacodontidae (correctly: Distacodontidae), Prioniodontidae (correctly: Prioniodontidae), Prioniodontidae, Polygnathidae, and Gnathodontidae (younger synonym of Idiognathodontidae). The validity of this classification is unaffected by the circumstance\* that the structural difference between fibrous and lamellar conodonts was misunderstood. The definitions of the families are different from those in the utilitarian Treatise classification. Both classifications falter because they ignore the assemblages, however.

Figure 2: Phylogeny of main superfamilies, families, and subfamilies of conodonts.

The available criteria for a classification are outer shape; micromorphology; internal structure, including the distribution and structure of white matter; and the composition of the natural assemblage or conodont apparatus. The following classification is based on these criteria.

Order Westergaardodinida. U- or W-shaped, or conodont-like structures, consisting mainly of organic material, with phosphate as a minor component. (Middle?-) Upper Cambrian to Middle Ordovician.

Order Conodontophorida. Conodonts in the strict sense. Upper Cambrian to Upper Triassic (to Upper Cretaceous?).

1. Superfamily Distacodontacea
  - Family Proconodontidae. Subfamilies: Proconodontinae and Cordylodontinae.
  - Family Clavohamulidae
  - Family Distacodontidae
2. Superfamily Chirognathacea (= "Suborder Neurodontiformes")
  - Family Oistodontidae
  - Family Chirognathidae

- Family Rhipidognathidae
- 3. Superfamily Panderodontacea
  - Family Acanthodontidae. **Subfamilies:** Acanthodontinae and Protopanderodontinae
  - Family Panderodontidae
- 4. Superfamily Prioniodontacea
  - Family Periodontidae
  - Family Prioniodontidae
  - Family Balognathidae
  - Family Icriodontidae
- 6. Superfamily Bryantodontacea
- 7. Superfamily Gondolellacea
- 8. Superfamily Polygnathacea
  - Family Spathognathodontidae
  - Family Polygnathidae
  - Family Pseudopolygnathidae
  - Family Bactrognathidae
  - Family Idiognathodontidae
  - Family Neospathodontidae

**Superfamilies** 4–8 are closely related; the Prioniodontacea probably evolved from distacodontids in the Early Ordovician.

#### THE GEOLOGICAL OCCURRENCE OF CONODONTS

Geologic  
ranges

The oldest fossils claimed to be conodonts occur in the Middle Cambrian Kalby Clay of Bornholm, Denmark. They are horn-shaped, hollow objects, evidently consisting of phosphate. Because no further diagnostic characters are known, it is uncertain whether these fossils are conodonts. The Upper Cambrian contains a group of more or less conodont-like fossils here brought to the order Westergaardodina. They have a lamellar structure and consist of organic material and phosphate. The colour is black or dark brown. Only simple forms and U- or W-shaped structures are known. **Westergaardodina** are not known from beds younger than Middle Ordovician. Workers on these fossils have regarded them as primitive conodonts, but this supposition has been questioned.

Conodonts in the strictest sense appear in the uppermost part of the Upper Cambrian (Figure 2). They are simple forms belonging to the Proconodontidae. In the Ordovician, conodonts become very frequent and diversified. Simple distacodontids are dominant forms in many Lower Ordovician faunas. The most long-lived major group of simple forms is that of the panderodontids that are common throughout the Silurian.

Compound forms belonging to the Prioniodontacea are characteristic elements of most Ordovician faunas. The Devonian, like the Ordovician, contains exceptionally rich conodont faunas. These are often found to be dominated by the Polygnathacea. The continuous conodont record ends in the Upper Triassic, and reports on Jurassic conodonts appear to be doubtful.

Conodonts have been discovered in Upper Cretaceous beds at the Mungo River in Nigeria. The species are the same as in the Upper Triassic. From the taxonomic and evolutionary point of view, it is therefore most likely that the fauna is reworked from Upper Triassic beds. No such beds are known in the region, however, and it may be difficult to reconcile the existence of Triassic marine fossils in this area with widely accepted ideas on continental drift (*q.v.*), according to which the South Atlantic Ocean did not exist until the Cretaceous.

Conodonts are among the most useful index, or guide, fossils of the geological systems in which they occur. They are easy to recover in quantities sufficient for stratigraphic purposes. The standard method is to dissolve samples from marine limestone beds in diluted acetic or monochloroacetic acid. Acetic acid works more slowly but more gently than the latter. The conodonts are screened from the undigested residue. A good yield may be about 100 conodonts in a one-kilogram (2.2-pound) sample, although certain samples from the Ordovician and Devonian may contain over 10,000 conodonts in one kilogram of rock. Determinable conodonts also may be found in sandstone and on shale surfaces.

The rapid evolution of certain conodonts, most notably the platform elements, has provided a great number of easily recognizable index species. The short life of such

species gives precision to age determinations by conodonts. The near-ubiquity of conodonts in marine deposits is a further reason for their usefulness as stratigraphic indicators.

Rapid dispersal kept pace with rapid evolution, allowing conodont species to spread over the whole world. In the Devonian and Mississippian, practically identical conodont successions have been encountered in Europe, North America, and Australia. Similar conditions are known from the other systems, though, for instance, in the Ordovician certain conodont faunas are geographically restricted. Thus, some early prioniodontaceans of the Lower Ordovician are rare outside a North European-Atlantic province, and the genus *Phragmodus*, a Middle–Upper Ordovician periodont, seems to be restricted to areas outside this province (*e.g.*, central North America). *Cavusgnathus*, a Lower Carboniferous idiognathodont, is missing locally in western Europe. Nevertheless, conodonts are exceptionally useful for intercontinental as well as local correlation.

The lowermost Ordovician is characterized by **proconodontids**; *e.g.*, the genus *Cordylodus*. In the Lower Ordovician of Europe, index fossils are found among the distacodontids and prioniodontids. The Lower Ordovician of other geographic provinces appears to be dominated by panderodontaceans belonging to the subfamilies Acanthodontinae and Protopanderodontinae. In the Middle and Upper Ordovician, the balognathids yield widespread index fossils (*Amorphognathus* and *Polyplacognathus*). Chirognathaceans (*Chirognathus*, *Leptochirognathus*, *Rhipidognathus*) are important and locally very common in areas of central and western North America.

In the Silurian, several zonal indices belong to the spathognathodonts. In the Lower–Middle Devonian, species of the genus *Icriodus* are particularly important for local and intercontinental correlation. Upper Devonian conodont faunas are mostly dominated by **polygnathids**. Species of *Palmatolepis* are among the best index fossils known to stratigraphy. *Polygnathus* and *Ancyrodella* are also stratigraphically important. The Lower Mississippian is characterized by the polygnathid genus *Siphonodella*. The Mississippian to Pennsylvanian sequence is marked by a succession of **idiognathodontids** belonging to the genera *Gnathodus*, *Streptognathodus*, *Idiognathodus*, *Idiognathoides*, and *Cavusgnathus*.

The gondolellaceans and neospathodontids appear in the middle to upper parts of the Pennsylvanian. The superfamily Gondolellacea contains a number of important guide species for stratigraphic levels in the Permian and Triassic.

A particular stratigraphic problem depends on the chemical resistivity and hardness of the conodonts. Conodonts may remain as a residue even after the embedding sediment has been eroded or weathered away. The exposed conodonts may become parts of a new sediment. The reworked fauna indicates the age of the first, destroyed sediment, not that of the younger deposit in which it is included. When recognized, such ghost faunas are highly useful for paleogeographic reconstruction, because they may be all that is left of certain phases of marine sedimentation.

Conodonts are found only in marine sediments. In deltaic and coal swamp deposits they are restricted to marine bands, formed during temporary sea transgressions. They occur in all kinds of sedimentary rocks formed in the sea, together with fossils of all major groups of marine animals. They are most frequently encountered in thin, very slowly formed deposits. The greatest conodont faunas have been found in shales, cherts, and limestones with evidence of slow sedimentation but also in certain thin bands of sandstone. In most cases the type of sediment on the sea floor did not influence the conodonts very strongly. Only a few cases are known in which the sedimentary substrate and certain conodont species are consistently related. A particularly instructive instance from the Upper Ordovician of the Cincinnati region has been described. There two subspecies of *Rhipidognathus symmetricus* lived, one of which evident-

Guide  
fossils

Rock  
types and  
environ-  
ments

ly preferred extremely shallow water, whereas the other dwelt in more tranquil water farther from the shore. Other cases are known in which shallow-water deposits do not contain conodonts.

#### THE QUESTION OF ZOOLOGICAL AFFINITY

When conodonts were described for the first time, they were regarded as fish teeth, and this idea never has been universally abandoned. It is founded principally on superficial morphological resemblance to teeth and on chemical composition. The latter is not decisive, for there are phosphatic skeletal parts in other animal groups (e.g., inarticulate brachiopods). The resemblance to teeth is fallacious. In vertebrate teeth the mineral lamellae are added from the outside inward, whereas conodonts grew outward. Vertebrate teeth are external and if broken cannot be regenerated. Conodonts, on the other hand, were internal structures that could be repaired if broken. Furthermore, the seizing, cutting, and grinding function of teeth could not be fulfilled without breakage by the more slender forms of conodonts.

The inner structure of conodonts is not diagnostic, because it consists of simple lamellae. A simple, lamellar structure, consisting of phosphate, occurs in certain primitive vertebrates. It is known as aspidin and seems to be the only vertebrate tissue with any resemblance to conodonts. Its outer form is random, however, and bears no evident relation to a constant, vital function. The fundamental plan of the main conodont assemblages, on the other hand, remained the same from the Early Ordovician to the Late Triassic. The structure of conodont white matter has not been identified in vertebrate tissues. Unlike the vertebrates, conodonts evidently never invaded the freshwater environment.

Whereas no apparatus recalling the conodont assemblage is known in the vertebrates, there is a considerable resemblance between this assemblage and the jaw apparatus of the polychaetes. Of the hypotheses assuming close affinity between the conodonts and any still-existing group, the polychaete hypothesis is the most plausible. Polychaete jaws, since their first known appearance in the Ordovician, have consisted of organic material. This does not absolutely refute the affinity. Polychaete jaws are exposed in the pharynx, however, where they perform seizing and masticating functions. Conodonts seem to have been embedded in living tissue and, for the greatest part, were unsuited for a principal function as jaws. Polychaete jaws have no part resembling the ornamented platform of the conodonts.

Most asymmetrical conodonts occur as right and left elements. The conodont animals were as a rule bilaterally symmetrical. This symmetry, and the absence of a protective shell or external skeleton, indicates that they were free moving and possibly wormlike. Their comparatively great independence of sedimentary substrate, as well as the global spread of a great many species, suggests a swimming, pelagic mode of life. The porous white matter could serve to reduce weight in a swimming animal, but its disadvantage would be reduction of the strength of the elements. The elements of most conodont genera stayed separate; fusion during growth has been observed in only one instance. Thus, mobility between the elements probably was essential for the functioning of the apparatus.

The conodonts grew embedded in the tissue by which they were secreted. Broken parts were crudely regenerated by lamellae laid down about the stump. The constant, fairly elaborate plan of the main types of conodonts suggests a fixed relationship to the function of surrounding tissue. It is unlikely that the outer morphology of this tissue was greatly different from that of the conodonts. This suggests a papillate or tentaculate surface. Much of conodont morphology can be understood as a means of surface enlargement, which would be of help to any organ serving food-gathering or metabolic function. Conodonts tend to add complexity during growth. For a food-gathering mechanism this is necessary. The required volume of food generally increases as the cube of the length of the animal. According to this interpretation, the conodonts supported a lophophore-like organ that

strained small microplankton from the seawater and, if possible, also was able to manipulate larger, soft-bodied microplanktons. The biologically successful group of animals to which the conodonts belonged is probably distinct from all other known groups.

(M.L.)

## Conrad II, Emperor

German king and Western emperor Conrad II, in a short reign, from **1024** to **1039**, proved that the German monarchy had become a viable institution. Since the survival of the monarchy was no longer primarily dependent on a compact between sovereign and territorial nobles, it was henceforth invulnerable to prolonged rebellion on their part. Conrad also proved that at that time—within certain limits and despite the elective character of the monarchy—a self-made man could rise to kingship and establish a new Salian dynasty, which would last for almost a century.

Conrad II, detail from a miniature from the manuscript *Codex Aureus* Echternach, c. 1045; in the Real Biblioteca de San Lorenzo de El Escorial, Spain.

Conrad was born around **990**, the son of Count Henry of Speyer, who had been passed over in his inheritances in favour of a younger brother. Henry was descended, through the marriage of his great-grandfather Conrad the Red to a daughter of Emperor Otto, from the Saxon house. Left poor, Conrad was brought up by the Bishop of Worms and did not receive much of a formal education; but, conscious of the deprivations suffered by him and his father, he matured early. Prudent and firm, he often displayed great chivalry as well as a strong sense of justice, and he was determined to gain the status that fortune had denied him. In **1016** he married Gisela, the widowed duchess of Swabia and a descendant of Charlemagne. Conrad, however, was distantly related to Gisela. When strict canonists took exception to the marriage, Emperor Henry II, who was jealous of the growth of Conrad's personal influence, used their findings as an excuse for forcing Conrad into temporary exile. The two men later became reconciled, and, by the time Henry II

The polychaete hypothesis

The lophophore hypothesis

Crowned  
king

died, in 1024, Conrad presented himself to the electoral assembly of the princes at Kamba on the Rhine as a candidate for the succession. After prolonged debates, the majority voted for him, and he was crowned king in Mainz on September 8, 1024.

Intelligent and genial, Conrad was also fortunate. Soon after his election, even the minority opposition was persuaded to pay their homage. Early in the following year, the sudden death of Bolesław Chrobry of Poland, a tributary to the German monarchy who had styled himself an independent king, spared Conrad the necessity of military interference. In Germany, a rebellion fomented by nobles and relatives of Conrad was joined by many lay princes of Lombardy; and, although the Italian bishops paid homage at a court in Constance in June 1025, the lay princes sought to elect William of Aquitaine as anti-king. But, when the King of France refused his support, the rebellion collapsed. Early in 1026, Conrad was able to go to Milan, where Archbishop Ariberto crowned him king of Italy. After brief fighting, Conrad overcame the opposition of some towns and nobles and managed to reach Rome, where he was crowned emperor by Pope John XIX on Easter 1027. When a renewed rebellion in Germany forced him to return, he subdued the rebels and imposed severe penalties on them, not sparing members of his own family.

Conrad not only showed strength and incorruptible justice in maintaining his power but also displayed enterprise in legislation. He formally confirmed the popular legal traditions of Saxony and issued a new set of feudal constitutions for Lombardy. On Easter Sunday 1028, at an imperial court in Aachen, he had his son Henry elected and anointed king. In 1036 Henry was married to Kunigunde, the daughter of King Canute of England. Eventually, he became inseparable from his father and acted as his chief counsellor. Thus, the succession was virtually assured and the future of the new house looked bright.

In the meantime, Conrad had been comæelled, after all, to campaign against Poland in 1028. After severe fighting, Mieszko—Bolesław's son and heir—was forced to make peace and surrender lands that Conrad's predecessor had lost. Even so, Conrad had to continue to campaign in the east, and in 1035 he subdued the heathen Liutitians.

Political  
triumphs

Although occupied intermittently in the east, Conrad was able to gain political triumphs in the west. Earlier, the childless King Rudolf of Burgundy had offered the succession to his crown to Emperor Henry II, who, however, died before Rudolf. Thus, when Rudolf died in 1032, he left his kingdom to Conrad over the opposition of the Burgundian princes, who two years later, on August 1, 1034, paid homage to Conrad at Ziirich.

Although Conrad's relations with his son remained close, King Henry at times showed independent initiative. He once concluded a separate peace with King Stephen of Hungary and on another occasion gave his oath to Duke Adalbero of Carinthia never to side against him. Thus when Conrad fell out with Adalbero in 1035, Henry's oath severely strained relations between father and son. Conrad managed to overcome his son's partisanship only by humbling himself before him. In the end, Conrad's determination prevailed, and Adalbero was duly punished.

In 1036, Conrad appeared for a second time in Italy, where he proceeded with equal vigour against his old ally, Archbishop Aribert of Milan. Italy was rent by dissensions between the great princes, who, together with their vassals—the *capitanei*—had suppressed both knights and the burghers of the cities, the *valvassores*. Conrad upheld the rights of the *valvassores*, and, when Aribert, claiming to be the peer of the emperor, rejected Conrad's legislative interference, Conrad had him arrested. Aribert managed to escape, however, and succeeded in raising a rebellion in Milan. Through luck and skillful diplomacy, Conrad succeeded in isolating Aribert from his Lombard supporters as well as from his friends in Lorraine. Conrad was thus able to proceed in 1038 to southern Italy, where he installed friendly princes in Sa-

lerno and Anversa and appointed the German Richer as abbot of Montecassino.

On his return to Germany the same year along the Adriatic coast, his army succumbed to a midsummer epidemic in which both his daughter-in-law and his stepson died. Conrad himself reached Germany safely and held several important courts in Solothurn (where his son Henry was invested with the kingdom of Burgundy), in Strassburg, and in Goslar. He fell ill during the following year (1039) and died on June 4 in Utrecht. He was buried in the newly built cathedral of Speyer.

**BIBLIOGRAPHY.** There is no biography of Conrad II. The only useful treatment in English is G. BARRACLOUGH, *The Origins of Modern Germany*, 2nd rev. ed. ch. 3 4 (1947); in German, K. HAMPE, *Deutsche Kabergeschichte in der Zeit der Salier und Staufer*, 11th ed., ch. 1 (1963). For important revision due to modern research, see T. SCHIEFFER, "Heinrich II und Konrad II," *Deutsches Archiv*, 8:384-437 (1951). An authoritative summary by M.L. BULST-THIELE may be found in B. GEBHARDT, *Handbuch der deutschen Geschichte*, 9th ed., vol. 1, pp. 299-307 (1970).

(P.Mu.)

## Conrad. Joseph

By birth a Pole of Russian nationality, British by adoption, Joseph Conrad was during his lifetime admired for the richness of his prose and his renderings of dangerous life at sea and in exotic places. But his initial reputation, based on the public's view of him as a masterful teller of colourful adventures of the sea, masked his fascination with the individual when faced with nature's invariable unconcern, man's frequent malevolence, and his inner battles with good and evil. To Conrad, the sea, of which he held not the romantic but the sailor's workmanlike view, meant the tragedy of loneliness. A writer of complex skill and striking insight, but above all of an intensely personal vision, he has, since his death, been increasingly regarded as one of the greatest English novelists and short-story writers.

and Manuscript Library, Yale University

Conrad. 1904.

Józef Teodor Konrad Korzeniowski was born December 3, 1857, at Berdichev, in what is now the Soviet Ukraine. On both sides he came of Polish landed gentry. His father, Apollo Nałęcz Korzeniowski, a poet and an ardent patriot, was one of the organizers of the clandestine City Committee of Warsaw that, as the National Central Committee, in 1863 directed the Polish insurrection against Russian rule. He himself took no part in the insurrection led by the Committee, for he had been arrested by the Russians in October 1861 and seven months later sent into exile at Vologda in northern Russia, where his family followed him.

The climate of Vologda was "murderous"; the four-

Youth

year-old **Józef** almost died on the way there. His mother was suffering from advanced tuberculosis, and though the family was allowed to move to a milder climate, she died in April 1865. Apollo, shattered by his wife's death and by the failure of insurrection, degenerated according to Conrad, "into mysticism touched with despair." Broken in health and resources, and no longer capable of original work, Apollo turned to translation, particularly of Shakespeare and Hugo. In *A Personal Record* Conrad relates that his first introduction to the English language was at the age of eight, when his father was translating *The Two Gentlemen of Verona*. In those solitary years with his father, he read Sir Walter Scott, James Fenimore Cooper, Captain Marryat, Dickens, and Thackeray in Polish and French. Apollo was also ill with tuberculosis, however, and died in Cracow in 1869.

Responsibility for the boy was assumed by his maternal uncle, Tadeusz Bobrowski, a lawyer, who for the rest of his life was indefatigable in plying his nephew with advice, admonition, financial help, and love. He sent Conrad to school at Cracow, but the boy was bored by school, and by 1872 he yearned to go to sea. A year later, his uncle sent him to Switzerland, accompanied by a tutor, whose function, Conrad believed later, "was to talk me out of my romantic folly." They argued endlessly and eventually the tutor left, calling Conrad "an incorrigible, hopeless Don Quixote." In October 1874, Conrad left Cracow for Marseilles.

**French merchant service.** Bobrowski made him an allowance of 2,000 francs a year and put him in touch with a merchant named Delestang, in whose ships Conrad sailed while he was in the French merchant service. His first voyage, on the "Mont-Blanc" to Martinique, was as a passenger; on her next voyage he sailed as an apprentice. In July 1876, he again sailed to the West Indies, as a steward on the "Saint-Antoine." What happened to Conrad during this voyage of 18 months is obscure, except that he seems to have taken part in some unlawful enterprise, probably gun-running, and to have sailed along the coast of Venezuela, memories of which were later to find a place in *Nostromo*. The first mate of the vessel, a Corsican named Dominic Cervoni, was the model for the hero of that novel and was to play a picturesque role in Conrad's life and work.

Between voyages, Conrad seems to have frequented the company of the Delestangs and made himself at home in artistic circles in Marseilles; but his sojourn in the city is shrouded in mystery. It is known, however, that his uncle visited him in February 1878, summoned by a cable announcing that Conrad was wounded and in need of money. Eighteen months later, Bobrowski wrote a friend of Conrad's father that he had found Conrad saddled with debt and recovering from a self-inflicted wound, although he told everyone else that Conrad had been wounded in a duel. What actually happened can only be surmised. In the chapter "The Tremolino," in *The Mirror of the Sea*, Conrad tells how, with three others—an Englishman, an American, and a Provençal—he bought a 60-ton vessel, the "Tremolino," and, with Dominic Cervoni as master of the ship and Cervoni's nephew César, engaged in smuggling arms into Spain on behalf of the pretender Don Carlos. César Cervoni, however, betrayed Conrad and his associates, and to escape capture they drove the "Tremolino" on the rocks.

The gun-running episode also occurs in the late novel *The Arrow of Gold*, in which Conrad (the M. George of the novel) fights a duel with the American, Blunt, for love of the beautiful young Doña Rita and is wounded in the chest. The events related in "The Tremolino" and *The Arrow of Gold* were accepted as autobiographical by Conrad's wife and by his first biographer. Conrad himself allowed his family and friends to believe that the scar on his left breast was the result of a duel. Yet, his uncle Bobrowski would scarcely have written that Conrad had attempted suicide unless he had good reason for thinking so.

Whatever had happened, certainly Conrad was heavily in debt. Moreover, as a sailor in the French Merchant Navy he was liable to conscription when he came of age.

In April 1878, he signed on as a deckhand on the "Mavis," a British freighter bound for Constantinople with a cargo of coal. On the return journey, the ship, with a cargo of linseed, docked at Lowestoft, England, on the 18th of June. It was Conrad's first English landfall. Knowing no one in England and ignorant of the language, he spent three weeks in London and then joined the coaster plying between Lowestoft and Newcastle, on which he made six voyages. In the following October, he shipped as an ordinary seaman on a wool clipper, on the London-Sydney run.

**Career in the British merchant navy.** Conrad was to serve 16 years in the British merchant navy. In June 1880, he passed his examination as second mate, sailing as a ship's officer for the first time two months later on another wool clipper on the Australia run. He was back in London the following April, and five months later joined the "Palestine," a bark of 425 tons. This move proved to be an important event in his life; it took him to the Far East for the first time, and it was also a continuously troubled voyage, which provided him with literary material that he would use later. Caught in a gale, the "Palestine" was 15 days sailing from the Thames to the Tyne in the north of England and, on leaving, was rammed by a steamer and delayed another three weeks. Then gales forced her to put into Falmouth, where there was trouble with the crew; 30 seamen either deserted or were discharged. Months later, as the "Palestine" neared Java Head, her cargo of coal caught fire and the crew had to take to the lifeboats, so that Conrad's initial landing in the East, on an island off Sumatra, took place only after a 13-and-a-half hour voyage in an open boat. In 1898 Conrad published his account of his experiences on the "Palestine," with only slight alterations, as the short story "Youth," a remarkable tale of a young officer's first command.

He returned to London by passenger steamer and soon after spent a month with his uncle at Marienbad (now Mariánské Lázně). In September 1883, he shipped as mate on the "Riversdale," leaving her at Madras to join the "Narcissus" at Bombay. This voyage gave him material for his novel *The Nigger of the "Narcissus,"* the story of an egocentric Negro sailor's deterioration and death aboard ship. The winter of 1884 he was in London studying for his first mate's certificate. The next April he signed aboard a sailing ship bound for Singapore. From there, he wrote his earliest known letters in English, to a Polish émigré friend in Cardiff to whom he revealed his dissatisfaction with the sailor's life and discussed plans for going into whaling or commerce. Soon after his return to London, two notable events occurred: he became a British subject on August 19, 1886, and, three months later, obtained his master mariner's certificate.

He did not wait for a ship of his own before going to sea again. In February 1887, he sailed as first mate on the "Highland Forest," bound for Samarang, Java. Her captain was John McWhirr, whom he later immortalized under the same name as the heroic, unimaginative captain of the steamer "Nan Shan" in *Typhoon*. During the voyage, Conrad was disabled by a spar and went into the hospital in Singapore. Discharged, he joined the "Vidar," a locally owned steamship trading among the islands of the southeast Asian archipelago. During the five or six voyages he made in four and a half months, Conrad was discovering and exploring the world he was to re-create in his first novels, *Almayer's Folly*, *An Outcast of the Islands*, *Lord Jim*, and several short stories. He met Almayer himself and got to know him "pretty well"; he also met others who appear in his works under their own names—Tom Lingard, for instance, who was a well-known trader in the region.

After leaving the "Vidar," Conrad unexpectedly obtained his first command, of the "Otogo," sailing from Bangkok, an experience out of which he was to make his stories "The Shadow-Line" and "Falk." He took over the "Otogo" in unpropitious circumstances. The captain Conrad replaced had died at sea, and by the time the ship reached Singapore, a voyage of 800 miles that took three weeks because of lack of wind, the whole ship's

company, except Conrad and the cook, was down with fever. Conrad then discovered that his predecessor had sold almost all the ship's supply of quinine. At Singapore, he took on a new crew, went to Sydney, then sailed to Mauritius and then to Melbourne. He returned to England as a passenger on a steamship.

**Experiences in Africa.** Back in London in the summer of 1889, he took rooms near the Thames and, while waiting for a command, began to write *Almayer's Folly*. The task was interrupted by the strangest and probably the most important of his adventures. As a child in Poland, he had stuck his finger on the centre of the map of Africa and said, "When I grow up I shall go there." In 1889 the Congo Free State was four years old as a political entity and already notorious as a sphere of imperialistic exploitation. Conrad's childish dream took positive shape in the ambition to command a Congo River steamboat. Using what influence he could, he went to Brussels and secured an appointment. What he saw, did, and felt in the Congo are largely recorded in "Heart of Darkness," his most famous, finest, and most enigmatic story, the title of which signifies not only the heart of Africa, the dark continent, but also the heart of evil—everything that is corrupt, nihilistic, malign—and perhaps the heart of man. The story is central to Conrad's work and vision, and it is difficult not to think of his Congo experiences as traumatic. He may have exaggerated when he said that "before the Congo I was a mere animal," but in the real sense the dying Kurtz's cry, "The horror! The horror!" was Conrad's. He suffered psychological, spiritual, even metaphysical shock in the Congo, and his physical health was also damaged; for the rest of his life, he was racked by recurrent fever and gout.

Conrad was in the Congo for four months, returning to England in January 1891. He was in a hospital for some weeks and then visited a hydropathic establishment near Geneva, where he worked on *Almayer's Folly*. Back in London in the summer in a depressed state and unable to get a ship, he worked as manager of a waterside warehouse, which increased his depression. In November, he joined the "Torrens," a 1,300-ton clipper and one of the most famous passenger ships of the day, as first mate and made two voyages on her to Adelaide, Australia, and back, on the second of which he met a passenger who was to become one of his closest friends, the novelist John Galsworthy.

Back in London in July 1893, he found a letter from Bobrowski urging him to visit him. Within a month he was in the Ukraine, ill and being nursed by his uncle. On his return to London, he resumed *Almayer's Folly* and looked around for a ship. Offered the post of first mate on a ship scheduled to transport emigrants to Canada, he joined her at Rouen but, because no emigrants arrived, he returned to London in January 1894. Two weeks later, he heard that Tadeusz Bobrowski, the "wisest, firmest, most indulgent of guardians," as he was to call him, was dead.

**Termination of sea life.** Though he did not know it, Conrad's sea life was over. In the spring of 1894 he sent *Almayer's Folly* to the London publisher Fisher Unwin, whose reader, the critic Edward Garnett, soon to be Conrad's close friend, urged him to begin a second novel; so that, before *Almayer's Folly*, dedicated "To the memory of T.B.," was published in April 1895, he was already writing *An Outcast of the Islands*. It was as the author of *Almayer's Folly* that Conrad adopted the name by which he is known: he had learned from long experience that the name Korzeniowski was impossible on British lips.

*Almayer's Folly* achieved a *succès d'estime* only. The first edition consisted of 2,000 copies, and it was seven years before a third impression was called for. *An Outcast of the Islands*, published March 1896, had a comparable reception, though the anonymous reviewer of the *Saturday Review* called it "perhaps the finest piece of fiction that has been published this year, as *Almayer's Folly* was one of the finest that was published in 1895." The reviewer was H.G. Wells.

Three weeks after *An Outcast of the Islands* was pub-

lished, Conrad, aged 38, married the 22-year-old Jessie George, by whom he had two sons, Borys (1898) and John Alexander (1906). Inevitably, the nature and scope of his life changed, confined to the southeast corner of England with occasional forays abroad and reduced to the arduous and miseries of authorship, which were exacerbated by poor health, near poverty, and difficulties of temperament. Besides John Galsworthy, Edward Garnett, and H.G. Wells, from his earliest days as a writer he could count among his friends the writers Henry James, Stephen Crane, R.B. Cunninghame Graham, W.H. Hudson, Ford Madox Hueffer (later Ford Madox Ford), and Arnold Bennett, but his critical reputation was out of all proportion to his readership and even after the turn of the century he was still contemplating going back to sea.

It was not, indeed, until 1910, after he had written what are now considered his finest novels—*Lord Jim*, *Nostromo*, *The Secret Agent*, and *Under Western Eyes*, the last three novels of political intrigue and romance—that his financial situation became relatively secure. He was awarded a Civil List pension of £100. The American collector John Quinn began to buy his manuscripts—for what now seem ludicrously low prices, as they did to Conrad himself when Quinn put them on the market in New York in 1923. In 1910 also the *New York Herald* asked him for a novel for serialization. He thereupon went back to *Chance*, which he had put aside unfinished five years earlier. Serialization began in January 1912, and when the novel was published in London two years later its American success was repeated. *Victory*, published in 1915, was no less successful, but it was not until his best work had been done that he became a popular or even fashionable author.

He was in Cracow, then in Austria, when war broke out in 1914, but was enabled to return to England by the good offices of the American ambassador to Vienna. "This war," he said, "attends my uneasy pillow like a nightmare." He was too old and unwell for active service and found writing increasingly difficult, though, in order to write articles on the war at sea, he did make some short trips on minesweepers and even a flight in a naval airplane. His relief, when the fighting ended, was offset by his pessimism about the future: he found an "awful sense of unreality" in President Wilson's idealistic postwar plans, was horrified when the Bolsheviks were invited to send delegates to the peace conference, and inflamed in his patriotism when the Red Army attacked the new republic of Poland.

In 1919 he settled at Oswalds, Bishopsbourne, near Canterbury. In 1923 he visited the United States as the guest of his publisher and enjoyed a reception in New York appropriate to his status as one of the most famous of living novelists. He crossed on ocean liners, but the inveterate sailor regarded them with contempt as "nothing but locomotives." By now he was a sick man. In March 1924, he sat for the splendid portrait bust of him by Sir Jacob Epstein, who records in his autobiography that Conrad "was crippled by rheumatism, crotchety, nervous, and ill." A month or so later he refused the offer of a knighthood from the prime minister, Ramsay MacDonald. He died on August 3, 1924, after a heart attack and was buried at St. Thomas' Roman Catholic Church, Canterbury. His second name, Teodor, is spelled incorrectly on the tombstone.

**Character and reputation.** Devoted to England though he was, Conrad was very much an exotic in the English scene. "He had the most perfect manners," the writer Virginia Woolf recalled on his death, "the brightest eyes, and spoke English with a strong foreign accent." His perfect manners, the evidence suggests, were the counterpart of a temperament of extreme sensibility, one irascible and quick to take offense. He was the most formal of men, which made it difficult for him to come to terms in the ordinary traffic of life with men like Shaw and Wells, for whom formality meant nothing. Perhaps the most vivid impression that remains of him, and certainly the noblest, is from a man who on the surface would seem to have nothing in common with him except aristocratic

Illness

lineage. Bertrand Russell met him in 1913, saw him infrequently, but was so impressed with him that eight years after their initial meeting, he sought permission to name his first son Conrad. Russell sums up the novelist's vision in these words: "he thought of civilised and morally tolerable life as a dangerous walk on a thin crust of barely cooled lava which at any moment might break and let the unwary sink into fiery depths," and concludes his brief memoir, "His intense and passionate nobility shines in my mind like a star seen from the bottom of a well."

Conrad's influence on later novelists, William Faulkner in the United States, André Malraux in France, and Graham Greene in England, has been profound, not only because of his masterly technical innovations but also because of the vision of man expressed through them. He is the novelist of man in extreme situations. "Those who read me," he wrote in his preface to *A Personal Record*, "know my conviction that the world, the temporal world, rests on a few very simple ideas; so simple that they must be as old as the hills. It rests, notably, among others, on the idea of Fidelity." For Conrad, fidelity is the barrier man erects against nothingness, against corruption, against the evil that is all about him, insidious, waiting to engulf him, and that in some sense is within him unacknowledged. But what happens when fidelity is submerged, the barrier broken down, and the evil without acknowledged by the evil within? At his greatest, that is Conrad's theme.

#### MAJOR WORKS

NOVELS: *Almayer's Folly* (1895); *An Outcast of the Islands* (1896); *The Nigger of the "Narcissus"* (1897); *Lord Jim* (1900); with F.M. Hueffer (Ford), *The Inheritors* (1901) and *Romance* (1903); *Nostromo* (1904); *The Secret Agent* (1907); *Under Western Eyes* (1911); *Chance* (1913); *Victory* (1915); *The Shadow-Line: A Confession* (1917); *The Arrow of Gold* (1919); *The Rescue* (1920); *The Rover* (1923); with F.M. Ford, *The Nature of a Crime* (1924).

SHORT STORIES: *Tales of Unrest* (1898); *Youth: A Narrative, and Two Other Stories*, "Heart of Darkness" and "The End of the Tether" (1902); *Typhoon and Other Stories* (1903); *A Set of Six* (1908); *Twixt Land and Sea* (1912); *Within the Tides* (1915); *Tales of Hearsay* (1925).

OTHER WORKS: *The Mirror of the Sea, Memories and Impressions* (1906); *Some Reminiscences* (1912; U.S. title, *A Personal Record*, 1912); *Notes on My Books* (1921); *Last Essays* (1926).

## Consanguinity

Consanguinity is the sharing of some common ancestors. The word is derived from the Latin *consanguineus*, "of common blood," which implied that Roman individuals were of the same father and thus shared in the right to his inheritance. Kin are of two basic kinds: consanguineous (sharing common ancestors) and affinal (the kinsmen of one's spouse). In some societies other pairs of in-

dividuals also treat each other as relatives—for example, the wives of a pair of brothers, relatives by adoption, and persons such as godparents who have special *kinlike* relationships (fictive kin). Consanguineous kinship is a universal type; it includes those with common ancestors and it excludes individuals who lack ancestors in common.

In the modern sense, consanguinity is a genetic concept. From the biological point of view the term itself is unsuitable (as are the terms mixed blood and good blood) because the genetic contributions of ancestors do not flow to their descendants as blood, but through the genes contained in the chromosomes in the cell nuclei. The chromosomes are made up of nucleic acids (DNA, or deoxyribonucleic acid) and proteins. The DNA is the part of the chromosome that carries the genes and is coded in specific ways to produce and control protein synthesis; parts of each parent's coded message are transmitted to the offspring. Besides genetic determinants carried in the DNA, there are other biological influences of parents on offspring, such as the environment in the mother's womb; indeed, there is even cultural inheritance through learning, which in turn influences nutritional and other habits and hence affects growth and development. In genetics, consanguinity affects the probabilities of specific genotypes—the combinations of genetic characteristics. Consanguinity results in inheritance, from common ancestors of both parents, of their transmissible capacities to synthesize and control nucleic acids and proteins, the essential substances of all organisms.

Consanguineous relatives are said to be of various degrees, according to the likelihood of their sharing genetic potentialities from the common ancestors. Thus, pairs of brothers and sisters (siblings) have all the same ancestors, whereas pairs of first cousins (cousins germane) who are not otherwise related share only one-half of their ancestors. A child inherits only about one-half of the coded information from each parent; hence a pair of brothers or sisters have about half of their chromosomal constitution in common (the doubt about the exact fraction is due to the chance element in transmission of material during meiosis, the cell division that produces sperm and egg).

Genetically the degree of consanguinity of siblings is thus the same as that between a parent and child, and both may be called consanguineous in the first degree. An aunt or uncle shares with his niece or nephew about half the chance of common inheritance of a pair of siblings, and aunts and uncles may be called consanguineous kin of the "second degree." First cousins may be called consanguineous of the "third degree."

Legal systems of designating degrees of consanguineous kin exist in Roman law, common law, and canon law. None of these systems depends on the genetic facts, however, and they have no place in a classification of the biological relationships between individuals.

A great-grandfather and great-grandson are genetically related to the same degree as a pair of first cousins. The grandparent is a linear kinsman, however, whereas the cousin is a collateral one. In genetics the degree of consanguinity is the sole factor of significance, but in social relations in various societies important considerations of collateral versus lineal types of relationship as well as age, birth order, and other factors may determine social behaviour. In fact, consanguineous kin of various degrees and even nonconsanguineous kin may be called by the same name and treated similarly by custom or law (the term uncle, for instance, may be applied to a grand-uncle or to the husband of an aunt).

One of the two main applications of data on consanguinity is with respect to the probability that two individuals of a known degree of consanguinity with another individual will share the traits of that person. This probability depends upon the mode of inheritance and on the degree of penetrance or expressivity of genetic factors. The mode of inheritance may, for example, be dominant or recessive. A pair of genes in the same relative positions in a set of two chromosomes in the cell nucleus (these genes are called alleles) are for two alternative traits, such as greenness and yellowness in peas; both alleles

Degrees of consanguinity

may be for one of the traits, or they may differ, so that one allele is for one trait and one for the other. The trait that appears—is "expressed"—in an individual, when the pair of alleles differ, is the dominant trait and the inheritance is dominant; if a trait does not appear unless both alleles are for that trait, it is recessive. Another mode of inheritance is sex-linked inheritance. Genes for hemophilia, for example, are present in both males and females, but the disease tends to affect only males. The degree of penetrance is the frequency with which any trait or effect is shown in a group or population that has the gene corresponding to that trait. Expressivity is the degree to which traits are shown in an individual.

**Inbreeding** Another significant application of data on consanguinity is the measurement of inbreeding by the degree of consanguinity between two parents. The coefficient of inbreeding ( $F$ ) is used. This is the probability that two alleles will be identical and derived from the same forebear. The application of this principle is most easily demonstrated by example. If brother and sister marry, the offspring would have one chance in four of inheriting a pair of identical alleles from the grandparent. With each further degree of consanguinity the likelihood is halved, so that the likelihood in the child of a mating between aunt and nephew would be one in eight, and in a child of first cousins, one in 16.

In construction of pedigrees, if horizontal lines are used to connect symbols of siblings and mates and vertical lines to connect parents with their offspring, all inbreeding is represented by one or more loops (see the Figure);

(Left) Absence of inbreeding: horizontal lines connect mates, vertical lines connect parents with their child. (Right) An inbreeding loop: the horizontal bar at the top of the loop connects brother and sister; all other lines and bars as at left.

and each loop involves consanguinity. The coefficient of inbreeding for the individual is the sum of that calculated for all the loops that include his parents. The inbreeding coefficient of a population is the average  $F$  of its members. The highest values of  $F$  are found in small populations whose members marry one another over many generations. Such groups are called isolates. Thus, the Samaritans, who remained a small but distinctive group since before the time of Christ, are considerably inbred. In the United States some religious groups also live in agricultural colonies as isolates (for instance, the Amish and Hutterites).

**Effects of consanguinity.** In genetics an allele that is carried at the same position in both of a pair of chromosomes is called homozygous. An allele may be rare in the general population, but, if the parent possesses it, it is transmitted from parent to child with the same probability as a common one. Therefore the chance of receiving a rare allele in the chromosomes derived from both mother and father—that is, the chance of being homozygous for that allele—is greatest in the offspring of consanguineous mating. In theory, since repeated mutations are rare, homozygosity of even common alleles may be ascribed to distant consanguinity.

Mendel's classical experiments with peas and much subsequent work show that when an allele is present in double dose (homozygous), the effects may be very different from those when it is inherited only from one parent (heterozygous). In medical genetics there are many proteins, especially enzymes, that are produced in adequate amounts if either chromosome carries the appropriate allele. Absence of the gene in both of a pair of alleles produces a deficiency in the protein it determines. The rare diseases and anomalies of this kind are relatively less rare in the offspring of consanguineous unions. In fact, in 1902, within two years after the rediscovery of Mendel's laws, the high frequency of consanguinity in the parents of individuals with three inborn errors of metabolism was used as evidence of recessive Mendelian inheritance in man. One of the defects noted was albinism, a condition in which the skin is pink and the hair white, the eyes lack pigment, and the subjects are uncomfortable in bright sunlight and usually squint. Such adverse genetic effects in the offspring of consanguineous unions is appreciable only in rare hereditary diseases; the rarer the occurrence, the more frequently the parents are found to be consanguineous. A large proportion of offspring of consanguineous mating of the first degree die or have serious defects by six months of age. In the offspring of first-cousin marriages and in other instances of similar or lesser consanguinity, few deleterious effects have been observed. Furthermore, because rarity is a factor in this effect, the overall influence of inbreeding in the general population is very limited. The modest socioeconomic differences between the kinds of people who mate with consanguineous kin and those who do not may account for some of the increase in disease and mortality that has been ascribed to consanguinity.

From the social, as opposed to the individual, point of view, close inbreeding does not increase the number of deaths from recessive disease; it merely precipitates these so-called genetic deaths in earlier generations. In heterozygous form, with no adverse influence on the individual who carries them, such alleles contain the possibility of future deaths from recessive disease; and death for infant offspring of consanguineous parents reduces that possibility for the next generation. The principle of deliberate inbreeding is used with domestic animals to eliminate such covert recessive alleles from the stock. Nevertheless, there seem to be problems of health from very highly inbred "pure" lines, and heterozygosity in some alleles seems to be advantageous. Many species, including man, have been established by episodes of isolation and inbreeding interspersed with outbreeding; they apparently thrive in this way.

**Legal and social considerations.** All human societies have some incest taboos. These are rules and laws that prohibit marriage or sexual relations, or both, between certain kinds of kin. The kinds of kin always include some consanguineous classes, and one theory of the establishment of incest laws is folk knowledge of undesirable inbreeding effects in offspring of such unions. Incest taboos are not uniform restrictions to a particular grade, however, and often extend to nonconsanguineous relations. Thus, in traditional Chinese society a man may marry his mother's brother's daughter, for instance, but he may not marry any person with his own surname. Other theories of the origin of incest, therefore, include analysis of its effects on stability of the family as an economic and educational unit and ascribe the definition of incest in various societies to social and psychological motives.

**BIBLIOGRAPHY.** The genetic aspects are well covered in C. STERN, *Principles of Human Genetics*, 2nd ed., ch. 19 (1960); the classic social study is L.H. MORGAN, "Systems of Consanguinity and Affinity of the Human Family," *Smithson. Contr. Knowl.*, vol. 17, no. 218 (1870). Perhaps the most extensive study of inbreeding is W.J. SCHULL and J.V. NEEL, *The Effects of Inbreeding on Japanese Children* (1965); some evidence of the deleterious effects of close inbreeding is contained in M.S. ADAMS and J.V. NEEL, "Children of Incest," *Pediatrics*, 40:55-62 (1967).

(G.W.L.)

## Conservation Laws and Symmetry

Conservation laws in physics state that certain measurable quantities, called physical properties, do not change in the course of time within an isolated physical system. Common examples are the conservation laws of electrical charge, mass–energy, and linear and angular momentum. The existence of conservation laws is directly related to the symmetry of the laws of nature; *i.e.*, to their **invariance** or changelessness under various symmetry operations such as rotations, translations, and reflections of the spatial and temporal coordinates.

### GENERAL CONSIDERATIONS

The most familiar law of conservation concerns matter. A clearly stated philosophical recognition that certain aspects of matter might remain unaltered through every conceivable kind of transformation was first made, according to some interpretations of his works, by the Greek philosopher Anaxagoras (c. 450 BC). The principle was reiterated from time to time by such natural philosophers as Sir Francis Bacon (1620), but the first scientific statement of it was made toward the end of the 18th century—on the basis of precise observations of chemical reactions—by Antoine Lavoisier, the French chemist. This law of conservation of matter may be stated as follows: the sum total of matter in the universe cannot be changed; *i.e.*, matter can neither be created nor destroyed. The next concept of conservation concerned energy, which, by the middle of the 19th century, had become mathematically definable. The law of conservation of energy merely substitutes the word energy for the word matter: the sum total of energy in the universe remains unchanged no matter what events take place; *i.e.*, energy cannot be created or destroyed. Eventually, after Einstein posited the equivalence of matter and energy, these two conservation laws had to be restated into the law of conservation of matter and energy: the sum total of matter and energy in an isolated system remains the same.

Familiar  
symmetry

The concept of symmetry is familiar from such figures as a circle or square in elementary geometry because they can be made to coincide with themselves under the operation of rotation. Other kinds of symmetry are revealed in the behaviour of subatomic particles.

The underlying basis for the existence of all conservation laws in macroscopic physics—*i.e.*, the physics of bulk matter—can be shown to be the geometric symmetry of space, which can be extended to include time as another dimension. In microscopic physics—*i.e.*, physical phenomena at or below the atomic level of magnitude—the same symmetry-based conservation laws apply, but here they play an even more important role; they account for the transport or propagation of such quantities as energy and electric charge. Finally, in the theory of subatomic particles, which must be treated according to quantum mechanical symmetry operations (a mathematical description of the behaviour of subatomic systems undergoing rotations, reflections, and translations, not only in real space–time but in certain abstract spaces), the application of symmetry operations leads to a classification of the particles and their interactions with each other and to a number of new conserved quantities that have no macroscopic counterparts.

This whole subject, clearly, involves modern physics, and in a brief discussion such as this it is impossible to provide the necessary mathematical background that supports concepts and physical details. Thus, in this article, the nature of conservation laws and symmetry can be treated only generally. (For more detailed and technical treatment, see **ATOMIC STRUCTURE; PARTICLES, SUB-ATOMIC; NUCLEUS, ATOMIC; GEOMETRY, EUCLIDEAN; GEOMETRY, PROJECTIVE; ALGEBRAIC STRUCTURES; MECHANICS, CLASSICAL; MECHANICS, QUANTUM; RELATIVITY.**)

Geometrical symmetry. Of Greek origin, the word symmetry at first had the meaning "balanced proportions, or beauty of form arising from such proportions," but in later usage, it took on a more precise geometrical meaning. For example, an object is said to have bilateral

symmetry if there is a median plane such that the left half of the object is the exact mirror image of the right half. If any two-dimensional curve is rotated about an axis lying in its plane, the resulting three-dimensional figure is said to possess cylindrical symmetry or rotational symmetry about the axis. Other examples of this concept are rotational symmetry about a point (spherical symmetry) and the symmetries possessed by the regular polygons (equilateral triangle, square) in a plane, or the regular solids (polyhedrons) in space.

Geometrical symmetries are characterized by a set of mathematical operations that can shift a figure but leave it undistinguishable from itself in its former position, called the group of symmetry transformations. To illustrate, any regular polygon, a closed plane figure bounded by straight lines, may be considered, with its corners labelled counterclockwise *A, B, C*, etc. If the polygon has *n* sides, then in the symmetry operation, rotating the polygon counterclockwise about its centre will bring the polygon into congruence (coincidence) with itself a certain number of times. For example, if the polygon is a square, there are four sides ( $n = 4$ ), and therefore there will be congruences when the figure is rotated  $\frac{1}{4}$ ,  $\frac{2}{4}$ , and  $\frac{3}{4}$  times 360°; *i.e.*, 0°, 90°, 180°, and 270°. In general terms, if *m* is any integer that is equal to 0, or 1, or 2 through (*n* – 1), then congruence will take place by rotating the polygon (*m/n*) times 360°. Each rotation is thus a member, or element, of a symmetry group.

Polygon  
rotations

Another set of congruences of the regular polygon is obtained by considering reflection, as in a mirror. In such a case, the counterclockwise labelling *A, B, C*, etc., would appear to be clockwise. Thus, reflection in one of the planes of bilateral symmetry is an operation that changes the ordering of the labels *A, B, C*, etc., from counterclockwise to clockwise.

If, instead of the polygon, one considers a circle, any rotation about its centre will bring the circle into itself if one imagines its points to be ordered counterclockwise.

It is possible also to consider translational symmetry, by which a straight line is carried into congruence with itself (*i.e.*, slid along its length), and dilatational symmetry, which results in a consideration of similarities rather than mere congruences, such as a square within a square.

Symmetry in art and nature. Many examples of all these symmetries can be found both in art and in nature. One- and two-dimensional translation symmetry are frequently found in friezes and wallpaper patterns if these are imagined to be continued indefinitely. Columns and rosette decorations possess rotational symmetry, as do some entire buildings and monuments. Biological forms frequently possess bilateral or rotational symmetry and, in the case of such free-floating microscopic animals as the radiolarians, even have the shapes of the regular polyhedrons. Some molecules, as well as the external forms of most minerals, exhibit the symmetries of crystals; *i.e.*, combinations of rotations and reflections. These external crystalline forms arise from the symmetrical arrangements of the atoms within the smallest or unit crystal cell, which, in turn, is repeated three-dimensionally throughout the volume of the crystal in a symmetrical way to form a periodic lattice (see **CRYSTALLOGRAPHY**).

The arrangements of the atoms in the unit crystal cell, and its repetition in the lattice, determine its electrical, optical, acoustical, and other physical properties. In the case of magnetic materials, a given magnetic state can be reversed by reversing all currents, the effect being the equivalent of the exchange of north and south poles of the magnetic crystal. The magnetic crystal can be restored to its original state by a combination of this operation, called time-reversal operation, *T*, and one of the geometrical operations described above. There are 32 types of crystals, or point groups, that exhibit symmetry in the absence of a time-reversal operation and 58 more that require an additional time-reversal operation, giving a total of 90 magnetic-symmetry groups.

### SYMMETRY AND THE LAWS OF PHYSICS

From the earliest days of natural philosophy (Pythagoras in the 6th century BC), symmetry has furnished insight

Derivation  
of conservation  
laws from  
symmetry

into the laws of physics and the nature of the cosmos. The two outstanding theoretical achievements of the 20th century, relativity and quantum theory, involve notions of symmetry in a fundamental way. Einstein's special theory of relativity can be economically stated as the invariance (that is, unchanging form) of the laws of physics under a continuous group of symmetry transformations known as the **Poincaré** (or inhomogeneous **Lorentz**) group. It is notable that in quantum theory every symmetry yields a conservation law; *i.e.*, for every symmetry operation that leaves the laws invariant, there exists a measurable physical property (*e.g.*, charge) of an isolated or undisturbed system that does not change during the development of that system in the course of time.

Some of these conservation laws can also be deduced in classical physics, in which they are closely related to the classical laws of physics. For example, the physics of Galileo and Newton states that the total linear momentum of a system (the sum of the linear momenta, mass times velocity, of each mass point) is constant, providing that the system is not acted upon by an external force. This conservation law is related to the translational symmetry of geometrical space, as can be seen intuitively by considering a two-dimensional analogy: on a huge, flat, smooth, horizontal table, a flat object is sliding without friction; until the edge is reached, nothing will act to change the momentum. If the table is curved, tipped, or rough, however, or if it contains holes, the momentum will not be conserved; for then the system will be acted on by an external force, gravity or friction. Similarly, a three-dimensional space in which the law of conservation of momentum holds contains by analogy no roughness, curvature, edges, or other local features to disturb the motion. That is, each part of empty space is assumed to be like every other part. Similarly, every direction in empty space is assumed to be equivalent to every other direction, a complete rotational symmetry, the consequence of which is the conservation of the quantity called angular momentum, a physical property of a body having magnitude and direction that is related to its mass and angular velocity. These symmetries assumed for the geometrical space are summarized by saying that the space is homogeneous (translational symmetry) and isotropic; *i.e.*, has properties with the same values when measured along axes in all directions (rotational symmetry).

In relativity, and in classical theory as well, time can be imagined as a fourth dimension, distinct from the three dimensions of ordinary space. If the laws of physics are assumed to be the same at different times, they are said to be invariant under translations in time. The consequence of this assumption can be shown to be the conservation of energy. Finally, if it is assumed that the laws of physics are unchanged and that the velocity of light is constant for observers moving with any constant relative velocity, the result is the special theory of relativity in which, for example, moving objects appear contracted in length and their masses appear to increase, and moving clocks appear, to an observer outside the moving frame of reference, to run more slowly (see RELATIVITY).

**Conservation of mass and energy.** Perhaps the best known result of the special theory is Einstein's relation, which states that the total energy (*E*) of an isolated system is equal to its mass (*m*) times the square of the velocity (*c*) of light:  $E = mc^2$ . The total energy includes the kinetic energy of the particle so that the mass represents the increased mass caused by the motion; *i.e.*, relativistic effect. Two separate conservation laws of classical physics, that of mass and that of energy, are thus united into a single conservation law—that of mass-energy. Particles held together by mutually attractive forces—*e.g.*, neutrons and protons bound together in the atomic nucleus—have a total mass smaller than that of their separate masses, whereas particles repelling each other have a larger mass. Indeed, the stability of the nucleus is based upon the fact that energy must be supplied to separate it into its parts. In the case of certain nuclei, such as the naturally occurring uranium-235 nuclei, which are heavier than the two parts (other nuclei) into which it can

split, the nucleus is unstable and undergoes spontaneous fission with the release of a considerable amount of energy.

**The subatomic particles.** It will be helpful to review the forces, or interactions, that prevail between subatomic particles, which have symmetries. The most familiar of the subatomic, or elementary, particles (see PARTICLES, SUBATOMIC) are the proton and neutron, constituents of the nucleus of the atom and called nucleons, and the electron. A simple lettering system is used in discussing these: an atom of mass number *A* (equal to the sum of neutrons and protons) has an atomic number *Z* equal to the number of protons in its nucleus, each proton having a single positive electrical charge; the number of electrically neutral neutrons is, then, *A* − *Z*. In a normal atom, the nucleus is surrounded by electrons, *Z* in number, each having a single negative electrical charge. The nuclear particles (nucleons) are much heavier than the electron, the proton being 1,836.1 times as heavy and the neutron being slightly heavier than the proton. Many other subatomic particles are known and some are listed in Table 1 with their masses given in energy units as millions of electron volts (MeV) according to the relation  $E = mc^2$ .

Because every elementary particle has wavelike properties (see MECHANICS, QUANTUM), its size is not well defined but depends upon its mass, its interaction properties, and its state of motion. A measure of the size of one of the massless particles listed in Table 1 is furnished by its wavelength (represented by the Greek lambda,  $\lambda$ ), the value of which can be obtained by combining Planck's relation that a quantum of energy (*E*) is equal to a constant (*h*) times the frequency (represented by the Greek nu,  $\nu$ ) of the wave that it represents, or  $E = h\nu$ , with the simple wave equation that the product of a wave's frequency and wavelength is constant, or  $\lambda\nu = c$  (*E* being its energy, *h* Planck's constant of action,  $\nu$  the wave frequency, and *c* the speed of light). This equation yields a wavelength ( $\lambda$ ) equal to the product of Planck's constant and the velocity of light divided by the energy of the particle, namely,  $\lambda = hc/E$ . The same measure applied to the particles with mass of the lepton group (*e.g.*, electron and muon), gives, upon substitution of the mass-energy equivalent ( $mc^2$ ) for the total energy *E* in the above equation, a quantity known as the Compton wavelength,  $\lambda_c = h/mc$ . Although the Compton wavelength is a good measure of the particle size when its velocity is large, at lower velocities the Heisenberg indeterminacy principle (which states that uncertainty in the momentum of a particle multiplied by its uncertainty in position is greater than or equal to  $h/4\pi$ ) prevents specifying its position anywhere within a radius of one de Broglie wavelength; *i.e.*, the wavelength associated with a particle,  $h/mv$ , in which *v* is the speed of the particle and *m* is its mass. Thus in the hydrogen atom, the "size" of the electron is roughly the size of the atom itself (about  $10^{-8}$  centimetre in diameter).

Atomic  
mass and  
atomic  
number

Table 1: Some Elementary Particles			
particle	symbol	spin (units of $\hbar/2\pi$ )	rest mass ( $mc^2$ in MeV)
Graviton	<i>g</i>	2	0
Photon	$\gamma$	1	0
Leptons			
Neutrino (electron)	$\nu_e$	$\frac{1}{2}$	0
Neutrino (muon)	$\nu_\mu$	$\frac{1}{2}$	0
Electron	$e^-$	$\frac{1}{2}$	0.5111
Muon	$\mu^-$	$\frac{1}{2}$	105.7

3 − 3 resonance ( <i>S</i> = 0)	$\Delta$	$3/2$	1,236.0

Strong  
interaction

In the case of the particles that respond to nuclear forces—that is, strongly interacting particles (called **hadrons**), including baryons and mesons (see Table 1)—their size is taken as the distance over which they can interact with other particles, about  $10^{-13}$  centimetre. This distance, which can be measured experimentally, is called the Fermi unit. These particles have the ability to emit and reabsorb numbers of other hadrons and may be visualized by thinking of each hadron as having surrounding "clouds" of other hadrons. For example, the proton "size" is nearly the Compton wavelength of the pion, which is equal to  $h/mc$ , Planck's constant divided by the velocity of light times the pion's mass, which forms the most extended cloud.

**Quantum statistics.** In quantum mechanics a system of particles is described by a mathematical expression known as a wave function. When two or more particles of the system are of identical type, that wave function must remain unchanged or, at most, change sign when the coordinates of the two particles are exchanged in the function. Wave functions, which change sign through exchange, are said to have odd exchange symmetry or to be antisymmetric; if they do not change sign they have even exchange symmetry and are said to be symmetric. If two identical particles have an antisymmetric wave function they are said to obey Fermi–Dirac statistics; if their wave function is symmetric, they are said to obey Bose–Einstein statistics.

**Spin properties.** Another important property of an elementary particle is its intrinsic angular momentum, or the spin it has about its own axis, measured in units of Planck's constant divided by  $2\pi$ , or  $h/2\pi$ , that can be represented by a vector (an arrow symbolizing magnitude and direction). This spin is always one of the values 0,  $1/2$ , 1,  $3/2$  . . . (*i.e.*, either integer or half-integer) allowed by quantum mechanics. Identical particles with half-integer spins (leptons and baryons) have what are called Fermi–Dirac statistics and obey the Pauli exclusion principle; *i.e.*, a given quantum state in a system can be occupied by at most one of a set of identical particles. In consequence, these particles form systems having layered or shell structure (neutron and proton shells in atomic nuclei, electron shells in atoms). Particles with integer spins have a different type of statistics, called Bose–Einstein statistics, which tends to concentrate identical particles in the same state (*e.g.*, photons of light in a laser beam. The same distinction as to statistics applies to identical agglomerates of elementary particles. Total spin of an atomic nucleus depends on the spins of the constituent particles; when the total spin is integral (*e.g.*, that of the helium isotope with mass 4, helium-4) the nucleus obeys Bose–Einstein statistics, whereas when the total spin is half-integral (*e.g.*, the isotope of helium with mass 3, helium-3) it obeys Fermi–Dirac statistics.

**Magnetic properties.** An important property of electrical charges possessing angular momentum is magnetic moment; *i.e.*, magnet-like behaviour. Even electrically neutral spinning hadrons (see Table 1), like the neutron, possess magnetic moments—another indication that they have internal structure. This structure may be due to electrically (but not magnetically) compensating clouds of mesons or, possibly, to the circulation of other more elementary constituents.

**Forces within the nucleus.** In order to clarify the notions of range and strength of interaction mentioned above, it is necessary to deal with the forces found within the nucleus. They are the electrostatic force between charged particles (like charges repel, unlike attract), also common to macroscopic physics, and two nuclear forces (called strong and weak) found only in subatomic physics. While it is possible to begin with the electrostatic interaction of two point charges ( $e_1$  and  $e_2$ ), separated by a distance  $r_{12}$ —that is, the charges can be said to attract or repel each other with a force equal to the product of the electrostatic charges divided by the square of their distance of separation, or  $e_1 e_2 / r_{12}^2$ —it is more convenient to consider their potential energy (or what is called their Coulomb interaction energy), which is simply the product of the charges divided by the distance to the first

power, namely,  $e^2/r_{12}$ . If the charges are in motion relative to each other, the force is much more complicated (see **MAGNETISM**) but is always proportional to the charges, which, in that sense, measure the strength of interaction. In the case of the strong nuclear forces, the laws analogous to those of electricity—that is, of moving charges or electrodynamics—are unknown, although they are thought to be at least as complicated as those of electricity. In the following section, interactions are stated mathematically.

**Mathematical formulations of interactions.** An approximation of the nuclear force between two stationary nucleons, however, can be represented as the product of the strengths of interaction ( $g_1$  and  $g_2$ ) divided by the distance of separation ( $r_{12}$ ) between them, times the exponential value of minus the ratio of the separation to the range ( $\lambda$ ) of the force; *i.e.*, the approximate distance of separation at which the nuclear force becomes relatively small:  $g_1 g_2 / r_{12} \exp(-r_{12}/\lambda)$ . This form for the potential energy, known as the Yukawa interaction, was proposed in analogy to the quantum theory of moving charges, or electrodynamics, which considers the electromagnetic interaction as being caused by the exchange of photons (a quantum of energy, or the particle form of electromagnetic radiation) between electric charges. In Yukawa's theory, these field quanta, known as mesons, analogous to the photons in quantum electrodynamics, have a mass  $m$  intermediate between that of electron and proton and the range of the force that they carry is  $\lambda$ , equal to their Compton wavelength divided by  $2\pi$ —that is, equal to Planck's constant divided by the product of  $2\pi$  times meson mass times the velocity of light, or  $\lambda = h/2\pi mc$ .

In this last equation, if the mass of Yukawa's meson is set in million electron volts equal to 140 divided by the velocity of light squared ( $m = 140/c^2$ ), the observed mass of the pion (from  $mc^2 = E$ ), a Compton wavelength for the meson equal approximately to  $10^{-13}$  centimetre is obtained, which agrees with the observed range of nuclear forces. Also, if the strengths of interaction are set equal to a coupling constant ( $g$ )—that is,  $g_1 = g_2 = g$ , in which the coupling constant measures the strength of the meson interaction with the nucleon-experiment gives a dimensionless measure of the interaction between nucleons a value ( $g^2/2hc$ ) of approximately 15.

In the electromagnetic theory, from which the meson analogy was drawn, the electric charges measure the strength of coupling of the photon to its source, the charged particle. For two electrons, equating  $e_1 = e_2 = -e$ , the analogous dimensionless measure of the strength of electrical forces ( $e^2/2hc \approx 1/137$ ) of approximately  $1/137$  is obtained.

**Comparison of forces.** In comparing the above strengths of interactions, the nuclear forces are seen to be hundreds of times stronger than electrical forces. Because the mass of the photon is zero, the range of force ( $\lambda$ ) is infinite, and examination of the Yukawa equation for nuclear interaction shows that it tends to the (Coulomb) interaction equal to the coupling constant squared divided by the separation ( $g^2/r_{12}$ ) when the range tends to infinity. (A similar quantum field theory of gravitation can be formulated, the massless field quantum analogous to the photon being called the graviton. The range of force is again infinite and the source of the quanta is the particle's mass. No dimensionless measure of the strength exists, but in the physics of elementary particles, the gravitational forces between particles are about  $10^{40}$  times weaker than the electrical forces and thus negligible.)

In addition to the pion, more than 20 heavier mesons have been identified experimentally, and it is probable that there are many others not yet observed. Each of these mesons can serve as the quantum of a field having shorter range than the pion field, so that the account given in the previous paragraph describes only the longer range part of the nuclear force. In high-energy scattering experiments, which probe the inner nucleon structure, a complicated set of forces is revealed. The mathematical description of this "shape" of the nucleon, revealed by using a beam of high-energy electrons as an electromagnetic probe, is called the nucleon form factor.

Yukawa  
potential

Shell  
structures

Nucleon  
shape

**Weak interaction.** Another type of nuclear force, the weak interaction, has a range so short that the corresponding field quantum would have to be at least several times as massive as the proton. This conjectured particle, called a weak boson (or W-meson), has been searched for using high-energy accelerators but so far has eluded observation. As in the case of gravitation, no dimensionless measure of the strength of weak interactions is possible, but it is roughly  $10^{12}$  to  $10^{14}$  times weaker than the strong nuclear forces.

To summarize, three types of force are important in the atomic and subatomic domain: electromagnetic forces, and strong and weak nuclear forces. Their ranges and strengths differ greatly. Particles that participate in strong interactions are called hadrons (mesons and baryons); the others are leptons. The photon is exceptional, being neither a hadron nor a lepton. Both baryons and leptons have weak interactions. All particles that have either electric charge or electric-charge structure (such as the neutron) have electromagnetic interactions. As will be seen below, each type of interaction has its characteristic symmetry properties, and, corresponding to the hierarchy of interactions, there is a remarkable hierarchy of symmetries such that the stronger the interaction the more symmetrical it is.

**Relationship of quantum theory to conservation laws.** In the elementary particles, quantum theory and the special theory of relativity play pre-eminent roles. Conservation laws and their related symmetries become most important. Some reasons for this may be briefly stated:

1. The equations of motion from classical mechanics are known; thus while the recognition of the symmetries they imply is aesthetically satisfying and often provides a powerful analytical method, the laws in themselves are already complete and nothing essentially new is added. In those parts of quantum theory in which the laws are only partially known, however, an attempt is often made to find those predictions that follow only from accepted (or assumed) symmetry principles and conservation laws.

2. Quantum theory is usually applied to the simpler systems, such as crystals, molecules, atoms, nuclei, and elementary particles, in which intrinsic symmetries are more readily observable. Also, there are more symmetries in quantum theory than in classical theory.

3. Classical physics can be considered as a special application of quantum physics when the effect of the constant of action  $h$  (Planck's constant) is negligible; that is, in the limiting case, when the effect of Planck's constant tends to zero, the separation between states of definite energy tends to zero, so that a classical state is an ensemble of many quantum mechanical states. For example, an elementary magnet in a uniform magnetic field is restricted to one of a finite set of discrete orientations in quantum theory, whereas in classical theory it may have any orientation whatsoever. When the number of possible orientations is small, powerful restrictions can be placed on the internal complexity of the system because of symmetry principles, whereas in classical theory this is not possible.

As an example of this type of reasoning, there is the proof that the neutron cannot have an electric dipole moment (separation of charges to produce effective positive and negative regions), providing time-reversal is a valid symmetry. The neutron, being electrically neutral but possessing an internal structure, may be regarded as an equal mixture of positive and negative charge. If the spin is represented by a vector (an arrow pointing upward along the axis when the sense of the spin is positive and vice versa), a positive electric dipole moment would mean a net separation of the charges, with more of the positive charge near the point of the arrow. The time-reversal transformation, however, would reverse the spin and hence would exchange the point and tail of the arrow but would not change the distribution of the charge. Thus the sign of the electric dipole moment, referred to the sense of the spin, would change. If the time-reversal symmetry is a valid one for the neutron, however, it would mean that an intrinsic static property like the electric dipole moment (static because the electric dipole moment

does not depend on rotation) cannot change sign and must therefore be zero.

**Dynamical symmetries.** Two types of symmetries can be seen to lead to conserved quantities in elementary particle physics. The first type is referred to as dynamical symmetry, associated with properties of the space-time continuum assumed by the special theory of relativity, sometimes called geometrical symmetry. This leads to the absolute conservation (constancy in time for an isolated system) of the vector linear momentum (*i.e.*, the product of mass and its velocity in a certain direction), the tensor of total angular momentum (*i.e.*, the analogous quantity for rotation), and the total energy. The behaviour of the physical laws under the operations of space and time inversion can also be studied as dynamical symmetries.

The term operator as used in theoretical physics represents a symbolic means for changing a mathematical expression that describes a physical entity or system. In quantum mechanics such operators are generally theoretical representations of measurements on the described system. Operations (or measurements) that leave the system unchanged have the special significance of providing numbers that describe the quantum mechanical state called quantum numbers (except for the trivial identity operator that leaves all states unchanged). Tests or measurements of symmetry are, of course, also represented by operators.

**Space inversion.** The space inversion operator, called the parity operator  $P$ , has the meaning of reflection in the origin of the space coordinates of a particle or system; that is, the three space dimensions  $x$ ,  $y$ , and  $z$  become, respectively,  $-x$ ,  $-y$ , and  $-z$ . A right-handed coordinate system is one in which turning the  $+x$ -axis into the  $+y$ -axis, the system advances in the direction of increasing  $z$ , just as a right-hand screw would advance when rotated. Under parity change, a right-handed coordinate system changes to a left-handed coordinate system and vice versa. As another example, when a particle is moving along a path and is also spinning about its direction of motion in the same direction that would advance a right-hand screw, it is said to have positive helicity; under the parity operation  $P$  it would acquire, instead, negative helicity. If the laws of physics were invariant under parity, the laws and all their predictions could be expressed mathematically in such a way that it would be impossible to tell whether a right-handed or left-handed coordinate system had been employed.

Helicity

**Time inversion.** The time inversion, or time reversal operator  $T$ , means the reversal of motion. Thus under the time reversal operation  $T$ , a particle of positive helicity remains of positive helicity, applying the right-hand rule above, because both the sense of spin and the direction of motion are reversed by the operation. Time-reversal invariance (or symmetry) holds if, whenever a motion is allowed by the laws of physics, the reversed motion is also an allowed one. Thus if a motion picture were taken of the motion of a body and viewed when run backward, it would be possible to say that the observed motion is an allowed motion.

The laws of classical physics are, indeed, invariant under the space-inversion and time-reversal operations  $P$  and  $T$ , but in the classical case this condition does not lead to any conservation laws. For an example of this invariance under the parity operator, the components of a vector representing electric field change direction (as  $x$ ,  $y$ , and  $z$  directions cited earlier), but the components of the magnetic field vector do not; the currents that are the source of the magnetic field and those that are acted upon by magnetic fields, however, also reverse their sense of direction, with the result that there is no observable effect of changing from a right-handed to a left-handed description of magnetic phenomena.

The invariance of physical phenomena under time reversal may seem surprising at first. If, for example, an egg is cracked into a bowl and beaten, a motion picture of these actions shown in reverse would strain one's credulity. It is necessary to go further and to imagine the situation if all the final microscopic motions of the egg

Dipole  
moment of  
neutron

episode were reversed. Theoretically, the egg would reform itself; however, this is an operation impossible to achieve in practice, and this is the reason that time appears to be unidirectional.

**Violation of conservation law.** Until 1956 the laws of quantum physics were generally assumed to be invariant under parity and time reversal. In that year, however, in order to explain an apparent lack of conservation of the parity quantum number in the decay of K-mesons (kaons) (see Table 1) into two or three  $\pi$ -mesons (pions), two Chinese physicists in the United States, Tsung-Dao Lee and Chen Ning Yang, pointed out that the conservation of parity had not been experimentally tested in the weak nuclear interactions previously observed (e.g., nuclear beta minus decay, symbolized  $\beta^-$ , the emission of negative electrons from a nucleus) and proposed several new experiments. When these experiments were carried out during 1957, the nonconservation of parity was decisively verified. In 1964 when the decay of kaons into pions was investigated by others, another new and surprising result was obtained and was interpreted as being due to a violation of the conservation law associated with time reversal in a new superweak nuclear interaction.

**Charge conjugation.** The inversion symmetries of space and time are associated in relativistic quantum field theory with another symmetry, that of charge conjugation (C). In theories that conserve parity and time reversal, such as quantum electrodynamics or the strong nuclear interaction, invariance under charge conjugation, which changes the sign of the electric charge, implies that every charged elementary particle has an oppositely charged partner, its antiparticle. The antiparticle of an electrically neutral particle may be identical to the particle, as in the case of the neutral pion, or it may be distinct, as in the case of the antineutron. All of the expected antiparticles have been observed, beginning in 1933 with the discovery of the antielectron, or positron. Weak nuclear interactions, however, do not conserve charge conjugation, a phenomenon that poses a paradox for the theoretical prediction of the existence of antiparticles.

**Time reversal/charge conjugation/parity.** The difficulty may be resolved. Physicists have shown that **invariance** under the combined symmetry **time reversal/charge conjugation/parity** (TCP) is sufficient to demand the existence of antiparticles. The meaning of a combined symmetry may be illustrated in the case of the weak (but not superweak) nuclear interaction that conserves CP but not C and P separately. In the above discussion of parity, reference was made to the notions of positive and negative helicity. Neutrinos, which enter only into the weak interactions, are found to have negative helicity, whereas antineutrinos have positive helicity. Thus invariance under charge conjugation alone, which would imply the existence of neutrinos and antineutrinos of the same helicity, is violated. The same conclusion would follow if **P-invariance** were to hold because parity changes the sign of the helicity without changing neutrino to antineutrino. Under the combined inversion CP, however, a neutrino of negative helicity becomes an antineutrino of positive helicity, in accord with observation. Similarly, the existence of antiparticles is predicted even if charge conjugation, parity, and time reversal are violated separately, providing TCP is still a valid symmetry.

**Internal symmetries.** The dynamical symmetries considered so far are related to the properties of space and time, and the continuous symmetry transformations such as translation in space, time, and velocity (or, alternatively, Lorentz transformation) all lead to such absolutely conserved quantities as energy and momentum. In the case of the discrete transformations, charge conjugation, parity, and time reversal, however, it has been seen that certain interactions—the weak nuclear interactions—would not conserve these symmetries separately but would do so in certain combinations. A number of other symmetries in elementary particle physics, some absolute and some approximate, are extremely useful for classifying the particles and lead to selection rules; *i.e.*, rules that tell which reactions among the particles are allowed and

which are forbidden. The information in the following sections requires a broader knowledge of high energy physics that can be found under: ELECTRON; FIELDS, THEORY OF (PHYSICS); MATTER AND ANTIMATTER; NUCLEUS, ATOMIC; and PARTICLES, SUBATOMIC.

**Absolutely conserved charges.** There are four absolutely conserved charges: electric charge  $Q$ , baryon number  $B$ , and two lepton numbers  $l_e$  and  $l_\mu$ , associated respectively with electrons and muons. In the sense that all known electric charges are integral multiples of the fundamental charge  $e = 1.60 \times 10^{-19}$  coulomb, the electric charge  $Q$  may be regarded as a quantum number that, like  $B$ ,  $l_e$ , and  $l_\mu$ , takes on only integer values. In other respects, however, the electric charge is distinguished from the other absolutely conserved quantities, being a property of both leptons and hadrons and being the source of the electromagnetic field. In any elementary particle reaction, if  $a$  and  $b$  represent reactants and  $c$ ,  $d$ , etc., the products, an equation can be written:  $a + b \rightarrow c + d + \dots$ ; in this equation, the sum of the charges on the left side of the arrow must equal the sum of the charges of the particles on the right. (Here, and below, the arrow indicates decay or transformation of particles on its left into particles on its right.)

Baryon number  $B$  is a property only of the hadrons; those in which  $B$  equals zero are called mesons, those in which  $B$  equals one are called baryons, whereas antibaryons have  $B$  equal to minus one. Protons and neutrons are baryons, and hence the mass number  $A$  of the atomic nucleus is identical with its baryon number. It is the absolute additive conservation of baryon number and of energy that makes the free proton absolutely stable because it is lightest of the baryons. The neutron, being slightly heavier than the proton, can undergo the weak nuclear interaction in which the neutron ( $n$ ) decays into a proton ( $p$ ), electron ( $e^-$ ), and antineutrino ( $\bar{\nu}$ ) according to the equation:  $n \rightarrow p + e^- + \bar{\nu}$ . This process is called beta decay. If one did not take into account the energy and momentum carried by the massless neutral particle  $\bar{\nu}$  (the antineutrino of the electron), the other three quantities would appear to be not conserved. It was on this basis that the neutrino's existence was predicted by Wolfgang Pauli, a German physicist, in 1931. It is sometimes (energetically) possible for protons bound in nuclei to undergo the following decay reaction in which  $e^+$  is the positron (antiparticle of the electron) and  $\nu_e$  is the neutrino (the massless particle) associated with the production of the positron,  $p \rightarrow n + e^+ + \nu_e$ .

Additive conservation of the lepton (electrons, neutrinos, and muons; see below) number  $l_e$  is also illustrated by the decay processes of the neutron and proton mentioned in the previous paragraph. The leptons ( $\nu_e$  and  $e^-$ ) are assigned the lepton number  $l_e = +1$ , and the antileptons ( $\bar{\nu}_e$  and  $e^+$ ) are assigned the lepton number  $l_e = -1$ . On both sides of each arrow above (in time: before and after the reaction takes place), the total electron lepton number  $l_e$  (the sum of the lepton numbers for each particle) must be the same. In addition to the electron, there is another charged lepton, the muon, which is much heavier than the electron and which occurs typically as a product in the decay of pions or kaons (see Table 1). Free charged pions, for example, undergo the decay processes  $\pi^+ \rightarrow \mu^+ + \nu_\mu$  and  $\pi^- \rightarrow \mu^- + \bar{\nu}_\mu$ . Again, the particles  $\mu^-$  and  $\nu_\mu$  are assigned (conventionally) the lepton number  $l_\mu = +1$ , and their antiparticles  $\mu^+$  and  $\bar{\nu}_\mu$  are assigned  $l_\mu = -1$ . That the neutrinos associated with electron and muon are different, implying the existence of two different lepton numbers  $l_e$  and  $l_\mu$ , was established in the early 1960s. One consequence is that whereas the muon decays (in about  $10^{-6}$  second) by the process  $\mu^- \rightarrow e^- + \bar{\nu}_e + \nu_\mu$ , processes such as  $\mu^- \rightarrow e^- + e^- + e^+$  are forbidden and do not occur.

**Strangeness and hypercharge.** Other internal symmetry properties such as strangeness, treated below, belong to hadrons alone (see Table 1). From 1947 on, a number of hadrons, both mesons and baryons, have been observed with the following property: although produced copiously, in strong interactions such as proton-proton collisions, they are unable to decay by strong or electro-

Baryon  
number

Anti-  
particles

magnetic interactions even when that is allowed by all the conservation laws considered so far in this article. As a consequence, these particles are relatively stable, with lifetimes of  $10^{-10}$  to  $10^{-8}$  second, characteristic of the weak nuclear interaction. The apparent contradiction between their behaviour in production and decay is resolved by assigning a new quantum number, the strangeness number  $S$ , and requiring that it be conserved by strong and electromagnetic interactions. In production, then, two or more particles of nonzero  $S$  can be produced, providing their total strangeness adds up to zero. The conservation of strangeness does not hold for the weak interactions by which the particles decay, but it can change by one unit. The strange particles have antiparticles of opposite strangeness. Examples of reactions permitted by the strangeness selection rule are a pion and proton producing a kaon:  $\pi^- + p \rightarrow K^+ + A$  (associated production), and an antiproton and proton producing lambda plus antilambda particles:  $\bar{p} + p \rightarrow \Lambda + \bar{\Lambda}$ ; as the  $\pi^-$  (pion), and  $\bar{p}$  (antiproton) have strangeness numbers  $S = 0$ ,  $A$  (lambda) has  $S = -1$ , and  $K^+$  (kaon) and the antilambda  $\bar{\Lambda}$  have  $S = +1$  (see Table 1).

A quantity closely related to the internal symmetry property strangeness, which is useful in the symmetry classification of hadrons, is the hypercharge  $Y$ , defined as equal to the sum of the baryon and strangeness numbers:  $Y = B + S$ . Because the baryon number is absolutely conserved, the change of strangeness in any reaction is always the same as the change of its hypercharge.

**Isospin symmetry.** A typical characteristic of the hadrons is that they occur in families of the same spin, intrinsic parity, baryon number, and of closely similar mass. Such groupings of particles, differing in electric charge but not in hypercharge—such as proton and neutron, or such as the three pions—are called charge multiplets, or isospin multiplets. It is believed that the small mass differences that can exist between differently charged members of a charge multiplet would vanish if only the strong nuclear interactions were present and that, except for small electromagnetic and weak interaction corrections, their strong interactions would be identical. In atomic nuclei, for example, the forces between a pair of protons, a pair of neutrons, or a neutron and a proton appear to be the same except for corrections that can be reasonably ascribed to their differing electromagnetic properties. This concept is called the charge independence of nuclear forces.

In this situation, the proton and neutron are regarded as different charge states (of charge  $Q = 1$  and  $Q = 0$ ), respectively of a single particle, the nucleon. The pions  $\pi^+$ ,  $\pi^0$ , and  $\pi^-$  are regarded as charge states of a single particle, the pion, having charges  $Q = 1$ ,  $Q = 0$ , and  $Q = -1$ . In visualizing the symmetry corresponding to the charge independence of the strong nuclear interaction, it is useful to represent the charge states of the nucleons as vectors in an abstract, two-dimensional complex space (one spatial coordinate is complex; *i.e.*, its magnitude is multiplied by the imaginary quantity  $\sqrt{-1}$ , called the charge space, or isospin space). Charge independence, or isospin invariance, is then the statement that the strong nuclear interaction is invariant under arbitrary rigid rotations of the axes in this abstract space. The three operators that generate these rotations have the same algebra as the three operators that generate the rotations in real space (angular momentum operators), hence the name isospin. One of them,  $I_3$ , is related to charge and hypercharge by the relation:  $Q = I_3 + \frac{1}{2} Y$ . The largest value of  $I_3$  within a multiplet is called  $I$ , and there are  $2I + 1$  charge states in the multiplet. The continuous symmetry transformations (called the Lie group, after Marius Sophus Lie, a Norwegian mathematician), which lead to the conservation of angular momentum in the real space and of isospin in the abstract space, belong to the special unitary group in two dimensions,  $SU(2)$ . As stated, the generator  $I_3$  of this group is related to the value of the charge, whereas  $I_1$  and  $I_2$  are related to the transformation from one charge state to another.

**$SU(3)$  and higher symmetries.** By considering a three-dimensional abstract complex vector space and the group

of rotations in this space,  $SU(3)$ , larger family groupings can be accommodated, which may be called charge-hypercharge multiplets. In this larger space, there are eight generators of rotations: the three isospin operators  $I_1$ ,  $I_2$ ,  $I_3$ , the hypercharge  $Y$ , and four others related to the change of strangeness. Although isospin multiplets may contain any number of members,  $SU(3)$  multiplets are limited to sets, representations of the group, containing prescribed numbers of members. According to the presently accepted  $SU(3)$  scheme (proposed in 1962 by a U.S. physicist, Murray Gell-Mann, and an Israeli physicist, Yuval Ne'eman), known as the "eightfold way," the simplest nontrivial representation employed by the hadrons has eight members. For example, a certain meson octet contains three pions, four kaons, and an eighth, a neutral meson, the eta. The baryon octet contains one proton, one neutron, one lambda, and five other strange baryons. About a dozen or more such representations have been identified.

In contrast to the well-established charge independence of the strong nuclear force,  $SU(3)$  invariance is not an excellent symmetry, for it appears to be violated not only by the weak and electromagnetic interaction but by a part of the strong interaction force itself. The strong symmetry-breaking interaction is not well understood, but its presence is indicated by the fact that the average mass difference between isospin multiplets that make up an  $SU(3)$  representation is far larger than the electromagnetic mass differences within the isospin multiplets. The eta mass, for example, is four times that of the pion.

A great deal of theoretical research has been concerned with the attempt to understand the breaking of  $SU(3)$  symmetry and to explore still larger symmetry groups such as  $SU(6)$ , with the object of relating the properties of larger sets of particles to each other and to understanding the dynamics of the strong interactions. Particular emphasis has been placed upon the algebra of the conserved and partially conserved currents, related to the generators of the symmetry groups just as the electric current is related to the electric charge.

**Quark models.** As the properties of atomic nuclei are related to the constituent protons and neutrons, so the properties of hadrons would find a natural explanation if they could be regarded as composites of more elementary constituents.  $SU(3)$  symmetry would require a triplet of half-spin constituents, called quarks. The quark triplets,  $q_1$ ,  $q_2$ , and  $q_3$ , with their quantum numbers, are given in Table 2. There are also postulated three anti-

Hadrons composed of quarks

Table 2: Quantum Numbers for Quarks

	$I$	$I_3$	$S$	$B$	$Y$	$Q$
$q_1$	$\frac{1}{2}$	$\frac{1}{2}$	0	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{2}{3}$
$q_2$	$\frac{1}{2}$	$-\frac{1}{2}$	0	$\frac{1}{3}$	$\frac{1}{3}$	$-\frac{1}{3}$
$q_3$	0	0	-1	$\frac{1}{3}$	$-\frac{2}{3}$	$-\frac{1}{3}$

quarks, the quantum numbers of which are the negatives (except for  $I$ ) of those of the quarks. The quarks  $q_1$  and  $q_2$  form an isospin doublet (like proton and neutron) and  $q_3$  is an isospin singlet (like lambda). In the strong nuclear interaction, it is assumed that each variety of quark is separately conserved in the same sense as baryon number and lepton number (*i.e.*, number of quarks minus number of antiquarks of a given variety). Conservation of strangeness is explained as the conservation of the strange quark  $q_3$ , whereas weak interactions occur by a transformation of quark type.

Because each quark is assigned baryon number  $B = 1/3$ , baryons ( $B = 1$ ) are made of three quarks, and mesons ( $B = 0$ ) are made of one quark and one antiquark. All hadrons so far observed can be constructed from the three quarks and their antiquarks and their masses, mass differences, and interaction properties can be qualitatively understood in terms of their quark structures. The values of electric charge  $Q$  given in Table 2 are derived only from theoretical relationships. Intensive searches for particles of nonintegral electric charge

Isospin space

have failed so far to provide conclusive evidence for their existence, which suggests that the quarks may be extremely heavy particles, if indeed they exist.

## Conservation of Natural Resources

Although the history of conservation is as old as mankind, the use of the word in the contemporary context is relatively recent. Over the years conservation has acquired many connotations: to some people it has meant the protection of wild nature, apart from man; to others the sustained production of useful materials from the living resources of the Earth—e.g., fisheries, wildlife, forests, agricultural croplands—along with the wise use of fuels and minerals. But by the 1970s achievement of the highest sustainable quality of living for mankind by the rational utilization of the environment had become the definition of conservation that was most widely accepted by such organizations as the International Union for the Conservation of Nature and Natural Resources. The emphasis was on man; by stressing the quality of living rather than the sustained production of commodities, however, the scope of the definition was broadened so that conservation now includes, in addition to the protection of wild nature to enrich the life of man, the control or elimination of environmental pollution in its many manifestations.

Because conservation is a social attitude as well as a social movement, it is necessarily partisan. It advocates practices that will perpetuate the resources of the Earth on which man depends or in whose continued existence he takes an interest and is opposed to the view that resources may always be used in the short run for personal profit or for the immediate benefit of living generations. Conservation derives its tenets from a knowledge of ecology, the science concerned with interrelationships between living things and their environment. Because ecology encompasses a body of scientific knowledge as well as the associated attitudes and techniques for acquiring further knowledge, it is one of the many disciplines employed by the conservation movement in its efforts to protect the environment.

This discussion of the many scientific and technological aspects of conservation, as well as its various social, economic, and political ramifications, is divided into the major sections indicated below. Other articles of interest include ECOSYSTEM; TERRESTRIAL ECOSYSTEM; AQUATIC ECOSYSTEM.

This article is divided into the following sections:

- I. Concepts important to conservation
  - Man's need for natural resources
  - Primary and secondary needs
  - Rational use of resources
  - Multiple use and restoration
  - The importance of conservation
  - Values to mankind
  - Conflicting attitudes and issues

## II. The history of conservation

- Early beginnings
  - Ancient conservation practices
  - Conservation during and following the Renaissance
  - Rise of the modern conservation movement
- Recent history
  - Spread of modern conservation practices
  - New conservation problems and approaches

## III. Types of natural resources

- Renewable resources
  - Plants and animals
  - Ecosystems
  - Solar energy, air, and water
- Nonrenewable resources
  - Fossil fuels
  - Nuclear fuels
  - Minerals

## IV. Management of natural resources

- Managing nonliving resources
  - Soils
  - Water
  - Air
  - Subsurface deposits
- Managing living resources
  - Natural communities
  - Wildlife and fisheries management
  - Multiple-use management
  - Intensive wild-land uses
  - Agricultural management
- International problems of resource management
  - Effective international agreements
  - Territorial limits and marine resources
  - International trade in animals and plants
- The pollution of natural resources
  - Water pollution
  - Land pollution
  - Noise pollution
  - Chemical pollutants
- The future of conservation
  - The role of population, industry, and technology
  - Problems in need of solutions
  - Extraterrestrial conservation

## I. Concepts important to conservation

### MAN'S NEED FOR NATURAL RESOURCES

Like "conservation" itself, the term natural resources has also undergone an expansion in meaning as a result of man's greater understanding of his relationship with the world he inhabits. Early in the 20th century natural resources were viewed primarily as sources of useful commodities. They were the raw materials in the environment that were used or capable of being used by man for some purpose: minerals and fuels, forest and grazing resources, wildlife, fisheries, and the like. In a restricted sense, the term is still used in this way. More recently, however, the concept of natural resources has been broadened to include the total natural environment—the entire surface layer of the planet—because all parts of the Earth's surface are of use and of value to man *in* that they contribute to the production of the necessities and amenities that people require or demand. **Thus**, when considered in this respect, the atmosphere, oceans, deserts, and polar regions have all become valuable resources that must be managed with care to provide for the future of man.

**Primary and secondary needs.** Certain primary needs or natural-resource requirements are necessary for man's existence. These include energy in the form of organic foods that are digestible, are capable of being assimilated, and contain adequate amounts of proteins, fats, carbohydrates, vitamins, and minerals; water with a relatively low content of dissolved salts and free from toxic or injurious substances; air that contains an adequate quantity of oxygen but no harmful materials; and, in most climates, an external source of energy for heating purposes as well as various materials from which clothing and shelter can be fashioned to provide warmth in cold weather and coolness during excessively hot weather. These basic human needs were supplied to primitive man by wild vegetation and animal life, by springs and streams, and by the atmosphere and the Sun. Later, the discovery of fire made possible the heating of shelters and also made available a greater choice of foods—those that

Natural-resource  
"wants"

could be rendered palatable or more palatable by being heated.

The primary needs of man are the same today; however, with increased populations and depleted supplies of wild resources, a secondary category of needs has developed. These include those materials or energy sources needed to provide greater quantities of the primary materials from the spaces available for their production (e.g., fertilizers to increase crop yields). In addition to such needs, man also has a wide range of natural-resource "wants." These include the materials, experiences, or space needed to make existence more enjoyable.

Agricultural and urban development. The development of agriculture enabled man to produce greater amounts of food on a more reliable basis and from smaller areas of land than previously had been possible. He lost his direct dependence on the availability of wild food materials. Greater supplies of food made it possible to provide for greater numbers of people in the agricultural regions, and these numbers soon exceeded the capacity of the original or the still-existing natural environment to supply their primary needs. Thus, the first secondary needs developed—farming tools and, later, domestic animals to use the tools more effectively and, for the latter, the food supplies necessary to keep them alive. In time, to keep the agricultural soils productive, the need for fertilizers of various kinds developed. Increasing dependence upon foods that could not be eaten raw generated the need for materials from which cooking and eating utensils could be fashioned. Thus, requirements for a wide variety of nonliving natural resources developed along with the rise of agricultural lands and settled villages.

With the growth of civilization and the concentration of people into cities, natural-resource requirements increased as secondary needs expanded. It became essential to organize and direct agriculture over vast areas in order to provide for large numbers of urban inhabitants. Effective transportation from farmlands to cities became essential, as did metals and all kinds of other minerals, stones, and timber suitable for the construction of buildings, ships, and vehicles; in addition, greater numbers of domestic animals (cows, hogs, sheep, etc.) were required. Human wants were further increased as the greater leisure of civilized life enabled part of the population to look beyond the problem of mere survival. Thus, a desire for contact with wild nature developed as urban man became increasingly separated from it through urban existence.

Industrial and technological growth. The greatest expansion of human requirements for natural resources followed the Industrial Revolution during the latter half of the 18th and first half of the 19th centuries and the scientific and technological revolutions that succeeded it in the 20th. Resources that were of no value only a relatively few years ago are now used—beryllium for rockets and uranium for nuclear fuel. Although neither of these yet qualifies as a secondary need, uranium is rapidly moving into that category. Man now consumes enormous quantities of coal, natural gas, and petroleum—resources that were scarcely used only a century ago. The quantities of food now demanded require an enormous input into the agricultural economy of chemical materials and sophisticated farming implements as well as an input of fuel energy that in some areas exceeds the energy value of the food raised in these areas. Moreover, because both the demand for luxuries and the degree of wastefulness are excessive, not all consumption of resources is related to the supplying of needs.

In the confusion of needs, wants, and waste related to the current use of natural resources, it is notable that the primary requirements of man are still the same as they were in primitive times. It would be possible for mankind to survive, although in greatly reduced numbers, by using only wild vegetation and animal life to meet his resource needs. This is because the living resources of the Earth contain all the basic requirements for human survival. The need for other resources is the result of man's desire to live in greater numbers and at a standard

of living considerably higher than that enjoyed by his forebears. By reducing population growth in the future, it would be possible to enjoy a highly developed technology, a high material standard of living, and a wide range of wants and luxuries while still placing little strain upon the Earth's available resources. But, with the steadily growing human population, with an expanding technology that becomes increasingly more demanding, and with the growing demands for material goods, the pressure on the Earth's natural resources increases daily. Whether or not available quantities of these resources are sufficient to meet man's growing wants and needs is uncertain.

Rational use of resources. In its present usage, the conservation of natural resources includes a wide range of subsidiary concepts. One such concept is that of the rational use of the environment, which includes the preservation of certain areas or resources in an essentially undisturbed condition because they either are of scientific interest, have aesthetic appeal, or have recreational value. Preservation also serves an ecological purpose by maintaining the function of the total environment, such as the protection of forests to assure a sustained yield of water into urban reservoirs or the protection of estuaries in order to perpetuate an ocean fishery. But the preservation or the protection of natural resources is not the only concern of conservation; rational use also implies the direct use of resources for their commodity or recreational values. Thus, the harvesting of forest crops, the grazing of grasslands by livestock, the catching of fish, and the hunting of wild animals can be considered a legitimate part of the rational use of natural resources when they are carried out in such a way that the resource is perpetuated and not endangered. Such activities involve another concept, that of sustained yield, the understanding, in other words, that hunting or fishing should take only the annual surplus of individuals so as not to endanger the breeding stock of game animals or fishes and, similarly, that the cutting of trees or the grazing of grasses should remove either their annual increment or that portion realistically capable of being replaced over a period of years through the operation of natural processes with man's assistance when needed.

Multiple use and restoration. Also important to the concept of conservation is the recognition that natural resources have multiple values. In addition to its value as livestock forage, grass, for example, also supports wild animal life, holds soil in place, maintains the productivity of soil, keeps soil and water relationships in proper balance, and helps guarantee streamflow or yields of water to underground channels. Grasslands, moreover, have aesthetic, recreational, and scientific values. All of the many values of grassland must be considered before a decision is made to use a grassland for a particular purpose. Ideally, an area of land can serve many purposes simultaneously or sequentially; i.e., can have multiple uses.

Another of the more hopeful aspects of conservation is the concept of restoration. A forest that has been cut or burned can, with care, regenerate itself. Areas that have been mined and left barren often can be revegetated with reasonable expenditures of money and effort. Depleted animal or plant populations will recover their original abundance if suitably protected in an adequate habitat. The restoration of natural vegetation depends upon the ecological process of succession, in which plants with varying degrees of tolerance to extreme conditions in an environment will invade a disturbed or barren area and replace one another until a stable, self-perpetuating community is achieved. Restoration is possible, however, only as long as species are protected and the genetic diversity of life is maintained. When species become extinct the restoration of past conditions becomes impossible.

#### THE IMPORTANCE OF CONSERVATION

Values to mankind. Conservation is essential to the survival of man. Because life depends upon the proper functioning of the biosphere—the relatively narrow zone of air, water, soil, and rock in which all life on Earth

Sustained  
yield

Excessive  
resource  
demands  
and waste

The role of conservation in maintaining the biosphere

exists—the ultimate purpose of conservation is to maintain the biosphere in a healthy operating condition. Although it is known that green plants supply oxygen to the atmosphere, that plants and animals recycle nutrients, and that plants and animals help maintain the fertility of soils, many of the elements that contribute to the proper functioning of the biosphere have not yet been identified. Because mankind lives with such environmental uncertainties, an attitude of care and protection toward the Earth's living resources has come to seem necessary.

Certain aspects of conservation, however, such as the prevention of pollution, have a more narrow and immediate importance to man's welfare. There are numerous illustrations of the serious impact of pollutants in air, water, or soil on human health and survival; for example, the accumulation of sulfur dioxide in the air of London during the 1950s led to many deaths that probably would not have otherwise occurred. The dumping of mercury-containing wastes in waters around Japan caused the death of many people and destroyed the health of others, and continuing accumulations of such toxic metals as lead, cadmium, and arsenic in air and water threaten widespread damage to human health.

**Economic value.** Unless viewed in terms of human survival, the economic value of conservation is sometimes difficult to demonstrate. Although the floating plants of the ocean, the microscopic phytoplankton, are of little direct economic value to man, for example, their elimination from the food chain of animals would quickly destroy the world's marine fisheries, which are a major source of human food; in time, even the world's oxygen supply would be severely depleted. Similarly, the economic value of pollution control as a factor in maintaining good health can be measured only indirectly in such crude terms as labour lost and cost of medical and hospital care.

As explained below, much of the apparent conflict in the economics of conservation results from the difference between short-term or individual interests and the long-term interests of groups or of all mankind. The long-term economic community benefits to be derived from stable and productive farmlands and forests are considerable when compared with farms that are exploited, eroded, and abandoned or with forests that are cut, burned, and allowed to deteriorate. Short-term economic considerations, however, may lead individuals or communities to exploit their farms and forests for maximum profit at minimum cost and then move on, leaving the deteriorated lands behind.

**Aesthetic and recreational value.** Appreciation of wild nature as a source of aesthetic pleasure and the use of wild lands and wild-animal resources for recreational enjoyment have long been recognized as among the more important values of conservation. Outdoor-based recreational activities, such as fishing, hunting, boating, swimming, picnicking, sunbathing, hiking, and skiing, are related to the continued existence of natural or near-natural environments as the sites for these activities. Although it is almost impossible to evaluate aesthetic and recreational values in terms of their psychological or sociological importance, because they may vary from one culture to another, evidence indicates that, as personal affluence and the freedom from the sheer struggle for survival increase, the demand for outdoor recreation and outdoor space also increases. Even in the absence of government activity, it has become financially attractive for private investors to provide facilities and opportunities that exploit outdoor recreational resources.

**Scientific value.** Conservation is also of great scientific value. Because relatively little is known about the past, present, and possible future of the biosphere, natural outdoor laboratories, including areas of undisturbed nature, must be maintained in order to conduct the studies needed to acquire knowledge. Moreover, there are many natural resources with undiscovered scientific and technological values. If, for example, all apparently worthless sources of high-grade uranium had been destroyed prior to the 1940s, the development and exploitation of nuclear energy in recent decades would have been seri-

ously impeded. Because each wild plant and animal contains a storehouse of genetic and biochemical information, the loss of a single species might result in the loss of information that could ultimately have great value for man's welfare or survival.

Conflicting attitudes and issues. Although the importance of conservation may seem obvious, most of the world's people live too close to the margin of existence to exercise concern for anything more than their immediate survival and well-being. Planning for the future becomes difficult when the present itself is in doubt, and activities that could help tomorrow's generations may seem quixotic to those for whom survival is at stake. Thus, while conservation has made great strides in some areas of the world, it is still too soon for man to have any feeling of security about the future of his environment.

**Short-term versus long-term views.** There would seem to be no apparent need for any conflict between the attitude of conservationists and those of other responsible humans toward the environment, yet conflict does exist. As mentioned above, this conflict derives in part from the difference between short-term and long-term viewpoints. It is often regarded as essential to the survival or the enrichment of an individual or a group to use resources in such a way as to realize immediate gains or profits. Such shortsighted activities, however, may impair the future productivity of an area of land, exterminate a species, or destroy the usefulness of a site for any other purpose. In such a situation the short-term, private view conflicts with the long-term, public view. Though many would argue that the public view should be more conservation oriented, emphasizing proper safeguards to prevent deterioration of the environment, there are, nevertheless, times when governments take the short-term view in the face of real or imagined economic or political crises; they may, for example, authorize widespread destruction of resources as a temporary expedient to achieve a military goal or to strengthen the public treasury. But crises tend to become self-perpetuating if the destruction of resources weakens the country ecologically and economically. Thus, continued, unrestricted population growth in a country poorly equipped to manage its natural resources creates a continuing sense of crisis, because ever-expanding immediate needs are commonly met at the cost of future productivity and environmental stability.

As long as human populations were small and the pressures upon the environment were limited, conflicts between long-term and short-term interests made little difference. Deteriorated lands could be abandoned and new lands found, because there was sufficient time to permit natural repair of environmental damage. Presently, however, with great and increasing numbers of people on a planet of limited capacity, conservationists are insisting that the difference between short- and long-term points of view be resolved in favour of actions that guarantee the survival of mankind.

**Technological issues.** Technological progress is another important reason for many conflicts in matters pertaining to conservation. Although technology can be a boon to man in most instances, it can also be poorly related to environmental realities. Through the use of technology great environmental changes can quickly be brought about. Although these changes are usually intended to be beneficial, they frequently occur in natural environments in which all things are ecologically related to one another. As a consequence, the changes may produce side effects that were not anticipated or that were discounted as being of little importance, thereby disrupting other human activities or the environment as a whole. Examples of such situations include the polluting effects of certain industries or the spread of waterborne diseases following the construction of major irrigation projects.

**Use of global resources.** A further area of conflict lies in attitudes toward resources that are held in common, such as the atmosphere and oceans. In instances in which the use of such resources is essentially free to the user, and the power to control usage does not rest with any

Conflicting government roles

The appreciation of wild nature

recognized authority, the resource inevitably deteriorates. Although each fisherman may feel that his individual activities have very little effect on the resources of the ocean, the effect of the activities of all fishermen may threaten the existence of those resources. Similarly, each automobile driver does not feel that he is contributing much to the pollution of the global atmosphere, but all automobiles throughout the world contribute a total level of pollution that most critics feel cannot long be tolerated. When such situations exist, a recognized controlling authority is usually seen to be necessary.

## 11. The history of conservation

### EARLY BEGINNINGS

It is a familiar myth, expanded in the philosophical writings of Jean-Jacques Rousseau and others, that primitive man lived in a happy state of balance with nature; because of the direct relationship between early man and his environment, he purposefully developed conservation practices that guaranteed the continued health of his natural surroundings. The available evidence does not fully support this view, although there is no doubt that certain peoples and cultures did develop some conservation-oriented practices. For the most part, however, primitive man survived because his numbers were small and his technology limited, and he was unable to do any major harm to his environment. Even so, the only powerful technique that he possessed, the use of fire, was used virtually without discrimination and greatly modified many areas of the Earth. Animals were exterminated by effective, indiscriminately applied hunting techniques. Thus, the elimination of many large mammals from North America—*e.g.*, the mammoths, mastodons, camels, horses, and giant sloths—has been attributed to primitive hunters, as has the extermination of moas, the giant flightless birds that once inhabited New Zealand. When the Plains Indians of North America received the horse from the Spanish, they quickly developed an exploitative economy that threatened the continued survival of the American bison. Eskimos, when given modern firearms, quickly joined in the slaughter of Arctic wildlife, exceeding any immediate need.

Even agriculture was not immune to land abuse by early man. When practiced in humid forested regions, primitive agriculture did not cause serious degradations, because the people could not clear extensive forest areas with their available tools; in addition, forest soils tended to lose their fertility in a relatively short period, making them undesirable for continuous cultivation. Because the less fertile sites were abandoned before any severe damage had been done, they were revegetated quickly by forest plants and gradually restored to a productive condition. But, when grassland soils and drier forest areas were invaded by agriculture, the consequences were different. In the Asiatic homelands of Western agriculture there is widespread evidence of serious soil damage and loss during ancient times. Destruction of vegetation and the spread of deserts followed the rise of early civilizations in the Middle East and in northern Africa.

**Ancient conservation practices.** Certain conservation practices did develop in the earliest of times, however. Some species of animals were protected by religious taboos; religious sanctions prevented the destruction of forest groves and sacred mountains. The use of organic fertilizer to maintain soil fertility is found among many more recent primitive peoples and has had a long history in Western agriculture. The Bible is filled with various injunctions governing the use of land and resources that have a conservation function. Early civilizations such as those of the Phoenicians and the Incas developed sophisticated techniques of terracing to prevent soil erosion on hillsides and to make more effective use of water for irrigation. The earliest civilizations also show evidence of the creation of reserves or parks to protect wildlife or natural areas. Although they were hunting preserves for the use of royalty, they also served a conservation function.

As civilization developed, the accumulation of human experience led to increasingly sound land-use practices,

evidence of which is found in the written descriptions of Roman agriculture and, later, in the well-tended irrigated fields and gardens developed during the height of Muslim culture. The agricultural landscapes of preindustrial western Europe, Japan, and China reflected great skill in the conservation of soil resources. Irrigated lands in the Nile Valley and volcanic soils in tropical Southeast Asia have been kept fertile and productive over thousands of years.

In pre-industrial times, however, concern over wild nature was not widespread, largely because it was viewed as vast and inexhaustible relative to the domain, the numbers, and the power of man. This view was a justifiable one, because the 500,000,000 people who inhabited the world in 1600 lacked the energy sources and the machinery to effect great environmental changes. Moreover, most of the Earth's surface was uninhabited or sparsely settled.

### Conservation during and following the Renaissance.

Starting with the voyages of discovery in the 15th century, the influence of European man was spread over the world. By the 17th century Europeans were equipped with an increasingly powerful technology and a growing ability to modify large areas of the Earth and to subdue less sophisticated peoples. During this period the attitudes of explorers and colonists were oriented more toward immediate personal aggrandizement of the lands they visited and settled than toward any concern for the long-term health and productivity of the newly discovered countries. Soil erosion as well as the destruction of natural vegetation and wildlife accompanied the spread of European colonization in the Americas and later in Australia and Africa. Nevertheless, during the same period, various conservation ideas and practices were being promoted. Forest conservation, for example, developed sound beginnings in 17th-century England and France, in part because of the disappearance of natural forests as a result of the increasing demand for wood fuel for industrial uses. As early as the 18th century in eastern North America, such men as Thomas Jefferson already had sound ideas for land management and conservation, and a general interest in and concern for wildlife was developing.

The 19th century, however, witnessed unusually severe environmental depredations. In Australia, for example, livestock populations were allowed to increase to levels far above what the natural forage could support. Although millions of animals died during drought periods, the process of overforaging damaged the range lands to such a degree that they have not yet recovered. In southern Africa many forms of wildlife were hunted to extinction, and most of the larger mammals were reduced to numbers that endangered their survival. It was in North America, however, that the changes were most dramatic. The great herds of wildlife that inhabited the plains and prairies vanished as the numbers of bison, elk, antelope, and deer were reduced by hunters. Even the larger predatory animals were nearly exterminated, and some of them—varieties of grizzly bear, cougar, and wolf—subsequently became extinct. Many types of birds that once had occurred in great abundance—*e.g.*, the passenger pigeon, Carolina parakeet, and heath hen—were wiped out. Logging and fires combined to menace the once luxurious forests of New England, the states surrounding the Great Lakes, and the South. The grasslands were overgrazed, and in some areas such as California native vegetation was eliminated over most of its range and replaced by species of European and Asian origin. It is in the West Indies and other islands throughout the world that changes were most marked. Native plant and animal species were eradicated and replaced by exotic invaders. By contrast, in the long-settled areas of Europe and Asia, changes were much less marked, as conservation-oriented systems of land management persisted.

**Rise of the modern conservation movement.** It could have been predicted that the modern conservation movement would have its beginnings not in the settled lands of the Old World but in those areas of the New World where, within the memory of a single generation, there

Early development of sound land use

Environmental depredations in the 19th century

The  
establish-  
ment of  
national  
parks

had been extreme changes in the landscape and in the abundance of wildlife. The reaction to the destruction of natural resources in these areas precipitated the formation and growth of the conservation movement. As early as 1832, George Catlin, a U.S. artist and author, first proposed the idea of national parks encompassing major areas in which Indians and wild country could both be preserved. In the same decade the botanist William Bartram and the ornithologist John James Audubon were arousing an interest in wildlife and its conservation. A little later, writers Ralph Waldo Emerson and his friend Henry David Thoreau presented strong arguments concerning the importance of the continued survival of wild nature to the psychological well-being of man. Thoreau became one of the first literary advocates of wilderness conservation. The 1860s in America saw the first textbook on conservation, *Man and Nature*, by George Perkins Marsh. In 1864 the designation of the Yosemite Valley in California as a national park served as the forerunner of the world system of national parks. In the same period the author and naturalist John Muir settled in California and became a leading advocate of wilderness preservation. In 1872 the United States Congress not only proclaimed the Yellowstone region of Wyoming as a national park but also established for the first time a national-government role in the protection and administration of such areas. (Yosemite, the first national park in the United States, was administered by the state of California.) In 1891 the first of the U.S. forest reserves, forerunners of the system of national forests, was proclaimed in the area surrounding the Yellowstone National Park. The way was thus prepared for Theodore Roosevelt and his associates to establish in America the concept that the conservation of natural resources is an important concern of national government.

#### RECENT HISTORY

The recent history of conservation has been marked by a great expansion of government roles in protecting the environment and by a growth of public interest in and support for this process. National-park systems, dedicated to the preservation of wild nature and to the provision of outdoor recreation space, have grown rapidly from their early beginnings. National-forest systems, dedicated to the multiple use of wild-land resources, also became firmly established. In the United States the conservation of wildlife became a cause of national interest and led to the establishment of a far-ranging system of wildlife refuges and the gradual restoration of most wild animal species to levels approaching, in some cases exceeding, their primitive abundance. On private lands, however, and on government or public-domain lands not specifically reserved as national-forests, parks, or refuges, deterioration continued, reaching a peak in the 1930s, when it became widely recognized that those range lands in the public domain had been disastrously overgrazed and that many privately owned farmlands had been depleted or exhausted. Firm control over the management of lands in the public domain and federal intervention to establish soil conservation on privately owned lands were accepted as appropriate activities for the national government.

**Spread of modern conservation practices.** Conservation ideas spread widely, being most readily accepted by those countries that had experienced sudden environmental changes. By the 1920s national parks were to be found on all continents. In 1924 the Soviet Union established the first of its now extensive system of natural reserves (*zapovedniki*). Conservation-oriented management of forest lands, which grew more from its origins in Europe than from practices in the United States, also became more widely accepted throughout the world. The scientific basis for the management of wild grazing lands for the sustained production of forage for livestock was established in U.S. national forests in 1913 and soon spread to other countries. Aldo Leopold in the United States, in 1933, wrote a textbook on game management, in which the conservation and management of wild animal life for such recreational purposes as sport hunting

and fishing and for direct commodity values on a sustained basis received particular emphasis. Leopold's work drew heavily on earlier studies of animal ecology by Charles Sutherland Elton in England; in fact, the establishment in Europe of wildlife reserves and protective laws as well as the managing of lands to produce sustained crops of wildlife long preceded even Elton's work. Subsequently, the management of wild animals in extensive wilderness areas made major strides in Africa, which possesses unusual wildlife resources, and in the Soviet Union, which retains large areas of wild land.

**New conservation problems and approaches.** After World War II the field of conservation expanded as new problems arose and as some older approaches proved to have been inadequate. With growing populations and increasing pressures on land and resources, planning for their use by taking into account only a single factor or a few factors at the most was found to be highly unsatisfactory. One such instance was the development of more effective synthetic pesticides for use in the control of disease-carrying insects as well as those that prey most heavily upon agricultural crops. The initial results were remarkable. In such countries as Ceylon, where the insecticide DDT was used to control malaria-bearing mosquitoes, the disease was reduced from being an important cause of human illness and mortality to a low and manageable level. Similarly, agricultural pests were drastically reduced, and crop yields soared in many regions. Eventually, however, it was discovered that the pesticides had unexpected and severe consequences on the environment, and by the 1970s their use anywhere for any purpose was open to serious debate.

All forms of pollution also became a matter of major significance as populations and industrial activities increased after World War II. Air in major cities became toxic; water supplies in many heavily populated areas were contaminated. Nuclear radiations had become a major cause for concern during the 1950s and early 1960s when it was found that radioactive materials from test explosions of atomic and hydrogen bombs spread throughout the entire biosphere instead of being confined to the immediate areas in which the tests were conducted.

In response to the need for a much more integrated approach to environmental problems and to natural-resource management than existed at the time, many countries established ministries for the environment or their equivalent, and in 1969 the United States, by the National Environmental Policy Act, established a national Council on Environmental Quality to oversee and help coordinate those activities of government departments that could have an impact upon the environment.

By 1970, however, the problems of the environment had become international in scope. The oceans were seriously polluted, and no single country could control the situation. Pesticides and other toxic materials spread by air and water currents throughout the world were causing or threatening to cause environmental damage everywhere. But the need for an international approach to conservation problems found most nations generally unprepared to cope with the situation. Conservation-oriented recommendations aimed at controlling the use of radioactive materials, heavy metals, toxic pesticides, or the dumping of petroleum at sea could not be enforced internationally. The need to regulate the exploitation of marine resources was widely acknowledged, but such regulation was ineffective in the absence of an empowered international authority. In recognition of these problems many international conferences were held, new treaties and conventions were proposed, and the need for regulatory power over the environment at an intergovernmental level was stated frequently. The World Health Organization and the World Meteorological Organization began a global program to monitor pollution levels. The United Nations Educational, Scientific and Cultural Organization launched a major scientific program directed toward the problems of "Man and the Biosphere," and an international conference on environmental problems was held in Stockholm in June of 1972. But many

produc-  
tion of  
sustained  
"crops" of  
wildlife

Interna-  
tional envi-  
ronmental  
problems

critics feared that, until the nations of the world were more willing to delegate greater authority to international organizations and to support them financially, little progress toward the solution of global problems could be expected. In existing conditions of international relations, this left each nation to attempt to do what it could within its own boundaries.

### III. Types of natural resources

In classifying natural resources it has been traditional to distinguish between those that are renewable and those that are nonrenewable. The former were once considered to be the living resources—*e.g.*, forests, wildlife, and the like—because of their ability to regenerate through reproduction. The latter were considered to be nonliving mineral or fuel resources, which, once used, did not replace themselves. In practice, however, this separation is not entirely satisfactory, for reasons that will be dealt with in a later section. There are, nevertheless, certain aspects of conservation that apply specifically to nonliving resources. They are enumerated below.

1. Beneficiation is the upgrading of a resource that was once too uneconomical to develop. It usually depends upon technological improvements, such as those that make possible the concentration of a dispersed fuel or mineral so that it can be more easily handled, transported, or processed.

2. Maximization is the aggregate of those measures that avoid waste and increase the production of a resource.

3. Substitution involves the use of common resources in place of rare ones, as, for example, the use of aluminum in place of less abundant copper for a variety of products.

4. Allocation is the determination of the most appropriate use for a resource and the assignment of the resource to that purpose. Normally, allocation is controlled by economic factors—the higher the price a resource will bring when used for a particular purpose, the more likely it is that the resource will be used mostly for that purpose—but in government-controlled economies a resource may be reserved only for what are considered to be its most important uses.

5. Recycling, one of the most promising methods for conservation of mineral resources, involves the concentration of used or waste materials, their reprocessing (if this is required), and their subsequent reutilization in place of new materials. If carried out in an organized and consistent manner, recycling can greatly reduce the drain on supplies of minerals. It is also appropriate for products derived from living resources, such as the reuse of wood and paper as well as the reclamation of organic fertilizers from sewage.

Because all natural resources form a continuum, from those that are most renewable in the short term to those that are least renewable, they do not readily lend themselves to a single system of classification. It is useful, therefore, to examine the various types of natural resources in relation to their cycling time; *i.e.*, the length of time required to replace a given quantity of a resource that has been utilized with an equivalent quantity in a similarly useful form. From this point of view, renewable resources can be considered as those with short cycling times and nonrenewable resources as those with very long cycling times. Any resource can be nonrenewable, however, if the demand and rate of utilization exceed its cycling capacity.

Two kinds of natural resources, pasture grass and coal, can be used to illustrate the concept of cycling time. When grass is grazed by livestock or mowed, a crop of it is removed. If provision is made to protect the fertility and structure of the soil and to leave enough seed or adequate roots and vegetative parts to produce new growth, then a grass crop can be removed from a pasture each year for an indefinite period of time. Removal of one year's crop does not diminish the supply available for the next year if the land is cared for properly. The cycling time for this resource may be one year in areas in which climate limits growth, or it may be less than a year if growth can be continuous.

By contrast, the coal resources of the Earth were built up over millions of years. Most were laid down during the Carboniferous Period of geological time (from 345,000,000 to 280,000,000 years ago), when climates were warm. Extensive swamp forests covered large areas of the Earth, and conditions were favourable for plant debris to accumulate in extensive deposits without decomposing and breaking down organically. Subsequently, heat and pressure generated by the deposition of other materials on top of the organic debris and by movements of the Earth's crust transformed the plant remains into coal. Organic debris is still being produced in swamps and marshes, and over millions of years this, too, could become transformed into coal. The time scale is so great, however, that, for human purposes, coal can be considered as a nonrenewable resource. Thus, only the supplies presently available in the Earth's crust can be counted on for future use.

### RENEWABLE RESOURCES

**Plants and animals.** The most clearly recognizable renewable resources are those consisting of or produced by living things. Agricultural crops, animal forage, forest crops, wild and domestic animals—all can continue to reproduce and regenerate their populations as long as environmental conditions remain favourable and an adequate seed source or breeding stock is maintained. Moreover, all can be cropped or harvested without diminishing their supply, provided that the cropping does not exceed the reproduction or growth rate. If it does, the resources will be depleted; and, if the rate of cropping continuously exceeds the rate of replacement or regrowth, the resource ceases to be renewable, and the species involved are reduced to the point of extinction. A renewable resource thus can be said to be "mined"—that is, it is removed at a rate that does not permit renewal. The renewability of a living resource is further endangered if the environment required by that resource is allowed to deteriorate or disappear. Sheep in a mountain pasture are a renewable resource only as long as the pasture produces vegetation that will nourish and support the sheep. If the pasture is overgrazed, the vegetation destroyed, and the soil eroded, sheep cease to be a renewable resource in that locality.

**Species renewability.** The renewability of a living resource varies with the species and with the areas involved. Thus, annual plants, from which a high percentage of cultivated field crops are derived, grow to maturity each year and then die back. They are annually renewable and can be cropped at a relatively high rate. Perennial plants, such as fast-growing poplar trees, may have a much slower rate of renewability, although this depends upon the purposes for which they are used. If seedlings are in demand, they can be cropped annually, and a new supply can be grown from protected seed sources. More realistically, however, the cycling time for these trees depends on the length of time required for them to grow to maturity and to produce seeds from which a new crop can be grown. Certain conifers, such as the Monterey pine, can reach a size adequate to yield useful timber and other wood products in less than 30 years. Other conifers, desirable because of the quality of their mature wood, may be cropped only on a 100-year cycle. Old-growth redwood trees can almost be considered a nonrenewable resource, because the time required to produce their equivalent may be from 500 to several thousand years, well beyond the limits for which people are prepared to plan. Redwood forests used for timber production are managed on the basis of a much shorter cycle and the cutting of younger trees. Such management does not provide for the replacement of 1,000-year-old specimens.

**Landscape renewability.** A distinction should also be made between renewable species and the communities or landscapes they occupy. Although it takes about 100 years to replace a mature coniferous tree, certain types of coniferous forests that are managed for timber production can be logged almost indefinitely if the annual level maintains a sustained yield. When all the inter-

Renewability of annual and perennial plants

The concept of cycling time

relationships among such factors as soils and plant and animal life are considered, a natural forest that has not previously been disturbed by man may be far less renewable in its totality than the individual species within it. In other words, although the procedures employed in the harvesting of timber may assure a sustained yield, they may, nevertheless, be disruptive to other forms of life in the forest community, in which case species that are intolerant of such disturbance may disappear. It may be exceedingly difficult, therefore, to regrow a new community that resembles the original primitive forest if the area is to be disturbed periodically by timber cutting. It was this consideration, among others, that engendered the need to protect national parks, wilderness areas, and undisturbed research reserves. From certain viewpoints a wilderness is a nonrenewable resource; if it is seriously disrupted by human activity, the time required for the landscape to recover its appearance and for the restoration of the various natural combinations of plant and animal life that contributed to its original wilderness value could involve hundreds of years. The redwood-forest wilderness, as previously noted, could require many thousands of years for complete recovery following a major disturbance. Certain tropical rain forests that were disturbed more than 400 years ago still have not regained their original balance of species and do not resemble undisturbed, primary rain forest in the same region.

**Ecosystems—  
tema  
defined as  
resources**

Ecosystems. Resources that contain a combination of interacting living and nonliving components are called ecosystems. It is impossible to separate an ecosystem into its living and nonliving components, because the whole constitutes a dynamic system in which there is a flow of energy from sunlight, gases from the atmosphere, and minerals and water from the soil. As a natural resource, soil, in turn, is also a combination of living and nonliving components: it consists of atmospheric gases, water, living and dead organic materials, and more or less finely divided mineral substances. Moreover, soil is a product of the interaction between the living and the nonliving environment. The living components of soil conform to the definition of renewable resources, within the limitations that have been noted, and the mineral components conform to the definition of nonrenewable resources. As long as the living components of soil remain healthy and continue to function, the mineral components are recycled from the soil, through the organic life within it (e.g., bacteria and other micro-organisms), and back to the soil following the decay and breakdown of dead organic materials. Because most forms of terrestrial life are dependent upon it for their continued existence, soil must be maintained in a renewable state. Mining soil, or using it in such a way that its fertility is exhausted and it is washed or blown away by too-rapid erosion, reduces the likelihood that life can continue to exist in the area affected.

Solar energy, air, and water. Solar energy, air, and water are sometimes classed as renewable resources, but solar energy is an inexhaustible resource relative to human time scales and the uses that man can make of it. The supply of solar energy is not affected by any human activities, and the potential lifetime of the Sun is in the hundreds of millions of years, barring any cosmic accidents. The actual amount of solar energy reaching the surface of the Earth, however, is determined by the condition of the atmosphere, which can be and is affected by man.

Air is also an inexhaustible resource in the sense that the uses made of it by man and other living organisms have little effect on its total quantity. The quality of air, however, as measured in terms of its chemical composition or its physical state, is subject to human interference. For life to exist on Earth there must be a proper balance among the nitrogen, oxygen, carbon dioxide, water vapour, and other components of the atmosphere. A layer of the gas ozone, for example, must be maintained in the upper atmosphere to screen out damaging ultraviolet light from the Sun. The accumulation of toxic materials in the air must be kept to a minimum, and

the concentration of solid and liquid particles in the atmosphere must not be allowed to reach a level such that it interferes with the influx of solar radiation. All of these factors are affected by human activity and by the effects of this activity on other forms of life.

Water may also be considered an inexhaustible resource, because the total supply of water in the biosphere is scarcely affected by the activities of man or other living organisms. Water is not destroyed by most human uses, although it may be held for a time in combination with other chemicals. But, when needed in a particular place and of a quality useful to man, water must be regarded as a renewable resource, with cycling times dependent on its location and use. Water that falls from the atmosphere as various types of precipitation and then runs off the land surface to form streams and rivers that eventually reach the ocean generally operates on a one-year-renewal cycle. From the ocean the water is evaporated by solar energy and returned to the atmosphere, from which it again falls as rain or some other form of precipitation. In certain locations, however, water has a much longer cycling time; after entering the ground from rainfall, it may percolate slowly through underground channels until it reaches underground reservoirs. In certain arid regions the total water supply may be underground water that accumulated during past ages, when the climate of the region was more humid; since that time there may have been little or no addition to this supply because of the existing climatic conditions. Because its cycling time may be extremely long and dependent upon the frequency with which wet and dry climates alternate in a particular region, such a water resource can be virtually nonrenewable. The total movement of water from oceans to air to land and back to oceans, with all of the various pathways involved, is known as the hydrologic cycle. It is the renewal cycle that determines the amount of water available for human use and for all other purposes in any particular location.

Hydrologic  
cycle as an  
annual  
renewal  
cycle

#### **NONRENEWABLE RESOURCES**

As just noted, renewable resources include resources with widely different cycling times, some so long as to make the resources essentially nonrenewable. Those resources that are usually classified as nonrenewable—e.g., fossil and nuclear fuels and minerals—also exhibit a wide range of properties that affect their management. Fossil fuels, such as coal and petroleum, are the least renewable of such resources because they are effectively exhausted by use and because their rate of formation is exceedingly slow. Most minerals, on the other hand, are not destroyed by use; thus, in a sense, they are renewable and inexhaustible because they can be recycled for further use. But useful supplies of these minerals in accessible locations are exhaustible, and thus they are nonrenewable for human purposes.

Fossil fuels. Fossil fuels are those organic materials that have been converted from their original form by physical and chemical processes within the Earth's crust into a solid mineral state (coal), a liquid (petroleum), or a gas (natural gas). If these substances are completely burned (oxidized) when used as fuel, the end products are carbon dioxide, water, and heat energy. These cannot be reconstituted into organic substances without either elaborate synthesis in a chemical laboratory or the natural photosynthetic processes of green plants. Thus, burning destroys fossil fuels as useful energy sources available to man.

On the basis of existing knowledge of the amount of fossil fuels in the Earth's crust, it has been predicted that supplies of petroleum and natural gas may be exhausted by 2070 if used at the rates anticipated. Although coal supplies are greater, projected rates of use indicate that they cannot be expected to last for more than a few centuries. These predictions can be changed, of course, if rates of use change, which is expected to happen with, for instance, the further development of nuclear-power sources. Fossil fuels are used for purposes other than fuel, however. Coal and petroleum are used industrially for the manufacture of a wide variety of carbon-con-

Possibility  
of  
exhausting  
fossil fuels

taining materials, such as plastics, synthetic fibres, medicines, and food.

**Nuclear fuels.** Although nuclear fuels are inorganic substances, like fossil fuels they are destroyed when used in the production of heat energy. Unlike fossil fuels, however, they are also destroyed by spontaneous disintegration, through natural radioactivity. Uranium, for example, ultimately changes to lead, but the rate of change is slow; its half-life (the length of time it takes for half the atoms of a given amount of a radioactive substance to disintegrate) is 7,600,000,000 years. Of the naturally occurring nuclear fuels, uranium and thorium, only uranium-235 can be used directly in a nuclear reactor to produce power. The more common form of uranium, uranium-238, must first be converted into plutonium before it can be used as a nuclear fuel. Similarly, thorium must be transformed into uranium-233 before it is usable for fuel purposes.

Although supplies of uranium and thorium are relatively abundant, they are exhaustible and nonrenewable. By replacing nuclear fission with nuclear fusion as a power source, however, deuterium (an isotope of hydrogen) can be used as the fuel. Because it occurs in substantial quantities in seawater, deuterium is practically an inexhaustible resource for human purposes.

**Minerals.** Certain minerals, such as iron and aluminum, are so widely distributed throughout the crust of the Earth that the amounts exceed any foreseeable human needs. Other minerals, such as the precious metals (e.g., gold, platinum, silver), are much more limited in their distribution and quantity. The usefulness of a mineral to man, however, depends upon its accessibility and concentration; therefore, minerals that are highly dispersed throughout the Earth are essentially unavailable, even though their total quantity may be great.

**Ores and reserves.** Most efforts to obtain minerals are directed toward finding mineral ores, which are deposits in which the concentration and quantity of a mineral are such that it can be extracted profitably. Mineral reserves are those that are known to exist or can reasonably be inferred to exist from geological evidence. It follows that certain deposits of minerals that are not considered either ores or reserves today may become so if the technology for their extraction improves, if the supplies of energy available for their extraction increases, or if their economic value increases.

It is obvious from past experience that ore deposits can be exhausted. Because the gold mines around Virginia City, Nevada, and the tin mines of Cornwall no longer can produce significant quantities of minerals, they can be considered as virtually exhausted resources. The rich iron ores of the Mesabi Range in Minnesota have largely been depleted, and mining activity in this area has shifted to lower grade iron deposits. The supplies available from any mineral deposit, at least on dry land, are exhaustible and nonrenewable, because the geological processes that led to the formation of these deposits operate slowly and over long periods of time.

Some mineral deposits, however, are renewable. Manganese ore, for example, is relatively scarce on dry land but is continuously being formed in nodules on the ocean floor, as are cobalt, nickel, and copper. The rate at which the nodules of manganese, cobalt, and nickel are growing through chemical precipitation from seawater currently exceeds the rate at which these minerals are being used. Although the nodules are not yet being collected, the technology for doing so is being developed. Then these metals will be considered as renewable natural resources only so long as the rate of use does not exceed the rate of formation.

**Recycling of minerals.** The use of most metals does not destroy them, although rusting may reduce their quantities by a small amount when they are in use. As commercial products, some metals are found in such large quantities in urban areas that their new concentration may exceed that which existed while they were in the ground. Cities, therefore, may be considered as ore deposits for certain minerals. At present, however, it is cheaper to mine new ores than to recycle used or waste

Figure 1: Manganese nodules on the southern Pacific Ocean floor.

BY courtesy of the Lamont-Doherty Geological Observatory, Columbia University

metals, but this economic balance does not take into account the cost of disposing of the metallic wastes that accumulate in urban regions. Thus, it is likely that sometime in the future many metals now considered as exhaustible, nonrenewable resources will be treated as recyclable resources.

Not all minerals can be recycled under existing conditions, however. The concentrated phosphates that are used in fertilizers and detergents, for example, are dispersed widely over the farmlands and waters of the Earth, from which they enter the life cycles of various organisms and eventually, through erosion or in wastes, reach the oceans. Because these phosphates are virtually irretrievable and because the rate at which available reserves are being used probably exceeds the rates at which new reserves are formed, such minerals are considered as nonrenewable and exhaustible resources.

#### IV. Management of natural resources

##### MANAGING NONLIVING RESOURCES

**Soils. Formation of soil.** Soils are the basis of support for most terrestrial life and a source of nutrients for freshwater and marine life. As noted above, soil is formed over time as the result of interaction between the living and the nonliving environment—climate, organisms, and the physical surface of the Earth. Rocks are broken apart by the action of sun, wind, rain, snow, sleet, and ice. With the aid of wind and water movements as well as gravity, rock particles from high elevations are deposited on mountain slopes or in valleys, where they are further acted upon by the local climate, by plant and animal life, and by such other environmental factors as fire until they become soil. Nitrogen from the atmosphere, formed into nitrates by the action of lightning and atmospheric water vapour, may enter the soil with rainfall. Other nitrates may be added by the action of such living organisms as soil bacteria and various algae that can convert atmospheric nitrogen into the nitrates required for plant growth. These and other chemicals in the soil eventually become part of the living tissue in plants and animals. The chemicals are returned to the soil as organic wastes and litter that form humus, which is partly decomposed organic material. As humus continues to decompose, the chemicals within it enter the soil for further use by plants and animals.

Soils vary from place to place depending upon the rocks and minerals from which they are derived, the nature of the local climate, and the kinds of organisms that live in or on them, as well as the amount of time that these factors have been operating. Developmental soils—i.e., those still being modified by climate and organisms—reveal the nature of the parent materials from which they are derived; mature soils, those that have achieved a balance among the various forces op-

Developmental and mature soils

erating on them, show in particular the influence of the climate and vegetation in which they develop. Soils also differ greatly in their inherent fertility and in their ability to support life. Those derived from quartz sand, for example, may be naturally deficient in calcium, magnesium, and other elements essential to plant growth. The surface layers of those soils developed in humid, forested regions are often heavily leached, as rainwater containing weak organic acids percolates through them and dissolves the more soluble minerals.

Because soils are essential to man for such purposes as growing crops, forage, and timber, it is important that they not be allowed to wash or blow away more rapidly than they can be regenerated, that their mineral fertility not be exhausted, and that their physical structure remain suited to the continued production of desired plant materials. The objective of soil management, therefore, is to keep soil in place and in a state favourable to its highest possible productive capacity.

**Soil erosion.** In the past and, to a considerable degree, even now, soils have not been managed effectively. Those exposed through cultivation to the erosive effects of wind have been blown away; those laid bare on sloping ground have been washed downhill by rainfall. Although soil erosion has long been recognized as a major conservation problem, erosion as such—and its converse, the deposition of eroded soil particles—is not a problem but a normal and natural process leading to both soil development and maintenance. Soils exist only because of past erosion and deposition. The conservation problem involved in soil erosion is the accelerated erosion that occurs when soil cover in the form of living or dead plant material is removed. In such cases the soil then erodes at a rate faster than it can be replaced by normal deposition of particles on the soil surface or by the breakdown of rocks and minerals. In severe cases, such erosion leads to the formation of deep gullies that cut into the soil and then spread and grow until all the soil is removed from the sloping ground. Under severe wind action, the finer particles of surface soil are blown away and form drifts and dunes, leaving only the coarser sands and gravels on the soil surface.

Although measures to stop soil erosion are now widely used in most technologically advanced countries, the problem remains a major one in the developing nations of the world. It is particularly severe in the tropics, where high rainfall and steeply sloping ground favour the rapid loss of any soil exposed by agriculture, and around the edges of the world's deserts, where destruction of natural plant cover by cultivation or livestock grazing causes soil loss through wind action and the spread of desert-like conditions.

To prevent wind erosion, shelter belts of trees have been planted to break the force of the wind. The practice of covering soils with plant litter (mulch) when they are not actually covered with growing plants also helps to hold them in place. Cultivating at right angles to the direction of the wind further serves to prevent wind erosion.

Water erosion on sloping ground may be prevented by terracing on steep slopes or by contour cultivation on more gentle slopes. In the latter a slope is plowed along horizontal lines of equal elevation. Strip-cropping, in which a close-growing crop is alternated with one that leaves a considerable amount of exaused ground, is another technique for reducing water erosion; the soil washed from the bare areas is held by the closer growing vegetation. In the tropics a shelter over the ground serves as a means for breaking the force of raindrops, thus reducing their erosive power, and also to screen out direct sunlight. In addition to causing damage to certain crops, sunlight can accelerate the breakdown of organic materials in the soil at a rate that is faster than is desirable.

**Soil fertility.** A conservation problem equally as important as that of soil erosion is the loss of soil fertility. Most agriculture was originally supported by the natural fertility of the soil; and, in areas in which soils were deep and rich in minerals, farming could be carried on

**Figure 2: Soil erosion and ways to prevent it.** (Top) Eroded farmland in west Tennessee, resulting from tenant-absentee-owner relationship. (Centre) Contour farming in Pennsylvania. (Bottom) Concrete dam built to protect field from erosion at Delavan, Illinois.

Erosion by  
wind and  
water

for many years without the return of any nutrients to the soil other than those supplied through the natural breakdown of plant and animal wastes. In river basins, such as that of the Nile, annual flooding deposited a rich layer of silt over the soil, thus restoring its fertility. In areas of active volcanism, such as Hawaii, soil fertility has been renewed by the periodic deposition of volcanic

ash. In other areas, however, natural fertility has been quickly exhausted. This is true of most forest soils, particularly those in the humid tropics. Because continued cropping in such areas caused a rapid decline in fertility and therefore in crop yields, fertility could be restored only by abandoning the areas and allowing the natural forest vegetation to return. Over a period of time the soil surface would be rejuvenated by parent materials, new circulation channels would form deep in the soil, and the deposition of forest debris would restore minerals to the topsoil. Primitive agriculture in such forests was of a shifting nature: areas were cleared of trees and the woody material burned to add ash to the soil; after a few years of farming, the plots would be abandoned and new sites cleared. As long as populations were sparse in relation to the area of forest land, such agricultural methods did little harm. They could not, however, support dense populations or produce large quantities of surplus foods.

Fertilizers  
and crop  
rotation

Starting with the most easily depleted soils, which were also the easiest to farm, the practice of using various fertilizers was developed. The earliest fertilizers were manures, but later larger yields were obtained by adding balanced combinations of those nutrients (*e.g.*, potassium, nitrogen, phosphorus, and calcium) that crop plants require in greatest quantity. Because high yields are essential, most modern agriculture depends upon the continued addition of chemical fertilizers to the soil. Usually these substances are added in mineral form, but nitrogen is often added as urea, an organic compound.

Early in agricultural history it was found that the practice of growing the same crop year after year in a particular plot of ground not only caused undesirable changes in the physical structure of the soil but also drained the soil of its nutrients. The practice of crop rotation was discovered to be a useful way to maintain the condition of the soil and also to prevent the buildup of those insects and other plant pests that are attracted to a particular kind of crop. In rotation systems a grain crop is often grown the first year, followed by a leafy-vegetable crop in the second year and a pasture crop in the third. The last usually contains legumes (*e.g.*, clover, alfalfa), because such plants can restore nitrogen to the soil through the action of bacteria that live in nodules on their roots.

**Salinization of soil.** In irrigation agriculture, in which water is brought in to supply the needs of crops in an area with insufficient rainfall, a particular soil-management problem that develops is the salinization (concentration of salts) of the surface soil. This most commonly results from inadequate drainage of the irrigated land; because the water cannot flow freely, it evaporates, and the salts dissolved in the water are left on the surface of the soil. Even though the water does not contain a large concentration of dissolved salts, the accumulation over the years can be significant enough to make the soil unsuitable for crop production. Effective drainage solves the problem; in many cases, drainage canals must be constructed, and drainage tiles must be laid beneath the surface of the soil. Drainage also requires the availability of an excess of water to flush the salts from the surface soil. In certain heavy soils with poor drainage, this problem can be quite severe; for example, large areas of formerly irrigated land in the Indus basin, in the Tigris-Euphrates region, in the Nile Basin, and in the Western United States have been seriously damaged by salinization.

**Watershed soil.** The soils of wild lands in all areas that yield water to streams and rivers are as important to man's welfare as are those in which he raises agricultural crops. If these soils are kept in place and in good condition, they support trees, forage, and wild animal life and yield clear water for human use. If, however, these soils are damaged physically by being compacted or are allowed to erode, they lose not only their capacity to support vegetation but also their capacity to hold and slowly yield useful water to streams or springs. Furthermore, eroded soils cause siltation of waterways;

they will also accumulate in lakes and reservoirs, filling them and thereby reducing the useful purposes that these bodies of water serve.

In order to maintain soils in watershed areas, their vegetative cover must be retained. This requires avoiding excessive disturbance of forest vegetation and soil cover through logging, avoiding the excessive grazing and trampling of pasture lands, and preventing the kinds of wild-land fires that destroy plant cover and expose the soil. Often, the success of intensive land and water use downstream depends on the care taken of the soils in the less intensively used forest or range watersheds upstream.

**Water.** Life originated in the oceans, and the chemical composition of body fluids in land animals reflects their primeval origin. The dependence of life on water is complete; it is the major constituent of plant and animal cells. Most of the major groups of animals still live in water; a relatively small number have adapted to life on dry land.

Depen-  
dence of  
life on  
water

**Uses of water.** Man requires water for a variety of purposes; water for drinking is still paramount, and such water must be relatively pure. Water is also required by domestic animals and plants; and, if it is not supplied in sufficient amounts through precipitation, it must be supplemented by irrigation systems. Irrigation, however, is one of the most wasteful uses of water in areas in which it is scarce, because great quantities are lost through evaporation in both storage areas and transport. In many regions irrigation is, nevertheless, essential for human survival.

Water for transportation has always been important to man, as indicated by the fact that most major cities are located on the shores of oceans and other large bodies of water or along rivers and other types of navigable waterways. Despite recent advances in ground and air transportation, water transportation has an economic advantage for the movement of goods that have a relatively low value per unit of weight or volume, such as raw mineral ores, fuels, and various types of construction materials. Water for urban use other than drinking serves a multitude of purposes, such as fire fighting, street cleaning, sanitation, and sewage disposal. Steel mills, pulp mills, chemical factories, and most other industrial processes that involve the conversion of raw materials into finished products require water. Next to agriculture, one of the most extravagant uses of water is as a cooling fluid in the generation of power from fossil and nuclear fuels, with the latter consuming far greater volumes. Water has been used directly as a source of power since the time of the first sailboat and the first waterwheel. A small but important part of the world's electrical supply now is generated by hydropower, in which the force of falling water is used to turn turbines that produce electricity.

**Husbandry of water supplies.** Although water is a renewable resource, the many demands for water of a desired quantity and quality in a particular place require careful husbandry of the supply. After reaching the surface of the Earth as rain, water enters a supply system either by penetrating the ground and moving through subsurface channels, known as aquifers, or through runoff into streams and rivers. As mentioned above, the supply and quality of water depend in part on the management of the vegetation and soil in the watershed areas. Also involved is the control of streamflow or the control of pumping from underground sources. In many parts of the world, where rainfall is seasonal, streams run at flood levels during the wet season but are extremely low or completely dry at other times of the year. River-basin-management techniques attempt to equalize this variable supply for human purposes, in part through watershed management and in part through the capture of water by dams and its storage in reservoirs.

When water is mismanaged, a high percentage is lost through evaporation in watersheds. Moreover, as a result of poor management of watersheds, the seasonality of water flow is more acute: floods that destroy lands in the river basins become more frequent during the wet season, and there is an increase in the frequency of droughts

Conse-  
quences of  
misman-  
agement  
of water

during the dry or low-rainfall season. Soil eroded from watersheds impairs the functioning of dams, reservoirs, and other structures downstream. Furthermore, because of mismanagement water becomes polluted at various stages in its movement from atmosphere to land and thence to the oceans.

Effective water management starts when precipitation first reaches the ground, after which the quality and quantity of water must be protected at every critical point along the hydrologic cycle. Hence, although it may have been practical to use streams, lakes, and the oceans as dumping areas when populations were low and water was abundant, this practice becomes untenable when populations increase and supplies of water decrease relative to human needs. Thus, except in sparsely populated areas of the world, population and technological growth have made necessary the prevention of erosion, the recycling of wastes so that nutrients are restored to the soils and useful minerals are reclaimed for reuse, and the reuse of water to the maximum possible degree.

"New" sources of water. Lack of water of proper quality and quantity has been a major factor affecting urban and industrial growth. To overcome this problem, water has been transported great distances—e.g., the channelling of Rocky Mountain water from the Colorado River to the city of Los Angeles. One project, now only projected, involves the reversal of Siberian rivers to meet the demands of urban and rural areas along rivers flowing into the Caspian and Black seas.

The use of the oceans as sources of fresh water is being developed in many areas. The nation of Kuwait, a desert amirate in Arabia, now receives much of its water supply through the desalinization of seawater, as do a number of small communities and several large urban centres elsewhere in the world. With the further development of nuclear energy as a power source, it is expected that seawater will be used to an even greater extent as a source of fresh water. Moreover, the materials reclaimed from seawater could, if power is available for their separation and concentration, help in meeting many of the world's mineral needs. It seems unlikely, however, at least with foreseeable sources of power, that desalinated ocean water will be extensively pumped to inland regions. Meeting the growing needs of such areas will require the purification of waters polluted by urban or industrial use or of waters that have become salinized through their use in irrigation. The reuse of such waters could go far toward reducing the need for new water by inland communities.

**Air.** Concern about the quality of air is a relatively recent development, although polluted air has been a problem of urban communities for many centuries. As early as the 13th century in London, a royal decree forbade the use of soft coal for heating because it was a source of obnoxious fumes. The decree was not enforced very long, and by the 19th century the widespread use of soft coal for heating had become the cause of London's infamous "black fogs." In addition to emitting particles of smoke and soot that contribute to black fogs, the burning of soft coal also produces sulfur dioxide, a gas that, when combined with water vapour, forms sulfurous acid. Because sulfur dioxide poisoning was believed to have been responsible for the deaths of thousands of persons in London during the decades before 1960, stringent measures to curtail air pollution were enacted. As a result, air pollution from industrial sources and space heating has been greatly reduced. At the same time, however, the less visible but equally dangerous pollution from automobile engines has increased.

Air pollution results from a variety of causes, not all of which are man's responsibility. Dust storms in desert areas and smoke from forest and grass fires contribute to chemical and particulate pollution of the air. Forest fires that swept the state of Victoria, in Australia, in 1939 caused observable air pollution in Queensland, over 2,000 miles (3,000 kilometres) away. Dust blown from the Sahara has been detected in West Indian islands. The discovery of pesticides in Antarctica, where they have never been used, suggests the extent to which aerial trans-

port can carry pollutants from one place to another. Probably the most important natural source of air pollution is volcanic activity, which at times pours great amounts of ash and toxic fumes into the atmosphere. The eruption of such volcanoes as Krakatoa, in the East Indies, and Katmai, in Alaska, has been related to measurable climatic changes.

Air pollution may affect humans directly, causing a smarting of the eyes or coughing. More indirectly, the effects of air pollution are experienced at considerable distances from the source, as, for example, the fallout of tetraethyl lead from urban automobile exhausts, which has been observed in the oceans and on the Greenland ice sheet. Still less directly experienced are the possible effects of air pollution on global climates.

Urban air pollution. It is the immediate effect of air pollution on urban atmospheres that is most noticeable and causes the strongest public reaction. The city of Los Angeles has been noted for both the extent of its air pollution and the actions undertaken for control. Los Angeles lies in a coastal plain, surrounded by mountains that restrict the inward sweep of air and that separate a desert from the coastal climate. Fog moving in from the ocean is normal to Los Angeles climate. Temperature inversions characterized by the establishment of a layer of warm air on top of a layer of cooler air prevent the air near the ground from rising and thus effectively trap pollutants that have accumulated in the lower layer of air. In the 1940s, Los Angeles air became noticeably polluted, interfering with visibility and causing human discomfort. Attempts to control pollution, initiated during the 1950s, resulted in the successful elimination of such sources of pollution as industrial effluents and the outdoor burning of trash and debris. Nevertheless, pollution continued to increase as a result of the increased number of motor vehicles. Exhaust fumes from the engines of automobiles contain a number of polluting substances, including carbon monoxide and a variety of complex hydrocarbons, nitrogen oxides, and other compounds. When acted upon by sunlight, these substances undergo a change in composition producing the brown, photochemical smog for which Los Angeles is well known. Efforts to reduce pollution from automobile engines and to develop pollution-free engines may eventually eliminate the more serious air pollution problems. In the meantime, however, air pollution has driven many forms of agriculture from the Los Angeles basin, has had a serious effect upon the pine forests in nearby mountains, and has caused respiratory distress, particularly in children, elderly people, and those suffering from respiratory diseases.

Los Angeles is neither a unique nor the worst example of polluted air. Tokyo has such a serious air-pollution problem that oxygen is supplied to policemen who direct traffic at busy intersections. Milan, Munich, Rio de Janeiro, and Buenos Aires face similar problems. The small town of Knapsack, in Germany, was completely abandoned by its citizens in 1971 as a protest against industrially caused air pollution. Although New York City produces greater quantities of pollutants than Los Angeles, it has been spared from an air-pollution disaster only because of favourable climatic circumstances.

The task of cleaning up air pollution, although difficult, is not believed to be insurmountable. Use of fuels that are low in pollutants, such as low-sulfur forms of petroleum; more complete burning of fossil fuels, at best to carbon dioxide and water; the scrubbing of industrial smokestacks or precipitation of pollutants from them, often in combination with a recycling of the pollutants; and the shift to less polluting forms of power generation, such as nuclear fuels in place of fossil fuels—all are methods that can be used for controlling pollution. The example of London, as well as of other cities, has shown that major improvements in air quality can be achieved in ten years or less.

Climatic effects of polluted air. Less obvious than local concentrations of pollution but potentially more important are the climatic effects of air pollutants. Thus, as a result of the growing worldwide consumption of fossil

The air pollution problem of Los Angeles

Desalinization of seawater

The  
"green-  
house  
effect"

fuels, atmospheric carbon dioxide levels have increased steadily since 1900, and the rate of increase is accelerating. Now the output of carbon dioxide is believed by some to have reached a point such that it may exceed both the capacity of plant life to remove it from the atmosphere and the rate at which it goes into solution in the oceans. In the atmosphere carbon dioxide creates a "greenhouse effect." Like glass in a greenhouse, it allows light rays from the Sun to pass through, but it does not allow the heat rays generated when sunlight is absorbed by the surface of the ground to escape. An increase in carbon dioxide, therefore, can cause an increase in the temperature of the lower atmosphere. If allowed to continue, this might conceivably cause melting of the polar ice caps, raising of the sea level, and flooding of the coastal areas of the world. There is as yet, however, little evidence that such an increase in temperature is taking place.

Counterbalancing the effect of carbon dioxide is the increase of particulate matter in the air, a result of the output of smoke, dust, and other solids associated with human activity. Such an increase might, in turn, increase the reflectance, or albedo, of the atmosphere, causing a higher percentage of solar radiation to be reflected back into space. This, in time, could cause a lowering of the Earth's surface temperature and, potentially, a new ice age. It is not known, however, which of the two effects is more likely to occur, because until relatively recently there existed no monitoring system able adequately to measure the necessary parameters of the atmosphere and to detect the changes that are taking place globally. Such a system is now in operation; after measurements have been made over a period of years, scientists will be better able to predict the consequence of man's activities on the composition of the atmosphere.

**Radioactive contamination of the atmosphere.** During the 1950s the effects of atmospheric testing of atomic and hydrogen bombs became a source of major concern. The danger of radioactive pollution of the air and the fallout of radioactive particles to the surface of the Earth stimulated serious investigation, resulting in the discovery of some potentially dangerous conditions. It was observed, for example, that radioactive materials of many kinds, such as radioactive iodine and strontium, are concentrated in living tissue and can cause damage even when the general level of environmental contamination is low. Fortunately, atmospheric testing of nuclear bombs was stopped, and radioactive fallout has not become the worldwide menace that was anticipated. Concern is still expressed, however, over possible air pollution from nuclear-power plants, and scientists disagree on its importance. Further study and free public access to all of the facts are essential to remove fears connected with the use of nuclear energy for any purpose.

**Subsurface deposits.** Several types of conservation activities are associated with the use of fossil fuels and minerals. First are those that involve making the available fuel and mineral reserves serve the most worthwhile purposes for the longest period of time. Second are the problems associated with extracting fuels and minerals from the ground and their subsequent transport, processing, and manufacture, all of which can directly affect the quantity or quality of other resources or the general environment. Third are the side effects, which, because they involve pollution, are considered in the next section.

**Conserving exhaustible fuel and mineral resources.** As has already been noted, fossil fuels and minerals fall into two categories: those that are destroyed by use and those that retain their physical and chemical characteristics during use and are capable of being reclaimed for other uses. The outlook is most bleak with respect to the conservation of those fuels and minerals that are destroyed by use. If petroleum continues to be used at its present rate, the supply will be exhausted or reduced to a level at which further use may be restricted by the high cost of the remaining resource. Because the situation is generally recognized, conservation need involve only allocating the resource to those uses for which it is best suited and restricting its use in those cases in which other

materials, less likely to be exhausted, can be equally well substituted. Thereafter, it is necessary to maximize the available resource. This can be done by avoiding waste in its extraction, transportation, and processing and by utilizing fully all that can be made available. Thus, several oil companies no longer pump competitively from the same oil field, leaving only unobtainable oil in the ground. Instead, fields have been unitized; companies now cooperate in bringing out oil by using only strategically located pumping units. The practice of burning the natural gas from oil fields has been replaced by tapping and piping the gas for use as a fuel. Unrestrained gushers are a thing of the past; more important are the new methods of drilling and of injecting gas or water under pressure to force out oil that previously would have been left in the ground. Improved methods for refining petroleum have eliminated much of the waste that once occurred in this process. Yet accidental losses still do occur. The leaking well that caused such extensive damage to wildlife and recreational resources in the Santa Barbara, California, channel in 1969 resulted in part from failure to use available safety devices. A similar failure was involved in an oil well off the Louisiana coast in 1970. Great quantities of oil are still wasted and waters polluted because of improper navigation of oil tankers and because some such tankers are so poorly constructed that excessive quantities of oil can escape as a result of relatively minor damage to the hull.

Beneficiation, the concentrating of relatively dispersed or low-grade resources into a form in which they can be handled economically, is another means of extending the supply of exhaustible petroleum resources. There are, for example, great quantities of petroleum available in oil shales and tar sands in various parts of the world. As long as petroleum was plentiful in a more concentrated form in oil fields, it was not economical to extract the more dispersed petroleum in such shales and sands. Now, with the prospect of a shortage of petroleum, techniques are being devised for concentrating these lower grade supplies. One method has involved the use of underground nuclear explosions; the resulting heat and pressure force oil and gas into cavities created by the blast.

Conservation in the case of recyclable minerals will involve reuse. For this to be accomplished, incentives and methods may be necessary to encourage the gathering of used materials for reprocessing. Provisions have been made for the collection of junked automobiles, waste cans, bottles, and other containers and for the reuse of building materials from demolished structures. Although much of this is done more to prevent pollution than to reclaim the materials, it does serve both purposes. Another conservation measure is waste-processing technology and the growth of industries concerned with the recycling of wastes.

Just as applicable to the conservation of minerals as they are to the conservation of petroleum are such other techniques as the allocation of scarce resources to their most essential uses, the substitution of other resources for those that have become scarce, and the maximization of supplies. Moreover, there has been great progress toward the development of composite materials, in which relatively small amounts of metal are used in combination with plastics and ceramics. Metallic alloys that minimize the need for scarce materials (as in the substitution for copper or silver in coins of various cheaper metallic alloys and the substitution of aluminum alloys for copper or steel wire, for roofing materials, or for tin in cans) are in many cases more effective than those used for the same purposes. Beneficiation has been used increasingly; thus, low-grade taconite and jasperite ores are now being mined and pulverized, and their iron components separated and pelleted before being shipped to smelters. Such techniques make possible the use of iron deposits that previously would not have been considered economical sources of ores.

Because of the many ways for making better use and reuse of the available supply of metals and other minerals and because the extent of new discoveries cannot be foretold, it is difficult to predict the likelihood of de-

Maximiz-  
ing  
available  
resources

pleting any particular mineral resource; for example, the wasteful use of metals and minerals in most affluent societies creates a drain upon supplies that is entirely unnecessary. Predictions of resource use based on the continuation of wasteful practices are likely to prove unrealistic if these practices are changed voluntarily or forced to change by a scarcity of materials.

**Conservation problems caused by mining.** Some of the most serious conservation problems are associated not with the use of minerals or fuels but with the methods used to extract these resources. Mining for coal has created widespread devastation in the Appalachian Mountains, in Bohemia (Czechoslovakia), and, in the past, in England and Germany because deposits in these regions are found near the surface. In the removal of the coal, soil and all living resources have been destroyed, leaving behind a barren, denuded, and eroded wasteland. Because mining wastes often contain much sulfur, their watery runoff contains sulfuric acid, which destroys aquatic life in streams. Similar problems are associated with the surface mining of nickel in such places as New Caledonia and Australia. In the former, as much as one-quarter of the island may be destroyed if current practices continue. Dredging for tin in Malaysia has also created widespread conservation problems. The mining of phosphates has brought destruction to many Pacific islands; one-half of the island of Nauru has already been devastated, and the other half is now being mined. Titanium mining in the sands along the Australian coast has destroyed natural vegetation on beaches, sand islands, and dunes and opened pathways for dune movement that destroys still greater areas of vegetation. Dredging for gold has damaged many streambeds and riverbeds because it is destructive to aquatic life and water quality.

The means for preventing damage by surface mining do not exist, but damage can be controlled and minimized, in part by the creation of erosion-control structures and the prevention of water pollution. The rehabilitation of mined-over land may involve, among other things, the removal and safe storage of topsoil before mining begins and its restoration after mining operations have been completed. It may also involve the shaping of mining wastes into landforms that can be covered with soil, replanted, and revegetated. In England and Germany attractive recreational landscapes have been created on land that once would have been left a devastated wasteland. Of equal importance, however, is the decision not to mine areas that have high surface-resource values—e.g., highly productive forest or farmlands, certain urban areas, and areas with natural qualities of scenery, plant life, or wildlife that make them suitable to be maintained as parks or reserves. The ores in such areas are not mined unless the need for their minerals is most urgent.

#### MANAGING MINING RESOURCES

Any area of land and water not yet modified by man can be managed in a number of ways. Certain choices must

be exercised early, however, because even minor deterioration of an area through unplanned use may make it unusable for its intended purposes. Other choices, particularly those involving modification of the natural features of the landscape, may be exercised at virtually any time; any previous changes in the character of the living resources in a region to be modified have no effect on the ultimate structural modification of that region. In planning for the use of any undeveloped area, therefore, those purposes that have the most exacting requirements must be considered first; they often depend upon the continuance of relatively undisturbed conditions as well as upon the maintenance of the full variety of wild species and the natural environment within the area.

**Natural communities.** The idea that biological communities should be protected for their own intrinsic value is of relatively recent origin. Although natural communities have been protected since ancient times, the reasons for doing so have not been related to the value of the community per se but to some special feature that was of value to man. Thus, hunting preserves were protected in ancient Mesopotamia, in China, and in England, where the New Forest was set aside by William the Conqueror. While such preserves protected natural areas, their major purpose was to provide a setting for royal hunting. Temple gardens have been preserved over the centuries in China and Japan; the cedars of Lebanon were maintained around holy places. But, again, such preservation was fortuitous rather than intentional.

The idea of preserving wild areas for their own value had its origin in the United States with Catlin, Thoreau, Muir, and others of similar mind. Only more slowly has this concept been accepted in other countries. Appreciation of wild nature is acquired along with scientific knowledge, particularly ecological knowledge. It is a sophisticated taste not usually to be found among those who earn their livelihood in close contact with the wild. Nevertheless, by the 1970s the concept of preserving wild nature for its own value had been widely accepted, although the means for implementing it were not necessarily available in most countries.

Natural communities, little affected by man's activities, are thought to be worth preserving for a variety of reasons. First, perhaps, is the scientific benefit to be derived from studying them, particularly concerning the functioning of the biosphere. From studies of undisturbed ecosystems much can be learned about the behaviour of those systems modified by man for the production of useful materials. Also, the value of wild species to man has been little explored; in their totality they are known to be essential to the function of the biosphere, but the importance of individual species is little understood.

Past experience has demonstrated that wild species of little apparent value may prove to be of major importance to medical research and human health. Sea urchins, for example, are used in studies of embryology; nonhu-

Value of natural communities

Figure 3: Strip mining and its consequences. (Left) Strip-mining coal in Missouri. (Right) Wise County Fair Grounds constructed on coal strip mine spoil in Virginia

man primates (*e.g.*, monkeys and apes) are used for many studies of human functions and diseases; and a great variety of wild plants are used as sources of drugs and medicines. Much of man's knowledge about the growth of populations and social behaviour under various conditions of crowding has come from the study of wild mammals. Furthermore, it is known that more or less undisturbed natural communities are important to the continued operation of those systems that man has created. Watershed forests are protected so as to maintain streamflow and to avoid siltation of reservoirs; estuaries are protected so as to guarantee the continued production of forms of marine life important to man for food or other purposes. Finally, there are aesthetic and recreational values attached to wild areas and wildlife. It would appear that outdoor activities in a natural setting or contact with plants and animals in a wild state are important to man's psychological well-being, because people of all races and cultures seek such experiences when they achieve the affluence that enables them to do so.

Biological communities can be protected in a variety of ways, depending upon the desired objectives. The most difficult and exacting task is the protection of unmodified natural communities, with their full array of wild species, for use in scientific research. Because such communities are becoming increasingly rare, the major efforts to protect them are undertaken at an international level, as well as at the national level. The International Biological Programme, a worldwide research effort, has focussed attention on the many kinds of natural communities that require protection. The International Union for the Conservation of Nature, a semigovernmental international agency, devotes an important part of its activities to the establishment of reserves and parks for the protection of natural communities. The United Nations, through its Food and Agricultural Organization and the UN Educational, Scientific and Cultural Organization, has contributed to the establishment of many parks and reserves in developing nations. Yet, despite such activities, certain kinds of natural communities will be irrevocably lost unless there is greater effort toward their conservation.

The danger to natural communities and wild species comes from many causes. One long-standing problem derives from the exploitation of wild species that have commercial value, as, for example, the widespread removal of mahogany trees and other valuable timber from the forests around the Caribbean area. The uncontrolled hunting of whales and other sea mammals has brought some species to the point of near-extinction, and at least one, the Steller sea cow, has been exterminated. The demand for such high-fashion products as shoes and handbags made from crocodile skins or coats and wraps made from the skins of tigers and leopards has endangered the continuing existence of these animals.

Control of those species considered detrimental to man's welfare has led to an unreasonable warfare against predatory animals. As a result, the wolf, cougar, lion, lynx, eagles and hawks of various species, and other carnivorous animals have been eliminated from the vicinity of human settlements or from pastoral lands, even though the evidence that some of these species do any appreciable damage is not well substantiated. But the greatest single cause for the depletion of natural communities and wild species has been the desire to use land for more productive purposes. This has led to extensive clearing of forests and woodlands, burning of vegetation, and the cultivation of previously undisturbed land for crop production. Many of the lands that are cleared eventually prove to be poorly suited for the purposes for which they are intended and are ultimately abandoned; however, it is then no longer possible to protect the natural communities that previously existed in these areas.

Programs for the protection of natural communities must involve, first, rational planning for the use of land and control over its exploitation by agencies charged with such responsibilities. Adaptation of land use for commodity production by using only those sites best suited for such purposes is a first step toward protecting other lands that are now being cleared unwisely. Although the

establishment and proper management of parks and reserves permits the survival of certain species in certain areas, a more general program of rational management and use of all lands and species is essential to the long-term survival of wild nature throughout the world.

**Strict nature reserves.** The decision to maintain an area in a more or less unmodified condition usually is determined by its overall scientific and aesthetic value. It may also be determined by the contributions the protected area can make to the region as a whole, as, for example, the regulation of water yield and streamflow or perhaps as a reservoir of wild species that subsequently can move or be moved into other modified regions. The most restrictive category of land use is that of the scientific reserve, which is also known as a strict nature reserve. Such areas may be selected because of their unique geological or biological features. Or they may be selected because they are representative of widespread biological communities that will be transformed elsewhere for the needs of commodity production, recreational use, or other more intensive purposes. Retaining representative areas in an unmodified condition provides standards by which the health and productivity of the modified sites can be tested.

Strict nature reserves and other types of scientific reserves often occupy only a relatively small area of land. The amount of land occupied, however, depends to a large extent on the biological requirements of the species to be protected and the interactions of the area with the surrounding region. Thus, in the rolling taiga country (swampy coniferous forests) of northern Europe, Asia, and North America, the decision to maintain a bog in a natural state may involve the protection of only a small area—the bog and those immediately adjacent slopes that drain into it. On the other hand, the decision to protect the natural habitat and population of migratory caribou in the same region could involve an area several hundred miles in length and more than 100 miles in width—a sizable area that might include taiga and tundra. The decision to protect the natural habitat of a species of migratory waterfowl would be even more far-reaching. In addition to protecting the tundra breeding ground of such birds, protection of their resting and wintering grounds, which could lie in a different hemisphere, might also be involved. It is always easier to protect rooted plants than mobile animals. And the more mobile the species, the more difficult the task; for many migratory species, international action is required.

Any decision to protect an area in an undisturbed condition, however, must take ecological reality into account. The experience of Everglades National Park in the United States, which protects only the lower end of an extensive watershed, is illustrative. The stormy history of this park has involved efforts to control water and land use in areas outside the park because its future existence depends upon the flow and quality of water from these areas. By contrast, high mountain reserves, such as those surrounding Mount Kinabalu, in Borneo, Mount Kenya, in East Africa, or Glacier National Park, in Montana, offer no such difficulties.

The designation of an area as a strict nature reserve is often proclaimed by law and recognized only by the appropriate governmental authorities, with no cognizance of the action by others. Such areas must have boundaries that are clearly demarcated and identifiable to prevent accidental intrusion and modification.

Because a strict nature reserve is set aside for scientific purposes, its use for recreation or any other purpose may disturb its natural integrity. Even scientific use itself can be a disturbing factor; hence, the use of such reserves is regulated by scientists. Usually a scientific advisory committee must rule on the appropriateness of any proposed research to the long-term future of the area.

The decision to protect a natural area for scientific purposes is not a simple one. In the case of most of the less affluent countries, in which neither money nor technical expertise is available, it is virtually impossible to proclaim a strict reserve and have it maintained as such except in the most remote areas. Usually international as-

**Difficulty  
in  
protecting  
migratory  
species**

sistance is required, in money or manpower, if such reserves are to be established.

**National parks.** The establishment of national parks in the United States represented one of the first national efforts to protect wild nature. Yet, in establishing Yellowstone National Park, Congress made clear that it was viewed as "a pleasuring ground" for people and not as an area intended only to safeguard communities of plants and animals. It was not until the formation of the U.S. National Park Service in 1916 that the concept of managing parks so as to maintain their natural qualities was accepted. Nevertheless, the practice of killing predatory animals as "undesirable" elements of wild nature continued in U.S. national parks into the 1930s and lasted in some African national parks as late as the 1960s.

Unlike a strict nature reserve, a national park may be made available for various purposes but usually only for those forms of recreational use that do not create great changes in or require significant modifications of the natural environment. National parks usually are selected on the basis of their unique qualities, outstanding natural beauty, unusual geological formations, or remarkable array of wild animal or plant life. They may also be selected, however, to protect areas of anthropological, archaeological, or historical importance along with the natural or artificially modified landscapes that surround them. In the United States, national parks are dedicated solely to recreational activity. National parks in England may protect cultural as well as natural landscapes, in that some may be dedicated to the preservation of traditional forms of land use that are disappearing elsewhere. Some national parks, such as in Peru, protect primitive peoples along with their hunting and gathering grounds.

Thus, exactly what constitutes a national park varies according to the nations and people involved. The dedication of an area as a national park is everywhere a highly restrictive form of land use, in which all incompatible activities are prohibited. Hunting, logging, mining, commercial fishing, agriculture, and livestock grazing are excluded from most such parks, as are urban and industrial uses not directly related to recreation. There is much debate as to whether tourist facilities should be within or outside national parks; because of their disruptive effects, the trend is to locate such facilities outside.

National parks, at a minimum, require equally extensive boundary demarcation and perhaps policing and patrolling as are necessary for strict nature reserves. They also require the careful planning of trails, roads, and other means of human access in order to channel the activities of visitors in ways that will not disrupt the resources or landscapes. Not only must certain fragile areas be set aside and protected from visitors, but visitor use must be concentrated in those places in which human activities will do a minimum of harm. The trend has been to divide national parks into zones that range from areas of intensive public use at one extreme to the most remote wilderness or strict nature reserves at the other.

Usually a considerable amount of money and manpower must be invested in the planning and management of a national park. This is often beyond the resources of the less affluent countries unless international assistance can be provided. Because of their attraction as sites for outdoor recreation and their appeal to tourists, however, national parks often more than pay for themselves in a short period of time. In East Africa, for example, national parks are the major source of foreign exchange of the countries in which they are located because of their unique wild animal life. As a result of the body of expertise that has developed in the planning and management of national parks and because of their growing economic importance, expert direction in the establishment and maintenance of national parks is now available throughout the world whenever it is requested. Within the United Nations such assistance is offered to developing countries by UNESCO and the Food and Agricultural Organization; outside the United Nations, assistance is available from the International Union for Conservation of Nature and from the World Wildlife Fund.

**Refuges and sanctuaries.** A less restrictive use of an area of wild land is that directed toward the protection of certain species or groups of wild animals or plants. This type of land use includes wildlife refuges and sanctuaries as well as various kinds of botanical reservations. In such areas, use of the land that could interfere with the well-being of the protected species is excluded. Other forms of land use may be encouraged, however, if they are not in conflict or if they actually assist with the creation of a suitable environment for the protected forms of life.

Refuges and sanctuaries often are established for the preservation of endangered species of wildlife or plants, particularly those whose numbers and distribution have been seriously curtailed; examples include the Umfolozi Game Reserve, in South Africa, in which the southern species of the white rhinoceros is protected, and the Mountain Zebra National Park, in the same country. The refuges for the California condor and the Torrey pine in California are of a similar nature. Refuges and sanctuaries may also be provided for more abundant species that require protection at certain periods of their life cycle or in certain areas where they gather in order to reproduce. Many wildlife refuges and sanctuaries in the United States and Europe are of this type; they provide protected sites for the resting, breeding, or wintering of wildlife species (particularly waterfowl) that otherwise are hunted outside of the refuge. In such places management measures are necessary to enhance the habitat for the protected species and to remove any competitors or predators that might interfere with the breeding and survival of the young. Such measures would be inappropriate to parks or strict nature reserves, because their purpose is to protect a total biological community without favouring a particular species.

The various measures employed for the protection and management of living resources on land also apply to water areas. Marine and other aquatic parks and reserves have been established in many parts of the world to protect various forms of saltwater and freshwater plant and animal life. Australia, for example, has reserves that protect important areas of the Great Barrier Reef; Kenya and Tanzania have marine parks and reserves on their coasts. Lake Baikal, in the Soviet Union, is now included in a major national park designed to protect not only its unique freshwater life but also its watershed areas.

**Wildlife and fisheries management.** The protection of most wild animal life cannot be accomplished solely through parks and reserves. Consequently, wildlife conservation and management represent an activity that extends into other areas. As has been mentioned previously, one form of wildlife conservation with a long history of laws, regulations, and proclamations dating back to ancient centres of civilization was the protection of royal game. Wildlife conservation is also closely related to the management of fisheries, because both are directed toward the preservation of wild species and their habitats and toward increasing the productivity and yield of these species. Increased productivity in wildlife or fish may contribute to a commercial harvest, or it may make contributions to human well-being through sport hunting or fishing, wildlife viewing, or some other form of recreation.

The basis for wildlife and fishery management includes research into the ecological requirements and breeding potentials of the species involved. Protective laws and regulations are necessary to control the allowable commercial or sport take in order to guarantee that it remains within the sustainable yield. Means for enforcing such laws should include the employment and deployment of adequate protective forces, preferably specially trained wildlife and fisheries wardens who are capable of identifying species likely to be killed or captured and who are familiar with the ways of hunters and fishermen. Management activities intended to maintain or improve the habitat for the wild animals concerned are also important. Special refuges of the kind already described may be essential both to control hunting and fishing pressure and to allow animals to reproduce, rest, or winter

Refuges as protected sites for abundant wildlife species

Facilities needed in national parks

Commercial value of fish and wildlife

without being disturbed. In addition to these activities, wildlife conservation also involves the management of the requirements needed by wildlife in the areas in which the land is used for other purposes.

Commercial fishing, which is of great economic importance in countries with extensive inland waters or with access to the seas and oceans, contributes a significant share of world food, particularly protein.

It has been estimated that ocean fisheries yield more than 55,000,000 tons of fish to commercial markets, and future sustained yields in excess of 110,000,000 tons have been projected. The problems of fisheries conservation are many, however. It is essential first to locate the fish and derive some estimate of their abundance. Much of the recent increase in yield by world fisheries has come from the discovery of previously little known and unexploited sources of fish. It is also necessary to determine the maximum sustained yield of the fish population. Finally, the most difficult task is the supervision and control of the fishery. Even in national waters, fisheries have been overexploited and depleted to a level such that the species concerned no longer has any commercial value—the sardine fishery of the California coast is an example. In international water it is much more difficult to regulate and control the activities of fishermen.

The commercial use of terrestrial wildlife, although not in the same economic category as fisheries, is nevertheless significant to some countries. Wild animals are killed for their meat, hides, furs, fats, oils, bones, ivory, antlers, and other by-products. Live animals are captured for zoos, for medical research, and for the pet trade. The exceedingly high prices paid for certain species, such as various primates used for medical research or those that are valued for their furs, has been of great importance in causing the reduction of some species to a dangerously low level. Despite the high commercial value of some wildlife, however, in many parts of the world their recreational or sporting value has an even greater economic importance. In the United States, for example, the commercial hunting and sale of game animals is generally prohibited, as is the commercial harvesting of certain game fish, because such wildlife is reserved for recreational use.

In technologically advanced countries it has proved practical and economically desirable to manage wildlife and fisheries so that no species becomes severely depleted. But, in those countries in which a high percentage

of the people are illiterate or live near a poverty level, the protection and management of wildlife and fisheries is much more difficult to achieve. In such nations protective laws are not easy to enforce because trained wardens are not widely available and because the laws are neither understood nor accepted by the general population. Thus, the depletion of wildlife and fisheries through hunting and fishing continues in these countries, and growing numbers of species are now endangered.

**Multiple-use management.** The use of an area for wildlife conservation may include its use for other purposes. Throughout the world many areas of public wild land are managed on a policy of multiple use; that is, they can provide either at the same time or sequentially a variety of wildland products or services. National forests, for example, are used for recreation and to produce timber and range forage for domestic livestock, wildlife, and fish; and at the same time they stabilize watersheds and yield sustaining water supplies to natural bodies of water or to man-made reservoirs.

The decision to manage an area for multiple use, however, necessitates minimization of conflicts between the various forms of use. Thus, removing the timber from an area involves the construction of logging roads, landings, and other facilities; and, while the area is being logged, most other uses are restricted. Furthermore, during and following logging, care is taken not only to provide a site and seed trees suitable for growing the next crop of trees but also to protect the natural reproduction of trees, young seedlings, and saplings. In cases involving more intensive management, seeds or seedlings are planted and given protection during the period when they are becoming established. Moreover, the value of the site for recreation or for other purposes may be greatly reduced during this process, particularly when certain systems are used for cutting timber; thus, clear-cutting, which involves the total removal of all large trees from an area, creates an appearance of greater devastation than is seen in selective cutting, in which only a few trees of a particular species and age class are removed. Obviously, clear-cutting then favours wildlife species that prefer open areas at the expense of those that require dense forest cover. Generally speaking, however, logging of timber involves the exclusive use of an area for this purpose over a period of time; other uses may not be fully restored until the vegetation or animal life has recovered from the effects of timber removal.

Conflicts in multiple use

Figure 4: The cutting of timber.  
(Left) Clear-cut timber in Oregon. (Right) Selective cutting of timber in the Chuska Mountains, New Mexico.

Development of an area for grazing by domestic livestock often includes fencing; the demarcation of livestock trails for the transfer of animals from one area to another; the provision of watering points, salt grounds, and other items essential for the welfare of the animals; and sometimes the construction of special corrals or handling chutes. When livestock are in an area, they cannot be disturbed too frequently. Livestock owners also demand the removal of any predatory animals that are likely to attack their stock. Such needs obviously restrict the development of the same site for purposes that could conflict with its use as a livestock range.

Factors involved in development for water power

Intensive development of an area for water power (e.g., the construction of dams, power stations, pipe lines, canals, and power lines) entails complete change of the area affected and removes much of its wild or natural quality. Although such a location is obviously less suited for wilderness or wild-country recreation, it often is enhanced for certain forms of mass recreation, such as fishing, boating, and water sports in reservoirs. Recreational development on any intensive scale also involves considerable modification of an area. The construction of tourist and visitor facilities of various kinds—trails, ski runs, campsites, roads and parking areas, lodges, and picnic grounds—necessarily restricts the use of such an area for other purposes.

Figure 5: Hoover Dam, Colorado River, on the border of Arizona and Nevada, used for irrigation and hydroelectric power.

The concept of multiple use thus applies mostly to the management of large areas of wild land, although within such areas various special uses may from place to place and from time to time be emphasized. Nevertheless, the governing policy of multiple use is valuable because it prohibits the exclusive use of a particular area for the benefit of any one segment of society and, instead, forces accommodation to the greatest variety of uses that best suit a particular site.

Intensive **wild-land** uses. **Timber production.** Loss of the natural character of an area usually accompanies the decision to manage it for maximum production of such crops as timber or range forage. Thus, if a forested area is to be managed for maximum timber production, establishment of fast-growing species of trees that will make the most efficient use of the soils, water, and climate is necessary. Crops of timber or other wood products are cut and removed regularly and other trees planted in their place, usually from nursery stock. Roads and other facilities are constructed to facilitate the removal or protection of the forest products. The ultimate objective is usually a high-yielding plantation or tree farm, often using exotic species of trees or specially developed varieties that combine high-yielding capabilities with resistance to insect pests or diseases. Seldom do such forests have any value for other purposes, except possibly for soil protection and water yield. Aesthetically, such a forest may even lose its wild aspect and have all the regularity and artificiality of an orchard or cornfield. Recreational uses

often are discouraged; even if they are not, the recreational appeal of such areas usually is slight. Few if any of the larger forms of wild animal life can find a suitable habitat in a forest plantation, and those that do become established often are regarded as pests if they interfere in any way with tree production. Such forests, however, produce far more timber, pulp, and other kinds of wood products than can be obtained from an equivalent area of wild forest. Moreover, intensive development of production forests in suitable locations can spare areas of natural forest for other purposes. Privately owned forests in North America are increasingly managed in this way, a practice that increases with the demand for forest products; government-owned production forests and forest plantations in other countries receive similar treatment. Such intensive development, however, is economically feasible only at sites with soils and other habitat conditions favourable to high yields.

**Livestock production.** Management of range and pasture lands for livestock production can become almost a single-purpose use of the land. A range, any area of wild land that is covered with natural vegetation, is usually located in the more arid mountainous or colder regions of a country; such land is suitable for the production of the larger grazing or browsing animals. Pastures, on the other hand, are grazing areas with better growing conditions than ranges because they are located either in regions of higher rainfall or in areas suitable for irrigation. Because of the nature of pasture, more intensive management is economically practical, including regular cultivation and planting to replace the natural vegetation with higher yielding domestic, exotic, or artificially bred varieties of forage plants. Livestock production on pastures is a single-purpose use of the land, although pastures are often included as part of a rotation system in the raising of farm crops. The intensive use and management of pastures effectively removes such areas from the category of wild land.

Management of the forage on range lands requires skillful manipulation of natural processes of plant succession and the balancing of livestock numbers to the carrying capacity of the vegetation; that is, the number of animals the vegetation can support without deteriorating and endangering its future productivity. Efforts are made to avoid overgrazing, which reduces the vegetation to a less productive state, and excessive trampling by animals, which can compact the soil and interfere with its water relationships and productivity. A flexible method of livestock handling is essential to success on ranges: animals are not allowed to concentrate excessively in any one area, and their use of vegetation must be consistent with continued production of the more nutritious and palatable forage plants. Moreover, during dry periods, when there is low forage production, the number of livestock using a range must be reduced in order to avoid damage to the range; otherwise, feed lots are provided or the animals are moved to irrigated pastures.

As a primary use of range land, livestock production requires the construction of various facilities—fences, water holes, corrals, roads, and troughs for salt or other forage supplements. On productive range lands it may be economically profitable to provide fertilizers, usually by spraying or dusting from aircraft, to encourage higher forage yields. Undesirable vegetation is sometimes burned, crushed, or sprayed with herbicide to provide more space for the better forage plants; ranges also may be seeded with higher yielding or more disease-resistant forage plants. Such activities necessarily restrict use of the land for other purposes. Nevertheless, except in cases of intensive management, range lands can provide recreation and often are highly suited to various forms of wildlife management. There is considerable evidence from many parts of the world that some combination of domestic animals and wildlife can provide greater yields and profits from drier, colder, or steeper range lands than can be obtained from such lands when used exclusively for domestic-livestock production.

**Agricultural management.** The most intensive forms of rural land use for agricultural purposes are those con-

Range and pasture as single-purpose use of land

**Figure 6: Livestock production on range and pasture land.** (Left) Rangeland in southwestern Washington. (Right) Angus cattle on bluegrass pasture land in Kentucky. (Left) Ray Atkeson, (right) J.C. Allen and Son

## Green Revolution

cerned with the raising of harvestable crops or with the production of animal products. Unlike primitive agriculture, which involved only the temporary removal of natural vegetation and depended for a short period of time on natural soil fertility, modern agriculture requires large inputs of chemicals, energy, and technical skills to produce increased yields of crops or animals. In the technologically advanced countries food production is now so much greater than population growth that it is possible to retire former farmlands from use and to produce crops according to demand without approaching the maximum yields obtainable. The so-called Green Revolution of recent years has been based on the spread of improved farming skills to less developed nations of the world. It has been made possible by the breeding of high-yielding forms of grain specifically adapted to the ecological conditions of the countries involved.

The decision to use an area of land for high-yield agriculture essentially rules out its use for other purposes. The intensive production of farm crops in an agricultural region may also have undesirable side effects; as has been previously noted, these may include the pollution of other areas when the pesticides, herbicides, or other agricultural chemicals blown or washed from farmlands affect vegetation and animal life elsewhere. Nevertheless, committing an area to intensive agricultural production does not rule out its future restoration for other uses. As long as the soils are well cared for, such areas can be converted quickly to other purposes if it is not necessary to keep them in farm production. Abandoned farmlands in the southern United States, for example, are now highly productive forest areas, and former farming lands elsewhere are being used to support wildlife and outdoor recreation. In general planning for conservation of natural resources, intensive use and high production in those areas best suited for farming must be encouraged—provided, of course, that the polluting effects of these activities on the general environment are avoided. Such concentration can spare the destruction of other resources through attempts to use inadequate lands for marginal farming activities.

### INTERNATIONAL PROBLEMS OF RESOURCE MANAGEMENT

The management of living resources requires a high degree of international cooperation and a willingness on the part of nations to agree to some forms of international control. This is particularly true for the management of those aquatic animals that occupy international waters; it is equally true for migratory animals that move from one country to another. Furthermore, the animals and plants that are commodities in international trade must also be protected through international agreements. Finally, when an international agency or an agency from a particular country works with the resources of a less developed nation in an effort to help that nation improve its economy, care is taken to avoid any adverse effects on the conservation of that nation's environment.

Despite general recognition of these problems, few na-

tions have shown a willingness to forgo any of their sovereign rights or to cede authority over their affairs to international bodies. International laws and regulations remain, for the most part, gentlemen's agreements among nations. A country can and often does ignore the rules when it is economically advantageous for it to do so. Only international public opinion or, more rarely, the threat of force by one nation or by a group of nations can serve as an effective deterrent in compelling a country to stop certain activities that are endangering a resource. Yet, despite the generally chaotic state of international rules governing the management of environmental resources, there are some excellent international agreements concerning this matter. Such agreements provide hope that the general field of conservation may serve as an area in which nations can learn to work together more effectively for their mutual benefit.

**Effective international agreements. The Antarctic Treaty.** The Antarctic continent remained unknown and unexplored during the period when most other parts of the world were being claimed and colonized by European powers. Uninhabited and, until recently, of little or no value to any country, Antarctica never became an area for international dispute. Although segments of the continent and sub-Antarctic islands have been claimed by various nations, including the United States, the Soviet Union, Great Britain, Australia, New Zealand, Chile, and Argentina, the validity of these claims has never been tested. It was not until the latter half of the 20th century that the potential future importance of Antarctica and the knowledge to be gained from scientific research in and exploration of the continent were recognized. As a consequence, nations with an interest in Antarctica signed the Antarctic Treaty in 1961. This could be considered de facto establishment of the Antarctic continent as the world's largest strict nature reserve. The treaty provided for joint scientific research to be conducted by the signatory nations, with the results to be shared by all. It also prohibited the exploitation by any one nation of living Antarctic resources as well as any activities that would cause deterioration of those resources. The treaty has been respected, Antarctic research has gone forward, and the wild animals and sparse plant life of the continent have been protected.

**Whaling agreement.** Unfortunately, agreements covering the Antarctic have not included the oceans surrounding the continent. The value of the animal resources in these waters has been known since the 18th century, and exploitation of them was begun during the 19th century. Of particular importance were the huge herds of whales that congregated in the Antarctic seas to feed upon the abundant plankton in these nutrient-rich waters. (One component of this plankton is the krill, a shrimplike crustacean; it occurs in such large quantities that, according to calculations, its exploitation alone, if properly conducted, could have increased the 1970 world yield of ocean fisheries by more than half.) The early whaling ships concentrated their efforts on the larger

Problems in enforcing international conservation regulations

Slaughter  
of blues  
and other  
whales

whales, which could yield the greatest quantities of whale oil, whalebone, and other useful products. The most sought after of these creatures, the blue whale, was the world's largest mammal. It is estimated that when whaling began there were 200,000 blue whales in the Antarctic; by 1965, however, the population of blues had been reduced to about 2,000. Preceding the period of concentration on blue whales, whalers had pursued the various species of right whales in the world's oceans and had reduced their numbers to a similar low level. The gray whale of the Pacific was also brought to a point of near-extinction. The efforts of Antarctic whalers then shifted to smaller species; the humpback, once abundant, was reduced to an estimated 1,000 in 1962. Fin whales and sperm whales also bore the brunt of whaling pressure for a time; when they become scarce, the still smaller sei and Minke whales were killed.

Despite the efforts of conservationists, attempts to restrict the activities of whalers met with little initial success. As whale populations dwindled and the danger of extinction became evident, however, the principal whaling nations agreed to sign the International Whaling Convention in 1946. This led to the establishment of the International Whaling Commission, which was authorized to sponsor scientific studies of whale populations and to recommend to the whaling nations limitations on harvest that were necessary to perpetuate whale populations and the whaling industry. Because the nations involved did not give the commission any firm power or enforcement authority, any nation could dispute the recommendations of the commission's scientific advisers and insist upon higher quotas than had been recommended. Everything depended on the willingness of the nations to obey the rules and to report honestly the number of each species of whales taken during the whaling season. Although there is no evidence that the nations involved deliberately disobeyed the recommendations finally agreed upon by the commission or that they failed to provide the commission with anything but accurate figures, the number of whales continued to decline. Sustained pressure from conservation interests, however, finally accomplished results. After 1967 the endangered whales—the blue, right, gray, and humpback—were given complete protection. And, starting in the 1970s, quotas for other species were reduced to limits that enabled the whales to maintain their populations at certain levels. Thus, the record of international cooperation provided by the International Whaling Convention is a mixed one. Although it did not accomplish all of the desired results, neither did it fail entirely. Indeed, the record of whale conservation would be much worse had it not been for this international agreement.

**Protection of fur seals and migratory birds.** Other activities intended to control the international exploitation of environmental resources have had some successes and many failures. Among the most successful treaties has been one to protect the northern fur seal, a species that breeds in the Pribilof Islands, in the Bering Sea. During the 19th century fur seals were reduced to a dangerously low level as a result of the heavy slaughter at their breeding grounds to obtain skins for the manufacture of fur coats and various other sealskin products. In 1911, Canada, Japan, Russia, and the United States signed a treaty to limit the annual harvest of seals to a quantity that would not only sustain the population but also increase it annually. In addition, the profits from sealing were to be divided proportionately among the signatory nations. The treaty was adhered to; the seals have increased and now stock the available breeding grounds.

A good example of an international agreement governing the conservation of species that migrate between two or more nations is the International Migratory Bird Treaty. Established in 1918 between the United States and Canada, this treaty was subsequently extended to include Mexico. The treaty, which has been adhered to by the nations concerned, limits the kill of migratory waterfowl. It also provides for the protection of migratory species in their breeding grounds, along their migration routes, and at their wintering areas.

**Territorial limits and marine resources.** For the most part, however, international control of species occupying habitats within several national jurisdictions, particularly when the habitats are in international waters, continues to be a serious problem. Agreements have yet to be reached on what constitutes national and international waters. The traditional three-mile territorial limit was loosely agreed upon by coastal nations for military reasons; it evolved in the days when that distance was beyond the range of shells fired from guns aboard naval vessels offshore. Today, however, this limit has become useless for defense and is not widely recognized for any other purpose. Disputes over fishing rights have led to a more general acceptance of a 12-mile (19-kilometre) limit to the seaward boundaries of national territories, but even this is not acceptable to all nations. Many Latin American countries now insist on jurisdiction over waters to a distance of 200 miles (300 kilometres) from their shores.

In 1970 it was proposed that resources lying on or beneath the floor of the continental shelf (the zone of shallow ocean floor that gradually slopes from the seashore to an abrupt drop-off) be under national jurisdiction out to a point at which the mean water depth is 200 metres (650 feet). Beyond that depth, which generally marks the limit of the continental shelf, the resources of the continental slope down to the floor of the ocean would be internationally owned but under the management and control of the coastal state involved. National exploitation of these resources would be permissible but with a payment of royalties to an international body. Farther out at sea, exploitation of the resources on and under the floors of the ocean basin would be entirely governed by an international agency. The proposal, which has not yet been generally accepted, is intended primarily to govern the exploitation of mineral and fuel resources as well as other uses of the ocean floor. It does not propose a change in jurisdiction over the ocean waters or their fisheries resources.

The problems concerning the conservation of marine resources have already received much international attention, and they probably will receive more both in meetings held under the auspices of the United Nations and in those conducted by other international agencies. It is apparent, however, that, until nations are willing to agree to international regulation and to provide the means for enforcing such regulation, there can be no great hope for solving those problems concerned with the rational use and conservation of international marine resources.

**International trade in animals and plants.** Special problems are involved in the regulation of trade and commerce in living animals and plants as well as in the products derived from them. Demands by wealthy nations for certain animal and plant products create particularly severe problems in less affluent countries. As mentioned previously, the trade in endangered species of wildlife is illustrative. The demand for furs and skins of rare animal species is artificially created in the fashion centres of the world. Prices paid by wealthy people for these items in affluent countries exceed the lifetime income of most people in the countries from which the leopards, crocodiles, tigers, and other wild species come. Poachers go to great lengths to obtain these animals wherever they can be found, including inside national parks and reserves. Because effective policing is virtually impossible, legal and illegal trade in wildlife begin to overlap, and both become firmly established. Exporters of wild animals and their products are the end links of profitable business chains that include far greater numbers of hunters and trappers in remote areas. Furthermore, for each animal or skin that reaches a foreign market, many more are destroyed in hunting, trapping, and transporting.

Only the purchasing countries can control the illegal trade in wildlife. This can be done in several ways: elimination of the demand created by changing fashions; refusal of purchasers of live animals (e.g., zoo directors) to buy species that are endangered; or, least effectively,

The fur  
seal  
treaties

Furs and  
skins for  
the fashion  
market

by controlling their clearance through customs offices of international airports and seaports. In March 1973 representatives of 80 countries signed the Convention on International Trade in Endangered Species of Wild Fauna and Flora, which prohibited commercial trade in 375 endangered species of wild animals. The treaty, which had yet to be ratified by the 80 governments, would forbid trade in products derived from the animals (*e.g.*, hides) as well as in living animals. In addition, trade in 239 species was allowable only on the granting of permits by both the importing and the exporting country. The provisions also included endangered plants (such as rare orchids that are now being removed from even the most remote tropical forests).

Perhaps even more serious than the trade in wild animal species is the international exploitation of other living resources, particularly the tropical forests of the world. These forests, which contain many hundreds of species of trees growing in diverse mixtures, were spared from exploitation in earlier decades because of their inaccessibility, the relatively low value of most of the trees for timber purposes, and the limited world demand. Heavily exploited for special uses were a few species of high value, such as teak, ebony, sandalwood, mahogany, and other furniture woods. Most tropical forests were not greatly disturbed, however. This situation has changed, and a wide variety of woods previously considered worthless are used for pulp, chipboard, and fibreboard or as cellulose for plastics production. With new machines and better transportation, it has become profitable to remove trees from previously remote areas and to ship logs, bolts, wood chips, or other partially processed materials to foreign markets. Faced with a high demand for their forest products, most developing nations have been willing to sign over timber rights to foreign companies, hoping thereby to increase their national incomes and to advance the general material welfare of their people. Unfortunately, most of these timber contracts contain few or no provisions for conservation. Forest industries that have excellent management and conservation records in their home countries behave differently in other lands. Great areas of tropical forest have been laid waste, soils bared to erosion, and the wildlife within them destroyed. Because no laws are violated in either the exploited or the home country, there is no effective redress. General international agreements governing the conservation of such living resources would provide an answer to this problem, but they are unlikely to be implemented in time to prevent the devastation of large areas of the tropical world.

Equally if not more unfortunate have been the side effects of some well-intentioned international development projects. These are sometimes sponsored by international agencies concerned with such affairs and sometimes by the foreign-assistance departments of individual donor nations. Usually the projects are intended to benefit one segment of the economy of the recipient nation; but, because ecological advice generally is not sought and because of the broad effect of the proposed development on other resources or on the total environment, the side effects of some of these activities often far outweigh any benefits that are derived. An example is the Aswān High Dam of Egypt, where the need to increase the supply of water for irrigation and power was considered paramount. The environmental side effects, however, have been enormous and include the spread of the disease bilharziasis (schistosomiasis) by snails that live in the irrigation channels, loss of land in the delta of the Nile River from erosion once the former sediment load of the river was no longer available for land building, and a variety of other consequences. Furthermore, water-development projects in the semi-arid lands of Africa, sponsored by international agencies and funded by various donor organizations, have quite frequently been far more destructive than constructive. Failure to take ecological and social factors into consideration has resulted repeatedly in overgrazing and creation of deserts in an area intended to be improved by the expenditure of money. The responsibility of agencies concerned with international development to seek the best environmental advice is now generally accepted,

but implementation of this responsibility has been slow.

#### THE POLLUTION OF NATURAL RESOURCES

Although various problems related to pollution of the environment have already been mentioned, the following is a more general discussion of pollution as a phenomenon. Pollution may be defined as the addition of any substance or form of energy (*e.g.*, heat, sound, radioactivity) to the environment at a rate faster than the environment can accommodate it by dispersion, breakdown, recycling, or storage in some harmless form. A pollutant need not be harmful in itself. Carbon dioxide, for example, is a normal component of the atmosphere and a by-product of respiration that is found in all animal tissues; yet in a concentrated form it can kill animals. Human sewage can be a useful fertilizer, but when concentrated too highly it becomes a serious pollutant, menacing health and causing the depletion of oxygen in bodies of water. By contrast, radioactivity in any quantity is harmful to life, despite the fact that it occurs normally in the environment as so-called background radiation.

Pollution has accompanied mankind ever since groups of people first congregated and remained for a long time in any one place. Settlements of primitive man can be recognized by their pollutants—shell mounds and rubble heaps. But pollution was not a serious problem as long as there was enough space available for each individual or group. With the establishment of permanent human settlements by great numbers of people, however, pollution became a problem and has remained one ever since. Cities of ancient times were often noxious places, fouled by human wastes and debris, and, in the Middle Ages, unsanitary urban conditions favoured the outbreak of population-decimating epidemics. During the 19th century, water and air pollution and the accumulation of solid wastes were largely the problems of only a few large cities. But, with the rise of advanced technology and with the rapid spread of industrialization and the concomitant increase in human populations to unprecedented levels, pollution has become a universal problem.

The various kinds of pollution are most conveniently considered under three headings: air, water, and land. Air pollution involves the release into the atmosphere of gases, finely divided solids, or finely dispersed liquid aerosols at rates that exceed the capacity of the atmosphere to dissipate them or to dispose of them through incorporation into solid or liquid layers of the biosphere.

**Air pollution.** The problems of air pollution are discussed at length above (see Management of natural resources: Managing nonliving resources: Air. See also POLLUTION CONTROL: Air pollution).

**Water pollution.** Water pollution involves the release into lakes, streams, rivers, and oceans of substances that become dissolved or suspended in the water or deposited upon the bottom and accumulate to the extent that they interfere with the functioning of aquatic ecosystems. It may also include the release of energy in the form of radioactivity or heat, as in the case of thermal pollution. Any body of water has the capacity to absorb, break down, or recycle introduced materials. Under normal circumstances, inorganic substances are widely dispersed and have little or no effect on life within the bodies of water into which they are released; organic materials are broken down by bacteria or other organisms and converted into a form in which they are useful to aquatic life. But, if the capacity of a body of water to dissolve, disperse, or recycle is exceeded, all additional substances or forms of energy become pollutants. Thus, thermal pollution, which is usually caused by the discharge of water that has been used as a coolant in fossil-fuelled or nuclear-power plants, can favour a diversity of aquatic life in waters that would otherwise be too cold. In a warmer body of water, however, the addition of heat changes its characteristics and may make it less suited to species that are considered desirable.

Pollution may begin as water moves through the air, if the air is polluted. Soil erosion adds silt as a pollutant. The use of chemical fertilizers, pesticides, or other materials on watershed lands is an additional factor con-

Unintended  
side effects  
of interna-  
tional  
assistance

Thermal  
pollution  
of water

tributing to water pollution. The runoff from septic tanks and the outflow of manures from livestock feedlots along the watershed are sources of organic pollutants. Industries located along waterways downstream contribute a number of chemical pollutants, some of which are toxic if present in any concentration. Finally, cities and towns contribute their loads of sewage and other urban wastes. Thus, a community far upstream in a watershed may receive relatively clean water, whereas one further downstream receives a partly diluted mixture of urban, industrial, and rural wastes. The cost of cleaning and purifying this water for community use may be high, and the process may be only partially effective. To add to the problem, the cities and towns in the lower, or downstream, regions of the river basin contribute additional wastes that flow into estuaries, creating new pollution problems.

The output of industries, agriculture, and urban communities generally exceeds the biological capacities of aquatic systems, causing waters to become choked with an excess of organic substances and organisms to be poisoned by toxic materials. When organic matter exceeds the capacity of those micro-organisms in water that break it down and recycle it, the excess of nutrients in such matter encourage rapid growth, or blooms, of algae. When they die, the remains of the dead algae add further to the organic wastes already in the water; eventually, the water becomes deficient in oxygen. Anaerobic organisms (those that do not require oxygen to live) then attack the organic wastes, releasing gases such as methane and hydrogen sulfide, which are harmful to the oxygen-requiring (aerobic) forms of life. The result is a foul-smelling, waste-filled body of water, a situation that has already occurred in such places as Lake Erie and the Baltic Sea and is a growing problem in freshwater lakes of Europe and North America. The process by which a lake or any other body of water changes from a clean, clear condition—with a relatively low concentration of dissolved nutrients and a balanced aquatic community—to a nutrient-rich, algae-filled body and thence to an oxygen-deficient, waste-filled condition is known as accelerated eutrophication.

**Land pollution.** Land pollution involves the deposition on land of solid wastes—*e.g.*, used cars, cans, bottles, plastic containers, paper—that cannot be broken down quickly or, in some instances, cannot be broken down at all by the action of organic or inorganic forces. (The term biodegradable is used to describe those materials that can be decomposed and recycled by biological action.) When such materials become concentrated within any one area, they interfere with organic life and create unsightly accumulations of trash. Methods of disposal other than recycling include ocean dumping, which creates water pollution and destroys marine habitats; landfill, which often requires the availability of low-lying ground and frequently involves the destruction of marshland or swamps that have high biological value; or burning, which increases air pollution. Obviously, none of these methods is entirely satisfactory, although using landfill to create artificial landscapes, which then are covered with soil and planted with various kinds of vegetation, is a possibility that remains to be fully developed. It is the great quantities of debris produced by urban communities, more so than a shortage of raw materials, that forces the development of more effective means for recycling wastes. Land pollution also involves the accumulation on land of substances in a dispersed solid or liquid form that are injurious to life. This has been particularly noticeable with those chemicals (*e.g.*, DDT) that are spread for the purpose of exterminating pests but then accumulate to the extent that they can do damage to many other forms of life.

**Noise pollution.** One form of pollution that is characteristic of industrial societies is noise. The intensity of sound is measured in logarithmic units known as decibels; a change from a level of ten decibels to one of 20 decibels actually represents a 100-fold increase in the sound level. At a level of 80 decibels, sound is annoying; permanent loss of hearing can be caused by steady exposure to noises in excess of 90 decibels, a level that is

frequently exceeded by many common urban sounds, such as jackhammers, jet planes, and excessively loud music. In addition to causing loss of hearing, there is some evidence that noise can produce other deleterious effects on human health and on work performance.

Many large cities have taken measures to decrease the level of urban noise; the problem has received much attention with the advent of supersonic jet airplanes. These aircraft, which travel at speeds faster than the speed of sound, create sound waves (sonic booms) equivalent to those of major explosions and capable of damaging structures. The extent to which continuous exposure to sonic booms affects human health and functioning has yet to be determined. Nevertheless, in 1971 the United States Congress voted down appropriations to support the development of supersonic transport planes; Great Britain, France, and the Soviet Union, however, have developed such planes.

**Chemical pollutants.** In 1971 a special committee established by the International Council of Scientific Unions reviewed the existing problems of global pollution and selected those forms believed to be of such a widespread and serious nature as to require a worldwide monitoring program. The pollutants selected for this attention were the chlorinated hydrocarbon pesticides, such as DDT, aldrin, and dieldrin; the polychlorinated biphenyls (PCBs), which are used in a variety of industrial processes and in the manufacture of many kinds of materials; and such metals as mercury, lead, cadmium, arsenic, and beryllium. All of these substances persist in the environment, being slowly, if at all, degraded by natural processes; in addition, all are toxic to life if they accumulate in any appreciable quantity.

The persistent pesticides have created serious ecological problems. As they move through successively higher organisms in food chains, they accumulate in increasingly concentrated forms at each level, causing damaging effects to the predators at the end of the chains—*i.e.*, they are present in low quantities in simple organisms but become more concentrated as these organisms are consumed by more complex ones, which are themselves consumed by predators. Among the species known to be adversely affected are such meat-eating birds as falcons, hawks, and eagles and such fish-eating birds as pelicans, petrels, cormorants, and egrets. The reproduction capacity of all of these birds has been affected by an accumulation of DDT or a similar compound in their tissues. This is manifested by an impairment in the ability of the females to form eggshells properly. As a result, some species lay soft-shelled or shell-less eggs that cannot be hatched, and there has been a general decline in the numbers of these birds in Europe, Japan, and North America. Although the effects of the same chemicals on mammals is less obvious and still a matter for investigation, some studies suggest that DDT can reduce the productivity of plant plankton, upon which all other marine life depends.

As the widespread biological effects of pesticides become better known, there is growing evidence that they lose the ability to control the pests they were designed to kill. Many insect species have developed immunity to a wide range of synthetic pesticides, and the resistance is inherited by their offspring. Furthermore, it has been observed that repeated use of such chemicals creates pest populations in areas in which none previously existed. This happens because the pesticides destroy populations of carnivorous, predatory insects that previously kept the plant-eating insects in check.

Among other materials that are harmful to most forms of life are such metals as mercury, lead, and arsenic. The increasing release of these substances into the biosphere by industrial processes has created conditions that are now generally viewed as harmful to human welfare. Studies have been conducted on metallic pollutants to determine the normal environmental levels, the levels that are toxic to man, and the extent to which industrial processes are responsible for the problem.

The ultimate control of pollution will presumably involve the decision not to allow the escape into the en-

Sonic  
booms

Eutrophication of  
bodies of  
water

vironment of the substances that are harmful to life, the decision to contain and recycle those substances that could be harmful if released into the environment in excessive quantities, and the decision not to release into the environment substances that persist and are toxic to living things. Essentially, therefore, pollution control does not mean an abandonment of existing productive human activities but their reordering so as to guarantee that their side effects do not outweigh their advantages.

#### THE FUTURE OF CONSERVATION

The Earth has supported civilized man for more than 5,000 years and agricultural man for twice that period. Before that, reaching back an unmeasured number of years into the past, human or near-human groups occupied various parts of the Earth, modifying them to some degree in the course of hunting, fishing, and food gathering. Patterns of land use were determined over many centuries of trial-and-error experimentation by people equipped with primitive tools who depended on the biological communities of the Earth for their energy supplies. Today, however, with abundant fossil fuels, growing amounts of nuclear energy, and sophisticated tools and machines, it is possible to modify quickly entire landscapes, changing long-established natural patterns into new ones with new purposes. The opportunity to enhance the material welfare and general well-being of great numbers of people is available, as is the opportunity to cause great damage and to impair the capacity of Earth to support life. What the outcome will be will depend on man's ability to plan properly for the use and conservation of the Earth's living and nonliving resources.

**The role of population, industry, and technology.** Uses of lands and resources are being modified in the expectation of continued population growth, industrial expansion, and accelerating technological change. Yet it is possible that in the future—perhaps early in the 21st century—uses of lands and resources will be planned with the expectation of population stability, little industrial expansion, and a technology directed toward a reorganization and a rearrangement of man's activities to achieve a better environmental relationship. Although certain countries of the world have already reached some degree of population stability—e.g., Ireland, Hungary, East Germany, France, Sweden, Switzerland, and Japan—industrial expansion and rapid technological change continue in these countries, in part because of the demands made by other expanding nations. The existing expansionist phase of technological civilization cannot, however, be expected to continue indefinitely. The ecological limitations on any population growth in a limited space with limited resources lead most workers in the field to predict an inevitable end to this expansion, even if mankind fails voluntarily to limit its own growth.

Need for ecological considerations and advance planning. Current decisions made about land and resource use have important consequences for the future. If extensive areas of the Earth are badly damaged or their productivity destroyed by the present expansion of technological civilization, they will be difficult, if not impossible, to restore in the future. If a species becomes extinct, for example, it cannot be brought back. It is essential, therefore, that care be exercised in further modifying the planet to suit human purposes. Yet in many developing regions of the world, those where the greatest changes may be expected, little attention is being given to planning for and carefully controlling the use of land and resources. Thus, important tropical, semi-arid, and subpolar regions of the Earth—the three principal climatic belts that have not yet undergone major technological development—are now being changed drastically without much consideration for their environments. In many parts of the world, ecologically trained experts are not available; in others, because of strong economic pressures toward development, ecological advice is either not sought or ignored.

Comparatively speaking, the failure to apply current ecological knowledge to the changing land and resource

use taking place in tropical, semi-arid, and sub-Arctic lands is equivalent to the modification of the more temperate lands that took place centuries ago, when ecological knowledge was not available. In earlier centuries, however, the capacity to do irreparable damage was restricted by the lack of machinery, industry, and fuel energy. Today, capabilities are such that major destruction can be accomplished quickly. There is, therefore, a need to call upon environmental expertise during the process of economic development in any area of the world if natural resources are to be conserved and the future welfare of humanity is to receive due consideration.

Ecologists now largely believe that, although it was once possible to allow the development of a region to proceed more or less at random, based on individual wants, aspirations, and decisions about the use of lands and resources, such a process now holds too much risk for the well-being of society as a whole and for the future of the resources on which that society depends. Planning, they argue, must precede development, and regional planning is required if the use of major areas of land and its resources is to be brought into accord with environmental necessities and with the long-term needs of society. More detailed land-use and urban planning are necessary if all lands and resources are to be managed with a view to their conservation. Further, it would appear that population planning to limit growth in areas in which it is not desired and to encourage it in areas in which it can have beneficial effects will have to accompany the planning of resource and land use if such planning is to be effective.

In densely populated and technologically advanced nations, such as those of western and northern Europe, most of the land-use decisions that would affect large areas have already been made. Although changes do occur, mostly in relation to growing urbanization and increasing material wealth on the part of citizens, it seems likely that the remaining woodlands and fields will continue to be devoted to their present uses. In England the interest of the central government in the planning and control of land use and population distribution was marked by the passage of the Town and Country Planning Act shortly after the end of World War II. This legislation led to decisions to limit the growth of London and to develop instead a pattern of new towns outside a greenbelt of agricultural and recreational land that surrounds the metropolis. In France, where there are still large areas of open space, a system for regional planning and control of land use and development (*aménagement du territoire*) has been formulated. It has already resulted in the establishment of new cities and recreational sites in previously undeveloped areas along the Mediterranean coast.

It is in the sparsely populated areas in the underdeveloped countries of Africa, Asia, and Latin America as well as in such technologically advanced countries as Canada, Australia, and the Soviet Union that the greatest range of options and choices for the future are available. Because these areas have yet to undergo drastic environmental change, the need for local and regional environmentally oriented planning for resource and land use is most urgent in these countries.

Areas of promise. Many of the current vexing conservation problems may be solved by technological developments. Perhaps the greatest need for the continuation of a highly technological society is an abundant and reliable source of cheap energy. Present promising research on nuclear fusion as a source of power indicates that this process may replace nuclear fission in the near future. If this is true, the use of nuclear energy to generate power will no longer depend on such relatively rare and expensive nuclear fuels as uranium-235 and plutonium. Instead, the almost limitless quantities of heavy hydrogen (deuterium) present in seawater can suffice as a fuel. Moreover, with abundant, cheap power, the desalinization of seawater and the reclamation and concentration of minerals dissolved within it would have possibilities both as a continuing source of abundant

Changing  
patterns of  
land use

land use  
and  
population  
distribution

Climatic  
belts  
currently  
being  
exploited  
by man

fresh water and, more important, as a new source of the minerals now being depleted. Mineral exploitation could operate on a sustained-yield basis, just as the harvesting of living resources now can be conducted.

Apart from the development of major new sources of power, the greatest promise for the future of mineral resources and for the prevention of pollution of the environment lies in new technologies involving the recycling and reclamation of what are now considered waste products. Demands for new minerals will be greatly reduced when those already available in population centres can be reused more readily. Reclamation of sewage and other organic wastes and restoration of these materials to soils can help to arrest losses in soil fertility and structure and to reduce the need for new supplies of chemical nutrients for soil fertilization. If development of technologies for recycling and reutilization continues, many of the existing problems of environmental pollution will be solved.

In addition to the breeding of new strains of crop plants, the development of techniques for the control of diseases and pests of crop plants that do not involve the release of persistent, poisonous chemicals into the environment holds much promise for the production of greatly increased quantities of food and fibre from smaller areas of the Earth's surface. Much more intensive development of aquaculture (cultivation of the natural produce of water), perhaps utilizing coolant water from nuclear-power plants, can also produce much higher food yields from smaller areas than are now usually obtainable. As a result of these advances in intensive food production, agriculturally marginal lands and the wilder aquatic areas would be spared for the continued support of wild species as well as for the adventure and recreation of mankind, thus helping to solve one of the most troublesome of all conservation problems, the conservation of wild nature.

**Problems in need of solutions.** Considering the potential of industrial and agricultural technology and the accompanying advances in medical science and technology, it is possible to foresee a world in which a relatively stable human population lives at a high level of material affluence, wild nature continues to exist in abundance, and relatively undisturbed lands remain available for human enjoyment. But this scientific and technological optimism is not supported by existing world conditions. Because the scientific and technological knowledge now available is more than adequate to solve most of the world's major environmental problems, those of the 1970s are not problems of science and technology but of the arrangements and functioning of human institutions and of the attitudes of individuals. Thus, while research in forestry science continues in all the forestry schools of the world, tropical forests are being devastated in ways that suggest that forestry science and management never existed. Although the techniques for managing livestock on natural ranges and pasture lands have reached a high level of sophistication, overgrazing continues around most of the world's major deserts, and animals die of hunger, people suffer from deprivation, and the deserts spread. Obviously, the knowledge available to the technician does not reach or influence the behaviour of most of the pastoral people on Earth.

**Population growth.** During the 1970s population growth continued at a rate estimated to be approximately 2 percent per year. Whereas in 1970 there were over 3,500,000,000 people on Earth, predictions indicate that the population of the world will not be stabilized, even under the best of conditions, before it attains a level of 6,000,000,000–7,000,000,000 people. These predictions assume, of course, that there will be no major catastrophes—outbreaks of war, famine, or disease—that would cause drastic reductions in human numbers. There is little doubt that rapid population growth interferes with orderly economic development, leads to a deterioration of the human environment, places a severe strain on human institutions, and constitutes a growing threat to the survival of wild animal and plant life.

Although techniques for birth control are effective and

well-known among educated people, they are virtually unknown, unavailable, and apparently unacceptable to those people having the most rapid rate of population growth—the ones who also live in the most precarious balance with their environment. This does not mean that the prospects for controlling population increase are poor; actually, they are better than at any time in the past. But ecologists insist that, in order to be effective, the materials needed to control births must be made more available; in addition, more education is needed to encourage people to limit the size of families, and the prospects for material and economic advancement for those who have fewer children must be made more obvious. Because all of these needs are expensive, they usually cannot be provided by nations with high rates of population increase and low economic productivity. Thus, control of world population growth is an international responsibility, but it is one toward which most nations give limited support at best.

**Pollution control.** Next to population growth, the conservation problem of greatest magnitude is the control of pollution; it might even be argued that it is even more urgent and important than the control of population growth. The knowledge and technology needed to control pollution effectively are now available: pollution-free engines can be built, pollution-free factories have been put into operation, and techniques for controlling agricultural insect pests with a minimum use of persistent pesticides have been developed. For economic reasons, none of these measures, however, is being applied universally, and political and social pressures have not yet forced their application. Moreover, emerging nations have expressed fear that excessive concern over pollution could impede their economic development. Indeed, some of these countries have become sanctuaries for industries that find it less expensive to operate in areas with more lax standards. It is apparent that pollution control, regardless of the state of its technology, will become a reality only when people demand it and only when nations are willing to agree on appropriate international standards.

**Control over use of resources.** Equally as important to the future of world conservation as population growth and pollution is the failure of most nations to exercise adequate controls over land, water, and other resource use. Effective means for controlling land use do not exist in most countries; laws and regulations that permit governments to exercise such control, when existent, often cannot be enforced because of the danger of strong public resentment and resistance. Although it is essential for conservation that lands and all other resources be used with a view to preserving their future productivity, this view all too often conflicts with present needs or demands of the resource users. Unlike other conservation problems, however, the solution to this conflict is not within the scope of science or technology; instead, it is a legal, economic, and political matter as well as one for the social and behavioral sciences. Its resolution also requires a much more effective use of environmental education that has been practiced thus far in most countries.

**Extraterrestrial conservation.** Space exploration has begun at a time when man's willingness to manage the Earth's resources is in doubt. Experiences gained from early space efforts, however, have helped promote an awareness of planetary realities among a growing number of people. The need to provide the requirements of life to men confined for long periods of time in spaceships and the problems of waste disposal in such vehicles have cast new light on similar problems within Earth-bound communities. The view of Earth from outer space has engendered the concept that the planet is, in effect, a large spaceship with a limited capacity to support life and that it is highly vulnerable to damage from poorly planned human activities.

Exploration of other planets has been undertaken in full realization of the dangers involved, both in the pollution of a satellite or planet being visited by Earthlings and in the potential danger to life on Earth by

Necessity  
for curbing  
birth rates

Possibility  
of aqua-  
culture  
for food  
production

Spaceship  
Earth

materials brought back from other celestial bodies. Although there is as yet no reason to expect the existence of life on those planets nearest the Earth and every reason to doubt its existence on planets farther away in the solar system, the most rigid precautions are still necessary. Experience with the rapid spread of diseases in new locations has demonstrated the dangers to other forms of life if other planets were to be contaminated with organisms brought from Earth or if Earth were to be exposed to agents from other planets capable of contaminating life on this one.

If planets capable of supporting life are reached someday, they will offer an opportunity to science never before available. The study of life that has evolved under different conditions in a different world could add greatly to an understanding of the Earth's biological systems as well as provide a great intellectual challenge to mankind. Perhaps the hard lessons of conservation, which have yet to be completely understood or accepted on Earth, will be applied to other worlds before irrevocable damage is done.

At the present time, however, the available knowledge brought back from outer space indicates only that Earth is unique, the one planet where life can thrive. Its inhabitants, therefore, are vested with a special responsibility: to keep it functioning.

GLACKEN, *Traces on the Rhodian Shore* (1967), an account of the philosophies and ideas relating to man's attitudes toward nature from ancient times to the 18th century; GEORGE PERKINS MARSH, *Man and Nature* (1864), a classic of conservation and the first general view of how man changes the Earth and affects its living resources; RODERICK L. NASH (ed.), *The American Environment: Readings in the History of Conservation* (1968), a review of the important developments in the evolution of conservation in the United States with readings from the works of those who contributed to its development; HENRY DAVID THOREAU, *Walden* (1858, reissued 1961), a classic philosophical exploration of man's relationship with nature and the values to be found in living apart from civilization and its artifacts, by one of the first advocates of wilderness preservation; STEWART L. UDALL, *The Quiet Crisis* (1963), a review of the history of conservation and the growing crisis in conservation, with emphasis on public lands and living resources in the United States.

*Ecology:* CHARLES S. ELTON, *Animal Ecology* (1927), a classic in ecology and the forerunner to the application of animal ecology in the management of wildlife; EUGENE P. ODUM, *Fundamentals of Ecology* (1971), a standard textbook on general ecology, emphasizing the nature and functions of ecosystems with a discussion of the relationships between ecology and the environmental problems of today.

*Pollution:* RACHEL CARSON, *Silent Spring* (1962), a popular best-seller that first alerted the general public to the dangers inherent in the widespread use of persistent pesticides; BARRY COMMONER, *Science and Survival* (1966), a discussion of how science and technology can cause unanticipated changes in the environment, with particular reference to pollution resulting from the use of nuclear energy; COUNCIL ON ENVIRONMENTAL QUALITY, *Environmental Quality* (annual), a review of the state of U.S. environment with particular emphasis on problems relating to pollution; ROBERT L. RUDD, *Pesticides and*

*the Living Landscape* (1964), a scholarly review of the ways in which pesticides enter into the ecological networks in natural and man-made environments, with a discussion of the dangers involved in their continued use.

*Population, resources, and technological development:* GEORGE BORGSTROM, *The Hungry Planet* (1965), a review of the food needs of mankind and the prospects for meeting them, with particular attention to the use of ocean resources; ARTHUR B. BRONWELL (ed.), *Science and Technology in the World of the Future* (1970), generally optimistic accounts by selected experts of man's prospects in meeting his future needs for energy and mineral resources; M.T. FARVAR and J. MILTON (eds.), *The Careless Technology* (1971), a collection of case histories and related discussions concerning the unexpected side effects of economic and technological development; HANS H. LANDSBERG, *Natural Resources for U.S. Growth: A Look Ahead to the Year 2000* (1964), a review of the needs of society for natural resources and the prospects of meeting them from available or foreseeable supplies; WILLIAM VOGT, *Road to Survival* (1948), a classic on the relationship between populations and resources that is written from an emotional viewpoint in an attempt to draw attention to the coming population crisis, emphasizing the growing threat of world hunger as well as the impact of man on soils and renewable resources.

*Management of living resources:* RAYMOND F. DASMANN, *Wildlife Biology* (1964), an introductory college textbook reviewing the principles of wildlife biology and their application to the conservation and management of wild animals; S. HADEN-GUEST, J.K. WRIGHT, and E.M. TECLAFE (eds.), *World Geography of Forest Resources* (1956), a survey of the forest resources of the world, the extent to which they are being used, and the problems associated with their management; G.V. JACKS and R.O. WHYTE, *Vanishing Lands* (1939), a classic that reviews the nature of world soils and describes their destruction by erosion as a result of misuse; ALDO LEOPOLD, *Game Management* (1933), the first textbook of wildlife management that has become a conservation classic; *A Sand County Almanac and Sketches Here and There* (1949), the ethics and aesthetics of conservation with emphasis on land, wildlife, and wilderness; L.A. STODDART and AD SMITH, *Range Management*, 2nd ed. (1955), a textbook on the principles and practices affecting the use of range and pasture lands by grazing animals.

(R.F.D.)

## Conservatism

The term conservatism, although it has had different implications in varying historical and geographical contexts, is best reserved to denote a preference for institutions and practices that have evolved historically and that are thus manifestations of continuity and stability. Political thought, from its beginnings, contains many strains that can be retrospectively labelled conservative, but it was not until the late 18th century that conservatism began to develop as a political attitude and movement reacting against the French Revolution of 1789. The noun seems to have been first used after 1815 by French Bourbon restorationists such as François-René, vicomte de Chateaubriand. It was used to describe the British Tory Party in 1830 by John Wilson Croker, the editor of *The Quarterly Review*; and John Calhoun, a formulator of conservative minority rights against majority dictatorship in the United States, also used the term in the 1830s. The generally acknowledged originator of modern, articulated conservatism (although he never employed the term) was the British parliamentarian and political writer Edmund Burke in his essay *Reflections on the Revolution in France* (1790). Pro-parliamentarian opponents of the French Revolution, such as Burke, believed that the violent, untraditional, and uprooting methods of the Revolution outweighed and corrupted its liberating ideals. More authoritarian opponents, such as the polemicist and diplomat Joseph de Maistre, also rejected the ideals themselves. The general revulsion against the course of events in France provided conservatives with an opportunity for restoring the pre-Revolutionary traditions, and a sudden flowering of more than one brand of conservative philosophy followed.

#### CONSERVATIVE ATTITUDES

Because Burke's case against radicalism and revolution has also influenced liberals, there is often no sharp dis-

inction between liberals and conservatives in action. In philosophy, however, conservatism has maintained certain sharply nonliberal assumptions about human nature.

Whether intentionally or unconsciously, whether literally or metaphorically, for example, conservatives tend to assume in politics the Christian doctrine of man's innate original sin, and herein lies a key distinction between conservatives and liberals. Men are not born naturally free or good (conservatives assume) but are naturally prone to anarchy, evil, and mutual destruction. What the 18th-century French philosopher Jean-Jacques Rousseau denounced as the "chains" that hinder man's "natural goodness," are for Burkeans the props that make man good. These "chains" (society's traditional restrictions on the ego) fit man into a rooted, durable framework, without which ethical behaviour and responsible use of liberty are impossible.

The conservative temperament may be, but need not be, identical with conservative politics or right-wing economics; it may sometimes accompany left-wing politics or economics. Regardless of a conservative's politics or economics, however, it can be said that two characteristics of the conservative temperament are: a distrust of human nature, of rootlessness, of untested innovations; and a corresponding trust in unbroken historical continuity and in traditional frameworks within which human affairs may be conducted. Such a framework may be religious or cultural or may be given no abstract or institutional expression at all. In relation to the latter aspect, many authorities on conservatism—a minority in France and a majority in England—consider conservatism an inarticulate state of mind and not at all an ideology. Liberalism argues; conservatism simply *is*. When conservatism becomes ideologized, logical, and self-conscious, then it resembles the liberal rationalism that it opposes. According to this British approach, logical deductive reasoning is too doctrinaire, too 18th century. Whereas the liberal and rationalist mind consciously articulates abstract blueprints, the conservative mind unconsciously incarnates concrete traditions. And, because conservatism embodies rather than argues, its best insights are almost never developed into sustained theoretical works equal to those of liberalism and radicalism.

Conservatism is often associated with some traditional and established form of religion. After 1789, the appeal of religion redoubled for those craving security in an age of chaos. The Roman Catholic Church, because its roots are in the monarchical Middle Ages, has appealed to more conservatives than any other religion. Himself a Church of England Protestant, Burke praised Catholicism as "the most effectual barrier" against radicalism. But conservatism has had no dearth of Protestant and strongly anticlerical adherents also.

Conservatives typically view society as a single organism and condemn as "rationalist blueprints" the attempts of progressives to plan society in advance from pure reason instead of letting it evolve naturally and unconsciously, flowering from the deep roots of tradition. They dismiss a liberal society as "atomistic," meaning composed of disrupted elements held together merely mechanically. A society, they argue, has to be rendered whole by religion, idealism, shared historical experiences, commitment to its long standing political institutions, and by the emotions of reverence, cooperation, and loyalty; a society, they believe, can, to the contrary, be rendered atomistic by materialism, class war, excessive laissez-faire economics, greedy profiteering, overanalytical intellectuality, subversion of shared institutions, insistence on rights above duties, and by the emotions of skepticism and cynicism. Except for the German Romantic school, conservatives do not carry their conceptions of the organic wholeness of society to the extreme at which the individual becomes nothing, society everything, for they recognize that, at that extreme, one no longer has conservatism but totalitarian statism.

#### VARIETIES OF CONSERVATISM

The Burkean foundations. Burke did more than any other thinker to turn the intellectual tide from a rational-

ist contempt for the past to a traditionalist reverence for it. An Irishman, he loved England, including its established Anglican Church and its nobility, with an outsider's passion. In 1765 he became private secretary to Charles Watson-Wentworth, 2nd marquess of Rockingham, the head of the less liberal wing of the Whig Party. Against the untraditional tyranny of George III, Burke defended the American Revolution of 1776, which he viewed as being in defense of traditional liberties, but attacked the radical French Revolution of 1789 as tyranny by mobs and deracinated theorizers. At a time (1790) when the French Revolution still seemed a bloodless utopia, he predicted its later phase of terror and dictatorship, not by any lucky blind guess but by an analysis of its devaluation of tradition and inherited values.

Indeed, the core of Burke's thought and of conservatism is fear of rootlessness. Rousseau's *Social Contract* of 1762 had favoured a contract merely among the living, to arrange government for their mutual benefit. Burke, instead, argued:

Society is indeed a contract . . . [but] as the ends of such a partnership cannot be obtained in many generations, it becomes a partnership not only between those who are living, but between those who are living, those who are dead, and those who are to be born. . . . Changing the state as often as there are floating fancies, . . . no one generation could fink with the other. Men would be little better than the flies of a summer.

Burke's veneration of the past may be contrasted with the rationalist hostility of Karl Marx, the most influential social critic of modern times: "The legacy of the dead generations weighs like a nightmare upon the brains of the living." But for Burke the contract is with "the future" as well as with the past, and he thus urges improvement, as long as it is evolutionary: "A disposition to preserve and an ability to improve, taken together, would be my standard of a statesman."

Burke was defending not conservatism in the abstract but, rather, one concrete instance of it, the unwritten British constitution. His arguments, however, were not always consistent. Sometimes he justified that constitution by "natural rights"; more often by "prescriptive right." Natural rights meant a universal code external to any given constitution; prescriptive right, a local code authoritative (prescriptive) by virtue of its age and its links with the past, which are *prima facie* evidence of its value. Sometimes he argued that natural rights preceded the constitution and gave it "latent wisdom." But, when arguing against French rationalists, who would justify their own revolutionary constitution by natural rights, he argued instead, and more typically:

Our constitution is a prescriptive constitution . . . [whose] sole authority is that it has existed time out of mind . . . without any reference whatever to any other more general or prior right.

Burke shocked his century by his brutal frankness in defending "illusions" and "prejudices" as socially necessary. In doing so, however, he was, in fact, being not so much a cynic as one of the few old-fashioned Christians among 18th-century intellectuals. He was an old-fashioned Christian in the sense of believing man innately depraved, innately steeped in original sin, and incapable of bettering himself by his feeble reason. So defined, man could be tamed only by following an ethically trained elite and by education in "prejudices," such as family, religion, and aristocracy. He called landed aristocrats "the great oaks" and "proper chieftains," provided they tempered their rule by a spirit of timely reform from above and remained within the constitutional framework. He defended the Church of England for its political as well as its religious function, "To keep moral, civil, and political bonds, together binding human understanding."

Coleridge and Wordsworth. After Burke, the English poets Samuel Taylor Coleridge and William Wordsworth were significant figures in the formulation and expression of conservative sentiment. They began, however, as utopian liberals supporting the French Revolution. Wordsworth spoke for a whole generation of European intellectuals with his famous salute to the new dawn in France:

Burke's conception of the social contract

Conservatism as a state of mind

"Bliss was it in that dawn to be alive, but to be young was very heaven." Disillusionment followed, and Coleridge and Wordsworth reacted against liberalism and rationalism and turned to traditional monarchy and the Church of England.

In 1798 Wordsworth and Coleridge jointly published their book of poems, *Lyrical Ballads*, marking the revolt of the human heart against abstract 18th-century rationalists and thereby helping to create a new philosophical climate. Conservatism was permanently influenced by Coleridge's prose works: *Lay Sermons*, 1816–17; *Biographia Literaria*, 1817; *Philosophical Lectures*, 1818–19; *Aids to Reflection in the Formation of a Manly Character, on the Several Grounds of Prudence, Morality, and Religion*, 1825; and his various *Letters and Specimens of Table Talk*. His public lectures exercised an indirect influence by molding the minds of university students who later became national leaders.

Coleridge's  
views on  
social  
classes

According to Coleridge, society divided its functions among different "class orders." Each class had its valuable function, but this did not necessarily include the right to vote and rule. That right was best left to an ethically trained aristocracy, functioning within the strict lawful limits of Parliament. All classes, Coleridge argued, must cooperate harmoniously within the organic unity of the constitution. His greatest influence on practical politics was through his disciple Benjamin Disraeli, later to be Conservative prime minister, and his disciple's disciple, Sir Winston Churchill. Coleridge considered businessmen often subversive, not conservative; they allegedly gnawed at the foundations of Christian monarchy by substituting a newfangled, un-Christian religion known as economic profit. Thus Coleridge, defining "shopkeepers" as "the least patriotic and the least conservative" class, fought against the Whig Reform Bill of 1832, which made "hucksters" the dominant voting group.

Maistre and Latin conservatism. It would convey an unbalanced picture of conservatism to present only the moderate and British brand founded by Burke and to omit the more extreme and Latin brand founded by Maistre (died 1821). Whereas Burkean conservatism is evolutionary, the conservatism of Maistre is counter-revolutionary. Both favour tradition against the innovations of 1789, but their traditions differ: the former fights against 1789 for the sake of traditional liberties, the latter for the sake of traditional authority. The former is not authoritarian but constitutionalist—and often parliamentary—whereas the latter, in its stress on the authority of some traditional elite, is often justifiably called not conservative but reactionary. To call it totalitarian, however, would be to go much too far, for its authority does not try to be "total," in the sense of taking over the total personality, the total culture, but is restricted to politics—and sometimes also religion. The distinction between the authoritarian and the totalitarian separates even the most reactionary conservative from the totalitarian Nazis and Communists.

After the breakdown of the French Revolution, Maistre became the most influential philosophical spokesman for the *ancien régime*. Against the slogan "liberty, equality, fraternity," he seemed almost personally to embody the slogan "throne and altar." His program consisted of a restoration of hereditary monarchy but a more religious and less frivolous monarchy than before. He was an international refugee after the French, during the Revolution, invaded his native Savoy—then a French-speaking province of the Italian-speaking monarchy of Piedmont-Sardinia. He became for 14 years Sardinian ambassador to Russia, where his restorationist faith was strengthened by the example of the absolute monarchy still functioning there.

Maistre on  
the role of  
monarchy

Both restorationist and evolutionary conservatives defended monarchy as a social cement needed to hold society together, to keep it "organic," not "atomistic." But, while the Maistre school (key source of conservative thought in Spain and Italy as well as France) defends monarchy as absolute, the evolutionary British school defends it merely as being "pragmatic"; that is, useful.

Maistre and many continental monarchists carried their belief in the monarchy to the extreme of demanding "love" even for an "unjust" ruler, earthly or heavenly:

We find ourselves in a realm whose sovereign has proclaimed his laws. . . . Some . . . appear hard and even unjust . . . What should be done? Leave the realm, perhaps? Impossible: the realm is everywhere. . . . Since we start with the supposition that the master exists and that we must serve him absolutely, is it not better to serve him, whatever his nature, with love than without it?

This chain of authoritarian reasoning reached its climax in a logical if inhuman paradox: "The more terrible God appears to us . . . the more our prayers must become ardent. . . . Cruel as these arguments sound, the motive of the personally mild Maistre was humane: revolts against cruel authority would inflict even crueler sufferings on mankind. He drew from the French Revolution the lesson that submission to traditional authority, though admittedly a bitter pill, was Europe's cure for a still more bitter chaos.

Maistre's politics were a theological drama in which "order" (his key concept) was angelic, "chaos" diabolic, and "revolution" original sin. Seduced by the glittering *Social Contract* of Rousseau, giddy and inexperienced nations might lust after democracy or a plebeian Bonapartist dictatorship. But they would come to a perfectly dreadful end, which would serve them right for provoking the wages of sin: "Because she [Europe] is guilty, she suffers" (1810). From suffering, Maistre argued, Europe would learn that the purest order is a fatherly Christian monarchy. Even kings must avoid rocking the boat of order with liberal "innovations": Europe must "suspect" the word "reform." In *Du Pape* (1817; "Concerning the Pope"), he analyzed "order" further: its hierarchical pyramid logically required one supreme apex. That apex must be no earthly monarch, of which there were so many, but the union of earthly and spiritual power in the papacy.

The vast extent of the instability following the French Revolution surprised even its supporters, and the problem of how to restabilize society emerged as one of some practical importance. According to Maistre's *Soirées de Saint-Petersbourg* (left unfinished 1821; "Evening Conversations in St. Petersburg"), the solution was more faith and more police. That combination he summed up in his own frank formula: "the pope and the executioner." The pope was the positive bulwark of order: he gave faith. The executioner was the negative bulwark: he suppressed disorder. Himself an intellectual, Maistre indicted intellectuals as "rebellious" and "insolent" fomenters of disorder.

Maistre, this very secular exalter of clericalism, resembled not the Church Fathers but the very rationalists he attacked. He arrived at his glorification of unreason and of divine authority not by mystic intuition—not even by unthinking acceptance of traditional authority—but by using his own mind independently, rationally, and with steps of deductive logic. Though Maistre would never have admitted it, he might be characterized as the last abstract rationalist of the whole Voltairean Age of Reason. Even more than the rationalist Voltaire and as much as the rationalist Jacobins, Maistre believed in pure and absolute ideas, although his idea was absolute authority rather than absolute reason. In Maistre the destructive deductive logic of the 18th century was carried so far that it destroyed even itself—pure reason committing suicide for the sake of pure order.

This division into Burke and Maistre wings does not mean both were equal in importance or influence. No work of Maistre or any other anti-Jacobin has approached the influence of Burke's classic essay. Burke, above all, was the first to formulate the rebuttal to the French Revolution; his arguments were borrowed, sometimes word for word, by all later conservatives, including the restorationists. Maistre's rigid hierarchical conservatism is in the latter part of the 20th century dying out, whereas Burke's more flexible brand is stronger than ever, permeating all parties of the West, **emphatically** including democratic Socialists with their increasing stress,

in Great Britain and Germany, on what a Fabian Socialist has called, in good Burkean language, "the inevitability of gradualness."

Later  
French  
conserva-  
tism

French conservatism after Maistre presents a diversified range of views, from the thought of Charles Maurras (died 1952), the far-right editor of *L'Action Française* who seemed more Fascist than conservative and became a Nazi collaborator, to the anti-authoritarian Alexis de Tocqueville (died 1859), author of *Democracy in America* and the most Burkean French critic of the Revolution and of plebiscitarian mass democracy. To some extent, however, Tocqueville, an evolutionary parliamentarian, can also be regarded as a liberal thinker. In between Maurras and Tocqueville come the great anti-Jacobin Hippolyte-Adolphe Taine; the philosophical novelist Maurice Barrès, more a nationalist than anything else but conservative in his stress on organic roots; and Louis-François Veuillot, the editor after 1843 of the newspaper *L'Univers Religieux* and a clerical restorationist who ably re-adapted Maistre to the industrial modern world. An influential right-wing extremist, less clerical and more statist than Maistre and Veuillot, was Louis-Jacques-Maurice de Bonald (died 1840), the apologist for Napoleon's empire and then for the Bourbon Restoration.

Metternich and the Concert of Europe. The problems posed by the widespread social unrest of the Revolutionary and Napoleonic periods and their aftermath, and the insecurity of governments in the face of demands for constitutions and liberal reforms, provoked a reaction of more immediate and far-reaching consequence than the writings of conservative theorists. During the period 1815–48, Prince Metternich, a major influence in Austria and in Europe generally, devoted his energies to erecting an anti-revolutionary chain of international alliances throughout Europe in order to protect the multinational empire that he administered.

Metternich viewed the liberal revolutions of the 1820s and 1830s in Italy, Spain, and Germany as being unhistorical and unrealistic. Liberals were trying to transplant from England free institutions, which had no historic roots on the Continent. He retorted with Burkean arguments about the need for old roots and orderly organic development. Hence, his sarcastic comments on the liberal revolutions in Naples and elsewhere:

A people who can neither read nor write, whose last word is the dagger—fine material for constitutional principles! . . . The English constitution is the work of centuries . . . There is no universal recipe for constitutions.

Though his repressive Carlsbad Decrees of 1819 infringing inexcusably on basic liberties, his attitude was not always so negative. Just before his fall in 1848, he was at last winning acceptance from the archdukes of his sincere, thoughtful, and practical plan (postponed too long by the reactionary emperor Francis I) to convoke delegates from all the provincial estates to a representative body in Vienna.

Metternich was a dominating figure at the Congress of Vienna, the international peace conference of 1815 after the Napoleonic Wars. The Vienna peace was based on certain conservative principles shared by the Austrian delegate Metternich, the British delegate Robert Castlereagh, the French delegate Talleyrand, and the formerly liberal Russian tsar Alexander I. These principles were conservatism, in reaction against Revolutionary France; traditionalism, in reaction against 25 years of rapid change; legitimism (the principle of hereditary monarchy as the only lawful rule); and restoration (the principle of restoring the kings ousted after 1789).

The European great powers also aimed at the enforcement of peace by subsequent conferences between kings, and those subsequent conferences gave rise to a period of international cooperation known as the Concert of Europe. As liberal democrats correctly pointed out, the weakness of that first successful attempt at a "United Nations" was its narrowly aristocratic base. But it did achieve the positive function—and important precedent—of peacefully arbitrating several disputes. The debit of the conservative Concert of Europe was its bigoted suppression of democratic social progress.

the Napo-  
leonic  
Wars

Goethe's spiritual conservatism. Johann Wolfgang von Goethe was Germany's greatest dramatist, poet, and personality. In his youthful "storm and stress" period of the 1770s, Goethe went through a phase of revolt and of nationalism. In his old age, however, he became Germany's greatest cultural influence for classical balance and for antinationalist cosmopolitanism, influencing many outside Germany, including, in England, Coleridge. In 1815 Goethe and Metternich both took pride in being "good Europeans," not German nationalists. After a friendly personal conversation with Metternich, Goethe wrote that Metternich "inspires with the assurance that reason, reconciliation, and human understanding will lead us out of present chaos." Later, in 1830, Goethe urged a mature synthesis between a conservative framework and liberal goals:

The genuine liberal tries to achieve as much good as he can with the available means to which he is limited; but he would not use fire and sword to annihilate the often inevitable wrongs. Making progress at a judicious pace, he strives to remove society's deficiencies gradually without at the same time destroying an equal amount of good by violent measures. In this ever-imperfect world he contents himself with what is good until time and circumstances favor his attaining something better.

His rhymed credo "Nature and Art" (1802) expressed his conservative and classic stress on voluntary submission to law: "Only in self-restriction does the master reveal himself. And only law can give us liberty." His political drama *Die natürliche Tochter* (1803; *The Natural Daughter*) reflected his hostility to the French Revolution, radicalism, and mass movements. Much quoted by classicists, such as the United States' Irving Babbitt, was Goethe's definition: "The classical I call the healthy and the romantic the diseased." Yet his *Faust* drama (Part I published 1808, Part II 1832) retained the liberal-minded stress of his younger days on constant change, "constant striving," as salvation. His most unique achievement consisted of his being, so to speak, self-invented. By sheer strength of character, he remolded his naturally revolutionary and romantic temperament into what the world accepted as a conservative and classicist temperament.

Perhaps Germany's most mature conservative thought came from her great historians. Friedrich Karl von Savigny (died 1861) and Leopold von Ranke (died 1886) were outstanding as pupils of Burke in their reverence for history as organic growth. Savigny stressed that custom, operating over centuries, creates its own framework. On custom, Savigny founded an entire science of historical jurisprudence, denying the abstract, liberal "rights of man." Similarly, Ranke saw every society in terms of its own unique evolution. He opposed the universal generalizations of the 18th-century Enlightenment; every people, he wrote, "is related directly to God" in its own concrete way.

Savigny  
and Ranke

**Tsarist and Dostoyevskyan conservatism.** Whereas Western conservatism arose from reactions to the French Revolution, Russian tsarist conservatism had different and older origins. The practice of the absolute Tatar khans and the theory of Byzantine caesarism combined to produce an un-Western elephantiasis of autocracy. Nevertheless, two antiliberal traditionalists of Russia made such an impact on the West—the first by politics, the second by art—that their mention is indispensable: Konstantin Pobedonostsev (died 1907) and Fyodor Dostoyevsky (died 1881). The former was the tutor and chief ideologist of two tsars (Alexander III and, until the Revolution of 1905, Nicholas II). His book *Reflections of a Russian Statesman* (1898) denounced free press, trial by jury, parliamentary government, secular education, skepticism toward the divine mission of tsars, and, above all, intellectuals.

Dostoyevsky's disillusionment with his youthful radicalism resembled Coleridge's in its psychological as well as literary consequences. Both turned to an organic, religious, and monarchic society, to which they paid more homage via literature than via politics. Dostoyevsky attacked Socialism, liberalism, materialism, and atheism. He preached Greek Orthodox tsarism, Slavic traditional-

ism, and the redemption of mankind by "Holy Russia." His novel *The Possessed* (1871–72) pictured the idealistic ends of Socialists as corrupted by their terroristic means, and he boasted somewhat fawningly to Alexander III about the book's effectiveness against radicals. His novel *The Brothers Karamazov* (1880) contrasted a dry Western rationalism with a more deeply moving Russian mysticism. To the end he retained from his young Socialist days his characteristic compassion for what he called "the insulted and injured"; only now he expressed this in the more spiritual creed of Christian love. What influences many modern readers so compellingly is not his political but his cultural conservatism, exalting vision beyond external material progress.

**American conservatism.** The American Revolution owed many of its ideals to Burke's interpretation of the British heritage of 1688, the heritage of mature self-government. Burke favoured the Revolution as defending the traditional rights of freeborn Englishmen against newfangled royal usurpations. In that sense, one might describe it not as the Revolution but as the "Conservation" of 1776.

In *The Rights of the British Colonies Asserted and Proved* (1764) the American spokesman James Otis typically argued that the demand for no taxation without representation was an old British tradition. America, he said, was conserving "the British Constitution, the most free one on earth." "We claim nothing," added George Mason of Virginia, "but the liberty and privileges of Englishmen." Almost all other revolutions, colonial or otherwise, have been radical in the sense of demanding new or increased liberties and a new order. In contrast, the American demand of July 6, 1775 (*Declaration of the Causes & Necessity of Taking Up Arms*), was for conserving old liberties and the old order: "in defence of the freedom that is our birth right and which we ever enjoyed until the late violation of it." Such words promulgated no democracy, no abstract "Rights of Man"; rather, they promulgated what Burke called "prescriptive right. . . considering our liberties in the light of an inheritance." Despite important exceptions, which should not be minimized, it was not until the election of the more truly "revolutionary" Andrew Jackson (1828) that the democratic doctrines of the pamphleteer Thomas Paine gained solid roots in the United States, dividing the nation between conservative and progressive traditions. Paine was the man whom the Burkean John Adams (president 1797–1801) came to loathe most—for eternally sloganizing about apriorist utopias. A leading historian, Daniel Boorstin, has observed in *The Genius of American Politics* (1953):

The ablest defender of the Revolution—in fact, the greatest political theorist of the American Revolution—was also the great theorist of British conservatism, Edmund Burke. . . . Ours was one of the few conservative colonial rebellions of modern times.

Conservative doctrines of Hamilton and Madison

The spirit of the United States was partly molded by two masterpieces of Burkean conservatism, both published in 1787–88: *The Federalist*, by Alexander Hamilton, James Madison, and John Jay, and *Defence of the Constitutions of Government of the United States of America*, by John Adams. The achievements attributed by historians to the *Federalist* papers exceed those of any other series of newspaper articles in history, for they forged a close-knit unity during a separatist crisis. In the context of the Shays's Rebellion of 1786 against the judiciary, they saved government by law from government by mob and established minority rights against majority dictatorship. They based American liberty on the Burkean principle of historical roots, prescriptive right, and judicial precedent instead of on vague grand rhetoric about democratic utopias and the masses. Similar in thought and richer in historical background was the *Defence* by Adams, one of the most penetrating analyses of self-government ever written.

The U.S. Constitution was drawn up in Philadelphia by the U.S. Constitutional Convention of 1787. The objectives of many liberal democrats were: easy amendment; facilities for mass pressure and rapid change; unchecked

popular sovereignty; universal manhood suffrage; a single parliamentary body; and the basing of liberty on a long list of universal apriori abstractions, such as Burke later criticized in the French Declaration of the Rights of Man and of the Citizen. But in the Constitution of 1787 the Federalists foiled each of these objectives. They made amendments slow and difficult, greatly reduced the number of voters by property restrictions, created a congress of two parliamentary bodies, and based liberty primarily, though not entirely, on the concrete, inherited precedents of British tradition. Except for the House of Representatives (a sop to democrats), the main cogs of government—president, Senate, justices—were not to be chosen directly by the people but, respectively, by the electoral college, state legislatures, and appointment, and not until 1913 did an amendment eliminate this intentionally undemocratic election of senators. The judicial branch (Supreme Court) continues to be a nonelective, nonremovable elite not responsible to democratic majorities. Yet it can veto as unconstitutional measures passed by a democratic majority of the two elective, removable branches of Congress.

The American Founding Fathers adopted a conservative constitution in reaction against current mob excesses and against the democratic utopian rhetoric of the earlier Declaration of Independence (drawn up by Thomas Jefferson) with its grand abstractions about "life, liberty, and the pursuit of happiness." Yet the Constitution was the Burkean, not the reactionary brand of conservatism. Thus it defeated not only the liberal objectives but also the more extreme conservative ones, including a hereditary, titled aristocracy and Hamilton's notion of a president for life with absolute veto power.

The United States' only consistently conservative party was the Federalist Party of John Adams and Alexander Hamilton. Hamilton was perhaps too much the reckless commercial adventurer to be classified under conservative or any other principles, but Adams remains the closest New World equivalent to Burke. After the death of the Federalist Party in the early 1800s, two mutually hostile kinds of political conservatism emerged: that of the urban New England Brahmins and that of the Southern semi-feudal landowners. The latter received their most persuasive defense in the famous *A Disquisition on Government and Discourse on the Constitution and Government of the United States* of Calhoun, the closest New World equivalent to Maistre. This more extreme, very regional Calhoun conservatism still dominates much of the American south in the 1970s, typically cutting across Democrat or Republican party lines and still alien to New England conservatism.

Modern U.S. political parties, being pragmatic alliances of geographic patronage groups rather than matters of doctrine, cannot realistically be classified under "isms." It is nearer to reality to look for conservatism, instead, in the indirect diffusion—cutting across all party lines—of the above described restraining principles of the Constitution.

#### CONSERVATISM IN THE 20TH CENTURY

The 19th and, particularly, the 20th century (that is, the period since the 18th century Enlightenment) have in many ways been antithetical to conservatism, both as a political philosophy and as a program of particular parties identified with conservative interests. As described above, the consciously articulated conservatism of Burke was formulated in reaction to the French Revolution; similarly, the anti-liberal, anti-revolutionary policy that was a major factor in European international relations during the Metternich period (1809–48) was a reaction to the political discontent aroused by demands for liberal reforms and constitutions. The Enlightenment, in fact, had resulted in the propagation of certain attitudes and ideas that were to have far-reaching political consequences during the succeeding centuries, the most significant of which were a belief in the possibility of improvement in the human condition—a belief, that is, in the idea of progress—and a concomitant disposition to tamper with or discard existing institutions or practices in

pursuit of progress, a disposition that has been characterized as "rationalist." Such rationalist politics embrace a broad segment of the political spectrum, including much of liberal reformism, socialism of the welfare-state or mixed-economy variety characteristic of western Europe, and Marxist socialism. The changes that have been wrought under the banner of rationalist politics have thus been immense and point to what has been described as a dilemma of modern conservatism—the extent to which, in face of constant rationalist innovation, conservatives may be forced to adopt a merely defensive role, so that the political initiative lies always in the other camp.

The responses of conservatives to this predicament have naturally varied considerably in differing political contexts; an account of some of these responses is given below. An analysis of the role of conservatism in contemporary politics, however, cannot be confined merely to an account of the programs of political parties identified with the conservative cause, for conservatism makes its influence felt in a variety of ways less direct than through expression in party platforms. Conservatism in the 20th century has in fact been a pervasive force in the political life of those parliamentary democracies in which rationalist politics have seemed to hold sway, as well, of course, as in less liberal political climates, such as in Spain and Portugal.

Conservative influences operate indirectly (*i.e.*, other than via the programs of political parties) largely by virtue of the fact that, while man is undeniably a persistent innovator, there is also much in the human temperament that is naturally or instinctively conservative: among such conservative traits are the tendency to fear and avoid sudden change and the tendency to act according to habit. While these are traits of the individual, they may find collective expression in, for example, resistance to imposed political change and in a whole cluster of value preferences that contribute to the formation and stability of a particular culture. The tendency for value preferences to find expression in cultural forms and political institutions (the so-called pragmatism of the British, for example, in their unwritten constitution) constitutes a profound conservative influence in political life over and above any explicit articulation of particular conservative interests that may be undertaken by a political party, for it gives rise to practices and institutions that are products of a long process of social and political evolution and are closely related to other culture-related factors, such as religion and property relationships. The existence of such cultural restraints on political innovation constitutes in all societies a fundamental conservative bias, the implications of which have been aphoristically expressed by an English commentator, F.J.C. Hearnshaw: "It is commonly sufficient for practical purposes if conservatives, without saying anything, just sit and think, or even if they merely sit." Mere inertia, however, has rarely sufficed to protect conservative values in an age dominated by rationalist dogma and by social change related to continuous technological developments. The conservative reaction, however, is best analyzed in specific political contexts. Historians, it may be noted, cannot safely agree on there being more than four great political parties of the 20th century deserving of the name: the Conservative Party of England, the Christian Democrats of Italy and of Germany, and the Liberal Democrats of Japan.

In England, Disraeli's successor, Lord Salisbury, was prime minister in 1885, from 1886 to 1892, and from 1895 to 1902; Arthur Balfour succeeding him from 1902 to 1905. This longest era of Conservative rule was characterized by imperialism, high tariffs, and the gradual erosion of the party's working class vote, which Disraeli had so far-sightedly nurtured by extending the franchise to the workers in 1867. The party had thereby broadened its original class basis (landed aristocracy and established church) to outflank from below and above the new commercial class and its Liberal Party. It may be said that conservatism in Great Britain since Disraeli's time has veered between a passive and largely resigned acceptance

of changes introduced by its Liberal and, later, Labour opponents and a more positive conservatism, the aim of which has been to foster a social environment in which the individual is encouraged to advance his own interests without undue hindrance from, or reliance on, the state—a policy descended from the liberal individualism of the 19th century, associated particularly with the Liberal Party. This positive conservatism of liberal individualism tinged with a strong sense of social conscience was given its earliest formulation by Disraeli, who combined a desire to mitigate harsh conditions suffered by the working class under conditions of unrestrained capitalism with a belief in the value of existing institutions such as the monarchy, the church, and the class system. Disraeli's foreign policy, which emphasized the need for Britain to act constructively as a "moderating and mediatorial" power and to maintain its interest in its empire, also reflected the view that conservatism must be a force shaping events rather than merely reacting to them. These three elements—the improvement of material conditions both by encouragement of individual initiative and timely reform of abuses, emphasis on the value of traditional institutions, and belief in the need for an active foreign policy—have been recurring themes of British conservatism in the 20th century. Later conservative thinkers have elaborated on the value of divergency of personality and attitudes, the role of property as an expression of individuality, and the central role of the family in providing a stable environment in which the individual may develop.

In its less positive periods (as, for example, during the interwar period), conservatism in Britain has been identified with the defense of class privileges and of the status quo, an unconstructive opposition to socialism, and, during the 1930s, a deal-making commercialist approach to the rising Nazi menace. Faced, however, with the introduction of a mixed economy and the vast extension of state welfare services by the Labour Party after 1945, the Conservatives, when returned to power in 1951, reversed very few of their socialist predecessors' innovations, emphasizing instead their claim to be more able to administer the welfare state more efficiently and to some extent outbidding their opponents, especially in areas of social policy related to their fundamental beliefs—the encouragement of a heavy program of house building being an example.

Western Europe. It is of significance that the British Conservative Party has been the more ardent of the two major British parties in championing British membership of the European Economic Community (EEC), reflecting an internationalism voiced by Sir Winston Churchill when, in 1940, he appealed for a Franco-British union and, in 1946, for a European union. Originally conceived as a means by which the economies of the European countries might be integrated—so that war between them would be impossible—the nascent community assumed significance during and after the Cold War as a means of strengthening western Europe against the threat of external Communist aggression and internal subversion. Together with the military North Atlantic Treaty Organization alliance, it thus assumed a role as a bulwark of parliamentary democracy and capitalism.

In the arena of party politics, conservatism in western Europe is generally represented by two or more parties, ranging from the liberal centre to the moderate and extreme right. Three types of party may be discerned: agrarian parties (particularly in Scandinavia), Christian democratic parties, and conservative parties linked strongly with big business interests and sometimes with a markedly nationalistic outlook. Such categories are very general and are not mutually exclusive.

Among parties of the right, the Christian democratic tradition has the longest continuity, the predecessors of contemporary parties having emerged during the first half of the 19th century to represent supporters of the church and the monarchy against liberal elements. Especially after World War I, business interests became a third important element. The clerical interest is strongest in the Democrazia Cristiana (DC; Christian Democrat

Non-political manifestations of conservatism

The Christian democratic tradition

Party) of Italy, which has dominated government since 1945. Through this party, Catholicism has set limits on policy concerning such church-related matters as divorce and contraception; in regard to other social questions, however, the party has never presented a coherent policy, largely because it comprises little more than an alliance of disparate and often conflicting interest groups.

In West Germany, a country divided between Catholics and Protestants, the church plays a far less significant role in the main conservative party, the *Christlich-Demokratische Union* (CDU; the Christian Democratic Union). After 1950, following debate within the party over economic and social questions, advocacy of a free-enterprise economy coupled with a strong commitment to maintain and improve social insurance and other welfare provisions became established policy. The conservative temper of the political climate in Germany since the beginning of economic recovery may be judged from the fact that since the early 1950s the main opposition party, the *Sozialdemokratische Partei Deutschlands* (SPD; the Social Democrats), has progressively eliminated the socialist content of its program, a congress at Bad Godesberg (1959) in fact going so far as to champion the profit motive.

France provides an exception to the general pattern of the representation of moderate conservative opinion by a Christian democratic party; the closest equivalent has been the Catholic, right-wing, *Mouvement Républicain Populaire*, moribund in the early 1970s. Instead, a large proportion of conservatives in France have supported Gaullist groups such as the *Union pour la Défense de la République*. Gaullist conservatism has been markedly nationalistic, involving assumptions concerning French leadership of a united Europe and emphasizing tradition, order, and the regeneration of France. Gaullists espouse divergent views on domestic social issues, however, as do non-Gaullist groups such as the *Centre National des Indépendants et Paysans*. The number of conservative groups, their lack of stability, and their tendency to be identified with local issues defy simple categorization. Conservatism in France, however, as in Italy and Germany, has been the dominant political force since World War II.

Conservatism in Europe is thus revealed as a dominating political influence in the major states, finding expression in parties of very different character. These parties represent traditional bourgeois values and oppose unnecessary state involvement in economic affairs and any radical attempts at income redistribution. They are also characterized by an absence of ideology and often of even a well-articulated political philosophy, but this tends to be of little consequence in terms of their influence since they give political expression to the conservatism of temperament mentioned above as an important underlying bias in political conflict, as well as to persistent culture-related values that are of great importance in terms of continuity and stability.

**Japan.** The relationship between conservatism as an underlying bias related to psychological factors and cultural values and conservatism as an articulated political credo is illustrated by the history of party politics in Japan since its opening to Western influence in the middle of the 19th century. The political and social changes that took place following the Meiji Restoration (1868) were of major proportions, involving the abolition of feudal institutions and the introduction of such Western political ideas as constitutional government. But despite institutional innovations and the dislocations resulting from rapid industrialization, traditional loyalties and attitudes proved to be more important factors in shaping political developments.

Except for the period of intervention by the militarists during the 1930s and 1940s, Japan has been ruled by conservatives since the beginning of party politics in the 1880s. The conservative parties (the two most important of which merged to form the Liberal-Democratic Party in 1955) have been dominated by personalities rather than by ideology and dogma; and personal loyalties to leaders of groups within the party (factions) rather than

commitment to policy have determined the allegiance of conservative members of the Diet. As one American scholar, Nathaniel B. Thayer, has described it, the factions

have adopted the social values, customs, and relations of an older Japan. . . . The old concepts of loyalty, hierarchy, and duty hold sway in them. And the Dietman (or any other Japanese) feels very comfortable when he steps into this world.

The Liberal-Democratic Party is intimately linked with big business interests, and its policies are guided primarily by the objective of fostering a stable environment for the development of Japan's free-enterprise economy; to this end, the party functions as a broker of conflicting business interests. Policy toward other Asian countries, national defense, and internal security are other conservative preoccupations.

**The United States.** It may be argued that the United States has no nationwide conservative or liberal parties but instead only two fluctuating, all-inclusive coalitions. Both the Democrat and Republican coalitions include interest groups occasionally labelled conservative—the racists among southern Democrats, for example, and such Republican off-shoots as the local New York Conservative Party. On a journalistic level the word conservative has been used loosely for a segment of the Republican party associated with Sen. Barry Goldwater and a governor of California, Ronald Reagan. A more historical approach, however, applies the more precise label Manchester liberal to so unconservative an outlook—so *laissez-faire* and so untraditional.

Modern American conservatism has been most influential not in the unphilosophic realm of politics but in the literary and religious realm in such masterpieces of conservative outlook as Irving Babbitt's *Democracy and Leadership* (1924) or the aristocratic traditionalism of the Nobel Prize-winning novelist William Faulkner. Indeed, such figures as the novelist Herman Melville and the theologian Reinhold Niebuhr, usually independent of each other and eschewing conservative labels, have performed the nation's spiritual arithmetic, calculating the spiritual price of material progress and of a robotizing technology. Unconsciously conservative in this sense, even when under radical slogans, is the impulse among young people in the 1970s to conserve ecology and environment against what Melville called "the impieties of progress." These unconscious young conservers sublimate the old class-based elitism into a new value-based elitism, open to all: thereby rescuing quality (the cultural as well as physical ecology) from the parvenu plutocrats of quantity (mass culture and robot technology).

The impact of the horrors allowed at Auschwitz has purged—in effect conservatized—many modern liberals out of their most unconservative axiom: the Rousseauist doctrine of the "natural goodness" of man and the masses. For many, the real battle for the future now seemed to be an alliance of such chastened liberals with conservatives in jointly defending their shared constitutional and ethical framework against extremist destroyers from a mirror-image right and left.

It is arguable that conservatism, whether its influence operates through political parties or through psychological, cultural, and institutional factors, is a far more persuasive influence in democratic societies than the rate of social and economic change and the welter of rationalist dogma would suggest. That it is often lacking in articulation and that, as critics of conservatism point out, there is a comparative lack of persuasive presentations of the conservative cause compared with the abundant literature of rationalist politics is in part a consequence of its underlying strength and in part a result of a certain coyness among the best conservative thinkers deriving from the fear that a conservatism that needs to present itself in the same terms as the doctrines it opposes is no longer conservatism or is a conservatism in retreat. In the latter part of the 20th century, however, many would say that it may be argued that the predilection of governments to extend their role in social life is so strong as to necessitate a more articulate, even ag-

gressive, conservatism. One particularly important task of conservatives will be to emphasize that the social sciences, particularly anthropology and psychology, so long enlisted in the cause of social engineering and liberal utopianism, also reveal much about the role of tradition, custom, and evolution in the survival of societies.

**BIBLIOGRAPHY.** Among "Burkean-conservative" works sharing an anti-extremist centre with moderate liberals are DANIEL J. BOORSTIN, *The Genius of American Politics* (1953); THOMAS I. COOK and MALCOLM MOOS, *Power Through Purpose* (1954); ERIC HOFFER, *The True Believer* (1951); ROSS J.S. HOFFMAN and PAUL LEVACK (eds.), *Burke's Politics* (1949); HENRY A. KISSINGER, *A World Restored* (1957); WALTER LIPP-MANN, *The Cold War* (1947); REINHOLD NIEBUHR, *The Irony of American History* (1952), *Christian Realism and Political Problems* (1953), and *The Self and the Dramas of History* (1955); ROBERT A. NISBET, *Community and Power* (1962); CLINTON L. ROSSITER, *Conservatism in America*, 2nd ed. rev. (1962); GEORGE SANTAYANA, *Dominations and Powers* (1951); LEO STRAUSS, *Natural Right and History* (1953) and *What Is Political Philosophy? and Other Studies* (1959); FRANK TANNENBAUM, *A Philosophy of Labor* (1951); PETER VIERECK, *Conservatism Revisited* (1949; paperback rev. ed., 1965), *The Unadjusted Man* (1956), and *Shame and Glory of the Intellectuals* (1953; paperback rev. ed., 1965); ERIC VOEGELIN, *The New Science of Politics* (1952); and *Order and History*, 3 vol. (1956–58); FRANCIS G. WILSON, *The Case for Conservatism* (1951). For British Conservatives, see LEOPOLD AMERY, *The Forward View* (1935); ARTHUR BRYANT, *The Spirit of Conservatism* (1929); LORD HUGH CECIL, *Conservatism* (1912); HENRY FAIRLIE, *The Life of Politics* (1968); QUINTIN HOGG, *The Conservative Case*, rev. ed. (1959); F.J.C. HEARN-SHAW, *Conservatism in England* (1933); MICHAEL J. OAKESHOTT, *Rationalism in Politics, and Other Essays* (1962); and PEREGRINE WORSTHORNE, *The Socialist Myth* (1971).

More extreme views, whether right-wing nationalist in politics or militantly business-oriented in economics (mainly by contributors to the contemporary New York periodical *National Review*), may be found in WILLIAM F. BUCKLEY, JR., *God and Man at Yale: The Superstitions of Academic Freedom* (1951) and *Up from Liberalism*, rev. ed. (1968); JAMES BURNHAM, *Congress and the American Tradition* (1959) and *Suicide of the West* (1964); MILTON FRIEDMAN, *Capitalism and Freedom* (1962); BARRY GOLDWATER, *Conscience of a Conservative* (1963); JEFFREY P. HART, *The American Dissent* (1966); NELLIE D. KENDALL (ed.), *Willmoore Kendall contra mundum* (1971); RUSSELL KIRK, *The Conservative Mind, from Burke to Santayana* (1953), *Prospects for Conservatives* (1956), and *Enemies of the Permanent Things* (1969); ERIK VON KUEHNELT-LEDIHN, *Liberty or Equality* (1952); FRANK S. MEYER, *In Defense of Freedom* (1962) and *The Conservative Mainstream* (1969); THOMAS S. MOLNAR, *The Counter-Revolution* (1969); ENOCH POWELL, *Freedom and Reality* (1969); RONALD REAGAN, *The Creative Society* (1968).

Useful anthologies include PETER VIERECK (ed.), *Conservatism: From John Adams to Churchill* (paperback rev. ed. 1956); and PETER WITONSKI (ed.), *The Wisdom of Conservatism* (1971).

## Constable, John

John Constable, with J.M.W. Turner, dominated English landscape painting in the 19th century. But the works of these two contemporaries are widely different in aim and effect. Turner never lost the ambition to fuse landscape with literary, mythological, or historical overtones. He loved to represent the most dynamic forces of nature and in his later works evolved pictorial drama out of the sheer element of light and colour. In direct contrast, Constable's aim was to represent the English countryside with as much truth to natural appearances as he could achieve from his long study of the scenes familiar to him and the varying aspects of the sky. He was thus the last great exponent of the tradition of naturalistic landscape painting fostered by the 17th-century Dutch artists.

Constable was born in East Bergholt, Suffolk, on June 11, 1776. His birthplace was, and remains, a small village, standing on a ridge a short distance from the River Stour, which separates Suffolk from Essex. The Stour Valley in this region is rich in corn, pastureland, and fine trees and was known in the late 18th century for its efficient agriculture no less than its natural beauty. The men of Suffolk felt a jealous patriotism for their own county, and Constable remained at heart a Suffolk man, although

he constantly crossed the bridge over the River Stour at Flatford into Essex.

The artist's father, Golding Constable, was a man of means who owned mills at Flatford and Dedham, on the Suffolk and Essex banks of the Stour, respectively. His business consisted of grinding corn raised in the local fields and shipping it round the coast of East Anglia to the London market. The Stour had been made into a canal, navigable beyond these mills, and the grain was transported on its waters in broad, flat-bottomed barges. The fact that Constable was born into the midst of the practical realities of country life has a direct bearing on his career and is reflected throughout his painting. He showed intellectual promise as a child and was brought up for the church; when this idea was abandoned he was trained to enter his father's business. But he had already conceived an enthusiasm for painting. This was fostered by his friendship with an amateur painter, John Dunthorne, the local plumber and glazier, and further encouraged by Sir George Beaumont. Constable's determination to make painting his profession was sealed by his acceptance as a probationer in the Royal Academy Schools in 1799, when he was 23.

**Artistic development.** At this time his performance did not reveal any marked promise; his execution was laboured and his drawing from the life weakly academic. But he already had a clear mental image of the type of pictures he wanted to paint and worked doggedly to overcome his technical defects. Seven or eight years after he had started his formal training, he discovered how to embody his idea of the English countryside in a manner both more realistic and more spirited than his predecessors. There were some modest successes to record in this period of self-training. He exhibited at the Royal Academy shows annually from 1802, with one single exception in 1804. He went on two of the sketching expeditions that it was then the practice for landscape painters to undertake, going to the Peak District, Derbyshire, in 1801 and the Lake District in 1806. He painted portraits of the Suffolk and Essex farmers and their wives and in 1805 attempted an altarpiece of "Christ Blessing the Children," in the manner of the American expatriate painter Benjamin West. But when he took stock of his progress after his return from the Lake District, he realized that he had been attempting too wide a range of subject and style, thus dissipating his energies. He then determined to concentrate on the scenes that had delighted him as a boy: the village lanes, the cornfields and meadows running down to the Stour, the slow progress of barges drawn by tow horses, the bustle of vessels passing the locks at Flatford or Dedham.

In the years 1809 to 1816 he established his mastery and evolved his individual manner; but these were years of personal stress. He was obliged to live much of each

Early works

Years of  
personal  
stress

year in London, where his professional associates were to be found and where he could participate in exhibitions. But he was uneasy at these enforced absences from the countryside, in which he felt most at home, and tried to pay yearly visits to Suffolk. The assiduity with which he studied the landscape on these visits is shown by two pocket sketchbooks, one of 1813 and one of 1814, which, still intact, are preserved in the Victoria and Albert Museum. These contain between them over 200 small sketches made in a limited area around his home village and reflect most aspects of the summer life of the fields and the river.

Deeper than the strain of exile from these scenes was the unhappy progress of his courtship of Maria Bicknell, with whom he had fallen in love in 1809 but whose grandfather, the elderly and tyrannical rector of East Bergholt, opposed her marriage to an impecunious artist. Nevertheless, Constable stuck to his purpose with a tenacity equal to that which he displayed in his art, and, in her unaggressive way, Maria was just as determined. A further anxiety for Constable came from the failing health of his parents; his mother died in 1815, and his father the following year. He was genuinely devoted to them and spent prolonged periods at home during their illnesses. But his father's death in 1816 provided a sufficient measure of economic independence for him to marry Maria Bicknell and to settle into the domestic life that was a prerequisite for his calm development and the full maturing of his art.

Once he had married, on October 2, 1816, and had established himself and his wife in a London home, Constable set to work to show what he could achieve in his art. He was 40 years old, and had painted a handful of accomplished pictures, which were original but on a small scale. These included "Dedham Vale: Morning," (1811; Sir Richard Proby Collection, Elton Hall, Huntingdonshire); "Boatbuilding near Flatford Mill," (1815; Victoria and Albert Museum, London); "The Stour Valley and Dedham Village," (1815; Museum of Fine Arts, Boston). But these were still products of the years of preparation. Most significant was the large number of small oil sketches and drawings that were to form the basis of his future and more ambitious painting. These sketches, of which he made a considerable number after 1808, were painted in the open air in front of the subject. They are most frequently in oils on paper about 12 inches wide, and they record the form of the landscape, the colours that predominate and also the more evanescent qualities of atmosphere and the reflection of light on particular details. Now they are recognized to be among Constable's most individual achievements and to have been unique at the time they were painted. But to the artist they were means to an end. His main ambition was to embody his concept of the Suffolk countryside in a series of larger canvases monumental enough to make an impression in the annual summer exhibitions of the Royal Academy. The first attempt was the "Flatford Mill on the River Stour" which he exhibited in 1817. It shows a reach of the river running up to the mill, in which Golding Constable had lived till within two years of Constable's birth, bordered by a meadow that has just been scythed.

**Mature works.** This was succeeded by a series of six paintings that are now among his best known and most highly regarded works. In order of exhibition they are "The White Horse"; "Stratford Mill"; "The Hay-Wain"; "View on the Stour near Dedham"; "The Lock"; "The Leaping Horse." These six canvases portray scenes on the River Stour that were easily within the compass of Constable's childhood walks; between the most easterly, "The Hay-Wain," and the most westerly, "Stratford Mill," there is hardly more than two miles distance in a direct line. To this unity of place is joined a unity of subject matter. With the exception of "The Hay-Wain," all show barges being manoeuvred along the canals. The appearance in these works of the fruits of Constable's deep, unprecedented study of the formation of clouds, the colour of meadows and trees, and the effect of light glistening on leaves and water enables them to communicate

the concrete actuality of these everyday-life country scenes, as well as the feeling they evoked in him.

This series of Stour scenes was interrupted in 1823, when Constable's chief exhibit was a view of "Salisbury Cathedral from the Bishop's Grounds," in which the artist transmuted a commission from Bishop Fisher, intended mainly as a record of an architectural monument, into his own idiom, framing the spire between overarching trees, emphasizing the play of light and shade on the Gothic stonework, and setting the whole under a sky in which rain clouds are impending. This romantic treatment did not please the Bishop but was admired by the Bishop's nephew and Constable's old friend, Archdeacon John Fisher, who had already shown his faith in the artist by buying "The White Horse" at the exhibition of 1819.

A revealing correspondence between Constable and Fisher has been preserved. In it the painter gives his most intimate thoughts on his art without concealment or false modesty. There was much he could be satisfied with at this time. He was aware that he had achieved in his art a great deal of what he had set out to do. In addition, his work had deeply impressed the painters of the French Romantic school. Théodore Géricault had admired "The Hay-Wain" on its first exhibition in 1821; and when this work (along with the "View on the Stour near Dedham") was shown at the Paris Salon in 1824, it not only created a sensation but inspired Eugène Delacroix to repaint parts of his "Massacre at Chios." In England recognition was slower in coming. Although Constable had been made an Associate of the Royal Academy in 1819, full membership was delayed for ten years.

Meanwhile the presence, from 1819, of Hampstead scenes and, from 1824, of Brighton scenes among his repertoire of subjects indicates a deepening shadow over his domestic happiness. Mrs. Constable had long been delicate, and Constable took houses in these places in search of purer air. Her death from consumption in 1828, at the age of 41, was a loss from which he never fully recovered, though he bestirred himself into activity for the sake of his seven children, in whom he delighted. His financial situation had been eased by a large legacy from his father-in-law, and he became a full Academician in 1829. But from this time an increased restlessness is to be found in his paintings. "Hadleigh Castle" and "Salisbury Cathedral from the Meadows" show his growing recourse to broken accents of colour, sombre tones, and stormy skies. It was in 1829 also that he began his preparations for the publication of *English Landscape Scenery*, a selection of mezzotints executed by David Lucas from Constable's paintings and sketches in which the same dramatic qualities of light and shade are translated into a black-and-white medium. The admiration of his friend, the American-born artist C.R. Leslie, prompted the writing of the *Memoirs of the Life of John Constable, R.A.* This biography was first published in 1843 and still remains an indispensable source of information on Constable.

In the 1820s the use of colour by Constable's great contemporary and rival in landscape painting, J.M.W. Turner, was becoming bolder and even more uninhibited. This may have contributed to the greater readiness for change that we see in Constable's late works. His "Waterloo Bridge from Whitehall Stairs" is a monumental record of the opening ceremonial, painted in a high key of colour. His use of watercolour became more frequent, and in 1834, after he had been seriously ill, he sent no oils at all to the Royal Academy, depending for his principal exhibit on a large and remarkable watercolour, "Old Sarum" (Victoria and Albert Museum, London). A visit to Arundel in the same summer imbued him with enthusiasm for a new type of countryside dominated by steep wooded slopes.

In 1836 Constable sent "The Cenotaph at Coleorton" to the Royal Academy exhibition. It was the last painting he showed in his lifetime. He died suddenly during the night of March 31, 1837. The painting on which he had been working the day before, "Arundel Mill and Castle" (Toledo Museum of Art, Toledo, Ohio), was suf-

Effect of

grief on  
his  
paintings

Late  
works

ficiently completed to be shown posthumously at the Academy. At his death his reputation was limited, but those who admired his work did so intensely. This admiration grew slowly throughout the 19th century, becoming more widespread as his sketches became available and their freshness and spontaneity were recognized. In 1843 his first biographer, C.R. Leslie, wrote that he was "the most genuine painter of English landscape," and that is a judgment now almost universally reaffirmed.

#### MAJOR WORKS

"Malvern Hall, Warwickshire" (1809; Tate Gallery, London); "Boatbuilding near Flatford Mill" (1815; Victoria and Albert Museum, London); "Wivenhoe Park, Essex" (1816; National Gallery of Art, Washington, D.C.); "Flatford Mill on the River Stour" (1817; Tate Gallery); "The White Horse" (1819; Frick Collection, New York); "Dedham Lock and Mill" (1820; Victoria and Albert Museum); "Stratford Mill" (1820; Sir Reginald and Lady Macdonald-Buchanan Collection, Cottesbrooke Hall, Northamptonshire); "The Hay-Wain" (1821; National Gallery, London); "View on the Stour near Dedham" (1822; Huntington Library and Art Gallery, San Marino, California); "Salisbury Cathedral from the Bishop's Grounds" (1823; Victoria and Albert Museum); "The Lock" (1824; private collection, England); "The Leaping Horse" (1825; Royal Academy of Arts, London); "The Cornfield" (1826; National Gallery, London); "Chain Pier, Brighton" (1827; Tate Gallery); "Dedham Vale" (1828; National Gallery of Scotland, Edinburgh); "Hampstead Heath: Branch Hill Pond" (1828; Victoria and Albert Museum); "Hadleigh Castle" (1829; Mr. and Mrs. Paul Mellon Collection, Virginia); "Salisbury Cathedral from the Meadows" (1831; Lord Ashton of Hyde Collection, Moreton-in-Marsh, Gloucestershire); "The Grove (or Admiral's House) at Hampstead" (1832; National Gallery, London); "Waterloo Bridge from Whitehall Stairs" (1832; private collection, England); "A Cottage at East Bergholt" (c. 1835; Lady Lever Art Gallery, Port Sunlight, Cheshire); "The Cenotaph at Coleorton" (1836; Tate Gallery); "Stoke-by-Nayland" (after 1830; Art Institute, Chicago).

Pencil and oil sketches exist for many paintings, and the largest collection of these is in the Victoria and Albert Museum. This includes the full-scale sketches for "The Hay-Wain" (1821) and "The Leaping Horse" (1825); among the 92 oil sketches painted on a small scale in the open air two of the best known are "Barges on the Stour" and "Flatford Lock and Mill" (both c. 1810).

**BIBLIOGRAPHY.** C.R. LESLIE (ed.), *Memoirs of the Life of John Constable, Composed Chiefly of His Letters*, rev. ed. (1951), is written with affectionate understanding of its subject and with narrative power. R.B. BECKETT, *John Constable's Correspondence*, 6 vol. (1962–68), contains a transcription of all the known letters to and from Constable, with an explanatory account. These volumes, including the companion volume *John Constable's Discourses* (1970), are invaluable to the student. G. REYNOLDS, *Constable: The Natural Painter* (1965), is an up-to-date summary of the artist's life and work.

(G.R.)

## Constantine the Great

Constantine I the Great, the first Roman emperor to profess Christianity, initiated not only the evolution of the empire into a Christian state but also provided the impulse for a distinctively Christian culture that prepared the way for the growth of Byzantine and Western medieval culture. He was born on February 27 of an unknown year, but probably in the later AD 280s, at Naissus (modern Niš in Yugoslavia) in the province of Upper Moesia, on the strategic road leading from Pannonia through Sirmium and Singidunum (Belgrade) to Byzantium. He was a typical product of the military governing class of the later 3rd century, the son of Flavius Valerius Constantius, an army officer, and his wife (or concubine) Helena. In AD 293, when Constantine was still a boy, his father was raised to the rank of Caesar, or deputy emperor, and was sent to serve under the Augustus (emperor) Maximian in the west. At the same time he had to separate from Helena in order to marry a stepdaughter of Maximian; and Constantine was brought up in the Eastern Empire, at the court of the senior emperor Diocletian at Nicomedia (modern İzmit in Turkey). Constantine was seen as a youth by his future panegyrist, Eusebius, bishop of Caesarea, passing with Diocletian through Palestine on the way to a war in Egypt; later, as a young officer,

Constantine the Great, colossal marble head, c. AD 330. In the Capitoline Museum, Rome.

Constantine took part in a successful campaign on the lower Danube.

**Career and conversion.** Constantine's experience as a member of the imperial court—a Latin-speaking institution—in the eastern provinces left a lasting imprint on him. Educated to less than the highest literary standards of the day, he was always more at home in Latin than in Greek: later in life he was in the habit of delivering edifying sermons, which he would compose in Latin and pronounce in Greek from professional translators. Christianity he encountered in court circles as well as in the cities of the east; while from 303, during the great persecution of the Christians that began at the court of Diocletian at Nicomedia and was enforced with particular intensity in the eastern parts of the empire, Christianity was a major issue of public policy. It is even possible that members of Constantine's family were Christians. Constantine himself was said to have converted his mother: his father's conduct in Britain during the persecution is uncertain; but the name of a half-sister of Constantine, Anastasia, has been thought to show Christian influence.

In 305 the two emperors, Diocletian and Maximian, resigned, to be succeeded by their respective deputy emperors, Galerius and Constantius. The latter were replaced by Maximinus Daia in the east and Severus in the west, Constantine being passed over. Constantius now requested his son's presence from Galerius: this was grudgingly conceded, and Constantine made his way through the territories of the hostile Severus to join his father at Boulogne. They then crossed together to Britain and fought a campaign in the north before Constantius' death at York in 306. Immediately acclaimed emperor by the army, Constantine now threw himself into a complex series of civil wars in which Maxentius, the son of the old Western emperor Maximian, rebelled at Rome, with his father's help suppressing Severus, the deputy emperor, who was replaced by Licinius. When Maximian was rejected by his son, he joined Constantine in Gaul, only to betray him and be forced to commit suicide (310). Constantine, who had in 307 married Maximian's daughter Fausta as his second wife, invaded Italy in 312 and after a lightning campaign defeated his brother-in-law Maxentius at the Milvian Bridge near Rome. He then

confirmed an alliance that he had already entered into with Licinius (Galerius having died in 311). Licinius, after defeating his rival Maximinus Daia, became Eastern emperor but lost territory in the Balkans to Constantine in 316. After a further period of tension, Constantine attacked Licinius in a second war of 324, routing him at Adrianople and Chrysopolis and becoming sole emperor until his death in 337.

Throughout his life, Constantine ascribed his success to his conversion to Christianity and the support of the Christian God. The triumphal arch erected in his honour at Rome after the defeat of Maxentius ascribed the victory to the "inspiration of the Divinity" as well as to Constantine's own genius. A statue set up at the same time showed Constantine himself, holding aloft a cross and the legend, "by this saving sign I have delivered your city from the tyrant and restored liberty to the Senate and people of Rome." After his victory over Licinius in 324, Constantine wrote that he had come from the farthest shores of Britain as God's chosen instrument for the suppression of impiety, and in a letter to the Persian king Shāpūr II he proclaimed that, aided by the divine power of God, he had come from the borders of the ocean to bring peace and prosperity to all lands.

Constantine's adherence to Christianity was closely associated with his rise to power. He fought the Battle of the Milvian Bridge in the name of the Christian God, having received instructions in a dream to paint the Christian monogram (☩) on his troops' shields. This is the account given by the Christian apologist Lactantius; a somewhat different version, offered by Eusebius, tells of a vision seen by Constantine during the campaign against Maxentius, in which the Christian sign appeared in the sky with the legend, "In this sign, conquer." Despite the Emperor's own authority for the account, given late in life to Eusebius, it contains anachronisms and is in general more problematic than the other: but a religious experience on the march from Gaul is suggested also by a pagan orator, who in a speech of 310 referred to a vision of Apollo received by Constantine at a shrine in Gaul.

Yet to suggest that Constantine's conversion was "politically motivated" means little in an age in which every Greek or Roman expected that political success followed from religious piety. The civil war itself fostered religious competition, each side enlisting its divine support; and it would be thought in no way unusual that Constantine should have sought divine help for his claim for power and divine justification for his acquisition of it. What is far more remarkable is Constantine's subsequent development of his new religious allegiance to a quite extreme personal commitment.

Commitment to Christianity. After the defeat of Maxentius, Constantine met Licinius at Milan to confirm a number of political and dynastic arrangements. A product of this meeting was the so-called Edict of Milan, extending toleration to the Christians and the restoration after the persecution of their personal and corporate property. The extant copies of this decree are actually those posted by Licinius in the eastern parts of the empire. But Constantine went far beyond the joint policy agreed upon at Milan. By 313 he had already donated to the Bishop of Rome the imperial property of the Lateran, where a new cathedral, the Basilica Constantiniana (now S. Giovanni in Laterano) soon rose. The Church of St. Sebastian was also probably begun at this time: and it was in these early years of his reign that Constantine began issuing laws conveying upon the church and its clergy fiscal and legal privileges and immunities from civic burdens. As he said in a letter of 313 to the proconsul of Africa, the Christian clergy should not be distracted by secular offices from their religious duties "... for when they are free to render supreme service to the Divinity, it is evident that they confer great benefit upon the affairs of state." In another such letter, to the bishop of Carthage, Constantine mentioned the Spanish bishop Hosius, important later in the reign as his adviser and possibly—since he may well have been with Constantine in Gaul before the campaign against Maxentius—instrumental in the conversion of the Emperor.

Constantine's personal "theology" emerges with particular clarity from a remarkable series of letters, extending from 313 to the early 320s, concerning the Donatist schism in North Africa. The Donatists maintained that those priests and bishops who had once lapsed from the Christian faith could not be readmitted to the church. Constantine's chief concern was that a divided church would offend the Christian God and so bring divine vengeance upon the Roman Empire and Constantine himself. Schism, in Constantine's view, was "insane, futile madness," inspired by the Devil, the author of evil. Its partisans were acting in defiance of the clemency of Christ, for which they might expect eternal damnation at the Last Judgment (this was a Judgment whose rigours Constantine equally anticipated for himself). Meanwhile, it was for the righteous members of the Christian community to show patience and long-suffering. In so doing they would be imitating Christ, and their patience would be rewarded in lieu of martyrdom—for actual martyrdom was, as Constantine observed, no longer open to Christians in a time of peace for the church. Throughout, Constantine had no doubt whatever that to remove error and propagate the true religion was both his personal duty and a proper use of the imperial position.

Such pronouncements, expressed in letters to imperial officials and to Christian clergy, make untenable the view that Constantine's religious attitudes were even in these early years either veiled, confused, or compromised. Openly expressed, his attitudes show a clear commitment.

Constantine's second involvement in an ecclesiastical issue followed the defeat of Licinius as promptly as the involvement in Donatism followed that of Maxentius; but the Arian heresy, with its intricate explorations, couched in difficult Greek, of the precise nature of the Trinity, was as remote from Constantine's educational background as it was from his impatient, urgent temperament. The Council of Nicaea, which opened in May 325 with an address by the Emperor, had already been preceded by a letter to the chief protagonist, Arius of Alexandria, in which Constantine stated his opinion that the dispute was fostered only by excessive leisure and academic contention, that the point at issue was trivial and could be resolved without difficulty. His optimism was not justified: neither this letter nor, despite its subsequent authority, the Council of Nicaea itself, nor the second letter, in which Constantine urged acceptance of its conclusions, was adequate to solve a dispute in which the participants were as intransigent as the theological issues were subtle. Indeed, for 40 years after the death of Constantine, Arianism was actually the official orthodoxy of the Eastern Empire.

The Council of Nicaea coincided almost exactly with the celebrations of the 20th anniversary of the reign of Constantine, at which, returning the compliment paid by the Emperor's attendance at their council, the bishops were honoured participants. But Constantine's visit to the West in 326, to repeat the celebrations at Rome, brought the greatest political crisis of the reign. During his absence from the East, for reasons that remain obscure, Constantine had his eldest son, the deputy emperor Crispus, and his own wife Fausta, Crispus' stepmother, slain. Nor was the visit to Rome a success. Constantine's refusal to take part in a pagan procession offended the Romans; and when he left after a short visit, it was never to return.

These events set the course of the last phase of the reign of Constantine. Already after his defeat of Licinius he had renamed Byzantium as Constantinople: immediately upon his return from the West he began to rebuild the city on a greatly enlarged pattern, as his permanent capital and the "second Rome." The dedication of Constantinople, in May 330, effectively confirmed the divorce, which had been in the making for over a century, between the emperors and Rome, the traditional capital of the empire. Rome had for long been unsuited to the strategic needs of the empire: it was now to be left in splendid isolation, as an enormously wealthy and prestigious city—still, as time would show, the emotional focus of the empire, but of limited political importance.

stantinople

It was perhaps in some sense to atone for the family catastrophe of 326 that Constantine's mother, Helena, embarked soon afterward on a pilgrimage to the Holy Land. Her journey was attended by almsgiving and pious works; above all, it was distinguished by her church foundations, on the Mount of Olives at Jerusalem and at the Cave of the Nativity at Bethlehem. By the initiative of another lady of the imperial house, Constantine's mother-in-law Eutropia, a church was also built at Mamre, where, according to an interpretation of Genesis shared by Constantine and Eusebius, Christ had first shown himself to men in God's appearance to Abraham; but the most famous of these foundations followed the sensational discovery of the Holy Sepulchre at Jerusalem. The discovery was taken up with enthusiasm by Constantine. In a letter to Macarius, bishop of Jerusalem, the Emperor instigated the building of a great new basilica at the spot, offering unlimited help with labour and materials and personal suggestions as to design and decoration.

Constantine's interest in church building was expressed also at Constantinople, particularly in churches of the Holy Wisdom (the original Hagia Sophia) and of the Apostles. At Rome, the great church of St. Peter was begun in the later 320s and lavishly endowed by Constantine with plate and property. Meanwhile, churches at Trier, Aquileia, Cirta in Numidia, Nicomedia, Antioch, Gaza, Alexandria, and elsewhere owed their development, directly or indirectly, to Constantine's interest.

The Emperor was always an earnest student of his religion and spent hours discussing it with bishops. Even before the defeat of Licinius he had summoned to Trier the aged theologian and polemicist Lactantius, to be the tutor of Crispus. In later years, he wrote to Eusebius to commission new copies of the Bible for the use of the growing congregations at Constantinople. He composed a special prayer for his troops and went on campaign equipped with a mobile chapel in a tent. He issued numerous laws relating to Christian practice and susceptibilities: for instance, abolishing the penalty of crucifixion and the practice of branding certain criminals, "so as not to disfigure the human face, which is formed in the image of divine beauty"; enjoining the observance of Sunday and saints' days; extending privileges to the clergy while suppressing at least some of the more offensive pagan practices.

Constantine had hoped to be baptized in the River Jordan, but perhaps because of the lack of opportunity to do so—together no doubt with the reflection that his office necessarily involved responsibility for actions hardly compatible with the baptized state—delayed the ceremony until the end of his life. It was while preparing for a campaign against Persia that he fell ill at Helenopolis. When treatment failed, he made to return to Constantinople but was forced to take to his bed near Nicomedia. There, Constantine received baptism, putting off the imperial purple for the white robes of a neophyte; and he died on May 22, 337. He was buried at Constantinople in his Church of the Apostles, whose memorials, six on each side, flanked his tomb. Yet this was less an expression of religious megalomania than of Constantine's literal conviction that he was, in a quite precise sense, the successor of the evangelists, having devoted his life and office to the spreading of Christianity.

Assessment. The reign of Constantine must be interpreted against the background of his clear and unambiguous personal commitment to Christianity. This is not to say that his public actions and policies were entirely without ambiguity. Roman opinion expected of its emperors not innovation or revolution but the preservation of traditional ways; Roman media of propaganda and political communication were conditioned, by statement, allusion, and symbol, to express these expectations. It is significant, for instance, not that the pagan gods and their legends survived for a few years on Constantine's coinage but that they disappeared so quickly: the last of them, the relatively inoffensive "Unconquered Sun" had been eliminated within little over a decade after the defeat of Maximian.

Some of the ambiguities in Constantine's public policies were therefore exacted by the respect due to established practice and by the difficulties of expressing, as well as of making, total changes suddenly. The suppression of paganism, by law and by the sporadic destruction of pagan shrines, is balanced by particular acts of deference, such as the permission given in 326 to a pagan Athenian to use the imperial transport service to visit the Valley of the Tombs of the Kings in Egypt (a traditional centre of pagan "pilgrimage"). A town in Asia Minor mentioned the unanimous Christianity of its inhabitants in support of a petition to the Emperor; while, on the other hand, one in Italy was allowed to hold a local festival incorporating gladiatorial games and to found a shrine of the imperial dynasty—although direct religious observance there was firmly forbidden. In an early law of Constantine, priests and public soothsayers of Rome were prohibited entry to private houses; but another law, of 320 or 321, calls for their recital of prayer, "in the manner of ancient observance," if the imperial palace or any other public building were struck by lightning. Traditional country magic was tolerated by Constantine as salutary in object and inoffensive in practice. Classical culture and education, which were intimately linked with paganism, continued to enjoy enormous prestige and influence; provincial priesthoods, which were as intimately linked with civic life, long survived the reign of Constantine. Constantinople itself was predominantly a Christian city, its dedication celebrated by Christian services; yet its foundation was also attended by a famous pagan seer, Sopatros, who seems to have been requested to devise rites for the dedication of the new city.

An objective assessment of Constantine's secular achievements is not easy—partly because of the predominantly religious significance with which the Emperor himself invested his reign, partly because the restlessly innovatory character that dissenting contemporaries saw in his religious policy was also applied by them to the interpretation of his secular achievement. Some of Constantine's contributions can, in fact, be argued to have been already implicit in the trends of the last half century. So may be judged the further development, taking place in his reign, of the administrative court hierarchy and an increasing reliance upon a mobile field army, to what was considered the detriment of frontier garrisons. The establishment by Constantine of a new gold coin, the *solidus*, which was to survive for centuries as the basic unit of Byzantine currency could hardly have been achieved without the work of his predecessors in restoring political and military stability after the anarchy of the 3rd century. Perhaps more directly linked with Constantine's own political and dynastic policies was the emergence of regional praetorian prefectures with supreme authority over civil financial administration but with no direct control over military affairs: this they yielded to new *magistri*, or "masters," of the cavalry and infantry forces. The reduction of the prefects' powers was seen by some as excessively innovatory; but the principle of the division of military and civil power had already been established by Diocletian. A real innovation, from which Constantine could expect little popularity, was his institution of a new tax, the *collatio lustralis*. It was levied every five years upon trade and business and seems to have become genuinely oppressive.

A lavish spender, Constantine was notoriously open-handed to his supporters and was accused of promoting beyond their deserts men of inferior social status. Yet he was not the first emperor to incur this criticism. More to the point is the accusation that his generosity was only made possible by his looting of the treasures of the pagan temples as well as by his confiscations and new taxes; and there is no doubt that some of his more prominent supporters owed their success, at least partly, to their timely adoption of the Emperor's religion.

The foundation of Constantinople, an act of crucial long-term importance, was very much Constantine's personal achievement. Yet it, too, had been foreshadowed; Diocletian had already enhanced Nicomedia to an extent that was considered to challenge Rome. The city itself

Secular  
achievements

Final years

exemplified the "religious rapacity" of the Emperor, being filled with the artistic spoils of the Greek temples; while some of its public buildings and some of the mansions erected for Constantine's supporters soon showed signs of their hasty construction. Its Senate, too, created to match that of Rome, for long lacked the aristocratic pedigree and prestige of its counterpart.

In military policy, Constantine enjoyed unbroken success, with triumphs over the Franks, Sarmatians, and Goths to add to his victories in the civil wars; the latter, in particular, show a bold and imaginative mastery of strategy. Constantine was totally ruthless toward his political enemies, while his legislation, apart from its particular concessions to Christian sentiment, is mainly notable for a brutality that becomes only too characteristic of late Roman enforcement of law. Politically, Constantine's main contribution was perhaps that, in leaving the empire to his three sons, he re-established a dynastic succession; but it was secured only by a sequence of political murders immediately after his death.

Above all, Constantine's achievement was perhaps greatest in social and cultural history. It was the development, after his example, of a Christianized imperial governing class that, together with his dynastic success, most firmly entrenched the privileged position of Christianity; and it was this movement of fashion, rather than the enforcement of any program of legislation, which was the basis of the Christianization of the Roman Empire. Emerging from it in the course of the 4th century were two developments that contributed fundamentally to the nature of Byzantine and Western medieval culture: the growth of a specifically Christian, biblical culture that took its place beside the traditional Classical culture of the upper classes; and the extension of new forms of religious patronage, as initiated by Constantine, between the secular governing classes and bishops, Christian intellectuals and holy men. Constantine left much for his successors to do; but it was his personal choice made in 312 that determined the emergence of the Roman Empire as a Christian state. It is not hard to see why Eusebius regarded his reign as the fulfillment of divine providence—nor to concede the force of Constantine's assessment of his own role as that of the thirteenth Apostle. Constantine would not have objected to being told that he had changed the course of history.

**BIBLIOGRAPHY.** Two accounts remain classic: chapters 14–18 of EDWARD GIBBON, *The History of the Decline and Fall of the Roman Empire*, 6 vol. (1776–88); and JACOB BURCKHARDT, *Die Zeit Constantins der Grossen*, 2nd ed. (1880; Eng. trans., *The Age of Constantine the Great*, 1949). A.H.M. JONES, *The Later Roman Empire, 284–602*, 3 vol. (1964), should also be consulted. N.H. BAYNES, *Constantine the Great and the Christian Church* (1931; 2nd ed., with a preface by HENRY CHADWICK, 1972), has fundamentally influenced modern work by its emphasis on Constantine's own writings, of the genuineness of which there is now no question. See also A.H.M. JONES, *Constantine and the Conversion of Europe* (1948, reprinted 1972); ANDRAS ALFOLDI, *The Conversion of Constantine and Pagan Rome* (1948, reprinted 1969); and RAMSAY MACMULLEN, *Constantine* (1969). On Constantine's church building, RICHARD KRAUTHHEIMER, *Early Christian and Byzantine Architecture* (1965), is reliable.

**Sources:** For Constantine's letters, see especially EUSEBIUS, *Ecclesiastical History*, Book X, and his *On the Life of Constantine* (both trans. in *A Select Library of Nicene and Post-Nicene Fathers of the Christian Church*, 2nd Series, vol. 1, 1961); OPTATUS, *Appendix* (ed. by C. ZIWSA, *Corpus Scriptorum Ecclesiasticorum Latinorum*, vol. 26, 1893; not translated); also LACTANTIUS, *De Mortibus Persecutorum* (trans. in *Fathers of the Church*, vol. 54, 1965). The ancient secular accounts are exiguous; the fullest, though tendentiously hostile, is ZOSIMUS, *Historia nova*, trans. by J.J. BUCHANAN and H.T. DAVIS (1967). The bulk of Constantine's surviving legislation is in the *Theodosian Code*, trans. by CLYDE PHARR (1952).

(J.F.Ma.)

## Constantine VII Porphyrogenitus

Neither a great ruler nor an imaginative writer, but an unusually erudite, industrious, and well-meaning man, Emperor Constantine VII is regarded not only as one of

the best sources of factual information on the Byzantine Empire and its neighbours but also as a typical exponent of the Byzantine upper class mentality, its ideals, and its foibles. His fame rests mainly on the books he wrote (no doubt with the assistance of a large secretarial staff) and on those he ordered to be written. For the spectacular recovery of the empire in his time from its previous weakness he is generally given no credit, on the ground that he was immersed in his studies while others took care of war and administration—a not altogether unwarranted judgment but one that should probably be qualified.

Constantine VII, coin. In the British Museum  
By courtesy of the trustees of the British Museum

Constantine's surname, Porphyrogenitus (that is, born in the Purple Chamber of the Imperial Palace in Constantinople, as befitted legitimate children of reigning emperors), pointedly answers the doubts expressed about the legitimacy of his birth in 905, which slowed down his career and contributed to his shyness. His mother was Zoe Carbonopsina, the mistress of his father, Leo VI, who married her shortly after, against the bitter opposition of the patriarch Nicholas Mysticus. It was Leo's fourth marriage, and the Greek Church normally forbade a widower to remarry more than once. As the infant was Leo's only male offspring, he had to be accepted and, in 911, was proclaimed co-emperor. But, on the death of his father, in 912, the succession fell to his uncle Alexander, whose death the next year cleared the way for seven-year-old Constantine. The Patriarch Nicholas, who became regent, found it expedient to appease the powerful tsar Symeon of Bulgaria—who had severely defeated the Byzantine armies and coveted the Byzantine imperial crown—by promising that the child emperor would marry Symeon's daughter. A palace revolt foiled the scheme, which looked like a betrayal of Byzantium to the Bulgarians. It was only after several years that a combination of diplomacy and successful defense of Constantinople succeeded in inducing Symeon to settle for recognition as emperor of the Bulgarians only. The strategist of this success, Adm. Romanus Lecapenus, rewarded himself by having Constantine marry his daughter (919) and crown him co-emperor (920). Gradually Constantine was made to play second fiddle not only to Lecapenus but to his sons as well.

It is not surprising that the young emperor slipped into a pattern of noninvolvement in government. His mother had been relegated to a convent. His father-in-law relieved him of the burdensome tasks of politics and war and shouldered them masterfully but treated him with deference and left him a full share of the prestige and income belonging to the crown. From his father, Constantine had apparently inherited a passion for learning and writing; he worked full-time at it until he was almost 40, when he became sole emperor. Nor did he change tastes thereafter. *De thematibus*, probably his earliest book, is mainly a compilation of older sources on the origins and development of the provinces of the empire. An apologetic biography of his grandfather Basil I, which he appended to an anonymous chronicle known as *Theophanes Continuatus*, stressed the glory of the founder of his dynasty. *De administrando imperio*, a handbook of foreign

**Non-  
involve-  
ment in  
govern-  
ment**

politics, is perhaps his most valuable work, a storehouse of information on Slavic and Turkic peoples about whom little else is known except through archaeology.

Yet, the longest book and the one that tells the most about the Byzantine mentality (and most particularly the mind of the writer) is *De ceremoniis aulae Byzantinae*, basically a minute description of the elaborate ceremonial and processions that made the emperor a hieratic symbol of the state and strove to impress foreigners with his grandeur. There is no doubt that it helped Byzantium in its relations with the northern "barbarians" and even with western Europe. A monument to Byzantine patriotism, the book bears traces of the spoken vernacular that crept into the stilted Greek of more academic writers. The more voluminous, encyclopaedic works compiled under Constantine's directions are not worth describing, but he exhibited notable zeal in recruiting teachers and students for the "university" of Constantinople, inviting them to court and preferring them for public offices. He signed pieces of legislation and is said to have dabbled in various fine and mechanical arts.

Late in 944 the sons of Romanus Lecapenus, impatient to succeed their father, had him deposed; but the populace of the capital, fearing only that the Porphyrogenitus emperor might be included in the purge accompanying the seizure of power, rioted until Constantine appeared at a window of the palace. This show of loyalty emboldened him to banish Romanus' sons January 945; he then ruled alone until his death in 959. He appointed to the highest army commands four members of the Phocas family, which had been in disgrace under Romanus Lecapenus, but took no further reprisals, except for an incidental remark, in *De ceremoniis*, that Romanus Lecapenus was neither an aristocrat nor a cultured man. That he did not depart from the Admiral's basic policy—at home, maintaining a delicate balance among civil and military officers, landed aristocrats, and peasant soldiers; abroad, friendship with the Russians, peace with the Bulgarians, a limited commitment in Italy, and a resolute offensive against the Muslims—may be ascribed to statesmanship as well as to timidity. The policy continued to be effective. Constantine's gently personal touch is apparent in his warm relations with his wife and children, his love for court ceremonial and spectacles, and his disarming kindness.

**BIBLIOGRAPHY.** The only book-size biography, A.N. RAMBAUD, *L'Empire grec au dixième siècle: Constantin Porphyrogénète* (1870), is partly outdated, but the essential elements may be found in ch. 4 of GEORGE OSTROGORSKY, *Geschichte des byzantinischen Staates* (1965; Eng. trans., *History of the Byzantine State*, 2nd ed., 1968); and, still better, in *Cambridge Medieval History*, 2nd ed., vol. 4 (1966), ch. 4 by HENRI GREGOIRE. The latter two contain exhaustive bibliographic data on Constantine's life and works.

(R.S.L.)

## Constants, Physical

Throughout all of the formulations of the basic theories of physics and their application to the real world, there appear again and again certain fundamental invariant quantities. These quantities, all of which are associated with specific and universally used symbols, called the fundamental physical constants, are of such importance that they must be known to as high an accuracy as is possible. They include the velocity of light in vacuum ( $c$ ); the charge on the electron ( $e$ ), which is the fundamental unit of electric charge; the mass of the electron ( $m_e$ ); Planck's constant ( $h$ ); and the fine-structure constant, symbolized by the Greek letter alpha ( $\alpha$ ). These will all be considered in detail below.

There are, of course, many other important quantities that can be measured with high accuracy—the density of a particular piece of silver, for example, or the lattice spacing (the distance between the planes of atoms) of a particular crystal of silicon, or the distance from the Earth to the Sun. These quantities, however, are generally not considered to be fundamental constants. First, they are not universal invariants because they are too specific, too closely associated with the particular proper-

ties of the material or system upon which the measurements are carried out. Second, such quantities lack universality because they do not consistently appear in the basic theoretical equations of physics upon which the entire science rests, nor are they properties of the fundamental particles of physics of which all matter is constituted.

It is important to know the numerical values of the fundamental constants with high accuracy for at least two reasons. First, the quantitative predictions of the basic theories of physics depend on the numerical values of the constants that appear in the theories. An accurate knowledge of their values is therefore essential if man hopes to achieve an accurate quantitative description of the physical universe. Second, and more important, the careful study of the numerical values of these constants, as determined from various experiments in the different fields of physics, can in turn test the overall consistency and correctness of the basic theories of physics themselves.

### DEFINITION, IMPORTANCE, AND ACCURACY

The constants named above, five among many, were listed because they exemplify the different origins of fundamental constants. The velocity of light ( $c$ ) and Planck's constant ( $h$ ) are examples of quantities that occur naturally in the mathematical formulation of certain fundamental physical theories, the former in James Clerk Maxwell's theory of electric and magnetic fields and Albert Einstein's theories of relativity, and the latter in the theory of atomic particles, or quantum theory. For example, in Einstein's theories of relativity, mass and energy are equivalent, the energy ( $E$ ) being directly proportional to the mass ( $m$ ), with the constant of proportionality being the velocity of light squared ( $c^2$ )—i.e., the famous equation  $E = mc^2$ . In this equation,  $E$  and  $m$  are variables and  $c$  is invariant, a constant of the equation. In quantum theory, the energy ( $E$ ) and frequency, symbolized by the Greek letter nu ( $\nu$ ), of a photon (a single quantum unit of electromagnetic energy such as light or heat radiation) are related by  $E = h\nu$ . Here, Planck's constant ( $h$ ) is the constant of proportionality.

The electron charge ( $e$ ) and the electron mass are examples of constants that characterize the basic, or elementary, particles that constitute matter, such as the electron, alpha particle, proton, neutron, muon, and pion. Additionally, they are examples of constants that are used as standard units of measurement. The charge and mass of atomic and elementary particles are usually expressed in terms of the electron charge ( $e$ ) and the electron mass ( $m_e$ ); the charge of an alpha particle, the nucleus of the helium atom, is given as  $2e$ ; whereas the mass of the muon is given as  $206.77 m_e$ .

The fine-structure constant ( $\alpha$ ) is an example of a fundamental constant that can be expressed as a combination of other constants. The fine-structure constant is equal to a numerical constant times the velocity of light times the electron charge squared divided by twice Planck's constant, or  $\mu_0 e^2 c^2 / 2h$ ,  $\mu_0$  being the so-called permeability of free space, numerically equal to exactly  $4\pi \times 10^{-7}$ . (The system of measurement units used in this article is the *Système Internationale d'Unités* [International System of Units], or SI.) Because this particular combination of constants always appears in theoretical equations in exactly the same way, however, the fine-structure constant is really a fundamental constant in its own right. For example, the fine-structure constant is the fundamental constant of quantum electrodynamics, the quantum theory of the interaction (mutual influence) among electrons, muons, and photons. As such it is a measure of the strength of these interactions. Another quantity that is a combination of other constants is the Rydberg constant (symbolized  $R_\infty$ ), which is equal to the product  $\mu_0^2 c^3 e^4 m_e / 8h^3$ . It sets the scale (magnitude) of the various allowed electron energy states or levels in atoms such as hydrogen.

The accuracy with which many of the fundamental constants can be currently measured is a few parts in a million. By accuracy is meant the relative size of the

Decision  
to rule  
alone

Uncertainty in measuring constants

uncertainty that must be assigned to the numerical value of any quantity to indicate how far from the true value it may be because of limitations in experiment or theory. This uncertainty is a quantitative estimate of the extent of the doubts associated with the value. The most commonly used uncertainty, the standard deviation, symbolized by the Greek letter sigma ( $\sigma$ ), is such that there is about a 68 percent chance that the true value lies within plus or minus  $\sigma$ . Furthermore, there is a 95 percent chance that the true value lies between plus and minus two standard deviations,  $2\sigma$ , and a 99.7 percent chance that it lies between plus and minus  $3\sigma$ . (All uncertainties quoted in this article will be one standard deviation.)

In practice, an accuracy or uncertainty of one part per million (abbreviated ppm) is rather respectable. It corresponds to determining the length of a United States football field (100 yards, or about 91 metres) to within the thickness of two of these pages (one page is about 0.0022 inch thick). There are several quantities that have been measured with uncertainties approaching one part in 1,000,000,000,000 (one in  $10^{12}$ ); this uncertainty corresponds to determining the distance from New York to San Francisco to within one-tenth the thickness of this page.

Table 1 displays the best values for the six fundamental constants mentioned above and gives their uncertainties (in ppm) as accepted in the early 1970s. Here,  $1/\alpha$ , the inverse of the fine-structure constant, is given rather than  $\alpha$  because it is a simpler number. The fine-structure constant is dimensionless; *i.e.*, it is a pure number and, therefore, has no units.

Table 1: Values of Some Selected Fundamental Constants				
	symbol	units	value*	uncertainty (ppm)†
Velocity of light in vacuum	c	10 <sup>8</sup> metres per second	2.9979250(10)	0.33
Electron charge	e	10 <sup>-19</sup> coulomb	1.6021917(70)	4.4
Planck's constant	h	10 <sup>-34</sup> joule-second	6.626196(50)	7.6
Electron rest mass	$m_e$	10 <sup>-31</sup> kilogram	9.109558(54)	6.0
Inverse fine-structure constant	$1/\alpha$	—	137.03602(21)	1.5
Rydberg constant	$R_\infty$	10 <sup>7</sup> per metre	1.09737312(11)	0.10

\*The numbers in parentheses are the standard-deviation uncertainties in the last digits of the quoted values. †Parts per million.

HISTORICAL MEASUREMENTS

One of the earlier experiments to measure a fundamental constant to high accuracy, as well as an example of how the accurate determination of a fundamental constant using different methods can lead to an improved understanding of a particular physical phenomenon, was the measurement of the fundamental unit of charge ( $e$ ) by Robert A. Millikan, a physicist in the United States. From about 1907 to 1917 he carried out his now-famous oil-drop experiment to determine  $e$ . In this method, the displacement of small, charged oil drops (the charge on the drop is usually just a few  $e$ ) moving in air between two horizontal and parallel metal plates (with and without an applied known voltage) is followed as a function of time. The value of the fundamental constant  $e$  is then calculated from many observations on different drops and knowledge of other relevant quantities, especially the viscosity (resistance to flow) of the air. Millikan's final value, reported in 1917, was:  $(4.774 \pm 0.002) \times 10^{-30}$  esu (esu being the electrostatic unit, one of the units of charge in the centimetre-gram-second [cgs] system of units; this cgs-esu system was in wide use before the general adoption of the SI system).

That this value was significantly in error became clear in the 1930s with the development of a new but indirect method for obtaining the value of  $e$ . The technique consisted of separately measuring  $N$ , the Avogadro constant (the number of atoms or molecules contained in a mole, which is defined as a mass in grams equal to the atomic or molecular weight of a substance), and  $F$ , the Faraday constant (the amount of charge that must pass through a

solution to electrolytically deposit a mole of a singly charged, or monovalent, element contained in the solution). These two quantities are related by the simple equation that states that the Faraday constant is equal to the Avogadro constant times unit of charge, or  $F = Ne$ . It therefore follows that  $e = F/N$ ; so that the constant  $e$  can readily be obtained if the two constants, Faraday and Avogadro, are known.

The Avogadro constant ( $N$ ) was determined by measuring the density, molecular weight, and crystal lattice spacing of a particular crystal species such as rock salt, using X-ray techniques. The Faraday ( $F$ ) was determined by measuring the mass of material (*e.g.*, silver) electrolytically deposited onto an electrode when a known current flowing for a known time was allowed to pass through a solution containing the material. The indirect value of the electron charge ( $e$ ) deduced in this way was  $(4.8021 \pm 0.0009) \times 10^{-10}$  esu, significantly different from the Millikan value. The major source of this disturbing discrepancy was traced in the latter part of the 1930s to the use by Millikan of an incorrect value for the viscosity of air. Millikan had taken a value that was almost entirely based on a measurement by one of his students; but it was later shown that the student had made a rather subtle experimental error. When Millikan's data were re-evaluated with a correctly determined value for the viscosity of air, the value of  $e$  obtained agreed with the indirect value calculated from the Faraday and the Avogadro constant.

Although this case is an example of the general fact that the experimentally determined value of a constant varies with each determination, it must be realized that it is just these variations from determination to determination in the measured numerical values of the constants that often furnish important clues to errors in experiment and theory.

The fundamental-constants field has advanced so rapidly since mid-20th century that nearly all of the measurements carried out before World War II may be considered historical (if not the method, at least the result). Indeed, few measurements of constants existed before about the turn of the 20th century, because not until then did the modern era of physics begin. Relativity, atomic physics, and quantum theory all emerged after 1900. Some of the more important historical measurements made before 1940, in addition to Millikan's oil-drop measurement of  $e$ , the early iodine and silver measurements of the Faraday made about 1910 to 1915, and the early determinations of the Avogadro constant in the 1930s by physicists in the United States, Joyce A. Bearden and others using X-ray techniques, include:

**Velocity of light in vacuum (c).** To determine a velocity requires knowledge of both a distance and a time. Attempts to achieve measurements of the speed of light ( $c$ ) date back to the 16th- and 17th-century Italian scientist Galileo Galilei, who supposedly tried unsuccessfully to determine  $c$  by having two men stand at a known distance from each other and alternately cover and uncover their hand-held lanterns as soon as they saw the light from the other man's lamp, thus seeking to determine the elapsed time for light to travel the known distance between the two men. A 17th-century Danish astronomer, Ole Rømer, calculated a value of  $c$  from the dependence of the period of revolution of a moon of Jupiter on the Earth's orbital position about the Sun. Similarly, in 1726, an English astronomer, James Bradley, determined  $c$  from the apparent change in position of a number of stars in the sky as the Earth moved about the Sun.

The problem of overcoming the short time interval associated with light travelling a readily measured distance on the Earth's surface was first solved by a French physicist, Armand-Hippolyte-Louis Fizeau, in the mid-19th century. He did this by having the light pass through a gap between the teeth of a toothed wheel rotating at a known rate, reflect off a fixed mirror a known distance away, and return to the wheel. A related method utilizing a rotating mirror was also employed by another French physicist, Jean Foucault, in 1862.

Millikan's oil-drop experiments

Michelson's determinations of  $c$

The classic pre-World War II measurements of the constant  $c$  are associated with Albert A. Michelson, a physicist in the United States. From 1924 to 1926, Michelson measured  $c$  by reflecting light between a rotating mirror with a number of faces and a fixed mirror some 35 kilometres (22 miles) away. A second measurement using essentially the same method but in a 1.6-kilometre (one-mile) evacuated tube was carried out by Michelson and his associates over the period 1931 to 1935.

**Ratio of the electron charge ( $e$ ) to the electron mass ( $m_e$ ),  $e/m_e$ .** Numerous direct measurements of this quantity were carried out over the period 1897 to 1938. The experiments usually involved the deflection of beams of free electrons by electric and magnetic fields. Many of the experiments required the measurement of the velocity of the electrons combined with a simultaneous determination of the voltage used to initially impart kinetic energy (*i.e.*, velocity) to the electrons. Often the electron velocity was determined by a null deflection method in which the magnitudes of crossed electric and magnetic fields, through which the electron beam travelled, were so adjusted that the electric and magnetic deflecting forces just balanced each other. An English physicist, Joseph John Thomson, was the first to use this technique in 1897.

**Ratio of Planck's constant ( $h$ ) to the electron charge ( $e$ ),  $h/e$ .** The very first precision determination of the ratio  $h/e$  used the photoelectric effect: when light of a particular wavelength is allowed to impinge upon a metal surface, electrons are emitted from the surface. If a retarding voltage, or potential, is applied to the metal so that the electrons are just prevented from leaving the surface, then a unique relationship can be shown to exist between the wavelength of the light, the voltage, and the ratio  $h/e$ . Millikan, using sodium and lithium, first reported a result from this method in 1916.

A second method to determine the  $h/e$  ratio is the so-called short wavelength limit of the continuous X-ray spectrum. In this technique, a beam of electrons is accelerated through a known voltage and is allowed to strike a metal target. The maximum-energy X-ray (that is, the one having the highest frequency or shortest wavelength) is emitted when all of the electrical potential energy of an electron in the beam is converted to a single X-ray photon. By measuring the voltage and the wavelength of the emitted X-ray, the ratio  $h/e$  can be determined. The first precision measurement of this type was reported in 1921.

**The Newtonian gravitational constant ( $G$ ).** The universal, or Newtonian (after Isaac Newton), gravitational constant ( $G$ ) is the constant of proportionality in the equation relating the gravitational force between two separated bodies to their respective masses. There have been two different classes of experiment to measure the constant  $G$ . The first involves estimating the mass of the Earth and separately determining the radius of the Earth and the acceleration of an object falling toward the Earth because of gravity at its surface. Attempts to measure the mass of the Earth have been of two kinds. In 1775, a British astronomer, Nevil Maskelyne, used the deflection of a plumb line from the vertical when placed on either side of a mountain of known shape and density. In 1854 another astronomer, George Biddell Airy, of England, measured the gravitational constant by comparing the period of a pendulum's swing at the Earth's surface and at the bottom of a mine shaft of known depth.

The second general class of experiment for determining the gravitational constant, a significantly more accurate one, consists of measuring the gravitational force attracting two masses in the laboratory. In 1798 Henry Cavendish of England using a torsion balance designed a few years earlier, carried out the first such experiment. He suspended by a thin fibre a light, stiff rod with two solid five-centimetre (two-inch) diameter lead spheres attached at either end. He then brought two 30-centimetre diameter (12-inch) lead spheres near the smaller spheres. The gravitational attraction between them pro-

duced a torque, or turning force, that twisted or deflected the suspension fibre. The most accurate value of the gravitational constant currently available was obtained using the same general method during the period 1932–42.

#### MODERN MEASUREMENTS

The great progress made in determining the numerical values of the fundamental constants after World War II is the direct result of the advances made in the general fields of electronics, microwaves, and other technologies during the war. These advances have not only resulted in new and improved measurements of some of the constants listed earlier (for example, a 1957 velocity of light determination using a microwave interferometer) but for the first time permitted the direct measurement of a whole new group of constants and related quantities. The more important of these new measurements are as follows, the first two of which are concerned with the proton, an atomic particle having a mass approximately 1,836 times that of an electron and a charge identical to the electron charge, only positive:

**Gyromagnetic ratio of the proton.** This quantity, symbolized by the Greek letter gamma followed by a subscript  $p$ ,  $\gamma_p$ , is a measure of how fast the axis of the proton's intrinsic rotational motion, or spin, precesses (swings) in a magnetic field much as does a child's top. It may be determined by first establishing a known magnetic field that has been produced by the passage of a known electric current through a precision coil, or solenoid, of known dimensions and then measuring by means of standard electronic techniques the precession frequency of the protons in a water sample within the solenoid. This procedure is the low-field method, in which the accurately determined magnetic field is only about 20 times the Earth's magnetic field. In the high-field method, the magnetic field, established by an electromagnet, may be 10,000 times larger. For this case, the field is determined by measuring the force it exerts on a small coil of known dimensions carrying a known current; this apparatus is often called a Cotton balance. The gyromagnetic ratio of the proton was first determined to high accuracy by the high-field method in 1950 and by the low-field method in 1957.

**Magnetic moment of the proton.** The magnetic moment of the proton in nuclear magnetons ( $\mu_p/\mu_n$ , in which  $\mu$  is the Greek letter mu), is the ratio of the above-mentioned spin axis precession frequency of a proton in a magnetic field to the frequency of the proton's orbital, or circular, motion in the same field, called the cyclotron frequency. The first measurement of this ratio was reported in 1949 by physicists in the United States, John A. Hipple and his associates, using a small, metal, boxlike device called an omegatron. In this method, an adjustable radio-frequency electric field is applied to the omegatron at right angles to the direction of the magnetic field. When the frequency of this electric field is properly adjusted, protons in the omegatron are accelerated by it and spiral outward until they hit an internal collector and are detected. The frequency of the proton's orbital motion can then be determined from the adjusted frequency of the electric field.

**Fine structure of atomic hydrogen.** The term fine structure refers to the differences between certain states of energy or energy levels in atoms. The fine structure of atomic hydrogen was first measured with high accuracy by a United States physicist, Willis E. Lamb, Jr., and co-workers and reported in a series of classic papers over the period 1950 to 1953. In these experiments, changes in the energy state of particular atoms or, equivalently, transitions between energy levels in the atoms themselves were induced by irradiating a beam of the atoms with microwaves of a properly adjusted and known frequency as the beam was passed through a known magnetic field. The energy differences, or fine structure, could then be accurately calculated from the field and frequency.

**Free electron  $g$  factor.** Because the electron has an electric charge and an intrinsic rotational motion, or

Measuring the magnetic moment

Cavendish's measurement of the gravitational constant

spin, it behaves in some respects like a small bar magnet; that is, it is said to have a magnetic moment. Because the electron also has mass, it behaves in some respects like a spinning top; that is, it is said to have spin angular momentum. The  $g$  factor of the electron is defined as the ratio of its magnetic moment to its spin angular momentum. This factor is nominally 2 and was first measured with high accuracy during the period from 1961 to 1963. Using electric and magnetic fields, electrons were trapped with spins prealigned in a particular direction for a known length of time. The  $g$  factor was then obtained from the change in spin direction during the trapping period and the magnitude of the trapping magnetic field. Recent improvements in this basic method of measuring the  $g$  factor reduced the original 0.027 parts per million uncertainty obtained earlier to 0.003 parts per million.

**Ground state hyperfine splitting (hfs) in atomic hydrogen.** The ground state, or lowest energy state, hyperfine splitting in hydrogen is basically equal to the energy difference between a hydrogen atom in which the spin of the orbital electron is in the same direction as that of the spin of the central proton and a hydrogen atom in which the spins of the electron and proton are in opposite directions. Polykarp Kusch, a physicist working in the United States, reported the first high-accuracy measurement of this quantity in 1955, using a microwave-excitation method not too unlike that used for fine-structure measurements.

A much more accurate value was obtained in 1963 by a U.S. physicist, Norman F. Ramsey, and co-workers using the so-called hydrogen maser, which is a type of microwave amplifier. In this device, excited hydrogen atoms are focussed by a magnetic field onto an aperture in a Teflon-coated quartz bulb that is located in a radio-frequency-resonant metallic cavity. When the cavity fre-

quency is tuned to the frequency corresponding to the hyperfine-splitting-energy difference, maser-like oscillations are produced. The measurable oscillation frequency then equals the hyperfine splitting.

**NEW DETERMINATIONS AND INTERRELATIONSHIPS AMONG THE CONSTANTS**

To these important post-World War II measurements must be added the determination of the ratio of twice the electron charge to Planck's constant ( $2e/h$ ). First reported in 1967 by the United States physicists William H. Parker, Barry N. Taylor, and Donald N. Langenberg, this low-temperature physics experiment is probably the best example in recent years of the important consequences that can follow from a high-accuracy determination of a fundamental constant. Furthermore, its discussion naturally leads to the exploration of other ideas such as the interdependency of the constants, standards of measurement, conversion factors, and least squares adjustments of the constants.

The  $2e/h$  measurement in question is based on a remarkable phenomenon in superconductors (metals that lose their electrical resistance at extremely low temperatures) known as the alternating current (ac) Josephson effect. In 1962, a physicist, Brian Josephson of Cambridge University, England, showed theoretically that, if two superconductors are weakly connected together, then an alternating resistanceless current, or ac supercurrent, will flow between them if they are maintained at a finite voltage difference ( $V$ ). He also showed that the frequency, symbolized by the Greek letter nu ( $\nu$ ), of the ac supercurrent is proportional to the voltage difference, the constant of proportionality being simply  $2e/h$ . Thus,  $\nu = (2e/h)V$ . Because the Josephson frequency-voltage relation is believed to be exact and independent of a wide variety of experimental variables, the determination of the ratio  $2e/h$  is rather straightforward when compared with most other fundamental-constants experiments. It is necessary to measure only the voltage difference between the two superconductors and the frequency of the oscillating supercurrent. Indeed, the final result of these measurements of the ratio  $2e/h$  had an uncertainty of only 2.4 parts per million, some 20 times less than the best previous value that had been determined from an X-ray experiment. More recent Josephson-effect measurements of  $2e/h$  by several different workers have reduced the uncertainty to a few tenths of a part per million.

The Josephson-effect determination of the constant  $2e/h$  has had its greatest impact in the field of quantum electrodynamics (QED). QED is the quantum theory of interacting electrons, muons, and photons, and as previously noted, the fine-structure constant ( $\alpha$ ) determines the strength of these interactions. It is one of the most important of the modern theories of physics and one of the few that are capable of making highly accurate numerical predictions. Such predictions, however, are only possible if an accurate value of  $\alpha$  is available, because of the fact that the theoretical expressions derivable from QED that describe the various physical quantities of interest are generally in the form of mathematical expressions involving  $\alpha$ .

Heretofore, the most accurate values of the fine-structure constant ( $\alpha = \mu_0 c e^2 / 2h$ ) were obtained from experiment with the aid of theoretical equations containing significant contributions from quantum electrodynamics itself. This situation made it difficult to compare QED theory and experiment unambiguously. Now, however, by combining the value of  $2e/h$  obtained from the alternating current Josephson effect with the measured values of certain other constants, a highly accurate indirect value of  $\alpha$  can be obtained without any essential use of quantum electrodynamics theory. As a result, definitive comparisons can be made between QED theory and experiment.

In practice, there are several ways of obtaining an indirect value of the fine-structure constant from the value of  $2e/h$ . One method involves combining it with some accurately known constants, such as the Rydberg con-

Use of a maser to measure hyperfine splitting

Rydberg constant for infinite mass	$R_\infty$	10,973,731.2(1.1)	$\text{m}^{-1}$	0.10
*The numbers in parentheses are the uncertainties in the last digits of the quoted values. †Parts per million. Abbreviations are as follows: mgal = milligal ( $10^{-3}$ cm/sec <sup>2</sup> ); amu = atomic mass unit ( $^{12}\text{C}=12$ ); $p'$ = "for protons in a spherical sample of water."				

stant ( $R_e$ ) and the velocity of light ( $c$ ), and a value for the proton gyromagnetic ratio ( $\gamma_p$ ). Another involves combining the value of  $2e/h$  with an experimental value for the Faraday ( $F$ ), again some accurately known constants, and a value for the magnetic moment of the proton in nuclear magnetons ( $\mu_p/\mu_n$ ).

In principle, there are also other potential sources of information on the fine-structure constant that do not require the use of either quantum electrodynamic theory or the quantity  $2e/h$ . For example, a value of  $\alpha$  can be obtained from a measurement of the electron Compton wavelength, which is symbolized by the Greek letter lambda ( $\lambda_c$ ). This value is the wavelength of the radiation emitted by an electron at rest when it annihilates with a positive electron, or positron, at rest.

The implied equations in the last two paragraphs above not only illustrate the complex relationships that exist among the constants but, more importantly, the fact that a particular constant may be determined by a direct measurement or indirectly by an appropriate combination of several other directly measured constants. Indeed, the indirect value is often so much more accurate than the direct value that the latter is discarded.

This situation is true in the case of the electron charge ( $e$ ); the oil-drop determination of the electron charge has such a low accuracy compared with indirect methods that it is never used. If the direct and indirect values do in fact have comparable accuracy, then both must be taken into account in order to arrive at a best value for that quantity. (By "best value" is meant that numerical value for the quantity that is believed to be closest to the true but unknown value.) Clearly, because of the interrelationships existing among the constants and the concomitant existence of indirect values, a new determination of one constant will generally affect significantly the best values of others.

Unfortunately, the problem of determining a best value for the fine-structure constant that is independent of quantum electrodynamic theory or otherwise, as well as similar values for other fundamental constants, is made still more difficult by the existence of conversion factors relating absolute units to as-maintained units (see below for definitions).

#### STANDARDS OF MEASUREMENT, CONVERSION FACTORS, AND RELATED CONSIDERATIONS

**Conversion factors.** The measurement of any quantity must be carried out in terms of certain units. The dominant system of units currently in use throughout the world is called the *Système Internationale d'Unités*, or SI (see WEIGHTS AND MEASURES). It is based in part on the kilogram, metre, second, and ampere. In practice, everyday working standards of mass, length, and time can be constructed that are directly traceable to their fundamental SI definitions and that have an accuracy comparable with that implicit in the definition. This situation is not true, however, of the ampere; because a current is a flow of charge, it is not easy to construct a storable working current standard. Instead, standards of voltage and resistance must be separately maintained, usually by the national standards laboratories, and a standard of current must be derived by the application of Ohm's law—i.e., current equals voltage divided by resistance.

In terms of such as-maintained amperes, currents can usually be measured to an accuracy of about 0.1 parts per million. No experiment has yet been devised, however, that will allow a given current to be determined in SI units to anything like the 0.01 ppm accuracy inherent in the definition of the SI ampere; present current balances (those that measure the force between current carrying coils) can at best give a result accurate to between 5 and 10 ppm. This means that the uncertainties of the conversion factors relating the different as-maintained amperes to the defined SI ampere are 5 to 10 ppm. (This uncertainty applies to as-maintained volt to SI volt conversion factors as well, because as-maintained ohm to SI ohm conversion factors can be determined to an accuracy of a few tenths of a ppm using the calculable capacitor method.) Because many fundamental-constants experiments require the accurate measurement of a current, or a voltage, the rather large uncertainty in the current, or voltage, conversion factor is of great significance. Indeed, the conversion factor may be considered equal in importance to the associated fundamental constants, and separate experiments must be undertaken for its determination.

Another example of a conversion factor comes from the

field of X-rays. Wavelengths of X-rays and lattice spacings of crystals are most conveniently measured in terms of a standard wavelength or a standard crystal lattice spacing. To convert the measurements to metres, the SI unit of distance, requires the use of an appropriate conversion factor that must be separately determined.

Summarizing, then, the main points of the last two sections, it may be stated that:

1. The determination of  $2e/h$  using the ac Josephson effect is of great importance because it enables a value for the fine-structure constant ( $\alpha$ ) to be determined without essential use of quantum electrodynamic theory. QED theory and experiment can then be compared unequivocally.

2. There are several ways of obtaining a value of  $a$  from the value  $2e/h$ , and, in fact, information bearing on

the value of any specific constant can come from several different fundamental-constants experiments. A series of complex relationships exist among the constants, and both direct and indirect values must be taken into account when determining best values.

3. The units in terms of which constants are measured can play an important role. Conversion factors often enter the equations relating the different fundamental constants, and these conversion factors must be considered constants in their own right.

Now in general, each of the many different routes that can be followed, both direct and indirect, in order to obtain a value for a particular constant will give a slightly different answer—that is, value. A situation such as this may best be handled by a mathematical technique known as least squares.

\*The unified atomic mass scale  $^{12}\text{C} = 12$  has been used throughout; amu = atomic mass unit, C = coulomb, G = gauss, Hz = hertz = cycles per second, J = joule, K = kelvin, T = tesla ( $10^4$  G), V = volt, and W = watt. Where formulas for constants are given, the relations are written as the product of two factors. The second factor, in parentheses, is the expression to be used when all quantities are expressed in cgs units, with the electron charge in electrostatic units. The first factor, in brackets, is to be included only if all quantities are expressed in SI units. With the exception of the auxiliary constants which have been taken to be exact, the uncertainties of these constants are correlated, and therefore the general law of error propagation must be used in calculating additional quantities requiring two or more of these constants. †The numbers in parentheses are the standard deviation uncertainties in the last digits of the quoted value. computed on the basis of internal consistency. ‡Parts per million.

**Least squares adjustments of the constants.** The least squares method provides a self-consistent procedure for calculating best compromise values of the constants from all of the available measurements. For a given set of data, it automatically takes into account all the possible routes for obtaining values of each of the constants being calculated. It then determines a single final value for each constant by automatically weighting the values of the constant obtained from the various routes according to their relative reliability or uncertainty. The uncertainty for each route is determined from the uncertainties of the individual measurements comprising the original set of data. A United States physicist, Raymond T. Birge, first pioneered least squares studies of the constants in the late 1920s and continued them into the mid-1940s. Similar studies have been continued to the present by a number of physicists, including Jesse W.M. DuMond and E. Richard Cohen, and Bearden and colleagues. The latest and most comprehensive critical analysis and least squares adjustment of the constants was made by Barry N. Taylor and co-workers in 1969.

A least squares adjustment of the constants is generally carried out by first dividing the available measurements into two groups. One group, known as the auxiliary constants, contains quantities that have uncertainties sufficiently small so that they can be considered as exactly

known (see Table 2). An example is the Rydberg constant ( $R_\infty$ ), which has an uncertainty of 0.1 part per million. The other group contains the more imprecise, or stochastic, input data. An example of these is the proton gyromagnetic ratio ( $\gamma_p$ ) with its approximate 4 ppm uncertainty. Next, a subset of constants is chosen in terms of which all of the stochastic input data can be individually expressed, if necessary, with the aid of the auxiliary constants. It is actually the constants comprising this subset that are directly subject to adjustment and that are termed the adjustable constants. In the adjustment carried out by Taylor and colleagues in 1969, the adjustable constants were taken to be the fine-structure constant ( $\alpha$ ), the electron charge ( $e$ ), the conversion factor (K), equal to the ratio of the ampere as maintained by the United States National Bureau of Standards to the SI ampere, and the Avogadro constant (N). With just these four quantities and the aid of the auxiliary constants, a series of equations, known in general as observational equations, were formed for all the stochastic input data. The actual data considered for use by Taylor and his co-workers are summarized in Table 3. Table 3 summarizes the 13 pieces of stochastic input data considered for use in the least squares adjustment to obtain best values of the constants independent of quantum electrodynamic theory. *The numbers in parentheses are the standard deviation uncertainties in the last digits of the quoted value, computed on the basis of internal consistency. †Parts per million.				

are as follows: T = tesla (an mks unit of magnetic induction, weber per square metre); V = volt; A = ampere; Hz = hertz (cycles per second); and s = second. The subscript “NBS” means “in units as maintained by the U.S. National Bureau of Standards.” The different methods used for measuring the proton magnetic moment in nuclear magnetons, μ<sub>p</sub> / μ<sub>N</sub> are all similar in that radiofrequency fields are used to alter the motion of protons (or other ions) which are moving in a fixed magnetic field.

Once the actual numbers are substituted for the auxiliary constants and stochastic data, it is a rather straightforward procedure, with the aid of a computer, to solve the observational equations for the least squares adjusted values of the adjustable constants, in the case under consideration, *a*, *e*, *K*, and *N*. Although numerical values (with uncertainties) for the adjustable constants are the sole result of an adjustment, optimum values for all of the constants are actually obtained, because any constant not chosen for direct adjustment can be calculated from appropriate combinations of those subject to the adjustment—that is (for the present case), from *a*, *e*, *K*, and *N*. For example, the mass of the electron (*m<sub>e</sub>*) may be obtained from the equation *m<sub>e</sub>* = μ<sub>0</sub>R<sub>∞</sub>*e*<sup>2</sup>/α<sup>3</sup>.

One of the main problems in carrying out a least squares adjustment of the constants is making the critical analysis of the input data and deciding what uncertainty should be assigned to each measurement. Correct uncertainty assignment is of the utmost importance, because the weight any particular experiment carries in an adjustment is proportional to the reciprocal of the square of its uncertainty—if one measurement of a particular quantity has half the uncertainty of another, it carries four times as much weight. One reason for the uncertainty problem is that, in most experiments, sufficient data is taken to reduce the so-called random, or statistical, uncertainty to negligible amounts, and the final uncertainty assigned the measurement is determined from

estimates of the systematic uncertainties. Systematic uncertainties arise from effects that the experimenter knows little about; their estimation is somewhat subjective and is usually obtained from what can only be called educated guesses.

Another difficult task associated with the adjusting of constants is deciding what to do with discrepant data—that is, measurements for which the assigned uncertainty seems to be correct but that differ from each other “more than they should.” By this phrase is meant that the difference between two values of the same quantity is large compared with the standard deviation of the difference, as obtained by taking the square root of the sum of the squares or root-sum-square of the standard deviations of the individual measurements. If two measurements differ by between two and three times the standard deviation of their difference, they are inconsistent and one or the other is highly likely to be incorrect. Such data are not to be included in an adjustment uncritically because the inconsistencies imply either fallacious error estimates or the presence of unknown systematic uncertainties.

When faced with inconsistent data, the constants adjuster has two major choices: (1) to use as input data all apparently reliable measurements even though they may be inconsistent, but to expand (increase) the assigned uncertainties sufficiently so that they are compatible; and (2) to decide, on as sound an experimental and theoretical basis as is possible, which of the inconsistent data are least reliable and expurgate them, but expand no errors. Clearly these two possibilities indicate some of the arbitrariness or subjectiveness in the fundamental-constants field and the fact that different adjusters might treat the same data differently, thereby arriving at a slightly different set of best values.

Implications of the ac Josephson effect value of *a*. As intimated above, the quantum electrodynamics or QED independent adjusted value of the fine-structure constant

Discrepancy in data

Table 6: Comparison of 1963 and 1969 Adjustments

constant	symbol	units	value 1969 adjustment*	uncertainty (ppm)†	value 1963 adjustment*	uncertainty (ppm)†	change (ppm)†

\*The numbers in parentheses are the standard-deviation uncertainties in the last digits of the quoted values.  
†Parts per million.

( $\alpha$ ) resulting from the data of Table 3, and therefore from the ac Josephson effect value of  $2e/h$ , has had its greatest impact in the field of quantum electrodynamics. The adjustment result is  $1/\alpha = 137.03608$ , with an uncertainty of 1.9 parts per million (ppm). Before the ac Josephson effect measurement of  $2e/h$ , the accepted value was 137.0388, with an uncertainty of 4.4 ppm. The two values are in clear disagreement; their difference exceeds the standard deviation of their difference by more than four times. The probability for this to occur by chance is less than one in 15,000.

This previously accepted value of  $\alpha$  led during the mid-1960s to what was termed one of the major unsolved problems of quantum electrodynamics. It concerned an apparent discrepancy between the theoretically calculated and experimentally measured values for the ground state hyperfine splitting (hfs) in hydrogen. The theoretical equation for the hydrogen hfs obtained from QED involves only accurately known auxiliary constants and  $\alpha$ , but it is limited to an accuracy of a few parts per million because of the difficulty in calculating from theory some of the terms in the equation. One such term is called the proton polarizability correction, symbolized by the Greek letter delta with subscript N,  $\delta_N$ . It arises from the fact that the proton in the hydrogen atom cannot be regarded as simply a charged spinning ball. The proton has an internal structure of its own that affects the magnitude of the hyperfine splitting. To date, however, all calculations of  $\delta_N$  show it to be rather small—1 or 2 ppm at most.

The small size of the theoretical value for the correc-

tion  $\delta_N$  is in marked contrast to what is implied by the old value of the fine-structure constant. If this value is used to compare theory and experiment, then it is found that  $\delta_N = 43$  ppm with an uncertainty of 9 ppm. This means that the probability for  $\delta_N$  to be as small as predicted by theory—that is, one or two ppm—is only one in 20,000. The discrepancy and resulting challenge to quantum electrodynamics is clear. On the other hand, if one uses the value of  $\alpha$  implied by the ac Josephson effect measurement of  $2e/h$ , it is found that  $\delta_N = 2.5$  ppm with an uncertainty of 4.0 ppm, quite consistent with what is predicted theoretically. Thus, the Josephson effect value of  $\alpha$  removes the discrepancy and resulting challenge to QED. This case is, therefore, an excellent example of how fundamental-constants experiments carried out in one field of physics can have significant implications for other fields and how accurate measurements of the fundamental constants can illuminate apparent inconsistencies in the physical description of nature.

**Recommended set of fundamental constants.** To obtain a final best or recommended set of fundamental constants, Taylor and colleagues considered all of the available data, not just measurements that did not require quantum electrodynamic theory for their analysis. Such a set may be readily found by combining the most reliable QED data with the non-QED data previously used (Table 3) and carrying out a new least squares adjustment. This procedure was, in fact, followed, and some of the resulting values of this final adjustment are given in Table 4. In Table 4 the stochastic input data include items 1 through 13 (with the exception of 11 and 12) of Table 3, plus a value of the fine-structure constant derived from the theoretical expression for, and the experimental measurement of, the ground state hyperfine splitting (hfs) in atomic hydrogen. It should be noted that not all of these constants result from the least squares adjustment; for example, the auxiliary constants such as  $c$ ,  $R_\infty$ ,  $M_p$ , and  $G$ . Table 5 is a list of energy conversion factors.

In Table 6 the values for some of the more important constants are compared with the corresponding previously accepted best values resulting from the 1963 adjustment of Cohen and DuMond. It is evident from Table 6 that the values have changed by several times the uncertainties assigned the old values and that the uncertainties resulting from the 1969 adjustment are significantly less than the corresponding 1963 adjustment uncertainties. The changes serve as a good example of the intimate relationships that exist among the fundamental constants—a significant shift in the value of one constant will generally cause important shifts in the values of others.

It is also of interest to consider how knowledge of the fundamental constants has changed over the years. As a typical example, the Figure shows the variation of the accepted value of the electron mass ( $m_e$ ), resulting from several different adjustments carried out since 1950. It is clear from this graph that significant changes in the electron mass from one adjustment to another are common. This figure graphically illustrates the fact that no set of fundamental constants should be taken as final.

**Official adoption of values for the fundamental constants.** Until the 1960s, there were no national or international bodies established for the express purpose of of-

Combining  
results

Variation of the accepted value of the rest mass of the electron ( $m_e$ ). Each value resulted from a least squares adjustment of the constants in the year indicated. The actual quantity plotted is the parts per million (ppm) deviation of the different values of  $m_e$  from the 1969 adjusted value. (The deviations themselves are the numbers in parentheses.) Also given (in units of  $10^{-31}$  kilograms) are the actual values of  $m_e$  resulting from the different adjustments. The vertical bars correspond to plus and minus the assigned standard deviation uncertainty.

ficially adopting a particular set of recommended values for the fundamental constants. In the past, various international organizations adopted values for individual constants that related directly to their areas of interest. In 1961, the Advisory Committee on Fundamental Constants under the National Academy of sciences-National Academy of Engineering-National Research Council (United States) was established as a study group for the purpose of arriving at best values for the more important constants. The work of this new committee led to the 1963 set of adjusted constants of Cohen and DuMond. These were adopted officially throughout the United States, and more or less throughout the world, but not officially because the academy committee was only national in scope and membership.

About 1968, the academy committee was to a large extent supplanted by the creation of an equivalent international one, the Task Group on Fundamental Constants, under the auspices of the International Council of Scientific Unions, Committee on Data for Science and Technology (Codata). Although this committee has yet to generate or adopt a new set of constants, it is anticipated that it will do so sometimes in the 1970s.

**BIBLIOGRAPHY.** E. RICHARD COHEN, KENNETH M. CROWE and JESSE W.M. DUMOND, *The Fundamental Constants of Physics* (1957), a good historical review of the fundamental constants field from its earliest days up to about 1955; B.N. TAYLOR, W.H. PARKER, and D.N. LANGENBERG, *The Fundamental Constants and Quantum Electrodynamics* (1969), the most recent critical review and least-squares adjustment of the constants currently available; K.D. FROOME and L. ESSEN, *The Velocity of Light and Radio Waves* (1969), a detailed, historical account of the various measurements of the velocity of light carried out from the 16th to the mid-20th centuries; D.N. LANGENBERG and B.N. TAYLOR (eds.), *Proceedings of the International Conference on Precision Measurement and Fundamental Constants* (1971), includes 90 or so papers given at a conference held at the United States National Bureau of Standards that brought together theoretical, experimental, and applied scientists for the purpose of discussing modern techniques of precision physical measurement and their application; J.A. BEARDEN and J.S. THOMSEN, "A Survey of Atomic Constants," *Nuovo Cim.*, Series 10, vol. 5 suppl. (1957), a long article reviewing the status of the fundamental constants field as of about 1957.

(B.N.T.)

## Constitutional Law

Constitutional law is the body of doctrines and practices that govern the operation of the political state. All states may be said to have constitutions, whether or not they are written in documentary form. Modern constitutional law is an offspring of nationalism. As states have multiplied in number, so have constitutions and with them the body of constitutional law.

The article is divided into the following sections:

- I. Constitutions and constitutional law
  - The nature of constitutional law
  - Characteristics of constitutions
- II. Unitary and federal systems
  - The distinction between unitary and federal states
  - Quasi-federal systems
  - Unitary systems
- III. Executives and legislatures
  - The constitution and the executive
  - Unicameral and bicameral legislatures
- IV. Judicial review: the unique role of the United States judiciary
  - The Supreme Court and the separation of federal powers
  - The Supreme Court and the federal system
  - The Supreme Court and individual rights

### I. Constitutions and constitutional law

#### THE NATURE OF CONSTITUTIONAL LAW

In the broadest sense, a constitution is a body of rules governing the affairs of an organized group. A parliament, a church congregation, a social club, or a trade union may operate under the terms of a formal written document labelled constitution. This does not mean that all of the rules of the organization are in the constitution, for usually there are many other rules such as by-

laws and customs. Invariably, by definition, the rules spelled out in the constitution are considered to be basic, in the sense that all other rules must conform with its provisions. Thus the presiding officer of a club is obliged to rule that a proposal is out of order if it is contrary to a provision of its constitution. Implicit in the concept of a constitution is that of a higher law that is operative, a law that takes precedence.

Every national state has a constitution, at least in the sense that it operates its important institutions according to some fundamental body of rules. In this sense of the term, the only conceivable alternative to a constitution is a condition of anarchy. Constitutions may be written or unwritten; they may be complex or simple; they may provide for vastly different patterns of governance. Even if the only rule that matters much is the supreme authority of an absolute dictator, that may be said to be the constitution.

Constitutional law describes the whole body of interpretations that apply the constitution to the myriad institutions, functions, and problems of the state. In some countries, jurists look to judicial decisions for much of their constitutional law. But not all constitutional questions are justiciable, such as those relating to the conduct of foreign affairs by the American president, and for such matters constitutional law is developed by branches of government other than the judicial. In a larger sense, in all states, the meaning of the constitution derives from the interpretations of all who are involved in processes of government. When a legislative body adopts a statute, it may well establish or expand thereby the meaning of a constitutional provision, and acts of the executive often have the same impact. The citizen also, by his behaviour, helps to establish the content of constitutional principles. The scope of free speech often depends as much upon the limits of public tolerance as upon how judges define it in law cases. Constitutional law, therefore, embraces the whole body of doctrines and practices that derive from the constitution among all who live under it and who are subject to its provisions.

That the political community is governed by law and that its highest law is rooted in natural law concepts has been a central element of political theory and jurisprudence in the Western world since the time of the Greek city-states of antiquity. Ancient Greece recognized the existence of a higher law derived through reason from nature and regarded this law as being universal, divine, and immutable. Plato taught that human law is at best only an imperfect image of an ideal law of nature.

Aristotle (384–322 BC) recognized various kinds of constitutions. He classified them as good or perverted depending upon the ability of any particular system to achieve justice through rule in the common interest by persons chosen for their ability. Monarchy, defined as rule by a virtuous man, was characterized as best, whereas rule by a selfish man was a tyranny, the worst of the perverted systems. Second best was aristocracy, or rule by a virtuous few, and third best was a polity, or moderate democracy. Extreme democracy, described as mob rule, was regarded as the best of the perverted forms of government, and oligarchy, or rule by a selfish, wealthy minority, was considered the perverted form of aristocracy. Ancient Greek thinkers devoted a great deal of attention to the analysis of internal changes within the state, which is to say that they were deeply concerned with constitutional problems.

Aristotle did not share Plato's belief in the possibility of discovering and training philosopher-kings to rule the state. Since Aristotle did not believe it possible to find perfect men to rule, he emphasized constitutionalism and the rule of law. To him constitutionalism meant that governments must be responsible to the governed, that citizens should be involved in the process of making the laws and that they are obliged to obey, and that, however else men may be unequal, they are equal under the law.

The development of law was Rome's greatest contribution to Western civilization. While it was accepted that the emperor was the chief source of law, under his

authority scholars and jurists developed the body of Roman law, culminating in the 6th-century Justinian Code. There was a gradual development of the concept of law as legislation and of the concept of the need for popular consent to law. Political and jurisprudential writers agreed that the highest law in the community was the law of nature. Cicero held that the law of nature was the constitution of the world. In *De re publica* ("On the Republic") he declared that "true law is right reason in agreement with nature; it is of universal application, unchanging and everlasting. . . ." It is impossible to annul this law, he wrote, and people can never be absolved from the obligation to obey it. It is derived from God, and he who disobeys it denies thereby his own true nature. The best state, Cicero taught, was a mixed one that combines elements of monarchy, aristocracy, and democracy, and one that seeks to promote the common good and achieve justice.

The early church fathers taught that government is of divine origin and is both necessary and sacred. It followed that the individual has a duty to obey the law, and that there is no right of resistance; bad rule was God's way of punishing sin. The state, in cooperation with the church, keeps the peace and maintains order.

Although political obligations were regarded as contractual in the feudal system, in which obedience was traded for protection, there was a strong element of consent in the medieval concept of fundamental law. The dominant thought of the Middle Ages was that the law was the people's and applied even to the ruler.

The medieval schoolmen brought God and reason together. They believed that natural law is divine in origin and that man is a rational creature. The influential St. Thomas Aquinas divided law into four categories: (1) external law, derived from God; (2) natural law, ascertained by reason; (3) divine law, spelled out in the Bible; and (4) human law, consisting of codes and customs.

This general theme continued into the late Middle Ages. Marsilius of Padua, rector of the University of Paris, in *Defensor pacis* (1324) taught that good government rests upon popular sovereignty, that the king is elected by the people and is responsible to them, and that he is bound by the laws. Indeed, William of Ockham argued that the power of the secular ruler was based on the consent of the people and is limited by law.

The tradition that the ruler's authority is derived from the people and that a ruler who violates the law may be resisted and removed was strengthened during the 16th century in the writings of a group known as the monarchomachs, who resisted the divine-right claims of the rising national monarchs. Such was the position of the French Huguenots, one of whose spokesmen, François Hotman, wrote in *Franco-Gallia* (1573) that the king derived his power from the people, not from God, that as a matter of history, the people are sovereign and have a right, through their representatives in the *estates-general*, to remove a tyrant from office. Similarly, Theodore Beza wrote that the people have natural rights that are protected by a contract entered into between the ruler and his subjects and that, if the king violates the contract, the people have a right to resist.

So powerful was this body of doctrine that even such a stout defender of the sovereignty of the ruler as Jean Bodin pointed out in his *Six Livres de la République* (1576) that there are limitations upon the king. He must secure his office in a lawful way; he may not deprive the family of its natural right to property; he may not impose taxation without the consent of the taxed; he is subject to the law of nature; he is limited by fundamental or constitutional principles, such as that which forbids alienation of the domain or any change in the succession to the throne; and he is limited by his oaths. This marks a long stride in the direction of modern concepts.

During the period of the Puritan Commonwealth in England in the mid-17th century, considerable efforts were made to state basic principles of constitutional law in specific documentary form. Repeated attempts in the Cromwell era to create a formal written constitution foundered on the inability of those engaged in the effort

to reconcile the authority of the head of the state with the authority of the people as represented in Parliament. It was precisely in this Commonwealth period that James Harrington in his widely read *Commonwealth of Oceana* (1656) advocated the written constitution as an essential element of the ideal state. Harrington was well known in the American colonies, and contributed to the American taste for written constitutions.

Much of modern thinking about constitutionalism derives from the writings of the English common-sense philosopher John Locke (1632–1704). In his *Two Treatises of Government* (1690), he provided a classic analysis of the concept of the state that involves natural law and the social compact. He maintained that man originally lived according to the law of nature in what he described as a "state of perfect freedom" and equality. Although Locke did not believe, as Thomas Hobbes (1588–1679) had argued before him in *Leviathan* (1651), that the state of nature was intolerably bad, he did believe that it was not a very convenient condition because of the lack of "established, settled, known law"; the lack of "known and indifferent (impartial) judges"; and the absence of an executive to enforce judgments. Accordingly, by unanimous consent, men abandoned the state of nature and entered into a social compact that created a government designed to protect their natural rights. The only right surrendered in the process was the right to enforce the law. According to Locke, government rests upon consent of the governed and is bound to observe the terms of the compact that created it; if government violates its trust, men have a right to resort to revolution. This became the rational justification for the Glorious Revolution of 1688 in England, and it supplied the basic line of argument in defense of the revolution in the American colonies a century later. Thus, in the opening of the Declaration of Independence (1776) Thomas Jefferson affirmed that all men are created equal in that they are endowed by their creator with certain unalienable rights that government is instituted to secure; when government fails in accomplishing this basic purpose, the people have a right to abolish it and in its place institute a new government.

When independence from England was declared in 1776, the 13 former colonies promptly began to write constitutions spelling out the basic terms upon which the new state governments would function. In 1777, Congress prepared a written constitution for the whole country, the Articles of Confederation, which after ratification by the states was put into effect in March 1781. Since this constitution soon proved inadequate, a new constitution was drafted by a convention of delegates from the states in 1787 and became effective in 1789. This, the oldest surviving written national constitution, inaugurated a period of constitution writing that has continued to the present day. Most, though not all, national governmental entities now have written constitutions. In a broad sense, the idea of constitutionalism may be described as universal, though the content and effectiveness of the concept varies a great deal from country to country.

#### CHARACTERISTICS OF CONSTITUTIONS

Every state has a constitution, since every state functions on the basis of certain rules and principles. It has often been asserted that the United States has a written constitution but that the constitution of Great Britain is unwritten. This is true only in the sense that in the United States there is a formal document called the Constitution, whereas there is no such document in Great Britain. In fact, however, many parts of the British constitution exist in written form, whereas important aspects of the American constitution are wholly unwritten. The British constitution includes the Bill of Rights (1689), the Act of Settlement (1700–01), the Parliament Act of 1911, the successive Representation of the People acts (which extended the suffrage), the statutes dealing with the structure of the courts, the various local government acts, and many others. These are not ordinary statutes, even though they were adopted in the ordinary legislative way, and they are not codified within the structure of a single

Modern  
consti-  
tution  
making

orderly document. On the other hand, such institutions in the United States as the presidential cabinet and the system of political parties, though not even mentioned in the written constitution, are most certainly of constitutional significance. The presence or absence of a formal written document makes a difference, of course, but only one of degree. A single-document constitution has such advantages as greater precision, simplicity, and consistency. In a newly developing state such as Israel, on the other hand, the balance of advantage has been found to lie with an uncoded constitution evolving through the growth of custom and the medium of statutes. Experience suggests that some codified constitutions are much too detailed. An overlong constitution invites disputes and litigation, is rarely read or understood by the ordinary citizen, and injects too much rigidity in cases in which flexibility is often preferable. Since a very long constitution says too many things on too many subjects, it must be amended often, and this makes it still longer. The United States Constitution of **7,000** words is a model of brevity, whereas many of that country's state constitutions are much too long—the longest being that of the state of Louisiana, whose constitution now has about **255,000** words. The very new, modern constitutions of the recently admitted states of Alaska and Hawaii and of the Commonwealth of Puerto Rico have, significantly, very concise constitutions ranging from **9,000** to **15,000** words. The **1949** constitution of India, with **395** articles, is the wordiest of all national constitutions. In contrast, some of the world's new constitutions, such as those of Japan and Indonesia, are very short indeed.

Normative  
and  
nominal  
constitu-  
tions

Some constitutions are buttressed by powerful institutions such as an independent judiciary, whereas others, though committed to lofty principles, are not supported by governmental institutions endowed with the authority to defend these principles in concrete situations. Accordingly, many juristic writers distinguish between "normative" and "nominal" constitutions. A normative constitution is one that not only has the status of supreme law but is also fully activated and effective; it is habitually obeyed in the actual life of the state. A nominal constitution may express high aspirations, but it does not, in fact, reflect the political realities of the state. Article **125** of the **1936** constitution of the Soviet Union and article **87** of the **1954** constitution of the People's Republic of China both purport to guarantee freedom of speech, but in those countries even mild expressions of dissent are likely to be swiftly and sternly repressed. Where the written constitution is only nominal, behind the verbal facade will be found the real constitution containing the basic principles according to which power is exercised in actual fact. Thus in the Soviet Union the rules of the Communist Party describing its organs and functioning are more truly the constitution of that country than are the grand phrases of the **1936** Stalin constitution. Every state, in short, has a constitution, but in some a real constitution operates behind the facade of a nominal constitution.

Many juristic writers, notably Lord Bryce (1838–1922), have classified constitutions as being either "rigid" or "flexible" depending upon the methods by which they are changed. The British constitution was described as flexible because it can be amended by Parliament in the ordinary legislative way. Since the U.S. Constitution can be amended only by an extraordinary (two-thirds) majority of both houses of Congress plus ratification by three-fourths of the states, it has been characterized as a rigid constitution. This distinction may not be very significant; indeed, it may serve to obscure other more important aspects of constitutions. It is quite true that the British Parliament could, by the seemingly simple device of the enactment of a statute in the ordinary way, abolish the writ of habeas corpus or eliminate all aspects of local self-government, but on such fundamental institutions as habeas corpus and local self-government neither the Parliament nor the people of Britain are in actual fact very flexible.

In the long history of the state constitutions of the United States, one finds little, if any, correlation between

the ease of amendment and the actual number of amendments adopted. States having identical methods of constitutional change often diverge considerably in the frequency with which the amending process has been utilized. States having what seem to be simple methods of change often have a history of fewer changes than other states that have sought to make the amending process more difficult. The decisive factors seem to be the generality or detail of the constitutional document, the tempo of social and economic change in the community, the class structure, and the nature of the struggle for power, which are quite unrelated to the formal processes of constitutional amendment.

Constitutions can be amended in many different ways, and these differences may be significant. The constitutions of Great Britain, Colombia, and Israel may be amended by the national legislature acting through an ordinary parliamentary majority. In some countries, including Argentina, Cambodia, and Chile, the constitution may be amended by the national lawmaking body but only through a special parliamentary majority. Where such majorities are needed there may be additional requirements, such as joint sessions of bicameral bodies, more than one debate, or the lapse of a certain amount of time between proposal and debate. Many constitutions cannot be amended by the legislature alone but require action by other bodies as well. Thus the United States Constitution can be amended only by (1) a two-thirds majority vote in each house of Congress or (2) a convention called by two-thirds of the states—with subsequent ratification, in either case, by the legislatures or especially elected conventions of three-fourths of the states. Still other constitutions can be amended only through some sort of popular voting: an amendment to the Australian constitution must secure, after an absolute majority in parliament, a majority vote in a popular referendum; the Belgian constitution may be amended by a two-thirds vote of both houses of parliament but only after a dissolution of that body and an intervening election; the Japanese constitution requires a two-thirds vote of the parliament followed by a popular referendum; after the Danish parliament has adopted a constitutional amendment it is dissolved, an election is held, and the new parliament must then vote in favour of the same amendment before it goes into effect; the Irish constitution may be amended by a simple majority of both houses of parliament subject to approval by a popular referendum.

The **50** states of the United States, all of which have written constitutions, exemplify in their history a vast amount of experience with problems and techniques of constitutional change. Generally speaking, state constitutional amendments are initiated by the legislature, although in **14** states amendments may also be initiated by popular petition. Where amendments are proposed by the legislative bodies, the size of the required vote is a simple majority (**18** states) or a two-thirds vote (**18** states) or a three-fifths vote (**9** states). A few states have rather special provisions. In Connecticut, an amendment may be initiated by a majority vote in each house of the legislature in two sessions or a three-fourths vote in each house in one session; whereas Vermont requires a two-thirds vote in the Senate and a majority vote in the House on first passage and a majority in both houses on the second. In **13** states a constitutional amendment must be approved by two sessions of the legislature, and this is an alternative method in three other states. In all states but Delaware the amendment must be ratified by the electorate, usually by a simple majority of those voting.

Some constitutions may be characterized as indigenous, in the sense that they are rooted in the historical experiences of the states that produced them. Others are essentially imitative. Clearly the constitution of France's Fifth Republic (**1958**) is an indigenous document rooted in French political history. On the other hand, the Japanese constitution of **1947** is an imitative document imposed upon a nation defeated in war and controlled at the time by an occupying army.

Methods of  
constitu-  
tional  
amend-  
ment

Other  
differences  
among  
constitu-  
tions

The constitutions of the English-speaking countries have proved to be very stable. Many Latin American constitutions, on the other hand, have been exceedingly fragile. Among the new nations that emerged from the liquidation of the British Empire, some constitutions have proved to be quite stable while others have not. Thus the constitutions of India, Kenya, and Malaysia have functioned effectively with relatively few changes, whereas the constitutions of others, such as Pakistan, Ghana, and Nigeria, have not.

Some writers have contrasted "organizational" documents with "constitutional" documents. The organizational, such as those of Sri Lanka and Indonesia, are concerned mainly with describing the principal political institutions of the state. The constitutional documents, such as that of India, emphasize general principles, spell out the rights of the citizen, and are concerned with how these principles are to be enforced. Constitutions also differ fundamentally in how they deal with that most important institution, the political party. The constitutions of the Western liberal democracies do not mention parties at all. On the other hand, the constitutions of the Communist countries—e.g., the Soviet Union, China, Albania, Romania, and Yugoslavia—have much to say about political parties. So do the constitutions of many of the new African states, such as Tanzania and Malawi. Where the central fact of the nation's political life is the domination of a single party endowed with a monopoly of power, it is to be anticipated that the constitution will not ignore the subject.

## II. Unitary and federal systems

### THE DISTINCTION BETWEEN UNITARY AND FEDERAL STATES

States may be described as unitary or federal depending upon the distribution of powers between central and local governments. Modern states, even rather small ones such as Denmark and Costa Rica, cannot be governed altogether from a central point. Almost all modern states find it necessary to have local as well as central governments. A unitary system differs from a federal system in the way this division of powers is made. In a unitary system the central government defines and by hypothesis may re-define the powers of local government. In a federal system the powers of local government derive from a constitution that is not subject to change by the central government itself. In other words, the powers of local government in a federal system are not at the mercy of the legislative body of the central government.

This does not mean that local governments in unitary states are without power or influence. Nor does it matter what the local governments are called. The principal local governments of the United States and Australia are called states, and the systems as a whole are federal in character. The principal local governments of India and West Germany are also called states, but the systems are at best quasi-federal in character. Italy, France, and Japan have unitary systems, but no constitutional significance attaches to the fact that the principal local governments in Italy are called provinces, in France *départements*, and in Japan prefectures.

A comparison of the British and American systems of government will facilitate an explanation of the basic difference between unitary and federal systems. Since the British system is unitary, the powers of local government are defined by statutes enacted by Parliament, the legislative organ of the central government. This does not mean that local government is unimportant in Britain. On the contrary, the English counties and boroughs are significant units of government endowed with very real powers. It should be added that the unitary character of the British system does not warrant the inference that the people of the country do not have a high regard for their local institutions. It means only that as a matter of constitutional law the powers of local government are defined by acts of Parliament and that Parliament is free to expand or reduce or rearrange these powers. The system of the United States is federal because, as a matter of constitutional law, the powers of the states cannot be

altered by the national government acting alone. In the Constitution the powers of the national government are enumerated, whereas the powers of the states are not. The states have what is left over, the so-called residual powers. But there is no special significance in this pattern of power distribution. In the Canadian system, which is also federal, the powers of the provinces are enumerated and the national government possesses the residual powers. Either way, the system is federal so long as local powers do not derive from the central government.

These distinctions are to some degree formal, as can be seen from a closer examination of actual experience in the life of the United States Constitution. Although it is quite true that the distribution of powers spelled out in that Constitution and confirmed by the explicit command of the Tenth Amendment cannot be altered formally by the central government acting alone, it is equally significant that the central government is the final judge of the scope of its delegated powers. If Congress enacts a statute, and the president signs it, and the Supreme Court finds, in the course of appropriate litigation, that it is constitutional, there is nothing, as a matter of law, that the states can do about it. Article VI of the federal Constitution specifically declares that all statutes enacted by Congress shall constitute the supreme law of the land, anything in the laws of the states to the contrary notwithstanding. To be sure, the Supreme Court has on occasion ruled a federal statute unconstitutional on the ground that it invaded the reserved powers of the states, but this has not happened very often. It must be remembered that the Supreme Court, as umpire of the federal system, is a national institution in no way subject to state control; in the long sweep of American legal history the court has on the whole taken a nationalist rather than a state point of view. Nor is this development unique to the United States. In all federal systems in modern times there has been a drift in the direction of stronger and more pervasive central government, often at the expense of the powers of local government.

The best examples of federalism in the contemporary world are the governmental systems of the United States, Canada, Australia, and Switzerland. The Swiss system illustrates many important facets of the federal idea. A federation of the 22 cantons was the only feasible way of creating national unity without eliminating traditional local autonomy. The federal system also facilitated the unification of the country by permitting regional adjustment to religious and linguistic differences. In all countries where federalism has been adopted, the main thrust has been to seek an equilibrium between unity and diversity, to achieve centralized authority for the nation as a whole without sacrificing local loyalties, cultures, and institutions. The 1848 constitution of Switzerland, as extensively revised in 1874, delegates certain powers to the national government, the cantons retaining all residual powers. The powers delegated to the central government are greater than those delegated to the national government by the United States Constitution, particularly with respect to governmental monopolies, the definition of criminal and commercial law, conservation, and social welfare. Furthermore, there is no supreme court in Switzerland with the power to declare a statute of the central government unconstitutional, and federal law always prevails over any contrary cantonal law. Even so, the cantons exercise important powers with regard to the administration of law and order, health and sanitation, public works, and education. In addition, the federal laws are, for the most part, administered by the cantons; for example, the national criminal code is enforced in the cantonal courts. The federal character of the Swiss constitution is also reflected in the nature of the amending process, for all constitutional amendments must be approved by a majority vote in a national referendum, with a favourable decision in a majority of the cantons. Amendments may be initiated by a popular petition signed by 50,000 voters or by the national legislature, and it is to be noted that the cantons are represented equally in the upper house, the Council of States.

Swiss  
federalism

The British  
and  
American  
systems

QUASI-FEDERAL SYSTEMSGermany  
and India

Several governmental systems that are usually called federal are, in fact, only quasi-federal. That the Federal Republic of Germany is at best only partly federal is reflected in the magnitude of the powers vested in the central government and in the fact that if there is any conflict between the laws of that government and those of the states, or *Länder*, the laws of the national government must always prevail. The constitution gives the central government exclusive legislative powers in such areas as foreign affairs, the postal system, citizenship, railroads, and the currency, and concurrent powers with the *Länder* over many significant areas such as the definition of civil and criminal law, control of the economy, labour, agriculture, public welfare, and shipping on the high seas. The ten *Länder* are given primary responsibility over education and cultural affairs, and they administer most federal laws. The constitution may be amended by a two-thirds vote in each house of parliament, and there is a special federal constitutional court endowed with the power of judicial review. This is a federal system that leans strongly upon the national government. To a very considerable extent it is a system of centralized legislative power tempered by local administration.

The pattern of government in India is often described as federal, for it is a union of 21 states and 8 union territories; the constitution provides, in elaborate detail, for a territorial division of powers. The various subjects of legislation are grouped in three lists: a union list of 97 subjects (including defense, foreign affairs, currency, banking, communications, and customs), over which the union parliament has exclusive jurisdiction; a state list of 66 subjects (including police and public order, agriculture, education, public health, and local government), over which the state legislatures have exclusive authority; and a concurrent list of 47 subjects (including economic and social planning, labour, and price controls), over which both the central and state governments may legislate. But this division of powers is seriously qualified by the fact that the national Parliament may legislate on any subject in an emergency or if it deems a subject to have national importance. The governor of each state is appointed by the union president, and Parliament has the power to abolish the legislative council of any state and create a new one. In the light of these facts, the government of India cannot be characterized as a truly federal system. The same is true of the Soviet Union, whose constitution purports to provide for a union of various socialist republics but where power is so highly centralized as to warrant the conclusion that the system as a whole is only partly federal. The governmental systems of Argentina, Austria, Brazil, Burma, Mexico, Libya, South Africa, Venezuela, and Yugoslavia are all described in their constitutions as federal in nature, but they are doubtfully so. In some of them there is a considerable amount of local administration of national laws, and in others the central governments have devolved significant powers upon the local governments, but these are quite compatible with unitary government.

UNITARY SYSTEMSItaly,  
France,  
and  
Britain

The essential characteristics of unitary systems are suggested by an analysis of the Italian constitution of 1948. Though the Italian system of government has been unitary ever since the establishment of the modern state in 1870, this has never meant that local government in Italy is unimportant. There are 20 regions, 94 provinces, and 8,056 communes (in 1971), each having an elective council. Although each region is said to be autonomous, the central government exercises many controls; a commissioner selected by the national government represents it in the region; he must approve of regional legislation, but if he disapproves his decision may be appealed to the constitutional court or to Parliament. The regional government has no independent taxing power, all of its financial authority being spelled out in national statutes. Furthermore, the president of the republic has the power to dissolve any regional council. There is even greater

central control over the provinces and the communes. Most of the powers exercised by them are set out in national statutes, and they depend very heavily upon financial subventions from the national state. The chief representative of the national state in the provinces is a prefect, who is chosen by and is responsible to the government of the nation. He has vast powers in regard to the maintenance of law and order and may veto any act or financial decision of the provincial and communal governments. The prefect also has the authority to suspend any local official or employee and to dissolve the provincial or communal councils. Thus, although there is a great deal of important activity in Italy below the national level, the relationship between the central and local governments is, as a matter of law, one of dominance and subservience—the hallmark of the unitary pattern.

The French and British systems of government have always been unitary, even though local units in England have more power than those in France. In both countries the powers of local government are spelled out in national statutes. The same is true in New Zealand, where the local governments (counties, boroughs, and town districts) derive their authority from statutes enacted by Parliament. Although the Republic of South Africa is often described as a union of provinces, each of which has its own elected council, the system as a whole is unitary; the administrators of the provinces are appointed by the president in council, and all ordinances of the provincial councils are subject to veto by the president in council.

**III. Executives and legislatures**THE CONSTITUTION AND THE EXECUTIVE

States may be classified as monarchical or republican. From another point of view, they may be described as having presidential or parliamentary executives (see below).

Monarchical  
and  
republican  
executives

Though the institution of monarchy is as old as the recorded history of man, the modern age has been moving steadily in the direction of republican government. Depending on how they are counted, there are today about 28 or 30 monarchies. Many monarchs, as in Great Britain, Japan, the Scandinavian countries, and the Low Countries, are best described as constitutional monarchs. This means that they are mainly titular heads of state and do not in fact possess important powers of government. Most of the executive powers are in the hands of ministers, headed by a prime minister, who are politically responsible to the parliament and not to the king. The executive powers of government in Great Britain, for example, are exercised by ministers who hold their offices by virtue of the fact that they command the support of a majority in the popularly elected House of Commons. The monarch can act only on the advice of his ministers; he cannot exercise an independent will of his own. The position of the monarchs in Scandinavia and the Low Countries is precisely the same as that of the British: they reign but they do not rule. In countries where no political party has a majority of its own in the parliament, the king may exercise some discretion in deciding whom to invite to serve as prime minister and to form a government. Even so, since the king must first consult with the various party leaders, he is not likely to have much discretion. In a country with a stable two-party system, all the king can do is offer the prime ministership to the leader of the majority party. A constitutional monarch is the head of the state, not of the government. Standing above party and the active political controversies of the day, he is a focus of national loyalty and a useful symbol of the nation's unity and its historical past.

In a few monarchies, however—for example, those of Ethiopia, Jordan, Iran, and Saudi Arabia—the king exercises real powers of government. The ministers are chosen by and are responsible only to the king, rather than to some elective parliamentary body. The constitution of Ethiopia declares that "supreme power rests in

the hands of the emperor," that his person is "sacred," and that his power is "indisputable." Hereditary rulers with this sort of personal power were quite common in the 18th century, but they are rare today.

Far more significant than the distinction between monarchy and republicanism is the contrast between presidential and parliamentary executives. Since the United States has for long been the world's leading exponent of presidential government and Great Britain the oldest and most successful practitioner of parliamentary government, their systems may be taken as models with which the systems of other countries can be compared.

The American system is based upon the concept of separation of powers: the executive, legislative, and judicial powers of government are vested by the Constitution in three separate branches. The president is not selected by Congress, nor is he a member of Congress. He has a fixed term of office of four years, and he holds it no matter how his legislative program fares in Congress and whether or not his political party controls either or both houses of Congress. The members of the Cabinet are chosen by the president and are politically responsible to him. The Constitution does not permit them to be members of Congress; it provides that "no Person holding any Office under the United States, shall be a member of either House during his Continuance in Office."

The parliamentary executive system proceeds upon radically different assumptions. In Great Britain, whose system many countries have chosen to emulate, the executive officers of the state are not separated from the legislative branch. On the contrary, the British Cabinet may be described as the leading committee of Parliament. Although the prime minister, the head of the government, could at one time hold a seat in either the House of Lords or the House of Commons, the contemporary convention is that he be a member of the House of Commons. The other ministers who make up the cabinet must be members of one or the other house of Parliament. If the prime minister wants someone who is not in Parliament to serve in his Cabinet, he must either appoint him to the peerage or find a vacancy in the House of Commons to which he can be elected.

Whereas in the American system, with its separation of powers, the chief executive and his Cabinet officers are institutionally apart from the legislature, in Great Britain the ministers of the crown hold their powerful executive positions only so long as they enjoy the support of a majority of the House of Commons. A Cabinet that loses that support must either dissolve the House and call a new election, thus in effect putting the issue to the voters, or resign and permit others to form a government. In the 20th century most changes in power have occurred as a result of the outcome of a general election.

It follows that in the British Parliament the prime minister and his Cabinet colleagues are fully in charge. They are responsible, as the guiding committee of Parliament, for the preparation and enactment of most legislation and of the budget. There can be no permanent or serious conflict between the House of Commons and the Cabinet, for responsibility means that the government of the day must either prevail or give way to another government. Thus the deadlocks between the chief executive and the Congress that are a frequent occurrence in the United States cannot occur under the parliamentary system.

A system may appear to be parliamentary or presidential without actually being either. In Latin American and African states, many presidential systems have been converted into military dictatorships. The Communist governments of central and eastern Europe are parliamentary in form, but power is effectively in the hands of a party leader. The fact that the head of state is called a president does not mean that the system is presidential. The head of the Italian state, for example, is a president elected for a seven-year term by a joint session of Parliament, but the executive power is in fact exercised by a prime minister and other Cabinet ministers who are responsible to Parliament. In former monarchies that now have parliamentary systems, the abolition of monarchy

invariably led to the substitution of a president for the hereditary ruler.

There are some hybrid forms of government that combine features of both presidential and parliamentary systems. France's Fifth Republic (1958) is a good example. According to the terms of a constitutional amendment adopted in 1962, the president of the republic is elected by direct vote of the people for a seven-year term. This gives him an enormous moral power derived from the fact that he is a product of universal suffrage. Although in the exercise of some of his powers the president needs the signature of the prime minister or of some other minister, he has great substantive powers of his own: he appoints the prime minister; he dominates the management of foreign relations; he may dissolve the National Assembly, though not more often than once a year; and he possesses vast emergency powers. The cabinet, called the Council of Ministers, is presided over by the president. Members of the council cannot be members of Parliament, but they have access to both chambers; and they may speak there, though they do not vote. The council is responsible to the National Assembly and can be defeated by censure motion. Thus the French system of government is neither presidential nor parliamentary in form; it combines elements of both in a unique fashion.

The governmental system of the Federal Republic of Germany is mainly parliamentary but with some interesting variations. The head of state is the president, elected for a five-year term by a body known as the Federal Assembly, which consists of members of the lower house of Parliament (the Bundestag), plus a Bundesrat chosen by the legislatures of the *Länder*. The head of government is the Chancellor, who must have majority support in the Bundestag; but only he, and not the Cabinet, is responsible. The Bundestag can express its lack of confidence in the chancellor only by electing a successor by majority vote. In this fashion it was hoped to eliminate some of the weaknesses of the Weimar constitution of the post-World War I period. The chancellor may seek a vote of confidence, and if he fails he may ask the president to dissolve the Bundestag and call a new election.

The governmental system of India is more typically parliamentary in form. The president is elected for a five-year term by an electoral college consisting of all members of the national Parliament and of the state legislative assemblies. He can act only on the advice of ministers who are responsible to Parliament. The lower House of the People is subject to dissolution. Similarly, the president of the Republic of South Africa is elected for a seven-year term by an electoral college consisting of a joint meeting of the two houses of Parliament. The executive power is in fact exercised by the prime minister and ministerial colleagues whom he selects, and they are responsible to Parliament, both houses of which are subject to dissolution.

The Swiss executive is quite unique. The national Cabinet consists of seven persons elected for four-year terms by the parliament (the Federal Assembly). They are elected as individuals, and they are never forced to resign; in fact, they are almost always re-elected, some serving for as long as 25 to 30 years. A disagreement with the Federal Assembly leads neither to resignation of the Cabinet nor to a dissolution of the parliament; the ministers simply adjust their positions to conform with the wishes of the parliamentary majority. This does not mean that the Cabinet is not an important body; as a group it originates most new legislation, and its members, as individuals, head up the great departments of government. Each year the parliament elects a member of the cabinet to serve as president of the confederation. The president is chairman of the Cabinet and titular head of state. Although this system has not been adopted in other countries, it has worked very well for the Swiss.

#### UNICAMERAL AND BICAMERAL LEGISLATURES

A central feature of any constitution is the legislature. It may be a unicameral body with one chamber or a bicameral body with two chambers.

Bicameralism and federalism

Unicameral legislatures are to be found in small states with unitary systems of government, among them Denmark, Finland, Israel, and New Zealand, or in very tiny states such as Andorra, Luxembourg, and Liechtenstein. They are also found in states undergoing very rapid social and political change, such as the Socialist states of eastern Europe and newly freed and developing states such as Kenya and Indonesia. Federal and quasi-federal states, whether large or small, tend to have bicameral legislatures, one house of which represents the main territorial subdivisions. The classic example is the Congress of the United States, which consists of a House of Representatives of 435 members elected for two-year terms from single-member districts of approximately equal population, and a Senate consisting of two persons of each state elected by the voters of the state. The fact that all states are represented equally in the Senate, regardless of their size, stems from the federalistic character of the American union.

The federal character of the Swiss constitution is likewise reflected in the makeup of the nation's central legislature, which is bicameral. One house, the National Council, consists of 200 members apportioned among the cantons according to population; the other house, the Council of States, consists of 44 members elected by direct ballot—two from each canton. The Canadian Parliament is also bicameral, but both houses are apportioned on the basis of population.

Bicameralism is also characteristic of governmental systems that are best described as quasi-federal. Here, too, bicameralism is expressive of the territorial subdivisions that are joined together to form the national state. The parliament of the Federal Republic of Germany includes a Bundestag elected by general suffrage and a Bundesrat appointed by the ten *Under*, or state governments. Since most members of the Bundesrat are ministers in the *Land* governments, the chamber is a significant link between the *Länder* and the central government. The Parliament of India includes a Council of States and a House of the People, the former elected by the state legislative assemblies and the latter elected directly from territorial constituencies. The Parliament of the Republic of South Africa is also bicameral, but both houses are apportioned more or less on the basis of population.

Bicameralism and unitary systems

A unitary governmental system does not imply unicameralism in the legislature. Most legislatures of unitary states are, in fact, bicameral, though one chamber is usually more powerful than the other. This is true for the world's oldest and most successful parliament, that of Great Britain, which consists of a House of Lords and House of Commons. The House of Commons has become by far the more powerful of the two chambers, and the Cabinet is politically responsible only to it. The House of Lords has no control over finances and, with respect to other legislation, only a modest suspensory veto, which can be easily overcome in the House of Commons by a second vote at an early date. The parliaments of Italy, Japan, and France are also bicameral. In the United States, all of the 50 states except Nebraska have bicameral legislatures, even though their governmental systems are unitary. In all states the two houses have equal legislative authority, but the so-called upper houses, usually called senates, have the special function of confirming the governors' appointments.

#### IV. Judicial review: the unique role of the United States judiciary

The power of United States courts to rule on the constitutionality of legislation and to refuse to enforce legislation that in their judgment violates the Constitution has come to be known as judicial review. Few courts in the world have this extraordinary power. Thus a statute passed by the British Parliament may indeed violate the constitution of the realm—for example, a gross statutory invasion of free speech—but no British court has the right to refuse to enforce it on constitutional grounds. Parliament is sovereign, but in the United States the

Constitution, as construed by the courts and as the embodiment of the will of the whole people, is sovereign. Therefore, it is necessary here to offer a separate survey of the almost unique position of the U.S. Supreme Court in constitutional law.

Judicial review is not explicitly mentioned in the Constitution and is itself a product of judicial construction. Chief Justice John Marshall in *Marbury v. Madison* (1803) reasoned that since the Constitution is the supreme law of the land (it says as much in Article VI) and since it is the province of the Supreme Court to uphold the law, it follows that when a statute is inconsistent with a provision of the Constitution the latter must be preferred to the former because it declares the law of superior obligation. Without judicial review, he argued, a written constitution would be quite futile as a means of limiting the abuses of governmental power.

Although the Supreme Court possesses the ultimate power of declaring federal and state legislation invalid on constitutional grounds, it has exercised it with great restraint. Only about 85 federal statutes had by the early 1970s been so declared, though the number of state statutes held invalid was much larger. The court exercises this power only if necessary to decide cases and controversies and does not give mere advice to Congress or the executive in the form of advisory opinions. Judicial review, therefore, always grows out of concrete litigation in which the rights of adversary parties are actually involved. Furthermore, the Supreme Court imposes a number of its own restraints upon the exercise of judicial review. It always begins with the assumption that the legislative body did not intend to violate the Constitution when it adopted the challenged statute. Therefore the burden of proof rests upon the party who questions the validity of the statute. If the court can possibly decide the case without ruling on the constitutionality of the statute, it will prefer to do so; it comes to constitutional questions last, not first, and seeks to dispose of cases on minimal grounds. If a statute is susceptible of any reasonable interpretation that will save it, the court will adopt that interpretation. In cases of reasonable doubt, the constitutionality of legislation is upheld.

The court takes a strict view of the question of who is eligible to raise constitutional questions to litigation: to be able to sue in court, a party must have a direct and substantial interest at stake. Thus it was held that a mere citizen and lawyer has insufficient interest to question in court the qualifications of a particular justice for his office (*Ex parte Levitt*, 1937). A mere taxpayer qua taxpayer does not have sufficient interest in the United States Treasury to attack in court the validity of a federal appropriation act (*Frothingham v. Mellon*, 1923). This rule, which bars federal taxpayer suits, closed the door to a possible flood of litigation that would have been most embarrassing to the government. The court opened the door a little bit, however, in 1968 in *Flast v. Cohen*, in which it was held that a federal income taxpayer had standing to challenge an expenditure of federal funds designed to finance instruction in religious schools on the ground that the First Amendment, which forbids an "established" or national church, operated as a specific constitutional limitation upon the exercise by Congress of its taxing and spending powers. But a statute may be assailed only by one who relies upon an alleged invasion of his own constitutional rights; one does not have standing to sue in behalf of others.

Finally, the thrust of judicial review is limited by the doctrine of the political, nonjusticiable question. Certain questions arising under the Constitution are regarded by the court as being political in character and therefore outside the scope of judicial action. For example, the Constitution (IV, 4) declares that "The United States shall guarantee to every State in this Union a Republican Form of Government." But it was early decided (*Luther v. Borden*, 1849) that whether a particular state government is republican in form is for the political branches of the government—that is, Congress and the president—to decide, not the courts. Similarly, the president's

Grounds for review

duty to see to the faithful execution of the laws is political and therefore not subject to judicial process (*Mississippi v. Johnson*, 1867).

Many military questions, such as the necessity for calling out the militia, and foreign policy questions, such as the government's power to recognize a particular foreign government or international boundary or treaty, are considered political in character and therefore nonjusticiable.

#### THE SUPREME COURT AND THE SEPARATION OF FEDERAL POWERS

The framers of the Constitution accepted as an unchallengeable maxim that the only way to avoid governmental tyranny is to put the legislative, executive, and judicial powers in separate departments. This separation of powers is not only a political theory about the proper organization of government but also a doctrine of constitutional law involving the Supreme Court. It is in accordance with this principle that the federal courts decline to perform nonjudicial functions and that the exercise by Congress of nonlegislative functions in connection with legislative investigations tends to be judicially censured.

Since the legislative power is vested in Congress, the lawmaking power as a whole cannot be delegated to the president. It was on this theory that the court in 1935 invalidated the National Industrial Recovery Act (NIRA), holding that the code-making authority given the president vested in him a virtually unfettered discretion to make law (*Schechter Poultry Corp. v. United States*). This was an unusual holding, since government without large-scale delegations is quite impossible, and as Chief Justice Hughes said in the case, the court had "repeatedly recognized the necessity of adapting legislation to complex conditions involving a host of details with which the national legislature cannot deal directly." This is well illustrated in the great regulatory commissions, such as the Interstate Commerce Commission (ICC) and the Federal Communications Commission (FCC), established by Congress to deal with exceedingly complex and rapidly changing sectors of the economy. All of these agencies operate under the authority of broad delegations of power by Congress and necessarily exercise legislative and judicial, as well as administrative, functions.

The steady growth in the power and prestige of the office of president became a leading feature of U.S. constitutional government in the 20th century. Contrary to 18th-century assumptions about the separation of powers, the president takes the initiative in proposing legislation; and, indeed, his record as chief executive is more likely to be judged by the success of his legislative program than by any other event. The president possesses vast delegated legislative powers given him in a multitude of statutes. Nevertheless, there are limits to what the president can do, dramatically illustrated in the 1952 holding of the Supreme Court that President Harry S. Truman's seizure of the steel mills without statutory authorization to avoid a strike during the Korean War was illegal (*Youngstown Sheet & Tube Co. v. Sawyer*). The court ruled that since Congress could have authorized the seizure under its various powers, in acting without permission of a statute the President usurped legislative power in violation of the separation of powers principle. It rejected the contention that the president could seize private property under his authority as commander in chief and as chief executive, his power being only to enforce the laws, not to make them. The Constitution clearly vests the lawmaking function in Congress, and while Congress undoubtedly has the right to authorize the taking of private property for public use under its power of eminent domain, "the Constitution did not subject this lawmaking power of Congress to presidential or military supervision or control!"

#### THE SUPREME COURT AND THE FEDERAL SYSTEM

A central fact of the U.S. Constitution is that it creates a federal system under which the powers of government

are divided between the national government and the states. As noted earlier, the national government has those constitutional powers that are delegated to it; the states, unless they are otherwise restricted, possess all of the remaining powers of government, often referred to as the residual powers.

Although the national government is limited to its enumerated powers, several important facts about these powers must be noted: (1) The national Constitution, and the statutes and treaties adopted pursuant to it, constitute, in the language of Article VI, "the supreme Law of the Land; . . . any Thing in the Constitution or Laws of any State to the Contrary notwithstanding." This means that any state law, otherwise valid, must yield if contrary to a valid federal law, since the latter is the supreme law of the land. (2) Although the national government is limited to the exercise of enumerated powers, these powers are spelled out in broad terms, and the "elastic" clause (I, 8) states that Congress shall have the authority "To make all Laws which shall be necessary and proper for carrying into Execution" the various powers vested in the national government by the Constitution. It follows that in addition to the specified powers, Congress possesses implied powers, a proposition definitively established by Chief Justice John Marshall in the celebrated case of *McCulloch v. Maryland* (1819). Here the Supreme Court held that Congress had the power to incorporate a national bank, in spite of the fact that the Constitution is silent on both the creation of corporations and the chartering of banks. It was concluded that since a national bank would facilitate the accomplishment of purposes confided to the national government, such as the collection of taxes and the maintenance of armed forces, Congress had a choice of means to achieve these proper ends. "Let the end be legitimate," said the chief justice, "let it be within the scope of the constitution, and all means which are appropriate, which are plainly adapted to that end, which are not prohibited, but consist with the letter and spirit of the constitution, are constitutional." This doctrine of implied powers became a powerful force in supplying the constitutional basis for the steady growth, over the years, of national power. (3) In the field of foreign affairs the doctrine of enumerated powers breaks down almost entirely, since the Supreme Court takes the view that whether enumerated or not, the national government, from the very nature of things, has full responsibility over foreign affairs and has the inherent power to do all things that sovereign nations customarily do in this area. Thus the court early took the position that the national government has unlimited power to exclude aliens from the country and very wide authority to deport them on any terms it desires, though the Constitution says not a word on this subject. Similarly, in 1936, in a decision upholding an arms embargo, the court went so far as to say that in contrast with the enumerated powers exercised internally, the federal powers of external sovereignty do not even depend upon affirmative grants of the Constitution.

Whether the national government or the states have overstepped the boundaries of their constitutional authority is ultimately a legal question for the Supreme Court to decide, if the issues can be brought to it in proper litigation. In this sense the Supreme Court may be said to be the umpire of the federal system. It has on occasion declared acts of Congress invalid as invading the reserved powers of the states, and it has often held state laws unconstitutional as being contrary to the supreme law of the land. Nevertheless, though the Supreme Court is the umpire of the federal system, it is chosen by only one side; it is a national, and in no sense at all a state, institution, and on the whole its leanings are toward the national position and an ever-expanding conception of national power.

In still another sense the Supreme Court is the umpire of the federal system, for it is given original jurisdiction by the Constitution over disputes between the states. The last recourse a state has in such circumstances is to sue

Defining  
the  
national  
powers

in the Supreme Court, and by the late 1950s every state in the union but one had been at least once a plaintiff or defendant in such lawsuits, involving such difficult questions as boundaries, debts, water rights, and water pollution. The court performs an important function in successfully adjudicating disputes, which might lead to the use of force in the case of independent nations similarly involved.

The competing concepts of federal supremacy and states' rights were brought early in U.S. history into sharp focus in the field of commercial regulation. The commerce clause (I, 8) of the Constitution simply authorizes Congress "To regulate Commerce with foreign Nations, and among the several States, and with the Indian Tribes." In the formative years of the republic the Supreme Court took a broad view of national power under this clause, as in the seminal case of *Gibbons v. Ogden* (1824) which held that the power of Congress over commerce includes navigation. As new methods of interstate transportation and communication came into use, ranging from the stagecoach, the railroad, and the telegraph line to the ticker tape, trucking, radio, airlines, and television, the court interpreted the national power to keep pace with the times.

Balancing  
national  
and state  
regulatory  
powers

The court nevertheless has not regarded the commerce power as being exclusively national, the states being up to a point conceded the right also to regulate interstate commerce. The problem was to locate the point. After considerable fumbling the court hit upon a formula (*Cooley v. Board of Wardens of the Port of Philadelphia*, 1851). Upholding state regulation of pilotage, the court ruled that the states may regulate those aspects of interstate commerce that Congress has not attempted to regulate and that do not "imperatively [demand] a single uniform rule" for the whole country. In areas in which Congress has been silent and diversity of treatment is desirable, the states enjoy the power of concurrent regulation; but where uniformity of treatment is imperative, the power of congress is "exclusive." In balancing competing local and national needs in commerce, the Supreme Court has since exercised a wide discretion in considering the equities of each case.

#### THE SUPREME COURT AND INDIVIDUAL RIGHTS

The national government is obliged by many provisions of the Constitution to respect the basic rights of man. Some civil rights limitations were imposed on this government in the original document, notably in the provisions guaranteeing the writ of habeas corpus and forbidding bills of attainder (legislative trials) and ex post facto laws and guaranteeing trial by jury in criminal cases. But the most significant limitations of this character upon the national government were added in 1791 with the ratification of the first ten amendments, the Bill of Rights. Here are guaranteed basic rights of conscience, such as freedom of religion, speech, press, and petition; fundamental guarantees of fair procedure for persons accused of crime, such as protection against unreasonable searches and seizures, compulsory self-incrimination and excessive bail, a speedy and public trial by a local, impartial jury before an impartial judge, and representation by counsel; and rights of private property, as in the provision that private property shall not be taken for public use without just compensation.

Applying  
the  
Fourteenth  
Amendment

For the protection of such rights as these against state, as opposed to federal, action, the citizen originally had to look to the state constitution, each state constitution possessing a more or less elaborate bill of rights enforceable by the state courts. But an important new federal limitation on the states was added to the national constitution with the ratification, in 1868, of the Fourteenth Amendment, by which the states are forbidden to deny any person life, liberty, or property without due process of law or to deny to any person the equal protection of the laws. By a process of interpretation at the hands of the Supreme Court these two clauses took on increased meaning.

The liberty that the due process clause of the Four-

teenth Amendment guarantees against state action has been held to include the liberties of religion, speech, and press that the First Amendment protects against violation by the national government. Similarly, some of the guarantees of a fair trial in other parts of the federal Bill of Rights, such as the defendant's right to an impartial judge and the assistance of counsel, have also been judicially absorbed into the Fourteenth Amendment. Indeed, a minority of Supreme Court justices argued that the Fourteenth Amendment was intended to incorporate as limitations upon the states all of the provisions of the federal Bill of Rights. But a majority of the court clung to the position that not all of the guarantees of the federal Bill of Rights are so fundamental to justice that they are required by due process of law. Thus, to cite an early example, the Fifth Amendment guarantee of indictment by grand jury was held inapplicable to the states (*Hurtado v. California*, 1884), and in fact most states abandoned this type of indictment in favour of allowing the public prosecutor to bring criminal charges. A number of the purely procedural guarantees of the federal Bill of Rights have been held inapplicable to the states, although they of course bind the agencies of the national government.

The other great limitation on the states in the Fourteenth Amendment, that no state shall deny any person within its jurisdiction the equal protection of the laws, has a long and important history in U.S. constitutional law. Thus over the years the Supreme Court has set aside many criminal convictions of Negroes on the ground that the state courts that convicted them arbitrarily and systematically excluded Negroes from their juries, this being construed as a denial of equal justice to members of the excluded group. By all odds the most spectacular and controversial application of the equal protection clause came on May 17, 1954, when the court ruled that states that practiced racial segregation in the public schools violated the Constitution (*Brown v. Board of Education*). In so ruling the court set aside the 1896 ruling (*Plessy v. Ferguson*) that "separate but equal" facilities satisfied the command of the Fourteenth Amendment, holding by unanimous vote that separate educational facilities, by creating feelings of inferiority, are inherently unequal.

It remains to be noted that none of the great constitutional rights of conscience, however vital to a free society, is absolute in character. Thus, while the constitutional guarantee of freedom of religion goes a long way, it does not serve to protect acts judged to be morally licentious, such as polygamous marriages. Children cannot be required to execute a flag salute forbidden by religious belief (*West Virginia State Board of Education v. Barnette*, 1943), but parents are not free to ignore child labour laws on the ground of religious practice (*Prince v. Massachusetts*, 1944). Similarly, freedom of speech, often defended by the courts, does not extend to the seditious utterances of a conspiracy that, in the considered opinion of Congress, poses a clear and present danger to the safety of the republic (*Dennis v. United States*, 1951). But the court has emphasized that the act of Congress on this subject, the Smith Act, does not forbid mere advocacy of abstract doctrine but only incitement to action designed to accomplish the illegal purpose of overthrowing the government (*Yates v. United States*, 1957). The state is not free to license the privilege of giving a speech (*Thomas v. Collins*, 1945), but it may punish utterance of "fighting words," which may lead to breaches of the peace (*Chaplinsky v. New Hampshire*, 1942), or the publication of obscene matter (*Roth v. United States*, 1957).

There was much concern at mid-20th century with the rights of persons accused of crime. The right of an indigent defendant to representation by counsel has been judicially underscored, and the courts appeared increasingly meticulous to safeguard the right to reasonable bail and the right to a fair trial, including a public, speedy trial before an unbiased judge and a jury free of mob domination. In 1966 a Cleveland osteopath, Samuel H. Sheppard, won a reversal by the U.S. Supreme Court of his conviction on the ground that his trial was prejudiced by excessive newspaper publicity. The uses of the writ of

habeas corpus were steadily expanded. Some rights, such as the privilege against self-incrimination, came under heavy public fire, but the proposition that no one should be compelled to testify oneself into jail retained its vitality in U.S. courts. In criminal cases, the burden of proof remained on the prosecution, and the accused carried the presumption of innocence.

## Constitution and Constitutional Government

The general idea of a constitution and of constitutionalism originated with the ancient Greeks and especially in the systematic, theoretical, normative, and descriptive writings of Aristotle. In his *Politics*, *Nicomachean Ethics*, *Constitution of Athens*, and other works, Aristotle used the Greek word for constitution (*politeia*) in several different senses. The simplest and most neutral of these was "the arrangement of the offices in a *polis*" (state). In this sense of the word, every state has a constitution, no matter how badly or erratically governed it may be.

### THEORIES ABOUT CONSTITUTIONS

**Classical conceptions.** Aristotle's famous and influential classification of the "forms of government" was intended by him as a classification of constitutions, both good and bad. Under good constitutions—monarchy, aristocracy, and the mixed kind to which Aristotle applied the same term *politeia*—one person, a few individuals, or the many rule in the interest of the whole *polis*. Under the bad constitutions—tyranny, oligarchy, and democracy—the ty-

rant, the rich oligarchs, or the poor *dēmos*, or people, rule in their own interest alone.

Aristotle regarded the mixed constitution as the best practicable arrangement of offices in the *polis*. Such a *politeia*, or mixed constitution, would contain monarchic, aristocratic, and democratic elements. Its citizens, after they had learned to obey, were to be given opportunities to participate in ruling. This was a *privilege* only of citizens, however, since neither noncitizens nor slaves would have been admitted to any political office by Aristotle or by his contemporaries in the Greek city-states. Aristotle regarded some humans as natural slaves, a point on which later Roman philosophers, especially the Stoics and jurists, disagreed with him. Although slavery was at least as widespread in Rome as in Greece, Roman law generally recognized a basic equality among all humans. This was because, the Stoics argued, all humans are endowed by nature with a spark of reason by means of which they can perceive a universal natural law that governs all the world and can bring their behaviour into harmony with it.

Roman law thus added to Aristotelian notions of constitutionalism the concepts of a generalized equality, a universal regularity, and a hierarchy of types of laws. Aristotle had already drawn a distinction between the constitution (*politeia*), the laws (*nomoi*), and something more ephemeral that corresponds to what could be described as day-to-day policies (*psēphismata*). The latter might be based upon the votes cast by the citizens in their assembly and might be subject to frequent changes, but *nomoi*, or laws, were meant to last longer. The Romans conceived of the all-encompassing rational law of nature as the eternal framework to which constitutions, laws, and policies *ought* to conform. The law of nature was the constitution of the universe.

**Influence of the church.** Christianity endowed this universal constitution with a clearly monarchical cast. The Christian God, it came to be argued, is the sole ruler of the universe. Unlike his Old Testament precursor, he is not arbitrary. His laws are passed down to humans and are to be obeyed. Christians were under an obligation to try to constitute their earthly cities on the model of the City of God, though in their ignorance and sinfulness they would never be able to succeed.

Both the church and the secular authorities, with whom the church came into conflict in the course of the Middle Ages, needed clearly defined arrangements of offices, functions, and jurisdictions. Medieval constitutions, whether of church or state, were considered legitimate because they were believed to be ordained of God or tradition or both. Confirmation by officers of the Christian Church was regarded as a prerequisite of the legitimacy of secular rulers. Coronation ceremonies were incomplete without a bishop's participation. The Holy Roman emperor travelled to Rome in order to receive his crown from the pope. Oaths, including the coronation oaths of rulers, could be sworn only in the presence of the clergy because oaths constituted promises to God and invoked divine punishment for violations. Even in an imposition of a new constitutional order, novelty could always be legitimized by reference to an alleged return to a more or less fictitious "ancient constitution." It was only in Italy during the Renaissance and in England after the Reformation that the "great modern fallacy" (as the Swiss historian Jacob Burckhardt called it) was established, according to which citizens could rationally and deliberately adopt a new constitution to meet their needs.

There is no state that is a member of the "family of nations"—whether Western or Eastern, "democratic" or "communist," advanced or traditionalist, developed or backward, monarchical, dictatorial, civilian-ruled, or militarist—that does not claim to have a constitution.

**The social contract.** The theoretical foundations of modern constitutionalism were laid down in the great works on the social contract, especially those of the English philosophers Thomas Hobbes and John Locke in the 17th century and the French philosopher Jean-Jacques Rousseau in the 18th century. They were writing in the aftermath of the Protestant Reformation, which had dis-

Influence  
of Roman  
law

	<p>turbed the fundamental constitution of Western Christendom.</p> <p>As a result of the Reformation, the basis of divinely sanctioned contractual relations was broken up. Catholic bishops encouraged subjects of Protestant princes to break their pledges of fealty in order that they might keep faith with God and his Catholic Church. The Holy Roman Empire was torn apart by the wars of the Reformation. Henry VIII made the Church of England independent of Rome. In these circumstances, it became necessary to search for a new basis of order and stability, loyalty and obedience. In their search, political theorists—and especially the Protestants among them—turned to the old biblical concept of a covenant or contract, such as the one between God and Abraham and the Israelites of the Old Testament. The assumption was that God had constituted the political unit by choosing his partners in an eternal covenant.</p> <p>In a sense, the secular theorists of the social contract almost reversed the process of choice. Instead of God choosing his people, a people through its representatives was now looked upon as choosing its governors, or its mode of governance, under God, by means of a social contract or constitution. According to modern theories of the social contract, the political unit is nevertheless established as in the biblical model by means of a promise or promises. Thomas Hobbes's state, or "Leviathan," comes into being when its individual members renounce their powers to execute the laws of nature, each for himself, and promise to turn these powers over to the sovereign—which is created as a result of this act—and to obey thenceforth the laws made by this sovereign. These laws enjoy authority because individual members of society are in effect their co-authors. According to Locke, individuals promise to agree to accept the judgments of a common judge (the legislature) when they accede to the compact that establishes civil society. After this (in one interpretation of Locke's <i>Second Treatise on Civil Government</i>), another set of promises is made—between the members of the civil society, on the one hand, and the government, on the other. The government promises to execute its trust faithfully, leaving to the people the right to rebel in case the government breaks the terms of the contract, or, in other words, violates the constitution. Subsequent generations accept the terms of the compact by accepting the inheritance of private property that is created and protected by the compact. Anyone who rejects the constitution must leave the territory of the political unit and go <i>in vacuis locis</i>, or "empty places"—America, in Locke's time. In his <i>Letters on Toleration</i>, Locke characteristically excluded atheists from religious toleration because they could be expected either not to take the original contractual oath or not to be bound by the divine sanctions invoked for its violation.</p> <p>For Rousseau, too, the willingness to subject oneself to the "general will" to which only the popular sovereign can give expression is the essential ingredient of the social contract. In taking this position, Rousseau may have been influenced by the experience of his native Geneva. The Swiss Confederation is still referred to officially, in German, as an <i>Eidgenossenschaft</i>, a term best translated as "fellowship of the oath."</p> <p>Hobbes's main contribution to constitutionalism lies in his radical rationalism. Individuals, according to Hobbes, come together out of the state of nature, which is a state of disorder and war, because their reason tells them that they can best ensure their self-preservation by giving all power to a sovereign. The sovereign may consist of a single person, an assembly, or the whole body of citizens; but regardless of its form, all the powers of sovereignty have to be combined and concentrated in it. Hobbes held that any division of these powers destroyed the sovereign and thereby returned the members of the commonwealth to the state of nature, in which the condition of man is "... solitary, poore, nasty, brutish, and short." Hobbes therefore preferred the singular sovereign since he was less likely than an assembly or than the whole body of citizens to become internally or functionally divided. Powers over war and peace, taxation, and the judiciary, along with all other governmental powers, should be concentrated in the sovereign. The individual should retain only his natural rights, which he cannot surrender into the common pool of sovereign powers. These rights include the right against self-incrimination, the right to purchase a substitute for compulsory military service, and the right to act freely in instances in which the laws are silent.</p> <p>Locke attempted to provide firm assurance of the individual's natural rights, partly by assigning separate though coordinated powers to the monarch and Parliament and partly by reserving the right of revolution against a government that had become unconstitutionally oppressive. Locke does not use the word sovereignty. In this as in other respects, he remained within the English constitutional tradition, which had eschewed the concentration of all powers in a single organ of government. The closest that English constitutionalists came to identifying the centre of sovereign power was in the phrase, used frequently from the 16th century onward, the king (or queen) in Parliament.</p> <p>Whereas Hobbes created his unitary sovereign through the mechanism of individual and unilateral promises and whereas Locke prevented excessive concentration of power by requiring the cooperation of different organs of government for the accomplishment of different purposes, Rousseau merged all individual citizens into an all-powerful sovereign whose main purpose was the expression of the general will. By definition, the general will can never be wrong; for when something contrary to the general interest is expressed, it is defined as the mere "will of all" and cannot have emanated from the sovereign. In order to guarantee the legitimacy of government and laws, Rousseau would have enforced universal participation in order to "force men to be free," as he paradoxically phrased it. In common with Hobbes and Locke, Rousseau required the assent of all to the original social contract. He required smaller majorities for the adoption of laws of lesser importance than the constitution itself. His main concern was to provide for legitimacy through universal participation in legislation, whereas Locke and Hobbes were more concerned to provide constitutional stability through consent. As a result, Rousseau's thought appears to be more democratic than that of his English predecessors. He has even been accused of laying the philosophical foundations of "totalitarian democracy," for the state he describes in <i>The Social Contract</i> would be subject, at the dictates of its universal and unanimous sovereign, to sudden changes, or even transformations, of its constitution.</p> <p>In the political thought of Hobbes, Locke, and Rousseau may be found theoretical consideration of the practical issues that were to confront the authors of the American and French constitutions. The influence of theories of the social contract, especially as they relate to the issues of natural rights, and the proper functions of government, pervades the constitution making of the revolutionary era that began with the U.S. War of Independence and is indeed enshrined in the great political manifestos of the time, the American Declaration of Independence and Bill of Rights, and the French Declaration of the Rights of Man and the Citizen.</p> <p>The constitutional experience of these two countries, and, of course, of England, had great influence on liberal thought in Europe and other parts of the world during the 19th century and found expression in the constitutions that were demanded of the European monarchies. The extent to which the ideal of constitutional democracy has become entwined with the practice of constitutional government will be apparent from the examination in the following section of the main features of constitutional government.</p>	
Impact of the Reformation		Rousseau's theory of the general will
Hobbes's view on sovereignty		Influence of social contract theory
<b>FEATURES OF CONSTITUTIONAL GOVERNMENT</b>		
Virtually all contemporary governments have constitutions, but possession and publication of a constitution does not make a government constitutional. Constitu-		

tional government is in fact comprised of the following elements.

*Procedural stability.* Certain fundamental procedures must not be subject to frequent or arbitrary change. Citizens must know the basic rules according to which politics are conducted. An action that is considered legal and constitutional today must not be condemned as illegal tomorrow. Stable procedures of government and politics provide citizens with adequate foreknowledge of the probable consequences of their actions. By contrast, under many nonconstitutional regimes, such as Hitler's in Germany and Stalin's in the Soviet Union, individuals, including high government officials, could never know from one day to the next whether the whim of the dictator's will would not turn today's hero into tomorrow's public enemy. The people did not even know the procedures by means of which the dictator's will would be made known to the general public.

*Accountability.* Under constitutional government, those who govern are regularly accountable to at least a portion of the governed. In a constitutional democracy, this accountability is owed to the electorate by all persons in government. Accountability can be enforced through a great variety of regular procedures, including elections, systems of promotion and discipline, fiscal accounting, recall, and referendum. In constitutional democracies, the accountability of government officials to the citizenry makes possible the citizens' responsibility for the acts of government. The most obvious example of this two-directional flow of responsibility and accountability is the electoral process. A member of the legislature or the head of government is elected by adult citizens and is thereby invested with authority and power in order that he may try to achieve those goals to which he committed himself in his program. At the end of his term of office, the electorate has the opportunity to judge his performance and to re-elect him or dismiss him from office. The official has thus rendered his account and has been held accountable.

*Representation.* Those in office must conduct themselves as the representatives of their constituents. To represent means to be present on behalf of someone else who is absent. Elections, of course, are not the only means of securing representation or of ensuring the representativeness of a government. Hereditary medieval kings considered themselves, and were generally considered by their subjects, to be representatives of their societies. Hobbes termed his sovereign *the* representative of the commonwealth. Of the social contract theorists, only Rousseau denied the feasibility of representation for purposes of legislation. The elected status of officeholders is sometimes considered no guarantee that they will be "existentially representative" of their constituents, unless they share with the latter certain other vital characteristics such as race, religion, sex, or age. The problems of representation are in fact more closely related to democratic than to constitutionalist criteria of government: a regime that would be considered quite unrepresentative by modern standards could still be regarded as constitutional so long as it provided procedural stability and the accountability of office holders to some but not all of the governed and so long as the governors were representative of the best or the most important elements in the body politic.

*Division of power.* Constitutional government requires a division of power among several organs of the body politic. Preconstitutionalist governments, such as the absolute monarchies of Europe in the 18th century, frequently concentrated all power in the hands of a single person. All powers of law making, enforcement, and interpretation were concentrated in the ruler himself so that the individual subject in conflict with his government faced the same single power or its agents no matter which way he turned. The same has been true in modern dictatorships such as Hitler's in Germany. Constitutionalism, on the other hand, by dividing power—between, for example, local and central government and between the legislature, executive, and judiciary—ensures the

presence of restraints and "checks and balances" in the political system. Citizens are thus able to influence policy by resort to any of several branches of government.

*Openness and disclosure.* Democracy rests upon popular participation in government, constitutionalism upon disclosure of and openness about the affairs of government. In this sense, constitutionalism is a prerequisite (and has, in fact, been the historical precursor) of successful democracy since the people cannot participate rationally in government unless they are adequately informed of its workings. Originally, because they were concerned with secrets of state, bureaucracies surrounded their activities with a dark veil of secrecy. The ruler himself always retained full access to administrative secrets and often to the private affairs of his subjects, into which bureaucrats such as tax collectors and the police could legally pry. But when both administrators and rulers were subjected to constitutional restraints, it became necessary that they disclose the content of their official activities to the public to which they owed accountability. This explains the provision contained in most constitutions obliging the legislature to publish a record of its debates.

As a result of the modern proliferation of bureaucracy, the Scandinavian countries established the office of ombudsman. The ombudsman can protect the constitutional rights of citizens against bureaucratic violations by forcing administrative offices to open to him—and through him to the public—the records of otherwise secret bureaucratic files and proceedings. The office of ombudsman has recently been copied by many constitutional governments. This office and the general constitutional requirements for openness and disclosure of official records contrast sharply with the secrecy surrounding the much more pervasive activities of those closed societies that are usually labelled totalitarian.

*Constitutionality.* Written constitutions normally provide the standard by which the legitimacy of governmental actions is judged. In the United States, the practice of the judicial review of congressional legislation for its constitutionality—that is, for its conformity with the U.S. Constitution—though not explicitly provided for by the Constitution, developed in the early years of the republic. More recently, other written constitutions, including the Basic Law of the Federal Republic of Germany and Italy's republican constitution, provided explicitly for judicial review of the constitutionality of parliamentary legislation. This does not necessarily mean that a constitution is regarded as being prior and superior to all law. Although several European countries, including France, Italy, and West Germany, adopted new constitutions after World War II, they kept in force their codes of civil law, which had been legislated in the 19th century; and the U.S. Constitution guarantees citizens certain substantive and procedural rights to which they deemed themselves entitled as subjects of the British crown under the ancient English common law. Despite the greater antiquity of law codes, however, portions of them have been revised from time to time in order to eliminate conflicts between the law and certain constitutional norms that are regarded as superior. Parts of German family law and of the criminal code, for example, were revised in order to bring them into conformity with the constitutional provisions regarding the equality of persons irrespective of sex and with the individual's constitutionally guaranteed right to the free development of his personality.

Conflicting interests or parties are, of course, likely to place different interpretations on particular provisions of a constitution, and means, therefore, have to be provided for the resolution of such conflicts. The constitution itself may establish an institution the task of which is to interpret and clarify the terms of that constitution. In the American system, the Supreme Court is generally regarded as the authoritative interpreter of the Constitution and, therefore, of the intentions of the founders and of later contributors to the total constitutional fabric. But the Supreme Court cannot be regarded as the "final" interpreter or arbiter of the meaning of the Constitution

Constitutional interpretation

for a number of reasons. The court can always reverse itself, as it has done. The president can gradually change the interpretative outlook of the court through the nomination of new justices, and the Congress can exert a more negative influence by refusing to confirm presidential nominations of justices.

Provision was made in the constitution of the Fifth French Republic for the interpretation of certain constitutional matters by a Constitutional Council. Soon after the French electorate, in a referendum in 1958, had voted to accept the Constitution, a controversy erupted in France over the question of whether the president of the republic could submit to popular referendum issues not involving constitutional amendments but on which parliament had taken a position at odds with the president's. The Constitution itself seemed to provide that the Constitutional Council could rule definitively on this question, but Pres. Charles de Gaulle chose to ignore its ruling, which was unfavourable to himself. As a result, the Constitutional Council lost authority as the final interpreter of the meaning of the Constitution of the Fifth Republic.

It may thus be seen that because of the inherent difficulties in assessing the intentions of the authors of a constitution and because of the possibility that the executive or legislative branch of government may be able to ignore, override, or influence its findings, it is difficult to ensure constitutional government merely by setting up an institution whose purpose is constitutional interpretation.

Constitutional change. Written constitutions are not only likely to give rise to greater problems of interpretation than unwritten ones; they are also harder to change. Unwritten constitutions tend to change gradually, continually, and often imperceptibly, in response to changing needs. But when a constitution lays down exact procedures for the election of the president, for relations between the executive and legislative branches, or for defining whether a particular governmental function is to be performed by the federal government or a member state, then the only constitutional way to change these procedures is by means of the procedure provided by the constitution itself for its own amendment. Any attempt to effect change by means of judicial review or interpretation is unconstitutional, unless, of course, the constitution provides that a body (such as the U.S. Supreme Court) may change, rather than interpret, the constitution.

Many constitutional documents make no clear distinction between that which is to be regarded as constitutional, fundamental, and organic, on the one hand, and that which is merely legislative, circumstantial, and more or less transitory, on the other. The constitution of the German Weimar Republic could be amended by as little as four-ninths of the membership of the Reichstag, without any requirement for subsequent ratification by the states, by constitutional conventions, or by referendum. Although Hitler never explicitly abrogated the Weimar Constitution, he was able to replace the procedural and institutional stability that it had sought to establish with a condition of almost total procedural and institutional flux.

A similar situation prevailed in the Soviet Union under the rule of Stalin. But Stalin took great trouble and some pride in having a constitution bearing his name adopted in 1936. Despite occasional efforts to replace the Stalin constitution with a more up-to-date document, it continues, together with the Rules of the Communist Party of the Soviet Union, to serve as the formal framework of government. The procedures established by both of these documents, however, have not been able to provide Soviet citizens and politicians with reliable foreknowledge of the rules of the political process from one year to the next or with guidance as to which institutions and practices they were to consider fundamental or virtually sacrosanct and which they could safely afford to criticize. As a result, changes in the personnel and policies of the Soviet Union and of similar Communist regimes have

rarely been brought about smoothly and have frequently required the use of violence.

Constitutional stability. If one distinguishes between stability and stagnation on the one hand and between flexibility and flux on the other, then one can consider those constitutional systems most successful that combine procedural stability with substantive flexibility—that is, that preserve the same general rules of political procedure from one generation to the next while at the same time facilitating adaptation to changing circumstances of internal and external economic, social, cultural, and power relationships. By reference to such criteria, those written constitutions have achieved the greatest success that are comparatively short; that confine themselves in the main to matters of procedure (including their own amendment) rather than matters of substance; that, to the extent that they contain substantive provisions at all, keep these rather vague and generalized; and that contain procedures that are congruent with popular political experience and know-how. These general characteristics appear to be more important in making for stability than such particular arrangements as the relations between various organs and levels of government or the powers, functions, and terms of tenure of different officers of state.

There is little evidence to support the thesis that a high level of citizen participation necessarily contributes to the stability of constitutional government. On the contrary, the English political economist Walter Bagehot, who in 1867 wrote a classic analysis of the English constitution (*The English Constitution*), stressed the "deferential" character of the English people, who were quite happy to leave government in the hands of the governing class.

Much more important than formal citizen behaviour, such as electoral participation, are informal attitudes and practices and the extent to which they are congruent with the formal prescriptions and proscriptions of the constitution itself. Constitutional government cannot survive effectively in situations in which the constitution prescribes a pattern of behaviour or of conducting affairs that is alien to the customs and way of thinking of the people. Whereas in many developing countries in the decades after World War II a new and alien kind of constitutional democracy is imposed or adopted, a gap may soon develop between constitutionally prescribed and actual governmental practice. This in turn renders the government susceptible to attack by opposition groups. Such attack is especially easy to mount in situations in which a constitution has a heavy and detailed substantive content, when, for example, it guarantees the right to gainful employment or the right to a university education for all qualified candidates. In the event of the government being unable to fulfill its commitment, the opposition is able to call the constitution a mere scrap of paper and to demand its improvement or even its complete replacement. Such tactics often have succeeded, but they ignore the dual strategic function of the constitution. It is meant not only to arrange the offices of the state, in Aristotle's sense, but also to state the goals toward which the authors and ratifiers of the constitution want their community to move.

Characteristics of stable constitutions

#### THE PRACTICE OF CONSTITUTIONAL GOVERNMENT

Britain. It is accepted constitutional theory that Parliament (the House of Commons and the House of Lords acting with the assent of the monarch) can do anything it wants to, including abolish itself. The interesting aspect of British government is that, despite the absence of restraints such as judicial review, acts that would be considered unconstitutional in the presence of a written constitution are attempted very rarely, certainly less often than in the United States.

The English constitution and the English common law grew up together, very gradually, more as the result of the accretion of custom than through deliberate, rational legislation by some "sovereign" lawgiver. Parliament grew out of the Curia Regis, the King's Council, in which

the monarch originally consulted with the great magnates of the realm and later with commoners who represented the boroughs and the shires. Parliament was, and is, a place in which to debate specific issues of disagreement between, initially, the crown, on the one hand, and the Lords and Commons, on the other. The conflicts were settled in Parliament so that its original main function was that of a court—it was in fact known as "the High Court of Parliament" as late as the 16th century.

The locus of power in the English constitution shifted gradually as a result of changes in the groups whose consent the government required in order to be effective. In feudal times, the consent of the great landowning noblemen was needed. Later, the cooperation of those commoners who were willing to grant revenue to the crown—that is, to pay taxes—was sought. The crown itself, meanwhile, was increasingly institutionalized, and the distinction was drawn ever more clearly between the private and public capacities of the king. During the course of the 18th century, effective government passed more and more into the hands of the king's first minister and his cabinet, all of them members of one of the two houses of Parliament. Before this development, the king's ministers depended upon their royal master's confidence to continue in office. Henceforward they depended upon the confidence of the House of Lords and especially the House of Commons, which had to vote the money without which the king's government could not be carried on. In this way the parlay that was originally between the monarch and the houses of Parliament was now struck between the ministry and its supporters, on the one hand, and opposing members of Parliament ("His Majesty's Loyal Opposition"), on the other. Parliamentary factions were slowly consolidated into parliamentary parties, and these parties reached out for support into the population at large by means of the franchise, which was repeatedly enlarged in the course of the 19th century and eventually extended to women and then to 18-year-olds in the 20th.

When a prime minister loses a vote of confidence in the House of Commons, he can either resign to let the leader of the Opposition form a new government or ask the monarch to dissolve Parliament and call for new elections. As a result of the strong party discipline that developed in the 20th century, prime ministers generally do not lose votes of confidence any more, and they call for new elections at the politically most favourable moment. According to an act of Parliament, elections must be held at least every five years—but another act of Parliament can change or suspend this apparently "constitutional" provision, as was done during World War II, when the life of the incumbent House of Commons was extended until the defeat of Germany. Similarly, relations between, and the relative powers of, the House of Lords and the House of Commons have been repeatedly redefined to the disadvantage of the House of Lords by acts of Parliament, to such an extent that the Lords retain only a weak suspensory veto. All such fundamental constitutional changes have occurred either informally and without any kind of legislation at all or as a result of the same legislative procedures employed to pass any other ordinary circumstantial bill.

**United States.** The U.S. Constitution is replete with phrases taken from the British constitutional vocabulary, such as the "advice and consent" required of the Senate for the ratification of treaties and the confirmation of presidential appointments, which echoes the advice and consent of the Lords and Commons to enactments of "the King's Most Excellent Majesty" in acts of Parliament. In several respects, the U.S. Constitution represents a codification of its authors' understanding of the English constitution, to which they added ingenious federalist inventions and the formal amending procedure itself. Despite the availability of this procedure, however, many if not most of the fundamental changes in American constitutional practice have not been effected by formal amendments. The Constitution still does not mention political parties or the president's cabinet. Nor was the Constitution changed in order to bring about or to sanction the

fundamentally altered relations between the executive and the Congress, between the Senate and the House, and between the judiciary, the legislature, and the executive. The presence of a constitutional document, however, has made American politics more consciously "constitutionalist," at least in the sense that politicians in the United States take more frequent recourse than their British counterparts to legalistic argumentation and to actual constitutional litigation. The United States, moreover, is denied the kind of flexibility illustrated by the postponement of British parliamentary elections during World War II since the Constitution explicitly provides the dates for congressional and presidential elections. It is one of the remarkable facts of American constitutional history that the constitutional timetable for elections has always been observed, even during external war and the Civil War of the 19th century.

**Europe.** France, Germany, and Italy, as well as most non-European countries influenced by continental concepts of constitutionalism, have no record of unbroken constitutional fidelity similar to that found in Britain and the U.S.

Because of the highly substantive and ideological content of most French constitutions, the best way to change them has been to replace them altogether with a new, ideologically different document. Only the constitution of the Third Republic (established in 1870) was exceptional in this respect, since it consisted of very short, highly procedural organic laws, which served France well for 70 years, until the German invasion of 1940.

The main political problem attributed to the constitution of the Third Republic was the instability of cabinets. The negative majorities that voted "no confidence" in a cabinet usually could not stay together for the positive purpose of confirming a new cabinet. The constitution of the Fourth Republic (1946–1958) made the overthrow of governments by the National Assembly more difficult. In fact, however, the life of the average cabinet in the Fourth Republic was even shorter than in the Third, and French government became virtually paralyzed when it had to deal with the problems raised by the Algerian independence movement. To avert a military takeover, General de Gaulle was given wide discretion in 1958 in the formulation of a new constitution, which was overwhelmingly accepted in a referendum. The constitution of the Fifth French Republic gives the president of the Republic the power to dissolve Parliament and the means of circumventing a hostile National Assembly through the referendum. Since 1958, French cabinets have been very stable indeed, and the 'constitution proved resilient during the "revolution of 1968."

Germany, which was unified as a national state only in 1871, established its first democratic constitution in 1919, after its defeat in World War I. Although some of the greatest German jurists and social scientists of the time participated in writing the Weimar Constitution, it has been adjudged a failure, largely because it was followed by Hitler's brutal dictatorship. Political parties became highly fragmented, a phenomenon that was explained partly by an extremely democratic electoral law (not a part of the constitution) providing for proportional representation. Some of the parties of the right, such as Hitler's Nazis, and of the left, such as the Communists, were opposed to the constitutional order and used violence in their efforts to overthrow the Republic. To deal with these threats, the President used his constitutional emergency powers under which he could suspend civil rights in member states of the federal system. Several chancellors (the German equivalent of a prime minister) stayed in office after the President had dissolved a Parliament in which the chancellor lacked a supporting majority. They continued to govern with the help of presidential emergency powers and by legislating on the basis of powers previously delegated to them by Parliament.

When a new constitution was being drafted for the Western zones of occupation after World War II, every effort was made to correct these constitutional errors, to which, in retrospect, the failure of the Weimar Republic

Constitutional government in France

was attributed. Under the Basic Law of Bonn, Parliament cannot delegate its legislative function to the chancellor, and civil rights cannot be suspended without continuous parliamentary surveillance. The president has been turned into a figurehead on the model of the French presidents of the Third and Fourth Republics, and Parliament cannot overthrow a chancellor and his cabinet unless it first elects a successor with a majority vote. Negative majorities cannot paralyze government unless they can agree on alternative policies and personnel. The extreme proportional representation used before Hitler came to power was replaced by a mixed electoral system under which half the members of the Bundestag (the lower house) are elected from party lists by proportional representation, while the other half are elected in single-member constituencies. In order to benefit from proportional representation, a party must obtain at least 5 percent of the votes nationally. As a result, the number of parties contracted during the first two decades of the Federal Republic and extremist parties were kept out of Parliament. Cabinets have been very stable, and each Parliament has served out its full four-year term. The provision for the "constructive vote of no confidence" has not been invoked.

**Latin America, Africa, and Asia.** The experience of constitutional government in continental Europe exerted great influence on the newly independent former colonies of Europe in the Middle East, Asia, and Africa. In the early years of their independence from Spain, most Latin-American countries adopted constitutions similar to that of the United States. But since they lacked the background that produced the American Constitution, including English common law, most of their efforts at constitutional engineering were unsuccessful. In Asia and Africa and in the Caribbean, many former colonies of Great Britain, such as India, Nigeria, Zambia, and Jamaica, have been comparatively more successful in the operation of constitutional government than former colonies of the continental European countries (e.g., Indonesia, Congo, and Haiti). The British usually left a modified and simplified version of their own constitution upon granting independence to their former subjects, some of whom they had previously trained in the complicated operating procedures of the British constitution. British parliamentary procedure proved sufficiently adaptable to remain in use for some time after the departure of the British themselves. France's former colonies in Africa, because they achieved independence after the founding of the Fifth Republic, modelled their new constitutions upon General de Gaulle's, partly because this enhanced the power of the leaders under whom independence had been achieved.

**BIBLIOGRAPHY.** Texts of more than 150 national constitutions appear in English translation in *Constitutions of the Countries of the World*, ed. by A.P. BLAUSTEIN and G.H. FLANZ, 14 vol., plus yearly supplements (1971– ). Another compendium of constitutions is A.J. PEASLEE (ed.), *Constitutions of Nations*, 3rd ed., 4 vol. (1965–70; 4th ed., vol. 1, 1974).

A comprehensive book on this subject is C.J. FRIEDRICH, *Constitutional Government and Democracy: Theory and Practice in Europe and America*, 4th ed. (1968). See also H.J. SPIRO, *Government by Constitution: The Political Systems of Democracy* (1959). The best study of constitutional change is W.S. LIVINGSTON, *Federalism and Constitutional Change* (1956, reprinted 1974). Aristotle's *Politics* is available in translation by SIR ERNEST BARKER (1962). Sir Ernest Barker has also edited *Social Contract: Essays by Locke, Hume, Rousseau* (1947, reprinted 1980). The best history of the origins of English constitutionalism is C.H. MCILWAIN, *The High Court of Parliament and Its Supremacy: An Historical Essay on the Boundaries Between Legislation and Adjudication in England* (1910, reprinted 1979). See also F.D. WORMUTH, *The Origins of Modern Constitutionalism* (1949). On the problems of accountability and responsibility, see H.J. SPIRO, *Responsibility in Government: Theory and Practice* (1969). For an understanding of American constitutionalism, *The Federalist* by ALEXANDER HAMILTON, JAMES MADISON, and JOHN JAY is indispensable. The classic exposition of *The English Constitution* was provided by WALTER BAGEHOT (1867, reprinted 1978); for a more recent analysis, see S.H. BEER and A.B. ULAM (eds.), *Patterns of Government: The Major Political Systems of Europe*, 3rd ed. (1973). On French constitutionalism, see also STANLEY HOFFMANN et al., *In Search of France* (1963), and *Decline or Renewal? France Since the 1930s* (1974). RALF DAHRENDORF,

*Society and Democracy in Germany* (1967), is a sociological account, complemented by A.J. HEIDENHEIMER, *The Governments of Germany*, 4th ed. (1975). For excerpts of constitutional documents of the major European governments, see J.J. WUEST and M.C. VERNON, *New Source Book in Major European Governments* (1966). The concept of congruence between political and social patterns of authority is elaborated by H.H. ECKSTEIN in *Division and Cohesion in Democracy: A Study of Norway* (1966). Studies of constitutional development include: H.J. SPIRO (ed.), *Patterns of African Development: Five Comparisons* (1967); B.O. NWABUEZE, *Constitutionism in the Emergent States* (1973); W.B. SIMONS, *The Constitutions of the Communist World* (1980); and L.W. BEER (ed.), *Constitutionalism in Asia: Asian Views of the American Influence* (1979).

## Consumer Credit

Consumer credit consists of short- and intermediate-term loans used to finance the purchase of commodities or services for personal consumption or to refinance debts incurred for such purposes. Consumer loans facilitate the purchase of automobiles, refrigerators, and other durable goods by enabling buyers to draw upon future income. The loans may be supplied by lenders in the form of cash loans or by sellers in the form of sales credit.

The volume of consumer credit available and used in industrialized countries has grown rapidly as more and more people have come to receive regular income in the form of fixed wages and salaries and as mass markets for durable consumer goods have become established. Its first growth was in the United States after World War I, but it subsequently developed on a large scale in other industrialized countries, especially in western Europe. The Soviet Union and other Communist countries began to introduce retail installment sales in the 1960s.

### TYPES OF CONSUMER CREDIT

**Installment credit.** Consumer loans may be classified into two broad categories: installment loans, to be repaid in two or more payments; and noninstallment loans, to be repaid in a lump sum. Installment loans, which are by far the most important, include (1) automobile loans, (2) loans for other consumer goods, (3) home repair and modernization loans, (4) personal loans, and (5) credit-card purchases. These are extended by many lenders, including commercial banks, sales finance and consumer finance companies, credit unions, savings and loan associations, mutual savings banks, pawnbrokers, and other financial intermediaries; installment loans in the form of sales credit are supplied by department stores, various other establishments, and financial institutions.

**Automobile loans.** Installment loans to finance the purchase of automobiles constitute the largest single segment of consumer credit. Approximately two-thirds of the new cars purchased in the United States between 1955 and 1980 were financed in this way. The terms of an automobile installment loan—the amount of the down payment, the term until maturity, and the interest rate—determine the size of the monthly payment. The maturity on loans for new cars has generally become standardized at 42 months, the down payment at about 20 percent, and the finance charge at 14–17 percent. When the terms on automobile loans are tightened, sales of automobiles decline because consumers become less willing to borrow.

**Other consumer goods loans.** Installment loans are also used for purchasing household appliances, boats, jewelry, furnishings, and mobile homes. They may be either cash loans or sales credit. This category also includes various types of revolving-credit and bank credit-card plans; these give consumers explicit credit limits that may be drawn upon at any time and are not necessarily restricted to the financing of particular durables.

**Repair and modernization loans.** Installment loans to finance home repairs and improvements usually have longer terms than do other types of installment credit. These loans typically have maturities of five to seven years.

**Personal loans.** Unsecured loans may be extended on a personal basis rather than for the purchase of durable goods. They may be used to pay taxes, to consolidate other debts, or to finance education and travel costs, auto repairs, and medical or funeral expenses.

Types of  
lenders

**Credit-card purchases.** Credit cards are issued by retailers and banks and offer the consumer revolving credit. A cardholder may defer payment on credit card purchases for up to 28 days, after which there is a finance charge on the unpaid balance. There were about 712,000,000 credit cards in 1978, 586,300,000 of them in the United States.

**Noninstallment credit.** Some consumer loans are designed to be repaid in a lump sum. The most common of these are single-payment loans by financial institutions, charge accounts of retail stores, and service credit extended by doctors, hospitals, and utility companies.

#### THE HISTORICAL DEVELOPMENT OF CONSUMER CREDIT IN INDUSTRIALIZED COUNTRIES

The tremendous growth in consumer lending after World War I was of fundamental importance in the development of mass markets for consumer durables and luxury goods. In many countries it required a change in the traditional attitudes toward moneylending. In medieval Europe, consumer loans were generally regarded as nonproductive, and charging interest on such loans was considered usury. Laws established maximum rates of interest and regulated the conditions under which loans could be made. The rise of capitalism brought about a rethinking of the concept of credit, led by such men as the French economist A.R.J. Turgot and the British philosopher Jeremy Bentham, who attacked the basic idea of legal control of interest rates. By the latter part of the 19th century their teachings had led to the abandonment of all control over interest rates in England and in most other countries of Europe.

The interest rate question. The repeal of the statutory maximum interest rate in England left unsolved the question of whether a particular rate was fair or unfair. The courts groped their way through innumerable cases of abuse and extortion, particularly in personal loans, to a method of providing relief when the transaction was harsh or unconscionable. A decision in 1880 established the power of chancery to reopen any interest transaction in order to relieve a borrower of excessive interest and in other ways soften the terms of an offensive contract. This power was subsequently incorporated in English statutes. Protection for installment purchasers was provided by the Hire Purchase Act of 1938 and subsequent enactments. In 1958 British banks began to offer their depositors personal loans for any reasonable purpose without security, in amounts from 50 to 500 pounds and at an effective rate of about 10 percent. West German banks began to do likewise in 1959 with loans of DM. 300 to DM. 2,000.

In the United States the so-called usury laws setting maximum interest rates remained on the books until well into the 20th century in most states. The maximum rate was often as low as 6 percent. As a result established financial institutions could not earn a reasonable profit on consumer loans, and they left the field to illegal lenders—commonly called loan sharks—who charged extremely high interest rates and used strong-arm collection techniques. These abuses stirred efforts to find other ways of meeting the legitimate needs of lower income borrowers.

One method followed by the Russell Sage Foundation, in its pioneering draft of a model small-loan law, was to recognize the purveyor of credit as a responsible businessman who must make a reasonable profit. This formed the basis of much state legislation in the United States. Such legislation requires verification of the lender's fitness and good character, along with licensing, supervision, and annual reports, imposes severe penalties for infractions, sets a maximum size for loans, and in some states establishes a monthly rate on the unpaid principal balance on the smallest loans, with graduated lower rates on larger loans. Such lenders are called loan companies, licensed lenders, or consumer finance companies.

The loan and investment approach known in the United States as the Morris Plan, founded in 1910 by Arthur J. Morris, follows the traditional bank method for business loans. The borrower contracts for a term loan at the statutory rate and agrees to make periodic deposits or to buy an investment certificate on the installment plan. Deposits or the paid-up certificate are sufficient to liquidate the loan upon maturity. The economic effect of the dual

transaction is that the initial loan is approximately twice the average loan outstanding, and the finance charge is double the contract rate.

Another way was to amend the state laws and permit the formation of credit unions by employees, members of fraternal organizations, and other groups. The first credit union in the United States was organized by a group of cotton mill workers in Manchester, New Hampshire, in 1909. There were about 22,000 credit unions by 1979. Credit-union members contribute to a common pool from which loans are made. Overhead is low because space, time, and effort are often contributed, permitting low interest rates. Until 1978, credit unions were the fastest growing type of financial institution in the United States. Some 20 states, however, have imposed a 12 percent usury ceiling on credit unions, making their position precarious when interest rates higher than that limit prevail.

As the production of automobiles and other household appliances grew, retailers often allowed customers the privilege of extended payments in return for a higher price, and out of this practice developed a legal notion called the time-price doctrine. Under this doctrine U.S. courts have held that the difference between a cash price of \$100 and a sales credit price of \$120 (\$10 a month for 12 months) is not interest, since no loan of money has taken place, but simply a time-price differential not subject to the usury laws. This legal distinction has influenced the regulation of retail sales financing in many states.

An indirect type of financing has been developed by sales finance companies, which buy, at a discount from dealers, notes given by consumers for time-payment purchases that they are unable or unwilling to pay in a lump sum. Effective rates since the early 1960s have run from 12 to 24 percent. Starting in the late 1930s, commercial banks also became heavily engaged in consumer credit.

A consequence of these ad hoc statutes and piecemeal regulations in the United States has been to fragment the consumer credit market, which from an economic point of view is essentially a single market. In the late 1970s, more than two-thirds of the states had separate laws for retail financing, industrial loans, and installment loans; nearly all of the states had special small loan and credit union laws. Many lenders were restricted by these laws to statewide or even to local markets, to a particular kind of loan, or to a particular kind of transaction. Thus commercial banks and credit unions were not allowed to deal directly in second-mortgage real estate financing. Retailers could not make cash loans. Finance companies could not make revolving loans, though retailers could. Various proposals were made to remove some of the restrictions on the ground that a more efficient consumer-credit market would result. The U.S. Credit Control Act of 1969 imposed a degree of uniformity on the consumer-credit market by giving the Federal Reserve authority to regulate the credit activities of all lenders nationwide, including department stores and finance companies.

The cost of credit. The finance charges on consumer loans run higher than the interest costs of business loans for several reasons. Most consumer loans are for relatively small amounts, and the costs of lending do not decrease for small loans. On the contrary, they increase in proportion to the total amount borrowed. These costs include credit investigation—more expensive in the case of a private household than of a business—and the expense of processing the loan. Charges range from 12 percent per annum to several times that amount on small, unsecured cash loans. The cost of borrowing is usually disguised by the way in which the charges are quoted. A loan of \$100 for a year may call for repayment in monthly installments of \$106; this is often described as \$100 plus a 6 percent "add-on rate." Or the loan may be of \$100 minus a 6 percent "discount," with monthly repayments of \$100. Or the interest may be charged at "1 percent per month" for a year. In each case, however, the actual charge to the borrower is 12 percent or more because interest is assessed on the full loan throughout the repayment period.

In the simple retail charge account, where there is no interest fee, the costs are borne by the seller or, in a sense, by the seller's customers in the form of higher prices.

Usury  
laws  
in the  
United  
States

Finance  
charges

In the United States during the late 1960s, there was much support among consumers for "truth-in-lending" laws to require lenders to disclose the actual cost of borrowing. This led to the Truth-in-Lending Act, which took effect in July 1969. An important provision requires lenders to state the effective finance charge in terms of an annual percentage rate, as a measure of the relative cost of credit in percentage terms, so borrowers may compare a finance charge stated in terms of dollars per month with perhaps a finance charge stated as an annual add-on rate.

It has been argued that changes in down payments, loan-to-value ratios, and maturities have a bigger effect on monthly payments than do changes in the finance rates and that borrowers may therefore be more sensitive to these other credit terms than to finance rates. The disclosure requirements under the 1969 law may provide some evidence on this point.

Other proposals have sought to simplify the rules under which lenders operate in the consumer credit market. These would include a uniform set of regulations applying to all lenders and to all consumer credit transactions as well as measures to encourage the entry of new lenders into the market, to facilitate more effective competition among existing lenders, and to provide borrowers with legal remedies for the redress of some abuses. In the United Kingdom a committee recommended in March 1971 that the existing accumulation of laws relating to consumer credit be replaced by uniform legislation. It proposed, among other things, that government controls over the terms of credit be abandoned and that lenders be required to state the true annual rate of interest being charged.

THE DIMENSIONS OF CONSUMER CREDIT

Quantitative estimates of the relative importance of various kinds of consumer credit are available for the United States, where it plays a larger part than it does in most other countries. The total amount of credit outstanding grew from \$21,500,000,000 in 1950 to \$380,200,000,000 in 1980, or from 7.5 percent of the gross national product to more than 14 percent. Installment loans grew from \$14,700,000,000 in 1950 to \$308,000,000,000 in 1980, as shown in the table. The relative amount of credit supplied

Credit and the economy

Major Categories of Consumer Credit in the United States, Selected Years (\$000,000,000)				
year	total consumer credit	installment credit		noninstallment credit
		total	automobile	
1950	21.5	14.7	6.1	6.8
1960	56.0	42.8	17.7	13.2
1970	126.8	101.2	35.5	25.6
1975	193.2	159.2	53.5	34.0
1980	380.2	308.0	116.5	72.2

Source: *Federal Reserve Bulletin*.

by retailers declined during the same period from about 20 percent to less than 9 percent, while the proportion supplied by commercial banks, credit unions, savings and loan institutions, and mutual savings banks rose to nearly 90 percent. Revolving credit reached \$55,500,000,000 by 1979, a threefold increase since 1976. Well over half of all U.S. households had installment loans outstanding in 1980, as compared with less than a quarter in 1950.

Official British statistics distinguish two categories of consumer credit. One comprises "hire purchase" and related types of installment purchases; the second consists of most other commercial forms of short-term credit, including credit cards. The total volume of credit outstanding in the two categories indicates that by 1980 consumer credit as a percentage of personal income in the United Kingdom (7 percent), was less than half that of the United States (18 percent). Comparisons among countries are difficult to make; according to one estimate, in 1967 the debt outstanding on passenger cars and other consumer goods was 4.2 percent of disposable income in the United Kingdom, 7.3 percent in Australia, 11.8 per-

cent in Canada, and 9.6 percent in the United States (N. Runcie, *The Economics of Instalment Credit*, 1969, p. 94).

The immense growth in consumer credit has raised the question of whether this mass of debt may have a destabilizing effect on an economy. If consumer credit is added to mortgage debt, then total household debt in the United States in 1980 reached \$1,727,155,000,000 (as compared with \$75,500,000,000 in 1950), or more than three-fourths of total personal income and savings. It is believed that consumer credit tends to increase when business is on the upswing, until consumers become so committed that their purchasing power for other purposes is reduced. If this is true it makes the economic system more vulnerable to shocks and exerts a downward pressure on economic activity. The fact that peaks and troughs in consumer credit accompany the peaks and troughs in business activity has been cited in support of this theory. But there is also some evidence suggesting that the supply of automobile loans may at times actually function as a stabilizer—by becoming more restrictive during peak levels of business activity and generally less so during recessions and the early stages of recovery. In general, changes in consumer credit do not appear as important an influence on economic activity as do changes in inventory accumulation or investment spending by businesses.

Efforts to control economic activity often include controls on the supply of consumer credit. Selective controls over consumer credit have been introduced in wartime and in times of severe inflation in the United States and the United Kingdom to discourage expenditures on consumer durable goods. The British monetary authorities administered selective consumer credit controls in the 1960s as a stabilization measure to help reduce inflationary pressures, while in 1980 the U.S. Federal Reserve Board briefly imposed limits on consumer credit. The most common methods of control are requiring a larger down payment, setting a maximum loan-to-value ratio, and shortening the repayment period. Selective controls are not popular, and their administration requires extensive monitoring. Stabilization efforts also may rely on monetary measures to influence the cost and availability of credit. Changes in money supply have a significant impact on the supply, availability, and cost of consumer loans, though the effects seem to be felt even more strongly in areas such as the home mortgage market.

Credit controls

CURRAN, *Trends in Consumer Credit Legislation* (1965); NATIONAL CONFERENCE OF COMMISSIONERS ON UNIFORM STATE LAWS, *The Uniform Consumer Credit Code* (1968); and the SENATE COMMITTEE ON BANKING AND CURRENCY, *Truth in Lending, 1967* (1967).

(D.I.F.)

Consumerism

Widespread concern about consumer protection and the growth of organizations whose objectives are to disseminate information about products and to persuade industry to provide better quality goods and services—both parts of a phenomenon usually described as consumerism—were largely developments of the 1960s and 1970s. It is possible, however, to point to examples of laws in ancient cultures whose purpose was to protect the purchaser. These included proscriptions against selling short-weight or adulterated goods, medieval concepts of a "just price," and laws against usury and the manipulation of markets. In some countries, legislation of the later 19th and early 20th centuries still serves as the basis of consumer protection, though such measures in the past were directed largely at marginal abuses or, in the case of more recent

The  
consumer's  
position in  
common  
law

legislation, at products, such as food and drugs, that may constitute a threat to public safety if certain minimum standards are not observed.

The fundamental relation between buyer and seller, however, was, and to some extent remains, that which is implied in the common-law maxim *caveat emptor* ("let the buyer beware"), according to which the onus is placed on the buyer to protect his own interests by ensuring that what he purchases is of sufficient quality to meet his needs. This doctrine, which has been progressively modified in the interests of the consumer to the extent that the law is governed more by the exceptions than by the rule itself, accorded well with the principle of *laissez-faire* capitalism that the buyer is served best by free competition between sellers. Certain changes that have occurred over the past century in the nature of industrial corporations and in the types of products available to the consumer have rendered this assumption invalid. First may be cited the growth of large corporations exerting monopoly influences—*i.e.*, setting prices and standards of quality for a particular product, so that the consumer is no longer afforded the opportunity to choose among effectively competing suppliers. Such corporations do not have to control a product's entire market, which may in fact be divided among several suppliers who offer the consumer products so similar in terms of price and quality that effective choice is impossible. Sometimes the impression of competition may be created by heavy advertising of "competing" brands or makes. Such a situation, known to economists as one of oligopoly, has often been typical of the markets for detergents and automobiles.

A second factor that has weakened the effectiveness of the consumer in protecting his own interests by rational choice among competing alternatives is the complexity of the products that modern technology has made available. There is, for example, little basis on which the consumer can decide between the merits of two different television sets, vacuum cleaners, or patent drugs without a mass of technical information, which he would probably be unable to evaluate even if it were given to him.

A third factor that is commonly alleged to have eroded the consumer's capacity to choose effectively in his own best interest is his increasing exposure to advertising and to new sales techniques. Advertising, it is argued, is predominantly persuasive rather than informative, serves to create demand for products that are unneeded, and often exploits the hidden fears, insecurities, and prejudices of the consumer; further, modern sales methods, ranging from so-called "introductory offers," "free gifts," and trading stamps to the "high-pressure" techniques practiced by door-to-door salesmen, are alleged to subject the consumer to an unjustified degree of influence.

It is against this background that a variety of pressures and methods for protecting consumer interests have developed.

#### MAIN AREAS OF REGULATION

As mentioned above, the common law has long provided certain safeguards to buyers, some of which have subsequently been incorporated into legislation. Of the safeguards derived from common law, the most important one—embodied in England's Sale of Goods Act (1893)—is the one that states that, whenever a buyer, expressly or by implication, makes known to the seller the particular purpose for which the goods are required, thus relying on the seller's skill or judgment, there is an implied condition that the goods sold shall be reasonably fit for such a purpose.

Other early legislation dealt mainly with adulteration of food and drugs. This was true, for example, of the Adulteration of Food and Drugs Act of 1872 (England) and similar, cumulative measures of 1848, 1890, and 1906 in the United States. The scope of such acts has been enlarged from time to time to include, for example, goods such as electrical products and automobiles, which could endanger the safety of the consumer if certain standards are not met. The provisions of such legislation are necessarily complex and vary from country to country, as well as, in the United States, from state to state. Various non-

statutory controls, such as standards laid down by national-standards institutions (see below), also interact with statutory controls. In the following survey both the statutory and non-statutory aspects of this subject are considered together.

**Controls on manufacturing and design.** Legislative controls. Of all industries, food and drugs are the most controlled by legislation. Other products in general are controlled by standards institutions, which lay down basic minimum standards for many different kinds of products. Legislative controls applying to food and drug manufacturers prohibit them from adding or removing anything from the product they sell that would make it injurious to health. Although this might appear to afford absolute protection for the consumer, manufacturers sometimes unwittingly add ingredients that are subsequently found to be harmful—for example, cyclamates, which were used for some years as an artificial sweetener. The frequency of such occurrences will clearly depend on the rigour of the standards of the official testing agencies concerned and the stringency with which such standards are applied.

Standards institutions. For nonfood products, legislation is less easily devised and far less easily enforced. Most countries, nevertheless, have developed minimum applicable standards. National-standards institutions were, in many instances, set up more for the benefit of manufacturers than for that of the ordinary, domestic consumer. In addition, government bodies were often formed to better control government purchasing. In the United States, for example, the General Services Administration laid down specifications and quality standards that had to be satisfied before the federal government would buy supplies. Other standards bodies, such as the British Standards Institute, started in 1901, were set up for the convenience of manufacturers so that one manufacturer's goods could be used in conjunction with another's, as in the standardization of electrical fittings.

By the 1950s, standards organizations had become far more aware of the needs of the ordinary consumer, but their legal status, for the most part, remained unaltered. Most recommendations are devised with the cooperation of industry, government departments, and consumers. The standards themselves are not usually legally enforceable but remain voluntary. They usually do not reflect the quality of the product as a whole but deal only with a specific aspect of it. The mark of a standards institution, for example, may well indicate that a hair dryer is sufficiently insulated against electrical-shock hazards, but not that it dries hair satisfactorily.

Though standards institutions in various countries may differ in some aspects, they are all basically the same. Some are entirely financed by the government (as in India); some are part of a government department (as in Japan); others are a mixture, as in the United States, where the General Services Administration is a federal agency and the American National Standards Institute (American Standards Association) is financed by manufacturers. For the world as a whole, the International Standards Organization draws up standards that can be adopted by all countries. Again, compliance with such standards is optional.

**Weaknesses of standards controls.** Although the standards institutions have assisted in raising the quality of many consumer products, their grip is weak. Most standards result from decisions of committees in which manufacturers usually have the final say. The recommended standard is thus more often a reflection of the industry's conscience than of the standard that would be required to provide satisfaction for the consumer. The standards laid down by manufacturers for a product can be so low that the consumer benefits little, if at all. Further, almost all standards refer to the safety of a product and not to its efficiency; and, with only a few exceptions, the recommendations of standards agencies are voluntary. The decision whether to adopt the standard is up to the company that markets the product, and such a decision necessarily involves an assessment of possible costs and returns. It is unfortunate that, in many

Usually  
unenforce-  
able  
voluntary  
standards

Early  
legislation  
concerning  
food and  
drugs

countries, the selling power of the standards symbol is less substantial than that of a good promotion campaign. Consumers, it would appear, are not sufficiently aware of the presence and significance of these symbols, perhaps because they tend to be little publicized by the manufacturers.

Apart from the formulation of standards, testing by various bodies occasionally results in the redesigning of certain products. Such testing has been most apparent in the automobile industry, in which cars have been recalled by their manufacturers so that alterations and improvements could be made. In the United States, for example, General Motors Corporation voluntarily recalled some 1,000,000 cars in 1971–72 for such changes.

Controls on advertising. Of all the criticisms levelled at manufacturers, those against their advertising probably have been the most vociferous. Advertising is necessarily vulnerable to these attacks: it is experienced by everybody, its products are on show for a long time, and its purposes are materialistic. Although the major purpose of company advertising, which is to attract members of the public toward buying a particular product, is fairly straightforward, the methods employed in this process have become increasingly complex. As business has become more competitive, so has the advertising that sells its products. Coupled with this increased competition has been the development of more powerful media—the most important of these being television.

Criticisms of advertising can be broadly divided into two: those that affect the consumer directly, and those that are concerned with economic matters, particularly the structure of industry.

From the consumer's point of view, the basic criticism of advertising is that it leads him to purchase goods that he has no wish to purchase by presenting misleading and untruthful statements or by creating wants, needs, and desires in his mind that might not otherwise exist. In the first instance it is accepted that the consumer, of his own volition, has a need that is filled by the description of the advertised product (but not necessarily by the product itself), whereas in the second the need is artificial and is stimulated entirely by the media.

From an economic viewpoint, critics of advertising point to the enormous amount of money involved—money that, they state, does not benefit the consumer although he is compelled to pay it. A second criticism is that advertising restricts competition because only large companies can afford expensive, nationwide campaigns, thus limiting freedom of entry of new firms into an established market.

A definitive answer to both these questions is obviously impossible. Regarding the first, it might be fair to say that economic growth and the creation of wealth might come about far more slowly without the aid of advertising. The development of national rather than regional brands—and the economies of scale implicit in this development—might be retarded. For all its drawbacks, advertising informs the consumer and enables him to make not only a choice between products but also a choice between the stores at which he can buy those products. For the manufacturer it justifies a heavy investment in capital and manpower in that it assures (to some degree at least) the quick development of sales.

Regarding the second major criticism—that advertising encourages the concentration of industry—there is no doubt that this is true. But not everyone agrees that industrial concentration necessarily acts against the interests of the consumer, particularly in the absence of outright monopolies or cartels. In some countries, such as the United States and Great Britain, anti-trust or monopoly laws act to restrain the more flagrant abuses of industrial power. Other countries, especially some in western Europe, have established monopolies boards, which monitor or oversee activities of large corporations in the field of takeovers and mergers.

The advertising industry has for many years been aware of the various criticisms and has accepted the need for some control over advertising methods in addition to the provisions of statutory regulations that exist in many

countries. In the United States the Federal Trade Commission can stop advertising it considers misleading. In the United Kingdom the Department of Trade and Industry has some powers to do this under the Merchandise Marks Act. These powers are necessarily used in conditions of the last resort, the advertising industry itself preferring to control its members voluntarily. One method of self-control has been the establishment prior to World War II of the International Code of Standards of Advertising Practice under the auspices of the International Chamber of Commerce; it codifies the views common to national advertising groups on what constitutes good practice.

The country with the most stringent advertising standards is usually thought to be Great Britain, where, for example, all television advertising is controlled by the Independent Television Authority (ITA). The ITA lays down some 32 separate controls on advertising, banning the use, for instance, of subliminal advertising (methods by which the viewer might be influenced without his becoming aware of it) and of advertising that plays on fear and on the minds of the superstitious.

The ITA has a further list of unacceptable products and services; in the early 1970s it included cigarettes, bookmakers, undertakers, fortunetellers, and matrimonial agencies. Other regulations involve methods of television reproduction, the wording and advertising of guarantees, and the enforcement of prices and other offers; furthermore, special conditions exist in specific cases—the viewing child, the employment of children in advertisements, and the advertising of certain products such as medicines and drugs and also finance.

The general character of governmental and private controls over the claims and methods of advertisers may be said to be one of considerable laxity. It seems likely that this situation will be changed not so much by the introduction of more stringent codes as by challenges to particular advertisers by consumer interest groups within the framework of existing legislation regarding truth in advertising.

Labelling standards. Labelling can be used either to inform or to deceive the consumer, and manufacturers, in their sales efforts, are often tempted by the latter expedient. Minimum standards of labelling exist for some products, but, as with controls on manufacturing quality, legislation tends to concentrate on food and drugs. Usually, every container carries a statement of contents, but, apart from food and drugs, content identification is not usually required. If it is provided, however, it must not misrepresent. In general, this means that labelling, when it is present at all, tends to be accurate.

Consumer movements and official bodies have, in many countries, seen the need for better systems of product labelling. Of methods proposed, one of the best may be the Varudeklarationsnämnden (Quality Labelling Board) system adopted by Sweden, which is financed by the Swedish government in conjunction with various national business and consumer organizations. In this system, labels must describe the most important characteristics of the product and must do so in words that by any standards are explicit, many being more than 200 words long. Price labels are of further importance to the consumer. With the advent of self-service shopping, the need for goods to be priced correctly is essential. Vendors, however, are under no legal obligation to indicate prices, and a major criticism by consumer groups has been that, even when prices are indicated, it is often difficult to make price comparisons because of the lack of standardization of the weights, or volumes of packages in which a product is sold.

Controls on sales methods. Generalizations cannot be made concerning statutory controls on sales methods because they vary from place to place. Sales practices have been controlled for over a century; early regulations were largely concerned with peddlers and hawkers. Legal progress has, in general, imposed a stricter control of selling methods to reduce the incidence of deception.

Particularly difficult to control is door-to-door selling, a method that for many years has drawn criticism from the

Regulation  
of  
labelling  
in Sweden

general public, even though the majority of door-to-door salesmen are fair and reputable tradesmen. Vacuum cleaners, floor polishers, sewing machines, and encyclopaedias have been sold by this method, some by salesmen who have exploited the purchasers' vulnerability. Salesmen's tactics often go far beyond the common foot-in-the-door technique. To persuade people to enter into a heavy financial commitment, salesmen have been known to misstate the terms of payment or the trade-in allowance, to conceal figures on the order form or agreement, and to resort to other deceptive practices. Some countries have outlawed such deceptions. In Sweden a Door-to-Door Selling Act leaves buyers free to withdraw from contracts signed in their own homes and at exhibition stands within a period of seven days. A similar law in Britain specifies a period of four days. Some American states likewise provide statutory protection. The Swedish legislation is part of a package designed to help the consumer and includes an Undesirable Terms of Trading Act (for monitoring standard contracts) and further legislation regarding credit sales and hire purchase, legal aid, holiday travel, and foodstuffs.

Switch  
selling

Another technique used in direct sales is that of switch selling. The salesman attracts his victims by placing an advertisement offering a domestic article at a remarkably low price; this is known as the "bait." Inquirers are personally visited by a salesman, who, from the outset, makes no attempt to sell them the product advertised. Having convinced the inquirer that the model is not worth buying, the salesman goes on to offer the customer another model that he happens to have with him at, of course, a higher price. Although this and similar methods often are in violation of statutes governing the sale of goods, enforcement is difficult. Extra protection is provided by legislation in some countries, and, in others, non-statutory regulations protect the consumer.

#### THE CONSUMER MOVEMENT

**The development of private consumer associations.** In the four broad fields of manufacturing, advertising, labeling, and selling, legislation in most countries provides a background of protection for the consumer. Nevertheless, gaps remain, partly from ignorance on the part of consumers themselves and partly from the reluctance of most governments to unduly restrict the activities of business.

As industry and commerce have developed during the 20th century, pressures on the consumer have adversely affected the balance of power between buyer and seller. The recognition of this imbalance and the desire to restore it originated in the United States. In 1927 an economist, Stuart Chase, and an engineer from the American Standards Association, F.J. Schlink, wrote *Your Money's Worth*, a book about the activities of the National Bureau of Standards—the organization that tests all goods supplied to government departments and services. Their book, a best seller, concluded that the government was indeed getting its money's worth; it furthermore concluded that most consumers were not—mainly because they did not pay sufficient attention to the real values of the goods they were buying. This was the beginning of an association, run by Schlink, called Consumers' Research, from which a splinter group, formed in 1935 by a close associate of Schlink, Arthur Kallet, emerged as the Consumers' Union of United States in 1936. The character of this organization, which proclaimed that the function of the union was "... to provide consumer information and counsel relating to consumer goods and services, to give information and assistance on matters relating to the expenditure of the family income. . . to initiate and to cooperate with individual and group efforts seeking to create and maintain decent living standards. . ." has been emulated and adapted by consumer groups operating in nearly every country in the world.

The Consumers' Union always was, and remains, totally independent of either industry or government. Its finance is derived solely from its members, who in 1971 numbered just over 1,800,000. Other associations have tended to differ in this regard, many of them government fi-

Objectives  
of the  
Con-  
sumers'  
Union

nanced either wholly or in part. In Sweden, for example, the government took over the Institute of Consumer Information in 1957. The Swedish organization aims not only to inform the shopper of products that provide value for money but also to influence and cooperate with industry so that better products are made. The influence of the Consumers' Union in the United States on manufacturers is far more indirect and derives from its influence over consumers.

Until 1957 the Consumers' Union concentrated much of its effort on the production of comparative test reports on consumer goods. In that year, Arthur Kallet, the original director, was not reappointed. Instead, Dexter Masters, a journalist, was asked to head the team. This move from engineer to journalist was mirrored by the broadening interest of the union in the wider aspects of consumer protection. It became more concerned with the problems of obtaining justice for the consumer—attacking, for example, such practices as selling cosmetics in jars with false bottoms, cereals in packets only three-quarters full, and goods at odd weights and at odd prices. Further, it has sometimes been argued that from the late 1950s the Consumers' Union began to adopt a slightly ideological approach to consumer protection, reflecting to some extent a general antipathy to big business and profit making.

Consumer associations in other parts of the world do not generally share this outlook, although they do tend to concentrate either on product testing or on the wider ranging issues of consumer protection. In Great Britain, for example, the Consumers' Association, an independent, self-financed organization, is largely oriented toward product testing, whereas in Germany, the *Arbeitsgemeinschaft der Verbraucherverbände* (Consumers' Union of the Working Community), financed by 20 member bodies, takes after the modern-day Consumers' Union, campaigning for consumers particularly on issues such as labelling and standardization. In France, the *Organisation Générale des Consommateurs* is concerned with general aspects of interest to consumers as much as with comparative testing. Also in France, the *Union Fédérale de la Consommation*, an independently financed organization that published comparative tests, was forced to cease operations because of a lack of sufficient interest.

Consumer organization in Japan differs considerably from that in other countries. First, it is extensive and increasingly well organized, particularly in consumer-boycott activity. Second, it is largely made up of women—500 housewives' groups, for example, comprise the biggest organization, called Shufuren. Through its quarterly magazine, Shufuren keeps its members informed of policy decisions—and also of which manufacturers are on its blacklist. Shufuren is active in product testing as well as in boycotts, which, in fact, remains its main work. Its members, however, see the need for a coordinated effort to be conducted on many fronts. The rapid development of the Japanese economy, which has been conducted largely behind the shield of high tariff barriers, has enabled manufacturers in Japan to have their own way for much of the time. Groups such as Shufuren are ensuring that this will change.

The increasing activism of certain sectors of the consumer movement has led to the formation of splinter groups of the well-established consumer associations. Of these, the U.S. consumerist Ralph Nader and his "raid-ers" (a group of mainly young helpers who gather information concerning suspected abuses) have received the greatest publicity. Nader has applied his own individual style to consumer protection, directing his campaigns mainly at particular manufacturers and their products. Nader's successes have been considerable and have been achieved largely by the effect of adverse publicity on manufacturers, rather than through the courts. His group also has acquired single shares of the stock of large industrial companies in order that it may monitor and, if necessary, criticize from the inside the operations and activities of these companies. Other similar groups have been formed on both sides of the Atlantic. Characteristically, their scope of operations is far wider than that of the original consumer organizations. They are, for ex-

Con-  
sumers'  
organiza-  
tions in  
Japan

ample, constantly directing attention to the social, ecological, and environmental problems that are affecting society.

**International organization of consumer movements.** The development of uniform business techniques throughout the world, particularly in the areas of marketing, advertising, and manufacturing, coupled with the growth of multinational companies, increasingly has brought about the supplying of international markets with the same goods. Consumer organizations from different countries consequently have begun to pool their resources. Thus, in the European Economic Community (EEC), or Common Market, the member countries have set up, within the EEC's commission, a Committee of Contact that is designed to represent the interests of consumers throughout the Common Market. The Committee of Contact also organizes comparative tests, known as Euro-tests, of products common to all markets.

In addition to regional groups, the International Organization of Consumers Unions (IOCU) provides for international coordination and cooperation. The IOCU, which was set up in 1960, was originally devised as a clearinghouse for testing methods, but over the years it has developed into an international forum for all kinds of consumer problems. One of its more important functions is the representation that it provides consumers within such international agencies as the Economic and Social Council of the United Nations. Strict rules limit the membership of the IOCU, particularly with regard to members' commercial and political links, and these constraints have tended to prevent the more politically oriented organizations from joining. However, the increasing interest in political matters that has been shown by some of the founder members, such as the Consumers Union, may force the international organization to change its policy. It seems likely, however, that the influence of the IOCU will continue to develop because its operations and methods of procedure are responsible and its suggestions tend to be practical and constructive.

**BIBLIOGRAPHY.** The literature on consumers and their problems transcends national boundaries. GUNTER VOIGT and WALTER BERNAUER, *Der Verbraucher im gemeinsamen Markt* (1963), deals with the countries of the European Economic Community. A broader approach is JEAN MEYNAUD, *La Défense des consommateurs dans les sociétés capitalistes* (1968). Two Japanese books on the consumer are NORIYUKI OGI, *Shōhisha mondai o kangaeru* (1969); and KAZUKI DAIMON, *Tōdatsu no ronri* (1970). A French study is UNION FÉMININE CIVIQUE ET SOCIALE, *A la recherche du bien commun* (1966). British books include GORDON J. BORRIE and AUBREY L. DAIMOND, *The Consumer, Society and the Law*, 2nd ed. (1968); and JOHN MARTIN and GEORGE W. SMITH, *The Consumer Interest* (1968). Among books published in the United States are: JOANNE MANNING-ANDERSON, *For the People* (1977); JAMES BISHOP, JR. and HENRY W. HUBBARD, *Let the Seller Beware* (1969); JEAN ENDE and CLIFFORD J. EARL, *Buy It Right* (1974); ROBERT N. KATZ (ed.), *Protecting the Consumer Interest* (1976); GRANT S. MCCLELLAN (ed.), *The Consuming Public* (1968); WARREN G. MAGNUSON and JEAN CARPER, *The Dark Side of the Marketplace: The Plight of the American Consumer* (1968); SIDNEY K. MARGOLIUS, *The Innocent Consumer vs. the Exploiters* (1967); RALPH NADER, LOWELL DODGE, and RALF HOTCHKISS, *What to Do with Your Bad Car* (1971); and PAUL WASSERMAN (ed.), *Consumer Sourcebook*, 2nd ed., 2 vol. (1978).

(Mi.Do.)

## Consumption, Economic

In economics the word consumption means the using up of goods and services. In modern economic terms it means, specifically, "final" consumption as distinguished from the using up of goods to produce other goods in a manufacturing industry. Final consumption must also be distinguished from the purchase by industry of fixed assets such as buildings and machinery, which is known as capital formation or investment. On the other hand, consumption expenditure by private persons is understood to include the purchase of durable goods, such as furniture or vehicles, as well as works of art that may increase in value over a period of time. The acquisition of such goods should actually be considered asset formation rather than consumption and should be classified with the

acquisition of other assets such as houses, schools, roads, and hospitals.

In modern industrial economies, consumption as previously defined accounts for 70 or 80 percent of total national expenditure. Table 1 shows that even in the Western capitalist countries a significant part of total consumption is determined directly by the expenditure of public authorities. Some of the benefits of this part of consumption, such as expenditure on defense or on public health, are widely diffused; others are directed by common consent to the benefit of particular sections of the community. These consist in part of specialized services such as education or medical care; but other services—such as unemployment compensation, state pensions for the elderly, and assistance to families deprived of the support of a wage earner—are designed to create greater equality in levels of consumption than would otherwise be obtained.

## PATTERNS OF NATIONAL CONSUMPTION

The ways in which people spend their incomes show much uniformity among countries at the same economic level. Expenditure patterns in the United Kingdom, for example, are typical of western Europe. Table 2 shows how British consumers distributed their expenditures among the main categories of goods and services in 1949, 1959, 1969, and 1979. In 1949 the pattern was still affected by postwar shortages and rationing, but the level of total consumption was not very different from what it had been before the war. In the 30 years that followed, private consumption expenditure per person (measured at constant prices) doubled. In addition there was a great increase in public services such as health and education. Yet the broad distribution of expenditures remained strikingly constant in spite of the introduction of many new commodities and considerable changes in their relative prices. A number of differences can be seen in Table 2. The percentage of total expenditure devoted to food fell, a phenomenon that usually accompanies a rising standard of living, and the largest proportionate increases were in the purchase and maintenance of private motor vehicles, of furniture and household goods, and of radio, television, and electrical goods. These three categories represent in part net additions to private wealth in the form of durable goods, and both reflect the effect of technical progress. As in other industrial countries, much of the improvement in living standards has taken the form of more travel, better communication services, and the acquisition of labour-saving equipment.

This trend, which may be found in all industrial countries, is not new. Over the past 150 years a similar process has been at work on a still larger scale. In 1824 an English domestic economist suggested ways in which families with different incomes might budget their expenditures (Table 3). From actual budgets collected around that time, it would appear that such patterns were not atypical. Food expenditure then absorbed about one-half of the total, the fraction declining as income increased. Expenditure on clothing then was about twice the proportion of 1979, even though more clothes were made in the home. Fuel and light (in 1824 consisting of coal and candles) also absorbed about double the 1979 proportion of expenditures in working-class families. On the other hand, the relative proportion spent on housing has remained almost the same.

The category "other expenditure" increased most rapidly with income in 1824; in 1979 it accounted for 46 percent of all private expenditure. In 1824 expenditure in this category largely represented purchases of direct labour services for the household and to a lesser extent purchases of horses, carriages, and the services of grooms and stable boys. In 1979 such direct labour services accounted for less than half of 1 percent of total expenditure, though somewhat more than this if one includes services that were then performed mainly in the home and are now obtained almost exclusively in commercial establishments outside the home, such as hairdressing, catering, and vehicle maintenance. But in 1979 much of the "other expenditure" category was devoted to commodities that

either had not been invented or were not being distributed on a mass scale in 1824. These include books, newspapers, magazines, most modern drugstore items, recreational equipment, motor vehicles, and electrical equipment. Another substantial part of "other expenditure" today is absorbed by specialized nondomestic services such as insurance, entertainment, travel, private education, and health care.

Differences among countries

The changes in private consumption patterns are shown in Table 4. In most of the industrialized countries there has been a compound rate of increase in the total volume of consumption expenditure per person of 10 to 12 percent per year, the main exceptions to this being the United Kingdom and Japan, where consumption has grown at double this rate. But the pattern of change is similar in almost all countries. Food consumption has grown less rapidly than total consumption, particularly in the Scandinavian countries, West Germany, and the countries of North America, where the rate of increase has been about 7 percent per year; expenditure on clothing has been growing at about the same rate as total consumption. Increases in rent outlays reflect higher energy costs in all of the industrialized countries. The acquisition of durable goods continues at a very high rate in all countries.

Comparable data on consumption in the poorer countries of the world are much harder to obtain and are

usually less reliable, but it is probable that, expressed as a proportion of total consumption, food expenditure is about twice as important in much of Asia, Africa, and Latin America as it is in western Europe and North America. In the most economically advanced countries, food expenditure represents only one-quarter to one-third of the total, whereas in countries where the total expenditure per household is less than the equivalent of U.S. \$1,500, the proportion rises to one-half or even greater (Table 5). It should be noted that in the rural regions of poor countries the housing expenditure is minimal; in these areas shelter is rudimentary and largely self-provided.

Food consumption varies in character from country to country. This variation is due in part to climatic factors, and it also reflects differences in national food habits. The diet that is normally eaten in northern Europe and in Scandinavia is relatively low in fruit and vegetables but it contains a high proportion of milk, fats, and sugar. In France the consumption of vegetables and meat is relatively high. Fruit and vegetable consumption is generally high in southern Europe, while milk consumption in this area is low. In the Mediterranean countries food grains are generally preferred to potatoes and sugar as sources of carbohydrates.

But aside from these regional variations, the influence of general living standards is evident. The North American diet, for example, with its low grain and potato consumption and high consumption of sugar, meat, eggs, and fats is attributable more to a high standard of living than to any regional peculiarities of taste. These characteristics can be observed in the diets of the wealthier classes of most countries.

The influence of the general standard of living is also shown in the relative priorities that are accorded to the increased consumption of particular foods as incomes increase. These priorities are measured by economic statisticians in the form of income elasticities of expenditure, defined as the percentage increase in the consumption of an item divided by the percentage increase in income that makes the increased consumption possible. These elasticities are usually calculated for a given country by comparing the budgets of wealthy households with those of poor families. Table 6 shows that the income elasticities for most items of food expenditure in the United States and the United Kingdom are 0.3 or less. This means that an increase in income of 10 percent will produce an increase of 3 percent or less in food expenditure. In fact, the consumption of cereal foods in those countries actually decreases as incomes increase. In the less developed countries the elasticities are usually considerably higher, particularly for fruit and for products of animal origin. In these countries the consumption of carbohydrate foods is also increasing fairly rapidly as incomes rise. Surveys of household expenditures in many countries of Africa, Southeast Asia, and Latin America show total consumption levels of no more than 2,500 kilocalories per person per day in rural areas and low consumption levels of proteins and important vitamins. The difficulty of raising these nutritional levels is enhanced by the rapid rate of population growth.

#### FACTORS INFLUENCING CONSUMERS

The theory and measurement of consumer behaviour forms an important part of modern economic theory. It was first developed during the 19th century on the basis of the following conceptions: that the purchase of any commodity gives the consumer a positive satisfaction or utility; the additional satisfaction derived from additional purchases of the same commodity declines as the consumer's supply of that commodity increases; and with a given amount of money to spend, the consumer distributes the expenditure among commodities to maximize the total satisfaction or utility attainable from all those purchases. This rather crude model of consumer behaviour has undergone considerable refinement by modern mathematical

economists. The advantage of this approach, which has had a strong and enduring effect on the theoretical and empirical work of economists, is that it separates the main economic variables influencing consumer behaviour—that is, income and prices—from all the remaining influences, such as individual preferences, social pressures, customs, and habits, but at the same time it unites them in a single analytical apparatus. Critics have often objected that the model assumes a rational person bent on scrupulously maximizing his satisfaction and that the model is thus part of a mechanistic stream of thought that has been substantially undermined by 20th-century advances in psychology. Still, the only useful criterion of any hypothesis is the range of situations in which the derivative model is shown validly to predict events. For example, it is useful to assume that the leaves of a tree attempt to maximize the amount of sunlight they receive, since the assumption implies that leaves are denser on the sunny side of trees than on the shady side, which can be checked from experience, or that billiard players make their shots as if they knew the mathematical formulas of mechanics. Similarly, to assume that consumers behave as if they were rational utility maximizers helps to provide accurate predictions of a broad range of market phenomena; e.g., a fall in the price of a commodity will generally lead to increased consumption of that commodity, and an increase in consumer income will lead to increased consumption of most commodities. Only persistent discrepancies between predictions and events require a modification of the model's assumptions; some examples of such cases are discussed below.

The theory points to the income of consumers as the most important single determinant of their consumption patterns. It follows that in any community both the average income level and the distribution of incomes are important influences on total consumption. A community in which incomes are equally distributed consumes fewer luxury goods and fewer low-quality goods than one containing a few wealthy individuals and many poor people. Among wealthy people in early 19th-century England, a dinner with five main protein dishes—fish, meat, game, poultry, and ragout with truffles—was described as the minimum, while in poor years the families of agricultural labourers ate mainly oatmeal and potatoes; today the standardized produce of modern agriculture is part of most diets.

The classic model of consumers' behaviour implicitly assumes that the individual enjoys a constant income. In practice it may fluctuate according to the season, from year to year, or more generally over a lifetime. In the short run the consumption of some commodities is much affected by these income fluctuations, while the consumption of others is affected very little. Wage-earning households commonly have a weekly housekeeping allowance, out of which the necessities of food and clothing are bought, while the variable excess of earnings is spent on tobacco, alcoholic drinks, and entertainment. The expected average level of future income therefore influences consumption habits as much as actual present income, and commodities may be divided into two classes. The

Spending in relation to incomes

first consists of goods people buy when temporarily affluent but give up when temporarily poor, and the second consisting of goods for which the pleasure of a temporarily higher level of consumption would not be worth the financial or psychological cost of giving them up in the future.

Consumers can also be influenced by their previous incomes. A person who owns an expensive car may continue to use it after his income falls, though at the lower level of income the individual would not choose to replace it with a similarly expensive vehicle in the long run. This may be a rational decision, in the sense that the value of the car in use may be greater than what it is worth in the second-hand automobile market; or it may be irrational, in the sense that an expensive habit that should have been abandoned is continued beyond the point where it can rationally be supported. The distinction is largely subjective and cannot be clearly made by an outside observer.

Over the life cycle as a whole, consumption patterns are markedly **different** in various occupations. In most of the unskilled or **semiskilled** occupations, the course of earnings is fairly stable: a young worker of 21 may earn as much as an older person. But in many of the professions an individual of 50 or 60 may earn many times the income of a person of 21; this gives the young wage earner a strong incentive to incur considerable debt with the expectation of amortizing it steadily throughout life, so that the typical consumption pattern of the occupation can be achieved earlier than otherwise. This applies particularly to such major purchases as houses, household furniture and equipment, and vehicles. Manual workers, on the other hand, whose expectations are little greater than their present consumption, generally prefer to rent living space rather than to own a house and are unwilling to raise their current consumption standards by incurring commitments of a longer term than that of ordinary installment credit.

Non-rational influences

To be fully rational and consistent, consumers need to have access to **sufficient** information on goods and their prices so that they can choose those with the lowest unit price for a given quality. But consumers do not always behave this way. Natural pearls are sold at a much higher price than cultured pearls, though the difference between them is demonstrable only by dissection or with X-rays, and their quality in use is identical. Brand-name drugs sell better and at higher prices than unbranded drugs that are manufactured from the same standard formula. To some extent this is due to what an American economist, Thorstein Veblen, called the desire for conspicuous consumption: part of the attraction of the good is simply its high price. It is also the result of consumers' ignorance, made more acute by the increasing sophistication of commodities whose qualities must be measured in many dimensions. If it is costly in time for the individual to become fully informed about the comparative qualities of competing products, it is not wholly irrational for the consumer to take the market price as an indicator of quality. The lack of information has given rise to consumers' organizations in most industrialized countries; these organizations test and report on a wide range of products for their subscribers.

The influence of modern advertising techniques must also be considered. Insofar as advertising informs the consumer of the range of alternatives, it can be argued that advertising merely increases the consumer's information; and insofar as **advertising** consciously or subconsciously changes consumer preferences, it remains one of the many factors determining consumer preferences that the economist takes as given. Advertising, however, cannot persuade the public to buy whatever the producer offers. Advertising is likely to be most effective in influencing consumers to choose one of several almost identical products being offered, such as toothpaste, cigarettes, or gasoline. But it may also raise the demand for the group of competing products as a whole. In addition, it can be argued that the total effect of modern advertising is to shift the preferences of consumers in favour of luxury goods rather than necessities, in favour of con-

sumption rather than saving, and in favour of employment rather than leisure.

#### NECESSITIES AND LUXURIES

The distinction between necessities and luxuries is imprecise. The dividing line varies with the income and social class of the classifier and shifts as technology develops and as social values change. Only in the most undeveloped communities can necessities be defined purely in terms of physiological needs. Adam Smith wrote in 1776:

By necessities I understand not only the kind of commodities which are indispensably necessary for the support of life, but whatever the custom of the country renders it indecent for creditable people, even of the lowest order, to be without... Under necessities, therefore, I comprehend not only those things which nature, but those things which the established rules of decency have rendered necessary to the lowest rank of people. All other things I call luxuries; without meaning by this appellation to throw the smallest degree of reproach upon the temperate use of them. Beer and ale, for example, in Great Britain, and wine, even in the wine countries, I call luxuries. A man of any rank may, without any reproach, abstain totally from tasting such liquors. Nature does not render them necessary for the support of life, and custom nowhere renders it indecent to live without them.

In the 19th century, with the development of more mathematical methods of reasoning based on a utilitarian calculus, the distinction came to be **phrased differently**. Necessities were defined as those **commodities** the demand for which has an income elasticity less than unity, and luxuries as those with an income elasticity greater than unity. These definitions imply that as a worker's income increases the expenditure on necessities increases less than, and the expenditure on luxuries more than, proportionately. But even with the elasticity approach the distinction must vary over time. In 1950 the demand for television sets had a high income elasticity, whereas now, in some countries, television often is regarded as a necessity.

Economists of the early 19th century all believed that the living standards of the **working** classes in capitalist societies would remain close to a subsistence level, meaning that luxuries would be more or less permanently denied them. But in modern industrialized economies even the poor consume goods that the early economists would not have considered necessary.

The historical and social role of luxury consumption is a subject of much interest. In the Mediterranean city-states during the Renaissance, the demand for luxuries provided a mainspring for the specialization of **skilled** labour and for the development of foreign travel and long-distance trade. The duke of Milan, Filippo Maria Visconti, possessed valuable English dogs, leopards from all parts of the East, and hunting birds from northern Europe. Some writers have argued that the luxurious consumption of the rich benefits the poor through the provision of employment opportunities that would not otherwise exist. A subtler version of this idea was proposed by Adam Smith, who contrasted the uselessness of menial labour employed by the rich for personal services with the benefits flowing from the employment of craftsmen who created luxurious products of enduring merit that eventually became available to society as a whole:

The houses, the furniture, the clothing of the rich, in a little time, become useful to the inferior and middling ranks of people... What was formerly a seat of the family of Seymour is now an inn upon the Bath road. The marriage-bed of James the First... was, a few years ago, the ornament of an ale-house at Dunfermline.

But Smith and most of the economists who succeeded him believed that if the money spent on luxurious consumption by the rich was invested in useful production, society would benefit as a whole. The Industrial Revolution brought an increasing demand for funds for productive investment and made possible a more rapid rise in general standards of living than the world had known before. The classical economists thus argued that all luxury consumption involved a selfish diversion of labour and capital and acted as a brake on human progress.

This view was not seriously challenged until the English

Changing attitudes toward luxury

economist J.M. Keynes published his *General Theory of Employment, Interest and Money* in 1935–36. Writing at a time when millions of workers were unemployed, Keynes argued that the consumption of luxuries was socially desirable if it provided jobs that would otherwise not exist. He also suggested that capitalism might be outrunning its investment opportunities, so that in the long run the problem of finding employment for capital itself would arise—a difficulty that might be postponed if the wealthy spent more on themselves:

In so far as millionaires find their satisfaction in building mighty mansions to contain their bodies when alive and pyramids to shelter them after death, ...the day when abundance of capital will interfere with abundance of output may be postponed.

In industrial countries since World War II, this pessimistic view has been overborne by a seemingly endless expansion in consumer industries. As fast as consumers accumulate durable goods, these goods become technologically or conventionally obsolete and are replaced by new goods. Instead of seeking more leisure, previously thought to be one of the main benefits of technical progress, the populations of the industrialized countries seem to prefer to work in order to buy more luxuries. To this extent the desire for leisure and the demand for luxuries are in direct competition.

In communist countries, public consumption has long been treated as more important than private luxury. In the 1970s this emphasis seemed to be giving way to the aim of catching up with the standards of consumption that prevail in capitalist countries. In the undeveloped countries of the Third World, the tension between the demand for luxuries and the low standard of living gives rise to acute economic and social problems. The rapid growth of international travel and communications since World War II has led the literate and skilled classes of every nation to seek similar standards of private consumption regardless of their national environment. This, in undeveloped countries, leads either to a highly unbalanced distribution of the national income or to the emigration of the skilled population. Thus the increasing awareness of the consumption habits of the most fortunate sections of the world's population is both a spur and a hindrance to general progress.

CIPOLLA, *European Culture and Overseas Expansion* (1970), an account of the cultural and commercial contacts between Europeans, Africans, and Asians during the Renaissance; JOHN KENNETH GALBRAITH, *The Affluent Society*, 3rd ed. rev. (1976), a critical study of the social and economic consequences of advanced industrialism in which basic human needs can be easily satisfied, but in which the economy is geared to the pursuit of luxury consumption by the middle and higher income groups; S.S. KUZNETS, *Modern Economic Growth* (1966), a comparative study of the historical development of modern economies, based on exhaustive statistical studies; E.J. MISHAN, *The Costs of Economic Growth* (1967), a critique of the goal of economic growth as a major aim of policy; VANCE PACKARD, *The Hidden Persuaders*, rev. ed. (1980), a somewhat partisan attempt to show that advertising techniques create artificial wants through psychological manipulation; THORSTEIN VEBLEN, *The Theory of the Leisure Class* (1899, reissued 1979), an argument that the consumption of the wealthy classes is aimed mainly at demonstrating status rather than satisfying basic needs.

(J.A.C.B.)

## Continental Drift

The large-scale horizontal displacements of continents, relative to each other and to ocean basins, during one or more episodes of geological time is termed continental drift. The opposing view is that continents have grown in their original position from nuclei that had fixed positions of latitude and longitude at the original formation of the Earth's crust. Continental drift was first proposed in a comprehensive manner in 1912 by Alfred Wegener, a German astronomer and meteorologist. His radical interpretation of the Earth's history aroused international interest and violent controversy. By 1930 the majority of earth scientists had abandoned the drift hypothesis, main-

ly because of geophysical evidence that the crust and mantle are both solid and possess adequate strength to resist displacement by any known tangential forces. Interest in continental drift later revived dramatically as a result of advances in rock magnetism (*q.v.*), **geochronology**, and oceanography. Sea-floor spreading (*q.v.*), a concept first introduced about 1960, has given rise to plate tectonics, a synthesis of geological and geophysical observations that views the Earth's surface as divided into a few rigid plates undergoing rotational motion relative to each other. The early model of the continents as icebergs floating on a dense fluid is obsolete, but evidence favours a modified continental drift theory. Estimated rates of movement between continents, or crustal plates, range from one to 15 centimetres per year.

## HISTORICAL BACKGROUND

The apparent fit of the bulge of eastern South America into the bight of Africa, which can be seen on any map or globe, is a striking physical feature that has caused many scientists to speculate on continental drift.

**Early theories.** The English philosopher and author Francis Bacon was perhaps the first observer to comment in writing on the correspondence of the shorelines across the Atlantic; he suggested in 1620 that the similarities were not accidental. The German naturalist Alexander von Humboldt proposed around 1800 that the lands bordering the Atlantic were once joined and had been scoured apart by the waters of the ocean. During the 19th century, several investigators published discourses on drifting continents; they were largely ignored because scientific thought was then dominated by the contraction theory and its model of a cooling, shrinking Earth, its crust crumpling and shearing under compression, but with continents and ocean basins maintaining a permanent configuration.

The concept of continents floating in isostatic equilibrium in a dense substratum was proposed because of measured gravity anomalies during the second half of the 19th century. By this principle, vertical movements are attributed to mass changes in crustal columns that arise because of such factors as erosion, intrusion, and chemical or phase changes at depth. Although isostasy is fundamental to the continental drift hypothesis, it does not itself imply that large-scale horizontal motion is possible.

Between 1885 and 1909, an Austrian geologist, Eduard Suess, published his masterwork, *Das Antlitz der Erde* (English translation *The Face of the Earth*), in which he described the contracting Earth as consisting of three rock shells, for which he coined the terms "nife" (Ni-Fe, for

Nickel-Iron) for the core, "sima" (Si-Mg, for Silicon-Magnesium) for the mantle, and "sal" (Si-Al, for Silicon-Aluminum) for the crust. The last two names (with "sial" substituted, by Wegener, for "sal") are now in common usage in the geological literature, but their meanings are variable. In outlining the distribution of shield areas (stable continental nuclei) and orogenic belts (zones of mountain building), Suess concluded that until the end of the Paleozoic Era (225,000,000 years ago) there had been several very large continental masses, two of them in the Northern Hemisphere and one, or possibly two, in the Southern Hemisphere, separated by an east-west seaway that was termed Tethys. He believed that large segments of these continental plates foundered during the Mesozoic Era (q.v.), forming new ocean basins, and that the Tethys closed under compression during the Tertiary Period (q.v.), producing mountain chains from Morocco to China.

Gondwana

Suess' southern continents included one he named **Gondwana**, meaning Land of the Gonds, for the typical locality of a distinctive series of Late Paleozoic sediments in India. He conceived of Gondwana, or Gondwanaland, as a vast sialic plate spanning over 150° of longitude, from South America across the Earth to the far side of peninsular India. Suess was uncertain whether to include Australia and Antarctica in the same crustal mass, but his followers tended to do so. Suess concluded that the continuity of Gondwana was destroyed by the faulting and foundering of the South Atlantic and Indian Ocean segments during the Mesozoic Era. His deductions that India belonged with the southern continents and that these landmasses had been continuous were later adopted into the canons of the continental drift hypothesis. However, his view that the oceans are fault valleys floored by sunken continents is clearly incompatible with drift. Indeed, this idea was one of the more powerful arguments used against the drift hypothesis until after World War II, when extensive gravity and seismic measurements made at sea demonstrated that the Atlantic and Indian oceans have basaltic floors.

Continental drift has repeatedly been ascribed to catastrophes involving the Moon. In 1882 Osmond Fisher, an English physicist, elaborated on the 1879 thesis of Sir George Darwin that the Moon had been torn from the Earth, early in its history, by resonance effects between the rotating planet and the solar tides. Fisher proposed that the Pacific Ocean Basin is the scar that was produced by this event and that the other oceans were formed as rifts in the remaining sial. In 1910 F.B. Taylor explained the world distribution of Tertiary mountain ranges by suggesting that two proto-continents, located over the Earth's poles, had ruptured and moved toward the Equator under the force of lunar tidal action. He knew that, at its present distance, the Moon could not have raised tides sufficient to the purpose, and so he postulated capture of the Moon at close range sometime during the Late Cretaceous Period.

Wegener's hypothesis. Alfred Wegener published two articles in 1912 outlining his wholly original continental drift hypothesis. His hypothesis was by far the most detailed and comprehensive then proposed. It sparked worldwide interest, a great deal of support, and violent opposition. Its effectiveness shocked orthodox scientists into a defense of their positions; on the other hand, it was hailed with enthusiasm by those who had found the contraction hypothesis insufficient to explain geological observations. Wegener continued his research and revisions until 1930, when he died while on an expedition to Greenland. Meanwhile, the international controversy over his concept made his name synonymous with continental drift, which is now universally referred to as "Wegener's hypothesis."

Wegener deduced from gravity measurements and the bimodal distribution of the Earth's surface elevations that the ocean floors consist of denser and more iron-rich rock than do the continents. To him, the geological similarities of widely separated continents indicated the splitting and drifting apart of what were formerly continuous landmasses. According to Wegener's model, the continental sial

(granitic rock with an average density of 2.70 grams per cubic centimetre) is balanced isostatically in the denser oceanic layer (basalt with an average density of 2.95 grams per cubic centimetre), which he called **sima** and regarded as the top of the Earth's mantle. He compared the continents with icebergs that are buoyed in water at heights proportional to their mass and moving through the yielding sima.

In support of his hypothesis Wegener plotted the distribution of orogenic belts, geologic contacts, paleoclimatic zones, and living and fossil plants and animals. He concluded that until the Jurassic Period (136,000,000 to 190,000,000 years ago) all the sial had been massed in one large protocontinent, termed **Pangaea**, which covered about one-half of the globe and was surrounded by the primeval Pacific Ocean. Pangaea was like a grounded ice floe undergoing internal rifting and healing throughout most of Earth history until a definite breakup began in the Jurassic. In Wegener's day this was believed to be about 40,000,000 years ago; today the beginning of the Jurassic is dated at about 190,000,000 years ago. Wegener believed that at that time separate continental blocks began floating apart in the partially liquefied sima, with both an equatorward and a westward component to their motion. He postulated that as the continents moved forward, new ocean basins opened behind them; that the western margins of the American continents finally en-

Base from E. Bullard, "Symposium on Continental Drift," *Philosophical Transactions* (1965); Royal Society of London, other data from P. Hurley and J. Rand, "Pre-drift Continental Nuclei," *Science*, Vol. 164, June 13, 1969; American Association for the Advancement of Science

Figure 1 Reconstruction of the fit of the continents around the Atlantic prior to drift showing Precambrian continental nuclei and continental margins to a depth of 1,000 metres

The international controversy

countered resistance from recongealed sima that in turn caused the crumpling and uplift of marine sediments and continental margins to form the major mountain systems; and that the island arcs (*q.v.*) of the western Pacific are festoons that dragged behind as Asia moved westward away from them. In order to explain the distribution of paleoclimates he proposed a long history of polar wandering, with the Mesozoic south pole located in southern Africa.

Wegener originally suggested two possible causes of drift: a pole-fleeing force, which tends to move matter equatorward; and lunar-solar tidal force, which moves it westward. Both forces exist but are very small indeed. Wegener believed that these forces would become effective if applied over many millions of years. Most geophysicists rejected these forces as totally inadequate regardless of time.

Wegener's views made a direct appeal to numerous geologists, particularly to Alexander Du Toit in South Africa and to Arthur Holmes in England. For many years after the death of Wegener both men continued to develop evidence for continental drift and to work on the problem of a driving mechanism. Each concluded independently that the Earth is neither shrinking nor expanding (the latter having been widely believed after the discovery of radioactivity in crustal rocks) but that horizontal displacements occur, largely as a result of thermally driven currents in the mantle. Du Toit developed the idea that gravity sliding, the creep of continental masses toward rimming geosynclinal depressions, was an important factor in drift.

By the mid-1920s proponents of continental drift were working against a great tide of opinion in North America and Europe. The hypothesis suffered primarily from the lack of a theoretically sound mechanism adequate to produce continental drift, from too many enthusiastic but unsupported claims of matching shorelines and moving landmasses, and from the fact that it explained only one very late episode in Earth history, whereas the continents show a long record of tectonic activity. A definite turning point in scientific attitude occurred in 1926 at an international symposium held in New York. After this symposium, continental drift suffered a widespread loss of support and, ceasing to be a subject of serious investigation, became instead a source of amusement and derision. This overwhelmingly negative reaction is difficult to understand, particularly because the chairman and about half of the participants favoured drift.

The reaction was essentially due to the opposition expressed in 1924 by Harold Jeffreys, an English geophysicist, whose enormous prestige proved decisive with many geologists. Jeffreys argued that the force of gravity is stronger than any known tangential force acting upon the Earth's crust and that because the continental and oceanic layers are sufficiently strong to maintain topographic features such as Mt. Everest and the deep ocean trenches without slowly spreading out under the pull of gravity they are clearly too strong to permit horizontal drifting of sialic blocks through the sima. He was particularly opposed to the apparent inconsistency in Wegener's view that as continents drifted apart in the yielding sima they eventually met resistance enough to cause the crumpling and uplift of mountains on their forward margins. The sima, he pointed out, is either soft enough to yield to moving rafts of sial or it is not, and seismic evidence indicates that it is not. Jeffreys expanded upon his arguments in numerous journals and through five editions of his book *The Earth*, and he remains today one of the strongest opponents of continental drift and also of the concept of convection in the Earth's mantle.

Creative thought on the continental drift hypothesis lapsed for a number of years, and the arguments became increasingly repetitive and sterile until new types of evidence began to appear after World War II and to proliferate during the 1960s. Once again it was a symposium, held in London by the Royal Society in 1964, that generated a marked change in the attitudes of scientists toward the subject. The papers presented included reviews of

paleomagnetic studies, new information on ocean-floor topography, and other relevant subjects. One memorable offering was a predrift reconstruction of the continents bordering the Atlantic Ocean prepared by Sir Edward Bullard and his colleagues (Figure 1). This reconstruction, produced by a computer programmed to find the best fit of the Atlantic margins, disposed of the earlier arguments that the fit is very poor or nonexistent. It also prompted investigators to use it as a base map in searching for geological contacts truncated by the ocean.

#### EVIDENCE FOR CONTINENTAL DRIFT

Continental drift is postulated to explain such geological and geophysical observations as the following: the apparent matching of continental margins, of truncated mountain belts, and of dated contacts between geological formations that are separated by oceans, particularly the Atlantic; the bizarre pattern of Late Paleozoic glacial deposits, plants, and animals; the apparent migration of the earlier magnetic poles along paths that differ for different continents, as suggested by remanent magnetism (that which is related to the Earth's magnetic field at the time of formation of a given rock) in rocks older than mid-Tertiary; the young ages of marine sediments and of the ocean floors; the linear patterns of magnetic anomalies that parallel the oceanic ridges, coupled with seismic evidence for transform faulting and sea-floor spreading (*q.v.*).

**Geological data.** The Atlantic shorelines of Africa and South America suggest complementary pieces of a fractured block, as do those of Europe and North America (Figure 2) when allowance is made for their broad

Opposition  
to drift

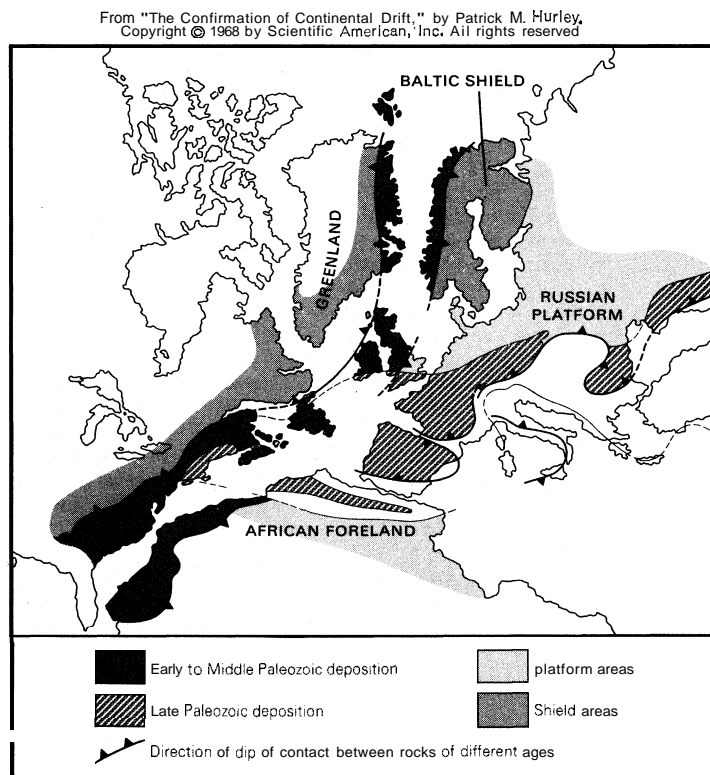

Figure 2: Geological fit across the North Atlantic, showing structural trends and ages of rocks.

continental shelves. Figure 1 illustrates the match along the 500-fathom line of the continental slopes. This configuration requires the rotation of Spain into the Bay of Biscay and the omission of most of Central America and the Caribbean Islands, including areas where Paleozoic rocks are known to occur. It is, nevertheless, so excellent a fit that it encourages a search for the matching of geological provinces.

**Ages of rocks.** Before the development of radiometric dating methods, the equivalent ages of orogenic belts

and rock contacts truncated by the Atlantic coastlines were often in question. Today, dated contacts showing a remarkable degree of continuity have been mapped across both the North and the South Atlantic. Joint investigations carried on by geochronologists in the United States and Brazil, for example, involved a contact in the crystalline basement rocks of Ghana. This was dated by both the potassium-argon and the rubidium-strontium methods, was plotted on the map shown in Figure 1, and then extended to northeastern Brazil. Subsequent sampling and dating disclosed the contact in its predicted location.

Farther south along the Brazilian coast a second belt of ancient rocks (2,000,000,000 years old) matches one in West Africa. The elegant fit of these contacts, in addition to that of the continental margins, makes a strong case for the continuity of Africa and South America during Precambrian time (*q.v.*). That this continuity persisted into the Mesozoic is suggested by the matching of Late Paleozoic fossiliferous strata and by the parallelism of Triassic dike systems in the two continents. Furthermore, the earliest marine deposits along the Atlantic coastlines of either Africa or South America are Jurassic in age, suggesting that the ocean did not exist prior to that time. Ancient rocks that are 1,700,000,000 to 3,500,000,000 years old occur in all continents and on present maps appear random in distribution. When they are plotted on the predrift reconstruction map of Figure 1, they fall into two groups that appear to represent ancient and rather small continental nuclei. These nuclei are rimmed and embayed by rocks 800,000,000 to 1,700,000,000 years old, which in turn are surrounded and crosscut by younger rock. Two conclusions have been derived from these data: (1) the continental crust has evolved from two ancient Precambrian nuclei and has grown at an accelerating rate throughout Earth history; and (2) these nuclei grew in place until the Jurassic when, according to the geological evidence cited above, they began to fragment and drift apart.

One of the most potent arguments against Wegener's hypothesis was that it accounted for only one late episode of continental drift in an Earth with a very long record of tectonic activity. The latest evidence from geochronology tends, however, to support Wegener's view that drift has occurred only once, beginning in the Mesozoic. It also supports Du Toit's conclusion that there were two original continental masses.

*Gondwana tillites.* Although the name Gondwana was chosen by Suess for a hypothetical continental plate stretching from South America to India, it is now commonly used for the much smaller protocontinent envisaged by Du Toit. The name comes from the typical locality in peninsular India of a highly distinctive series of flat-lying strata, about 20,000 feet thick, ranging in age from Late Pennsylvanian to Early Cretaceous (about 290,000,000 to 130,000,000 years old). The basal bed of the series is a thick tillite, indicating extensive and prolonged continental glaciation. Overlying the tillite are thousands of feet of sandstone, shales, and clay ironstones of predominantly continental origin, interbedded with minor marine deposits and thick seams of coal. Capping the sediments are massive flows of basalt. This succession, the Gondwana System, has counterparts in six landmasses of the Southern Hemisphere: Africa, South America, the Falkland Islands, Madagascar, Antarctica, and Australia (Figure 3). In some cases, the source areas of these sediments lay beyond the present continental margins. The overall resemblances of the Gondwana-type sediments demonstrate clearly that seven landmasses, now separated by oceans and distributed over 120° of latitude, had remarkably similar histories from the Late Paleozoic into the Cretaceous. Nothing resembling the Gondwana record has been found in the Northern Hemisphere except in India. While glacial tillites were being deposited at sea level on lands now straddling the Equator, the northern continents were free of continental ice caps. This pattern is so unlikely as to force a choice between continental fixity with extreme irregular-

Similar histories among separated land-masses

ity of climate or continental drift with climatic zoning based on latitude. The latter choice seems the more reasonable.

Many advances have been made in the study of climatic changes (see CLIMATIC CHANGE) based on the distribution of coral reefs, evaporites, red beds, and the temperature-sensitive oxygen isotope ratios in fossil marine shells. Some evidence appears to favour a Paleozoic climatic zoning similar to that of the present. In the end, however, the glacial tillites rank among the most dramatic and unambiguous indicators of paleoclimates, and those of the Permian-Carboniferous appear most understandable if they are grouped together near the South Pole.

*Distribution of fossils.* It is well known that the migration of some types of organisms can be prevented by seemingly minor environmental barriers of water, climate, or altitude. Famous examples of specialization due to short-distance marine barriers are the unique fauna of Australia and of several of the Galápagos Islands. A major biological problem arises, therefore, when identical species of plants or animals, strictly adapted to living on land or in freshwater, are found on both sides of very large marine barriers. The observation that lemurs occur in India, Madagascar, and Africa led in the last century to the postulated existence of Lemuria, an ancient landmass linking these three areas. Land bridges became common in geological thought as more and more faunal identities were discovered between widely separated continental masses. Wegener and Du Toit explained these similarities in terms of continental drift. Their arguments have, if anything, been strengthened by recent paleontological discoveries. Meanwhile, ocean-floor topography has become too well known to allow for sunken continental slabs or land bridges.

Glossopteris, a flora including two genera of seed plants totaling 58 species, is associated with the tillites in all the occurrences of the Gondwana formations. The Glos-

Similarities among faunas and floras

sopteris flora apparently thrived in subarctic to temperate conditions. Their present distribution, however, would require them to have crossed vast expanses of open ocean.

Vertebrate fossils are generally too limited in numbers in most Gondwana beds to yield useful evidence of continental relationships. Exceptions include the Permian reptile *Mesosaurus*, a Triassic amphibious labyrinthodont, and Devonian to Cretaceous freshwater fish. *Mesosaurus* was a small reptile adapted to shallow, brackish waters, whose skeletons are found in only two localities: the Early Permian Dwyka (tillite-bearing) Formation in Western Cape Province, South Africa, and 3,000 miles directly across the Atlantic in the similar Irararé Formation of Brazil. A mandible fragment from a Triassic labyrinthodont, discovered in 1968, is the first land vertebrate fossil to be found in Antarctica. It represents an amphibian, four feet long, whose remains also occur in Gondwana beds in Africa, South America, and Australia. Neither *Mesosaurus* nor the labyrinthodont was a marine creature, and without appeal to sunken land bridges it is difficult to account for their distribution other than by continental drift.

The modern freshwater fish of the Old and New Worlds differ substantially, with only 21 percent of North American genera represented in Europe. In the Devonian red beds, however, 57 percent of North American genera are also present in Europe, and a similar degree of identity persists throughout the Paleozoic.

In the Southern Hemisphere a striking correspondence has recently been found between linear geosynclinal troughs in Brazil and Gabon. These troughs, which appear to be segments of a once continuous basin, contain Jurassic to Middle Cretaceous nonmarine formations, including similar hydrocarbon occurrences, several identical species of freshwater fish, and 30 identical species of freshwater ostracods. The earliest marine bed in each trough is an Upper Cretaceous salt deposit that apparently marks the first appearance of the Atlantic Ocean between Brazil and Gabon.

Although these types of evidence support the concept of continental drift, other data on the distribution of plants and animals show anomalies that cannot be accounted for by any reasonable pattern of drifting landmasses. Furthermore, a careful study of the distribution of fossil and modern marine invertebrates by Francis G. Stehli indicates that numerous classes of these invertebrates exhibit much greater diversity of genera in the warm seas near the Equator than they do farther north and south. The diversity gradients for Permian marine invertebrates show a pattern of climatic zoning by latitude similar to that of today. Although this evidence does not contradict the idea that a westward drift of the Americas or a spreading of the Atlantic has taken place, it runs counter to the evidence of polar wandering and latitudinal migration of continents as deduced from paleomagnetic measurements.

**Paleomagnetic data.** The first indications that the continental drift hypothesis might be revived and re-examined came in the 1950s as a result of remanent magnetism measured in rocks by researchers in England and Japan. Paleomagnetic studies have produced three lines of evidence of the utmost importance to continental drift and plate tectonics: evidence of polar wandering, evidence of continental displacements and rotation, and evidence of reversals of the geomagnetic field.

Measurements of the fossil magnetism in unweathered rock samples from all continents show that for the past 20,000,000 years the locations of the Earth's magnetic poles have remained essentially unchanged.

**Polar wandering.** According to data assembled by S.K. Runcorn and his co-workers at Newcastle-on-Tyne, England, the position of the north magnetic pole moved at least 21,000 kilometres over a long curving path from western North America in the late Precambrian, through the present Pacific Ocean to northern Asia in the Mesozoic, and to the Arctic in the mid-Tertiary.

If rocks of the same age in all continents were to point to the same pole throughout a long migration, this phe-

nomenon could be ascribed to polar wandering, as though an outer shell of the Earth, including the crust and part of the mantle, had become decoupled and moved as a unit over the interior. The actual evidence from rock magnetism, however, permits no such simple solution.

Rocks older than 20,000,000 years from different continents point to different pole positions and describe systematically divergent paths of migration. This suggests that landmasses that were once joined have rifted and moved relative to one another and that their former positions can be reconstructed by superimposing their polar-migration curves. Many investigations have shown that continental reconstructions based on paleomagnetism coincide well with the requirements of the fit of continental blocks and with the pattern of paleoclimates.

An alternative interpretation of the data amassed from paleomagnetic measurements around the world has been presented by P.M.S. Blackett and his associates, who conclude that all the continents have drifted northward since the beginning of the Paleozoic and that most of them have also undergone some clockwise or counterclockwise rotation. Paleomagnetic measurements give no evidence as to longitudinal positions of samples and therefore cannot be used to trace eastward or westward motions if they occur. With respect to northward migration, the paleomagnetic data from India are of special interest for they definitely suggest that India lay in the southern hemisphere 150,000,000 years ago and has since drifted northward across the Equator. This interpretation of the data coincides with the stratigraphic and paleontological evidence that India was formerly part of the Gondwana landmass.

Those scientists who remain skeptical of geological interpretations based on paleomagnetism argue that the sampling is inadequate, the results are inconclusive, and the basic assumption of a permanently dipolar magnetic field is unjustified. However, more measurements are made each year and the method as a whole appears increasingly reliable.

**Oceanic data.** Evidence for continental drift has been derived mainly from the continents. During the past decade, however, new support has come from studies of the ocean basins. In comparison with the continents, which include rocks of all ages back to about 3,500,000,000 years, the ocean floors are geologically young.

**Marine sediments and sea-floor spreading.** The oldest marine sediments (*q.v.*) in dredge or core samples collected from any ocean are Jurassic, about 160,000,000 years old. The total thickness of deep-ocean sediments, red clay, and *Globigerina* ooze (largely composed of the remains of one-celled organisms) is everywhere surprisingly little, averaging about 400 metres in the Pacific and 500 metres in the Atlantic. At a mean rate of deposition of about 5 millimetres per 1,000 years, the sediments in both oceans could have accumulated in less than 200,000,000 years, beginning in the Triassic.

Deep-sea drilling near oceanic ridges (*q.v.*) has shown that the ages of sediments immediately overlying the bedrock in the South Atlantic increase linearly with distance away from either side of the mid-ocean ridge crest. Sediments deposited over the ridge when spreading began,

Marine sediment less than 200,000,000 years old

Figure 4: Three-dimensional diagram showing crustal generation and destruction according to the plate-tectonics principle.

and the Atlantic was a narrow rift, now lie near the continental shelves. The separation of these sediments, as dated by microfossils, suggests a sea-floor spreading rate of about two centimetres per year.

According to the sea-floor spreading hypothesis, the ocean floor is a thin rind on the upper mantle. The mechanism invokes the slow creep of hot crystalline materials: new rock rises in thin dike-like bodies up the ridges, cools, and then spreads horizontally away on both sides. A downward flow is assumed to occur where the ocean floor plunges into the mantle beneath continental blocks or along the linear trench systems that lie seaward from the island arcs. By this mechanism the oceanic bedrock is constantly renewed and the cover of sediments kept thin (Figure 4).

Given this type of movement in the upper mantle, the sialic continental blocks will presumably be floated passively away from the flanks of active ridges and centred over or between descending currents. The Red Sea is believed to be a new rift opening, with generation of ocean floor occurring at about three centimetres per year. The estimated rates of sea-floor spreading, based on the continental separation across the Atlantic and other ridges, range from 1 to 10 cm per year.

**Magnetic anomalies.** In 1963, linear magnetic anomalies symmetrically distributed in alternate strips along either side of oceanic ridge crests were reported by F.J. Vine and D.H. Matthews, English geophysicists, who suggested that the anomalies might record reversals of the Earth's geomagnetic field. Since that time it has been established that volcanic rocks on the continents record two main epochs of normal (north-seeking) polarity alternating with two of reversed polarity in the past 4,000,000 years. Oceanic rocks should respond to the same reversals, and if it is assumed that these rocks acquire their magnetism as they cool on the ridge crests, the widths of the anomaly belts indicate how far oceanic rocks have spread laterally during the past 1,000,000 to 4,000,000 years and, by extrapolation, over much longer periods. The rates of spreading, obtained by correlating oceanic and continental rocks of the same polarities and assumed ages, are identical to those that have been estimated from crustal separations: one to ten centimetres per year.

## PLATE TECTONICS

The concept of sea-floor spreading led to a revolution in Earth science. Given this concept, many new data and old puzzles began to fall into place, and geologists were forced to review the entire framework of global tectonics in terms of large-scale horizontal crustal movements. Within a very short time, geological and geophysical evidence for these crustal movements had been incorporated into a comprehensive system called plate tectonics.

Plate tectonics refers crustal movements to a spherical surface and analyzes the motions due to sea-floor spreading and transform faulting on a globe of constant area. The Earth's surface (lithosphere) is conceived of as being divided into a few rigid plates, each of which is bounded by three kinds of surfaces: a ridge or rise (zone of divergence), where new crust is generated; a trench or folded mountain range (zone of convergence), where crust is shortened or destroyed; and transform fault planes, along which relative movement between plates occurs. The motion of each plate over the mantle and relative to adjacent plates is seen as a rotation about an axis. Plate margins are all zones of seismic activity, and with some exceptions, notably within the North American and Asiatic plates, they account for most of the earthquakes of the world. The rises and fault planes are characterized by the occurrence of shallow-focus earthquakes and are also delineated by their topography and magnetic anomalies. The trench systems and other lines of convergence are the loci of deep-focus as well as shallow seismicity.

The present configuration of linear seismic zones divides the Earth's crust into at least six moving plates: two are wholly oceanic, and four consist of continental and oceanic crust coupled together (Figure 5). The assumption that continental rock possesses sufficient strength to permit the movement of massive blocks has always been fundamental to continental drift. Oceanic crust is too thin (only about five kilometres) to possess such strength. In the new global tectonics, therefore, the lithosphere is defined as a layer of significant strength, about 70 kilometres thick, including the crust and uppermost mantle. Beneath the lithosphere lies the asthenosphere, a solid layer close to the melting point and having no ef-

Earth's surface conceived of as rigid plates

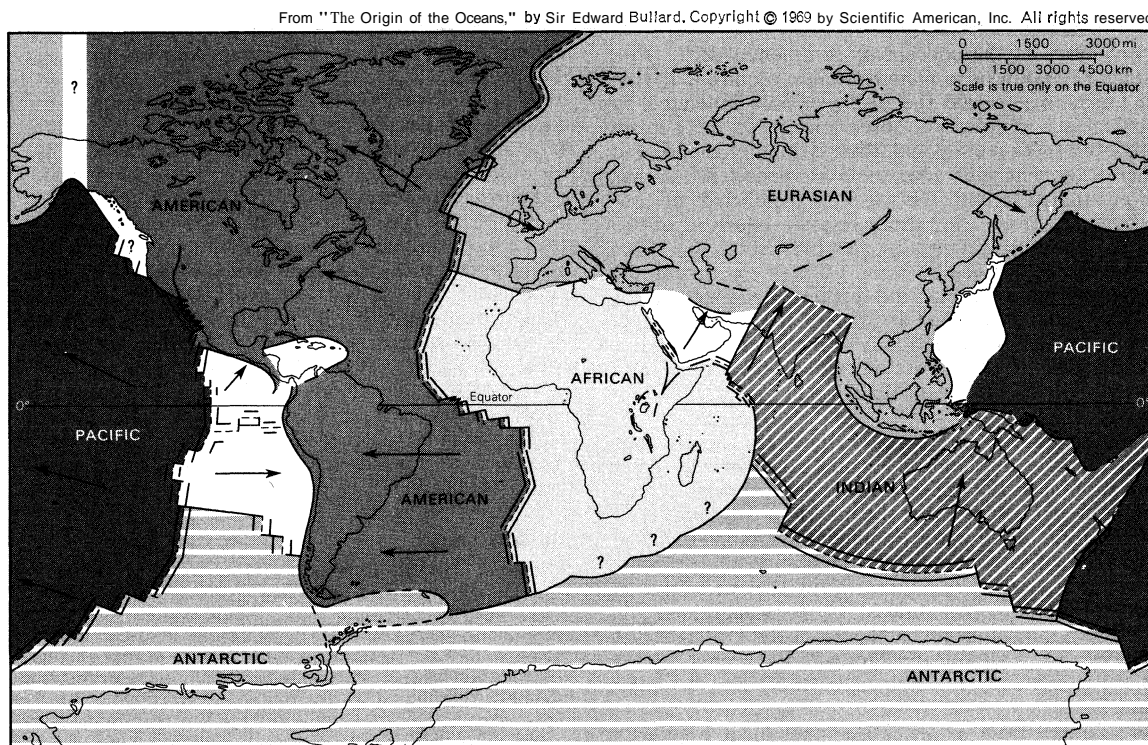

Figure 5: Relative motion of the six major plates or crustal segments today. The African plate is assumed to be stationary.

fective strength against long-term stress. The asthenosphere is not a homogeneous shell but includes at least three layers of increasing density and seismic velocity. It extends for some 700 kilometres down to the mesosphere, the inert lower mantle that is unaffected by tectonic movements.

The oceanic ridges have already been described as tensional zones where new crustal material is formed. Compensating for this crustal extension, the lithosphere must elsewhere be shortened by compression. Crustal shortening within continents is accomplished by folding and overthrusting in compressional mountain ranges. Within the ocean basins it occurs at plate margins where the oceanic lithosphere is thrust downward into the asthenosphere. This appears to be happening along the entire Pacific margin, where earthquake foci are distributed in planes dipping about 45° beneath the American continents, the Aleutian arc, and the system of trenches and island arcs rimming eastern Asia.

The underthrusting of thick slabs of cold lithosphere into a weaker, hotter substratum creates the Earth's zones of greatest tectonic instability. Shallow-focus earthquakes are frequent within the upper portions of the dipping slabs, and the Earth's only deep-focus quakes with foci down to 700 kilometres occur in the lower parts of the slabs. The landward side of the deeper-earthquake zones is marked by abnormally high heat flow and intense volcanism, of predominantly andesitic rather than basaltic petrology. Although the Pacific margins are fundamentally zones of compression, they bear superficial evidences of tension. Topographically the deep trenches resemble tensional rifts, but they are structurally controlled by the compressional furrow at the fault contact between two slabs of lithosphere.

Tension fractures are predicted along the bend in the oceanic slab where it begins to dip downward. These fractures may be filled with marine sediments that will be carried into the asthenosphere, heated, and mixed with mantle rock to produce silica-enriched hybrid magmas. Some petrologists ascribe the andesitic volcanics of the Pacific margin to this process; others believe andesites are primary differentiates from the mantle. Estimates of crustal shortening along the trenches, based on measurements of energy released in earthquakes, range from 1 to 15 centimetres per year.

#### THE PROBLEM OF MECHANISM

All variations of the concept of continental drift, from Wegener's hypothesis to plate tectonics, require a driving mechanism to generate the displacements indicated by geological and geophysical observations. No mechanism that is both theoretically and observationally sound, and is therefore generally acceptable to geoscientists, has been postulated to date. This lack of a sufficient mechanism was the reason for the wholesale rejection of the concept of continental drift by geophysicists in the 1920s and for the reluctance of some of them to accept the evidence for plate tectonics today. Suggested mechanisms that have been abandoned as inoperative or too ineffective to cause horizontal motions of the required sense or rates include global contraction, global expansion, tidal forces, gravity sliding, and a decrease in the gravitational constant.

Possibility  
of thermally  
driven  
mechanism

Today, proponents of plate tectonics are largely persuaded that the mechanism is some form of thermally driven motion in the upper mantle. Several lines of evidence, however, suggest that the mantle is too solid, elastic, and strong to allow for significant dynamic flow. The magnitude of Earth tides and the characteristic transmission of transverse seismic waves show that the effective rigidity of the mantle, at least in its deeper parts, is greater than that of steel. The figure of the Earth, out of equilibrium for a viscous medium with its present rate of rotation, is evidently maintained by the strength of the mantle.

There is increasing evidence that the upper mantle is markedly inhomogeneous and therefore not subject to mixing by convection. Gravity and heat-flow measure-

ments are, on the average, equal over continents and ocean basins, despite the fact that continental rock is lighter and also at least six times richer in heat-producing radioactive elements than are the oceanic basalts. These determinations suggest that continents are balanced by deep sialic roots and, deeper still, are underlain by columns of mantle rock that are radically depleted in radioactivity as compared to oceanic mantle. All these indications militate against horizontal flow and work in favour of the formulation supported by some geophysicists, namely, that once rocky material is located on a given Earth radius, it will always remain in the vicinity of that radius.

Despite these problems the evidence for large-scale horizontal movements of crustal plates is so impressive that numerous geophysicists have attempted to construct plausible mechanisms of upper mantle movement within the framework of the solid Earth. Since advocates of plate tectonics regard the rigid, moving plates of lithosphere as 100 kilometres thick, they abandon the much shallower and markedly undulating Mohorovičić discontinuity (zone at the base of the crust marked by a change of velocity of seismic waves) as a site of relative motion. They have also abandoned the strict distinction between continental and oceanic lithosphere and so have reduced the contrast in bulk chemistry. As a result, Wegener's iceberg model of floating continents and the conveyor-belt analogy of sea-floor spreading are both replaced by the conception of thick plates, likened to paving blocks jostling one another at different rates along shifting boundaries.

Orderly convection cells cannot be delineated with reference to present plate boundaries; in any case, the concept of convection as known in liquids is evidently inapplicable to the mantle, some layers of which respond as elastic solids to short-term stress but as fluids to long-term stress. The ultimate driving mechanism must therefore be some variety of thermally produced solid-state creep for which the mathematical model has yet to be constructed.

The large-scale motions associated with plate tectonics are inferred from geological and geophysical phenomena such as the separation of matching coastlines, the separation of linear magnetic anomalies, and the release of energy in seismic zones. The estimated magnitude of these motions ranges from 1 to 15 centimetres per year, which correlates well with geodetic measurements of 5 centimetres per year along the San Andreas fault zone of California.

Measuring  
crustal  
motion

In the future it may become possible to measure crustal motion by measurements from artificial earth satellites. At present, the locations of fundamental stations in a worldwide network of optical satellite-tracking stations are known to an accuracy of  $\pm 5$  metres. When lasers replace cameras, the accuracy can theoretically be increased to an ultimate limit of 3 centimetres. Before measurements of this magnitude become practical, many problems must be solved with respect to the shape and effect of the Earth's gravity field and of the atmosphere. Nevertheless, within a decade or so it should be technologically feasible to detect changes in the relative positions of stations located on crustal plates that are moving ten centimetres per year. If measurements can be continued for a number of decades, it should finally be possible to derive a worldwide picture of relative crustal motion and, if it is occurring, to prove the reality of continental drift.

PHINNEY (ed.), *The History of the Earth's Crust* (1968), excellent, up-to-date volume with chapters by many scientists, including Vine, Stehli, Hurley and Rand, and Bullard, with sections on the upper mantle, sea-floor spreading, and the continental crust; P.M.S. BLACKETT (ed.), *A Symposium on Continental Drift* (1965), includes the computer reconstruction map by Bullard et al., much data on paleomagnetism, oceanography, and transcurrent faults; work, however, was published before the development of our most significant evidence for crustal movements; A.E.M. NAIRN (ed.), *Problems in Paleoclimatology* (1964), essential background

on a wide variety of approaches to paleoclimatology; G.D. GARLAND (ed.), *Continental Drift* (1966), a short review of current ideas on drift followed by evidence from the Arctic and eastern seaboard of Canada; S.K. RUNCORN (ed.), *Continental Drift* (1962), includes much data on paleomagnetism and related subjects and an early article by Dietz on ocean-basin evolution by sea-floor spreading; T.F. GASKELL (ed.), *The Earth's Mantle* (1967), good collection of articles on the geophysics and geochemistry of the mantle.

*Books (classics):* A.L. WEGENER, *Die Entstehung der Kontinente und Ozeane*, 4th ed. (1929; Eng. trans., *The Origins of Continents and Oceans*, 1966), a clear exposition of ideas and principles, although geodetic data near end of book not to be taken seriously; A.L. DU TOIT, *Our Wandering Continents* (1937), excellent historical review of ideas on continental drift up to 1936, followed by much original work on Gondwanaland based in part on field experience; E. SUSS, *Das Antlitz der Erde*, 5 vol. (1883-1909), source book for Suess's ideas on Gondwanaland and foundering of ocean floors, plus monumental description of global geology; W.A.J.M. VAN WATERSCHOOT VAN DER GRACHT *et al.* (eds.), *Theory of Continental Drift* (1928), interesting chapters by leading geologists; of historical importance because this symposium killed the drift hypothesis for some 25 years.

(U.B.M.)

## Continental Shelf and Slope

The most regularly developed major feature of the Earth's topography is the continental terrace, also known as the continental margin. The upper surface is formed by the continental shelf, a broad shallow strip of seabed that extends from the coast to depths of 100-200 metres (330-660 feet). Some authors include the coastal plain on the landward side, but the shore represents a reasonable limit. The breadth of the shelf and the depth of its outer margin vary greatly. Beyond the shelf is the continental slope, a much steeper zone that merges with the deep-sea floor at a depth of about 4,000 to 5,000 metres (13,000-16,000 feet). In addition to its great variation in steepness and smoothness, the slope is diversified in some areas by terraces or by basins and ridges. The gradient of the continental slope tends to decrease over its lower half. This part is called the continental rise and is considered to be part of the deep-ocean floor. In some places, the continental slopes extend down to deep-sea trenches that parallel the coast. The nomenclature associated with the shelf and slope and the general dimensions are given in Figure 1.

Figure 1: Nomenclature and general dimensions of the continental shelf and slope regions.

There are few reaches of coastline facing the ocean or deep inland seas where the continental shelf and slope is entirely absent. Even most islands are surrounded by similar, but smaller, flat-topped features called island terraces. The continental shelf and slope each cover approximately 8 percent of the total sea floor. That surrounding the U.S. has an area that is more than one-third that of the land surface of the country.

The most spectacular result of detailed echo sounding of the continental margins has been to reveal the existence of many huge, steep-walled valleys that gash the terrace, namely the submarine canyons (see CANYONS,

SUBMARINE). Many canyons debouch on a delta-like feature, which is a gently sloping submarine fan. The outer margin of the shelf sustains islands or shallow banks. The most extreme examples occur where coral reefs have developed barrier reefs and atoll rims (see CORAL ISLANDS, CORAL REEFS, AND ATOLLS).

The economic value of the continental shelf is varied. Fisheries have vast potential and tin ore has been dredged for many years from submerged stream valleys of the Sunda Sea. Recently the search for oil and gas has intensified. Coal, salt, phosphate, sulfur, manganese, clay gravel and sand, diamonds, gold, silver, platinum, iron, titanium, chromium, and rare earths are other valuable products that the shelf can provide (see OCEANS AND SEAS).

The approaches to harbours traverse the shelf, and navigation always has been based on submarine topography and bottom sediment of this shallow area to assist in orientation and to help avoid dangerous shallows. Hydrography therefore has been almost entirely limited to the study of the shelves and coasts. Detailed charts now exist of practically all shelf areas. Although the advent of echo sounding has greatly speeded the survey of the continental slopes, these still are poorly explored.

Economic value of the shelf

### CONTINENTAL MARGINS: DEFINITIONS AND BATHYMETRY

Underwater topography is revealed by sounding. Until half a century ago sounding was carried out with rope or wire and the horizontal location was determined from landmarks. Later, echo sounding provided a much faster method and one that was more accurate because the position of a ship can be more exactly determined when it remains underway than when it is stopped and left to drift each time a sounding is taken. A depth recording is relatively useless if the location is not known, and the accuracy of surveying is as dependent on precise positioning as on the reliability of the actual depth determinations. Since World War II, position finding has been greatly improved, first by various radar systems that are useful near shore and quite recently over the entire world ocean by satellite methods. Echo sounding now has attained the stage of being more accurate than wire sounding in all depths, and it provides a continuous record along the line of travel.

**The continental shelf.** The shelf begins at the low-water line, but there is uncertainty whether to include estuaries (*q.v.*), tidal flats, or shallow lagoons (*q.v.*). There is less reason to exclude barrier-reef lagoons, and it can be argued that atoll lagoons and banks of the same depth as shelves also are part of the system (*e.g.*, the Bahama Banks). A similar problem is whether shallow inland seas should also be incorporated. The difficulty is that there are many transitions between enclosed seas such as Hudson Bay, and shelves with a few minor islands such as the Farilhões off Portugal or Sable Island opposite Nova Scotia.

The outer margin of the shelf formerly was defined as the 100-fathom or 200-metre line. A much better limit now can be set by the break in slope, or shelf break, between the nearly horizontal platform and the much steeper continental slope, which nearly always starts abruptly. The depth at this break averages 130 metres (430 feet), but it may be less than 40 metres (130 feet) or as much as 500 metres (1,600 feet). There are areas, however, where no distinct break in slope exists and the 200-metre line must be adopted for a limit.

The average slope is about one-tenth of a degree; near shore it normally is slightly steeper. The average width is 75 kilometres (45 miles). There is practically no shelf off Miami, Florida, or the French Riviera, but, in contrast, the Atlantic shelf off Patagonia is 500 kilometres (300 miles) wide. The surface of the shelf may be remarkably smooth or may consist of rocky or sandy shoals, depressions, or channels, one or two terrace-like features, and a gradual or abrupt longitudinal slope. In fact, the topography of continental shelves is at least as diversified as that of coastal plains.

Valleys on the shelf are of three distinct types. Some are broad with a fairly flat bottom and occur only in high latitudes. These evidently were scoured out by Pleistocene

Shelf topography, valleys, and river deltas

glaciers. Some valleys actually form the continuation of fjords onto the shelf. Others are more isolated, like the huge Cabot Strait Trough between Nova Scotia and Newfoundland, which is 500 metres (1,600 feet) deep and almost 100 kilometres (60 miles) wide. There also are many instances of glacial troughs parallel to the coast, exemplified by the trench curving around the southern extremity of Norway, which is up to 800 metres (2,600 feet) deep, 800 kilometres (500 miles) long and 80 kilometres (50 miles) wide.

A different kind of valley results from the action of tidal scour. It occurs when restrictions force tidal currents to sweep with extra force over the seabed—as between the Frisian Islands of the southeastern North Sea, for example.

The third valley type results from the drowning of a river valley. The Hudson Channel, extending from New York harbour to the outer margin of the shelf, and the "Sunda River," a dendritic system of valleys between Sumatra, Malay Peninsula, and Borneo, are examples of this phenomenon. No sharp distinction can be made between valleys and oblong depressions of tectonic origin that may be modified by external processes.

River deltas (*q.v.*) form on the shelf. Some, like the Rhône Delta, appear to pinch out on top of the shelf. Other deltas, such as those of the Nile and Niger rivers, have built out the continental slope so that the terrace locally bulges seaward. The Mississippi Delta is a multiple feature. The present bird-foot set of distributaries has built out onto the shelf and has reached the edge of the continental slope at one point. Similar structures of greater age overlap each other and have disappeared by subsidence and marine attack. Thin sediments have contributed to the construction of the continental terrace off Louisiana.

The great South American rivers, notably the Paraná and Amazon, have large estuaries and do not appear to have extended the shelf seaward. The same lack of out-building characterizes the Orinoco Delta, which is situated partly behind the island of Trinidad. This may be due to strong tidal currents and the preponderance of fine sediment that is washed away by currents, partly in a lateral direction along the coast and partly into the deep sea. Many great rivers such as the Irrawaddy and Indus appear to have filled sinking trenches but have not extended the land onto the terrace. Others, including the Euphrates and Po, have built deltas with sufficient rapidity to prevent inundation by the sea due to land subsidence.

The actions of water waves and ocean currents (*qq.v.*) have combined to throw up sandy barriers on some shelves that are approximately parallel to the coast and separated from the mainland by a lagoon. One of the most spectacular examples is Pamlico Sound, where Cape Hatteras extends out into the Atlantic halfway across the shelf. Sedimentation and plant growth will reclaim these lagoons, thus adding large areas to the land. In tidal flats the struggle between destructive and constructive forces is in full swing.

**The continental slope.** The continental slope is the declivity beyond the outer edge of the shelf; it extends to great depths, to the ocean basins (*q.v.*). The gradient varies between  $1^\circ$  and near vertical, but the average is just over  $4^\circ$  for the first 2,000 metres (6,600 feet). Most slopes are steepest at the top but a few are precipitous in the deeper portion. The total length of the continental slope is 300,000 kilometres (200,000 miles), almost eight times the circumference of the Earth. The junction with the deep-sea floor or with a continental rise on the floor is usually indistinct.

In addition to being deeply indented by the numerous submarine canyons, the slope is diversified by the presence of broad plateaus and other features. The Blake Plateau, at a depth of about 800 metres (2,600 feet) off the southeastern corner of the U.S., is an example of a major submarine plateau. Elsewhere, mounds and dents cause irregularities in the topography. The most typical continental borderland occurs off southern California, where a dozen basins of about 1,000 square kilometres

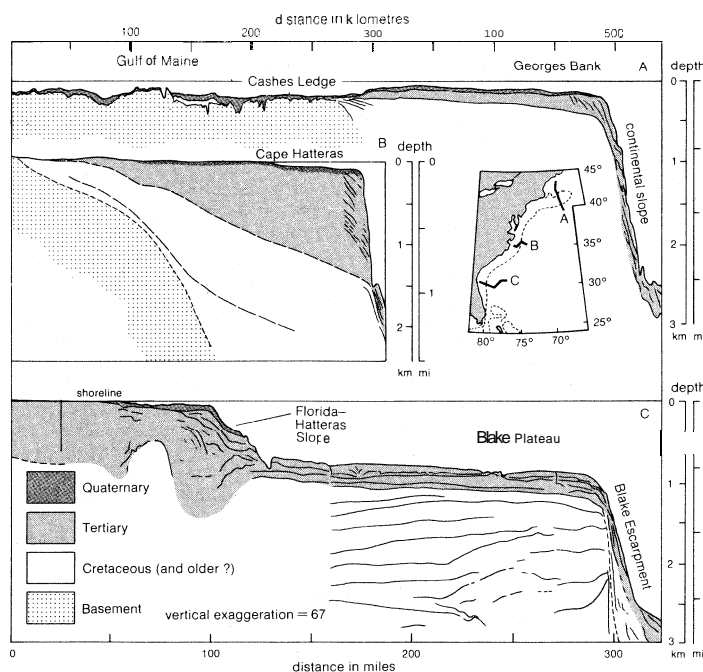

Figure 2: Three structure sections of the east coast terrace of the U.S. (inset), based on (A) dredging, (B) well data, and (C) seismic data.

(400 square miles) each are separated by submarine ranges, some topped by islands.

#### COMPOSITION

No model of the Earth's crust and its development that does not account for the features of the continental margins between continents and ocean basins can be satisfactory. Many ideas on the subject have been offered, but until the middle of this century these remained speculative because of the lack of facts.

The two main sources of information about the terrace, aside from soundings, are bottom sampling and the application of geophysical techniques. The old method of sampling employed tallow on the sounding lead, which made it possible for the mariner to determine whether the bottom consisted of rock, mud, sand, gravel, or shells. For more sophisticated investigations, complete samples must be obtained for study in the laboratory. Core samples from the sea floor are even more desirable, but they are difficult to obtain except in fine-grained deposits. The available data, however, are now sufficient to indicate the nature of the principal types of deposits and environments.

A severe limitation inherent in bottom sampling concerns the thickness that is sampled. It can reveal only surficial aspects of the terrace and the nature of its composition. The obvious remedy is to drill into the terrace. This was actually done long before World War II at Cape Hatteras; scientifically, it was the most profitable deep well ever sampled (Figure 2). It showed that the terrace had been built up in shallow water on a continuously subsiding foundation of weathered granite that sank to a depth of more than 3,000 metres (10,000 feet) in the course of about 100,000,000 years. Based on this information and the geology of adjacent land areas, it was then possible to interpret the geophysical evidence with some confidence.

Geophysical testing with the use of sound waves forms an invaluable counterpart to all forms of sampling. Dependent on the method used, the penetration of the returned vibrations can go right through the Earth's crust to the mantle beneath or any lesser distance within the crust.

The two main objectives of this work are to determine the speed of wave propagation, which provides information on rock composition, and to determine reflecting

Bottom  
sampling  
and data  
collection

horizons in the crust, which reveal stratification and buried surfaces. Folding, crumpling, faulting, wedging, and complicated distortions and intrusions can be identified and accurately analyzed (Figure 2).

Early measurements were widely spaced, but today the interval is so short for some types of testing that continuous records are obtained. After processing, a relatively complete section of the seabed structure along the ship's course is obtained. If samples that provide the rock type also are available, knowledge of the continental terrace is considerably enhanced.

An additional source of information is underwater photography, which has provided valuable data on sediment types and current systems on the terrace. Some of these will now be discussed.

Sediments and current systems. Depressions tend to collect fine material with a high percentage of organic matter, whereas topographic highs are coarser grained or consist of rocks and reefs. Near large rivers the sediment is fine, especially on the side to which dominant transport is directed. The northwest side of the Amazon, for example, receives so great a supply of mud near shore that serious trouble is experienced by shipping as far away as Guyana. The bulk of this mud is deposited along the coasts or fed into the Caribbean Basin. Calcareous ( $\text{CaCO}_3$ ) matter is frequently found as a shelly admixture with other materials. Pure calcareous deposits are encountered mainly in low latitudes, especially around coral reefs. OR formerly glaciated coasts, gravel and boulders are common.

Most beaches are bare rock, cobbles, or sand, although in protected sites mud can accumulate (mangroves). With distance from the beach and deepening of the water, the grain size decreases to fine sand or mud. But beyond this point, often 10 to 20 kilometres (6 to 12 miles) from shore, medium to coarse sand or patches of gravel form the seabed over wide areas, and in many cases no mud is present.

Narrow shelves usually are underlain by hard rock, with or without a thin veneer of unconsolidated sediments. The more exposed the bottom is to currents and wave action, the coarser the deposits tend to be. Because longer waves reach deeper than short ones, ocean swell is more able to stir the bottom at depths of a few dozen metres than are steep storm waves. In tidal scour channels the bottom consists of bare rock or a washed-out deposit of coarse material.

Most of the continental slope is covered by fine mud, consisting of clay and silt with a variable admixture of volcanic ash or shelly materials (see MARINE SEDIMENTS). But in areas where the declivity exceeds about  $10^\circ$ , the underlying rock bottom normally is exposed. Either hard rock (granite, basalt, consolidated sediment, reef rock, etc.) or semiconsolidated terrace sediments are most common.

On the continental rise and particularly on subsea fans, large corers often cut through sandy beds that are interstratified with normal deep-sea deposits. The structures and components show that these beds have been deposited by turbidity currents. These density currents ( $q.v.$ ) clean out the canyons and sweep the slopes at intervals of centuries or thousands of years. Within the confines of submarine canyons the deposits usually are coarse-grained. It is understandable that typical turbidity current deposits are missing there, because such flows are too mobile and competent to lose sediment in a steep gorge. The deposits that do occur represent the remainder of abortive turbidity currents—that is to say slides—and creeping beds modified by bottom currents that move independent of any sedimentary load.

Influence of the Ice Age. During the Pleistocene Epoch ( $q.v.$ ) sea level was lowered considerably during each major advance of the ice caps; the last such lowering amounted to about 100 metres (330 feet). Ice advances occurred about a half a dozen times in the course of the last 2,500,000 years. During intervening interglacial intervals sea level was equal to or higher than its present elevation.

The influence on the shelf has been dramatic. The breaker zone and its rough turbulence has passed down

the shelf surface and back again, disturbing the deposits and winnowing out the finer sediments. Exposure of the shelf by the lowering of sea level resulted in weathering ( $q.v.$ ) and overall degradation in some areas and deltaic deposition by minor rivers elsewhere. The larger rivers flowed down to the new coast on much steeper gradients than are usual in their unaffected lower courses. This tended to cause erosion of gorges on the exposed shelf. Vast amounts of sediment were brought to the outer edge of the shelf as a consequence of this process. The deposited material served partly to prograde the shelf; it also passed down submarine canyons and greatly stimulated the action of turbidity currents. Most estuaries ( $q.v.$ ) are the result of postglacial submergence of river valleys scoured out during stages of lowered sea level. They serve as sediment traps today and hence reduce present deposition on the shelves.

Since the end of the last glacial interval sea level has risen 100 to 120 metres (330 to 390 feet) in about 12,000 years, or about one centimetre per year. Over the last 5,000 years sea level has fluctuated slightly around its present stand (elevation).

Sea level was depressed approximately by the same amount over the entire globe, and the lowering was at least of the same order of magnitude for the major ice advances. The growth and waning of the ice sheets and glaciers ( $q.v.$ ) was irregular, and periods of stagnation or temporary reversal occurred. As a result, sea level sometimes remained almost stationary for longer periods, and this resulted in the cutting of terraces that are still preserved at various altitudes above and below sea level. But worldwide correlation is rendered difficult by local crustal movements.

Although the reality of all these effects of the Ice Age has been demonstrated, the configuration of the conti-

Beach,  
shelf,  
slope, and

ental terraces before the Ice Age is not yet clear. At present, there is a thin veneer of shallow-water and reworked beach deposits between 150-metre (490-foot) depth and the shoreline (Figure 3). This cover rests on a lower veneer of earlier marine deposits or lowland formations (fluvial deposits, marshes, dunes, boulder clay, etc.) of Pleistocene age that have been partly altered by weathering. This in turn is underlain by undisturbed preglacial shelf deposits. It is not unlikely that this picture is more complex where similar remnants of the earlier Pleistocene low levels have been partially preserved. A third veneer is now forming on the sea floor, consisting of sand (partly of organic origin) in very shallow water and mud farther offshore, out to a distance of a few dozen kilometres.

Beyond this recent covering deposit, the rock or coarse-grained Pleistocene formations have not been buried. These barren stretches of the shelf evidently are unsuitable for mud accumulation. The reason must be the action of incoming waves (long swell) and currents (tidal),

two factors that presumably act more energetically near the slope break but are damped off towards the coast. Not until the surf zone is approached does wave energy on the seabed increase again.

A complicating factor is the presence of bottom-dwelling animals — worms, bivalves, sea urchins, and others — that filter clay from the water and add it to the bottom as pellets. By burrowing and ploughing they also mix the sand with some fine-grained material deposited during periods of quiet.

#### STRUCTURE AND ORIGIN

It is obvious that the two main processes fashioning the shelf are deposition and erosion. On cliffed coasts wave action and currents are visibly making inroads on the terrestrial material. The retreat of an exposed coastline that is composed of unconsolidated sediments can be many metres per year, whereas in hard rock it is so slow that rates of retreat are very slight.

It once was assumed that waves eroded to depths of 100 metres, but it is now well established that they cannot attack hard rock at depths below a dozen metres. They can prevent sediment from accumulating at much greater depths, however. Because a wide, shallow platform of rock will effectively damp and absorb wave energy, marine erosion will have more influence when sea level changes with relation to the land than under stable conditions. The contribution from sedimentation is most readily demonstrated where the shelf bordering a delta has been built out into the deep-sea realm (*e.g.*, the Niger Delta).

Other possible origins are the subaerial development of a coast; plain, followed by subsidence beneath the sea. The elevation of a deeper zone to produce a shelf is less likely. It also has been postulated that the continental margin is due to down flexure beyond a hinge line that must evidently coincide with the break in slope. The precipitous slope south of the Riviera and its dendritic system of steep rocky valleys is considered to be an example. Most geologists assume that the location and shape of the break in slope was caused by the lowering of glacial sea level.

**Geophysical evidence.** Geophysical investigations have demonstrated a variety of internal structures. Shelves bordered on the oceanic side by hard rock are thought to be infilled lagoons behind barrier reefs, rocky basins containing accumulated sediment, or an erosional platform that has been veneered with sediment except at its rim.

The first seismic reconnaissance of terrace structure suggested that bedding planes tended to bend upward under the slope of the large Atlantic terrace of the United States. This could be interpreted in terms of basin structure below the shelf combined with general subsidence. Later work has cast doubt on this view. The whole crust beneath the continental margin is in the process of warping down along the Gulf coast. Deep wells have demonstrated that Tertiary and Late Mesozoic sediments have accumulated to a thickness of at least 10,000 metres (33,000 feet), mainly by upbuilding and partly by outbuilding into the Gulf. The base of this great prism of sediment has been depressed at least three times as deep as the present depth of the Gulf.

The amount of waste produced by coastal erosion is estimated at only 1 percent of the fluvial contribution to marine sedimentation. This accords very well with the finding that the dominant terrace structure is constructional and is the result of upbuilding combined with outbuilding. Details of the structure of many sections suggest the following development. Subsidence rapidly occurs over the area of the shelf and presumably part of the slope. Then, during the following period of crustal stability, sedimentation builds out from the landward side with a relatively steep dip slope, in some cases continuing beyond the break in slope and thus extending the slope into deep water. The cycle is then repeated by the onset of a new subsidence. The subsidence is attributable in part to the weight of the new sediment, which causes compaction of buried deposits and downwarping of the

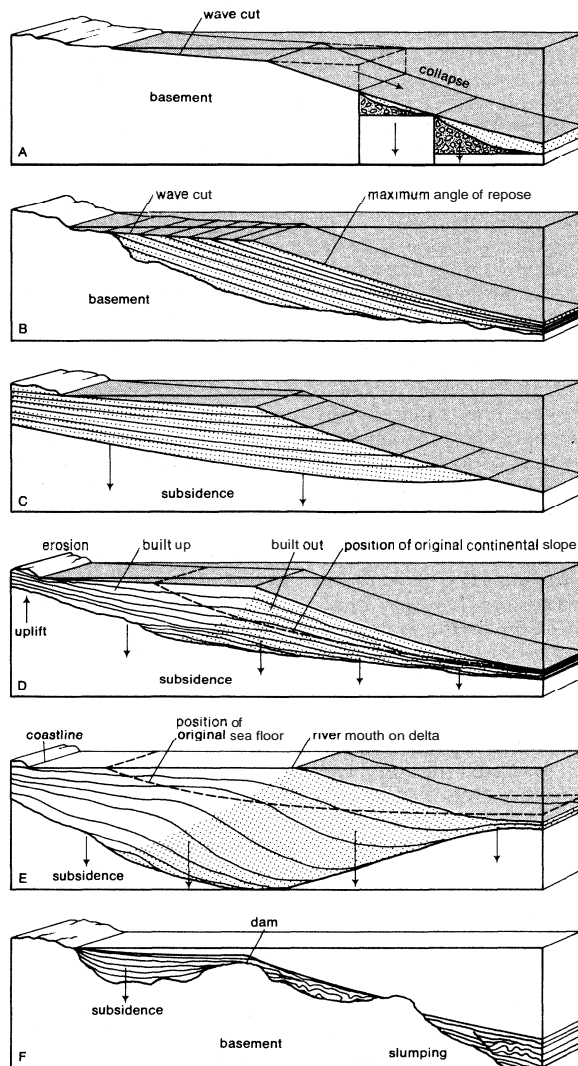

Figure 4: Various types of terrace structures. Structures resulting from (A) faulting and marine erosion, (B) outbuilding, (C) upbuilding in subsiding area, (D) combination of (B) and (C), (E) the same, but with great delta building by large river, and (F) tectonic dams and basins in a region of slumping.

From K.O. Emery, *Continental Shelf: Mineral Resources*

Earth's crust, and in part to internal causes such as consolidation of deeper layers, crustal thinning under tension, and loss of light material from below the crust by processes within the Earth's mantle.

Several origins are invoked for the continental slope. One possibility already mentioned is downwarping beyond a hinge line that would increase the slope. Another is subsidence of a subaerial slope together with the hinterland. This seems likely for the west coast of Corsica because the subaerial valleys continue all the way down to the deep floor of the Mediterranean without change in character. The likelihood of this subsidence is augmented by the presence of great volumes of quartz sand in Tertiary beds situated in southern France and the Apennines. This sand came from a former land area situated in the present Mediterranean, where the depth to the old land surface is now 3,000 metres (10,000 feet).

Some slopes have been built out, as shown by their internal structure. Others show outcrops of older rocks that evidently have been truncated on their seaward end. Erosion of the slope by turbidity currents, especially during low sea levels, and slumping of subaqueous landslides have both played a part. Where the beds thicken seaward from a point far inland of the coastline, there must be a slight tilting of the continental border toward the deep sea. Extremely precipitous slopes like the one to the west of Florida into the Gulf of Mexico are obviously huge fault scarps. The consequences of several possible pro-

Origin of the continental slope

Terrace structures

cesses and events on terrace structure are shown in Figure 4.

A special case is formed by the steep slope to the east of Florida. Deepwater drilling has revealed that the adjoining Blake Plateau is underlain by shallow water sediments and subsidence evidently has occurred. But the Gulf Stream has prevented sediment accumulation and it still sweeps the bottom clean.

A recent investigation of the continental margin of Europe has shown that three major events have occurred. In the course of the Mesozoic Era (*q.v.*) the margin developed by faulting and subsidence of an old land surface. During the Cretaceous a thick mass of sediment accumulated. Upbuilding amounted to a maximum of 4 kilometres (2.5 miles) and outbuilding to many kilometres. An episode of erosion followed at the close of the Mesozoic, and this resulted in turbidite deposition in the deep ocean and an unconformity within the terrace with respect to the later Tertiary sediment. The northern and western margin of Iberia were produced by faulting, but there appears to have been little terrace building.

A second erosional episode of faulting, slumping, and canyon cutting occurred at the end of the Tertiary. Possibly it was induced by glacial lowering of sea level. Since then, accumulation has again predominated, but a renewed advance of the ice would tip the balance in the opposite direction again.

Relation to  
continental  
drift

Geological relationships. The continental margins obviously have a bearing on the theory of continental drift and sea-floor spreading (*qq.v.*). The strongest case for drift is evidence that the Atlantic Ocean constitutes a rift that opened in the course of the Mesozoic between the Americas and Europe-Africa. This dovetails neatly with the Early Cretaceous age of the continental shelves on both sides that must have been constructed since the break. The theory originated from the good fit between the opposite margins of the Atlantic. But the most convincing proof of the rift is now supplied by paleomagnetism, deep-ocean drilling, geological fitting, the relics of the Permian Ice Age, and paleo-biogeography. It has become obvious that the shelf break is hardly better than the coastline or the margin of the continental rise as a feature by which to test the claim of a fit between the opposite coasts. The shelf edge came into being long after the rift, and the original continental margins appear to have been spread out and attenuated by loss of lateral support. The split off of the Rockall and Porcupine banks and the rotation of Iberia have caused deformations. Alpine mountain building has distorted the blocks themselves. Volcanism and delta building have inserted new masses. In spite of all these alterations the fit, whatever system of comparison is taken, is remarkably good. It is still a strong point in favour of the drift theory.

The origin and age of the Atlantic terraces and of the other margins created by continental rifting thus can be reasonably well accounted for. The younger ones of deep inland seas can be explained along the same lines; they developed after subsidence of their floors. But there remain the Pacific margins and a few others that have fronted the presumably primordial oceanic basin for a dozen times as long. These terraces are not more voluminous as one would expect but tend to be of modest size. It has been suggested that the continent has actively over-ridden the ocean floor and terrace or passively has allowed the ocean crust to be carried obliquely beneath them by mantle currents. The coastal ranges of continents could be tectonically compressed former terraces, but this would imply a radically different origin for all the great mountain chains crossing the continents, a consequence that is most unsatisfactory.

Even in broad view, the question of how the continental terrace has come into being requires a complex answer. Some coastal erosion is involved, but upbuilding and outbuilding on a subsiding margin are more important, and faulting and submarine erosion are also implicated. Sea level basically has had a unifying influence. The shallow inland seas are not genetically related to the terrace and they can be considered as typical continental areas that happen to have been flooded. Deep inland seas are widely

considered to be founded continental areas, in which chasms opened by continental drift. But in spite of the insight obtained, the origin and obliteration of many terraces remain obscure, especially those of the Pacific.

## Continents, Development of

Analyses of geological and geophysical data obtained from the ocean floors since the 1960s have greatly impressed most authorities and have given rise to the hypothesis of sea-floor spreading. Briefly stated, this hypothesis holds that molten material wells up along submarine mountain zones, called the midoceanic ridge system, and spreads laterally away from the ridges. This spreading creates a successively younger ocean floor, and the flow of material is thought to bring about the migration, or drifting apart, of the continents. The continents bordering the Atlantic Ocean, for example, are thought to be moving away from the Mid-Atlantic Ridge at a rate of about two centimetres (0.8 inch) per year, thus increasing the breadth of the ocean basin by twice that amount. Wherever continents are bordered by deep-sea trenches, as in the Pacific Ocean, the ocean floor is believed to plunge downward, underthrusting the continents and ultimately re-entering and dissolving in the deeper levels of the Earth from whence it originated (*i.e.*, in the mantle, the zone beneath the Earth's crust).

Concept of  
sea-floor  
spreading

A veritable legion of evidence supports this concept, including absolute age determinations of sea-floor material, patterns of rock magnetism that parallel oceanic ridges, heat flow measurements, and the age of marine sediments. The most ancient sediments of the ocean floor are not older than Jurassic in age—that is, they do not exceed 150,000,000 years in age. This suggests that today's ocean basins have gradually assumed their present configurations during that span of time and also that the continents have been drifting apart contemporaneously with sea-floor formation.

Information on the history of the ocean basins is therefore available principally for the last 150,000,000 years of Earth history. The continents, however, have existed for at least 3,500,000,000 years, or about 24 times as long, and thus have undergone development prior to the advent of sea-floor spreading. This point is emphasized here because many authorities would interpret the history of continents and ocean basins on the basis of the oceanic evidence described.

This article will treat the development of continents

from a somewhat different viewpoint. Specifically, an outline of present knowledge of the Earth's structure and composition will be followed by coverage of the processes of continental development and by treatment of the evolution of the several continental elements resulting from tectonic forces (movements of the Earth's crust) through time. It will not attempt to cover the development and configuration of the continents in relatively recent time, which are related to Tertiary mountain building (2,500,000 to 65,000,000 years ago) and Quarternary glaciations of the last 2,500,000 years. The interested reader should consult the several related articles suggested below for this and other supplementary information as well as for differing viewpoints on the subject. In this vein, see EARTH, GEOLOGICAL HISTORY OF; CONTINENTAL DRIFT; SEA-FLOOR SPREADING; MOUNTAIN-BUILDING PROCESSES; ISLAND ARCS; OCEANIC RIDGES; and ROCK MAGNETISM. See also EARTH, STRUCTURE AND COMPOSITION OF (particularly for details on the pyrolite model); PRECAMBRIAN TIME; and parallel articles on the history of the Earth's atmosphere and oceans—i.e., ATMOSPHERE, DEVELOPMENT OF; and OCEANS, DEVELOPMENT OF.

THE EARTH'S CRUST AND UPPER MANTLE

Composition and structure of the crust. The composition of the Earth's crust is relatively restricted from both a chemical and mineralogical viewpoint. Approximately 75 percent of the crust consists of oxides of silicon and aluminum (Table 1); the bulk of the rock-forming minerals are, accordingly, silicate minerals. The latter combine in various associations to form rocks of different mineral composition and origin.

Some rocks are of magmatic origin and were formed by the cooling and crystallization of molten material that flowed onto the Earth's surface (extrusive igneous rocks, such as basalt) or penetrated the crust and formed at depths below the surface (intrusive rocks, such as granite). The extrusive rocks occur as flows or layers, whereas intrusive rocks occur as massifs or as tabular bodies such as dikes and sills.

Sedimentary rocks form as a result of the erosion of pre-existing rocks and the transportation, deposition, and accumulation of the derived mineral materials on the surface of the Earth, mainly in marine basins. But sedimentation also occurs on the floors of lakes and rivers or, in fact, anywhere on the land surface.

Metamorphic rocks are formed by recrystallization of both sedimentary and magmatic rocks at high temperatures (300°–700° C [600°–1,300° F]) and pressures (from one to ten kilobars). In the process, the original composition can undergo change caused by the addition or removal of certain components.

The lower boundary of the continental crust is the Mohorovičić Discontinuity, characterized by an abrupt increase in the rate of propagation of seismic waves. Above the discontinuity, velocities do not exceed 7.4 kilometres (4.6 miles) per second for longitudinal waves, whereas below it they are usually equal to or greater than 8.1 kilometres (5.0 miles) per second. The depth of the Mohorovičić Discontinuity, which is the thickness of the continental crust, varies from 20 to 70 kilometres (10 to 40 miles). The former figure characterizes the crust of the Hungarian lowland, the latter, the Pamirs in Central Asia. Greater thicknesses generally are encountered under high mountains and lesser thicknesses under lowlands. The continental crust has a mean thickness of 43.6 kilometres (27.1 miles).

Three general kinds of layers may be distinguished in the crust: the sedimentary, the granitic, and the basaltic. The first consists of various sedimentary rocks and ranges in thickness from zero to 20 kilometres (zero to 12 miles); the mean thickness is 3.4 kilometres (2.1 miles). The granitic, or intrusive, rock layer reaches the surface in many places; it consists of about one-half granites and one-half gneiss and other metamorphic and magmatic rocks and is characterized by longitudinal seismic waves with velocities of 5.5 to 6.5 kilometres (3.4 to 4.0 miles) per second. The thickness of this layer varies from eight to 40 kilometres (5 to 25 miles), with a mean thickness of

20 kilometres (10 miles). The basaltic layer is complicated in composition: apparently, it consists of metamorphic rocks that have been intensely altered (the granulite and eclogite facies of metamorphism) and which are penetrated by numerous intrusions of basic and ultrabasic magmatic rocks (those rich in iron and magnesium) that have risen from the Earth's mantle. The basaltic layer is 15 to 40 kilometres (9 to 25 miles) thick, with a mean thickness of 20 kilometres (12 miles). In many instances, the crust exhibits many more subdivisions, which differ in their elastic properties. Seismic data suggest that the crust is everywhere divided by vertical fractures into blocks with different internal structure.

The mean chemical composition of the sedimentary (excluding carbon dioxide), granitic, and basaltic layers of the crust is shown in Table 1.

Table 1: Mean Composition of the Earth's Crust and Its Layers (in weight percent)

	average crust	sedimentary layer	granitic layer	basaltic layer
SiO <sub>2</sub>	61.9	49.95	63.94	58.23
TiO <sub>2</sub>	0.8	0.65	0.57	0.90
Al <sub>2</sub> O <sub>3</sub>	15.6	13.01	15.18	15.49
Fe <sub>2</sub> O <sub>3</sub>	2.6	2.98	2.00	2.86
FeO	3.9	2.82	2.86	4.78
MnO	0.1	0.11	0.10	0.19
MgO	3.1	3.10	2.21	3.85
CaO	5.7	11.67	3.98	6.05
Na <sub>2</sub> O	3.1	1.57	3.06	3.10
K <sub>2</sub> O	2.9	2.04	3.29	2.58
P <sub>2</sub> O <sub>5</sub>	0.3	0.17	0.20	0.30

The upper mantle. The composition of the upper mantle—a shell underlying the crust with a thickness of about 900 kilometres (550 miles)—is probably close to that of some meteorites. Alfred Edward Ringwood, an Australian geochemist, suggests a composition that he calls pyrolite (see Table 2).

Table 2: Chemical Composition of the Upper Mantle According to the Pyrolite Model (in percent)

weight		weight	
SiO <sub>2</sub>	45.16	CaO	3.08
TiO <sub>2</sub>	0.71	Na <sub>2</sub> O	0.57
Al <sub>2</sub> O <sub>3</sub>	3.54	K <sub>2</sub> O	0.13
Fe <sub>2</sub> O <sub>3</sub>	0.46	P <sub>2</sub> O <sub>5</sub>	0.06
FeO	8.04	Cr <sub>2</sub> O <sub>3</sub>	0.43
MnO	0.14	NiO	0.20
MgO	37.49	CoO	0.01

Within the upper mantle, at a depth of about 100 kilometres (60 miles) beneath the continents, a layer begins within which the seismic velocities are approximately 0.3 kilometre (0.2 mile) per second lower than in the overlying and underlying media. The thickness of this layer is obscure, but its base may be at a depth of 250 kilometres (150 miles). The peculiar properties of the layer result from the fact that the combination of temperature and pressure within it favours a partial melting of pyrolite with the emergence of films and drops of liquid basalt between the solid crystals (mainly of olivine). This process reduces the viscosity of the material and suggests the term asthenosphere, meaning a zone without strength. The partial melting should also produce a reduction of density in the asthenosphere, relative to the overlying upper mantle. The Earth's crust together with the solid layer of the upper mantle overlying the asthenosphere is called the lithosphere. The lithosphere and asthenosphere together are sometimes called the tectonosphere.

Processes that govern crustal development. The division of the Earth into a series of shells (upper and lower crust, upper and lower mantle, and outer and inner core) has occurred by geochemical differentiation of an initial Earth of much greater homogeneity. In the process of

Seismic characteristics and crystal layering

differentiation, the heavier components sank, and the lighter ones rose.

**Table 3: Elements Released and Layer Thickness of Mantle**

element	thickness of layer (km)
Si	60
Al	140
Mg	60
Ca	50
Na	180
K	1,300

The volume of the continental crust is equal to 6,500,000,000 cubic kilometres (1,500,000,000 cubic miles), and that of the transitional zones (continental margins) is 1,540,000,000 cubic kilometres (370,000,000 cubic miles). Considering the composition of the Earth's crust and mantle and the total volume of crust involved, the thickness of the mantle layer that would be required to yield the various elements of the crust by differentiation can be calculated. Table 3 gives this thickness for some elements in the crust. The figures—particularly those for potassium (K)—suggest that the material of the crust is intimately connected with considerably deeper layers of the Earth.

Exogenic and endogenic processes

The basic geological processes that are active on the surface of the continents and within the continental crust can be termed exogenic and endogenic, respectively. Exogenic processes include rock weathering and the formation of sedimentary rocks. Rock destruction ordinarily occurs in uplands and rock formation (sedimentary deposition) in lowlands. Because the location of uplands and basins changes during geological time, redistribution of sedimentary material is continuously occurring on the surface of the continents.

Endogenic processes include magmatism, metamorphism, and tectonism. Rising magma contributes new material to the crust; the entire crust was formed initially by magmatic outpourings. Because the mean composition of magma is much more acidic (richer in silica) than the composition of the mantle, the process of magmatism can be regarded as an expression of the geochemical differentiation of the Earth. Metamorphism leads to the recrystallization of rocks. A special form of metamorphism is granitization, in which partial melting and recrystallization of pre-existing sedimentary and metamorphic rocks gives rise to granitic rocks. This produces some important changes in the mechanical behaviour of the crust; it tends to "heal up" fractures and to promote greater homogeneity within the crust.

Tectonic movements are mechanical processes of several types that affect the entire crust. Slow vertical oscillations or undulations of general nature are a type that affects vast areas at the same time. These movements result in transgressions and regressions (advance and retreat) of the seas and to corresponding changes in the relationship between marine and nonmarine sediments.

Wavelike vertical oscillations of the crust are a second type of movement. They lead to a more or less stable division of the crust into adjacent zones of uplift and downward of long-term geological duration. The system of uplifts and depressions thus created may shift through time transforming absolute uplifts into relative ones and vice versa. Absolute uplifts have relief and undergo erosion, whereas depressions subside (sometimes over wide areas) and undergo filling. Depressions represent zones where sediments accumulate to thicknesses as great as the magnitude of the downwarping. They are called geosynclines and serve as loci for mountain-building.

Deep fractures that divide the crust into a mosaic of blocks produce structural zones and affect the location of boundaries between regions of uplift and subsidence; they constitute a third type of tectonism. Vertical displacements of individual blocks along abyssal fractures may measure as much as six to eight kilometres (four to five miles).

Large-scale transcurrent faults in the Earth's crust are also of fundamental importance. These faults are horizontal displacements of the crust bounded by vertical fractures. A prototype is the San Andreas Fault in California. During the earthquakes of the 19th and 20th centuries in that region, strike-slip movements (horizontal offsets along the trace of the fault) with amplitudes of several metres were observed.

Tectonic deformation includes folding (bending) of rock strata and attendant phenomena that occur in mountain ranges and belts. Such deformations do not embrace the entire crust but are always geographically confined.

#### ENDOGENIC REGIMES OF THE CONTINENTS

The continents are characterized by the effects of regular combinations of endogenic processes within the Earth. Such combinations constitute endogenic regimes, which appear in each interval of geologic time in definite zones that may be called tectonic zones.

**Geosynclines and platforms.** Geosyncline and ancient-platform regimes have been prominent on the continents during all of Phanerozoic time (the last 570,000,000 years); but they also existed earlier, in Precambrian time, although only certain aspects of these regimes are evident from those ancient rocks. The geosynclinal regime is characterized by tectonic undulations that divide the entire geosyncline into closely located zones of uplift and subsidence with a width of 50 to 100 kilometres (30 to 60 miles). Undulation amplitudes may attain 15 or 20 kilometres (9 to 12 miles), and regional metamorphism and granitization commonly occur. Strong linear folding and general crumpling of rock strata, together with block folding and injection folding give rise to a folded belt of mountains at the site of the geosyncline. Magmatic intrusions of several kinds may accompany and follow the folding and mountain building. The development of geosynclines is linked with intricate fracturing of the crust. A network of deep faults produces vertical movements of great amplitude and ensures high penetrability of the crust by magma.

Characteristics of folded zones

The ancient-platform regime is characterized by very slight contrasts in undulations. Broad and gently sloping uplifted and depressed areas have rounded irregular outlines; they are many hundreds of kilometres in diameter, and vertical movements have amplitudes of hundreds of metres to a few kilometres.

Regional metamorphism and granitization are absent, and only block folding and injection folding occur; there is no general crumpling of rock strata. Magmatism also is typically absent, and the regime characteristics all serve to indicate the presence of consolidated crust with low penetrability.

Intermediate regimes that comprise the entire spectrum from the typical geosyncline to the typical ancient platform also exist, but the rift regime and the regime of continental margins are quite distinctive.

**Rifts and continental margins.** In the rift regime, systems of large grabens (long tectonic depressions 30 to 60 kilometres [20 to 40 miles] in width and bounded by steep faults) are formed. The regime is confined to gentle archlike uplifts of the Earth's crust that are several kilometres in height and 1,000 to 2,000 kilometres in diameter. Rifts are invariably accompanied by intense volcanism (see further RIFT VALLEYS).

Faulting and volcanism

The regimes of continental margins are always characterized by subsidence of the crust. On Atlantic-type margins, the subsidence is quiescent, and the shelf gradually tilts toward the ocean. On Pacific-type margins, the subsidence occurs along fractures and is accompanied by intense volcanism and earthquakes.

**Evolution of endogenic regimes.** During the early part of Precambrian time (*q.v.*), regional metamorphism, granitization, and complicated deformations of rocks were widespread over the areas of the present continents (about 3,000,000,000 years ago). These phenomena point to the geosynclinal regime and suggest that it prevailed over the whole surface of the continents. During this stage of continental development the granite layer of the continental crust was formed; earlier, the upper part of

the crust may have been more basic (basaltic) in composition.

The crust later became divided: (1) into areas in which regional metamorphism, granitization, and rock deformation occurred, and (2) into areas in which such phenomena were absent during the same period of time. This stage marks the beginning of the division of the crust into geosynclines and platforms. Earlier than 1,600,000,000 to 1,800,000,000 years ago, however, the division into geosynclines and platforms was not stable, as the locations of these two regimes were constantly alternating. Thereafter, when a stable geosynclinal-platform regime did set in, the ancient platforms (shields) known today (North American, East European, Siberian, Chinese, South American, African, Indian, Australian, and Antarctic) began to form. They grew from the merger of a large number of small protoplatforms. Active endogenic processes ceased, and continental evolution became directed to the persistent growth of the area occupied by the platform regime. In this process the ancient platforms played a role of stabilization nuclei from which the platform regime was spreading over the continents.

As the area of the platforms expanded, the areas occupied by geosynclines diminished. As a result, the geologically young geosynclines, including those of Cenozoic age (the last 65,000,000 years), now form two well-defined linear zones — the Circum-Pacific and the Mediterranean (Tethyan) belts. The evolution of endogenic regimes toward lesser activity and more consolidation of the crust coincided, in certain places and times, with a reverse process of tectonic and magmatic activity. This reverse process was always subordinate, however.

The decrease in the area occupied by geosynclines indicates that the area where processes of differentiation, metamorphism, and granitization occurred also was decreasing, and that the formation of new continental crust was confined to gradually narrowing zones. The rift regime and the regime of continental margins left their marks only during the most recent geologic times.

**Tectonic cycles.** Determinations of the absolute age of metamorphic minerals suggest that Precambrian metamorphism was preferentially confined to certain intervals of time. These time intervals are (in 1,000 millions of years before the present): 3.0–2.8; 2.6–2.5; 2.2–2.0; 1.8–1.6; around 1.2; 1.0–0.9; and 0.6–0.5. These figures show that Precambrian metamorphism recurred at discrete intervals of 300,000,000 to 600,000,000 years. For the Phanerozoic Eon (the post-Precambrian record) it is possible to establish a recurrence of the entire complex of endogenic processes that proves to be almost synchronous for all continents, or for very large portions of them. Thus, it is possible to speak of endogenic cycles on a planetary scale; these are commonly called tectonic cycles.

Each cycle begins with subsidence of the crust and ends in uplift of the crust, thus giving rise to marine transgressions and regressions. Undulations are evident on platforms, where they are only slightly obscured by other phenomena; but, in geosynclines, undulations have greater amplitudes. During subsidence, the geosyncline becomes a sea basin of some depth; after uplift at the end of a cycle, it is transformed into a zone of folded mountains.

Magmatism in geosynclines during the endogenic cycle is divided into three stages: the initial stage, coinciding with the subsidence of the crust, consists in the outflow of basic lavas onto the bottom. During this same stage, basic, ultrabasic, and often intrusive rocks are formed. The middle stage coincides with the formation of granitic massifs. This process is closely related to regional metamorphism and occurs almost simultaneously. At the same time, most intensive folding begins. The final stage, coinciding with the uplift of a geosyncline, is represented by the formation of magmatic veins and dikes (very different in composition from previous intrusions) and by volcanic eruptions, this time with the outflow of andesitic and basaltic lavas.

Compressive forces and folding. Folding occurs on a much smaller scale than do vertical movements of the

crust, magmatism, and regional metamorphism. The basic types of folding are block folding, injection folding, and the folding associated with general crumpling. The latter type of folding is developed only in geosynclines. The other two types of folding occur both in geosynclines and on platforms. Only general crumpling, however, requires the direct action of horizontal compressive forces to explain it. Such forces may be generated within the geosyncline. The concept of external compression is in conflict with the shape of many folded zones, which often are sharply bent and break up into nearly closed ovals. This shape cannot be reconciled with external pressure, which would require that a single platform press on the geosyncline in different directions. The external-force idea also is contradicted by the history of folding in geosynclines. Folding always originates in the axial zone of the geosyncline, far away from the edges of the platform, and only later spreads toward the platform. If the folding were caused by pressure from the platform, the sequence would have to be reversed.

Moreover, the folding associated with general crumpling forms separate strips in the geosyncline, completely surrounded by zones of block folding and injection folding. The requirement that pressure applied from without "jumps over" the zones of block and injection folding to cause general crumpling in the strip cannot be explained. Horizontal compression of geosynclines should arise from within the geosyncline proper.

A model that accounts for the internal origin of the forces of compression stems from the assumption that the source of all deformations is the force of gravity. Three specific mechanisms have been suggested: the first is the slipping or flowing of layered rocks from the slopes of tectonic uplifts. This mechanism manifests itself in the formation of Alpine-type tectonic nappes (faulted and overturned folds). A second consists in a spreading of the upper part of uplifted crustal blocks as the vertical fractures bordering the blocks become inclined; the blocks then slip, exerting horizontal pressure on the surrounding rocks. A third mechanism consists of the formation of "deep diapirs" composed of granites, granite-gneisses, or metamorphic rocks that rise up through the overlying rocks of the Earth's crust. In the process, they undergo complicated deformations and also give rise to deformations in the surrounding rocks, which are pushed sideways.

#### ENDOGENIC REGIMES AND DEEP-SEATED PROCESSES

**Nature of geophysical evidence.** Information on the structure of deep-seated layers of the crust and the upper mantle is obtained by a variety of geophysical methods, principally seismic, gravimetric, and heat flow. These methods make it possible to trace the base of the Earth's crust and to establish its thickness at various sites.

**Crustal thickness.** It is known, for example, that the very high mountains, such as the Pamirs or Andes, are conspicuous by reason of the very thick crust (up to 70 kilometres [45 miles]) that underlies them. By contrast, beneath oceanic depressions the solid crust is very thin (five to seven kilometres [three to four miles]). In all other cases the relationship between the relief and the thickness of the crust varies greatly. Such ambiguous relations can be accounted for by several factors. First, there are great variations in mean density of the crust from place to place (horizontal inhomogeneities). In addition, the attainment of gravitational equilibrium (isostasy) depends not only on variations in the density and thickness of the crust but also on local variations in the density of the upper mantle. The situation is further complicated by the fact that structural peculiarities of the crust correspond not only to the more recent crustal regime but also to the previous history of the crust. Some deep structures have remained fixed in the crust for long periods of geologic time.

Rift valleys serve as an example of correlation between deep seismic structures and a recent endogenic regime. They are characterized by reduced thickness of the crust (about 20 kilometres [12 miles]) and by the presence of a lens of material between the crust and the upper mantle

matism

Origin of  
compressional  
forces

Density  
variations

with seismic velocities that are intermediate between these two shells (7.4–7.8 kilometres [4.6–4.8 miles] per second for longitudinal waves). Such a lens has a thickness of 20 to 30 kilometres (12 to 20 miles) and it is believed to be a mixture of crustal material and material of the upper mantle.

The regimes of the continental margins are related to reduced thicknesses of the crust. In North America the crust thickness at the centre of the continent reaches an average of 40 kilometres (25 miles), whereas at the Atlantic margin it falls to 30 kilometres (20 miles) and along the Pacific Coast to 18 kilometres.

**The asthenosphere and heat flow.** There is a correlation between the endogenic regimes on the surface and the underlying asthenosphere. Under the more stable sections of the ancient platforms—the crystalline shields—the asthenosphere can hardly be identified. It is much more evident under regions of intense recent uplifts. Under rifts, the asthenosphere is even more evident. And under the volcanic zone of the Kamchatka Peninsula and the Kuril Islands, a projection of the asthenosphere actually reaches upward to the base of the crust.

Important data have been derived from the study of the heat flow of the Earth. The average rate of heat flow on the continents is equal to the mean flow in the oceans and the mean for the whole Earth (1.47 microcalories per square centimetre per second). The lowest heat flow is observed on shields (the average is 0.98 in the same units). The mean value for platforms is close to the mean value for continents. But in the Tien Shan, in a Central Asian region of intense recent mountain uplift, the flow reaches 1.80. It is also high in rift valley areas, with the highest heat flows in volcanic regions. From these data it can be concluded that there is a correlation between heat flow and tectonic and magmatic activity.

The most active zones of continents are geosynclines. One of the processes confined to them is regional metamorphism. The study of the thermodynamic conditions of formation of various metamorphic minerals, with an evaluation of the most probable initial depth, has led to the conclusion that at the time of metamorphism the heat flow in geosynclines was three to five times higher than the average heat flow for continents. Because the metamorphic process occurs only during a particular stage of a tectonic cycle, the geosyncline apparently is a zone of high heat flow that undergoes periodic variations through time.

**Vertical-force basis of continent building.** All the processes described are connected with considerable depths of the Earth's interior, specifically with the asthenosphere, which differs beneath the various endogenic zones. But because the asthenosphere is dependent in its manifestations upon an influx of material and heat from deeper regions, the indicated relationships most obviously go still deeper. The repeated recurrence of a specific sequence of endogenic processes and the stable position of the ancient platforms, from which (as continental nuclei) the later regimes spread, point to a deep and long-term stability in the relationships between the continental surface and the interior. The mosaic character of the Earth's crust, in which regions with different regimes persist side by side for long periods of time, testifies to the fact that although vertical relations were long-term and deep, the horizontal relations and horizontal "mixing" of regimes were very restricted. This conclusion is in conflict with the hypothesis of sea-floor spreading, because it presupposes considerable horizontal movements both of the lithosphere of the continents and within the asthenosphere. Such movements would inevitably have disrupted all deep vertical relations.

**Heat and gravitational differentiation.** The basic process in the interior of the Earth has always been heating provoked by radioactive processes. Heating causes the gravitational differentiation of the material of the Earth mainly by means of partial melting. The mechanism of this process is the most mighty source of internal planetary energy. It is not necessary to postulate the existence of any large loops of convection. The mosaic structure of the crust indicates that gravitational convection has been

realized by the rising and sinking of relatively narrow streams, not surpassing the width of a separate tectonic zone in their horizontal dimension. The rising of relatively light material signifies a transfer of heat to the upper layers, within which the additional heating would stimulate differentiation. It is very probable that this mechanism of successive differentiation at different levels can account for the intricate complex of endogenic processes.

There is a possibility of differentiation within the Earth at depths of several hundred kilometres in accordance with the principle of zone melting. This process consists in the formation of a partly molten layer at a depth of 400–500 kilometres (250–300 miles) that subsequently moves upward and melts through the overlying material. In the process, the partly molten layer gradually cools off and becomes integrated with the surrounding material. Sometime thereafter, the second molten layer appears in the interior. The concept of a mobile and periodically renewed asthenosphere can be useful as an explanation of the tectonic cycles and large-scale undulations previously described. During this process of zone melting the volume of the mantle under the continents changes, leading to the periodical undulations on the surface relative to the level of the oceans. Upper layers of the mantle also are periodically enriched with the comparatively light material.

The next order of differentiation is probably located within the asthenosphere itself. Basalt is melted, and the material of the asthenosphere is altered in its mobility and density. If a relatively large volume of basalt is melted, the density of the asthenosphere decreases perceptibly and may become lower than the density of the overlying layers of the lithosphere. In this situation of density inversion on the surface of the asthenosphere, disturbances that could cause undulations in geosynclines may be expected.

Basaltic bodies (asthenoliths) that rise from the asthenosphere and penetrate the crust heat its material, thus stimulating metamorphism. The beginning of folding is closely connected in time with this event. The transition from a geosyncline to a platform may occur after repeated partial melting, when the composition of the asthenosphere becomes such that no further considerable melting is possible.

**Crustal-sinking hypothesis.** On the boundaries of continents and partly within them are seas and peripheral parts of oceans; the crust under both types of continental areas is of an oceanic type. The possibility exists that there has been a process of "basification" of the continental crust, a transformation of it into oceanic crust. This would occur as a result of a very intensive heating of the Earth's interior that would initiate a large-scale melting process and, in turn, would cause molten material to penetrate the continental crust in large quantities. There, the molten material would drive the contained water out of the crust and so alter its material that it would become heavier. After cooling, the crust would sink into the mantle in the form of separate blocks and there dissolve.

According to this concept the process of differentiation that leads to the formation of continental crust may be replaced in time by the process of basification, which tends to destroy the crust. Despite the fact that the continents have been under study for at least 200 years, many intricate mysteries about their development remain to be solved. An explanation of continental structure and history can only be set forth within the framework of plausible hypotheses, one of which has been presented in this article.

**BIBLIOGRAPHY.** A large and specialized literature treating the development of the continents and, in effect, the development of the Earth itself, is available. The interested reader can best consult two general works, however, which serve as a guide to many of the ideas mentioned or alluded to in this article and to additional references: P.J. HART (ed.), *The Earth's Crust and Upper Mantle* (1969); and V.V. BELOUSSOV, *Basic Problems in Geotectonics* (1962; Eng. trans. from the 2nd Russian ed. of 1962).

## Contracts, Law of

The nature of contract law

A contract, in the simplest definition, is a promise enforceable by law. The promise may be to do something or to refrain from doing something. The making of a contract requires the mutual assent of two or more persons, one of them ordinarily making an offer and another accepting. If one of the parties fails to keep the promise, the other is entitled to legal recourse against him. The law of contracts has to do with such questions as whether a contract exists, what the meaning of it is, whether a contract has been broken, and what compensation is due the injured party.

### THE EVOLUTION OF THE LAW OF CONTRACTS

Contract law is the product of a business civilization. It will not be found, in any significant degree, in precommercial societies. Most primitive societies have other ways of enforcing the commitments of individuals, through ties of kinship or by the authority of religion. In an economy based on barter, most transactions are self-enforcing as the transaction is complete on both sides at the same moment. Problems may arise if the goods exchanged are later found to be defective, but these problems will be handled in terms of property law—with its penalties for taking or spoiling the property of another—rather than in terms of contract law.

Even when transactions do not take the form of barter, primitive societies continue to work with notions of property rather than of promise. In early forms of credit transactions, kinship ties were relied upon to secure the debt, as when a tribe or a community gave hostages until the debt was paid. Other primitive forms of security took the form of pledging land or pawning an individual into "debt slavery." Some credit arrangements were essentially self-enforcing: livestock, for example, might be entrusted to a caretaker who received for his services a fixed percentage of the offspring. In other cases—constructing a hut, clearing a field, or building a boat—enforcement of the promise to pay was more difficult but still was based on concepts of property. In other words, the claim for payment was based not on the existence of a bargain or promise but on the unjust detention of another's money or goods. When a worker sought to obtain his wages, the tendency was to argue in terms of his right to the product of his labour.

A true law of contracts—that is to say, a law of enforceable promises—implies the development of a market economy. Where a commitment's value is not seen to vary as a function of time, ideas of property and injury are adequate and there will be no enforcement of an agreement if neither party has performed, since in property terms no wrong has been done. In a market economy, on the other hand, a person may seek a commitment today to guard against a change in value tomorrow; the person obtaining such a commitment feels harmed by a failure to honour it to the extent that the market value rises above the agreed price.

**Roman law.** The Roman law of contracts, as found in Justinian's law books of the 6th century AD, reflected a long economic, social, and legal evolution. It recognized various types of contracts and agreements, some of them enforceable, others not. A good deal of legal history turns upon the classifications and distinctions of the Roman law. Only at its final stage of development did Roman law enforce, in general terms, informal executory contracts—that is, agreements to be carried out after they were made. This stage of development was lost with the breakup of the empire. As western Europe declined from an urbanized, commercial society into a localized, agrarian society, the Roman courts and administrators were replaced by relatively weak and imperfect institutions.

The rebirth and development of contract law was a part of the economic, political, and intellectual renaissance of western Europe, including England. It was everywhere accompanied by a commercial revival and the rise of national authority. Both in England and on the Continent, the customary arrangements were found

to be unsuited to the commercial and industrial societies that were emerging. The informal agreement, so necessary for trade and commerce in market economies, was not enforceable at law. The economic life of England and the Continent flowed, even after a trading economy began to develop, within the legal framework of the formal contract and of the half-executed transaction (that is, a transaction already fully performed on one side). Neither in continental Europe nor in England was the task of developing a law of contracts an easy one. Ultimately, both legal orders succeeded in producing what was needed: a body of contract doctrine by which ordinary business agreements, involving a future exchange of values, could be made enforceable.

The new contract law began to grow up on the Continent and in England through the practices of merchants; these were at first outside the legal order and could not be upheld in courts of law. Merchants tended to develop informal and flexible practices appropriate for active commercial life. By the 13th century, merchants' courts had been established. The merchant courts provided expeditious procedures and prompt justice and were administered by men who were themselves merchants and thus fully aware of mercantile problems and customs.

In the 12th and 13th centuries, the development of the law of contracts on the Continent and in England began to diverge. In England the common law of contracts developed pragmatically through the courts. On the Continent the process was very different, with speculative and systematic thinkers playing a much larger role.

**The common law.** From perhaps the 13th century on, English common law dealt with contractual problems primarily through two actions: debt and covenant. When a fixed sum of money was owed, under an express or implied agreement, for a thing or a benefit given, the money was recoverable through a simple action at debt. Other debt action was available for breach of a promise, made in an instrument with a seal, to pay a fixed sum of money. A so-called action at covenant could also be brought for breach of a promise under seal. These actions did not, however, provide a remedy for the breach of an informal agreement to do something. In the 15th century, the common-law courts started to develop a form of action that would render such agreements enforceable, and by the middle of the 16th century, they had done so through the form of action known as *assumpsit* ("he has undertaken"). Originating as a form of recovery for the negligent performance of an undertaking, it came step by step to cover the many kinds of agreement called for by expanding commerce and technology. Having established in principle a comprehensive remedy, it was necessary for the courts to limit its scope. The courts found the limiting principle in the doctrine of "consideration," according to which a promise as a general rule is not binding unless something is presently given or promised in exchange. This consideration need not be of commensurate value, but it must be bargained for and cannot be simply a formality.

**Civil law.** On the Continent, the revived study of classical Roman law had an immense influence upon the developing law of contract. It stimulated men to rediscover or construct a general law concerning the validity of agreements. The Roman law, however, as crystallized in Justinian's law books, tended to confirm the notion that something more than an informal expression of agreement was required if a contract was to be upheld by a court. Another significant influence in the development of contract law on the Continent was the Roman Catholic Church. The church in its own law (canon law) strongly supported the proposition that a simple, informal promise should be binding (*pacta sunt servanda*). This attitude was to encourage the development of informal contracts. The natural-law philosophers took up such ideas as *pacta sunt servanda*, although they were slow to abandon the view that some contracts, especially contracts of exchange, should require part performance if they were to be held enforceable. By the time of the 18th century, the speculative and systematic thought of jurists and philosophers had finally and fully carried the

The law of merchants

day. The legal writers and legislators of the period generally considered informal contracts as enforceable in the courts. Thus in the French Civil Code of 1804, contract was approached essentially in terms of agreement; obligations freely assumed were enforceable except when the welfare of society or the need to protect certain categories of persons such as minors dictated otherwise. With the generalization that contract rests ultimately on agreement, the civil-law systems achieved a foundation quite different from the common law's view that contract is basically a promise supported by a consideration.

Flexibility  
of modern  
contracts

All the Western systems of modern contract law provide mechanisms through which individuals can voluntarily assume, vis-à-vis others, legally binding obligations enforceable by the other person. Contract law strives to give legal expression to the endlessly varying desires and purposes that human beings seek to express and forward by assuming legal obligations. The resulting system is open-ended; in principle, no limits are set in modern contract law to the number of possible types of variations of contracts.

#### THE SETTING OF STANDARDS

In theory, contractual obligations should be concluded between parties of substantially equal awareness and bargaining power and for purposes fully approved by society. The law reflects this utopian idea in the sense that it tends to conceive of contract as an arrangement freely negotiated between two or more parties of relatively equal bargaining power. The manifestations of intention required to form a contract are accordingly thought of as indicating real willingness, although in fact they may simply represent acquiescence.

Fairness and social utility. Much of the law of contract is concerned with ensuring that agreements are arrived at in a way that meets at least minimum standards, respecting both parties' understanding of, and freedom to decide whether to enter into, the transactions. Such provisions include rules that void contracts made under duress or that are unconscionable bargains; protection for minors and incompetents; and formal requirements protecting against the ill-considered assumption of obligation. Thus, section 138 of the German Civil Code renders void any contract "whereby a person profiting from the distress, irresponsibility, or inexperience of another" obtains a disproportionately advantageous bargain. In addition, more general social requirements and views impinge upon contracts in a number of ways. Certain agreements are illegal, such as—in the United States—agreements in restraint of trade. Others, such as an agreement to commit a civil wrong, are held by the courts to be contrary to the public interest. Certain systems discourage some purposes, such as the assumption of a legally binding obligation to confer a gift of money or other gratuitous benefit upon another by various special requirements.

Legal systems often have recourse to interpretation in the interest of fairness and social utility. Many litigated cases in which a remedy is sought for breach of contract are concerned with the meaning to be attached to the verbal expressions and acts of the parties in their dealing with each other. Ambiguities, for example, may be resolved against the party thought to have the superior bargaining position. This decision is common in cases in which one party is able to set the terms of a contract without bargaining. Again, a written agreement may be interpreted against the party who drafts or chooses the language. Or the court may prefer an interpretation it finds to be in accord with the public interest.

Although all legal systems try to achieve a reasonable approach to freedom of contract, there are bound to be contractual obligations that depart in some degree from the ideal. No one seeking to enforce a contract is required to show affirmatively that it advances specific ends desired by society or that the contracting process is without blemish. Such a requirement would be administratively cumbersome and expensive. In addition, it would reduce the general usefulness of the contract as an economic and social instrument. Differences in the economic resources available to individuals are found in most

societies; to the extent that these differences flow from general conditions and are reflected in, rather than produced by, individual contracts, it is usually not feasible to take remedial action through the law of contracts. A single contract, moreover, is often only one element in a complex of economic and legal relations. Thus, in times of severe inflation or deflation, it may simply not be feasible to seek to deal with the resulting inequities in terms of redoing individual contracts.

Contracts of adhesion. There are large areas of economic life in which the parties to contracts have such unequal bargaining positions that little real negotiation takes place. These contracts are often known as contracts of adhesion. Familiar examples of adhesion contracts are contracts for transportation or service concluded with public carriers and utilities and contracts of large corporations with their suppliers, dealers, and customers. In such circumstances a contract becomes a kind of private legislation, in the sense that the stronger party to a large extent assigns risks and allocates resources by its fiat rather than through a reciprocal process of bargaining. Enforcement of such standard contracts can be justified on the ground that they are economically necessary. The question then becomes whether these decisions are to be made by private enterprise or by other agencies of society—in particular, government—and to what extent the interest of those who deal with such economic enterprises can be represented and protected in the decision-making process.

Contract law in such cases provides only what can be called the legal relationship. The content of the relationship derives not from bargaining between the parties but from the fiat of the large enterprise often offset by the fiat of some government agency. In a sense, the socially regulated contract of adhesion seeks to eat the cake of bureaucratic rationality while having, as well, the cake of individual choice and decision. Doubtless both cakes are diminished in the process, but the result may well be more satisfying than if only one had to be chosen. At all events, the resulting legal-economic phenomenon is radically different from that envisaged by traditional contract law.

#### THE RULES OF DIFFERENT LEGAL SYSTEMS

Traditional contract law developed rules and principles controlling the voluntary assumption of obligations, regulating the performance of obligations so assumed, and providing sanctions for failure to perform.

Offer and acceptance. Some of the rules respecting offer and acceptance are designed to operate only when a contrary intention has not been indicated. Thus, in German law an offeror cannot withdraw his offer until the time stipulated in the offer or, if no time is stipulated, until a reasonable time has passed; but this rule yields to a statement in the offer to the effect that it shall be revocable. In Anglo-American common law, when parties contract by correspondence the acceptance takes place on dispatch of the letter, but the offeror can stipulate that no contract will be formed until the acceptance has reached him. These rules serve to fill in points on which the parties in their negotiations have not, for one reason or another, been specific.

Another function of rules relating to offer and acceptance is to enable the parties to understand and to mark when their discussions pass from an exploratory stage to the stage of commitment. The concepts of offer and acceptance are somewhat formal; they assume that the negotiations pass through clearly distinguishable phases, which is often not the case. But they help the parties to distinguish negotiation from commitment. The two words offer and acceptance become firmly associated with the assumption of obligations.

Different legal systems frequently advance comparable policies in quite different ways. Several distinctly different patterns are found in the approach of modern legal systems to the problems of whether an offeror is free to revoke his offer before acceptance, and of when an acceptance is effective to form a contract. Perhaps the polar extremes are represented by the German law, on one

Big  
industry  
and the  
public  
interest

The  
question of  
whether a  
contract  
exists

hand, and the Anglo-American common law on the other. In the German view, an offer binds the offeror for any stipulated period or, when the offer is silent as to time, for a reasonable period unless the offeror has expressly made the offer revocable. The common-law rule is the opposite: an offer is revocable until it has been accepted. The two systems also have sharply divergent rules with respect to the point at which, when the parties are contracting by correspondence, the acceptance takes effect to conclude the contract. In German law, the acceptance takes effect when it reaches the offeror, in the sense that he either knows or can learn of it. In the common law, on the other hand, if the offeree uses an appropriate means of communication, the acceptance is effective on dispatch unless the offeror stipulated the contrary in his offer. (A revocation by the offeror, however, does not take effect until received by the offeree.)

How are these divergencies in the rules respecting offer and acceptance to be explained? In particular, do they reflect fundamental policy differences or simply different techniques designed to forward quite similar purposes? An examination of a typical problem posed when parties contract by correspondence suggests the latter explanation. Upon receipt of an offer, the offeree frequently changes his position by, for example, refusing or ignoring other offers, neglecting to seek additional offers, or himself making propositions based on the offer made to him. For this reason the legal system sees a need to provide the offeree with a secure point of departure for his decision, in order both to protect him and to facilitate commerce generally. The German system provides this protection by making the offer in principle irrevocable. The common law, on the other hand, found this solution excluded by its doctrine of consideration; as the offeree does not give anything in exchange for the offer's irrevocability, consideration is lacking to support an obligation not to revoke. (On the other hand, the Uniform Commercial Code, which has been adopted everywhere in the United States except Louisiana, provides that a firm offer made by a merchant is irrevocable even though the other party has given no consideration. If legislation, rather than judicial development, were more usual in the common law, changes such as this one would presumably have occurred much earlier.) The common law is not entirely insensitive to the offeree's predicament. The rule that the acceptance is effective upon dispatch creates a situation in which the offeror who wishes to revoke his offer is uncertain whether or not he can still do so, since his revocation is not effective until receipt, whereas the offeree's acceptance, if one is made, takes effect on dispatch. This uncertainty makes the consequences of an attempted revocation unpredictable and thereby inhibits an offeror who might otherwise seek to revoke. In sum, the German and Anglo-American systems both try to achieve, and in a measure succeed in achieving, a fair balance between the offeror and the offeree.

**Unenforceable transactions.** In all systems of contract law, certain classes of transactions are treated as unenforceable by the judicial process because they are thought to involve unusual hazards for a contracting party or to be of marginal social utility. There are, in both civil-law and common-law systems, four kinds of concern that lead the systems to treat certain types of transaction as unenforceable. These four kinds of concern may be called evidentiary, cautionary, channelling, and deterrent. The evidentiary concern springs from the desire to protect both the individual citizen and the courts against manufactured evidence and insufficient proof. The cautionary concern seeks to safeguard the individual against both his own rashness and the importuning of others. The channelling concern seeks to mark off or label obligations that may be enforceable and to direct attention to the problem of the extent and kind of the legal obligation, so that the individual will know the legal significance that his action may have. Finally, the deterrent concern refers to those types of transaction that are discouraged because they are felt to be of doubtful value to society.

Two quite different techniques are used to delineate types of transaction that are unenforceable in their na-

tural, or normal, state. The first proceeds by describing the type in functional or economic terms. The common-law Statute of Frauds enacted by the British Parliament in 1677 provided that the following six kinds of contracts should be unenforceable unless expressed in writing: contracts to sell goods exceeding a certain value; contracts to sell any interest in land; agreements that are not to be performed within a year of their making; agreements upon consideration of marriage; suretyship agreements; and undertakings by an executor or administrator to be surety on a debt of the deceased for which the estate is liable. Civil-law systems typically describe as unenforceable in the absence of an appropriate formality noncommercial contractual obligations exceeding a certain value; mortgages created by contract; noncommercial compromise agreements; marriage contracts; agreements binding a party to transfer all, or a fractional part of, his property; leases to run for more than a year; assumptions of the obligation to stand as surety, at least when the operation is not a commercial one on the surety's part; promise of an annuity; and promises to make gifts.

Another less direct technique for delineating unenforceable types of transaction derives from the common law's doctrine of consideration. It holds transactions unenforceable in the absence of a bargained-for exchange. This class would include, for example, promises to make gifts. The approach tends to be too all-embracing, treating certain types of transaction as suspect when there is little or no practical justification for doing so. It is not clearly demonstrated, for example, that an option agreement made by two businessmen should be handled differently from many other kinds of commercial dealings. A strong argument exists that the common law's handling of commercial options, business compromises, and other business transactions lacking an element of exchange is more a logical deduction from the general doctrine of consideration than an expression of justifiable policy concerns.

Except in cases where the ground for unenforceability is radical, when a given transaction type is considered unenforceable the legal system should prescribe an extrinsic element the addition of which will cure the defect—for example, expressing the agreement in writing, performing it in part, or using a notarial contract, which involves the participation of a lawyer who holds a special appointment from the state and is charged with handling and recording various types of transactions.

A complex situation has arisen with respect to the two most generally available extrinsic elements, the seal and the payment of a nominal consideration. Various states of the United States no longer consider the seal as an effective extrinsic element. The seal's decline is rooted in its changed significance in the modern, literate, democratic world. The seal was originally an impression, usually in wax, of a device, or design, representing an individual or a family. In modern times, the courts, with legislative assistance in a fair number of the states of the United States, have recognized easy-going substitutes for the wax seal. The effect has been to render the seal progressively less effective, particularly from the cautionary perspective, and many courts now refuse to accept it as a satisfactory formality.

Nominal consideration is a subtle and ingenious formality. Its essence is the introduction of a contrived element of exchange into the transaction. Thus A, desiring to bind himself to give B \$10,000, requests B to promise to give (or give) A a peppercorn in exchange. B's promise (or performance) is an element, extrinsic to a normal gift promise, introduced by the parties in an effort to render the transaction enforceable (since the law does not treat normal gift promises as enforceable). Common-law courts often accept nominal consideration when used in a business context, such as in an option arrangement or a compromise agreement; its effectiveness is understandably more doubtful in the context of a gift promise, since such a transaction involves greater dangers for one party and is socially more marginal.

Civil-law systems have less need than the common law

Decline of  
the use of  
seal

The  
criteria of  
a legal  
contract

for a formality such as nominal consideration; they prescribe methods directly in their statutes. Interestingly enough, however, in some civil-law systems an analogous, judicially developed formality has emerged—the disguised donation (*donation déguisée*) of French law, in which the parties cast a gift promise in the form of an onerous transaction, such as a sale. It can be argued that both the nominal considerations and the disguised donation serve at least the cautionary and channelling functions of formalities mentioned above.

Another kind of extrinsic element recognized by some courts, especially in the common-law world, is one party's reliance upon the promise of the other. The fact of reliance argues in favour of enforcement because it indicates that an underlying understanding existed between the parties and because the relying party may suffer as a consequence of his change of position. Some courts will enforce initially suspect transactions when several extrinsic elements are present in combination. A common-law court, for example, may enforce a gift promise in which the element of reliance was present in addition to a seal or a nominal consideration. Other extrinsic elements, either alone or in combination with reliance, a seal, or a nominal consideration, may also render a transaction enforceable. Cases, for example, in which the promisor dies without attempting to revoke a gift promise could be enforced, as distinguished from cases in which the promisor seeks to revoke.

**Performance.** Contract law seeks to protect parties to an agreement not only by requiring formalities but in many other ways as well. Thus rules respecting deceit, fraud, and undue influence are designed to ensure that contractual obligations are assumed freely and without one party misleading the other. Other rules regulate the modification of ongoing contractual relations with a view to preventing a party with considerable bargaining power—a building contractor, for example—from unfairly imposing changes in the contract.

The law also allows contractual relations to be adjusted when they have been thrown out of balance by unforeseen circumstances. The task of adjustment is relatively easy in cases in which both parties made a mistake or in which one party laboured under a mistaken assumption that was, or plainly should have been, known to the other. The problem of mistake becomes more intractable when the error is chargeable to only one party. The solutions reached for such situations are complex and defy general statement.

Catastrophic events such as inflation, political upheaval, or natural disasters may upset the economy of a contract. In the case of natural catastrophes, relief is frequently available under theories of force majeure and "act of God." When the unsettling circumstances are economic in their nature, as with severe inflation or deflation, a solution is difficult to find. A party who benefits from inflation in one contractual or economic relation may suffer from it in another. A general readjustment in contracts would be enormously complicated and time-consuming and would interject an undesirable element of uncertainty into economic and business activity. Only under exceptional circumstances—and usually in the form of special legislation—does the law seek to adjust contractual relations to take into account the effects of severe economic dislocations.

**Failure to perform.** Another branch of contract law deals with the sanctions that are made available to a contracting party when the other party fails to perform his contractual obligations. When these sanctions take the form of money damages—as they usually do in practice, even though some civil-law systems have a theoretical preference for specific relief—the system must decide whether the plaintiff is to be put in the same position economically that he would have been in had the contract been performed (so-called expectation damages) or simply reimbursed for the actual losses, if any, flowing from his reliance on the contract (reliance damages). Reliance damages can, of course, be very large. A subcontractor who fails to deliver parts required for the construction of an ocean liner (or delivers faulty parts) may

be responsible for heavy reliance damages resulting from delay in the work or actual damage to the vessel. Legal systems utilize various techniques to limit both reliance and expectancy damages when otherwise they would be unreasonably large.

If a person has agreed to buy an article from a merchant, his refusing to take delivery will not ordinarily produce substantial reliance damages. Delivery costs will have been incurred, but the merchant will presumably not have lost sales elsewhere. In such circumstances, the merchant will seek to recover not his delivery costs but his lost profit—his expectation damages. The law allows relief on the basis that the expectancy created by an enforceable promise has a current economic value, measured by the economic gain that the party would derive if the particular agreement were performed.

In some circumstances, performance is not measureable in terms of market value—as, for example, when one relative has agreed to sell to another a family painting of sentimental value, but of little intrinsic worth. Many legal systems in such a case require specific performance. The availability of specific relief varies among contemporary legal systems, for reasons that seem more historical and doctrinal than practical.

**Other problems of contract law.** Many contracts involve more than two persons. The law of contracts provides special rules for regulating claims by multiparty plaintiffs or claims against multiparty defendants, or for determining rights among the parties. Multiparty problems arise in other contexts as well. There is the problem of whether the immediate parties to a contract can enter into an agreement that will confer rights upon a person not an original party to the contract. Probably because the dogmatic structure of contract law was largely formed on the model of the simpler two-party situation, and because the contract for the benefit of third parties did not have great practical importance until such relatively modern developments as the emergence of life insurance, many systems of contract law have encountered difficulty in working out the relationship between the third party and the underlying contract. English law took the view that, as a rule, a person cannot acquire a right on a contract to which he is not a party. Some of the problems posed are difficult of resolution: under what circumstances and to what extent should the third party control the underlying contract when, for example, the original parties desire to rescind or modify it?

Another variation of the party problem is presented by efforts to add or substitute parties to a contract. In the absence of an express regulation of the problem in the basic contract, the law works with the notion of the presumed intention of the contracting parties, based on considerations of fairness and practicality. A contracting party cannot, in principle, assign to another his right under a contract if the assignment would result in a significant change in the burden assumed by the other contracting party. A contractual right to receive money or goods is a different matter; it can ordinarily be assigned because the resulting burden on the person under obligation is not great, and because society as a whole benefits from having this flexible economic and legal instrument.

One pervasive problem of contract law that has been mentioned above deserves further consideration—the problem of interpretation. Many rules of contract law are simply presumptions, based on experience and tradition, as to what the parties ordinarily intend; if they clearly intend otherwise, the rules are not mandatory. Problems of interpretation frequently arise with respect to the particularities of a given agreement, and here the court seeks to determine what the parties actually had in mind. The effort to ascertain intention may encounter difficulties arising from the law of evidence. Many legal systems limit the use of testimonial evidence to explain a contract the essential elements of which have been stated by the parties in a written form.

#### CONTEMPORARY TENDENCIES

**Arbitration.** Modern commercial practice relies to a growing extent on arbitration to handle disputes, espe-

cially those that arise in international transactions. There are several reasons for the growing use of arbitration. The procedure is simple, it is more **expeditious**, and it may be less expensive than traditional litigation. The arbitrators are frequently selected by a trade association or business group for their expert understanding of the issues in the dispute. The proceedings are private, which is advantageous when the case involves trade or business secrets. In many legal systems the parties can authorize arbitrators to base their decision on equitable considerations that the law excludes. Finally, when the parties are from different countries, an international panel of arbitrators may offer a greater guarantee of impartiality than would a national court.

Despite these apparent advantages of arbitration, the development of contract law may **suffer** considerably by withdrawal from the courts of litigation of some of the more significant and **difficult** problems, all the more so because the reasoning in arbitral awards is usually not made public.

**Attempts at codification.** Trade and commerce flow increasingly across national and state boundaries. In response to this there have been many efforts to unify the traditional legal systems. In the United States, the Uniform Commercial Code has replaced earlier uniform statutes such as the Sales Act and the Negotiable Instruments Law. Internationally, during the 1960s there was significant progress toward uniform regulation of the law of sales. The creation of a uniform body of substantive rules is, of course, easiest when the communities involved have roughly similar rules and principles. In addition, the greater the volume of multistate transactions, the greater is the pressure for uniform regulation. It was understandably easier to achieve the Uniform Commercial Code within the United States than it is to create such a system internationally.

When a transaction has a significant relationship with more than one legal order, **difficult** problems of private international law often arise with respect to which law shall govern. A type of halfway house between legal diversity and unification—the creation of uniform rules for choice of law—is of some help, and in this area the Hague Conference on Private International Law has done significant work (see INTERNATIONAL LAW).

**BIBLIOGRAPHY.** A useful survey of the development of contract law from its beginnings in primitive societies is E.A. FARNSWORTH, "The Past of Promise: An Historical Introduction to Contract," *Columbia Law Review*, 69:576–607 (1969). A historical treatment of the common law of contract is C.H.S. FIFOOT, *History and Sources of the Common Law: Tort and Contract* (1949, reprinted 1970). Treatises on Anglo-American contract law include: G.C. CHESHIRE and C.H.S. FIFOOT, *The Law of Contract*, 9th ed. (1976); A.L. CORBIN, *On Contracts*, 8 vol. (1950–51); and S. WILLISTON, *A Treatise on the Law of Contracts*, 8 vol., rev. ed. by the author and G.J. THOMPSON (1936–45). An extensive discussion of French and German contract law may be found in A.T. VON MEHREN and J.R. GORDLEY, *The Civil Law System*, 2nd ed. (1977). A classic discussion of the law of contract damages is L.L. FULLER and W.R. PERDUE, JR., "The Reliance Interest in Contract Damages," *Yale Law Journal*, 46:52–96, 373–420 (1936–37).

(A.T.v.M.)

## Control Systems

A control system is a means by which a variable quantity or set of variable quantities is made to conform to a prescribed norm. In this broad sense the bodies of living organisms contain numerous natural control systems, such as body temperature and acidity. Like these, the control systems in modern technology, to which this article is confined, may either hold the values of the controlled quantities constant or may cause them to vary in a prescribed way.

A control system may be operated by electricity, by mechanical means, by fluid pressure (liquid or gas), or by a combination of methods. When a computer is involved in the control circuit, it is usually more convenient to operate all of the control systems electrically, although intermixtures are fairly common.

Control systems are intimately related to the concept of

automation, but the two fundamental types of control systems, feedforward and feedback, have classic ancestry. The loom invented by Joseph Jacquard of France in 1801 is an early example of feedforward; a set of punched cards programmed the patterns woven by the loom; no information from the process was used to correct the machine's operation. Similar feedforward control was incorporated in a number of machine tools invented in the 19th century, in which a cutting tool followed the shape of a model.

Feedback control, in which information from the process is used to correct a machine's operation, has an even older history. Roman engineers maintained water levels for their aqueduct system by means of floating valves, which opened and closed at appropriate levels. Dutch windmills of the 17th century were kept facing the wind by the action of an auxiliary fan that moved the entire upper part of the mill. The most famous example from the Industrial Revolution is James Watt's **flyball** governor of 1769, a device that regulated steam flow to a steam engine to maintain constant engine speed despite a changing load (see also STEAM POWER).

The first theoretical analysis of a control system, which presented a differential-equation model of the Watt governor, was published by James Clerk Maxwell in the 19th century. Maxwell's work was soon generalized and control theory developed by a number of contributions, including a notable study of the automatic steering system of the U. S. battleship "New Mexico," published in 1922. During the 1930s electrical feedback was used in long-distance telephone amplifiers and in the general theory of the servomechanism, by which a small amount of power controls a very large amount and makes automatic corrections. The pneumatic controller, basic to the development of early automated systems in the chemical and petroleum industries, and the analogue computer followed. All of these developments formed the basis for elaboration of control-system theory and applications during World War II, such as anti-aircraft batteries and fire-control systems.

Most of the theoretical studies as well as the practical systems up to World War II were single loop; that is, they involved merely feedback from a single point and correction from a single point. In the 1950s the potential of multiple-loop systems came under investigation; in these systems feedback could be initiated at more than one point in a process and corrections made from more than one point. The introduction of analogue and digital-computing equipment opened the way for much greater complexity in automatic-control theory, an advance since labelled "modern control" to distinguish it from the older, simpler, "classical control."

### BASIC PRINCIPLES

With few and relatively unimportant exceptions, all the modern control systems have two fundamental characteristics in common. These can be described, in somewhat oversimplified form, as follows: (1) The value of the controlled quantity is varied by a motor (this word being used in a generalized sense), which draws its power from a local source rather than from an incoming signal. Thus there is available a large amount of power to effect necessary variations of the controlled quantity and to ensure that the operations of varying the controlled quantity do not load and distort the signals on which the accuracy of the control depends. (2) The rate at which energy is fed to the motor to effect variations in the value of the controlled quantity is determined more or less directly by some function of the difference between the actual and desired values of the controlled quantity. Thus, for example, in the case of a thermostatic heating system, the supply of fuel to the furnace is determined by whether the actual temperature is higher or lower than the desired temperature. A control system with these fundamental characteristics is called a closed-loop control system, or a servomechanism (see illustration). Open-loop control systems are feedforward systems.

**Stability and transient response.** The stability of any control system is determined to a large extent by its re-

Feed-  
forward  
and  
feedback

Block diagram showing the essential components of a typical closed-loop control system.

sponse to a suddenly applied signal, or transient. If such a signal causes the system to overcorrect itself, a phenomenon called hunting may occur in which the system first overcorrects itself in one direction and then overcorrects itself in the opposite direction. Because hunting is undesirable, measures are usually taken to correct it. The most common corrective measure is the addition of damping somewhere in the system. Damping slows down system response and avoids excessive overshoots or overcorrections. If the damping is such that the correction produces exactly the desired result without any overshooting or undershooting, the system is said to be critically damped. If damping is such that it takes the system an excessively long time to reach equilibrium, the system is overdamped. If the system oscillates a few cycles around the desired condition before equilibrium is reached, the system is underdamped. Damping can be in the form of electrical resistance in an electronic circuit, the application of a brake in a mechanical circuit, or forcing oil through a small orifice as in shock-absorber damping.

The critically damped system is the most desirable for the control engineer to obtain. Rather than risk obtaining an overdamped system with resulting system sluggishness, a slightly underdamped condition is usually designed into the system. A common criterion is that the first overshoot must not exceed the desired equilibrium value by more than 20 percent, and succeeding overshoots and undershoots must die out very rapidly.

**Frequency response.** Another method of ascertaining the stability of a control system is to determine its frequency response—that is, its response to a continuously varying input signal at various frequencies. The output of the control system is then compared to the input with respect to amplitude and to phase—that is, the degree with which the input and output signals are out of step.

Frequency response can either be determined experimentally—especially in electrical systems—or can be calculated mathematically if the constants of the system are known. Mathematical calculations are particularly useful for systems that can be described by ordinary linear differential equations. Graphic shortcuts also help greatly in the study of system responses.

**Other factors.** Several other techniques enter into the design of advanced control systems. Adaptive control is the capability of the system to modify its own operation to achieve the best possible mode of operation. A general definition of adaptive control implies that an adaptive system must be capable of performing the following functions: providing continuous information about the present state of the system or identifying the process; comparing present system performance to the desired or optimum performance and making a decision to change the system to achieve some previously defined optimum performance; and initiating a proper modification to drive the control system to the optimum. These three principles—identification, decision, and modification—are inherent in any adaptive system.

Dynamic-optimizing control requires the control system to operate in such a way that a specific performance criterion is satisfied. This criterion is usually formulated in such terms that the controlled system must move

from the original to a new position in the minimum possible time or at minimum total cost.

Learning control implies that the control system contains sufficient computational ability so that it can develop representations of the mathematical model of the system being controlled and can modify its own operation to compensate for this newly developed knowledge. Thus, the learning control system is a further development of the adaptive controller.

Multivariable-noninteracting control involves large systems in which the size of internal variables is dependent upon the values of other related variables of the process. Thus the single-loop techniques of classical control theory will not suffice. More sophisticated techniques must be used to develop appropriate control systems for such processes.

#### CURRENT PRACTICE

There are many cases in industrial control practice in which theoretical automatic control methods are not yet sufficiently advanced to design an automatic control system or completely to predict its effects. This situation is true of the very large, highly interconnected systems such as occur in many industrial plants. In this case, operations research (*q.v.*), a mathematical technique for evaluating various possible procedures in a given situation, can be of value.

**Conventional control.** In determining the actual physical control system to be installed in an industrial plant, the instrumentation or control-system engineer has a wide range of possible equipment and methods to use. He may choose to use a set of analogue-type instruments, those that use a continuously varying physical representation of the signal involved—*i.e.*, a current, voltage, or an air pressure. Devices built to handle such signals, generally called conventional devices, are usually capable of receiving only one input signal and one resulting output correction. Hence they are generally considered single-loop systems, and the total control system is built up of a collection of such devices. Analogue-type computers are available that can consider several variables at once for more complex control functions. These are usually very specific in their applications, however, and thus are not commonly used.

The number of control devices added to an industrial plant may vary widely from plant to plant. They may comprise only a very few instruments that are used mainly as indicators of plant-operating conditions. The operator is thus made aware of off-normal conditions and he himself manually adjusts such plant operational devices as valves and speed regulators in order to maintain control. On the other hand, there may be devices of sufficient quantity and complexity so that nearly all the possible occurrences may be covered by a control-system action ensuring automatic control of any foreseeable failure or upset and thus making possible unattended control of the process. In the early 1970s the control systems of most industrial processes were somewhere between these two extremes. They are, however, tending toward the latter as more and more becomes known of the requirements for control of any particular process.

**Computer control.** With the development of very capable and very reliable models in the late 1960s, digital computers quickly became popular elements of industrial-plant-control systems. Computers (*q.v.*) are applied to industrial control problems in three ways: for supervisory or optimizing control; direct digital control; and hierarchy control.

**Supervisory or optimizing control.** In supervisory or optimizing control the computer operates in an external or secondary capacity, changing the set points in the primary plant-control system either directly or through manual intervention. A chemical process, for example, may take place in a vat the temperature of which is thermostatically regulated. For various reasons, the supervisory control system might intervene to reset the thermostat to a different level. The task of supervisory control is thus to "trim" the plant operation, thereby lowering costs or increasing production. Though the

Damping

Adaptive control

overall potential for gain from supervisory control is sharply limited, a malfunction of the computer cannot adversely affect the plant.

**Direct-digital control.** In direct-digital control a single digital computer replaces a group of single-loop analogue controllers. Its greater computational ability makes the substitution possible, with obvious cost savings, and also permits the application of more complex advanced-control techniques.

**Hierarchy control.** Hierarchy control attempts to apply computers to all the plant-control situations simultaneously. As such, it requires the most advanced computers and most sophisticated automatic-control devices to integrate the plant operation at every level from top-management decision to the movement of a valve. Though most work in this area was still in the development stages, in the early 1970s several partial installations were already operating.

The advantage offered by the digital computer over the conventional control system described earlier, costs being equal, is that the computer can be programmed readily to carry out a wide variety of separate tasks. In addition, it is fairly easy to change the program so as to carry out a new or revised set of tasks should the nature of the process change or the previously proposed system prove to be inadequate for the proposed task. With digital computers, this can usually be done with no change to the physical equipment of the control system. For the conventional control case, at least, some of the physical hardware apparatus of the control system must be replaced in order to achieve new functions or new implementations of them.

**Instrumentation and control in process industries.** Two major problems impede adoption of the computer-controlled process: lack of knowledge about particular processes and the theoretical relationship among all the variables involved, and lack of instrumentation for continuously measuring some of the process variables.

Continuous quantitative measurement of several physical conditions can now be made—e.g., temperature, pressure, level, weight, flow, and volume, together with viscosity, moisture content, conductivity, pH, liquid density, refractive index, specific gravity, and, in some cases, chemical composition (see also INSTRUMENTATION).

Much remains to be done. Not all the analyses can be undertaken continuously; few analytical techniques are fast enough to apply in a continuous control system, and reliability is still generally not high enough. Reliability is of prime importance because it is costly both to interrupt the process and to provide skilled maintenance. Another major problem preventing the widespread use of process analyzers is the difficulty of securing a representative sample of a process stream in various type of plants.

As plants become increasingly complex and more and more process variables are measured, the necessity for checking a large number of measured and controlled values makes some form of data reduction necessary and automatic scanning desirable. Much of the information gathered is of use only for research or during periods of disturbance or emergency. Data reduction and automatic monitoring and scanning of process variables are being used to an increasing extent. Such equipment in a power station will automatically and continuously scan and record at very high speeds the readings of instruments measuring flows, levels, pressures, and temperatures of boilers, furnaces, and turbine units. The system will print out the relevant data at regular intervals and will record and give warnings of any deviations from normal in the readings. It will also compute and record continuously the overall boiler efficiency.

**Control in manufacturing.** Control systems are also becoming a major component of the automation of production lines in modern factories. Automation (*q.v.*) began in the late 1940s with the development of the transfer machine, a mechanical device for moving and positioning large objects on a production line (such as partly finished automobile engine blocks). These early machines had no feedback control as described above. Instead, manual intervention was required for any final adjust-

ment of position or other corrective action necessary. Because of their large size and cost, long production runs were necessary to justify the use of transfer machines.

The need to reduce the high labour content of manufactured goods, the requirement to handle much smaller production runs, the desire to gain increased accuracy of manufacture, combined with the need for sophisticated tests of the product during manufacture, have resulted in the recent development of computerized production monitors, testing devices, and feedback-controlled production robots.

The "programmability" of the computer to handle a wide range of tasks along with the capability of rapid change to a new program has made it invaluable for these purposes. Similarly, the need to compensate for the effect of tool wear and other variations in automatic machining operations has required the institution of a feedback control of tool positioning and cutting rate in place of the formerly used direct mechanical motion. Again, the result is a more accurately finished final product with less chance for tool or manufacturing machine damage.

**BIBLIOGRAPHY.** The first major textbook on digital computer control was that of E.S. SAVAS *et al.*, *Computer Control of Industrial Processes* (1965). The field of direct digital control is summarized in T.J. WILLIAMS and F.M. RYAN (eds.), *Progress in Direct Digital Control* (1969). The science of automatic control originated with the study of the design of feedback amplifiers and filters for telephone networks. Two basic and classic papers in this area are H. NYQUIST, "Regeneration Theory," *Bell Syst. Tech. J.*, 11:126-147 (1932); and H.W. BODE, "Relations Between Attenuation and Phase in Feedback Amplifier Design," *Bell Syst. Tech. J.*, 19:421-454 (1940). These contributions, along with W.R. EVANS, "Control System Analysis by Root Locus Method," *Trans. Am. Inst. Elec. Engrs.*, 69:66-69 (1950), formed the basis of the so-called classical design procedures—the "Nyquist Diagram," the "Bode Plot," and the "Root Locus Method." During the late 1940s and the 1950s, a number of excellent textbooks appeared. Important among these were those of G.S. BROWN and D.P. CAMPBELL, *Principles of Servomechanisms* (1948); HAROLD CHESTNUT and R.W. MAYER, *Servomechanisms and Regulating System Design*, vol. 1 (1951); and the classic by J.G. TRUXAL, *Automatic Feedback Control System Synthesis* (1955). The first textbook in industrial-process control was R.C. OLDENBOURG and H. SARTORIUS, *Dynamik selbsttatiger regelungen* (1944; Eng. trans., *The Dynamics of Automatic Control*, 1948). The "Era of Modern Control" can be traced to the writings of NORBERT WIENER, of which *Cybernetics* (1948), is especially well known; R.E. BELLMAN, *Dynamic Programming* (1957); L.S. PONTRYAGIN *et al.*, *The Mathematical Theory of Optical Processes* (Eng. trans., 1962); and especially in the United States to R.E. KALMAN. His "On the General Theory of Control Systems," in J.F. COALES (ed.), *Automatic and Remote Control: Proceedings, First International Congress of the International Federation of Automatic Control*, vol. 1, pp. 481-492 (1961), is one of the most important of his many papers. Much of the early interest in the subject of process dynamics can be traced to the work of DONALD P. CAMPBELL, *Process Dynamics* (1958); and to the Conference on Automatic Control, the papers of which were edited by ARNOLD TUSTIN in *Automatic and Manual Control* (1952).

## Cook, James

As an outstanding sea captain, navigator, cartographer, and practical dietician, James Cook, on his three world-circling voyages, discovered more about the Pacific, the South Atlantic, the southern Indian, and the Arctic and Antarctic oceans than had been seen or imagined by all other navigators during the preceding two and one-half centuries. He defeated scurvy, established precise navigation as a common sea skill, and changed the face of the Pacific from the world's immense abode of myths and mystery to the map men know today.

James Cook was born October 27, 1728, at the village of Marton in Cleveland, Yorkshire, the son of a farm-hand migrant from Scotland. While Cook was still a child, his father became the foreman on a farm in a neighbouring village. Young James early showed signs of an inquiring and able mind, and his father's employer paid for his schooling in the village until he was 12 years old. His early teens were spent on the farm where his father worked, but a brief apprenticeship in a general

store in a coastal village north of Whitby brought him in contact with ships and the sea. At the age of 18, in 1746, he was apprenticed to a well-known Quaker shipowner, John Walker of Whitby, and at 21 was rated able seaman in the Walker collier-barks—stout, seaworthy, slow, 300- and 400-tonners mainly in the North Sea trade. When the ships were laid up for refitting (done by the apprentices and crews) at Whitby during the worst months of winter, Cook lived ashore and studied mathematics by night. The Whitby barks, constantly working North Sea waters off a dangerous and ill-marked lee shore, offered Cook splendid practical training: the young man who learned his seamanship there had little to fear from any other sea.

Promoted to mate in 1752, Cook was offered command of a bark three years later, after eight years at sea. Advancement of this nature opened up a career that would have satisfied most working seamen, but instead Cook volunteered as able seaman in the Royal Navy. The navy, he was sure, offered a more interesting career for the competent professional seaman, and greater opportunity than in the North Sea barks. Tall, of striking appearance, Cook almost immediately caught the attention of his superiors, and with excellent power of command, he was marked for rapid advancement.

Actions in the Seven Years' War. After advancing to master's mate, and boatswain, both noncommissioned ranks, he was made master of HMS "Pembroke" at the age of 29. During the Seven Years' War between Great Britain and France (1756–63) he saw action in the Bay of Biscay, was given command of a captured ship, and took part in the siege of Louisbourg in Nova Scotia and in the successful amphibious assault against Quebec. His charting and marking of the more difficult reaches of the St. Lawrence River contributed to the success of General Wolfe's landing there. Based at Halifax during the winters, he mastered surveying with the plane table. Between 1763 and 1768, after the war had ended, he commanded the schooner "Grenville" while surveying the coasts of Newfoundland, sailing most of the year and working on his charts at his base in England during the winters. In 1766 he observed an eclipse of the sun and sent the details to the Royal Society in London—an unusual activity for a noncommissioned officer, for Cook still rated only as master.

Voyages and discoveries. In 1768 the Royal Society, in conjunction with the Admiralty, was organizing the first scientific expedition to the Pacific, and the rather obscure 40-year-old James Cook was appointed commander of the expedition. Hurriedly commissioned as lieutenant, he was given a homely looking but extremely sturdy Whitby coal-hauling bark renamed HMS "Endeavour," then four years old, of just 368 tons, and less than 98 feet long. Cook's orders were to convey gentlemen of the Royal Society and their assistants to Tahiti to

observe the transit of the planet Venus across the sun. That done, on June 3, 1769, he was to find the southern continent, the so-called Terra Australis, which philosophers argued must exist to balance the landmasses of the Northern Hemisphere. The leader of the scientists was the rich and able Joseph Banks, aged 26, who was assisted by Daniel Solander, a Swedish botanist, as well as astronomers (Cook rating as one) and artists. Cook carried an early nautical almanac and brass sextants, but no chronometer on the first voyage.

**His success is history.** Striking south and southwest from Tahiti, where his predecessors had sailed west and west-northwest with the favouring trade winds, Cook found and charted all of New Zealand, a difficult job that took six months. After that, instead of turning before the west winds for the homeward run around Cape Horn, he crossed the Tasman Sea westward and, on April 19, 1770, came on the southeast coast of Australia. Running north along its 2,000-mile eastern coast, surveying as he went, Cook successfully navigated Queensland's Great Barrier Reef—since reckoned as one of the greatest navigational hazards in the world—taking the Coral Sea and the Torres Strait in his stride. Once the bark touched on a coral spur by night, but it withstood the impact and was refloated. After the "Endeavour" was grounded on the nearby Queensland coast and repaired, Cook sailed it back to England. He stopped briefly at Batavia (modern Djakarta) for supplies, and although the crew had been remarkably healthy until then, 30 died of fever and dysentery contracted while on land. None of the crew, however, died of scurvy (a dietary disease caused by a lack of ascorbic acid and that habitually decimated the crews of ships on lengthy voyages in the 18th century). This was because, in addition to ensuring cleanliness and ventilation in the crew's quarters, Cook insisted on an appropriate diet that included cress, sauerkraut, and a kind of orange extract. The health in which he maintained his sailors in consequence made his name a naval byword.

Back in England, he was promoted to commander, presented to King George III, and soon began to organize another and even more ambitious voyage. The success of the expedition of Joseph Banks and his scientists (which established the useful principle of sending scientists on naval voyages—e.g., Charles Darwin in the "Beagle," T.H. Huxley in the "Rattlesnake," and J.D. Hooker with Sir James Ross to the Ross Sea in the Antarctic) stimulated interest not only in the discovery of new lands but in the new knowledge in many other scientific subjects. The wealth of scientifically collected material from the "Endeavour" voyage was unique. Cook was now sent out with two ships to make the first circumnavigation of and penetration into the Antarctic.

Between July 1772 and July 1775 Cook made what ranks as one of the greatest sailing ship voyages, again with a small former Whitby ship, the "Resolution," and a consort ship, the "Adventure." He found no trace of Terra Australis, though he sailed beyond latitude 70° S in the Antarctic, but he successfully completed the first west-east circumnavigation in high latitudes, charted Tonga and Easter Island during the winters, discovered New Caledonia in the Pacific, and the South Sandwich Islands and South Georgia Island in the Atlantic. He showed that a real Terra Australis existed only in the landmasses of Australia, New Zealand, and whatever land might remain frozen beyond the ice rim of Antarctica. And, once again, not one of his crew died of scurvy. Back in England, he was promoted to captain at last, elected a fellow of the Royal Society, and awarded one of its highest honours, the gold Copley Medal, for a paper he prepared on his work against scurvy.

The last voyage. There was yet one secret of the Pacific to be discovered: whether there existed a northwest passage around Canada and Alaska or a northeast one around Siberia, between the Atlantic and Pacific. As the passages had long been sought in vain from Europe, it was thought that the search from the North Pacific might be successful. The man to undertake the search obviously was Cook, and in July 1776 he went off again on the "Resolution" with another Whitby ship, the "Discovery."

Lawrence

The voyages of Captain Cook

This search was unsuccessful, for neither a northwest nor northeast passage usable by sailing ships existed, and the voyage led to Cook's death. On February 14, 1779, at the age of 50, in a brief fracas with Hawaiians over the stealing of a cutter, Cook was slain on the beach at Kealakekua by the Polynesian natives.

Cook's voyaging left him comparatively little time for family life. Although Cook had married Elizabeth Batts in 1762, when he was 34 years old, he was at sea for more than half of their married life. The couple had six children, three of whom died in infancy. The three surviving sons, two of whom entered the navy, had all died by 1794.

Cook had set new standards of thoroughness in discovery and seamanship, in navigation, cartography, and the sea care of men, in relations with natives both hostile and docile, in the application of science at sea; and he had peacefully changed the map of the world more than any other single man in history.

**BIBLIOGRAPHY.** *The Journals of Captain Cook*, ed. by J.C. BEAGLEHOLE, 4 vol. (1955-67), the standard work on the three voyages, presenting Cook's own text for the first time, thoroughly annotated and explained, and containing a separate portfolio with reproductions of charts and views drawn on these voyages; J.C. BEAGLEHOLE, *The Exploration of the Pacific*, 3rd ed. (1966), provides the background to Cook's voyages; JAMES A. WILLIAMSON, *Cook and the Opening of the Pacific* (1946), useful for background; CHARLES DE BROSSES, *Histoire des navigations aux terres australes* (1756); JAMES BURNEY, *A Chronological History of the Discoveries in the South Sea or Pacific Ocean*, 5 vol. *men's Seaman*, 1967); G.M. BADGER (ed.), *Captain Cook, Navigator and Scientist* (1969), papers presented at the Cook Bicentenary Symposium, Australian Academy of science, Canberra.

(A.J.V.)

## Cooper, James Fenimore

The first major American novelist, James Fenimore Cooper established a permanent place for himself in literary history as the virtual inventor of the sea romance and the frontier adventure novel.

Cooper was born on September 15, 1789, at Burlington, New Jersey. His mother, Elizabeth Fenimore, was a member of a respectable New Jersey Quaker family; and his father, William, later founded a frontier settlement at the source of the Susquehanna River (now Coopers-town, New York) and served as a Federalist congressman during the administrations of George Washington and John Adams. It was a most appropriate family background for a writer who, by the time of his death, was generally considered America's "national novelist."

**Early years.** James was but a year old when William Cooper moved his family to the primitive settlement in upstate New York. He was doubtless fortunate to be the 11th of 12 children, for he was spared the worst hardships of frontier life while he was able to benefit educationally both from the rich oral traditions of his family and a material prosperity that afforded him a gentleman's education. After private schooling in Albany, he attended Yale from 1803 to 1805. Little is known of his college career other than that he was the best Latin scholar of his class and was expelled in his junior year because of a prank. Since high spirits seemed to fit him for an active life, his family allowed him to join the Navy as a midshipman. But prolonged shore duty at several New York

stations merely substituted naval for academic discipline. His father's death in 1809 left him financially independent, and in 1811 he married Susan De Lancy and resigned from the Navy.

For ten years after his marriage he led the active but unproductive life of a dilettante, dabbling in agriculture, politics, the American Bible Society, and the Westchester militia. It was in this amateur spirit that he wrote and published his first fiction, reputedly on a challenge from

his wife. *Precaution* (1820) was a plodding imitation of Jane Austen's novels of English gentry manners. It is mainly interesting today as a document in the history of American cultural colonialism and as an example of a clumsy attempt to imitate Jane Austen's investigation of the ironic discrepancy between illusion and reality. His second novel, *The Spy* (1821), was based on another British model, Sir Walter Scott's "Waverley" novels, stories of adventure and romance set in 17th- and 18th-century Scotland. But in *The Spy* Cooper broke new ground by using an American Revolutionary War setting (based partly on the experiences of his wife's British Loyalist family) and by introducing several distinctively American character types. Like Scott's novels of Scotland, *The Spy* is a drama of conflicting loyalties and interests in which the action mirrors and expresses more subtle internal psychological tensions. *The Spy* soon brought him international fame and a certain amount of wealth. The latter was very welcome, indeed necessary, since his father's estate had proved less ample than anybody had thought, and, with the death of his elder brothers, he had found himself responsible for the debts and widows of the entire Cooper family.

Novels. The first of the famous "Leatherstocking" tales, *The Pioneers* (1823), followed and adhered to the successful formula of *The Spy*, reproducing its basic thematic conflicts and utilizing family traditions once again. In *The Pioneers*, however, the traditions were those of William Cooper of Cooperstown, who appears as Judge Temple of Templeton, along with many other lightly disguised inhabitants of James's boyhood village. No known prototype exists, however, for the novel's principal character—the former wilderness scout Natty Bumppo, *alias* Leatherstocking. The Leatherstocking of *The Pioneers* is an aged man, of rough but sterling character, who ineffectually opposes "the march of progress," namely, the agricultural frontier and its chief spokesman, Judge Temple. Fundamentally, the conflict is between rival versions of the American Eden: the "God's Wilderness" of Leatherstocking and the cultivated garden of Judge Temple. Since Cooper himself was deeply attracted to both ideals, he was able to create a powerful and moving story of frontier life. Indeed, *The Pioneers* is both the first and finest detailed portrait of frontier life in American literature; it is also the first truly original American novel.

Both Cooper and his public were fascinated by the Leatherstocking character. He was encouraged to write a series of sequels in which the entire life of the frontier scout was gradually unfolded. *The Last of the Mohicans* (1826) takes the reader back to the French and Indian wars of Natty's middle age, when he is at the height of his powers. That work was succeeded by *The Prairie* (1827) in which, now very old and philosophical, Leatherstocking dies, facing the westering sun he has so long followed. (The five novels of the series were not written in their narrative order.) Identified from the start with the vanishing wilderness and its natives, Leatherstocking was an unalterably elegiac figure, wifeless and childless, hauntingly loyal to a lost cause. This conception of the character was not fully realized in *The Pioneers*, however, because Cooper's main concern with depicting frontier life led him to endow Leatherstocking with some comic traits and make his laments, at times, little more than whines or grumbles. But in these sequels Cooper retreated stylistically from a realistic picture of the frontier in order to portray a more idyllic and romantic wilderness; by doing so he could exploit the parallels between the American Indians and the forlorn Celtic heroes of James Macpherson's pseudo-epic *Ossian*, leaving Leatherstocking intact but slightly idealized and making extensive use of Macpherson's imagery and rhetoric.

Cooper intended to bury Leatherstocking in *The Prairie*, but many years later he resuscitated the character and portrayed his early maturity in *The Pathfinder* (1840) and his youth in *The Deerslayer* (1841). These novels, in which Natty becomes the centre of romantic interest for the first time, carry the idealization process further. In *The Pathfinder* he is explicitly described as an American Adam, while in *The Deerslayer* he demonstrates his fitness as a warrior-saint by passing a series of moral trials and revealing a keen, though untutored, aesthetic sensibility.

The "Leatherstocking" tales are Cooper's great imperfect masterpiece; but he continued to write many other volumes of fiction and nonfiction. His fourth novel, *The Pilot* (1823), inaugurated a series of sea novels, which were at once as popular and influential as the "Leatherstocking" tales. And they were more authentic: such Westerners as General Lewis Cass, governor of Michigan Territory, and Mark Twain might ridicule Cooper's woodcraft, but old salts like Herman Melville and Joseph Conrad rightly admired and learned from his sea stories, in particular, *The Red Rover* (1827) and *The Sea Lions* (1849). Never before in prose fiction had the sea become, not merely a theatre for but the principal actor in, moral drama that celebrated man's courage and skill at the same time that it revealed him humbled by the forces of God's nature. As developed by Cooper, and later by Melville, the sea novel became a powerful vehicle for spiritual as well as moral exploration. Not satisfied with mere fictional treatment of life at sea, Cooper also wrote a meticulously researched, highly readable *History of the Navy of the United States of America* (1839).

**Cultural and political involvement.** Though most famous as a prolific novelist, he did not simply retire to his study after the success of *The Spy*. Between 1822 and 1826 he lived in New York City and participated in its intellectual life, founding the Bread and Cheese Club, which included such members as the poets Fitz-Greene Halleck and William Cullen Bryant, the painter and inventor Samuel F.B. Morse, and the great Federalist judge James Kent. Like Cooper himself, these were men active both in cultural and political affairs.

Cooper's own increasing liberalism was confirmed by a lengthy stay (1826–33) in Europe, where he moved for the education of his son and four daughters. Those years coincided with a period of revolutionary ferment in Europe; and because of a close friendship that he developed with the old American Revolutionary War hero Lafayette, he was kept well-informed about Europe's political developments. Through his novels, most notably *The Bravo* (1831), and other more openly polemical writings, he attacked the corruption and tyranny of oligarchical regimes in Europe. His active championship of the prin-

stocking"  
tales

Return to  
America

ciples of political democracy (though never of social egalitarianism) coincided with a steep decline in his literary popularity in America, which he attributed to a decline in democratic feeling among the reading—i.e. the propertied—classes to which he himself belonged.

When he returned to America, he settled first in New York City and then for the remainder of his life in Cooperstown. In the gentlemanly tradition of Jefferson and Lafayette he attacked the oligarchical party of his day, in this case the Whig Party, which opposed Pres. Andrew Jackson, the exponent of a more egalitarian form of democracy. The Whigs, however, were soon able to turn the tables on Cooper and other leading Jacksonians by employing Jackson's egalitarian rhetoric against them. Squire Cooper had made himself especially vulnerable to popular feeling when, in 1837, he refused to let local citizens picnic on a family property known as Three Mile Point. This incident led to a whole series of charges of libel, and suits and countersuits by both the Whigs and Cooper. At this time, too, agrarian riots on the estates of his old New York friends shattered his simple Jeffersonian faith in the virtue of the American farmer. All of this conflict and unrest was hard to bear, and harder still because he was writing more and earning less as the years went by. The public, which had revelled in his early forest and sea romances, was not interested in his acute political treatise, *The American Democrat* (1838), or even in such political satires as *The Monikins* (1835) or *Home As Found* (1838). And though he wrote some of his best romances—particularly the later "Leatherstocking" tales and *Satanstoe* (1845)—during the last decade of his life, profits from publishing so diminished that he gained little benefit from improved popularity. Though his circumstances were never straitened, he had to go on writing; and some of the later novels, such as *Mercedes of Castile* (1840) or *Jack Tier* (1846–48), were mere hack work. His buoyant political optimism had largely given way to calm Christian faith, though he never lost his troubled concern for the well-being of his country. He died on September 14, 1851.

## MAJOR WORKS

NOVELS: *Precaution* (1820); *The Spy* (1821); *The Pioneers* (1823); *The Pilot* (1823); *Lionel Lincoln* (1824); *The Last of the Mohicans* (1826); *The Prairie* (1827); *The Red Rover* (1827); *The Wept of Wish-ton-Wish* (1829); *The Water Witch*; or, *The Skimmer of the Seas* (1830); *The Bravo* (1831); *The Monikins* (1835); *Homeward Bound* (1838); *Home As Found* (1838); *The Pathfinder* (1840); *The Deerslayer* (1841); *The Two Admirals* (1842); *The Wing-and-Wing*; or *Le Feu-follet* (1842); *Wyandotté*; or, *The Huttet Knoll* (1843); *Ned Myers* (1843); *Afloat and Ashore* (1844); *Satanstoe*; or, *The Littlepage Manuscripts* (1845); *The Chain-Bearer* (1845); *The Redskins*; Or, *Indian and Injin* (1846); *The Crater*; Or, *Vulcan's Peak* (1847); *The Sea Lions* (1849); *The Ways of the Hour* (1850).

OTHER WORKS: *Notions of the Americans: Picked Up by a Travelling Bachelor* (1828); *A Letter to His Countrymen* (1834); *Sketches of Switzerland* (1836); *Gleanings in Europe* (1837); *The American Democrat* (1838); *The History of the Navy of the United States of America* (1839).

**BIBLIOGRAPHY.** RE. SPILLER and P.C. BLACKBURN, *A Descriptive Bibliography of the Writings of James Fenimore Cooper* (1934), is now somewhat out of date but still standard. The major depository for Cooper's papers is the Beinecke Rare Book and Manuscript Library, Yale University. JAMES F. BEARD (ed.), *Letters and Journals of James Fenimore Cooper*, 6 vol. (1960–68), is a monument of precision and learning. Cooper's works have otherwise not been edited definitively. Important collected editions of his novels are *J. Fenimore Cooper's Works, Household Edition*, 32 vol. (1876–84), with introductions by Cooper's daughter Susan; and *The Works of James Fenimore Cooper, Mohawk Edition* (1895–1900). No collected edition is now in print, though his most popular individual works are available in paperback.

Until James F. Beard's promised critical biography of Cooper is published, the fullest and most accurate account is that contained in Beard's prefaces and notes to the *Letters and Journals*. JAMES GROSSMAN, *James Fenimore Cooper* (1949), is a sound and readable critical biography.

Important critical studies include: MARK TWAIN, "Fenimore Cooper's Literary Offences," *North American Review*, vol. 161 (1895), unfair, but shrewd and funny; D.H. LAWRENCE,

"Fenimore Cooper's Leatherstocking Novels," *Studies in Classic American Literature* (1923), factually inaccurate but brilliantly suggestive; YVOR WINTERS, "Fenimore Cooper, or the Ruins of Time," *In Defense of Reason* (1947), first published in 1938, a masterly reappraisal of Cooper's life and writings; HENRY NASH SMITH, *Virgin Land* (1950), establishes Leatherstocking's place in the development of the mythology of the American West; MARIUS BEWLEY, *The Eccentric Design* (1959), includes a useful study of Cooper's social values and literary methods; THOMAS PHILBRICK, *James Fenimore Cooper and the Development of American Sea Fiction* (1961), a definitive study, notable for exhaustive scholarship and penetrating criticism; DONALD A. RINGE, *James Fenimore Cooper* (1962), an able critical survey of Cooper's fiction; KAY S. HOUSE, *Cooper's Americans* (1966), a pioneering study of Cooper's character types and methods of characterization; and GEORGE DEKKER, *James Fenimore Cooper* (1967), examines Cooper's achievement as a historical novelist.

(G.De.)

## Coordination Compounds

Coordination compounds are substances with characteristic chemical structures in which a central metal atom is surrounded by nonmetallic atoms (or groups of atoms), called ligands, joined to it by chemical bonds. The class includes a number of important biological materials, such as vitamin B<sub>12</sub> and hemoglobin, the red colouring matter of blood. It also includes a number of industrially important materials used as dyestuffs and pigments; as agents for extracting, purifying, and analyzing metals; and as catalysts for preparing such useful organic substances as the polyethylene plastics. Coordination compounds have been much studied because of what they reveal about molecular structure and chemical bonding, as well as because of the unusual chemical nature and the useful properties of certain coordination compounds.

The general class of coordination compounds—or complexes, as they are sometimes called—is extensive and diverse. The substances in the class may be composed of electrically neutral molecules or of positively or negatively charged species (ions). (The formula for a compound lists the kinds of atoms in the molecule and, in subscripts, the number of each atom. Water, for example, is composed of molecules that consist of two atoms of hydrogen and one of oxygen: H<sub>2</sub>O. The electrical charge on an ion is represented by a superscript following the symbol of the element—e.g., K<sup>+</sup> for the potassium ion—or following a group of atoms enclosed in brackets—e.g., [NH<sub>4</sub>]<sup>+</sup> for the ammonium ion.)

Among the many coordination compounds having neutral molecules is uranium hexafluoride. The molecular formula of this compound, UF<sub>6</sub>, indicates that six atoms of fluorine (F) are joined to one atom of uranium (U). The structural formula of the compound represents the actual arrangement of atoms in the molecules:

In this formula the solid lines, which represent bonds between atoms, show that four of the fluorine atoms are bonded to the single atom of uranium and lie in a plane with it, the plane being indicated by dotted lines (which do not represent bonds); whereas the remaining two fluorine atoms (also bonded to the uranium atom) lie above and below the plane, respectively.

An example of an ionic coordination complex is the hydrated (water-containing, with formula H<sub>2</sub>O) ion of nickel, symbol Ni, molecular formula [Ni(H<sub>2</sub>O)<sub>6</sub>]<sup>2+</sup>, the structure of which is

Neutral  
coordination  
compounds

in which the symbols and lines are used as above and the brackets and the "two plus" ( $2+$ ) sign show that the double positive charge goes with the whole unit.

The central metal atom in a coordination compound itself may be neutral or charged (ionic). The coordinated groups—or ligands, as they are usually called—may be neutral molecules such as water (in the above example), ammonia, or carbon monoxide; negatively charged ions (anions) such as fluoride (in the first example above) or cyanide ion; or, occasionally, positively charged ions (cations) such as hydrazinium or nitrosonium ion.

Complex ions—that is, the ionic members of the family of coordination substances—may exist as free ions in solution, or they may be incorporated into crystalline materials (salts) with other ions of opposite charge. In such salts, the complex ion may be either the cationic (positively charged) or the anionic (negatively charged) component (or, on occasion, both). The hydrated nickel ion (above) is an example of a cationic complex. An anionic complex is the hexacyanide (composed of carbon, C, and nitrogen, N) of ferric (symbol Fe) ion,  $[\text{Fe}(\text{CN})_6]^{3-}$ , or

in which the symbols have the same general meaning as in the above examples. Crystalline salts containing these ions are potassium (symbol K) ferricyanide (with iron, Fe; carbon, C; and nitrogen, N), formula  $\text{K}_3[\text{Fe}(\text{CN})_6]$ , and the hexahydrate of nickel chloride, formula

in each case the charge on the complex ion being neutralized by appropriate numbers of ions of opposite charge. In the case of potassium ferricyanide, three positively charged potassium ions,  $\text{K}^+$ , neutralize the charge on the complex, and in the nickel complex the charges are neutralized by negative chloride ions,  $\text{Cl}^-$ .

Each molecule or ion of a coordination compound includes a number of ligands, and, in any given substance, the ligands may be all alike or they may be different. Attachment of the ligands to the metal atom may be through only one bond or it may be through several bonds. When only one bond is involved, the ligand is said to be **unidentate**; when two are involved, it is **bidentate**; and so on. In general, ligands utilizing more than one bond are said to be **multidentate**. Because a **multidentate** ligand is joined to the metal atom in more than one place, the resulting complex is said to be **cyclic**—i.e., to contain a ring of atoms. Coordination compounds containing multidentate ligands are called **chelates** (Greek *chele*, "claw"), and their formation is termed **chelation**. Chelates are particularly stable and useful (see below *Multidentate*). An example of a typical **chelate** is the complex formed between cupric ion ( $\text{Cu}^{2+}$ ) and the organic compound ethylenediamine (formula  $\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ ). The formula of the complex is

the structural formula is

The total number of bonds from the ligands to the metal atom is called the **coordination number**; generally, coordination numbers range between 2 and 12, with 4 and 6 being the most common. The ligands surround-

ing the central atom often are referred to collectively as the **coordination sphere**.

The distinction between coordination compounds and other substances is, in fact, somewhat arbitrary. The designation coordination compound, however, is generally restricted to substances the molecules or ions of which are discrete entities and in which the central atom is metallic. Accordingly, molecules such as sulfur hexafluoride and carbon tetrafluoride are not normally considered to be coordination compounds because sulfur and carbon are nonmetallic elements. Yet there is no great difference between these compounds and, say, uranium hexafluoride. Furthermore, such simple ionic salts as sodium chloride or nickel difluoride are not considered to be coordination compounds because they consist of continuous ionic lattices rather than discrete molecules. Nevertheless, the arrangement (and bonding) of the anions surrounding the metal ions in these salts is similar to that in coordination compounds. Coordination compounds generally are characterized by a variety of distinctive physical and chemical properties, such as colour, magnetic susceptibility, solubility and volatility, an ability to undergo oxidation-reduction reactions, and catalytic activity (see below).

#### GENERAL ASPECTS

**History.** Among the earliest recorded examples of a coordination compound is the substance Prussian blue, containing iron (Fe), carbon (C), and nitrogen (N), with formula  $\text{Fe}_4[\text{Fe}(\text{CN})_6]_3$ , which has been used as an artist's pigment since the beginning of the 18th century. Another early example of the preparation of a coordination compound is the use of a sparingly soluble compound, potassium hexachloroplatinate, formula  $\text{K}_2[\text{PtCl}_6]$ , in 1760 to refine the element platinum.

The sustained and systematic development of modern coordination chemistry, however, usually is considered to have begun with the discovery in 1798 that **ammoniacal** solutions of a cobalt chloride,  $\text{CoCl}_2$ , on standing overnight, deposited orange crystals with the composition  $\text{CoCl}_2 \cdot 6\text{NH}_3$  (cobalt, Co; chlorine, Cl; nitrogen, N; ammonia,  $\text{NH}_3$ ), the correct formulation of which is now recognized to be  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_2$ ; this shows that the six ammonia groups are associated with the cobalt atom and the whole is neutralized by three chlorine atoms. The feature of this observation that was particularly significant was the recognition that two independently stable compounds (i.e., cobalt chloride and ammonia) could combine to form a new chemical compound with properties quite different from those of the constituent compounds.

Discoveries of further cobaltamine complexes and many other coordination compounds were made in the 19th century, but it was not until 1893 that Alfred Werner, a Swiss chemist, proposed the first essentially correct formulation of such compounds and provided the first insight into the nature of their bonding. Werner reformulated a series of platinum complexes and showed that their dissociation into ions in solution took place as shown in Table 1. In each case, the number of ions

Formulations of Werner

Table 1: Platinum Complexes as Formulated by Werner

old formulation	Werner formulation	dissociation
$\text{PtCl}_4 \cdot 6\text{NH}_3$	$[\text{Pt}(\text{NH}_3)_6]\text{Cl}_4$	$\rightarrow [\text{Pt}(\text{NH}_3)_6]^{4+} + 4\text{Cl}^-$
$\text{PtCl}_4 \cdot 5\text{NH}_3$	$[\text{Pt}(\text{NH}_3)_5\text{Cl}]\text{Cl}_3$	$\rightarrow [\text{Pt}(\text{NH}_3)_5\text{Cl}]^{3+} + 3\text{Cl}^-$
$\text{PtCl}_4 \cdot 4\text{NH}_3$	$[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}_2$	$\rightarrow [\text{Pt}(\text{NH}_3)_4\text{Cl}_2]^{2+} + 2\text{Cl}^-$
$\text{PtCl}_4 \cdot 3\text{NH}_3$	$[\text{Pt}(\text{NH}_3)_3\text{Cl}_3]\text{Cl}$	$\rightarrow [\text{Pt}(\text{NH}_3)_3\text{Cl}_3]^+ + \text{Cl}^-$
$\text{PtCl}_4 \cdot 2\text{NH}_3$	$[\text{Pt}(\text{NH}_3)_2\text{Cl}_4]$	$\rightarrow \text{none}$
$\text{PtCl}_4 \cdot \text{NH}_3 \cdot \text{KCl}$	$\text{K}[\text{Pt}(\text{NH}_3)\text{Cl}_5]$	$\rightarrow \text{K}^+ + [\text{Pt}(\text{NH}_3)\text{Cl}_5]^-$
$\text{PtCl}_4 \cdot 2\text{KCl}$	$\text{K}_2[\text{PtCl}_6]$	$\rightarrow 2\text{K}^+ + [\text{PtCl}_6]^{2-}$

formed was determined by measurements of the electrical conductivity of the solutions and by analytical determinations of the free chloride ions (where these were formed). It is noteworthy that in Werner's formulations the coordination number of platinum retains the constant value of 6. This constancy of coordination number of

Complex ions

Chelates and chelation

metal atoms occurs frequently, though not invariably.

**Classification.** A coordination compound is characterized by the nature of the central metal atom or ion; the oxidation state of the latter (that is, the gain or loss of electrons in passing from the neutral atom to the charged ion); and by the number, kind, and arrangement of the ligands. Because virtually all metallic elements form coordination compounds, sometimes in several oxidation states and usually with many different ligands, a large number of coordination compounds are known.

**Mononuclear, unidentate.** The simplest types of coordination compounds are those containing a single metal atom or ion (mononuclear compounds), surrounded by unidentate ligands. Most of the coordination compounds already cited, such as the platinum complexes of Werner, belong to this class. Among the ligands forming such complexes are a wide variety of neutral molecules, such as ammonia, water, carbon monoxide, and nitrogen, as well as monoatomic and polyatomic anions, such as the hydride, fluoride, chloride, oxide, hydroxide, nitrite, thiocyanate, carbonate, sulfate, and phosphate ions. Coordination of such ligands to the metal virtually always occurs through an atom possessing an unshared pair of electrons, which it donates to the metal to form a coordinate bond with the latter. Among the atoms that are known to coordinate to metals are those of virtually all the nonmetallic elements (such as hydrogen, carbon, oxygen, nitrogen, and sulfur), with the exception of the noble gases (helium, neon, argon, krypton, and xenon).

**Multidentate.** The chelate complex of a copper ion and ethylenediamine mentioned above is an example of a compound formed between a metal ion and a bidentate ligand. Two further examples of chelate complexes are shown below. These are a nickel complex with a tetradentate large-ring ligand, known as a porphyrin, and a calcium complex with a hexadentate ligand, ethylenediaminetetraacetate. Because metal-ligand attachment in such chelate complexes is through several bonds, such complexes tend to be very stable.

nickel - porphyrin complex

calcium - ethylenediamine-tetraacetate complex

Certain ligands may be either unidentate or multidentate, depending on the particular compound in which they occur. The carbonate ion, formula  $(\text{CO}_3)^{2-}$ , for example, is coordinated to the cobalt ions in two cobalt compounds,  $[\text{Co}(\text{NH}_3)_5(\text{CO}_3)]^+$  and  $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]^+$ , through one and two oxygen atoms, respectively.

**Polynuclear.** Polynuclear complexes are coordination compounds containing two or more metal atoms, or ions, in a single coordination sphere. The two atoms may be held together through direct metal-metal bonds, through bridging ligands, or both. Examples of each are shown below, along with a unique metal-cluster complex having six metal atoms in its nucleus.

**Nomenclature.** Further discussion of coordination compounds requires a knowledge of electronic structure, chemical reactions, and vocabulary that cannot be provided in this article. The necessary background, however, can be found in detail in the articles ATOMIC STRUCTURE; CHEMICAL ELEMENTS; PERIODIC LAW; CHEMICAL COMPOUNDS, ORGANIC; and CHEMICAL REACTIONS.

Generally, the systematic naming of coordination compounds is carried out by rules recommended by the International Union of Pure and Applied Chemistry (IUPAC). Among the more important of these are the following:

1. Neutral and cationic complexes are named by first

complex with metal-metal bond (Re is rhenium)

complex with bridging ligands  
( $\text{C}_2\text{H}_5$  is ethyl radical, Pt is platinum, P is phosphorus, and Cl is chlorine)

complex with metal-metal bond and bridging ligands

complex with metal-cluster nucleus

○ = molybdenum atoms

○ = chlorine atoms

identifying the ligands, followed by the metal and its oxidation number (in Roman numerals enclosed within parentheses). Anionic ligands are cited ahead of neutral ones, and inorganic ligands ahead of organic ones. When the complex contains more than one ligand of a given kind, the number of such ligands is designated by one of the prefixes di-, tri-, tetra-, penta-, and so on, or, in the case of complex ligands, bis-, tris-, tetrakis-, pentakis-, and so on. The oxidation number of the metal is defined in the customary way as the residual charge on the metal if all the ligands were removed together with the electron pairs involved in coordination to the metal. The following examples are illustrative:

$[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$	chloropentaamminecobalt(III)
$[\text{Ni}(\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2)_3]^{2+}$	tris(ethylenediamine)nickel(II)
$[\text{Fe}(\text{CO})_5]$	pentacarbonyliron(0)
$[\text{Al}(\text{H}_2\text{O})_6(\text{OH})]^{3+}$	hydroxopentaquoaluminum(III)
$[\text{RhH}(\text{CO})(\text{P}[\text{C}_6\text{H}_5]_3)_3]$	hydridocarbonyltris(triphenylphosphine)rhodium(I)

2. Anionic complexes are similarly named, except that the name is terminated by the suffix -ate; e.g.,

$[\text{PtCl}_4]^{2-}$	tetrachloroplatinate(II)
$[\text{Ag}(\text{S}_2\text{O}_3)_2]^{3-}$	bis(thiosulfato)argentate(I)
$[\text{OsNCl}_5]^{2-}$	nitridopentachloroosmate(VI)
$[\text{Cr}(\text{SCN})_4(\text{NH}_3)_2]^-$	tetrathiocyanatodiamminechromate(III)

3. In the case of salts, the cation is named first, then the anion; e.g.,

$[\text{Pt}(\text{NH}_3)_3\text{Cl}]\text{Cl}$	chlorotriammineplatinum(II) chloride
$\text{K}_3[\text{Fe}(\text{CN})_6]$	potassium hexacyanoferrate(III)
$[\text{Cr}(\text{NH}_3)_6][\text{Co}(\text{CN})_6]$	hexaamminechromium(III) hexacyanocobaltate(III)

4. Polynuclear complexes are named as follows, bridging ligands being identified by a prefix consisting of the Greek letter mu ( $\mu$ ):

$[(\text{CO})_5\text{Mn}-\text{Mn}(\text{CO})_5]$	decacarbonyldimanganese(0) or bis(pentacarbonylmanganese)
$[(\text{NH}_3)_5\text{Cr}-\text{OH}-\text{Cr}(\text{NH}_3)_5]\text{Cl}_2$	$\mu$ -hydroxo-bis(pentaamminechromium(III)) chloride

Coordination via unshared electron pair

In addition to their systematic designations, many coordination compounds are also known by names reflecting their discoverers or colours. Examples are:

$K[PtCl_3(C_2H_5)]$	Zeise's salt
$NH_4[Cr(NH_3)_2(SCN)_4] \cdot H_2O$	Reinecke's salt
$[Co(NH_3)_6(H_2O)]Cl_2$	rosecobaltic chloride (red)
$Fe_4[Fe(CN)_6]_3$	Prussian blue

**Coordinate bonding.** Werner originally postulated that coordination compounds could be formed because the central atoms carried the capacity to form secondary or coordinate bonds, in addition to the normal or valence bonds. A more complete description of coordinate bonding, in terms of electron pairs, became possible in the 1920s following the introduction of the concept that all covalent (nonionic) bonds consist of electron pairs shared between atoms, a concept advanced chiefly by the U.S. chemist Gilbert N. Lewis. In Lewis' formulation, when both electrons are contributed by one of the atoms, as in the boron–nitrogen bond, which is formed when the substance boron trifluoride combines with ammonia, the bond is called a coordinate bond:

In these formulas, the valence (or bonding) electrons are indicated by dots, each pair of dots between two atomic symbols representing a bond between the corresponding atoms.

Following Lewis's ideas, the suggestion was made that the bonds between metals and ligands were of this same type, with the ligands acting as electron donors and the metal ions as electron acceptors. This suggestion provided the first electronic interpretation of bonding in coordination compounds. The coordination reaction between silver ions and ammonia illustrates the resemblance of coordination compounds to the situation in the boron–nitrogen compound. According to this view, the metal ion can be regarded as a so-called Lewis acid and the ligands as Lewis bases (for further information on Lewis acids and bases see ACID–BASE REACTIONS AND EQUILIBRIA):

In the above formulas, the dots again represent valence electrons.

Considerable success in understanding certain coordination compounds also has been achieved by treating them as examples of simple ionic or electrostatic bonding. This view attributes the bonding in coordination compounds to electrostatic forces between the positively charged metal ions and negatively charged ligands or, alternatively, in the case of neutral ligands (*e.g.*, water and ammonia), charge separations (dipoles) that appear within the molecules. Although this approach meets with considerable success for complexes of metal ions with small electronegative ligands, such as fluoride or chloride ions or water molecules, it breaks down for ligands of low polarity (charge separation), such as carbon monoxide. It also requires modification to explain why the spectral (light absorption) and magnetic properties of coordinated metal ions generally differ from those of the free ions and, for a given metal ion, depend on the nature of the ligands. Thus, the complex ion hexafluoroferrate(III) ( $FeF_6^{3-}$ ), has magnetic properties to be expected from a substance with five unpaired electrons, as does the free iron(III) ion ( $Fe^{3+}$ ), whereas the magnetic properties of the closely related hexacyanoferrate(III)  $[Fe(CN)_6]^{3-}$  correspond to only one unpaired electron.

Since 1950 it has been apparent that a more complete theory, which incorporates contributions from both ionic and covalent bonding, is necessary to give an adequate account of the properties of coordination compounds. Such a theory is the so-called ligand-field theory, which has its origin in the more general theory of chemical bonding called the molecular-orbital theory (molecular orbitals describing the spatial distributions of electrons in molecules, just as atomic orbitals describe the distributions in atoms). This theory accounts with remarkable success for most properties of coordination compounds (see also CHEMICAL BONDING).

The ligand-field theory

An important conclusion from ligand field theory is that two types of bonds, called sigma bonds and pi bonds, occur in coordination compounds just as they do in ordinary covalent (organic) compounds. Sigma bonds are the more usual of the two, and they are symmetrical about the axis of the bond; pi bonds, which are less common, are unsymmetrical with regard to the bond axis. In coordination compounds, pi bonding may result from donation of electrons from ligands, such as fluorine or oxygen atoms, to empty d orbitals of the metal atoms (the designation d merely being a way of indicating the particular orbitals involved). An example of this type of bonding is the chromate ion,  $(CrO_4)^{2-}$ , in which the oxygen atoms donate electrons to the central chromium ion. Alternatively, electrons from d orbitals of the metal atom may be donated to empty orbitals of the ligand. This is the case in the compound tetracarbonylnickel, in which empty pi orbitals in the carbon monoxide molecules accept d-orbital electrons from the nickel atom.

**Coordination number and geometry.** Among the essential properties of coordination compounds are the number and arrangement of the ligands attached to the central metal atom or ion—that is, the coordination number and the coordination geometry, respectively. The coordination number of a particular complex is determined by the relative sizes of the metal atom and the ligands, by spatial (steric) constraints governing the shapes (conformations) of multidentate ligands, and by electronic factors, most notably the electronic configuration of the metal ion. The influence of the latter is illustrated by the examples in Table 2. The numbers labelled

Table 2: Coordination Numbers and Geometries of Metal Cyanide Complexes

electron configuration*	metal ion	cyanide complex	geometry	total number of valence electrons
$d^2$	$Mo^{4+}$	$[Mo(CN)_6]^{4-}$	dodecahedral	18
$d^3$	$Cr^{3+}$	$[Cr(CN)_6]^{3-}$	octahedral	15
$d^4$	$Mn^{3+}$	$[Mn(CN)_6]^{3-}$	octahedral	16
$d^5$	$Fe^{3+}$	$[Fe(CN)_6]^{3-}$	octahedral	17
$d^6$	$Co^{3+}$	$[Co(CN)_6]^{3-}$	octahedral	18
$d^7$	$Co^{2+}$	$[Co(CN)_6]^{3-}$	square pyramidal	17
$d^8$	$Ni^{2+}$	$[Ni(CN)_4]^{2-}$	square planar	16
$d^8$	$Ni^{2+}$	$[Ni(CN)_5]^{3-}$	square pyramidal or trigonal bipyramidal	18
$d^{10}$	$Cd^{2+}$	$[Cd(CN)_4]^{2-}$	tetrahedral	18
$d^{10}$	$Ag^+$	$[Ag(CN)_2]^-$	linear	14

\*Number of d electrons indicated by superscript.

"total number of valence electrons" in this table comprise the d electrons of the metal ion together with the pair of electrons donated by each of the ligands.

Contributing to the pattern of coordination numbers in Table 2 is the 18-electron rule (sometimes called the noble gas rule), which states that coordination compounds in which the total number of valence electrons approaches but does not exceed 18 (the number of electrons in the valence shells of the noble gases) are most stable. The stabilities of 18-electron valence shells are also reflected in the coordination numbers of the stable mononuclear carbonyls of different metals—*e.g.*, tetracarbonylnickel, pentacarbonyliron, and hexacarbonylchromium (each of which has a valence shell of 18).

The 18-electron rule

The 18-electron rule applies particularly to covalent

complexes, such as the cyanides, carbonyls, and phosphines. For more ionic (also called outer-orbital) complexes, such as fluoro or aquo complexes, electronic factors are less important in determining coordination numbers, and configurations corresponding to more than 18 valence shell electrons are not uncommon. Several nickel complexes, for example, including the hexafluoro, hexaaquo, and hexammine complexes, each have 20 valence shell electrons.

Any one metal ion tends to have the same coordination number in different complexes—e.g., generally 6 for chromium(III)—but this is not invariably so. Differences in coordination number, for example, may result from difference in the sizes of the ligands. The iron(III) ion, for example, is able to accommodate six fluoride ions in the hexafluoride complex, but only four of the larger chloride ions in the tetrachloride. In some cases, a metal ion and ligand form two or more complexes with different coordination numbers—e.g., tetracyanonickelate(II) and pentacyanonickelate(II).

**Isomerism.** Coordination compounds often exist as isomers—i.e., as compounds with the same chemical composition but different structural formulas (see ISOMERISM). Many different kinds of isomerism occur among coordination compounds. The following are some of the more common types.

**Ionization isomerism.** Certain isomeric pairs occur that differ only in that two ionic groups exchange positions within (and without) the primary coordination sphere. These are called ionization isomers and are exemplified by the two compounds  $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{SO}_4$  and  $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{Br}$ , in the first of which the bromide ion is coordinated to the cobalt ion, and the sulfate ion is outside the coordination sphere; and in the second of which the sulfate ion occurs within the coordination sphere, and the bromide ion is outside it.

**Coordination isomerism.** Ionic coordination compounds in which both the positive and negative ions are ionic can exist as isomers if the ligands associated with the two metal atoms are exchanged, as in the pair of compounds shown by the formulas  $[\text{Co}(\text{NH}_3)_6][\text{Cr}(\text{CN})_6]$  and  $[\text{Cr}(\text{NH}_3)_6][\text{Co}(\text{CN})_6]$ . Such compounds are called coordination isomers, as are the isomeric pairs obtained by redistributing the ligands between the two metal atoms, as in the doubly coordinated pair,  $[\text{Pt}(\text{NH}_3)_4][\text{PtCl}_4]$  and  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2][\text{PtCl}_4]$ .

**Ligand isomerism.** Isomeric coordination compounds are known in which the overall isomerism results from isomerism solely within the ligand groups. An example of such isomerism is shown by the ions

**Linkage isomerism.** Isomerism also results when a given ligand is joined to the central atom through different atoms of the ligand. Such isomerism is called linkage isomerism. A pair of linkage isomers are the ions  $[\text{Co}(\text{NH}_3)_5(\text{NO}_2)]^{2+}$  and  $[\text{Co}(\text{NH}_3)_5(\text{ONO})]^{2+}$ , in which the nitro group is joined to the cobalt atom through nitrogen and oxygen atoms, as shown by designating the nitro group by the formulas  $\text{NO}_2^-$  and  $\text{ONO}^-$ , respectively. Another example of this variety of isomerism is given by the pair of ions  $[\text{Co}(\text{CN})_5(\text{NCS})]^{2-}$  and  $[\text{Co}(\text{CN})_5(\text{SCN})]^{2-}$ , in which an isothiocyanate ( $\text{NCS}^-$ ), and a thiocyanate group ( $\text{SCN}^-$ ), are bound to the cobalt ion through a nitrogen and a sulfur atom, respectively.

**Geometrical isomerism.** Geometrical isomers of coordination compounds differ from one another only in the manner in which the ligands are distributed; for example, in the isomeric pair of dichlorodiammineplatinum(II) compounds

the two ammonia molecules and the two chlorine atoms are situated next to another in one isomer, called the cis

(Latin: "on this side") isomer, and across from one another in the other, the trans (Latin: "on the other side") isomer. A similar relationship exists between the cis and trans forms of the dichlorotetraamminecobalt(III) ion:

**Optical isomerism.** Optical isomers possess the ability to rotate plane-polarized light in opposite directions (a property determined with an instrument called a polarimeter). Optical isomers exist when the molecules of the substances are mirror images but are not superimposable upon one other. In coordination compounds, optical isomerism can arise either from the presence of an asymmetric ligand, such as one isomer of an amino acid,

or from an asymmetric arrangement of the ligands. Familiar examples of the latter variety are octahedral complexes carrying three bidentate ligands, such as ethylenediamine,  $\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ . The two optical isomers corresponding to such a complex are depicted by the structures below:

For convenience, the ethylenediamine ligands above are indicated merely by a curved line between the symbols for the nitrogen (N) atoms.

Optical isomers differ from the other isomeric coordination compounds in that their physical and chemical properties are identical.

#### PRINCIPAL CLASSES

The tendency for complexes to form between a metal ion and a particular combination of ligands and the properties of the resulting complexes depend on a variety of properties of both the metal ion and the ligands. Among the pertinent properties of the metal ion are its size, charge, and electron configuration. Relevant properties of the ligand include its size and charge, the number and kinds of atoms available for coordination, the sizes of the resulting chelate rings formed (if any), and a variety of other geometrical (steric) and electronic factors.

Many elements, notably certain of the metals, exhibit a range of oxidation states—that is, they are able to gain or lose varying numbers of electrons. The relative stabilities of these oxidation states are markedly affected by coordination of different ligands. The highest oxidation states correspond to empty or nearly empty d subshells (as the patterns of d orbitals are called). These states are generally stabilized most effectively by small negative ligands, such as fluorine and oxygen atoms, which possess unshared electron pairs. Such stabilization reflects, in part, the contribution of pi bonding caused by electron donation from the ligands to empty d orbitals of the metal ions in the complexes. Conversely, neutral ligands, such as carbon monoxide and unsaturated hydrocarbons, which are relatively poor electron donors but which can accept pi electrons from filled d orbitals of the metal, tend to stabilize the lowest oxidation states of metals. Intermediate oxidation states are most effectively stabilized by ligands such as water, ammonia, and cyanide ion, which are moderately good sigma electron donors but relatively poor pi electron donors or acceptors (see above Coordinate bonding). These trends are illustrated in Table 3, in which the complexes formed by chromium with various ligands are related to the oxidation states and electron configurations.

Stabilization of oxidation states

Table 3: Chromium Complexes of Various Oxidation States

oxidation state	electron configuration*	coordination complex
+6	$d^0$	$[\text{CrF}_6]^{3-}$ , $[\text{CrO}_4]^{2-}$
+5	$d^1$	$[\text{CrO}_4]^{3-}$
+4	$d^2$	$[\text{CrO}_4]^{4-}$ , $[\text{Cr}(\text{OR})_4]^+$
+3	$d^3$	$[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$ , $[\text{Cr}(\text{NH}_3)_6]^{3+}$
+2	$d^4$	$[\text{Cr}(\text{H}_2\text{O})_6]^{2+}$
0	$d^6$	$[\text{Cr}(\text{CO})_6]$ , $[\text{Cr}(\text{C}_6\text{H}_5)_2]$

\*Number of d electrons indicated by superscript.  
+Capital R symbolizes an organic alkyl radical.

Aquo complexes. There are few ligands that equal water in respect to the number and variety of metal ions with which they form complexes. Nearly all metallic elements form aquo complexes, frequently in more than one oxidation state. Such aquo complexes include hydrated ions in aqueous solution as well as hydrated salts such as hexaaquochromium(III) chloride,  $[\text{Cr}(\text{H}_2\text{O})_6]\text{Cl}_3$ . For metal ions with partially filled d subshells (*i.e.*, transition metals), the coordination numbers and geometries of the hydrated ions in solution can be inferred from their light-absorption spectra, which are generally consistent with octahedral coordination by six water molecules. Higher coordination numbers probably occur for the hydrated rare-earth ions such as lanthanum(III).

When other ligands are added to an aqueous solution of a metal ion, replacement of water molecules in the coordination shell may occur, with the resultant formation of other complexes. Such replacement is generally a step-wise process, as illustrated by the following series of reactions that results from the progressive addition of ammonia to an aqueous solution of nickel(II) salt:

With increasing additions of ammonia, the equilibria are shifted toward the higher ammine complexes (those with more ammonia and less water) until ultimately the hexaamminenickel(II) ion predominates.

The tendency of metal ions in aqueous solution to form complexes with ammonia as well as with organic amines (derivatives of ammonia, carrying chains of carbon atoms attached to the nitrogen atom) is widespread. The stabilities of such complexes exhibit a considerable range of dependence on the nature of the metal ion as well as on that of the amine. The marked enhancement of stability that results from chelation is reflected in the equilibrium constants of the reactions—values that indicate the relative proportions of the starting materials and the products at equilibrium. Table 4, for example, shows the equilibrium constants for the formation of complexes of hexaaquonickel(II) ions with a series of polyamines—*i.e.*, for a series of reactions of the type

in which L is the ligand and  $n$  the number of water mole-

Table 4: Equilibrium Constants for the Formation of Various Nickel Amine Complexes

$n$	amine (L)	equilibrium constant $K_L$ , $\text{M}^{-1}$ *
1	$\text{NH}_3$	$5 \times 10^4$
2	$\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$	$4 \times 10^7$
3	$\text{NH}_2\text{CH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2\text{NH}_2$	$5 \times 10^{10}$
4	$\text{NH}_2\text{CH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2\text{NH}_2$	$1 \times 10^{14}$

\*M is molar concentrations.

cules displaced from the complex. In the table it can be seen that the equilibrium constants,  $K_L$ , increase dramatically as the possibilities for chelation increase—that is, as the number of nitrogen atoms (N) available for bonding to the metal atom increase.

It should be noted that in the particular examples cited above the coordination number of the metal ion is invariant throughout the substitution process, but this is not always the case. Thus, the ultimate products of the addition of the cyanide ion to an aqueous solution of hexaaquonickel(II) ion are tetracyanonickelate(II) and pentacyanonickelate(II). Similarly, addition of the chloride ion to a solution of hexaaquoiron(III) yields tetrachloroferrate(III).

Halide complexes. Probably the most widespread class of complexes involving anionic ligands is that of the complexes of the halide ions—*i.e.*, the fluoride, chloride, bromide, and iodide ions. In addition to forming simple halide salts, such as sodium chloride and nickel difluoride (in which the metal ions are surrounded by halide ions, these in a sense being regarded as coordinated to them), many metals form complex halide salts, such as potassium tetrachloroplatinate(II),  $\text{K}_2[\text{PtCl}_4]$ , that contain discrete complex ions. Most metal ions also form halide complexes in aqueous solution. The stabilities of such complexes span an enormous range—from the alkali-metal ions (lithium, sodium, potassium, and so on), the formation of whose halide complexes in aqueous solution can barely be detected, to extremely stable halide complexes, such as the tetraiodomercurate(II), tetrachlorothallate(III), and tetrachloropalladate(II) ions, the extent of whose dissociation is extremely small.

The stabilities of halide complexes reflect a pattern in which metal ions can be divided into two general classes, designated as A and B or, alternatively, as hard and soft, respectively. (Generally, the electrons in the atoms of the hard elements are considered to form a compact and not easily deformable group, whereas those in the atoms of the soft elements form a looser group—that is, one more easily deformed.) For the former class, which includes beryllium, magnesium, scandium, chromium, iron, nickel, copper, indium, and tin, the order of increasing stability of the halide complexes in aqueous solution is iodides, bromides, chlorides, and fluorides. Conversely, for the class B (or soft) ions, such as platinum, silver, cadmium, mercury, thallium, and lead, the order of increasing stability of the halide complexes is fluorides, chlorides, bromides, and iodides. In contrast to class A metals, those of class B also tend to form more stable complexes with sulfur-containing ligands than with oxygen-containing ligands and more stable complexes with phosphorus ligands than with nitrogen ligands.

Metal carbonyls. Following the discovery of the first metal carbonyl complex, tetracarbonylnickel, in 1890, many compounds containing carbon monoxide coordinated to transition metals have been prepared and characterized. For reasons already discussed, such compounds generally contain metal atoms or ions in low oxidation states. The following are some of the more common types of metal carbonyl compounds: (1) simple mononuclear carbonyls of zero-valent metals, such as tetracarbonylnickel, pentacarbonyliron, and hexacarbonylchromium—highly toxic, volatile compounds, the most stable of which have filled valence shells of 18 electrons; (2) salts of anionic and cationic carbonyls, such as tetracarbonylcobaltate(I) and hexacarbonylmanganese(I); (3) binuclear and polynuclear carbonyls, such as bis(tetracarbonylcobalt), the structural formula of which was shown earlier (see above Classification: Polynuclear); and (4) mixed complexes containing other ligands additional to CO: chloropentacarbonylmanganese, hydridotetracarbonylcobalt (I), and tricarbonylnitrosylcobalt.

Although molecular nitrogen,  $\text{N}_2$ , is isoelectronic with carbon monoxide (that is, has the same arrangement of electrons), its tendency to form complexes with metals is much smaller. The first complex containing molecular nitrogen as a ligand—*i.e.*, pentaamminenitrogenruthenium(II),  $[\text{Ru}(\text{NH}_3)_5(\text{N}_2)]^{2+}$ —was prepared in 1965, and many others have been discovered subsequently. Such

Complex ions in aqueous solution

Hard and soft ions

Equilibrium constants

Complexes of molecular nitrogen

complexes have attracted considerable interest because of their possible roles in the chemical and biological fixation of nitrogen.

Organometallic complexes. Organometallic complexes, complexes formed between organic (carbon-containing) groups and metal atoms, can be divided into two general classes: (1) complexes containing metal-carbon sigma bonds and (2) pi-bonded metal complexes of unsaturated hydrocarbons—that is, compounds with multiple bonds between carbon atoms.

The first of these classes is exemplified by dimethylmercury(II) and iodotrimethylplatinum(IV). Such complexes of transition metals tend to be unstable, and only since 1950 have a large number of them been prepared and characterized. Most of these contain, in addition to the organic ligands, other ligands, such as carbon monoxide, cyanide, or phosphines, that appear to exert a stabilizing influence. Examples of organometallic complexes stabilized by other ligands are pentacyanomethylcobaltate(III), chlorobis(triethylphosphine)methylplatinum(II), and pentacarbonylmethylmanganese(I).

Zeise's salt,  $K[PtCl_5(C_2H_4)]$ , discovered about 1830, is the earliest recorded example of a metal complex of an unsaturated hydrocarbon. This salt contains the trichloroethyleneplatinate(II) anion:

Analogous olefin complexes are formed by a number of other metal ions, including silver, copper, palladium, and ruthenium. The scope of this general field of chemistry was greatly expanded in 1951 by the discovery of the first "sandwich" compound, bis(cyclopentadienyl)iron(II), whose structure is depicted below. The term sandwich refers to the fact that the two flat cyclopentadienyl rings lie, respectively, above and below the iron atom (which is, in effect, sandwiched between them). A great variety of such compounds are now known, not only of the cyclopentadienyl type but also containing other unsaturated cyclic ligands; e.g., dibenzenechromium, benzenetricarbonylchromium, and cyclobutadienetricarbonyliron, all of which are also shown below. This class of compounds is characterized by great stability. Their bonding is closely related to that in the metal carbonyls and involves donation of pi electrons from the hydrocarbon ligands to unfilled d orbitals of the metal, together with "back donation" of metal d electrons to empty pi orbitals of the ligand (see ORGANOMETALLIC COMPOUNDS):

bis(cyclopentadienyl)iron

dibenzenechromium

benzenetricarbonylchromium

cyclobutadienetricarbonyliron

In these diagrams the polygons represent hydrocarbon rings, and the circles indicate rings of pi electrons.

#### GENERAL METHODS OF PREPARATION

The great variety of coordination compounds is matched by the diversity of methods through which such compounds can be synthesized. Complex halides, for example, may be prepared by direct combination of two halide salts (either in the molten state or in a suitable solvent). Palladium chloride and potassium chloride, for example, react to give the complex potassium tetrachloropalladate(II), as shown in the following equation:

Another widely used route to coordination compounds is through the direct combination of a metal ion and appropriate ligands in solution. Thus, the addition of a sufficiently high concentration of ammonia to an aqueous solution of a nickel(II) salt leads, through a series of reactions (see above Aquo complexes) to the formation of the hexaamminenickel(II) ion, which can be precipitated, for example, as the sulfate salt,  $[Ni(NH_3)_6]SO_4$ .

Complexes of metal ions in high oxidation states are sometimes more readily formed by adding the ligands to a solution of the metal ion in a lower oxidation state in the presence of an oxidizing agent. Thus, addition of ammonia to an aqueous solution of a cobalt(II) salt in the presence of air or oxygen leads to the formation of cobalt(III) ammine complexes such as hexaamminecobalt(III),  $[Co(NH_3)_6]^{3+}$ , and aquopentaamminecobalt(III),  $[Co(NH_3)_5(H_2O)]^{3+}$ , ions.

Complexes of metals in low oxidation states, such as the carbonyls of zero-valent metals, can sometimes be prepared by direct combination of the metal with the ligand as, for example, in the reaction of nickel metal with carbon monoxide:

More commonly, a salt of the metal is reduced in the presence of the ligand. An example of this type of synthesis is the reduction of cobalt carbonate with hydrogen in the presence of carbon monoxide to give bis(tetracarbonylcobalt):

Similar procedures are applicable to the synthesis of metal sandwich compounds containing cyclopentadienyl and benzene ligands. Dibenzenechromium, for example, can be prepared from chromic chloride, benzene, and aluminum, as shown in the following equation:

Hydrido complexes of transition metals can be prepared by reactions of suitable precursors either with molecular hydrogen or with suitable reducing agents such as hydrazine or sodium borohydride; for example,

Transition metal complexes containing metal-carbon bonds can be prepared by a variety of routes, some of the more important of which are illustrated by the following examples:

## PRINCIPAL REACTIONS

Acid-base. Coordination to a positive metal ion usually enhances the acidity (*i.e.*, the tendency to lose protons) of hydrogen-containing ligands, such as water and ammonia. Thus, metal ions in aqueous solution commonly exhibit acidic behaviour. Such behaviour is exemplified by hydrolysis reactions of the type shown in the following equilibrium:

in which M represents the metal ion,  $n$  its charge, and  $x$  the number of coordinated water molecules.

The acidities of such aquo ions depend upon the charge, size, and electronic configuration of the metal ion. This dependence is reflected in the values of acid dissociation constants, which range from about  $10^{-14}$  (a value only slightly larger than for pure water, for which the dissociation constant  $= 10^{-15.7}$ ) for the hydrated lithium ion, to about  $10^{-1}$  (a value equivalent to that of a fairly strong acid) for the hydrated uranium(IV) ion. Acid-base equilibria, such as shown in the above equation, are rapidly established in solution, generally within a fraction of a second (see ACID-BASE REACTIONS AND EQUILIBRIA).

In some cases, hydrolysis of a metal ion may be accompanied by polymerization to form dinuclear or polynuclear hydroxo- or oxygen-bridged complexes:

Even very weakly acidic ligands, such as ammonia, can acquire appreciable acidity through coordination to a metal ion. Thus, the hexammineplatinum(IV) ion dissociates according to the equilibrium

Substitution. One of the most general reactions exhibited by coordination compounds is that of substitution, or replacement, of one ligand by another. This process is depicted in a generalized manner by the equation  $ML_{x-1}Y + Z \rightarrow ML_{x-1}Z + Y$  for a metal complex of coordination number  $x$ . The ligands L, Y, and Z may be chemically similar or different. (Charges have been omitted here for simplicity.)

A class of substitution reactions that affords the widest possible comparison of different metal ions is the replacement of water in the coordination shells of metal aquo complexes in aqueous solution. The substitution may be by another water molecule (which can be labelled with the isotope oxygen-18 to permit the reaction to be followed) or by a different ligand, such as the chloride ion. Reactions of both sorts occur as shown below

(oxygen-18 is indicated by the symbol O\*):

Many such reactions are extremely fast, and it has been only since 1950, following the development of appropriate experimental methods (including stopped flow, nuclear magnetic resonance, and relaxation spectrometry), that the kinetics and mechanisms of this class of reactions have been extensively investigated. Rates of substitution of metal-aquo ions have been found to span a wide range, the characteristic times required for substitution ranging from less than  $10^{-9}$  second for monovalent ions, such as hydrated potassium ions, to several days for certain more highly charged ions, such as hexa-aquochromium(III) and hexa-aquorhodium(III). The rate of substitution parallels the ease of loss of a water molecule from the coordination shell of the aquo complex and thus increases with increasing size and with decreasing charge of the metal ion. For transition metal ions, electronic factors also have an important influence on rates of substitution.

There are two limiting mechanisms (or pathways) through which substitution may occur; namely, dissociative and associative mechanisms. In the dissociative mechanism, a ligand is lost from the complex to give an intermediate compound of lower coordination number. This type of reaction path is typical of octahedral complexes, many aquo complexes, and metal carbonyls such as tetracarbonylnickel. An example of a dissociative reaction pathway for an octahedral complex of cobalt is as follows:

The associative mechanism for substitution reactions, on the other hand, involves association of an extra ligand with the complex to give an intermediate of higher coordination number; then one of the original ligands is lost to restore the initial coordination number. Substitution reactions of square planar complexes, such as those of the nickel(II), palladium(II), and platinum(II) ions, usually proceed through associative pathways involving intermediates with coordination number 5. An example of a reaction following such a pathway is

A characteristic feature of this class of reactions is the sensitivity of the rate of substitution of a given ligand to the nature of the ligand in the *trans* position (that is, on the opposite side of the metal atom). The *trans* ligand activates a ligand for replacement as follows, in decreasing order: carbon monoxide, cyanide ion, or ethylene, greater than phosphines, or hydride, nitrite, iodide, or thiocyanate ion, greater than bromide or chloride ion, greater than ammonia or water. The *trans* effect may be utilized for synthetic purposes; thus, the reaction of the tetrachloroplatinate(II) ion with ammonia yields *cis*-dichlorodiammineplatinum(II); whereas the reaction of the tetraammineplatinum(II) ion with the chloride ion gives the *trans* isomer, *trans*-dichlorodiammineplatinum(II). The reactions are shown below. In both reactions the *trans* effect causes introduction of the ligand *trans* to chloride rather than *trans* to ammonia:

Isomerization. Coordination compounds that exist in two or more isomeric forms (see above *Isomerism*) may undergo reactions that convert one isomer to another. Examples are the linkage isomerization and *cis-trans* isomerization reactions depicted below. The first of these has been shown to proceed intramolecularly (*i.e.*, without dissociation of the nitrite ligand), whereas the second probably occurs through dissociation of one of the water-molecule ligands:

Oxidation-reduction. Transition metals commonly exhibit two or more stable oxidation states, and their complexes accordingly are able to undergo oxidation-reduction reactions. The simplest such reactions involve electron transfer between two complexes, with little if

Dissociative and associative mechanisms

Replacement of water

any accompanying rearrangement or chemical change. An example is shown below:

In other cases, oxidation–reduction is accompanied by significant chemical rearrangement. An example is

Two limiting mechanisms of electron transfer, commonly designated outer-sphere and inner-sphere mechanisms, have been recognized. Outer-sphere electron transfer occurs without dissociation or disruption of the coordination shell of either complex; *i.e.*, through both intact coordination shells. The first reaction above is of this type. On the other hand, inner-sphere electron transfer—*e.g.*, the second reaction above—proceeds by formation of a binuclear complex in which the two metal ions are joined by a common bridging ligand (in this case the chloride ion) through which the electron is transferred. Such electron transfer also may occur through polyatomic bridging ligands to which the two metal ions are attached at different sites separated by several atoms; for example, the reduction of pentaammine(isonicotinamide)cobalt(III) by chromium(II) ion through a bridged intermediate,

Strikingly large differences in rates of electron transfer are observed even among closely related reactions. Thus, the rate of reduction of the bromopentaamminecobalt(III) ion by the hexaaquochromium(II) ion is about  $10^7$  times higher than that of the acetatopentaamminecobalt(III) ion by the same chromium ion.

**Oxidative addition.** The oxidations of certain complexes, notably those of metal ions with nearly filled  $d$  shells, are accompanied by increases in their preferred coordination numbers in accord with the patterns shown in Table 2. Such complexes are particularly effective in reducing saturated molecules, such as chlorine, hydrogen peroxide, methyl iodide, and hydrogen, with accompanying incorporation of the fragments of reductive cleavage (the chloride ion, hydroxide ion, methyl carbanion, and hydride ion, respectively) into the coordination shells to achieve the necessary expansions of the coordination numbers. Three such classes of reactions, namely those characteristic of five-coordinate ( $d^7$ ), four-coordinate ( $d^8$ ), and two-coordinate ( $d^9$ ) complexes, are illustrated by the equations below:

Interest in the synthetic and catalytic applications of such oxidative addition reactions has prompted intensive study of these reactions since about 1960, which has resulted in the discovery of new reactions of this type, and in the elucidation of certain aspects of the mechanisms by which they occur.

#### SIGNIFICANCE AND APPLICATIONS

The applications of coordination compounds in chemistry and technology are many and diverse. Naturally occurring coordination compounds are vitally important to living organisms.

**Dyes and pigments.** The brilliant and intense colours of many coordination compounds render them of great value as dyes and pigments. The early use of Prussian blue as a pigment has already been mentioned. Phthalocyanine complexes—for example, copper phthalocyanine—containing large-ring ligands closely related to the porphyrins, constitute an important class of dyes for fabrics.

**Extraction and separation of metals.** Several important hydrometallurgical processes utilize metal complexes. Nickel, cobalt, and copper can be extracted from their ores as ammine complexes using aqueous ammonia. Differences in the stabilities and solubilities of the ammine complexes can be utilized in selective precipitation procedures that bring about separation of the metals. The purification of nickel can be effected by reaction with carbon monoxide to form the volatile tetracarbonylnickel complex, which can be distilled and thermally decomposed to deposit the pure metal. Aqueous cyanide solutions usually are employed to separate gold from its ores in the form of the very stable dicyanoaurate(I) complex. Cyanide complexes also find application in electroplating.

**Chemical analysis.** There are a number of ways in which coordination compounds are used in the analysis of various substances. These include (1) the selective precipitation of metal ions as complexes, for example, nickel(II) ion as the dimethylglyoxime complex (shown below); (2) the formation of coloured complexes, such as the tetrachlorocobaltate(II) ion, that can be determined spectrophotometrically—that is, by means of their light absorption properties; and (3) the preparation of complexes, such as metal acetylacetonates, that can be separated from aqueous solution by extraction with organic solvents:

**Sequestering.** In certain circumstances the presence of metal ions is undesirable, as for example in water, in which calcium and magnesium ions cause hardness. In such cases the undesirable effects of the metal ions frequently can be eliminated by “sequestering” the ions as harmless complexes through the addition of an appropriate complexing reagent. Ethylenediaminetetraacetic acid (EDTA) forms very stable complexes and is widely used for this purpose. Its applications include water softening (by tying up calcium and magnesium ions) and the preservation of organic substances, such as vegetable oils and rubber, in which case it combines with traces of transition metal ions that would catalyze oxidation of the organic substances.

**Catalysis.** A technological and scientific development of major significance was the discovery in 1954 that certain complex metal catalysts, *viz.*, a combination of titanium trichloride and triethylaluminum bring about the polymerizations (or joining together of the molecules) of organic compounds with carbon–carbon double bonds under mild conditions to form polymers of high molecular weight and highly ordered (stereoregular) structures. Certain of these polymers are of great commercial importance because they are used to make fibres, films, and plastic articles of many kinds. Other technologically important processes based on metal complex catalysts include the catalysis by metal carbonyls, such as hydrido-tetracarbonylcobalt(I), of the so-called hydroformylation of olefins—*i.e.*, of their reactions with hydrogen and carbon monoxide to form aldehydes—and the catalysis by tetrachloropalladate(II) ions of the oxidation of ethylene in aqueous solution to acetaldehyde (see also CATALYSIS).

**Biology.** Metal complexes play a variety of important roles in biological systems. Many enzymes, the naturally occurring catalysts that regulate biological processes, are metal complexes (metalloenzymes); for example, a hydrolytic enzyme important in digestion, carboxypeptidase, contains a zinc ion coordinated to several amino acid residues of the protein. Another enzyme, catalase, which is a very efficient catalyst for the decomposition of hydrogen peroxide, contains iron–porphyrin complexes. In both cases the coordinated metal ions are probably

the sites of catalytic activity. Hemoglobin also contains iron-porphyrin complexes, its role as an oxygen carrier being related to the ability of the iron atoms to coordinate oxygen molecules reversibly. Other biologically important coordination compounds include chlorophyll (a magnesium-porphyrin complex) and vitamin B<sub>12</sub>, a complex of cobalt with a macrocyclic ligand known as corrin.

## Copenhagen

Copenhagen (Danish København, or Merchant's Harbour), the capital of Denmark, lies on the eastern coast of the island of Zealand (Sjælland) and on the northern part of the island of Amager at the southern end of the Sound (Øresund) opposite Malmö, Sweden. It is the largest and most important city of Denmark, the seat of a number of cultural and social institutions, and a centre of trade and industry. The city proper had a population of about 813,000 (including the municipalities of Frederiksberg and Gentofte) in the early 1970s, but Greater Copenhagen had about 1,400,000 inhabitants, almost one-third of the population of Denmark.

The city's geographical position gives it a relatively mild climate for its latitude, particularly in wintertime when it draws warmth from the Gulf Stream. Temperatures go down to about freezing in January and February; the average in July and August is about 60° F (16° C). Average annual precipitation is 28 inches, more than in London, Paris, or Berlin. The rainiest months are July and August; winter and spring are relatively dry.

Until 1856 Copenhagen was a fortress town with ramparts and moats, surrounded by a ring of suburbs and villages that were later absorbed by the expanding city. The old town retains its narrow streets and Baroque and neoclassical buildings. Outside the former ramparts the buildings vary from five- or six-story apartment houses to high-rise apartment blocks and single-family houses with gardens.

Central Copenhagen and (inset) its metropolitan area.

The  
fortress  
town

A small village existed on the site of the present city as early as the year 900. In 1167 Bishop Absalon of Roskilde built a castle on an islet off the coast, the remains of which can still be seen underneath the present castle of Christiansborg. The Bishop marked out the boundaries of the town and surrounded it with ramparts and a moat. In the Middle Ages it had four churches, three convents, and a number of clerical establishments; a town hall and a university were inaugurated in 1479. In the civil and religious conflicts of the age of the Reformation the town was often attacked; the churches were plundered, and the convents were abolished.

During the latter part of the 16th century, Copenhagen's trade began to flourish and the city itself to expand, adding Christianshavn on the south and Ny København (New Copenhagen) on the northeast. Among the new buildings erected were the Børsen (Exchange), the Holmens Kirke (Holmens Church), Trinitatis (Trinity) Kirke, with the adjacent famous Round Tower, and the palace of Rosenborg (now the museum of the royal family).

During the wars with Sweden in 1658–60, the city was besieged for two years. In 1661 the King permitted Copenhagen to have its own City Council of 32 men elected by the leading citizens. In 1728 a fourth of the town was burned down; the rebuilding was done in a Baroque style that still characterizes some of the streets in the centre of the city. Another great fire occurred in 1795, and the houses built after that were all in neo-classic style. In 1807, during the war against England, the university quarter around Vor Frue Kirke (Church of Our Lady) was destroyed. The church, which dates from the 12th century, was rebuilt and adorned with marble works by Bertel Thorvaldsen, the most famous of which is the colossal statue of Christ.

The con-  
temporary  
city

The nucleus of the city is the area between the sea and the old ramparts and moats. West of the ramparts is a series of small freshwater lakes, Sankt Jørgens Sø, Peblinge Sø, and Sortedams Sø. Around the original city lie the densely populated districts built after the removal of the ramparts in 1856. In the early 20th century the city expanded still further, incorporating what are now the districts of Valby, Vigerslev, Vanløse, Brønshøj, and Husum on the Zealand side and Sundby on the Amager side, thus trebling its area and completely encircling the independent municipality of Frederiksberg.

The heart of the city is the Raadhuspladsen (Town Hall Square). From the square, an old crooked shopping street leads northeast to the former centre of the city, Kongens Nytorv (King's New Square), laid out in the 17th century. Buildings there include the Thott Palace (now the French Embassy) and the Charlottenborg Palace (now the Royal Academy of Arts), both of the 17th century, and the Royal Theatre, built in 1874. Kongens

Nytorv touches on a narrow arm of the harbour lined with picturesque old gabled houses. From the southern end of the square a street called **Holmens Kanal** winds past the National Bank to the **Holmens Kirke** (the naval church), which has a chapel containing the tombs of the great admirals Niels Juel and Peder Tordenskiold.

**Holmens Kanal** crosses a bridge to Slotsholmen (Castle Islet), where stands the Christiansborg Palace, built on the site of the old castle founded by Bishop Absalon in 1167. Since 1928 the palace has been occupied by Parliament, the Supreme Court, and the Foreign Office. Nearby buildings house other government offices. Slotsholmen also contains the Bertel Thorvaldsen Museum, the Arsenal, the state archives, and the Royal Library.

On the mainland to the west of Slotsholmen is the **Prinsens Palace**, now the National Museum. In Nytorv (New Market) is the former town hall built in 1815, now the city court, to the north of which is Gammeltorv (Old Market), the main square of the medieval town. From there an old street leads to the Vor Frue Kirke, the cathedral church of Copenhagen. Just north is the university, founded in 1479, and opposite it the Petri Kirke, in Gothic style, used after 1585 as a parish church for the German residents of the city. The area from Kongens Nytorv northeast to the 17th-century citadel includes the palace of Amalienborg and the castle and gardens of Rosenborg.

Southwest from the citadel a line of parks extends along the site of the former fortifications, skirted by wide boulevards. The botanical gardens laid out in 1874 have an observatory with a statue of the Danish astronomer Tycho Brahe. H.C. Andersens Boulevard runs past the Raadhuspladsen and crosses the harbour on the Langebro (Long Bridge) to residential districts on the island of Amager. It also skirts the Tivoli pleasure garden and passes the Ny Carlsberg Glyptotek, which has a fine collection of old and new art.

The old quarter of Christianshavn is on the harbour to the south. It contains the 17th-century Vor Frelzers Kirke (Church of Our Saviour). The western quarter contains the Frederiksberg Park, with its palace and a zoological garden.

Formerly a centre of trade and shipping, Copenhagen has also become a manufacturing city. In 1969 it had over 155,000 industrial workers, about 40 percent of the national total. One-third of all Danish factories are situated in the Greater Copenhagen area, and nearly half the working population is engaged in manufacturing and handicrafts, including shipbuilding, machinery production, and canning and brewing. Some of the internationally known firms include the East Asiatic Company, with its many subsidiaries; Burmeister & Wain's machinery and shipbuilding company; large engineering contractors such as F.L. Smidth & Co., Christiani & Nielsen, and Kampsax; the Carlsberg and Tuborg breweries; Peter F. Heering (Cherry Heering); the Royal Copenhagen Porcelain Factory and Bing and Grøndahl's porcelain factory; and the George Jensen silverworks.

The constitution of the municipality of Copenhagen dates back to 1857. Power resides in the Town Council of 55 members, with an executive council consisting of a chief burgomeister, five other burgomeisters, and five aldermen, all elected by the Town Council. The suburban municipalities of Frederiksberg and Gentofte, as well as the 19 other suburbs, all have similar governmental structures.

Like other contemporary cities, Copenhagen has seen a shift of population and industry to the suburbs. The population of the city declined from about 975,000 in 1950 to less than 875,000 in 1965. At the same time there has been an increase of automobile traffic in all parts of the city. A number of arterial streets carry traffic toward the centre, across the three harbour bridges. There are electric railways (*S-baner*) for commuters and a network of city bus lines. The last streetcars disappeared in 1972. Copenhagen's airport is at Kastrup, about five miles southeast of the city.

The University of Copenhagen had over 20,000 students in 1971–72. In addition, Copenhagen has a number

Municipal  
govern-  
ment

Sven Samelius

Arnløbe Palace (centre). Copenhagen, with the royal residence on the left.

of other institutions of higher education: the Technical University of Denmark, the Engineering Academy of Denmark, the Royal Danish Academy of Music, the Royal Veterinary and Agricultural College, the Royal Danish Academy of Fine Arts (established in 1754), a college of pharmacy, a dental college, several training colleges for the education of primary school teachers, the Copenhagen School of Economics and Business Administration, and several schools of commerce.

**BIBLIOGRAPHY.** Historical works (in Danish) include: OLUF NIELSEN, *Kjøbenhavns Historie og Beskrivelse*, 6 vol. (1877–92), a history and description of Copenhagen from its beginnings to about 1730; CARL BRUNN, *Kjøbenhavn: En illustreret Skildring af dets Historie, Mindesmaerker og Institutioner*, 3 pt. (1887–1901), on Copenhagen's history, memorials, and institutions; SVEND CEDERGREIN BECH, *Kjøbenhavns historie gennem 800 år. København* (1967), a modern history of Copenhagen covering a period of 800 years; and H.U. RAMSING, *Kjøbenhavns Historie og Topografi i Middelalderen*, 3 vol. (1940), a history of Copenhagen in the Middle Ages. There are very few books in English devoted wholly to this city. Among them are DANSKE SELSKAB, *Capital of a Democracy*, 3rd ed. (1964); OLIVER WARNER, *A Journey to the Northern Capitals* (1967); SYLVIA FURNESS, *Copenhagen in the "Great Centers of Art Series"* (1970); and MICHAEL BUSELLE, *Copenhagen* (1967), mainly photographs. Statistical data may be found in the *Statistical Yearbook* for the municipality of Copenhagen (1919–).

(S.L.)

## Copernicus

A major contribution to Western thought was the publication in 1543 of *De revolutionibus orbium coelestium, libri VI* (Eng. trans., *On the Revolutions of the Celestial Spheres*, 1952; Latin reprint, 1965) by Nicolaus Copernicus, Polish astronomer, who is noted for the Copernican theory of the heavens. By attributing to the Earth a daily motion around its own axis and a yearly motion around the stationary Sun, Copernicus developed an idea that had far-reaching implications for the rise of modern science. Henceforth, the Earth could no longer be considered the centre of the cosmos; rather, as one celestial body among many, it became subject to mathematical description.

By courtesy of the Museum of Jagiellonian University, Cracow, Poland

Copernicus, 17th-century copy by an unknown artist of a 16th-century self-portrait. In the Museum of Jagiellonian University, Cracow, Poland

Copernicus was born on February 19, 1473, at Toruń, near the Vistula River in eastern Poland, where his father was a merchant of social standing. In 1491 Copernicus entered the University of Cracow, where he became interested in the study of astronomy; he probably returned home in 1494 (or 1496). His maternal uncle, Lucas Wac-

zenrode, newly elected bishop of Ermeland, wanted him to enter the canonry of Frauenburg in order to secure lifelong financial independence. While waiting for a vacancy to occur, he was sent by his uncle in 1497 for further training to the University of Bologna, where he associated himself with the German students.

For three and a half years Copernicus studied the Greek language, mathematics, and the writings of Plato; he also became further acquainted with the astronomical thought of the day. In Bologna he also made his first recorded observation of the heavens, an occultation (overlapping, or eclipse) of the star Aldebaran by the Moon on March 9, 1497; the light of the former was shut off by the Moon. The same year he was elected (by proxy) a canon of Frauenburg. He travelled to Rome in 1500 for the great jubilee celebration and may have given informal lectures in mathematics there. In 1501 he briefly visited Frauenburg to claim his post on the cathedral staff, returning promptly to Italy under special leave of absence to continue his studies at the University of Padua. There, enrolled with other Polish students, he studied both law and medicine. Except for a short interruption in 1503, when he was granted the degree of doctor of canon law by the University of Ferrara, he spent almost four years in Padua.

On returning to Poland in 1503, he visited Cracow and later acted as adviser to his uncle until the latter's death in 1512. Copernicus settled permanently at Frauenburg, where he acted as representative of the cathedral chapter, his medical skill being used particularly in aid of the indigent.

As a result of his studies in Cracow and Padua, Copernicus may be said to have mastered all the knowledge of the day in mathematics, astronomy, medicine, and theology. Copernicus appears to have planned a systematic program of astronomical work. Although he did not make extensive observations, he did enough to enable him to recalculate the major components of the supposed orbits of the Sun, Moon, and planets around the Earth. He published 27 such observations made during the years 1497–1529, and a few others have been found entered in books in his private library. He also published for his uncle in 1509 a Latin translation of Greek verses of Theophylactus, a Byzantine poet of the 7th century AD, and from 1519 to 1528 prepared an exposition of the principles of currency reform for certain Polish provinces; the latter was not published in Warsaw, however, until 1816.

Copernicus' fame as an industrious student of astronomy rapidly increased, and in 1514 he was invited to give his opinion on calendar reform, which was then being considered by the Lateran Council, a general meeting of the church authorities. He refused to express any firm views, for he felt that the positions of the Sun and Moon were not known with sufficient accuracy to permit a proper reassessment.

Yet, as his studies progressed, Copernicus became increasingly dissatisfied with the Ptolemaic system of astronomy. He was not alone in this dissatisfaction; indeed, he himself said that the many divergent views prevalent in his day gave him cause for profound thought. Ptolemy's system, which contained not only original work but also a synthesis of the views of previous Greek philosophers, was basically geocentric and circular in conception. By the 16th century this geocentric interpretation of the heavens had become firmly entrenched in astronomical thought, virtually as an article of faith. Although certain Greek philosophers had suggested, as far back as the 3rd century BC, that the Sun—and not the Earth—was the centre of the universe, their ideas had not been widely accepted. Difficulties had arisen when ancient astronomers sought to account for the accumulated observations of the Sun, Moon, and planets. Accordingly, Ptolemy (q.v.) in the 2nd century AD had devised an elaborate geocentric model of the heavens composed of large circles, called deferents, and small circles, called epicycles. Each planet rode on the circumference of an epicycle, the centre of which revolved on the deferent. Ptolemy used this system to account for observed ir-

Dissatisfaction with the Ptolemaic system

regularities of the planets, such as changes in brightness, and particularly for their puzzling retrogressive motions, when they seemed to stop and move backward and forward in a loop. Moreover, to account for observed variations in velocity, Ptolemy introduced the equant, which was an imaginary point in space where uniform, circular speed would indeed be observed. This system enabled astronomers to account for the phenomena and to make predictions. As observations in succeeding centuries became more accurate, however, it became increasingly difficult to compute the future positions of the heavenly bodies, and much of the flexibility and elegance of the Ptolemaic system was thereby lost.

Copernicus concluded that, in view of the many circles and their displacements from the center of the Earth that the Ptolemaic system required to account for the observed motions of heavenly bodies, a simpler, alternative explanation might be possible. In consequence, he read the works of many original Greek authors and found that, indeed, heliocentric ideas had been suggested. The idea of a moving Earth seemed absurd at first, but, when Copernicus applied this assumption, the result was an aesthetically superior, although not much simpler, system, even though, as might be expected, he still believed that the planets moved with uniform circular motion. After many years of mathematical calculations, he became convinced that his new idea was true, yet he made no attempt to publish.

From about 1510 to 1514, Copernicus prepared a short manuscript to summarize his new idea, *De hypothesibus motuum coelestium a se constitutis commentariolus*, which he privately circulated among friends in 1514. Its main points were: that the apparent daily motion of the stars, the annual motion of the Sun, and the retrogressive behaviour of the planets result from the Earth's daily rotation on its axis and yearly revolution around the Sun, which is stationary at the centre of the planetary system. The Earth, therefore, is not the centre of the universe but only of the Moon's orbit. As the years passed, he developed his argument with diagrams and mathematical calculations. Lectures on the principles expounded in the *Commentariolus* were given in Rome in 1533 before Pope Clement VII, who approved, and a formal request to publish was made to Copernicus in 1536. But he continued to hesitate. It was only through the efforts of his friends—in particular, his pupil and disciple Georg Joachim Rheticus, who studied with him for two years—that he finally published his work. In 1540 Rheticus was permitted to take the completed manuscript to Nuremberg, Germany, for printing. Because of opposition from Martin Luther, Philipp Melanchthon, and other reformers, Rheticus left Nuremberg and went to Leipzig, where he passed on the task of publication to Andreas Osiander. Apparently fearing criticism of a treatise that proposed an annual motion of the Earth around a stationary Sun, Osiander, on his own responsibility, inserted a preface emphasizing that the hypothesis of a stationary Sun was only a convenient means for simplifying planetary computations.

A careful examination of the text makes it clear, however, that Copernicus had really come to believe in the heliocentric system—rather, heliostatic, since he placed the Sun at some distance from the centre—as a true picture of the universe. He wrote *On the Revolutions of the Celestial Spheres*, in six sections, as a mathematical reinterpretation of Ptolemy. He wished to provide an alternative computational scheme that would make possible more accurate predictions that would be used in calendar reform and eclipses, and that would, at the same time, explain the troublesome variations of brightness, retrogressions, and velocity with a simpler geometric system of points and circles.

In the first section, Copernicus gave some basic mathematical rules, countered the old arguments about the fixity of the Earth, and discussed the order of the planets from the Sun. He could no longer accept the old arrangement—Earth, Moon, Mercury, Venus, Sun, Mars, Jupiter, and Saturn, since this had been a consequence of an Earth-centred, or geocentric, system. He found it neces-

sary to adapt it to his Sun-centred, or heliocentric system and adopted the following order from the stationary Sun: Mercury, Venus, Earth with the Moon orbiting around it, Mars, Jupiter, and Saturn. In the second section, Copernicus applied the basic mathematical rules of the previous section to the apparent motions of the stars and planets, and attributed the motion of the Sun to the motion of the Earth. The third section contains a mathematical description of the Earth's motion, including the precession of the equinoxes, which is caused by the gyration of the Earth's axis. Sections four, five, and six deal with the motions of the Moon and of the five remaining planets.

In his heliocentric theory, Copernicus found himself able to describe the movements of the Moon and planets in a more elegant way than Ptolemy in his geocentric system. To fit the observations Ptolemy had been forced to offset the centres of regular motion a slight way from the centre of the Earth, and this Copernicus believed to conflict with the basic rule of true circular motion. In *De revolutionibus* the centres all lay at the centre of the Sun, although, because Copernicus still adopted circular motions at an unvarying speed, his system proved to be virtually as complex as Ptolemy's. Nevertheless, Copernicus believed that his system was aesthetically more satisfying and that it was a true picture of the divinely ordained cosmos.

A copy of the great work is believed to have been brought to Copernicus at Frauenburg on the last day of his life, May 24, 1543.

The Copernican system appealed to many independent-minded astronomers and mathematicians. Its attraction was due not only to its elegance but also, in part, to its break with traditional doctrines: in particular, it opposed Aristotle, who had argued cogently for the fixity of the Earth; furthermore, it provided an alternative to Ptolemy's geocentric universe. In Western Christendom both of these views had been elevated almost to the level of religious dogma; to many thoughtful observers, however, they stifled development and were overdue for rejection.

Scientifically, the Copernican theory demanded two important changes in outlook. The first change had to do with the apparent size of the universe. The stars always appeared in precisely the same fixed positions, but if the Earth were in orbit round the Sun, they should display a small periodic change. Copernicus explained that the starry sphere was too far distant for the change to be detected. His theory thus led to the belief in a much larger universe than previously conceived and, in England, where the theory was openly accepted with enthusiasm, to the idea of an infinite universe with the stars scattered throughout space. The second change concerned the reason why bodies fall to the ground. Aristotle had taught that they fell to their "natural place," which was the centre of the universe. But because, according to the heliocentric theory, the Earth no longer coincided with the centre of the universe, a new explanation was needed. This re-examination of the laws governing falling bodies led eventually to Newton's concept of universal gravitation.

The dethronement of the Earth from the centre of the universe caused profound shock. No longer could the Earth be considered the epitome of creation, for it was only a planet like the other planets. No longer was the Earth the centre of all change and decay with the changeless universe encompassing it. And the belief in a correspondence between man, the microcosm, as a mirror of the surrounding universe, the macrocosm, was no longer valid. The successful challenge to the entire system of ancient authority required a complete change in man's philosophical conception of the universe. This is what is rightly termed "the Copernican Revolution."

**BIBLIOGRAPHY.** For the general reader two short biographies are available: ANGUS ARMITAGE, *Sun, Stand Thou Still* (1947); and JOZEF RUDNICKI, *Nicholas Copernicus* (1943); the latter was written for the 400th celebration of the publication of *De revolutionibus orbium coelestium* and is particularly well illustrated. ## Copland, Aaron

Generally recognized as one of the significant musical artists of this century, Aaron Copland succeeded so well in assimilating the materials of American folksong into his own highly personal style that, in the eyes of the world, he came to be regarded as *the* American composer of his time.

The son of a Russian-Jewish immigrant to America, Copland was born on November 14, 1900, in Brooklyn and attended public schools there. "I was born," he wrote, "on a street that can only be described as drab. Music was the last thing anyone would have connected with it." Yet an older sister taught him the piano, and by the time he was 15 he had decided to become a composer. As a first step Copland tried to learn harmony through a correspondence course. Haltingly and in an environment not particularly conducive to art, he struggled toward his goal.

Copland.

In the summer of 1921 Copland attended the newly founded school for Americans at Fontainebleau, where he came under the influence of Nadia Boulanger, a brilliant teacher who shaped the outlook of an entire generation of American musicians. He decided to stay on in Paris, where he became Boulanger's first American student in composition. During his three years in Paris Copland's music became more and more experimental. He returned to New York in 1924 with an important commission: Nadia Boulanger had asked him to write an organ concerto for her American appearances. Copland composed the piece while working as the pianist of a hotel trio at a summer resort in Pennsylvania. That season the *Symphony for Organ and Orchestra* had its premiere in Carnegie Hall with the New York Symphony under the direction of the composer and conductor Walter Damrosch.

In his growth as a composer Copland mirrored the important trends of his time. After his return from Paris, he worked with jazz rhythms in *Music for the Theater* (1925) and the *Piano Concerto* (1926). There followed a

period during which he was strongly influenced by Stravinsky's Neoclassicism, turning toward an abstract style he described as "more spare in sonority, more lean in texture." This outlook prevailed in the *Piano Variations* (1930), *Short Symphony* (1933), and *Statements for Orchestra* (1933-35). After this last work, there occurred a change of direction that was to usher in the most productive phase of Copland's career. He well summed up the new orientation: "During these years I began to feel an increasing dissatisfaction with the relations of the music-loving public and the living composer. It seemed to me that we composers were in danger of working in a vacuum." Furthermore, he realized that a new public for modern music was being created by the new media of radio, phonograph, and film scores: "It made no sense to ignore them and to continue writing as if they did not exist. I felt that it was worth the effort to see if I couldn't say what I had to say in the simplest possible terms." Copland therefore was led to what became a most significant development after the 1930s: the attempt to simplify the new music in order that it would have meaning for a large public.

The decade that followed saw the production of the scores that spread Copland's fame throughout the world. Most important of these were three ballets based on American folk material: *Billy the Kid* (1938), *Rodeo* (1942), and *Appalachian Spring* (1944). To this group belong also *El Salón México* (1936), an orchestral piece based on Mexican melodies and rhythms; two works for high-school students—the "play opera" *The Second Hurricane* (1937) and *An Outdoor Overture* (1938); and a series of film scores, of which the best known are *Of Mice and Men* (1939), *Our Town* (1940), *The Red Pony* (1948), and *The Heiress* (1949). Typical too of the Copland style are two major works that were written in time of war—*Lincoln Portrait* (1942), for speaker and chorus, on a text drawn from Lincoln's speeches, and *Letter from Home* (1944), as well as the melodious *Third Symphony* (1946).

In his later years Copland refined his treatment of Americana. "I no longer feel the need of seeking out conscious Americanism. Because we live here and work here, we can be certain that when our music is mature it will also be American in quality." His later works include an opera, *The Tender Land* (1954); *Twelve Poems of Emily Dickinson*, for voice and piano (1950); and the delightful *Nonet* of 1960. During these years Copland also produced a number of works in which he showed himself increasingly receptive to the serial techniques of the so-called twelve-tone school of composer Arnold Schoenberg. Notable among such works are the stark and dissonant *Fantasy for Piano* (1957) and *Connnotations for Orchestra* (1962), which was commissioned for the opening of Lincoln Center for the Performing Arts in New York City.

For the better part of four decades, as composer, teacher, writer of books and articles on music, organizer of musical events, and more recently as a much sought after conductor, Copland has succeeded in expressing "the deepest reactions of the American consciousness to the American scene."

### MAJOR WORKS

OPERAS: *The Second Hurricane* (1937); *The Tender Land* (1954).

BALLETS: *Hear Ye, Hear Ye* (1934); *Billy the Kid* (1938); *Rodeo* (1942); *Appalachian Spring* (1944); *Dance Panels* (1959).

ORCHESTRAL MUSIC: *Symphony for Organ and Orchestra* (1924); *Piano Concerto* (1926); three symphonies (1928, 1933, and 1946); *El Salón México* (1936); *Billy the Kid* (1938), suite from the ballet; *An Outdoor Overture* (1938); *Rodeo* (1942), four dance episodes from the ballet; *Lincoln Portrait*, for speaker and orchestra (1942); *Letter from Home* (1944, rev. 1962); *Appalachian Spring* (1945), suite from the ballet; *Concerto for Clarinet and String Orchestra*, with harp and piano (1948); *The Tender Land: Orchestral Suite* (1957).

WORKS FOR BAND: *Billy the Kid* (1938); *Variations on a Shaker Melody* (1956); *Emblems*, for symphonic band (1964).

CHAMBER MUSIC: *Two Pieces for String Quartet* (1928); *Quartet for Piano and Strings* (1950); *Nonet for Strings* (1960).

Mature  
career

Years in  
Paris

VOCAL MUSIC (SONGS): *Twelve Poems of Emily Dickinson* (1950); *The Tender Land: "Laurie's Song"* (1954).

CHORAL MUSIC: *Old American Songs*, two sets (1950, 1952); *Canticle of Freedom* (1955, rev. 1965); *The Promise of Living* (1964).

FILM SCORES: *The City* (1939); *Of Mice and Men* (1939); *Our Town* (1940); *The Cummington Story* (1945); *The Red Pony* (1948); *The Heiress* (1949); *Something Wild* (1961).

**BIBLIOGRAPHY.** AARON COPLAND, *What to Listen for in Music* (1939, *The New Music, 1900–1960*, rev. ed. (1968), *Music and Imagination* (1952), and *Copland on Music* (1960), works that display Copland's writing style and his unusual ability to explain sophisticated musical concepts to the general public; JULIA SMITH, *Aaron Copland* (1955), a comprehensive account of the composer's life and works; ARTHUR BERGER, *Aaron Copland* (1953), a carefully detailed analysis of Copland's music.

## Copper Products and Production

Copper is one of the most useful and widely used of the metallic elements. This article describes copper mining, refining and recovery, the production and uses of the metal and its alloys, chemical compounds of copper, and its economic importance. For information on the element copper, its physical and chemical properties and occurrence, see TRANSITION ELEMENTS AND THEIR COMPOUNDS; NATIVE ELEMENTS; and ORE DEPOSITS.

### HISTORY

Copper was discovered and first used by Neolithic man during the Late Stone Age. Though the exact time of this discovery will probably never be known, it is believed to have been about 8000 BC. Copper is found in the free metallic state in nature; this native copper is the material that Neolithic man employed as a substitute for stone. From it he fashioned crude hammers and knives and, later, other utensils. The malleability of the material made it relatively simple to shape implements by beating the metal. Pounding hardened the copper so that more durable edges resulted; the bright reddish colour of the metal and its durability made it highly prized.

The search for copper during this early period led to the discovery and the working of deposits of native copper. Sometime after 6000 BC the discovery was made that the metal could be melted in the campfire and cast into the desired shape. Then followed the discovery of the relation of metallic copper to copper-bearing rock and the possibility of reducing ores to the metal by the use of fire and charcoal. This was the dawn of the metallic age and the birth of metallurgy.

The early development of copper probably was most advanced in Egypt. As early as 5000 BC copper weapons and implements were left in graves for the use of the dead. Definite records have been found of the working of copper mines on the Sinai Peninsula about 3800 BC, and the discovery of crucibles at these mines indicates that the art of extracting the metal included some refining. Copper was hammered into thin sheets and the sheets formed into pipes and other objects. During this period bronze first appeared. The oldest known piece of this material is a bronze rod found in the pyramid at Maydūm (Medum), the date of origin being generally accepted as about 3700 BC.

Bronze, an alloy of copper and tin, is both harder and tougher than either; it was widely employed to fashion weapons and objects of art. The period of its extensive and characteristic use has been designated the Bronze Age. From Egypt the use of bronze rapidly spread over the Mediterranean area: to Crete in 3000 BC, to Sicily in 2500 BC, to France and other parts of Europe in 2000 BC, and to Britain and the Scandinavian area in 1800 BC.

About 3000 BC copper was produced extensively on the island of Cyprus. The copper deposits there were highly prized by the successive masters of the island—Egyptians, Assyrians, Phoenicians, Greeks, Persians, and Romans. Cyprus was almost the sole source of copper to the Romans, who called it *aes cyprum* ("ore of Cyprus"), which was shortened to *cuprium* and later corrupted to *cuprum*. From this name comes the English name copper.

The first two letters of the Latin name constitute the chemical symbol Cu.

When copper and bronze were first used in Asia is not known. The epics of *Shu Ching* mention the use of copper in China as early as 2500 BC, but nothing is known of the state of the art at that time or of the use of the metal prior to that time. Bronze vessels of great beauty made during the Shang dynasty, 1766–1122 BC, have been found, indicating an advanced art. The source of the metals, however, is unknown.

The Copper Age in the Americas probably dawned between AD 100 and 200. Native copper was mined and used extensively and, though some bronze appeared in South America, its use developed slowly until after the arrival of Columbus and other European explorers. Both North and South America passed more or less directly from the Copper Age into the Iron Age.

As man learned to fashion his weapons from iron and steel, copper began to assume another role. Being a durable metal and possessed of great beauty, it was used extensively for household utensils, water pipes, and for marine uses and other purposes that required resistance to corrosion. The unusual ability of this metal to conduct electric current accounts for its greatest use during the 20th century.

Later uses  
for copper

### MINING TECHNIQUES

**Open-pit and underground mining.** Though it sometimes occurs in native form, copper is most often found mixed with other minerals in the form of various ores (see below). In these ores, the amount of copper may vary from less than 1 percent to more than 10 percent. When the ore contains small quantities of the desired metal, very large amounts of rock must be mined and processed to recover a profitable quantity of metallic copper. In deposits of this type, the open-pit method, involving the removal of ore from extensive deposits exposed by the large open pits, is used. In cases in which the percentage of copper in the ore is considerably higher and the deposit far below the surface, the underground method, which requires sinking a shaft to the deposit, is employed. For a more complete description of these mining methods, see MINING AND QUARRYING.

**Important ores.** Principal forms in which copper ores are found include native copper, porphyry copper, massive deposits, and mixed ores. Native copper is simply the metal found unadulterated in nature. Porphyry copper deposits, in which the copper materials are more or less uniformly scattered throughout the rock, account for the greatest tonnage of metal in the producing areas of the world. The copper minerals in the upper portions of such deposits are in general oxides (copper chemically combined with oxygen), those in the lower levels sulfides (copper with sulfur). The host rock is porphyry, schist, or other rock. Massive deposits are of higher metal content but of more limited extent and may be oxidized in the upper portion with sulfides lower down. In mixed ores, nickel, zinc, or lead usually accompany the copper; when such ore is mined, these other metals also are refined and sold as by-products. Table 1 shows the ore minerals of copper and their compositions.

### ORE PROCESSING

Copper metal of very high purity is recovered from mined rock by a three-step process. Since much copper ore is found mixed with large amounts of material that does not contain copper, the first step (ore dressing) involves separating the ore from this worthless rock or gangue. The second step frees copper metal from the concentrate; *i.e.*, separates it from other elements, such as sulfur and oxygen, with which it is chemically combined. The third step, refining, involves removing impurities from the copper metal in order to produce a metal of very high purity.

**Ore dressing.** Copper ores usually are treated either by smelting (pyrometallurgical methods) or by leaching (hydrometallurgical methods). Generally speaking, sulfide ores are first concentrated by the selective flotation method described below, while oxide ores are leached.

Discovery  
of casting  
and  
reducing

Qualities  
of bronze

**Table 1: General Classification of the Ore Minerals of Copper**

	formula	copper (percent) *
Native copper ore		
Native copper	Cu	99.9
Sulfide ores		
Chalcocite	Cu <sub>2</sub> S	79.9
Covellite	CuS	66.5
Chalcopyrite	CuFeS <sub>2</sub>	34.6
Bornite	Cu <sub>5</sub> FeS <sub>4</sub>	63.3
Enargite	Cu <sub>3</sub> AsS <sub>4</sub>	48.4
Tetrahedrite	Cu <sub>8</sub> SbS <sub>2</sub>	46.7
Oxide ores		
Cuprite	Cu <sub>2</sub> O	88.8
Tenorite	CuO	79.9
Malachite	CuCO <sub>3</sub> · Cu(OH) <sub>2</sub>	57.5
Azurite	2CuCO <sub>3</sub> · Cu(OH) <sub>2</sub>	55.3
Chalcanthite	CuSO <sub>4</sub> · 5H <sub>2</sub> O	25.5
Brochantite	CuSO <sub>4</sub> · 3Cu(OH) <sub>2</sub>	56.2

\*Approximate.

**Selective flotation.** In selective flotation the finely ground ore, mixed with water and selected reagents, is violently agitated with air to produce a heavy froth. The reagents are so selected that a great attraction exists between the surface of the valuable mineral particles and the air bubbles, with only a small attraction between the gangue particles, which are readily wetted by the water, and the air. As a result, the mineral particles cling to the bubbles of the froth and are carried to the surface while the gangue particles sink to the bottom of the container. Removing the froth then separates the minerals from the gangue material. Perfect separation is impossible, but with constant supervision, repeated treatment, and exacting control it is possible to concentrate 95 percent or more of the copper ore into 10 to 20 percent of the original weight and to eliminate most of the worthless gangue.

**Roasting.** In roasting, the copper concentrate is heated in air to expel volatile matter, such as arsenic and antimony, and to expel part of the sulfur from sulfide ores by oxidation to produce sulfur dioxide gas and copper oxide. The material that results from roasting, known as calcine, is a fine mixture of the sulfides and oxides of iron and copper, gangue material, and nonvolatile impurities. The total sulfur content has been reduced to that desired for the subsequent smelting operation.

**Metal recovery.** To separate metallic copper from the substances with which it is associated in copper ores, smelting of matte or electrolytic techniques may be employed. Sometimes copper is recovered from scrap.

**Matte smelting and converting.** The object of the first step in smelting is to produce a molten, artificial sulfide of copper and iron. This material, known as matte, should contain all the copper and the desired amount of iron and must be sufficiently heavy so that when melted, it will separate from the gangue material, other undesirable compounds, and the balance of the iron. When metallic oxides fuse in the presence of fire, they react as bases and will combine with acid anhydrides to form stable compounds of relatively low weight. These compounds, known as slags, are usually formed by the use of silica, SiO<sub>2</sub>, as the acid anhydride. The formation temperature and fluidity of the slag is a function of its composition. The action of the slag on the furnace lining is a function of its acidity. It is necessary then to balance the composition of the slag to achieve the desired results. This is done by adding to the furnace selected materials to give a slag of the desired composition and properties. These materials are known as fluxes; the most common are limestone and silica.

Matte is generally smelted in large oblong furnaces from 20 to 30 feet (six to nine metres) in width and from 90 to 130 feet (27 to 40 metres) in length, constructed with heavy, silica brick side walls and a low roof. These are called reverberatory furnaces because heat is radiated from the roof onto the material treated. Matte may also be smelted in blast furnaces or electric furnaces.

The conversion of matte involves the transformation of molten matte into copper metal (blister copper). Matte converting is based on the fact that copper has a lower affinity for oxygen than has iron or sulfur and the fact that the oxidation of iron and sulfur liberates large quantities of heat. Molten matte can be oxidized by introducing into it a stream of air. At the point at which the air enters, iron, sulfur, and copper are oxidized. The copper oxide immediately reacts with any iron sulfide still present to reform the sulfide of copper and form the oxide of iron. As air continues to flow through the molten mass, a time arrives when all the iron is present as the oxide and all the copper as the sulfide, and the sulfur that was originally with the iron has left the charge as sulfur dioxide. Since iron oxide forms a fusible slag with silica, it is necessary only to add to the molten mass sufficient silica to form the desired slag, and all the iron may be removed as an iron-silicate slag, while the heavy copper sulfide remains behind. The oxidation of the iron and its sulfur liberates sufficient heat to keep the material molten and to melt the necessary silica and any other solid charge that it may be necessary to add. If air continues to enter the charge after the removal of the slag, the oxidation of the sulfur and the copper continues, and the copper oxide so formed at once reacts with the copper sulfide remaining in the charge to form sulfur dioxide and metallic copper. These reactions liberate just sufficient heat to keep the charge molten. Ultimately, all sulfur is oxidized, and metallic copper and a small amount of copper oxide are present in the charge. Small amounts of minor impurities are also present.

**Hydrometallurgy.** Hydrometallurgy, or leaching, involves the treatment of the ore with a suitable solvent that takes the copper compound into solution and leaves all or a major part of the undesirable material unaltered. The copper is then recovered in relatively pure form from the solution.

The oxide ores of copper lend themselves to leaching. Sulfuric acid readily dissolves these oxides and has little effect on the common gangue materials, except for some of the salts of iron. Many oxide ores are not amenable to concentration, so it is necessary to treat or leach the ore as mined. The material is agitated or soaked with the leach solution. Elaborate systems of washing and filtering or settling are employed to recover the optimum amount of copper. After use, the leaching solutions are usually subjected to some type of purification for removal of the soluble iron and other objectionable impurities. This often involves neutralization and oxidation followed by removal of the precipitated ferric salts. For a more extensive description of hydrometallurgy, see METALLURGY.

**Electrolytic recovery.** When copper ores are leached with sulfuric acid, the metal may be recovered from the leach solution, in which it exists in the form of copper sulfate, by passing an electric current through the solution (electrolysis); this breaks down the sulfate and yields copper. An insoluble anode (positive terminal of an electrolytic cell) and a copper cathode (negative terminal) are used in the process; they are immersed in the leaching solution (copper sulfate), and an electric current is passed through the cell, and copper from the solution is deposited on the cathode.

**Recovery from scrap.** Because of its durability, large quantities of scrap or reclaimed copper become available each year from obsolete or discarded machinery and equipment. This material is readily converted into usable metal by its addition to smelter feed, or by remelting and refining (see also MATERIALS SALVAGE).

In the early 1970s pollution problems and economic considerations were bringing some shifts in the use of various methods of ore dressing and metal recovery. Smelting was under criticism in many places because of the release of sulfur dioxide to the atmosphere. Continuous smelting processes that minimize the problem were developed in Australia and Canada, and a combined roasting and smelting process, called flash smelting, in Finland and Canada. Higher prices for copper at the same time were encouraging the use of leaching, effec-

Producing blister copper

Electrolytic decomposition of copper sulfate

tive in exploiting low-grade copper-bearing material. In this procedure, dilute sulfuric acid is allowed to trickle through the ore, extracting the copper in the form of a solution of copper sulfate. The copper is recovered from the solution by precipitation on scrap iron.

**Refining.** Refining involves the removal of impurities from copper metal to yield a product containing less than  $\frac{1}{10}$  of 1 percent of impurities.

Oxidizing  
impurities

**Fire refining.** Blister copper contains copper oxide and small quantities of other impurities. Some of these impurities can best be removed by fire refining, which is done either in small reverberatory furnaces or in revolving furnaces, equipped with fuel burners that melt the charge, if necessary, and maintain it in a molten condition throughout the refining operation. Air is forced through the molten material to ensure complete oxidation of all impurities, and then the oxides are allowed to rise to the surface of the quiet pool from which they are skimmed. The oxidizing treatment is followed by a reducing treatment known as poling, in which the ends of green logs are forced into the pool of molten metal. The highly reducing gases resulting from the destructive distillation of the green logs reduce (remove the oxygen from) most of the copper oxide present in the metal. This reduction also can be effected by bubbling reformed natural gas through the bath. During this operation, frequent samples are examined to determine the degree of deoxidation. When the proper stage has been reached, the sample has a distinctive metallic rose colour. This metal is called tough-pitch copper, and may be readily cast into dense slabs.

Commercial tough-pitch copper is usable in this form. It still contains, however, any gold and silver recoverable from the original ore and traces of other impurities. The gold and silver are often worth recovering, and the removal of other impurities to produce the pure metal can be brought about by electrolytic refining.

**Electrolytic refining.** When an impure copper anode and a copper cathode are immersed in a solution of copper sulfate and sulfuric acid and an electric current is passed through the cell, copper ions from the solution migrate to the cathode and are deposited as metallic copper, and copper from the anode enters the solution. For each ion deposited on the cathode, an ion enters the solution from the anode. Impurities in the anode are liberated and settle to the bottom of the cell as a slime or accumulate in the solution. The net result is the consumption of the impure anode and the deposition of pure copper on the cathode along with the formation of a cell slime that contains the gold, silver, and other insoluble components. (A.W.S.)

#### THE METAL AND ITS ALLOYS: PRODUCTION AND USES

The major portion of the world's production of copper is utilized by the electrical industries; most of the remainder is combined with other metals to form alloys.

**Essentially pure metal.** Typical samples of electrolytic copper contain from 99.92 percent to 99.96 percent copper. About 0.03 percent oxygen is purposely left in the copper, since this amount slightly improves density and conductivity. Copper in this condition has a conductivity of 100 percent to 102 percent of the International Annealed Copper Standard. On this standard, 100 percent denotes a resistance of 0.15328 ohm for a length of one metre (39.37 inches) weighing one gram ( $\frac{1}{28}$  ounce) at 20° C (68° F); this standard has been universally adopted for industrial purposes.

Making  
copper  
wire

**Electrical conductors.** For making copper wire, electrolytic copper is first cast into wirebars, which are made in several standard sizes varying in weight from 135 to 500 pounds (60 to 225 kilograms). The wirebars are then reheated to 700° to 850° C (1,290° to 1,560° F) and are rolled without further reheating to rods approximately  $\frac{3}{8}$  inch or about ten millimetres in diameter. The rod is drawn cold into wire, through dies of successively smaller diameters until the desired size is reached. The dies are usually of tungsten carbide; for finer wires, diamond dies are used.

Much copper wire is marketed in the form of bare coils;

a considerable tonnage is subsequently covered with paper, fabric, rubber, plastic, or other insulating material for use in the form of covered conductors. Much of the wire is also supplied stranded; all of these operations are carried out on special machines that are largely automatic in operation.

Copper cables are often covered to render them resistant to moisture. Lead covering, extruded onto the outside of the cable by means of a special apparatus, often is used; hemp or metal armouring sometimes may be added for additional protection.

The electrical industries also use large quantities of bare copper strip for incorporation in electrical machinery. This ribbonlike form of the metal is produced mainly from wirebars that are rolled in a mill similar to that used for the production of wire. Copper strip of greater width and much thinner gauge also is produced in long lengths and supplied in the form of coils.

**Sheet and strip.** The term copper strip as distinct from copper sheet is usually applied to material less than 24 inches (61 centimetres) wide that is supplied in long lengths. The majority of the strip used is less than 12 inches (30 centimetres) wide. In the preliminary stages of manufacture, the copper castings are rolled hot, but in the later stages of manufacture all the rolling is carried out cold, the material being coiled on coiling drums on each side of the rolling mills. Material produced by this method is of very even gauge and possesses an exceptionally good surface finish. The coils can be handled easily and are in general use for the manufacture of stampings in the electrical and other industries. Copper strip is supplied in various degrees of hardness according to the rolling it has received subsequent to the last annealing. These various tempers are selected according to the amount of subsequent mechanical deformation to which they will be subjected.

Hardness  
of copper  
strip

Copper sheets are produced by somewhat similar methods of manufacture. In the United States the majority of copper sheets are made from electrolytic copper, but in Europe fire-refined arsenical copper is used frequently in the manufacture of sheets and plates.

**Alloys.** In variety of uses, the alloys of copper surpass all other nonferrous alloys and comprise mixtures of copper with zinc, tin, nickel, aluminum, lead, manganese, and other elements.

**Brass.** Brass is an alloy consisting mainly if not exclusively of copper and zinc. The brasses may be conveniently divided into two groups in terms of their malleability, the dividing line being approximately the composition of 55 percent copper and 45 percent zinc. All the higher copper alloys are workable either hot or cold and in some cases both hot and cold, while the remainder are not malleable at all. The unworkable brasses, known as the white brasses, are not industrially important.

The general mechanical properties of brass vary widely; indeed, it is this wide range in tensile strength, elongation, and hardness that makes brass such an important alloy. Brass is readily drawn into fine wire, rolled into very thin strips, or drawn into tubes and extruded as rods or sections (see also ZINC PRODUCTS AND PRODUCTION).

**Bronze.** Bronze, an alloy formed by adding tin to copper, fuses at a lower temperature than copper and is thus better suited for casting; it also is harder and less malleable. A soft bronze or gunmetal is formed from 16 parts of copper to one of tin; a harder gunmetal, such as that used in the past for bronze cannon, contained about eight parts copper for each part of tin.

Bronze is made harder and stronger when it is alloyed with phosphorus. Alloys prepared in this way, known as phosphor bronzes, may contain only about 1 percent of phosphorus in the ingot and a mere trace after casting, but their value is nevertheless enhanced for purposes in which a hard, strong metal is required, as for pumps, plungers, valves, and the bushings of bearings. Bronze is also improved by the presence of manganese in small quantities. Various grades of manganese bronze, in which there is little or no tin but a considerable percentage of zinc, are used in mechanical engineering (see also TIN PRODUCTS AND PRODUCTION).

Phosphor  
bronze

**Nickel.** Because copper and nickel are completely miscible (mix thoroughly) in the solid state, forming a complete series of solid solutions, the useful range of alloys is not confined within any definite limits of composition, although certain compositions have come into general use. Additions of 2 to 45 percent nickel to copper provide a series of alloys that are considerably stronger and more resistant to oxidation at high temperatures than is copper. Of these cupronickels, the one containing 30 percent nickel is the most important; it is widely-used for steam-condenser tubes.

The alloy formed of 20 percent nickel with the remainder copper is one of the most ductile of commercial alloys and may be subjected to the most severe cold-working without the need of any intermediate annealing. It is also readily forged and rolled at a temperature above 800° C (1,470° F). These properties make it a very suitable alloy for drop forgings and cold stamping and pressing. It has also found a variety of uses in automobile construction for exposed fittings, as it takes a high polish and is resistant to atmospheric tarnishing. Other uses include bullet sheathing, a widespread application. Another alloy in this series, containing either 45 percent or 40 percent nickel, became widely known under the name constantan. It has a high electrical resistance, which remains almost constant over a wide temperature range.

Monel metal is a so-called natural alloy prepared by the reduction of a copper-nickel ore; it contains 65 to 70 percent nickel, iron and manganese in small amounts, and certain impurities that influence its properties to some extent. It has been widely used for various engineering and ornamental purposes, and possesses exceptionally high strength at both normal and elevated temperatures. Alloys of similar nickel content are also manufactured by melting nickel and copper together.

**Beryllium-copper.** Unlike many kinds of steel, most copper alloys are not susceptible to improvements of hardness and strength by processes of heat treatment. One useful exception is the heat-treatable alloy beryllium-copper. This consists of copper with addition of about 2 percent of beryllium, with or without a smaller addition of nickel or cobalt.

When beryllium-copper is heated to about 800° C (1,470° F), quenched in cold water and then reheated to 275° C (525° F), it develops a tensile strength comparable to some of the stronger varieties of steel.

**Other copper alloys.** Copper also forms an important series of alloys with aluminum, classed under the general term aluminum bronzes. They may be classified into two main groups: those containing up to 7.5 percent aluminum are extremely ductile, whereas those containing 8 to 11 percent possess high tensile strength in the cast state. The ductile alloys containing less than 7.5 percent are especially useful for deep stamping, spinning, and severe cold-working of all kinds. They are useful as a substitute for brass and possess greater strength and resistance to atmospheric corrosion.

Silicon bronze usually contains about 96 percent copper. The remainder may be silicon alone, but more often a little manganese, tin, iron, or zinc is also added. These alloys were developed originally for the chemical industry because of their exceptional resistance to corrosion in many liquids. Their application later extended far beyond this field, chiefly because of their good casting qualities, strength, hardness, and ease of welding.

Manganese bronze is made in several varieties, exhibiting a range of compositions and properties. One type is in reality a brass to which a very little manganese has been added as a deoxidizer, less than 0.5 percent manganese remaining in the alloy. Another kind contains 2 to 5 percent manganese together with 2 to 4 percent iron and 3 to 7.5 percent aluminum. It has exceptionally high strength and is called high-tensile manganese bronze, or manganese-aluminum bronze.

(A.Bu.)

(cuprous) and the other a valence of 2 (cupric); several unstable compounds in which a valence of 3 is exhibited are also known. Since the cuprous ion is unstable in aqueous solution, its salts readily decompose to form the metal and cupric salts.

**Oxides.** Copper forms two oxides in accordance with its two valences: cuprous oxide,  $\text{Cu}_2\text{O}$ , and cupric oxide,  $\text{CuO}$ . Cuprous oxide, a red crystalline material, can be produced by electrolytic or furnace methods. It is reduced readily by hydrogen, carbon monoxide, charcoal, or iron to metallic copper. It imparts a red colour to glass and is used for antifouling paints. It is soluble in mineral acids to form colourless cuprous salts, most of which rapidly oxidize to the cupric state. Cupric oxide, a black powder, can be prepared by the ignition of suitable salts such as the carbonate, the hydroxide, or the nitrate of copper, or by heating of cuprous oxide. This compound oxidizes carbon compounds and finds a wide laboratory and commercial use for this purpose. Since it imparts a green colour to glass, it is used extensively for that purpose. It is soluble in mineral acids and forms with them blue or green solutions.

**Halides.** Cuprous chloride,  $\text{CuCl}$ , can be prepared by treating metallic copper and cuprous oxide with hydrochloric acid or by treating metallic copper and cupric chloride with hydrochloric acid. The hydrochloric acid solution of cuprous chloride readily absorbs carbon monoxide and acetylene and is used for this purpose in gas analysis. Cupric chloride,  $\text{CuCl}_2$ , can be prepared by dissolving cupric oxide in hydrochloric acid. This material finds some use as the base salt for the manufacture of pigments. Cuprous iodide,  $\text{CuI}$ , is prepared by the direct combination of copper and iodine. Cupric iodide,  $\text{CuI}_2$ , exists only in combination with ammonium salts or in complex organic compounds.

**Sulfates.** Cupric sulfate,  $\text{CuSO}_4$ , commonly known as blue vitriol, is the most important salt of copper. It usually crystallizes as  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  and has a bright blue colour. It is prepared by the treatment of copper oxides with sulfuric acid. While readily soluble in water it is insoluble in alcohol. The anhydrous salt is hygroscopic and is useful as a desiccating agent. Copper is readily displaced from aqueous solutions of the salt by metallic iron. Copper sulfate is the basic salt in the electrolytic refining of copper, and it also finds a wide use in the preparation of pigments.

**Carbonates.** Basic copper carbonates are formed when an alkaline carbonate is added to the solution of a copper

Table 2: World Mine Production of Copper by Major Producing Countries (1980)

#### CHEMICAL COMPOUNDS: PREPARATION AND USES

Copper forms two series of compounds, one in which it exhibits a valence (degree of combining power) of 1

Monel  
metal

Manganese  
bronze

Blue  
vitriol

salt. These compounds, which have a bright blue or green colour and are used in the preparation of pigments, occur in nature as the minerals azurite and malachite.

**Other compounds.** Copper forms a series of salts with arsenic, all of which are bright green in colour and poisonous. Wide use has been made of these compounds in the production of insecticides; some copper salts are used as superficial antiseptics. Cupric nitrate,  $\text{Cu}(\text{NO}_3)_2$ , can be prepared by dissolving metallic copper in nitric acid. The hydrated crystals are deep blue in colour. Copper silicates occur in nature and impart blue colour to many minerals.

(A.W.S.)

#### ECONOMIC IMPORTANCE

Although commercial deposits of copper ores occur in almost every continent, 70 percent of the world's known reserves are found in seven countries: Chile, the United States, the Soviet Union, Zambia, Canada, Peru, and Zaire. The greatest known reserve of copper ore in one body is the deposit at El Teniente mine in Chile. Many lesser deposits are being exploited, such as those in Alaska, China, Australia, and Europe.

Table 2 shows the most important producing nations and their percentage of the world total.

**BIBLIOGRAPHY.** METALLURGICAL SOCIETY OF AIME, PAUL E. QUENEAU (ed.), *Extractive Metallurgy of Copper, Nickel, and Cobalt* (1961), a collection of technical papers with a valuable bibliography of more than 1,000 references, the majority referring to copper; J.N. ANDERSON and PAUL E. QUENEAU (eds.), *Pyrometallurgical Processes in Nonferrous Metallurgy* (1967), technical articles confined to pyrometallurgy with about one-third of them concerned with copper; GEORGE R. ST. PIERRE (ed.), *Physical Chemistry of Process Metallurgy*, 2 vol. (1961), highly technical articles (only a few exclusively on copper); ALLISON BUTTS (ed.), *Copper: The Science and Technology of the Metal, Its Alloys and Compounds* (1954), contains authoritative chapters on all aspects of copper, each written by an expert, though somewhat outdated; ROBERT BOWEN and ANANDA GUNATILAKA, *Copper: Its Geology and Economics* (1977), a technical survey of principal copper deposits of the world; JOSEPH R. BOLDT, JR., *The Winning of Nickel: Its Geology, Mining, and Extractive Metallurgy* (1967), primarily concerned with nickel, but most nickel ores contain copper—hence, it is of interest; ALEXANDER SUTULOV, *Copper Production in Russia* (1967); RALPH HULTGREN and P.D. DESAI, *Selected Thermodynamic Values and Phase Diagrams for Copper and Some of Its Binary Alloys* (1971); statistical data also may be found in the publications of the U.S. Department of the Interior, Bureau of Mines; RAYMOND F. MIKESSELL, *The World Copper Industry: Structure and Economic Analysis* (1979), a comprehensive treatment of the world copper industry, including the operation of international copper markets and the economic prospects of the copper industry through the year 2000.

## Copyright Law

Copyright is the term used in English-speaking countries to characterize the legal recognition of rights to control or benefit from the communication of works of authorship. The word has a double meaning, stemming from its etymology. It denotes not only the right "to copy" but also the right to own and control "the copy," that is, the prototypic work of authorship itself. The word copyright is sometimes used interchangeably with vague terms such as literary property or intellectual property. None of these English-language labels, however, identifies the primary beneficiary of the rights they cover. In contrast, equivalent terminology in other languages—such as *droit d'auteur* (French) and *Urheberrecht* (German)—does identify the beneficiary and can usually be translated simply as "the right of the author."

Though similar in some ways, copyrights and patents are fundamentally different forms of legal protection. Copyrights protect works that owe their origin to the expressive efforts of a writer, composer, artist, or other creative individual. As long as a work is original in the sense that it was created independently, it can be copyrighted even if a closely similar work is already in existence. A copyright owner has rights only against those who use his work without his permission.

Both the criteria for obtaining a patent and the protection it offers are much greater than those applicable under copyright law. Patents protect the discoveries of inventors. A valid patent generally requires the invention of something that is both "novel," in the sense of never having existed before, and "unobvious," in the sense of being beyond the ordinary skill of an artificer or expert in the field. For as long as it lasts, the owner of a valid patent has a monopoly right to prevent anyone from using his invention, including other persons who have made the same discovery independently.

Both copyrights and patents are frequently confused with trademarks, which are words or other symbols that have come to identify the source or sponsorship of merchandise or services. Legal protection of trademarks is based not upon creative authorship, as in the case of copyrights, or upon inventive discovery, as in the case of patents, but upon the investment of time, money, and skill in selecting a mark and inducing the public to identify it with a particular source of goods or services.

#### THEORIES OF COPYRIGHT

The literature of copyright law is crowded with efforts to fit copyright under a single heading, including property, monopoly, statutory reward, natural right, and personal right. Writers who argued that copyright is a form of property no different from goods or land were led to demand unlimited, perpetual rights in copyrighted works. Their opponents, relying on the theory that copyright is a monopoly and that all monopolies are evil, contended that authors should be given as little protection as possible. The value of this dialectic is that, taken as a whole, the philosophical arguments illuminate the special characteristics of copyright and its unique legal nature.

Copyright as property. In its broadest sense, property is something of value created or acquired lawfully by a particular owner, who is entitled to transfer or deal with it in any way that does not conflict with the public interest. Although copyright cannot be considered an absolute property right, it can be classed as a form of property. As property, it is artificial and limited in the sense that the law of a country creates it and imposes conditions and limitations upon it. The differences between copyright and ordinary forms of property stem from certain unique characteristics of copyright. The purpose of creating a copyrighted work is to communicate its contents to the minds of others. Yet, once this disclosure takes place, the intangible work cannot be physically possessed or controlled; it has become capable of instantaneous and unlimited reproduction and dissemination. The task of the law in protecting this kind of property thus becomes much more difficult.

There are, of course, other forms of intangible property, apart from copyright, that the law protects as fully as it does land or goods. But in cases such as those involving securities or breaches of contract, the owner's rights are applicable only as against a particular person or limited group. In contrast, the copyright owner is owed a duty by the public at large and can enforce his rights against anyone who violates this duty.

Copyright as monopoly. Both patents and copyrights are monopolies, giving their owners the power to control the market for a particular item. A copyright is a more limited monopoly than a patent, since it does not prevent competition from similar works that have been created independently. But the question arises as to whether it shares the harmful economic and social effects usually attributed to monopolies.

The owner of copyright in a book or play has a monopoly in that particular work, and his control over the extent of its dissemination and the prices charged for its use, if arbitrary or unreasonable, may carry the monopoly taint. But anyone else may write a book or play on the same subject, and there are usually many other books or plays competing for the public's attention.

Copyright in a single work is a small monopoly that can promote competition by forcing others to create their own works. This conclusion does not necessarily extend to situations in which many copyrights are pooled and con-

trolled on a collective basis and in which the opportunities for monopoly abuse can become very real.

Copyright as a personal right. Copyrights, considered as unique forms of property and monopoly, are essentially pecuniary rights, but underlying them is a strong personal element. Authorship is an individual creative process, something quite different from ordinary labour or investment. By its nature copyright is linked inseparably with the individual author since it is he who should be stimulated to create and be rewarded for his work.

Many countries recognize this personal factor in their copyright laws through provisions giving an author a nontransferable "moral right" to prevent distortion of his work and to assure that he is identified as its author. Similarly, the duration of the copyright term throughout most of the world is based on the life of the author.

The purpose of copyright. Paralleling the dispute as to the legal nature of copyright has been a sharp conflict over its purpose: should it protect the author in something that is rightly his, or should it benefit the public by stimulating creation, or should it do both?

The view that the author should be the fundamental beneficiary of copyright protection is the foundation of copyright legislation in a number of countries, particularly in western Europe. In general, this was the philosophy underlying the **Berne** Convention for the Protection of Literary and Artistic Works (1886, as subsequently revised: see below). Where this view prevails, the law starts from the premise that protection should be as long and as broad as possible and should provide only those exceptions and limitations essential in the public interest. The opposing view lies behind the Universal Copyright Convention adopted in Geneva in 1952. Under this philosophy the law should give only as much protection as is necessary to induce authors to create and disseminate their works.

The middle ground between these opposing philosophies has been gaining acceptance since World War II and appears to have influenced recent legislation in a number of countries. Its basic premise is that the purpose of copyright is both to stimulate the creation and public dissemination of works and to give their authors a generous reward for their contributions to society. The process of balancing these aims is an infinitely delicate one, and among the many factors to be weighed are the educational needs and economic situation within a country, the importance of promoting national authorship, and the demands of the new technological methods for disseminating the works of authors.

#### HISTORICAL DEVELOPMENT OF COPYRIGHT BEFORE 1886

The word plagiarism is reputed to have been coined by Martial, who likened his poems to freed slaves and termed a rival poet, who had represented the poems as his own, an abductor (Latin *plagiarius*). There are other instances of literary theft throughout the classical and Middle ages, but, although the practice was sometimes the object of moral censure, it carried no legal consequences.

Copyright in the modern sense was born in the late 15th century, the offspring of Johannes Gutenberg's invention of printing with movable type and of the expansion throughout Europe of learning and religious ferment. At about the time William Caxton established a printing press at Westminster in 1476, the city of Venice inaugurated a system of granting "privileges," or monopoly rights, to print certain books.

The practice of sovereign grants of exclusive publishing rights spread quickly to other countries and became a common trade practice during the 16th and 17th centuries. The printer or publisher seeking the monopoly was willing to pay for the privilege and to submit the work for official approval. For the ruler making the grant, the system was thus a source of revenue and, more important, an opportunity for exercising political or religious censorship.

For more than 200 years this inchoate form of copyright was a matter involving tradesman and sovereign, and the individual author was rarely even an indirect beneficiary

of the transaction. In England the system of royal licenses to individual printers became a definite procedure, and the Stationers' Company was chartered in 1556, giving the members of this guild of London printers monopoly rights in the books they published. All books were required to be submitted for official approval and to be entered on the company's register; both unauthorized printing and failure to register were punished by decrees of the Court of Star Chamber.

This restraint on freedom of the press persisted for more than a century, but the unpopularity of the Star Chamber led to a new system recognizing perpetual rights in registered books. Parliament abolished the Star Chamber in 1641 but passed a new licensing act in 1643, which, with various lapses and renewals, survived until 1694. Indignation at the arbitrary power conferred by these licensing acts led to their final lapse in that year. The result was flourishing book piracy.

Pressure by owners of literary property to restore their protection prompted Parliament to act in 1710 but in an unexpected way. The Statute of Anne of April 10, 1710, in changing the conceptual nature of copyright, became the most important single event in copyright history. Two of the principles on which it rests were revolutionary: recognition of the author as the fountainhead of protection and adoption of the principle of a limited term of protection for published works. This statute influenced the development of copyright protection the world over.

The statute of 1710 limited protection in published works to a maximum of 28 years; but it left unanswered an important question. Assuming that authors had always enjoyed rights in their unpublished works, based on principles of the English common law, did these rights still continue after publication? In other words, the question was whether the Statute of Anne added to common-law protection already available or cut off all common-law rights, thus protecting published works only for the term of years and under the conditions specified in the statute.

This controversy produced two landmark decisions. In 1769 the case of *Millar v. Taylor* held that authors have common-law rights in their creations, that these rights are neither destroyed by publication of the works nor superseded by the Statute of Anne. In 1774, the House of Lords in *Donaldson v. Becket* upheld the Millar decision on the first two points, acknowledging that before the Statute of Anne the common law had provided perpetual copyright protection for all works, unpublished or published. It overturned the Millar case on the third point, however, holding that the statute destroyed and replaced all common-law rights in works after they had been published and that once the term of protection provided by the statute expires, the work enters the public domain and is free for anyone to use.

Twelve of the 13 states of the newly independent United States of America passed copyright legislation between 1783 and 1789, but it soon became apparent that these separate statutes were ineffective. The result, in 1789, was the adoption of a provision in the U.S. Constitution empowering Congress "to promote the progress of science and useful arts by securing for limited times, to authors and inventors, the exclusive right to their respective writings and discoveries." Congress exercised this power in 1790 by enacting a federal copyright statute closely patterned on the Statute of Anne.

The great English cases of *Millar v. Taylor* and *Donaldson v. Becket* found their American counterpart in the 1834 decision of the U.S. Supreme Court in *Wheaton v. Peters*. This important case dealt with the same basic question: What common-law rights continue to exist after a work has been published? Unlike *Donaldson v. Becket*, which held that common-law rights survive publication but are cut off by statute, the *Wheaton* case states that, regardless of the existence of a statute, common-law rights in the United States are cut off by publication of the work. Under this rule, a work enters the public domain unless there is a statute to protect it; and, if there is, the extent of protection depends on the provisions of that statute.

1741, and in 1793 France adopted legislation that was to serve as a model for copyright statutes in many civil law countries. Thereafter, throughout the 19th century, most independent nations enacted copyright laws; almost all of these statutes recognized the author as the fundamental beneficiary and offered protection for limited periods of time. The general trends established by 19th-century copyright legislation were toward increasing the classes of works eligible for protection, broadening the exclusive rights in these works, and providing a longer term of copyright.

#### THE ORIGINS OF INTERNATIONAL COPYRIGHT PROTECTION

The Industrial Revolution and the **expanding technology** of communications brought with them not **only a growth** in the number and scope of domestic copyright statutes but also the need for reciprocal protection of works between countries. At first national copyright laws generally denied any protection to works of foreign authors, and what few exceptions there were derived from bilateral treaties negotiated on a give-and-take basis.

A turning point occurred in 1852, when France extended protection to all works of authorship regardless of their national origin. Although this generous act set no pattern, it accelerated the movement toward a more broadly based multilateral system of international copyright. The Association Litteraire et Artistique Internationale (ALAI) was formed in Paris and took the lead in seeking ways to establish an international union of countries pledged to the protection of authors' rights. It sponsored a series of meetings and, in 1883, prepared a draft treaty that was considered at intergovernmental conferences held during the following three years. The draft provided the basis for the Berne Convention for the Protection of Literary and Artistic Works of September 9, 1886.

**Development of the Berne Union.** The original Berne Convention of 1886 was of fundamental importance: it was not only the first multilateral copyright convention in history, but it also established some enduring international copyright principles. Rather than adopting a merely reciprocal principle by which a country protects foreign works only to the extent that its own works are protected in return, the Berne Convention was based on the principle of national treatment or assimilation under which a country agrees to give foreign authors the same protection it accords its own authors. The convention set up an international copyright union of all member states, still known as the Berne Union. It required that, among union members, the right of translation (*i.e.*, the right to control the act of translating a copyrighted work into another language) be protected for a minimum of 10 years. The 1886 text established no other specific minimum requirements, but in the successive revisions of the Berne Convention the "minima" have expanded to the point that in the early 1970s the convention required members to offer a fairly high level of protection to works of other member countries.

The original Berne Union consisted of 14 countries, all but one of which remained members. The convention has gone through a series of partial or complete revisions, in 1896, 1908, 1914, 1928, 1948, 1967, and 1971. By the early 1980s the union consisted of more than 70 countries, more than 40 of which were bound by the 1971 version. Neither the United States nor the Soviet Union has ever been a member.

A revision of the Berne Convention in 1967 proved extremely controversial because of the broad concessions it offered to developing countries, and it failed to achieve the number of ratifications necessary to bring it into effect. This failure brought on a renewed effort to revise the Berne Convention in conjunction with revision of the other worldwide copyright treaty, the Universal Convention of 1952. Revisions of both conventions were signed at Paris on July 24, 1971, and are discussed together below. The 1971 Paris text of the Berne Convention superseded the Brussels text of 1948 for some purposes.

**The Brussels text of the Berne Convention, 1948.** Like the text of 1928, the Brussels revision of 1948, for a number of years the dominant version of the convention,

broadly defines the "literary and artistic" works a member country is required to protect. In addition to more traditional examples of copyrightable subject matter, such as books, dramas, musical compositions, and works of art, the Brussels text specifies as copyrightable a wide variety of subject matter including choreography, pantomimes, cinematographic works, architecture, and photographs.

From the 10-year exclusive translation right of 1886, the Berne Convention has expanded to embrace a wide range of exclusive rights that all members are required to grant to works first published in other member countries. These minimum rights include, in general, rights of public performance, broadcasting, wire diffusion, adaptation, arrangement, translation, recording, and motion picture adaptation. Most, though not all, of these rights are subject to limitations.

Probably the most important innovation of the Brussels revision was the introduction of the author's "moral right" as a mandatory requirement. Member countries are obliged to grant to an author of another member country, regardless of the ownership of copyright in his works, the right to claim authorship of the work and to object to any distortion or other alteration that would be prejudicial to his honour or reputation. The Brussels revision took another major step when it established as the general minimum term of copyright protection "the life of the author and fifty years after his death." For "anonymous and pseudonymous works" the minimum term is set at 50 years from publication, and member countries are left free to establish the duration of protection for motion pictures and photographs.

The Berne Convention specifically prohibits a country from making protection conditional upon the fulfillment of any formal requirements such as registration or the use of a copyright notice. An unpublished work is automatically protected if its author is a national of a Berne Union country, and a published work receives protection if it is first published in a Union country, either alone or simultaneously with publication elsewhere.

#### INTER-AMERICAN COPYRIGHT CONVENTIONS

During the formative stage of the Berne Convention, efforts were being made to develop multilateral copyright arrangements in the Americas. These efforts produced a series of Pan-American copyright conventions. The most important of them, and the only one of which the United States is a member, is the Buenos Aires Convention of 1910. In effect, it provides that a work is to be protected in a member country if it has been copyrighted in another member country and bears a form of copyright notice. The need for a bridge between the Pan-American conventions and the Berne Convention was a motivating force behind development of the Universal Copyright Convention.

#### THE UNIVERSAL COPYRIGHT CONVENTION

More than anything else, the copyright situation in the United States, with its notice, registration, and manufacturing requirements, was responsible for the second worldwide multilateral copyright convention, the Universal Copyright Convention. The ucc, as it is usually called, was adopted at Geneva in 1952, and took effect on September 16, 1955, with the United States as one of the original member countries. By the early 1980s more than 70 countries were parties to the ucc, including some 45 that were also members of the Berne Union. The Soviet Union became a ucc member in 1973.

The United States offered no copyright protection to foreign authors until 1891, did not participate actively in the adoption or revisions of the Berne Convention, and established a copyright system sharply diverging from that underlying the Berne Union. After World War II there was general recognition in the United States and most other countries that U.S. participation in a broad multilateral copyright arrangement was important for the future of international copyright. It was also realized that it would be futile for some time to think of the Berne Convention as that arrangement, since U.S. copyright practice

Revisions  
of the  
Berne  
Conven-  
tion

Complex-  
ity of U.S.  
copyright  
procedures

differed so much from that of the Berne Convention countries. The approach adopted was a new convention, which was intended to establish a minimum level of international copyright relations throughout the world without weakening or supplanting the Berne Convention.

In comparison with the later revisions of the Berne Convention, the Universal Copyright Convention represents a rather low-level compromise arrangement. Like the Berne Convention, the ucc is based on the principle of national treatment: works of other ucc countries must be protected to the same extent as domestic works. In addition to unpublished works by citizens of ucc countries and works first published in member countries, the treaty obligations apply to published works by authors who are citizens of member countries, regardless of where first publication takes place. The Universal Copyright Convention's minimum requirements as to exclusive rights are both modest and vague. They include a requirement that contracting states give exclusive translation rights for at least seven years and thereafter establish a compulsory licensing system for translations.

The great compromise of the ucc, embodied in Article III, provides that the formal requirements of a contracting state's copyright law, such as notice, registration, and domestic manufacture, are satisfied for foreign ucc works if from the time of the first publication all the copies of the work... bear the symbol © accompanied by the name of the copyright proprietor and the year of first publication placed in such manner and location as to give reasonable notice of claim of copyright.

This provided a bridge between the U.S. system, with its formal requirements, and the Berne system, which forbids such formalities.

The other main compromises in the Universal Copyright Convention were really concessions to the U.S. system. Subject to a range of detailed exceptions, the minimum term is to be either 25 years from the death of the author or from the date of first publication. Another main stumbling block impeding U.S. adherence to the Berne Convention has been its retroactive effect, requiring protection for works that have previously been considered in the public domain. In contrast, the ucc does not require a contracting state to protect works that are permanently in its public domain on the date the convention becomes effective in that state.

**Later developments.** A crisis in international copyright was precipitated by the adoption at Stockholm, in 1967, of a revision of the Berne Convention. The crisis resulted from the "Stockholm Protocol Regarding Developing Countries." This instrument, though self-contained, is an integral part of the Stockholm text and consists of sweeping concessions to developing countries, allowing them to make unauthorized use of works of other Union countries under broad and loosely defined compulsory licensing systems. The concessions were so broad that no developed country accepted the new text, and the result was an impasse that for a time threatened the future of the Berne Union.

In an effort to break this impasse, international conferences for the revision of both the Berne Convention and the Universal Copyright Convention were held at Paris in 1971. The coordinated program of these conferences resulted in a new text of the Berne Convention that retains the revisions in the body of the convention already adopted at the Stockholm Conference but drops the protocol in favour of an appendix making more realistic concessions to developing countries with respect to reproduction and translation of materials having educational value. The new text successfully meets the needs of developing countries without damaging the legitimate copyright interests of developed countries. Equivalent changes were made in the Universal Copyright Convention, which was also amended to require member countries to accord at least some minimum level of protection to the rights of reproduction, public performance, and broadcasting; the United States adhered to the revised version of the ucc, effective July 10, 1974.

Aside from the concessions to developing countries, the changes in the Berne Convention made at Stockholm

appear destined to come into effect in most Berne Union countries. Of these changes, the most basic involve the criteria of eligibility for protection of published works under the convention: the Stockholm text retains the traditional criterion that the work must be protected if it was first published in a Union country but makes it secondary to a new criterion that the work must be protected if the author's nationality is that of a Union country.

On March 10, 1974, the United States became a party to the 1971 Convention for the Protection of Producers of Phonograms Against Unauthorized Duplication of Their Phonograms, to which more than 25 other countries are also adherents.

Although they differ greatly in any number of detailed points and often approach copyright from conflicting theoretical premises, the copyright statutes of most major countries of the world follow a consistent pattern. As a rule, copyright in both published and unpublished works is secured automatically by the author. As long as his work is original, in the sense that he created it independently, the author need do nothing to secure and maintain his copyright, which lasts throughout his lifetime and for a period of years after his death.

Basic congruence of most national copyright systems

#### HISTORY OF U.S. COPYRIGHT LEGISLATION

The copyright law of the United States has been the subject of numerous individual amendments but has undergone only a few general revisions. The original act, that of 1790, granted to the authors of maps, charts, and books "the sole right and liberty" of printing, reprinting, and vending copies of their works for 14 years with the right of renewal for a second 14-year term; in effect the renewal could serve as a reversion to the author for his benefit or that of certain successors in interest if he had transferred to someone else his first-term copyright. An amendment in 1802 added prints to the list of protectable works and established the requirement that a notice of copyright be placed on the published copies of copyrighted works.

**The first general revision.** In 1831 the first general revision added music as a copyrightable category and increased the first term of protection to 28 years but left the renewal term at 14 years. An act was passed in 1834 calling for the recordation of instruments in writing for the transfer of copyrights. An amendment in 1856 accorded the right of public performance to dramas. An act approved by Pres. Abraham Lincoln in 1865 extended copyright protection to photographs.

**The second general revision.** The general revision of 1870 added such works as paintings, drawings, and statuary; it also centralized copyright registration and recordation in the Library of Congress, the earlier laws having provided for these things to be done in the clerk's office of the U.S. District Court in the district where the copyright owner resided. In 1891, as part of the law that provided a basis for the protection of the works of foreign authors, Congress included the so-called manufacturing clause, a protectionist device that required, as a condition of copyright, that books and certain other works be printed in the United States and that the importation of foreign-manufactured works be restricted. An amendment of 1897 granted for the first time the right of public performance to musical compositions. Another statute in the same year established the position of Register of Copyrights and led to the Copyright Office becoming a separate department of the Library of Congress.

**The third general revision.** The third general revision was the act of 1909. The terms of that statute, as amended over the years, remained in force until 1978 and may still be determinative of the copyright status of works that were subject to its provisions. That law, like all the earlier U.S. copyright statutes, provided for a dual system of protection: a common-law copyright, based on the laws of the several states, automatically protected unpublished works; and statutory copyright protected works published with the notice of copyright, as well as works registered in unpublished form.

Pursuant to the law of 1909, as amended, promptly after copyright was secured in a work by publication with

The manufacturing clause

The Stockholm protocol of 1967

notice, registration in the Copyright Office was required except for those foreign works exempted by the UCC provisions. Copyright protection began on the date of first publication, while the term for works registered in unpublished form was measured from the date of registration. The term of protection was 28 years, and the copyright was renewable for a second term of 28 years, twice the length of the renewal term under the previous statutes.

Protection of phonorecords and motion pictures

An important new feature of the general revision of 1909 was the protection of music against "mechanical" reproductions, principally in the form of phonorecords; this was effected by a provision establishing a compulsory licensing system, the first one in the history of U.S. copyright law, under which a musical composition could be used on a phonorecord without the consent of the copyright owner but with the payment of a royalty whose amount was specified in the statute.

Technical changes were made in 1955 by the amendment implementing the Universal Copyright Convention. In anticipation of the passage of a new general revision, there was enacted, effective September 19, 1962, the first of what became a series of nine acts that ultimately extended through December 31, 1977, the duration of all renewed copyrights that would otherwise have expired during this interval; such works thus could enjoy the renewal term totalling 47 years as provided by the act that took effect January 1, 1978. In 1972 an amendment added provisions for the copyright protection of sound recordings against unauthorized reproduction.

#### THE PRESENT U.S. COPYRIGHT LAW

A new U.S. copyright law was approved in 1976, to take full effect January 1, 1978. This new enactment, the fourth general revision, specifies that copyright subsists in original works of authorship fixed in any tangible medium of expression and provides that such works include literary, musical, and dramatic works; pantomimes and choreographic works; pictorial, graphic, and sculptural works; motion pictures and other audiovisual works; and sound recordings.

The concept of "fair use"

The act accords to the owner of copyright the exclusive right to reproduce and distribute the copyrighted work in copies or phonorecords, to prepare derivative works, and to publicly perform and display the work. These rights, however, are made the subject of numerous limitations, one of the most important being "fair use." According to this concept, a minor taking of copyrighted material from a work is not considered an infringement. This had its origin in 19th-century court cases in which judges sought to apply the rule of reason to the controversies they confronted. The statute specifies that fair use is not a copyright infringement and lists certain factors that are to be considered in determining whether use in a particular case is a fair use.

Among the other limitations imposed by the law on the rights of copyright owners are certain compulsory licenses. In addition to continuation of the compulsory license for musical works on phonorecords established by the act of 1909, these include compulsory licensing schemes covering certain retransmissions by cable television systems and the public performance of copyrighted musical works in coin-operated phonograph record players (*i.e.*, jukeboxes). The act establishes the Copyright Royalty Tribunal, with the power to adjust the royalty rates under these three compulsory licenses and to distribute the royalty fees paid under the cable and jukebox licenses.

Establishment of a unitary system of copyright

One of the most important provisions of the act specifies that all rights equivalent to any rights within the general scope of copyright are to be governed exclusively by the new act with respect to works of authorship that are fixed in tangible form and come within the subject matter of copyright. Thus, by preemption, statutory rights replace common-law copyright and there is, for the first time in U.S. history, a unitary rather than a dual system of copyright.

Another important feature of the new act is the establishment of the general term of copyright protection as the life of the author plus 50 years after the author's death. For anonymous works, pseudonymous works, and

works made for hire, the term is 75 years from first publication or 100 years from the date of creation of the work, whichever is shorter. For works under common-law protection when the new act took effect, the term of protection will not expire before the end of the year 2002; if such a work is published before that date, the term will not expire before the end of 2027.

For any statutory copyright that was secured before January 1, 1978, the period of protection is 28 years from the date when the copyright was originally secured, with the right to a renewal term of 47 years, making a total possible term of 75 years. Copyrights that were secured under the law prior to 1978, and that are in their first term, must still be renewed by registration in the U.S. Copyright Office during the last (the 28th) year of their first term in order to enjoy the renewal term and thus the full maximum period of 75 years. In short, the new law drops the renewal provision except for works that secured statutory copyright under the old law. The new law, however, retains the reversionary principle contained in the renewal system by permitting individual authors or their heirs to terminate in certain cases the grant of a transfer of rights as early as 35 years from the date of the grant, upon compliance with conditions set forth in the act. Under the new law all terms of copyright run through the end of the calendar year in which they would otherwise expire.

The new act contains the requirement of a notice of copyright to be affixed to copies and phonorecords of published works in such manner and location as to give reasonable notice of the claim to copyright. Although the provisions are complex, the notice for copies should generally contain the symbol ©, the word "Copyright," or the abbreviation "Copr.," together with the year of first publication and the name of the owner of copyright; for example, © 1982 John Doe. For phonorecords of sound recordings the notice should be the symbol © together with the year of first publication and the name of the owner of copyright in the sound recording; for example, © 1982 John Doe. Under the new statute, however, the notice requirements are less rigid than in the former law, and the omission of the notice does not invalidate the copyright if specified corrective steps are taken within certain time limits.

Notice of copyright

Registration, a feature of all previous U.S. copyright acts, is retained but is generally not a condition of copyright protection. In the ordinary case registration in the Copyright Office is made a condition to bringing an infringement suit, and inducements to early registration are added in the form of more effective remedies. The new law also provides that the owner of copyright in a work published with the copyright notice in the United States shall deposit in the Copyright Office two copies of the work for the use or disposition of the Library of Congress. This mandatory legal deposit, in many ways similar to such systems in other countries, is not a condition of copyright protection but serves as a means of enriching the collections of the national library. In addition, a provision for the recollection of the transfer of copyright ownership was retained in the new act.

The manufacturing clause, though narrowed in its scope, remains in the law but subject to a provision that would automatically abolish it, effective July 1, 1986.

Although the Congress, in the revision process, was made aware of virtually every problem in copyright law, including the effects of technological developments, some issues were not resolved. For example, while retaining the provision that sound recordings are protected against unauthorized duplication, Congress chose not to create a public performance right for such works but to leave the matter for further study.

Interest has revived in the question of U.S. adherence to the Berne Convention. Although the current law contains new provisions, such as the "life-plus-50" term of protection, that are in consonance with Berne, other minimal requirements of that convention have not been met. The United States would presumably have to choose to make additional changes if it were to join the Berne Convention.

## Coraciiformes

The birds of the order Coraciiformes include the kingfishers, todies, motmots, bee-eaters, rollers, hoopoes, and hornbills and are collectively referred to as roller-like birds. Among the members of the order that have attracted special attention are certain kingfishers that plunge headfirst into water for fish and are associated with classical mythology; according to the ancient Greeks, Ceyx and his wife Alcyone were shipwrecked at Delphi and changed into kingfishers. The Chinese used the shining blue feathers of some types of kingfishers to decorate picture screens. Bee-eaters (Meropidae) have been accused of preying on commercially valuable honeybees, and the North American belted kingfisher (Megaceryle *alcyon*) is sometimes considered a pest at fish hatcheries because it preys on young game fish. The kookaburra (*Dacelo novaeguineae*) has a loud, laughing, or braying voice that is commonly associated with the Australian outback, or backcountry. To the biologist, the sealing of the female of certain species of hornbills in her nest during incubation and brooding is one of the most intriguing behavioral modifications among birds.

**General features.** The roller-like birds are active by day (diurnal) and range in length from the size of a small sparrow (about 10 centimetres, or four inches) to more than 100 centimetres (40 inches). They have compact bodies, short to moderately long necks, large heads, rather long bills, small feet, and ample wings. The tail varies from short to very long and may be forked, square, or graduated; the outer or central tail feathers are, in some species, pointed or spatulate at the tip. All of these birds regularly perch in trees, where some feed; others fly in search of food, and a few walk or hop on the ground. The group's food is extremely varied, ranging from invertebrates (including insects) and small vertebrates to berries and fruit.

Figure 2: Body plans of larger Coraciiformes.  
Drawing by R. Keane

**Distribution.** Collectively, the 10 families of the order are almost worldwide in temperate and tropical areas, with the greatest number and diversity in the warmer parts of the African, southern Asian, and Papuan areas. Many species are common and conspicuous, and a few tolerate human settlement, although their direct importance to mankind is minimal.

Only the kingfishers (family Alcedinidae) are found in both Eastern and Western hemispheres. The motmots (Momotidae) and todies (Todidae) are restricted to the New World tropics; the bee-eaters (Meropidae), rollers (Coraciidae), and the hoopoes (Upupidae) to temperate and tropical regions of the Old World; and the hornbills (Bucerotidae) to the tropics of Africa and Asia. The wood hoopoes (Phoeniculidae) are found only in tropical and subtropical Africa; the cuckoo roller (Leptosomatidae) and the ground rollers (Brachypteraciidae) are found only on Madagascar.

Families  
of coraci-  
form birds

### NATURAL HISTORY

**Life history.** Most species live permanently in one region, but temperate-zone species move nearer the tropics for the winter. In the Old World tropics that have a dry-wet seasonal change, local movements of bee-eaters sometimes take advantage of the related crops of insects. In East Africa, where there are two dry and two wet seasons, it is thought that two periods of breeding may occur a year.

As a group, these birds are well endowed with voices, but their vocalizations are usually referred to as calls rather than songs. Some are harsh; others are soft or are whistled or hissed. Some are given as single notes, others as series in a trill, a rattle, or a hooting, and still others as a cacophony or medley of notes. Some calls are given from perches; others are given on the wing. Certain utterances may be related to courtship and mating or to territory; others seem to be simply a part of the bird's general daily activity. Pairs are formed to the accompaniment of simple posturing displays and series of calls, ranging from harsh to soft. Certain rollers use tumbling display flights. Both sexes usually share in the nest duties.

Many roller-like birds are solitary in feeding and nest-

Walling in  
of the  
female  
hornbill

ing, but some bee-eaters are gregarious and also nest in colonies. Hornbills and wood hoopoes move about in small parties most of the year, but they nest solitarily. The nest site is always in a cavity, which may be a hole or crevice in a tree, a bank, or a wall. The cavity may be among rocks or be a tunnel dug by the birds in the ground, or it can be an abandoned termite nest.

Normally, little or no nest material is added, except by the hoopoe (*Upupa epops*). In some (perhaps most) hornbills, however, the female enters the nest cavity before laying starts; the male brings mud and debris, which the female takes and plasters around the entrance until only a slit is left. The male passes food to the female through the slit until after the young are more or less grown. At that time she breaks out of the nest, and then both parents feed the young.

The members of the order lay two to nine eggs, with the tropical species laying the smaller clutches. Among the hornbills the larger species lay fewer eggs than do some smaller ones. The eggs are usually white but, in the hoopoe, may be olive, brownish, bluish, or greenish, and sometimes spotted. Incubation is performed by both male and female in kingfishers, todies, motmots, and bee-eaters and by the female alone in the hoopoe and hornbills when she is fed by the male. Incubation periods of 18 to 22 days have been recorded for some of the smaller members of the order.

The young are nidicolous (dependent upon the parents) and are naked, except for the hoopoe and some kingfishers that have varying amounts of down at birth. The recorded nestling period (25 to 28 days) of certain of the smaller species is only slightly longer than the incubation period, but large species have longer nestling periods, and the great hornbill (*Buceros bicornis*) has a total period (incubation to fledging) of three to four months. Except for the hoopoe and the walled-in hornbills, the young are fed by both parents. The male of these species brings food to the female, who passes it on to the young. The rate of feeding the young is apparently variable. In large species of hornbills, the male is recorded as making one trip per hour to the nest, during which he brings a gullet full of fruits and regurgitates them one at a time and passes them to the female. A much smaller species brings one item of animal food and holds it in his bill each trip and makes about six trips an hour.

Coraciiforms of several groups practice no nest sanitation, and regurgitated insects and other remains accumulate and are used to make a platform on which the young rest in later nest life. Hornbill nests are kept more or less clean, and, in one small species in which the female breaks out of the nest when the young are half grown, the young perform nest sanitation and also help to seal up the nest again after the female emerges.

When the young leave the nest, they are able to fly and usually are similar to, although sometimes duller or paler than, the adult in plumage. There is believed to be one molt a year, which occurs after the nesting season. In an unusual modification, the female of the African hornbills is walled in during incubation and throughout the nest life of the young. She molts during this period, losing and renewing all of her flight feathers.

**Locomotion and feeding.** Coraciiform birds tend to perch in trees and shrubs when at rest. Some favour exposed perches on which they are conspicuous, others seek the protection of foliage or the shade of the forest. Lacking cryptic coloration—many are nearly uniform in colour or boldly patterned—they do not rely on concealment for protection. Their flight varies from weak and laboured to strong, well sustained, and direct. The flight of some, such as the rollers, is swift and graceful. Some species, such as the kingfishers, use little bipedal locomotion; others (e.g., some hornbills) hop, walk, or scramble in the treetops, creep along branches (wood hoopoes), or walk or hop on the ground (hoopoe, other hornbills).

The food of the roller-like birds includes a wide variety of organisms. Among the animals taken are worms, snails, crustaceans, insects, fish, amphibians, reptiles, small birds, and mammals. Vegetable food consists

chiefly of the fruits of trees, usually gathered in the trees but sometimes picked up on the ground.

Some birds of this order seem to choose animal food more for its size than its type, and a single method of feeding tends to predominate in each family. Some families (Upupidae and Leptosomatidae) contain only one species; others are large and predictably diverse—e.g., the hornbills (Bucerotidae), with 45 species, and the kingfishers (Alcedinidae), with about 90 species. Each family or group of families tends to have a characteristic pattern of feeding behaviour, and the foraging patterns fall into four categories, or feeding niches: (1) watchful waiting on a perch, (2) aerial—i.e., spending much time on the wing, (3) searching on foot among branches of trees, and (4) walking on the ground.

The watchful waiters, the kingfishers, motmots, and todies, tend to sit quietly for long periods. When they see their prey on a leaf, a branch, the ground, or even in water, they fly out with swift, direct flight, seize the prey with the bill, and return to the perch. The todies catch more flying insects than do members of the other two families. A few kingfishers plunge headfirst into water from perches or from hovering flight, but these number only a few of the species-rich family Alcedinidae. The shovel-billed kingfisher (*Clytoceyx rex*) of New Guinea is partly terrestrial and is known to feed on beetles and earthworms; the latter are apparently dug from the soil of the forest floor with the bird's short, heavy bill. The ruddy kingfisher (Halcyon *coromanda*), widespread in Southeast Asia, eats many large land snails. It seizes a snail with its bill and beats it against a rock until the shell is broken and the meat can be extracted.

The term temperament, although tinged with human associations, seems applicable to certain traits that are common to many species within a family, as contrasted with members of another group. Kingfishers, motmots, and todies are stolid, phlegmatic birds that sit quietly for varying periods of time between sallies for food. Kingfishers often bob their heads and the forepart of their bodies when nervous or mildly alarmed; when startled into flight, some give sharp calls. Motmots have the habit of moving their tails from side to side.

Bee-eaters and rollers are aerial feeders but spend much time perched quietly, leaving their perches to make sallies for passing insects. Bee-eaters, especially, often spend long periods on the wing, gliding in circles while looking for insects, especially bees and wasps. Some forest bee-eaters perch in foliage and near flowers, securing their prey without flying. Rollers spend more time perched, but they too are graceful in flight and capture much of their food by hawking or by darting down to the ground. Members of both groups are often seen aloft, apparently not feeding but flying for diversion. The cuckoo roller (*Leptosomus discolor*) also flies above the forest canopy, but it is looking for large insects and small lizards in the outermost foliage. It may either seize them while on the wing or alight to capture them.

Feeding while clambering among the branches of trees is carried on by many of the larger hornbills and by the small wood hoopoes, but in quite different ways. The hornbills fly over or through the forest with strong, often noisy flight and, on alighting, scramble or hop among the branches reaching out for fruit, small animals, or both. The wood hoopoes have weak flight, and they do not fly much; they fly chiefly from one tree or clump of trees to the next, climbing about the trunks and branches of trees and lianas in acrobatic poses as they seek insects in crevices and on the bark surface.

Walking on the ground is the usual mode of feeding for the common hoopoe (*Upupa*), the ground rollers, and for a few hornbills. The hoopoe walks with quick steps, bobbing its head in time with the steps and pausing to probe with its long bill in the ground and in crevices, in search of large arthropods and small vertebrates. Its flight is strong and direct. When perched, it may quietly flash its long crest open and shut. The ground rollers, most of which are birds of the deep forest, also feed on the ground on food similar to that of the hoopoe. When disturbed, they fly or jump to low perches.

Types of  
foraging  
behaviour

Social  
feeding by  
ground  
hornbills

The ground hornbills (*Burcorvus* species) exhibit a definite social organization when foraging. Three or four members of a group searching for insects and other small animals on the ground may keep near each other, with the result that prey frightened into activity by one bird may be caught by one of the others. Several other species of hornbills occasionally forage solitarily on the ground.

Habitat selection and ecological diversity. Coraciiform birds, diverse in their structure and behaviour, occupy a variety of habitats. Each species is restricted in distribution by requirements of feeding and nesting areas. A species may be considered to occupy a feeding and, during the breeding season, a nesting habitat, and these may or may not be contiguous. Some species, such as certain African kingfishers, which nest in cavities excavated in termite mounds and feed on termites and other insects near the nest site, may be said to nest within their feeding habitat. Aerial feeders, such as bee-eaters, which nest in burrows, may be considered to occupy two habitats, one for feeding and one for nesting.

The factors that influence habitat suitability are evident in a few cases. One bee-eater requires a cut bank in a grassland area for its burrow, but must be near a forest because it feeds over the forest and the forest edge. The importance of suitable perches is illustrated by observations made on an insect-rich region of East African grassland, from which kingfishers were absent until a road was built. With the roads came telegraph wires, which provided the perches.

Relative  
diversity  
of Old and  
New  
World  
coraciiform  
families

The widest range of habitats occupied by members of the order Coraciiformes is found in Africa (including Madagascar), where eight of the ten families are represented. These exhibit all four basic feeding modes, but on Madagascar some niches are occupied by families different from those on the African mainland. Ground feeding in the forest, for example, is limited to the ground rollers in Madagascar; in Africa this niche is occupied by the hoopoe (except in dense forest) and by birds of other orders. The four coraciiform families found in temperate Eurasia occupy only three niches: ground feeding (hoopoe), darting from a perch (kingfishers, some bee-eaters), and aerial hawking (other bee-eaters, rollers). In Australia only the last two niches are occupied by coraciiforms, and these are the same families that hold these niches in Eurasia. In the New World, where three families are found, only one feeding mode is used, that of darting out from a perch; but this mode is geographically and ecologically subdivided between the diminutive todies, which are limited to the Greater Antilles where neither the kingfishers nor the *motmots* are represented, and the kingfishers (with the exception of the pygmy kingfisher, *Chloroceryle aenea*), which are specialized fish eaters.

Social behaviour. A number of coraciiform birds are markedly social, feeding in small parties and nesting in colonies. Some wood hoopoes forage in conspicuous, noisy bands of five to ten individuals. The acrobatic, climbing activity of a band is sometimes interrupted when the birds of a whole party bow and sway their bodies, pump their tails up and down, and join in a chorus of chattering calls. Moving from tree to tree, one bird follows another in weak undulating flight. Forest species of wood hoopoes are less social, and lone individuals sometimes call while perched high in a tree. Many hornbills may be seen flying through or over the forest, the beats of their broad wings giving a characteristic loud whooshing noise. They are usually found in small parties and actively move about in the branches, sometimes giving conversational notes. A study of a young captive hand-reared hornbill of a small species of *Lophoceros* (*Tockus*) has provided surprising data. This bird seemed to have a remarkably active, alert, intelligent personality recalling that of captive crows. It greeted its foster parents by raising its wings, pointing its beak upward, raising its head feathers, and chattering. It was jealous of attention given other animals, kept close to its foster parents when out of doors, and alighted on their shoulders. When accompanying them on walks, it flew

from tree to tree. It was busy and mischievous, attracted by anything bright, and fond of picking at knots or holes. This young hornbill had a passion for pulling up seedlings and sometimes amused itself by darting in and tweaking the tail of a larger, more lethargic, young *Bycanistes* hornbill.

Relationships with other species. Certain types of social behaviour of the Coraciiformes involve other birds or unrelated animals. Although some of these interactions are occasional and opportunistic, others are regular parts of everyday life and may be called symbiotic—i.e., one that brings mutual benefit to the different species involved.

The regular swarming of many bird species about grass fires to capture animals driven out of hiding by the flames is a phenomenon often related to human activity, for such events are often caused accidentally or deliberately by man. Among the birds that gather are both rollers and bee-eaters; they swoop down near the flames and into the smoke to seize fleeing insects. After the fire has passed, certain hornbills find good foraging on foot over the newly exposed ground.

Utilization  
of grass  
fires

More notable are a number of interspecific nesting relationships. Some bee-eaters make their colonial burrows in the same banks in which certain smaller swallows dig their burrows; there seems to be no conflict between the larger bee-eaters and the smaller swallows, despite the similarity in nesting and feeding habits. In southern Africa, the little bee-eater (*Melittophagus pusillus*) sometimes makes its nest burrow in the wall of the very much larger burrow of the aardvark (*Orycteropus afer*), and there is no further relationship between the bird and the mammal.

Sporadic incidents occur between species when one or both are foraging; a kingfisher may pilfer a food item from a dipper (*Cinclus*), and a savanna kingfisher will occasionally fly down to seize a grasshopper flushed by a man. Many associations are more frequent. Some bee-eaters in Africa often accompany large bustards, other large walking birds, and zebras and other game animals to feed on the insects roused from the grass by the animals. The bee-eater even uses the bustard's back as a perch. The bee-eater may also accompany an automobile driven through these grasslands to secure insects. There is also a regular association between hornbills and bands of monkeys in the treetops of African forests, with the birds seeking the insects stirred into activity by the fruit-eating monkeys.

In many parts of the Old World tropics, where large arboreal termite mounds are common and conspicuous, certain kingfishers usually excavate their burrows in them; in fact, some species are believed to nest only in them. The presence or absence of the termites might be expected to have an important effect on the populations of such kingfishers. The hoopoe commonly nests near buildings, especially in South Africa, and it is possible that the availability of such sites may affect the local abundance of the species. The presence of woodpecker holes used by hoopoes and wood hoopoes may also affect the size of their breeding populations.

Some African species of kingfishers, bee-eaters, hoopoes, and wood hoopoes are victimized by obligate social parasites, the honey guides (*Indicatoridae*, related to the woodpeckers). The honey guide lays its eggs in the host's nest and, with its bill or claws, often punctures the shell of the foster parents' eggs so they do not hatch. If the foster parents' eggs do hatch, the nestling honey guide usually disposes of the host's young by throwing them from the nest or by biting, crowding, or starving them to death. The honey guide's young are thus raised at the expense of the young of the host species. Apparently kingfishers, bee-eaters, hoopoes, and wood hoopoes are of great importance in the ecology of honey guides, and the frequency with which the roller-like birds are victimized by honey guides may be a serious factor in their population status.

A remarkable insect fauna has been found in the nest of an African hornbill. Though some nest sanitation is practiced by the birds, it is not complete. In one nest,

more than 400 individual insects, mostly larvae, were found (about half were moth larvae); they represented eight species and were feeding on the droppings and debris in the nest cavity, which was remarkably clean and had little odour. The hornbill provides microhabitats for the insects (albeit scattered and seasonal), and the scavenging of the insects may be of advantage to the hornbill.

#### FORM AND FUNCTION

**Size and plumage.** The coraciiform birds are a rather heterogeneous order, united mainly by features of their internal anatomy. Some characteristics of the beak and feet serve to separate them from other orders, such as perching birds (Passeriformes) and the woodpeckers and their allies (Piciformes), which appear to be their closest relatives.

No single coraciiform family encompasses the entire size range of the order. The todies are the smallest, with lengths of nine to about 11.5 centimetres (3.5 to 4.5 inches), and the hornbills, which range in length from about 40 to 160 centimetres (16 to 63 inches), are the largest. The kingfishers are from ten to nearly 46 centimetres long (four to 18 inches), the longest being those with extended tail feathers. Motmots and bee-eaters are in the same general size range as the kingfishers, but the smallest of them are larger than the tiniest kingfishers (*Ceyx*, *Ispidina*), and the largest motmots, although about 50 centimetres (20 inches) long, have not nearly the body bulk of the chunkier, but slightly smaller, kookaburras (about 45 centimetres, or 18 inches). The smaller families have, predictably, less size variation.

The plumage of the roller-like birds is firm and often highly colourful. The bee-eaters are collectively and individually among the most brilliantly coloured of all birds; one individual may be marked with green, yellow, red, blue, and black. Many kingfishers are also brightly coloured, with a tendency toward metallic blues and blue greens. The beak is often bright red or orange. Most hornbills, with ornamentation frequently found on the beak, are strikingly patterned in black, white, and shades of gray and are sometimes accented with rufous or yellow; many have areas of bare skin, blue, red, yellow, or black in colour, around the face.

**Morphological specializations.** A few of the external features, such as modifications of the wings and feet for locomotion and of the beak for food handling, are obviously related to behaviour and habitat. Even in these important aspects of the body plan, the common heritage is evident in such features as the small feet and fusion of the front toes.

The most obvious adaptation to behaviour is the shape of the wing. The size and shape of the wing correlates well with the type of flight. Aerial feeders have the longest, most pointed wings; the most extreme forms are found in the bee-eaters, but they are also well developed in the rollers and the cuckoo roller. The birds that watch for their prey and fly out after it (e.g., kingfishers) have moderate, rounded wings, while the ground feeders (ground rollers, hoopoes) have broad wings, as do those that feed on foot in the trees (hornbills, wood hoopoes).

The tail is highly diversified in length and shape. Forked tails occur only in the best fliers (bee-eaters and rollers), though some of these birds have square tails or elongated central tail feathers instead. Elongated central tail feathers also occur in the hornbills that practice direct flight, as well as in ground rollers that fly little. The small kingfishers have the shortest tails. The exact shape of the tail does not correlate well with locomotion, nor does the presence of spatulate tips on elongated tail feathers, which occur in motmots, rollers, and kingfishers and are perhaps of social importance.

The characteristic short tarsus (the lower leg) of the order and the fusion of the three front toes (except in the cuckoo roller) seem a heritage that has been modified but little with modification of behaviour. The foot is used only for perching in most family groups. In cases in which it is used extensively for terrestrial locomotion (ground rollers, hoopoe), the tarsus is lengthened some-

what in the former but not in the latter, and is also somewhat lengthened in the aberrant hornbill, known as the ground hornbill. The hornbills that feed in the tree branches have a broad pad on the toes, evidently an adaptation for perching. The wood hoopoes have long slender toes with long, sharp, curved claws, an obvious adaptation for the bark-climbing habits of these birds.

Figure 3: Feet of some Coraciiformes, plantar (bottom) view.

The most unusual foot in the order belongs to the cuckoo roller, whose outer toe is capable of being reversed. This makes a better perching foot for the bird that flies over the forest trees, scanning the branches for its prey, and alighting suddenly to seize a caterpillar, chameleon, or grasshopper.

The bills show remarkable diversity in bulk and shape. Basically, the long stout bill so common in this order seems to be an adaptation for seizing and subduing active animal prey that is large in proportion to the size of the bird. This is true for rollers, ground rollers, cuckoo rollers, and motmots, all of which have only moderately long and stout bills. The larger, rather stouter, straight bill of the kingfishers is an exaggerated version in birds that often take small invertebrates. The hornbills, with their very large, laterally compressed bills, often somewhat ornamented with a prominent horny casque in the male (smaller in the female), seem to have carried bill size beyond the point of a strictly functional feeding organ. Species that feed largely on fruit plucked from branches as well as species that take lizards and snakes and dig in the ground for insects all have exaggerated bills.

An advantage of a long bill can be seen in hornbills that feed on fruits among the outer branches of forest trees; the long bill enables the bird to reach fruit on slender, outer twigs. There is also the probability, evidenced by the sexual difference in bill ornamentation, that the bill serves in courtship and perhaps in other social contacts within the small parties characteristic of hornbills.

Another type of long bill in the order is that of the hoopoes and the wood hoopoes, which is a slender and slightly, to strongly, downcurved bill. The former use the bill to probe in the ground as it walks along, the latter to poke into crevices and crannies of the barks and branches of trees.

**Similarities to birds of other orders.** The size of the birds of this order and their propensity to take rather large prey bring them into competition with many other species of other groups. It is perhaps instructive to compare certain Old World groups with representatives of different orders in the New World tropics (see above Natural history). The most striking parallel is seen between the toucans (Rhamphastidae, order Piciformes) and the hornbills, which, with their enormous bills, small feet, general diet, behaviour, and appearance, are remarkably alike. A similar degree of convergence is seen between the bee-eaters and the jacamars (Galbulidae, order Piciformes) of tropical America and also between some wood hoopoes (*Rhinopomastes*) and American wood hewers (*Campylorhamphus*). Similar ecological conditions apparently have brought similar adaptations in external structure and behaviour between birds of quite unrelated orders, in widely separated areas.

## EVOLUTION AND CLASSIFICATION

**Evolution.** The history and some of the family relationships within the Coraciiformes are obscure, so that any treatment of the evolution of the order must be considered speculative. The present distribution and abundance of the ten families suggest an Old World origin, probably in the Ethiopian–Indian region, but the southern Palaearctic (Eurasia) may also have been involved; the limited number of fossils, consisting of a few hornbills from the Eocene (about 50,000,000 years ago) and Miocene (about 15,000,000 years ago), a roller from the upper Eocene or lower Oligocene (about 38,000,000 years ago), a possible wood hoopoe from the Miocene, and a kingfisher from the lower Oligocene, all have migrated from Europe. At the periphery of the Ethiopian region, the island of Madagascar has the endemic ground-roller and cuckoo-roller families, probably derived from separate colonizations of the early roller stock; the island was later colonized by the modern rollers, bee-eaters, kingfishers, and the hoopoe. Extending eastward through southern Eurasia, the modern hoopoe (*Upupa epops*) reaches Malaysia (making it the most widespread single coraciiform species); the hornbills have reached the Papuan area; and the roller, bee-eater, and kingfisher families have reached the Australian continent.

In the New World, the early arrival of a protokingfisher stock, via the Bering Strait, probably gave rise to the motmots of Central and South America and the todies of the West Indies. Later, a specialized, fish-eating branch of the kingfishers colonized the New World, evolving one species in the Nearctic region (North America) and several in the Neotropical region.

Considering the relative paucity of roller-like birds in tropical America and their comparative abundance and diversity in the Old World tropics, it seems likely that, by the time the coraciiform stock had reached the neotropics, many niches occupied by members of this order in the Old World were already filled by members of various piciform and passeriform families. The passeriform suborder Tyranni, with more than 600 New World species, is particularly diverse. The presence of highly adapted potential competitors, such as the toucans, jacamars, and puffbirds, endemic members of the Neotropical avifauna, may have retarded the colonization and evolution of the Coraciiformes in the New World.

**Classification.** *Distinguishing taxonomic* features. The external characteristics on which families are based are the size and shape of the beak and wing and the arrangement and amount of fusion (syndactyl) of the three front toes. The ten families are united, additionally, by features of the palate bones, the tendons of the leg, the configuration of the leg muscles, and the body pterylosis (pattern of feathers).

*Annotated classification.* The following classification is based on an arrangement used in 1960 by Alexander Wetmore, a U.S. ornithologist.

**ORDER CORACIIFORMES** (roller-like birds)

Small to medium-large land birds, with body lengths of about 10 to 160 cm. Most species conspicuously coloured. Beak prominent; straight, or slightly or strongly downcurved. Some syndactyl of toes (I, II, and III) in most families. Cavity nesters; young hatched blind and naked (except in Upupidae). Worldwide in temperate and tropical regions. About 191 species.

**Family Alcedinidae** (kingfishers)

Oligocene to Recent. Chiefly arboreal; short tarsus, small feet; syndactyl. Beak medium to long, straight, stout, usually spearlike. Wings short, rounded. Food: invertebrates and small vertebrates, including fish. About 90 species; distribution that of order, but greatest diversity in Indo-Australian Region; length 10–45 cm.

**Family Todidae** (todies)

Recent. Chiefly arboreal. Long, straight, flattened, blunt bill. Toes syndactyl. Wings short, rounded. Food: invertebrates, insects. Five species; West Indies; length 9–12 cm.

**Family Momotidae** (motmots)

Eocene to Recent. Chiefly arboreal. Moderately long, stout, pointed, slightly decurved bill usually with serrate cutting margins. Tarsus very short, toes syndactyl. Wing short and rounded. Food: invertebrates, lizards, and some fruit. About 8 species; South and Central America; length 17–50 cm.

**Family Meropidae** (bee-eaters)

Pleistocene to Recent. Arboreal and aerial. Bill long, compressed, tapering to a fine point, and slightly decurved. Tarsus short, anterior 3 toes slender, weak, and syndactyl. Wing long and pointed. Food: insects. About 24 species; Africa, southern Eurasia to Australia; 15–35 cm long, including elongated tail feathers.

**Family Coraciidae** (rollers)

Eocene to Recent. Chiefly arboreal and aerial. Bill stout, crowlike, slightly downcurved, terminally hooked. Tarsus short, foot strong; inner and central toes united at base. Wing long, moderately pointed. Food: chiefly insects. About 12 species; temperate and tropical parts of the Old World, greatest number of species in Africa; length 25–32 cm.

**Family Brachypteraciidae** (ground rollers)

Recent. Chiefly terrestrial in forest and desert brush. Roller-like birds with longer tarsus and short, rounded wings. Food: small animals of forest floor or desert brush. Five species; Madagascar; length 30–40 cm (including long, graduated tail of some species).

**Family Leptosomatidae** (cuckoo roller)

Recent. Arboreal and aerial. Bill moderately long, stout, slightly decurved, and terminally hooked. Tarsus very short and, unique in this order, toes semi-zygodactyl (the outer, anterior toe reversible). Wings long, moderately broad and somewhat pointed. Also unique in having a pair of powder-down patches, one each side of rump. Food: large insects, lizards. One species; Madagascar; length about 43 cm.

**Family Upupidae** (hoopoe)

Pleistocene and Recent; terrestrial and arboreal. Bill long, slender, slightly decurved. Tarsus short, slender; toes, long, with central and outer ones fused at base, claws short. Wing moderate, broad. Food: arthropods, and other invertebrates. One species; Africa, southern Eurasia, and Malaysia; length about 29 cm.

**Family Phoeniculidae** (wood hoopoes)

Miocene (Europe), Recent (Africa); arboreal. Bill long, slender, slightly curved to sickle-shaped. Tarsus very short; toes long, central and outer ones fused at base. Claws long, curved and sharp. Food: invertebrates chiefly. Six species. Length 22–38 cm.

**Family Bucerotidae** (hornbills)

Eocene (Europe) to present. Chiefly arboreal (1 species chiefly terrestrial). Large, slightly curved bill, often with casque or sculpturing (larger in males). Tarsus short to very short, toes syndactyl. Wings moderate to long and broad. Unique in order in having eyelashes. Food: insects, small vertebrates, and fruit. About 45 species; Africa, southern Asia to Papuan area; length 40–160 cm.

Critical appraisal. Paleontologists have called the order Coraciiformes a miscellaneous assemblage of birds with large bills and have pointed out that the anatomical differences between the families of birds within this and other orders are minor compared with differences found within some mammalian orders, such as the carnivores which include both cats and seals. The classification of birds into higher categories is justified by expediency and tradition. The roller-like birds include ten groups of birds here called families, the largest, the kingfishers and the hornbills, containing 90 and 45 species respectively, the smallest, the hoopoe and the cuckoo roller, a single species each. Each family is fairly uniform within itself, but between families some anatomical characters have a disconcerting habit of lacking a common linkage. The order does seem to have a common heritage, however, judging from the sum of the characters that place them high in degree of specialization, just below the perching birds (Passeriformes) and the woodpecker-like birds (Piciformes). They have been variously said to be distantly related to the cuckoos, parrots, owls, and even the nightjars, depending on the relative weight given to characters such as the condition of the bony palate, the notching of the sternum, the arrangement of the toes, the thigh muscles and foot tendons, the structure and location of the syrinx (sound-producing organ), the development of the ceca (blind pockets in the digestive tract), and the arrangement of the intestines, the arrangement and type of feathers and down, and the type of nesting.

Some authorities would include rollers, ground rollers, and cuckoo rollers as subfamilies of the Coraciidae. There is also a question as to whether the hoopoes and wood hoopoes are more nearly related to the hornbills or the rollers.

The families fall into six or seven well-defined groups: (1) kingfishers, todies, and motmots, (2) bee-eaters, (3) rollers and ground rollers, (4) cuckoo rollers, (5) hoopoes, (6) wood hoopoes, which are sometimes united with the Upupidae, and (7) hornbills.

## Coral Islands, Coral Reefs, and Atolls

The words coral reef have for centuries evoked a conflicting response in the minds of sailors, "coral" conjuring visions of colour and beauty and "reef" arousing feelings of apprehension. These reefs are masses of carbonate of lime built up from the sea floor by the accumulation of the skeletons of a profusion of animals and algae; eventually they rise to the surface of the water and become a danger to mariners. The several reef types include fringing reefs, which grow along the shores of a continent or island; patch or platform reefs, which occur as isolated patches on a continental shelf; barrier reefs, which commonly are found growing on or near the edge of a continental shelf, roughly parallel with the coastline; and atolls, ring-shaped reefs that in their grandest oceanic form mark the rims of sunken, truncated volcanic cones or guyots (tablemounts).

In ancient times "coral" meant the precious coral of commerce, *Corallium nobile* of the Mediterranean. Subsequently, in the phrase coral reef, it came to imply all the sedentary creatures growing on the reefs; namely, soft coral, stony coral, black coral, blue coral, organ-pipe coral, coralline algae, and so on. Today, when zoologists

speak of corals alone, however, they generally mean only the stony corals or Scleractinia. The Scleractinia of today are not confined to coral reefs; those that form reefs are dependent on warmth and sunlight (*i.e.*, are hermatypic). Reef corals grow best in shallow, sunlit water, between the low-water mark and six fathoms (36 feet, or 11 metres), but they can still construct reefs in water as deep as 22 fathoms (132 feet), and they may have a sparse existence between 22 and 30 fathoms (132 and 180 feet). They prefer water of normal salinity and with an annual maximum temperature above 72° F (22° C) but below 82° F (28° C); but their reef-building activities may be carried on in waters whose minimum temperature in winter is not less than 59° F (15° C).

A second group of corals in present-day seas grow in thickets and coppices that develop banks rather than reefs on the outer, deeper, colder, and darker parts of continental shelves and platforms. These organisms flourish in water with a winter minimum temperature ranging between about 39° and 59° F (4° and 15° C) at depths of about 33 fathoms to 110 fathoms (200 to 660 feet). In any one thicket there are commonly only two genera of delicately branching corals involved. Such coral banks are known along the eastern Atlantic shelf edge (or continental slope) from Norway to the Cape Verde Islands and again off the Niger River Delta and in the west Atlantic around the Gulf of Mexico, the Bahamas, and the Orinoco River Delta. ~~Off~~ New Zealand such banks have been recognized on the Campbell Plateau and the Chatham Rise; they also occur in the northwest Pacific near Japan.

The third coral assemblage of the modern seas is associated with even colder or deeper seas; it consists of small, solitary corals of relatively few genera, known from the abyssal floors of the oceans and from the shelves around Antarctica, Patagonia, and the Falkland Islands in waters 35° to 43° F (2° to 6° C) in temperature.

Buried fossil reefs on ancient continental shelves are targets for petroleum-exploration companies. The porosity of reefs and the characteristic curvature of nonporous enclosing sediments cause them to be prospective reservoirs for oil and gas. The rich oil fields of Alberta, for example, are associated with Devonian reefs (about 345,-

**Hermatypic corals and cold-water forms**

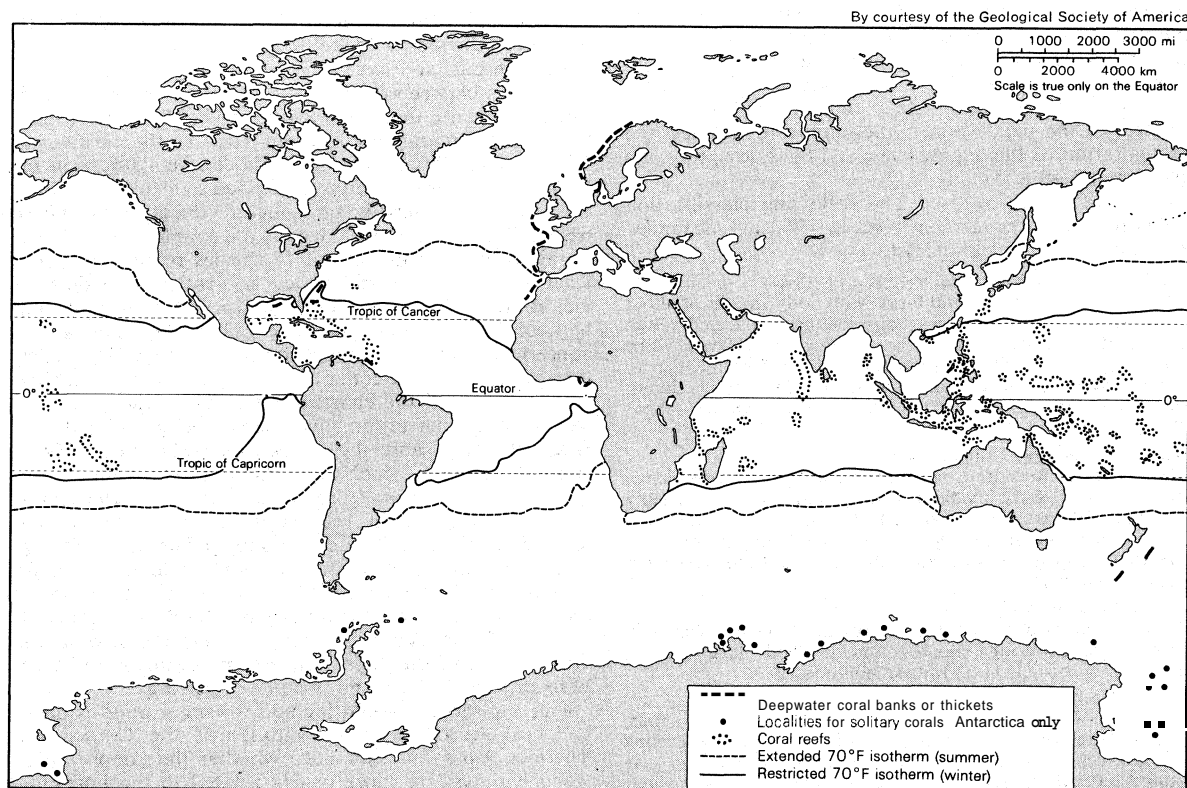

Figure 1: Distribution of coral reefs and their relation to controlling sea-surface temperature

000,000 to 395,000,000 years old). Fossil reefs recently have become targets for metal prospecting because some corals contain small percentages of metals such as zinc and copper, biogenetically extracted from seawater. A living coral reef may also have economic potential, in that it constitutes a major tourist attraction.

This article describes the reef-building organisms themselves, modes and geographic distribution of reef accumulation today, reefs of the geological past and their environmental significance, factors involved in reef growth, and the several theories of reef development. For relevant information on water and terrain characteristics that influence the location of coral reefs, see OCEANS AND SEAS; LAGOONS; CONTINENTAL SHELF AND SLOPE; MARINE SEDIMENTS; OCEAN BASINS. See also FOSSIL RECORD, for discussion of ancient reefs and their component organisms, and the several geographic articles on particular reefs and atolls, particularly GREAT BARRIER REEF. The concentration of elements by invertebrate organisms in the sea is treated in ELEMENTS, PHYSIOLOGICAL CONCENTRATION OF.

### REEF-BUILDING ORGANISMS

The role of organisms in the construction of a reef is threefold: whole skeletons may form a loose or tight framework; broken-up and overturned skeletons form the vast quantities of lime sand and mud that fills the interstices of the framework; and organisms such as encrusting algae, particularly red algae and blue-green algae, cement the framework and the interstitial material together.

Precambrian and Paleozoic forms. In Precambrian sediments (those older than 570,000,000 years) there are no records of animals with mineral skeletons, but some limestones, not unlike the laterally extensive reefs of today, were formed. These limestones were formed by stromatolites, successive mats or felts of tiny filaments of blue-green algae; each mat traps silt particles and becomes encased in a mold of fine calcareous dust that the algae precipitate by physiological processes. Stromatolites are thus sedimentological (layered) rather than skeletal; commonly they developed colonies of a consistent shape and show growth laminae (annual layers) but little or no organic microstructure.

The passage from Precambrian to Paleozoic time (570,000,000 to 225,000,000 years ago) was strikingly marked by the ability of most animal phyla to develop mineral skeletons, commonly calcareous. The first animals to take a framework role in the formation of reefs were Archaeocyatha (primitive invertebrates resembling sponges); the corals did not appear until later. The Archaeocyatha are a phylum with a very brief history. They appeared early in the Lower Cambrian and, except for a few stragglers, became extinct in the early Middle Cambrian. The basic form of their skeleton is an inverted cone ranging from 10 to 20 millimetres (0.4 to 0.8 inch) in average diameter and from 80 to 200 millimetres (3 to 8 inches) in height. The mineral of the skeleton is finely crystalline calcite. The cone may or may not be secured by holdfasts; in some there is only one wall, but in the great majority there are two walls with a central cavity. The walls are held together by radial-longitudinal and transverse plates, and all contain minute pores. Most Archaeocyatha are solitary, and colonial skeletons are rare. The Early Cambrian reefs were small, and the largest of those—from Siberia, where they are best known—attained a diameter of only 33 metres (108 feet) and a height of 25 metres (82 feet). The blue-green algae probably were the main organisms of these reefs, which are thought to have formed on a sea floor about 20 to 50 metres (70 to 160 feet) deep, but both solitary and some colonial forms of Archaeocyatha were also associated. In smaller growths, which are thought to have developed in deeper waters (50 to 100 metres [160 to 330 feet]) red-algal bushes are the main component, with Archaeocyatha found between the bushes. Associates were gastropods, brachiopods, trilobites, and other invertebrates. Also present are skeletons attributed to stromatoporoids, an extinct order of hydrozoans that formed calcareous skeletons of successive

lamellae (layers), usually irregularly perforated and connected one to another by pillars of varying types.

In the Ordovician (430,000,000 to 500,000,000 years ago) the first coral skeletons are found, but they are of different orders from Recent corals (those of the last 10,000 years). The exclusively colonial Tabulata, with relatively simple skeletons, were the first to appear, followed by the Rugosa, which included many solitary as well as colonial forms. Stromatoporoids became common, as did the Bryozoa (sea mats). All these orders are found in the small lenticular, or horizontally extended, thin reefs of the Ordovician carbonate provinces. The small reefs of the eastern United States and of Scandinavia are probably the best known.

In the Silurian Period (395,000,000 to 430,000,000 years ago) and the Devonian Period (345,000,000 to 395,000,000 years ago), stromatoporoids, corals, and Bryozoa again were the most abundant organisms of the fossil reefs, which were larger and more like those of today than the Ordovician reefs. Calcareous algae were few, but blue-green algae such as *Stromatactis* are thought to have played an important part. Echinoderms were important associates, particularly the crinoids, or sea lilies, the plates of whose calcareous skeletons were commonly massed by the local currents into banks (crinoidal limestones) abutting the reefs. Brachiopods, bivalves, gastropods, trilobites, and many others abounded in the interstices of the reef framework. The Silurian reefs of the Great Lakes region of North America and the beautifully exposed reefs of the Swedish island of Gotland resemble the patch reefs of the modern Great Barrier Reef. Wenlock Edge in Great Britain was probably a barrier reef. Stromatoporoids and tabulate and rugose corals all reached their acme in the Middle Devonian. In the Belgian Upper Devonian reefs it appears that profuse growths of corals formed on a subsiding sea floor beneath the zone of wave turbulence and grew upward into the zone of turbulence, where stromatoporoids were favoured. The Late Devonian reefs of the Kimberley district of Western Australia show all the sedimentation patterns of modern reefs, as do the Early Carboniferous (280,000,000 to 345,000,000 years ago) reefs of Derbyshire in England.

Carboniferous and Permian (225,000,000 to 280,000,000 years ago) reefs are strikingly different from those of the Devonian because of the great rarity of stromatoporoids and because Bryozoa generally are more abundant than corals. *Stromatactis* cavities abound in bryozoan reef knolls, which may not have grown to wave base (the lower limit of effective wave action). Banks of crinoidal debris are not uncommon. In the Urals, in the Soviet Union, Upper Paleozoic reefs were built up during continued complete submergence through successive ages. The shallowest reef builders were a group of marine hydroids called hydractinia; somewhat lower were the corals; and deeper still were porcelain-like algae or tubiphytes. The Permian barrier reef of Texas, the famous Capitan Reef, is built almost entirely of interlocking remains of encrusting algae and calcareous sponges. Behind the reef wall is a fossil-rich zone less than half a mile wide with filamentous and massive algae and pisolites (calcareous spherules larger than two millimetres in diameter); bryozoa; fusulines (single-celled marine organisms); large, heavy gastropods; heavy-shelled brachiopods; bivalves; straight cephalopods; and holothurians. In the fore reef, on the upper slopes, is a belt of filamentous algae with sponges. Corals are rare.

Mesozoic and Cenozoic forms. In the Early Mesozoic reefs (from 65,000,000 to 225,000,000 years ago), the order of corals that flourishes today, the Scleractinia, first appears. It may or may not have evolved from the rugose corals that became extinct at the end of the Paleozoic. The Triassic reefs of the Alpine region were dominantly constructed of algae, but more normal coral-line reefs are present in very thick (up to one kilometre [0.6 mile]) limestone. Jurassic reefs are quite like those of today. The famous reef structures of the southern Jura contain many corals, algae, and stromatoporoids, as well as rudistid bivalves, oysters, brachiopods, gastro-

Colonial forms and stromatoporoids

Crinoids, Bryozoa, and Late Paleozoic reefs

Stromatolites and Archaeocyathids as reef builders

Pods, echinoderms, and other invertebrates; these occur in nests in the white oolite among the irregular masses of unbedded coral limestone. Rudistid bivalves are very large; one valve is horn-shaped and the other fits into it like a lid; in the Cretaceous Period (65,000,000 to 136,000,000 years ago), particularly in the Tethyan region, an area occupied by ancient continental seas, they grew profusely and formed rudistid reefs; they were extinct by the end of the Mesozoic.

Cenozoic reefs (originating during the last 65,000,000 years), particularly the Miocene reefs below the atolls and barrier reefs of the Pacific, are very similar to modern types. Corals and calcareous algae are dominant and nearly all invertebrate orders are represented in their interstices or framework.

#### PRESENT REEF ACCUMULATION

**Tropical water conditions.** Water conditions favourable to the growth of reefs exist in tropical or near-tropical surface waters. Regional differences may result from the presence or absence of upwelling currents of colder waters or from the varying relation of precipitation to evaporation.

Tropical seas are well lit, the hours of daylight varying with the latitude. Light intensity and radiant energy also vary with the depth. Thus, at latitude 32°44' N (Madeira Island) the "day" in March has a length of 11 hours at a depth of 20 metres (70 feet), five hours at 30 metres (100 feet), and only about a quarter of an hour at 40 metres (130 feet). Nearer the pole these figures decrease further. Light intensity has a profound effect on the growth of the individual reef-coral skeleton, because of the symbiotic zooxanthellae of reef corals (see below *Biological factors*). The number of species present on a reef may also be related to light intensity and radiant energy.

Turbidity may be high in lagoons, where shallow water lies over a silt-covered sea floor and where storms and windy periods cause considerable disturbance of the bottom silt. The average transparency may be low (about 12 metres [39 feet]), and light penetration is reduced.

Inside the Great Barrier Reef, on the shallow continental shelf of Queensland, the oxygen content of the water is high, exceeding 90 percent saturation most of the time; in deeper water, during the calm periods of the rainy season, the saturation may fall to about 80 percent. Plant nutrients such as phosphate and nitrate show no seasonal change in quantity; both are present in very small quantities throughout the year. Constant mixing of the shallow sea prevents any stratification of the nutrients. As a result, growth of phytoplankton is possible and almost uniform throughout the year, providing a constant supply of food for the zooplankton which in turn form the chief food supply of the corals. Some nutrients enter the lagoonal waters with the oceanic water that flows through the reef openings, but the dissolved phosphates in the lagoons are probably derived chiefly from bacterial decomposition of the organic matter on the sea-bottom, as well as from detritus swept in from the reef surfaces. This environmental pattern is typical of many atoll lagoons.

**Geochemistry of reefs.** Minute quantities of metallic elements are present in solution in seawater and also occur in marine invertebrate skeletons, though not in the same proportions as in the surrounding water. Magnesium and strontium are the most frequently occurring trace elements in reef skeletons and are measured in parts per thousand, but barium, manganese, and iron are also present and can be measured in parts per million. In Pacific corals, 2.17 parts per million of uranium have been found; and in Florida coral, 2.36–2.95 parts per million. Strontium is concentrated in aragonitic skeletons, and magnesium in calcitic skeletons; coral aragonite has a higher strontium content than (some) molluscan aragonite; the magnesium content in the calcite of coral-line algae is high; that of barnacle shells is low (11.5 parts per thousand). By identifying these trace elements and their degree of assimilation in different organisms, sediments formed predominantly of coral-skeletal detritus can be distinguished from sediment derived chiefly from mollusks or coralline algae.

Quite recently it has been shown by atomic-absorption spectrophotometry that ultratraces of metals are present in the aragonite skeleton of the hydrozoan coral *Millepora* from a reef flat on the Coral Sea Plateau off Queensland. These are, in parts per 1,000,000,000: lead (100), copper (71), cadmium (23), cobalt (17), nickel (1,480), iron (507), and zinc (507).

The Pine Point lead-zinc ore body on the southern shore of Great Slave Lake, Canada, occurs mainly within or close to the Middle Devonian reef sequence known as the Presqu'île Formation. Geologists speculate that these metals may have been extracted from seawater by Devonian corals or other animals and subsequently concentrated within the reef rock by postdepositional changes.

Another aspect of reef geochemistry is the carbon and oxygen isotopic composition of coral skeletons and shells. Determination of the number of carbon isotopes present provides a method of assessing the age of a sample, and determinations of oxygen isotopes present are useful in indicating water-temperature changes that occurred during the period of growth of the reef.

**Winds, currents, temperature, and salinity.** Winds and currents are important in shaping individual reefs and in determining the orientation, shape, and position of the coral sand cays, or "low islands," that develop on reefs. Currents are primarily those generated by the prevailing winds, but, in areas where the tidal range is great, tidal effects may become paramount.

Cays may be round; oval, or boat-shaped; or irregular in outline. They originate when sediment is lifted from the reef surface and carried leeward by waves or tidal currents and then deposited where the water velocity is reduced abruptly. Thus, they commonly form on the more protected leeward end of the reef. Wind action at low tide on these deposits may build dunes above the high-water mark. Beach rock may form by carbonate cementation of grains in deposits lying between tide levels; it then acts as a stabilizing factor. Storm waves may drive forward coral fragments derived from "stag-horn" corals growing on the windward slopes of the reef, forming shingle banks; successive, superposed banks may thus be formed. The shingle on the banks may become cemented and thus add considerable stability to the cay, as does the growth of vegetation. Hurricanes, however, may carve back the shorelines of even stabilized cays. Huge, isolated boulders of coral or coral limestone are fairly common along reef margins. Some may be remnants of a once-emergent reef platform; others are hurricane or storm jetsam.

Coral reefs are best developed where the mean annual surface-water temperatures are approximately 73° to 77° F (23° to 25° C); no significant reefs occur where such temperatures fall below about 64° F (18° C), although a few reef-coral species can exist in temperatures considerably below this. Seasonal temperature differences on any one reef are usually slight, as are differences due to depths of water or situation on the reef.

Seawater of normal oceanic salinity (between 30 and 40 parts per thousand), to which corals are restricted, is normally supersaturated in calcium carbonate ( $\text{CaCO}_3$ ), so that adequate ionized calcium ( $\text{Ca}^{2+}$ ) is available for the skeleton-forming process. Floods of freshwater may destroy life on inshore fringing reefs. A luxuriant reef on Stone Island, near Bowen, Queensland, was killed to a depth of 3 metres (10 feet) below mean tide level by a week of cyclonic rains, in which 90.7 centimetres (35.7 inches) of rain coincided with full-moon spring tides.

**Biological factors.** The most significant biological determinant of reef accumulation is the presence of zooxanthellae in the living tissues of all reef corals and of many massive-shelled mollusks (Tridacnidae) and other shelled invertebrates, as well as in the soft-bodied hydrozoans, scyphozoans, and anthozoans. Zooxanthellae are now known to represent the vegetative stages of dinoflagellate algae, and their association with reef corals is symbiotic—that is, mutually helpful. In temperate seas they occur only occasionally. Their profusion in reef animals is no doubt connected with the greater light intensity and radiant energy of reef waters, for, like other

Effects of light, turbidity, and nutrients

Trace elements in reef skeletons

Restrictions on reef formation

plants, zooxanthellae require sunlight for photosynthesis. They remove at the source part of the carbon dioxide ( $\text{CO}_2$ ), together with nitrogen, phosphorus, and (doubtless) sulfur, produced by metabolic breakdown within the coral and which would otherwise be excreted by the corals. They greatly aid in the formation of the coral skeleton by increasing the speed with which the  $\text{CO}_2$  produced in coral metabolism is removed and the speed with which the skeletal  $\text{CaCO}_3$  is formed. Corals also may gain some nutrient from their zooxanthellae, but they probably do not need the oxygen produced during photosynthesis.

The productivity of reefs is a current focus of interest. A constant supply of food in the form of zooplankton is essential to reef corals, which are carnivorous. The zooplankton supply is dependent upon an adequate phytoplankton supply, and the phytoplankton, in turn, require an adequate supply of plant nutrients dissolved in the water. An atoll in the open ocean may be compared with an oasis in a desert, as a localized centre of high productivity. In the warm, well-lit, and well-mixed lagoon waters there is a rapid turnover of the endemic planktonic (floating or swimming) and benthic (bottom-dwelling) population, perhaps 12.5 times per year. Carbonate skeletal matter is accumulated perhaps 1,000 times faster on the summit of an atoll than in the surrounding deeps.

Certain biological factors may contribute to the destruction of coral reefs: the fish and invertebrates that feed on the soft tissues of reef builders and the organisms that bore into coral rock. Of the former, the most destructive such enemy yet known is *Acanthaster planci*, the crown-of-thorns starfish, which, during the last decade, has multiplied spectacularly and has removed the soft tissues from large areas of many reefs in the southwest Pacific. *A. planci* feeds by everting its stomach and liquifying and absorbing the tissues of the corals. Coral-rock borers include boring algae, boring sponges (of great significance), various polychaete and sipunculid worms, and many bivalves and a few gastropods. These organisms usually penetrate the rock mechanically but in some cases do so chemically. Extensive damage is caused both by their own activities and by the assistance they give to the erosive action of the sea.

Indo-Pacific and Atlantic communities. Two major coral-reef communities are clearly distinguishable in shallow tropical seas—the Indo-Pacific and the Atlantic. The corals of the Indo-Pacific community comprise about 80 genera and about 700 species, but the number of these that may be found on any one reef or set of reefs varies from region to region. Members of the community may be found from the Red Sea and east coast of Africa eastward across the Indian Ocean, through the East Indies, on to the Tuamotu Archipelago; and, indeed, they are still recognizable as far east as Panama. Within this great province the richest faunas may be found in optimum temperature conditions between the East Indies and the central Pacific; the number of species and of genera decreases both latitudinally and longitudinally from this central region. Latitudinal limits to distribution are in part imposed by the inhibiting effect of the lower temperatures on spawning.

The Atlantic coral-reef community is found in the Gulf of Mexico, the Caribbean Sea, and the West Indies; on the northern and eastern coasts of South America, south to Rio de Janeiro; and in the Gulf of Guinea off West Africa. It includes only 26 genera and 41 species. *Acropora* and *Porites*, as in the Indo-Pacific, are the two most important coral genera, but in the Atlantic each is represented by only three species, as against 150 and 30, respectively, in the Indo-Pacific. Nevertheless, there is prolific growth on many Atlantic reefs. On Pacific reefs, many of the reef-coral species can live exposed between tides, but there are few Atlantic reefs where living coral can be studied exposed at low tide.

A notable feature of Atlantic coral-reef communities is the fact that particular environmental niches may be occupied by a genus different from that occupying the same niche in an Indo-Pacific community, yet these separate genera may exhibit the same growth form and superficial appearance. Thus, the Atlantic faviid *Montastrea* occu-

pies the niches proper to the similar looking faviid *Plesiastrea* of the Indo-Pacific. There are at least 10 other pairs of similar genera. Many important Indo-Pacific genera are not represented in the Atlantic by such ecological equivalents. These include *Pocillopora*, *Stylophora*, *Seriatophora*, and *Montipora*, although all occur in the Tertiary (about 2,500,000 to 65,000,000 years ago) faunas of both the Atlantic and the Indo-Pacific. The Atlantic reef coral fauna as a whole seems to be a weakening relic of that of the mid-Tertiary Tethyan seas.

Many characteristic reef-coral associates are either absent or greatly reduced in variety in the Atlantic. Thus, calcareous algae play a minor role; there are no giant clams like *Tridacna*, no coral gall crabs, and no giant anemones with commensal fish and crustaceans; many mollusks present in great variety in the Indo-Pacific are missing or uncommon. One of the most striking differences is the absence of the alcyonarian corals *Heliopora* and *Tubipora* in the Atlantic; in addition, soft corals are a minor element. Gorgonian corals are very abundant in the Atlantic, but both alcyonarians and gorgonians are relatively insignificant in the Indo-Pacific.

#### ORIGINS AND DEVELOPMENT OF REEFS

The English evolutionist Charles Darwin concluded in 1842 that barrier reefs began as reefs fringing the land around which they now form a barrier, and that oceanic atoll reefs began as reefs fringing a volcanic island. Subsidence of the land fringed was thought to allow the reef to grow upward (and outward over its own forereef debris). Maximum growth would occur at the seaward edge, and lagoons would develop between the ascending barrier, or atoll, reef and the land or volcanic cone. When the volcanic cone became completely submerged, the

Darwin's theory of atolls

The menace of the crown-of-thorns starfish

Figure 2: Stages in reef development on a subsiding island.

atoll lagoon would contain only coral islands. Fundamentally, Darwin's concept is still valid, although many consider submergence by the rise of sea level, following melting of Pleistocene ice sheets, to be a better explanation of the latest upward growth of many reefs, particularly on continental shelves. A reef whose surface lies above high-tide mark, either by uplift or by eustatic regression of the sea (that determined by ice sheet-sea level relations), is subject to planing by marine erosion. If planing off is complete, a flat-topped submerged platform results; if subsidence or eustatic submergence intervenes, a wave-cut terrace is left around the reef. Terraces that may have formed in this way are known around many reefs. Some annular reefs may develop without relation to subsiding volcanic cones. When reef platforms have been uplifted above sea level, they are **subjected to sub-aerial erosion**. Surface slope, or gradient, determines the amount of runoff and is a prime factor in this erosion. Two secondary processes also are involved: (1) case hardening of steep, bare limestone surfaces by recrystallization caused by alternate wetting and drying, so that walls or knife edges result from weathering; and (2) continuous subsoil solution, if surfaces are nearly horizontal and runoff is diminished. These processes combine to produce a prominent rim and a saucer-shaped interior in emerged limestone islands. With submergence, algal and coral growth resumes, the fastest growth being on the rim and on any pinnacles that may be left. Thus an atoll or annular reef may develop along the rim around the low-lying central region, which becomes a lagoon, and coral knolls grow on former pinnacles in the lagoonal area.

Growth of fringing reefs

Types of reefs. Fringing reefs form a veneer in the shallow water near or at the shore of the mainland or of islands. On shorelines where bays receive large quantities of terrestrial mud, sand, and freshwater, fringing reefs are intermittent and are restricted to promontories. Along limestone coasts, however, coastal erosion is by solution, little mud or sand is supplied, and coral growth may be almost continuous along the shore. Fringing reefs may extend as far as 1,500 metres (4,900 feet) from shore; they show ecological zonation parallel to the shore. Along mainland shores with easily eroded rocks, mudbanks may be washed into the reef flat and colonized by mangroves. Inner parts of reef flats may show low mesas of middle Holocene (perhaps 5,000 years old) and even Pleistocene emergent reefs that have not been quite planed off by marine abrasion. Geomorphological features peculiar to raised fringing reefs have been described for the Solomon Islands, and there the complex problem of dead reefs and dead patches on reefs arises. The surface of the reef flat is mostly of dead coral, but pools occur in which live coral colonies flourish. An algal rim formed by growing red calcareous algae may develop on a fringing-reef margin if the reef faces strong waves and swells the year around. This rim is commonly less spectacular than the algal ridge of the windward edge of Pacific oceanic atolls and may be developed merely as an algal platform, or pavement, on which algal encrustation over corals is thin. The seaward slope of a fringing reef, like the seaward slope of an atoll reef, is characterized by a zone of grooves and spurs to a depth of perhaps 15 metres (50 feet), and it is in this zone that vigorous growth occurs. Under stable shelf conditions, the fringing reef will extend outward as the spurs elongate and the grooves fill or roof over with coral and algal growth. In tectonic belts (zones of uplift and deformation), fringing reefs may be uplifted intermittently, resulting in parallel, stepped subaerial terraces such as those of the Finisch Coast of New Guinea.

Growth of platform and patch reefs

Platform and patch reefs are characteristic of continental shelves: they may or may not lie behind a barrier reef. Reefs grow actively outward as well as upward, especially in the stable conditions of a continental shelf. Any given reef, having depth and temperature fixed by its location, will have its shape determined by the direction and force of the water currents that bring food and by the shape of the base on which it grows. Where the forces of growth are equal in all directions, radial expansion results in platform-like reefs. With further radial growth, lagoonal platform reefs develop. If the reef grows on a

sand bank, elongation may result. The shape of an elongated platform reef may be determined by the orientation of rising and falling tidal currents; these may be directly opposed to each other. The boat-shaped reefs of Torres Strait, between Australia and New Guinea, apparently developed in such a pattern. Where wave-generated currents are asymmetric, horseshoe reefs develop, with convexity facing the current and the leeward ends curving round to partly surround a lagoon. Low Isles, made famous by the Great Barrier Reef Expedition of 1928-29, is the best known example of this type. A sand cay (or cays) commonly develops on one or both of the leeward wings. Those parts of Pacific platform reefs that face strong and persistent currents characteristically have a low algal rim from which radiate grooves and spurs.

Barrier reefs commonly present to the ocean and the trade winds a steep wall, in some dropping abruptly 1,000 to 5,000 metres (3,300 to 16,400 feet). On the lagoon side they grade off gently with a wedge of sediment dotted by small patch reefs, coral knolls, and coral heads; depths in the lagoon may reach 50 to 80 metres (165 to 260 feet). According to the strength of surf and swell, an algal ridge, rim, platform, or pavement develops and is commonly emergent at low water. The seaward slope has radial grooves and spurs, the grooves forming surf channels and imparting great wave resistance. Ecological zonation on the seaward slope is difficult to study because of the dangers of surf and swell. Zonation on the reef flat, parallel to the wall, is dependent mainly upon depth.

Character of barrier and ribbon reefs

From *Encyclopedia of Geomorphology* by R. Fairbridge, copyright © 1968 by Litton Educational Publishing, Inc.; and C. Yonge, *Advances in Marine Biology*, Vol. 1 (1963), Academic Press

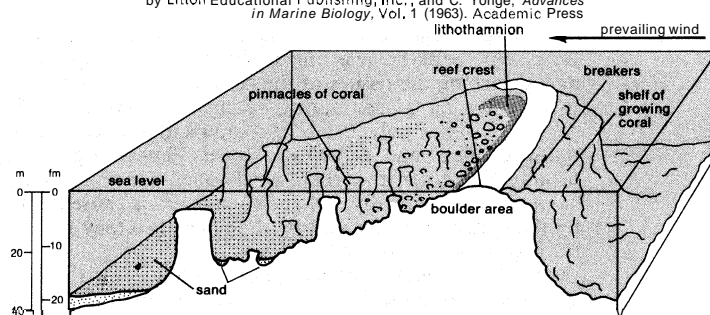

Figure 3: Section of an outer barrier reef, showing the relation of form to prevailing winds.

A characteristic form in a barrier reef system is the wall, or ribbon, reef, emergent at low tide, such as Yonge Reef, Queensland. A ribbon reef flat is commonly only 300 to 450 metres (1,000 to 1,500 feet) wide from the seaward wall to its lagoonward edge; its ends may curve leeward and border the passages between it and the next reefs in line. Rarely, there may be an unvegetated sand cay. A wall reef may develop irregular leeward prongs normal (perpendicular) to its axis by vigorous coral growth favoured by augmented turbulence associated with a high tidal range. The open leeward zone may be very wide (three kilometres or two miles) and support large, scattered reef clumps that are always submerged.

Atolls. The oceanic atoll reefs of the Pacific rise from volcanic cones that have subsided, probably intermittently, in areas of oceanic deeps. According to the Darwinian subsidence theory, the annular atoll reefs extend and grade downward into barrier reefs, which originated as reefs that fringed the volcanic cone. On the other hand, the compound atoll reefs of the Indian Ocean, such as the Maldiv Islands and Laccadives, and of the Coral Sea Plateau of the Pacific Ocean, are believed to have grown above foundered continental (rather than oceanic) crustal segments. The Nicaraguan atolls rise from a sea floor of 1,000 metres (3,300 feet) or more, in a volcanic province.

The basic environments of the atoll are the seaward slope, the reef flat, and the lagoon (including patch reefs). Each of these has windward sections intergrading with leeward sections. The ecological environments and depth zones of the oceanic atolls of the Pacific have been well studied, and the results from Bikini and other Marshall islands are summarized here.

Atoll environments and characteristics

The seaward slope of an atoll includes its intergrading windward and leeward sections. On the seaward slope to windward, observations are sparse because of the dangers of the heavy surf, but radial spurs and grooves are developed, down to perhaps 15 metres (50 feet), and surf-resistant coral heads grow in the grooves. The seaward slope to leeward of an atoll is much steeper, probably the result of smaller accumulation of talus; it has a rich upper zone dominated by great brackets of anastomosing (braided) and spreading branches of *Acropora*, beginning at about 3 metres (10 feet) and extending down to ten or 20 fathoms (60 to 120 feet). From about ten to 50 fathoms (60 to 300 feet), around the atolls of the Marshall Islands is a zone of such platelike corals as *Echinophyllia* and *Oxypora*. From 50 to about 80 fathoms (300 to 480 feet) in the Marshalls, below the zone of optimum growth of reef corals, there are delicate *Leptoseris* and other small colonies that are rather widely spaced. Below 80 fathoms (480 feet) only nonreef corals are known.

On the seaward slope of the windward side of Caribbean atolls, elkhorn *Acroporas* oriented with the surf grow profusely down to nearly three fathoms (18 feet), and below this domed colonies of *Montastraea* and *Porites* are common.

The reef flat of an atoll may be divided into outer (seaward) and inner (lagoonward) components, and these may each be described as windward or leeward, in relation to the direction of wind and waves. Thus, on the windward side of an atoll, the seaward part of the reef flat is windward, whereas the lagoonward part of the reef flat is leeward; and on the leeward side of an atoll, the seaward part of the reef flat is leeward, whereas the lagoonward part is windward.

The inner plus the outer flats of the windward side of a Pacific atoll are closely comparable with the ribbon reefs of the Pacific Barrier Reefs; the inner plus the outer flats of the leeward side are comparable to the windward side of an Atlantic atoll, for an algal ridge is absent from both.

The most notable feature of the seaward part of the windward reef flat of the Indo-Pacific atoll is the algal ridge, which dries at low water and is dominated by red, encrusting calcareous algae; the ridge is grooved radially seaward by surge channels. The seaward part of the reef flat of a windward reef extends inward from the algal ridge for a few tens or a few thousands of feet. Ecological depth zones may be distinguished that more or less parallel the algal ridge. First is a coral-algal zone, which may exhibit the greatest coral growth on the reef flat; then, in a low-tide depth of two to three feet or more, micro-atoll zones may be found or, alternatively, a green-algal zone.

The seaward part of the leeward sector of the reef flat of a Pacific atoll characteristically carries a richer growth of corals on the margins. The algal ridge is much less developed or even absent, and the slope from the shore (if there is a cay) toward the outer margin is relatively uniform. The marginal environments are like those of the windward flats, except that, where the algal ridge is very weak, the zone is dominated by low-growing species of *Pocillopora*, and, where the algal ridge is absent, by corymbose *Acropora*. Inward from these, the flat may be nearly barren of corals.

The reef flat inside the cays and sloping gently away from them toward the lagoon is regarded as part of the lagoonal environment. The lagoonal part of the windward sector of an atoll reef flat is leeward to the prevailing wind and in character is broadly similar to the seaward part of the leeward sector that lacks an algal ridge. It is, however, often relatively narrow and more sloping. Depths no greater than a fathom may extend 30 metres (100 feet) out from the cay shore. The coral patches tend to be elongated normal (perpendicular), rather than parallel, to the shore, with irregular sand-floored patches between them. Massive and branching corals grow luxuriantly and freely in the reef patches, and single colonies may attain great size—up to 6 metres (20 feet) across and three or more metres (10 feet) high. Corals are dominant, but there is a rich variety of crustaceans, echinoids, mollusks, soft alcyonarians, and the green alga *Halimeda*. On

the opposite side of the lagoon, where the lagoonward part of the leeward sector of the atoll reef flat is exposed to the prevailing winds and lagoon waves, red calcareous algae are able to grow to some extent, paving the reef flats and developing low algal ridges comparable to those of seaward reefs. The flat is rather wide; cemented platform slope from the shore at first to depths of two to three feet at low tide, then rise gently upward to a margin that may be awash at low tide, with a fairly steep talus slope down to the lagoon floor. Reef-coral zonation is roughly parallel to the margin, but the zones are less well defined than in the seaward flats, and an uneven, thin veneer of sand and silt makes coral growth patchy.

From the edge of the flat there may be a fairly steep slope into the lagoon, which may reach a depth of 27 to 30 fathoms (162 to 180 feet). Shrublike *Acropora* is abundant. Coral knolls rising from the floor of the lagoon bear a profuse coral assemblage in and around their summits; both branching and massive colonies are found. Calcareous algae are a minor element, but soft corals, usually absent from seaward reefs and scarce on lagoonward reef flats, are common. The general assemblage is a modified leeward-lagoonward reef assemblage living under optimum conditions in somewhat deeper waters.

Although there is minor variation in development from atoll to atoll, ecological environments on atoll reefs are basically similar. Profusion and variety of growth, together with specialized forms of coral colonies, are to be found in similar situations, particularly in regard to depth and the movement of water rich in food. The ecological environments of the annular reefs of the Atlantic differ more in degree than in kind; the algal ridge or rim is absent, and there is much less coral emergent at low tide.

## Corbusier, Le

Architect, city planner, and painter. Le Corbusier belonged to the first generation of the so-called International school of architecture and was their most able propagandist in his numerous writings. In his architecture he joined the functionalist aspirations of his generation with a strong sense of expressionism. He was the first architect to make a studied use of rough-cast concrete, a technique that satisfied both his taste for asceticism and for sculptural forms.

Le Corbusier was born Charles-Edouard Jeanneret on October 6, 1887 in La Chaux-de-Fonds, a small town in the mountainous Swiss Jura region, since the 18th century the world's centre of precision watchmaking. All his life he was marked by the harshness of these surroundings and the puritanism of a Protestant environment. His father was an engraver and enameller of watch faces; his mother, a piano teacher.

**Education.** At 13 years of age, Le Corbusier left primary school to learn his father's trade at the *École des Arts Décoratifs* at La Chaux-de-Fonds. There, Charles

Le Corbusier, photograph by Yousuf Karsh, 1954.  
© Karsh—Rapho Guilumette

L'Eplattenier, whom Le Corbusier later called his only teacher, taught him art history, drawing, and the naturalist aesthetics of Art Nouveau, a contemporary style of decoration that utilized an abundance of convoluted and sinuous plantlike motifs.

It was L'Eplattenier who decided that Le Corbusier, having completed three years of studies, should become an architect and gave him his first practice on local projects. From 1907 to 1911, on his advice, Le Corbusier undertook a series of trips that played a decisive role in the education of this self-taught architect who, unlike well-known contemporaries such as Walter Gropius and J.J.P. Oud, never continued his formal artistic training.

During these years of travel through central Europe and the Mediterranean, he made three major architectural discoveries. The Charterhouse of Ema at Galluzzo, in Tuscany, provided a contrast between vast collective spaces and "individual living cells" that formed the basis for his conception of residential buildings. Through the 16th-century Late Renaissance architecture of Andrea Palladio in the Veneto region of Italy and the ancient sites of Greece, he discovered classical proportion. Finally, popular architecture in the Mediterranean and in the Balkan peninsula gave him a repertory of geometric forms and also taught him the handling of light and the use of landscape as an architectural background.

During the same period Le Corbusier also met many of the European pioneers of the so-called Modern Movement in architecture. He claimed to have worked in Vienna for six months (1907) with Josef Hoffmann, head of the Viennese Secession (an association based on the principles of the English Arts and Crafts Movement). He was also associated in Paris for 15 months (1908–09) with Auguste Perret, an architect who was concerned with the importance of structure and the integrity of building materials and who first showed Le Corbusier the utilitarian and aesthetic aspects of reinforced concrete. Finally, Le Corbusier worked in Berlin for five months (1911) with Peter Behrens, who also formed the architects Walter Gropius and Ludwig Mies van der Rohe.

From 1912 to 1917, Le Corbusier was a teacher at his old school in La Chaux-de-Fonds. At the same time, he constructed several houses marked by the influence of Perret and Frank Lloyd Wright that he later considered less than worthy of inclusion among his "complete works."

**Founding of "L'Esprit Nouveau."** At the age of 30, in 1917, he returned to live in Paris, where his formation was completed a year later when he met the painter and designer Amédée Ozenfant, who introduced him to sophisticated contemporary art and had him paint his first

pictures. Ozenfant initiated Le Corbusier into Purism, his new pictorial aesthetic that rejected the complicated abstractions of Cubism and returned to the pure, simple geometric forms of everyday objects. Relations between Ozenfant and Le Corbusier, for the few years of their friendship, were constant and fervent. In 1918 they wrote and published together the Purist manifesto, *Après le cubisme*.

In 1920, with the poet Paul Dermée, they founded a polemic avant-garde review, *L'Esprit Nouveau*. Open to the arts and humanities, with brilliant collaborators, it presented ideas in architecture and city planning already expressed by the turn of the century architects Adolf Loos and Henri van de Velde, fought against the "styles" of the past and against the elaborate nonstructural decoration then prevalent in architecture, and defended functionalism and the newfound values of industrial society.

The association with Ozenfant was the beginning of Le Corbusier's career as a writer. Ozenfant and Le Corbusier (then still known as Jeanneret) together wrote a series of articles for *L'Esprit Nouveau* that were to be signed with pseudonyms. Ozenfant chose Saugnier, the name of his grandmother, and suggested for Jeanneret the name Le Corbusier, the name of a paternal forebear. A group of articles written between 1920 and 1921 by Le Corbusier were collected and published under the title *Vers une architecture*, illustrated with photographs selected by Ozenfant. Later translated as *Toward a New Architecture*, the book is written in a telling style that was to be characteristic of Le Corbusier in his long career as a polemicist. "Architecture is the conscious, correct and magnificent interplay of volumes assembled under light," is a definition that has become classic. "A house is a machine for living in" and "a curved street is a donkey track, a straight street, a road for men" are among the famous declarations of Le Corbusier. His books, whose essential lines of thought were born of travels and lectures, hardly changed at all in 45 years, constituted a bible for succeeding generations of architects. Among the most famous are *Urbanisme*, *Croisade*, *Quand les cathédrales étaient blanches*, published after his first trip to the United States, *La Charte d'Athènes*, and *Entretien avec les étudiants*, *Propos d'urbanisme*, and *Les Trois Établissements humains*.

**Association with Pierre Jeanneret.** *L'Esprit Nouveau* was the springboard for Le Corbusier's entrance into practice. In 1922 he became associated with his cousin Pierre Jeanneret, a former associate of Perret, and together they opened a studio at 35 rue de Sèvres, which Le Corbusier kept open until his death. The association of the two cousins, however, lasted only until 1940. It corresponds to the first of the two main periods, separated by World War II, that can be distinguished in Le Corbusier's work; the second period covers the years from 1944 to the architect's death in 1965. It has become clear that, during the years 1922 to 1940, Pierre Jeanneret's contribution to what had generally been considered the work of Le Corbusier alone was, in fact, decisive. Though Le Corbusier did the drawings and designs, it was Jeanneret who oversaw the actual work and who tackled technological problems that Le Corbusier never pretended to master.

**Early residential and city plans.** The period from 1922 to 1940 was as remarkably rich in architecture as in city planning projects. As was always to be the case with Le Corbusier, unbuilt projects, as soon as they were published and well circulated, created as much of a stir as did the finished buildings. In the Salon d'Automne of 1922, Le Corbusier exhibited two projects that expressed his idea of social environment and contained the germ of all the works of his first period. The Citrohan House, model for an industrially produced residential unit, displays the five characteristics by which the architect five years later defined his conception of what was modern in architecture: pillars supporting the structure, thus freeing the ground beneath the building; a roof terrace, transformable into a garden and an essential part of the house; an open floor plan; a facade free of ornamentation; and windows in strips that affirm the independence

Le Corbusier's definitions of architecture

Early architectural influences

The Citrohan House

of the structural frame. The interior provides the typical spatial contrast between open, split-level living space and the cell-like bedrooms. Accompanying the model was a diorama of a city of 3,000,000 inhabitants that illustrated ahead of its time the concept of green parks and gardens at the foot of a cluster of skyscrapers that house business offices. Apartment houses were placed in a rectangle around and outside the centrally located skyscrapers.

The ideas for city planning set forth at the Salon d'Automne, an annual semi-official exhibition, were taken up again and developed in 1925 at the Exposition des Arts Décoratifs in Paris, in a pavilion that was to be a "manifesto of the *esprit nouveau*." In this little duplex-flat, the interior walls violently coloured under the influence of the painter Fernand Léger, Le Corbusier exhibited his first collection of industrially produced furniture. But, foremost was the Voisin Plan of Paris, a project patronized by the automobile manufacturer Voisin. The plan proposed the complete demolition of deteriorated neighbourhoods, the replacement of them by parks, and the reorganization of businesses and administrative offices into two groups of cross-shaped skyscrapers, 250 metres (820 feet) tall. These were to be connected to each other and to residential buildings by means of express highways, consecrating, as it were, the role of the automobile in an industrial society.

This plan aroused the indignation of Parisians; it was, however, the basis of several more plans for vertical cities that eliminated conventional streets and located various urban functions in skyscrapers. Among the applications of the "radical city" principle are a series of seven plans for Algiers drawn up between 1931 and 1942. This is basically a project for a "viaduct" city in which the business centre is linked to the residential area by an expressway passing over the roofs of the apartment buildings.

During these years, in fact, Le Corbusier's social ideals were realized only on two occasions. One of these was in 1925 and 1926 when, thanks to the financial support of an industrialist, Henri Frugès, he built at Pessac, near Bordeaux, a workers' city of 40 houses in the style of the Citrohan House; the scorn for local tradition and the unconventional use of colour provoked hostility on the part of municipal authorities, who refused to provide a public water supply. Pessac was thus deprived of inhabitants for six years, and Le Corbusier did not forget this affront. In 1927 the architect, together with other architects, Gropius, Mies van der Rohe, Oud, Mart Stam, and others, participated in the international exposition of the Deutscher Werkbund, an association of various groups from art and industry concerned with producing functional objects of high aesthetic value. For this exposition Le Corbusier constructed two houses in the experimental residential quarter of Weissenhof at Stuttgart.

Although Le Corbusier was from the beginning most interested in building for large numbers of people, during the prewar period he built primarily for privileged individuals, friends or patrons who commissioned individual houses. These houses are conceived as "machines for living in." They were functional in design and ascetic in appearance, incorporating rigorous geometric forms and bare facades. The first was for Ozenfant in 1922, followed by, among others: the house of the Swiss collector Raoul La Roche (1923), which later became the quarters of the Le Corbusier Foundation in Paris (1968); the villa (1927) of Michael Stein, a brother of the expatriate American writer and patron of Fauvism and Cubism Gertrude Stein; the Savoye House (1929–30), at Poissy, set in a lush, rural landscape on slender concrete pillars and disposed around an interior ramp structure connecting its three floors like a staircase.

**The Geneva competition and first widespread public notice.** Le Corbusier's ambition, however, was not limited to domestic architecture. In 1927 he participated in the competition set by the League of Nations for the design of its new centre in Geneva. His project, with its wall of insulating and heating glass, is one of the finest examples of the architect's gift for functional analysis. For the first

time anywhere, he proposed an office building for a political organization that was not a Neoclassical temple but corresponded in its structure and design to a strict analysis of function. This plan was to become the prototype of all future United Nations buildings. It probably would have shared a first prize but was eliminated on the grounds of not having been drawn up in India ink as the rules of the competition specified. After the disappointment of Pessac, this disqualification, which was almost certainly the result of a conspiracy on the part of conservative members of the jury, further embittered Le Corbusier in his attitude toward official architectural circles. The scandal accompanying the elimination of his design, however, gave him needed publicity by identifying him with modern avant-garde architecture. An immediate consequence of the Geneva affair was the creation, in La Sarraz, Switzerland, in 1928, of the International Congresses of Modern Architecture (CIAM), intended at first to defend the avant-garde architectural values defeated in Geneva. By 1930 the organization had become oriented toward city planning theory. Le Corbusier, as secretary of the French section, played a very influential role in the five prewar congresses and especially in the fourth which issued in 1933 a declaration that elaborated some of the basic principles of modern architecture. It was later published simultaneously by both Le Corbusier (under the title *La Charte d'Athènes* in 1943) and the industrial architect José Luis Sert, each architect providing his own commentary.

The publicity from the Geneva competition also made possible for Le Corbusier a lecture tour in South America in 1929 that was the source for his *Précisions sur un état présent de l'architecture et de l'urbanisme* (1930; "Reflections on the Present State of Architecture and Urbanism") and a trip in 1928 to Moscow, where he was able to make contact with avant-garde constructivist architects and won the competition for the Centrosoyuz building (1929–35), originally meant to house the employees of the Central Office of the Cooperative (food distribution) Organizations of the U.S.S.R. This building (today housing The Gosplan administration) followed the design of the Geneva project in its segregation of functions and in its direct linking of the various buildings.

Le Corbusier constructed two other important buildings during this period, the Salvation Army Hostel in Paris, with its attempt at a "breathing" glass wall conceived as an unopenable glass surface equipped with an air conditioning system (a technological and financial failure), and the Swiss Dormitory at the Cité Universitaire in Paris (1931–32). In the latter structure Le Corbusier once again set apart the dormitory area, consisting of three floors of cells, from the common services areas located in a separate building. The two segments were connected by a stairway tower. Surfaces were left largely unfinished, and, for the first time, the massive pillars took on a sculptural value that set them in counterpoint to the curve of the stairway. At this point Le Corbusier's rational functionalism began to be balanced by a desire for expression.

**Activities of the late 1930s.** The end of the 1930s saw such especially famous projects as the masterplans for Algiers (1938–42) and Buenos Aires (1938); the building for the Ministry of Education and Health in Rio de Janeiro (1936); and an infinitely expandable museum for Philippeville (1938), in French North Africa. There was also a trip to the United States (1935), where Le Corbusier was already famous. For Le Corbusier, the Americans were a "timid" nation unwilling to push to its logical consequences the "conquest of height," the only "solution to the essential problems posed by city planning."

Le Corbusier's diverse activities corresponded to a chosen life-style. He was not a teacher, like his colleague Gropius, but the boss, who shut himself up alone in his office while his collaborators, who had come from all over the world and some of whom (José Luis Sert, Kunio Maekawa, Gyorgy Kepes, Affonso Reidy) would later become famous, worked outside in the long hall that served as a studio. Le Corbusier came to his office only in the

afternoons. His break with Ozenfant, in 1925, had not interrupted his painting career, and he usually spent his mornings painting at home. He was, by the mid-1930s, marked by the influence of Fernand Léger, who remained one of his few good friends. From 1934 on, Le Corbusier lived on the top floor of a solid but unpretentious apartment block he had built in Boulogne, where he sometimes organized expositions of primitive and naive art and of his own paintings on the bare stone walls of his studio. He led a simple and secluded life there with Yvonne Gallis, a former model whom he had married in 1930, the year he acquired French citizenship. Mme Le Corbusier, a southerner of unpretentious origins, had an exuberant and pugnacious nature that contrasted with the rather awkward reserve of Le Corbusier; she was present at his side until her death, bringing him a sense of balance and humour. It is through her that a woman first appears in Le Corbusier's paintings, in 1930, and she is the inspiration for the female figure often found in Le Corbusier's sketches.

World War II and the German occupation of France marked an interruption for Le Corbusier of his activity as a builder and a traveller, and of his 20-year association with Pierre Jeanneret, who, unlike Le Corbusier, had joined the French Resistance. Although he was prepared to work with the Vichy government, there was little building being done at the time in France, and his only activities were painting, writing, and reflection. His thoughts during this time led to the elaboration of the first bases of the "Modulor" concept, a scale of harmonic measures that set architectural elements in proportion to human stature. This theory was finally perfected in 1950, and Le Corbusier used it in designing all his subsequent buildings, wishing them to incorporate "on a human scale." By the time the war ended, Le Corbusier had welded the attacks launched against him by representatives of traditional architecture into a myth. He had become, for the public, the Picasso of architecture, and, for architecture students, the symbol of modernity.

Postwar city and residential plans. When the war ended, Le Corbusier thought that he would finally be able to apply his theories of planning in the reconstruction of France. He prepared in 1945 two plans for the cities of Saint Dié and La Pallice-Rochelle. At Saint Dié, in the Vosges Mountains, he proposed regrouping the 30,000 inhabitants of the destroyed town into five functional skyscrapers. Despite the support of two cabinet ministers, these plans were rejected by local authorities.

The plans for these towns, subsequently circulated throughout the world, became doctrine. But Le Corbusier was bitter at not being able to participate in the reconstruction of his adopted country. His bitterness increased when he was named a member of the jury of architects for the construction of the United Nations building in New York instead of being asked to design it himself. This feeling is revealed in the edition of Le Corbusier's complete works, published under his direction in 1946. He creates the image of a solitary and persecuted genius, going so far as to accuse the architect of the United Nations building of plagiarizing his own designs.

At last, in 1945, thanks to the unlimited support of the French government, Le Corbusier had the opportunity to construct a large (private) housing complex; he was commissioned to build, in Marseille, a residential complex that embodied his vision of a social environment.

The Marseille project (*unite' d'habitation*) is a vertical community of 18 floors. The 1,800 inhabitants are housed in 23 types of duplex (i.e., split-level) apartments. Common services include two "streets" inside the building, with shops, a school, a hotel, and, on the roof, a nursery, a kindergarten, a gymnasium, and an open-air theatre. The apartments are conceived as individual "villas" stacked in the concrete frame like bottles in a rack. The facade is composed of balconies interspersed with prefabricated concrete sunshades (*brises-soleil*), an element invented by Le Corbusier in 1933.

The Marseille *unite' d'habitation* was completed in 1952 at considerable cost. From the time construction began, it was the object of controversy; it was called "the Marseille folly" by critics, and the city's inhabitants had bap-

tized it "la Maison du Fada," ("the house of the mad architect"). Nevertheless, two more *unités* were built at other locations in France, at Nantes and Briey, as well as others in West Berlin. As art, the Marseille complex resembles a sculpture; its massive forms, unfinished materials, and painted decoration in violent colour relate it to the expressive qualities of archaic art. The Marseille *unite' d'habitation* characterizes the bold expressionist direction of the second period of Le Corbusier's work.

Diversified projects. Two religious buildings in France carry this tendency further. Both were commissioned as a result of the influence of the Dominican father Reverend Couturier, creator of the review *L'Art Sacré*. The more lyrical of the two, the chapel Notre-Dame-du-Haut at Ronchamp (1950–55), sacrifices Le Corbusier's famous principles of apparent functionalism; the wall has been built to a double thickness for visual effect and the roof, which only appears to be suspended, actually rests on a forest of supports. More brutal and austere is the convent of Sainte-Marie-de-la-Tourette at Eveux-sur-Arbresle, near Lyons. The square building imposes a fortress of concrete in a natural setting. In the three-tiered facade of glass at la Tourette, Le Corbusier first employed panes of glass set at "musical" intervals (calculated by the Greek engineer and composer Yannis Xenakis) to obtain a lyrical effect.

Ronchamp and la Tourette established once and for all Le Corbusier's reputation in France. Two large expositions of his work were organized in Paris in 1953 and in 1962. He was invited in 1965 to design the civic centre of the town of Firminy-Vert. The minister of cultural affairs, André Malraux, ordered plans for the French embassy in Brasilia and commissioned a Museum of the Twentieth Century neither of which was built.

Meanwhile, in 1952, the architect constructed for his own use, in Cap Martin, near Nice, a tiny cabin consisting of a single room containing two beds, a work table and the necessary plumbing installations, which he made the symbol of his life-style and where he liked to go to get away from the city. Le Corbusier continued to paint, and, from 1946 on, sculpted. He participated in the interior decoration of all his buildings and some tapestries have also been made according to designs.

At his studio there were frequent changes in personnel, often the result of Le Corbusier's shifting moods. Between 1948 and 1960 Xenakis especially left the mark of his personality on the productions of the workshop. In 1958, for the World's Fair at Brussels, Xenakis completed a design for an audio-visual spectacle involving music at the Philips Pavilion, which Le Corbusier designed.

International activity. Only from 1950 on did Le Corbusier become active on a large scale outside of France. He built the National Museum of Western Art in Tokyo (1960), the Carpenter Visual Art Center at Harvard University (1964), and designed an Exposition Pavilion in Zürich that was constructed posthumously (1964).

In 1951, the government of the Punjab named him architectural advisor for the construction of its new capital, Chandigarh. For the first time in his life, Le Corbusier was able to apply his principles of city planning on a metropolitan scale. He assigned the completion of the residential sectors to Pierre Jeanneret, whom he had asked to join him, and to the English architects Jane Drew and Maxwell Fry. He reserved for himself the Capitol, or administrative complex, the axial plan of which was inspired by examples of 17th-century urban design in the French classical manner such as Versailles. Totally without reference to local tradition, he designed the Palace of Justice, the Secretariat, and the Palace of the Assembly. Unfinished concrete, with windows sheltered by enormous *brises-soleil*, the sculptural facades, swooping rooflines, and monumental ramps are principal elements of his architecture, which immediately influenced architects all over the world.

Le Corbusier was not greatly impressed by his late recognition. He never forgave French authorities for having kept him out of the main city-planning projects of the 1960s. His last years were also saddened by the death of

his wife, in 1957. Nevertheless, he continued to conceive new projects until the end of his life: an art centre for Frankfurt (1963), the Olivetti computer centre in Milan (1963), the Palais des Congrès (for the European parliament) in Strasbourg (1964), and the French embassy in Brasília (1964).

Le Corbusier died suddenly on August 27, 1965, while swimming at Cap Martin. The man who had thought himself so misunderstood in his own time was given a national funeral, and in 1968 the Le Corbusier Foundation was created.

#### MAJOR WORKS

House at Vaucresson near Paris (1922); Ozenfant House, Paris (1922); La Roche and Jeanneret houses, Paris (1923); Pavillon de l'Esprit Nouveau, Paris (1925); Les Terrasses, Garches, near Paris (1927); Savoye House, Poissy (1929–30); Swiss Dormitory, Cité Universitaire, Paris (1931–32); Unité d'habitation, Marseilles (1946–52); Notre-Dame-du-Haut, Ronchamp, France (1950–55); Villa Shodan, Ahmādbād, India (1955–56); Convent of Sainte-Marie de la Tourette, Eveux-sur-L'Arbresle, France (1957–61); Chandigarh, India state capital of the Punjab (1950s; Palace of Justice, 1952–56, Secretariat, 1952–56); Carpenter Visual Art Center, Harvard University (1964).

PROJECTS: Domino housing project (not executed, 1914–15); Citrohan House projects (1919–22); A contemporary city for 3,000,000 inhabitants (1922); Voisin Plan of Paris (1925); Project of the Palais des Nations (1927–28); Plan for Algiers (1930–42); Plan for Saint-Dié (1945–46).

WRITINGS: *Vers une architecture* (1923); *Toward a New Architecture*, 1946; *L'Art décoratif d'aujourd'hui* (1924); *Urbanisme* (1925); *The City of Tomorrow*, 1929; *La Ville radieuse* (1935); *Quarzd les cathédrales étaient blanches* (1937); *When the Cathedrals Were White*, 1947; *La Charte d'Athènes* (1943); *Les Trois Établissements humains* (1945); *Protos d'urbanisme* (1946); *Le Modulor I* (1948); *The Modulor*, 1954).

**BIBLIOGRAPHY.** There is no complete bibliography of Le Corbusier; however, the Le Corbusier Foundation of Paris, which houses the Le Corbusier archives, is now preparing one. The principal sources on the man and his work are the *Oeuvre complète* published as follows with the assistance of the architect: W. BOESIGER, *Le Corbusier et Pierre Jeanneret 1910–1929* (1929); M. BILL, *Le Corbusier et Pierre Jeanneret 1929–1936* (1936); *Le Corbusier et Pierre Jeanneret 1936–1938* (1939); W. BOESIGER, *Le Corbusier Oeuvre complète 1938–1946* (1946); *Le Corbusier Oeuvre complète 1946–1952* (1953); *Le Corbusier Oeuvre complète 1952–1957* (1958); *Le Corbusier et son atelier rue de Sèvres 35, oeuvre complète 1957–1965* (1965); and the various theoretical works of Le Corbusier.

Monographs and articles devoted to Le Corbusier during his lifetime are generally distorted by a strong bias, either for or against the architect: F. DE PIERREFEU, *Le Corbusier et Pierre Jeanneret* (1932), the first book devoted to Le Corbusier; M. GAUTHIER, *Le Corbusier; ou, l'architecture au service de l'homme* (1944); S. PAPADAKIS (ed.), *Le Corbusier: Architect, Painter, Writer*, (1948), a series of essays by friends or former collaborators; F. CHOAY, *Le Corbusier* (1960), an attempt at a synthesis; and P. BLAKE, *Le Corbusier* (1964). In the works that have appeared since Le Corbusier's death: STANISLAUS VON MOOS, *Le Corbusier, Elemente einer Synthese* (1968; French trans., *Le Corbusier, l'architecte et son mythe*, 1971), a still very timid attempt to decipher Le Corbusier behind his myth; MAURICE BESSET, *Qui était Le Corbusier?* (1968; Eng. trans., *Who Was Le Corbusier?*, 1969), written by Le Corbusier's executor.

(F.C.)

## Cordoba

Córdoba (Cordova) is the capital of Córdoba province in the Andalusia region of southern Spain; it is located on the Guadalquivir River, 82 miles northeast of Seville.

Early history (to 8th century AD). Córdoba was probably Carthaginian in origin, identified by some as the biblical city of Tarshish. Roman Corduba was one of the four judicial centres of the Roman province of Baetica. According to the Greek historians Polybius (c. 200–118 BC) and Strabo (1st century BC), it was established as a Roman colony in 152 BC by Marcus Claudius Marcellus, who made it his winter quarters during a Spanish campaign. The followers of Pompey the Great used it as their base during their civil war against Julius Caesar, who sacked the city in 45 BC and slaughtered 20,000 of its in-

habitants. At the end of the Republic (late 1st century BC), it received the title of *colonia patricia* and became a flourishing commercial and cultural centre under the empire.

Geography contributed to Córdoba's prosperity. It stood in the middle of a rich agricultural district and served nearby mines. The Guadalquivir was then navigable up to the city itself, and Córdoba was connected by the Via Augusta to the cities of northern Spain and by other roads to Gades, Malaca, and Carthago Nova. Córdoba was the birthplace of both Senecas, the poet Lucan, and of Bishop Hosius, who influenced the conversion of the emperor Constantine. Though too little remains of Roman Córdoba to place all its main buildings with certainty, it is known that the Great Mosque was sited on the former temple to Janus.

Córdoba declined in importance under the Visigoths (ruled 6th–early 8th centuries), whose main centres of settlement were on the Meseta; but it was the centre of political revolt against King Agila (ruled 549–554) and of religious war (c. 570) in the struggle between Arians and Catholics.

Under Muslim rule (756–1236). Captured and largely destroyed by the Muslims in 711, Córdoba's recovery was impeded by tribal rivalries until 'Abd ar-Raḥmān I, a member of the Umayyad family, accepted the leadership of the Spanish Muslims and made Córdoba his capital in 756. He founded the Great Mosque, which was enlarged by his successors and completed about 976 by 'Abū 'Āmir al-Manṣūr. Though troubled by occasional revolt, Córdoba grew rapidly under Umayyad rule; and after 'Abd ar-Raḥmān III proclaimed himself caliph of the West in 929, it became the largest and probably the most cultured city in Europe. Arab historians claim it covered an area 24 miles by 6; contained a population of 1,000,000; and had 260,000 buildings, including 80,000 shops, 3,000 mosques, baths, palaces, and a principal library of 400,000 volumes — figures that others consider exaggerated.

The  
Umayyads

Archivo Mas. Barcelona, Spain

Western facade of the Great Mosque at Córdoba.

As capital of the western caliphate, Córdoba was famous for its industries, architecture, art and literature, scholarship, and urbanity. Its woven silks and elaborate brocades, leather work, and jewelry were prized throughout Europe and the East, and its women copyists rivalled Christian monks in the production of religious works. The Umayyads blended Roman and Byzantine designs in their buildings and ransacked the Mediterranean for the remains of earlier civilizations to incorporate into their palaces. The most celebrated of these, 'Abd ar-Raḥmān's palace city of *Madīnat az-Zahrā'*, largely destroyed in 1013, is said to have been roofed with silver and gold and to have had fountains of quicksilver. Education was actively promoted by the Umayyads and their successors the 'Āmirids, and Córdoba became a centre for foreign scholars from East and West, noted for its expertise in Qur'anic interpretation, Islāmic law, philology, music, medicine, and surgery. The refined manners of Baghdad, capital of the 'Abbāsīd caliphate, were popularized in

The  
Roman  
city

Córdoba by the singer *Ziryāb* (died 852), who established himself in Córdoba with his troupe and founded the Andalusian school of music and singing. Initially a certain tolerance was observed toward Córdoba's Christians, who were allowed to retain some churches and their own schools and libraries; this was curtailed by the later Umayyads who, under the pressure of the Christian reconquest, banned Latin and forced Christian children to attend Arabic schools. Arabic was the official language, but bilingualism in Arabic and a **Hispano-Roman** dialect was usual among the educated classes of both religions.

When the caliphate was dismembered by civil war early in the 11th century, Córdoba became the centre for a contest of power between the petty Muslim kingdoms (*taifas*) of Spain. It was severely sacked in 1013 and some of its most famous buildings were destroyed. After a brief interlude under the rule of the emir of Toledo, Córdoba was added to the domains of the 'Abbāids of Seville during the reign of the poet-sultan al-Mu'tamid (ruled 1069–91). The successive occupations of the city by two North African sects—the al-Murābitūn (Almoravids) in 1091 and the al-Muwahhīdūn (Almohads) in 1172—restored internal stability, though they initiated a period of intense religious and artistic intolerance. Nevertheless, though Córdoba lost much of its importance as a political and military centre, poetry and scholarship continued to flourish there, and the city produced Ibn Hazm (994–1064), a profound jurist, theologian, and philologist known as the author of *The Ring of the Dove*. The philosophers Averroës (1126–98) and Maimonides (1135–1204) were both born and educated in Córdoba, though the former was expelled as a heretic and the latter fled to escape persecution by Almohad fanatics.

On the death of the last Almohad caliph in 1223, Córdoba again became a weak *taifa* state and fell to the Castilian king Ferdinand III in 1236.

**History since 1236.** Isolated from the sources of raw silk in the Muslim kingdom of Granada, the city lost its silk manufactures though not its leather industries. After the Christian reconquest (mid-13th century) Córdoba lost its political and cultural leadership, but the city remained important for more than two centuries as the main military base in the frontier warfare against Granada; many Castilian noble families and several distinguished soldiers settled there. The fall of Granada in 1492 left Córdoba a quiet provincial city of churches, monasteries, and aristocratic houses, renowned for its fine wines, horses, and women. The exotic poetry of Luis de Góngora y Argote (1561–1627) briefly revived Córdoba's poetic prestige in the 17th century.

The city was stormed and sacked by the French in 1808 for its part in fomenting the movement of independence. It was one of the first cities occupied by Francoist forces in the Spanish Civil War (1936–39).

Córdoba's Moorish character, its fine buildings and churches—especially the Great Mosque—have made it a popular tourist attraction. The city is also noted for its textile manufactures and for its brewing and distilling industries. In the late 1960s, its population was about 225,000.

**BIBLIOGRAPHY.** J. DE LA TORRE, "Hallazgos arqueológicos junto a Córdoba," *Bol. de la Real Acad. de Hist.*, 79:419–427 (1921), is a useful introduction to Roman Córdoba. AL-MAK-KARL, *The History of the Mohammedan Dynasties in Spain* . . . , trans. by P. DE GAYANGOS, 2 vol. (1840–43), is the best primary source of information for Córdoba in the Mohammedan period; W. MONTGOMERY WATT, *A History of Islamic Spain* (1965), provides a useful and contemporary summary. For Córdoba in the Christian period up to the mid-16th century, the best primary source of information is AMBROSIO DE MORALES, *Historia general y antigüedades de Córdoba*, 3 vol. (1574–1586). More modern impressions of the city, and a summary of its history, may be found in JAMES A. MICHENER, *Iberia*, pp. 155–180 (1968).

## Corelli, Arcangelo

One of the major violinist-composers of the late 17th century, Arcangelo Corelli was the founder of a style of violin playing and also of the concerto *grosso*—a type of

musical composition in which there is interplay between a smaller and larger group of strings. His solo violin sonatas also became models for later developments in this field. Corelli's most important works in these genres are the *Concerti grossi*, Opus 6, and his 12 *Sonatas for Violin and Violone or Harpsichord*, Opus 5.

By courtesy of the National Gallery of Ireland, Dublin

Corelli, portrait by Hugh Howard (1675–1737). In the National Gallery of Ireland, Dublin.

Corelli was born in Fusignano, near Ravenna, Italy, on February 17, 1653. His mother, Santa Raffini, having been left a widow five weeks before his birth, named him after his deceased father, Arcangelo. There are no documented details on his first years of study. It is thought that his first teacher was the curate of San Savino, a village on the outskirts of Fusignano. Later, he went to Faenza and Lugo, where he received his first elements of musical theory. Between 1666 and 1667 he studied with Giovanni Benvenuti, violinist of the chapel of San Petronio in Bologna. Benvenuti taught him the first principles of the violin; and another violinist, Leonardo Brugnoli, furthered his education.

After a four-year stay in Bologna, Corelli went to Rome. Reliable evidence on his activities is lacking for the first five years, but it is likely that he played the violin at the Teatro Tordinona. Also, it is possible that in 1677 he made a trip to Germany, returning to Rome in 1680. On June 3, 1677, he sent his first composition, a *Sonata for Violin and Lute*, to Count Fabrizio Laderchi of Faenza.

By February 3, 1675, he was already third violinist in the orchestra of the chapel of San Luigi dei Francesi, Rome, and by the following year he was second violinist. In 1681 his 12 *Trio Sonatas for Two Violins and Cello, with Organ Basso Continuo*, Opus 1, dedicated to Queen Christina of Sweden, who had a residence in Rome, were published. The following year he took the post of first violinist in the San Luigi dei Francesi orchestra, a position he held until 1685, the year in which his 12 *Chamber Trio Sonatas for Two Violins, Violone and Violoncello or Harpsichord*, Opus 2, were published.

From September 1687 until November 1690, Corelli was musical director at the Palazzo Pamphili, where he both performed in and conducted important musical events. Corelli was particularly skilled as a conductor and may be considered one of the pioneers of modern orchestral direction. He was frequently called upon to organize and conduct special musical performances. Perhaps the most outstanding of these was the one sponsored by Queen Christina of Sweden for the British ambassador, who had been sent to Rome by King James II of England to attend the coronation of Pope Innocent XII. For this entertainment, Corelli conducted an orchestra of 150 strings. In 1690 he directed the performance of the oratorio *Santa Beatrice d'Este* by Giovanni Lulier, galled *del violino*, also with a large number of players

Under Christian domination

Entry into  
service of  
Cardinal  
Ottoboni

(33 violins, 10 violas, 17 cellos). The same year he entered the service of Cardinal Pietro Ottoboni, in which he spent the rest of his life.

In 1689 Corelli's *12 Church Trio Sonatas for Two Violins and Archlute, with Organ Basso Continuo*, Opus 3, dedicated to Francesco II, duke of Modena (he had been the Modenesi Count, 1689–90) was published; and in 1694 his *12 Chamber Trio Sonatas for Two Violins and Violone or Harpsichord*, Opus 4, intended for the academy of Cardinal Ottoboni, also appeared.

It is probable that Corelli also taught at the German Institute in Rome and certain that in 1700 he occupied the post of first violinist and conductor for the concerts of the Palazzo della Cancelleria. Also in 1700 his *12 Sonatas for Violin and Violone or Harpsichord*, Opus 5, dedicated to Sophia Charlotte of Brandenburg, was published.

In 1702 Corelli went to Naples, where he probably played in the presence of the king and performed a composition by the Italian composer Alessandro Scarlatti. There is no exact documentation for this, just as there is none for his contacts with George Frideric Handel, who was in Rome between 1707 and 1708. In 1706, together with the Italian composer Bernardo Pasquini and Scarlatti, he was received into the Accademia dell' Arcadia and conducted a concert for the occasion.

Corelli died on January 8, 1713, having already retired from an active artistic life. He did not live to see the publication of his Opus 6, consisting of 12 concerti grossi, which was published in Amsterdam the year following his death.

Corelli was reserved and withdrawn, absorbed in his ideal as a musician. He lived in isolation with the exception of a period during which he and his favourite pupil, Matteo Fornari, were inseparable. He is said to have shown no interest in women; he certainly never married. Although he was averse to making any sort of personal display, he had amassed in his lifetime a valuable collection of paintings and violins.

#### MAJOR WORKS

**INSTRUMENTAL MUSIC:** *Concerti grossi con duoi violini e violoncello di concertino obligati, e duoi altri violini, viola, e basso di concerto grosso ad arbitrio che si potranno radoppiare*, op. 6 (published posthumously 1714).

**CHAMBER MUSIC:** *XZI Suonate a tre, due violini e violoncello, col basso per l'organo*, op. 1 (published 1681); *XII Suonate da camera a tre, due violini, violoncello e violone o cembalo*, op. 2 (1685); *XII Suonate a tre, due violini e arcileuto col basso per l'organo*, op. 3 (1689); *XII Suonate da camera a tre, due violini e violone o cembalo*, op. 4 (1694); *XII Suonate a violino e violone o cembalo*, op. 5 (1700).

#### BIBLIOGRAPHY

*Contemporary accounts:* G.M. CRESCIMBENI, *Notizie storiche degli Arcadi morti* (1720), supplies information on Corelli's early studies. G.B. MARTINI, *Serie cronologica dei Principi dell'Accademia dei Filarmonici di Bologna* (1776, in manuscript), gives the earliest information on Corelli's birth, studies, and teachers. SIR JOHN HAWKINS, "The General History and Peculiar Character of the Works of Archangelo Corelli," in *Universal Magazine of Knowledge and Pleasure*, pp. 171–172 (April 1777), is a critical examination of Corelli's works, with information on his meeting with Handel in Rome.

*Critical works:* ALBERTO CAMETTI, "Arcangelo Corelli à Saint-Louis-des-Français à Rome," in *Revue musicale*, pp. 25–28 (January 1922); MARIO RINALDI, *Arcangelo Corelli* (1953, in Italian), presents the author's opinion that Corelli travelled in both France and Germany; MARC PINCHERLE, *Corelli et son temps* (1954), rejects Rinaldi's opinion that Corelli made a journey to France—of fundamental importance for the study of the composer's personality.

(G.Pan.)

## Corinth

Corinth (Greek Kórinthos) is the name of both an ancient and a modern city of the Peloponnesus, in Greece. The remains of the ancient city lie about fifty miles west of Athens, at the eastern end of the Gulf of Corinth, on a terrace some 300 feet above sea level, and at the foot of Acrocorinth—a Gibraltar-like eminence rising 1,886 feet above sea level. The site has been inhabited since Neolithic times, well before 3000 BC.

**History.** During the 8th century BC Corinth began to develop as a commercial and manufacturing centre, exploiting its geographical position, and producing fine pottery and bronze. Its political influence was increased through territorial expansion in the vicinity and through colonies, conspicuously, Corcyra and Syracuse. Toward 600 BC the controlling family, the Bacchiads, was overthrown by Cypselus, who became a "tyrant" and was succeeded by his even more famous son Periander. Colonial expansion was extended along the Adriatic and into Macedonia, and contacts were made with the Near East and Egypt.

After the Greco-Persian Wars Corinth joined the Peloponnesian faction led by Sparta against Athens, and it was often the commercial rivalry of Corinth and Athens that generated crises. The culmination of this rivalry in the Peloponnesian War brought about the military defeat of Athens but also the eclipse of real political power for Corinth. Subsequently, Corinth was involved in most of the contemporary conflicts, but after 338 it figured chiefly as a pawn in the struggles of greater powers because of the strategic value of its citadel.

The mingling of these events with the advancing fortunes of Rome led to the destruction of Corinth in 146 BC by the Roman general Mummius; but in 44 BC Julius Caesar re-established the city as a colony of Rome (a base for Roman government in Greece), and once again it became one of the great cities of the Mediterranean. It flourished as a provincial centre under the Roman Empire and is known to readers of the New Testament for the letters addressed to its Christian community by the Apostle Paul. It enjoyed some prosperity under Byzantine rule but declined in the later Middle Ages. After the Turkish conquest in 1458, it was reduced to a country town.

**Excavation and remains.** The site has been explored by the American School of Classical Studies at Athens, in excavations begun in 1896 and continued since with brief interruptions.

The central area of the city, as known from the excavations, appears to have developed from the beginning around a low hill, on which stand seven columns of a temple built in the archaic style shortly after 550 BC. Below this to the east is a valley opening onto the lower natural terrace to the north, through which a road led to Lechaëum, the harbour on the Corinthian Gulf. Southeast of the temple, facing on this valley, there was a spring called Peirene's, which was improved as a fountain house in the 6th century and frequently enlarged and embellished in succeeding centuries. Just south of the temple another smaller spring in a branch of the valley came to have a central function in a small sanctuary not yet fully explored; a small apsidal temple associated with it seems to have been equipped for oracular or other cult performances. A little west of the archaic temple was a third archaic fountain called Glauce's. Probably as early as the 5th century BC, a peculiar stoa (columned portico) was built below the archaic temple facing the road to Lechaëum, and industrial establishments developed on the eastern side of the road. South of the temple was a race track laid out in what must have been an extensive, rather open area. Below the temple to the north a bathing establishment and a small stoa were built—perhaps part of a small gymnasium—and northwest of this a large theatre.

By the end of the 4th century there was an enormous stoa over 500 feet long, which might have served as a kind of hotel, defining the area south of the temple as a major commercial marketplace, or agora. Another smaller stoa immediately below the temple soon gave clearer definition to the north edge of this area, while the enclosure for a large temple precinct marked the western extremity.

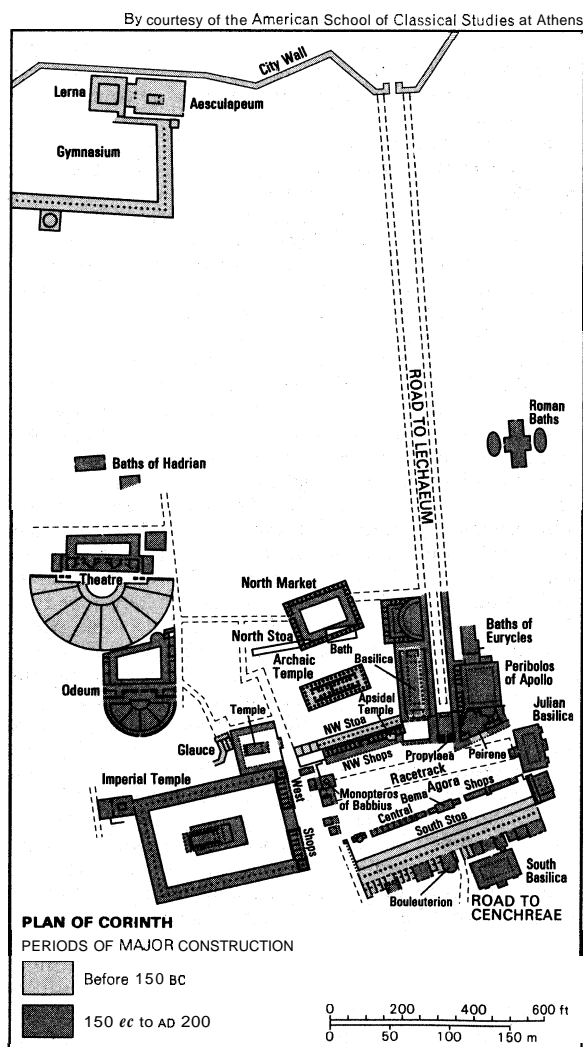

The general lines thus established by Hellenistic times were elaborated in detail during the first two centuries after Christ. The south stoa was gradually converted into a series of administrative offices; the open space of the agora was subdivided longitudinally by terracing and a

area

Ruins in the central area of Corinth. Left are the seven columns of the Temple of Apollo, c. 550 BC.  
J. Allan Cash—Rapho Guilleumette

row of shops with a *bēma* or "rostrum" in the middle; a basilica and a similar structure were built at the east end, and a row of temples emerged at the west. The entrance to the road to Lechaëum was adorned by a triumphal arch, and a large basilica and other buildings—religious and commercial—were built along the road itself. Between the fountain of Glauce and the theatre was built an odeum, or music hall, while the theatre itself was con-

Central area of ancient Corinth

verted from its Greek form to accommodate Roman theatrical and gladiatorial spectacles.

The surrounding parts of the city are known only in random spots. North of the theatre was a large gymnasium, partially excavated; just north of this was a temple and sanctuary of Asclepius, and further the city wall, which is about 600 yards north of the archaic temple. In connection with the sanctuary and gymnasium were elaborate arrangements of springs and cisterns—those near the Asclepeum possibly medicinal, those below the gymnasium perhaps for ordinary bathing. About 1,500 yards west of the archaic temple by the city wall were numerous early Greek pottery factories; almost as far to the east is a Roman amphitheatre of considerable size, excavated into the rock. Ancient writers speak of a luxurious suburb and resort area that lay close to the circuit wall in this region, some 1,500 yards southeast of the agora.

Heavily fortified and almost impregnable to assault from archaic times through the 17th century, the citadel on Acrocorinth, with its evidence of remodellings, is almost a museum of military architecture. The city itself was protected in Greek times by a circuit wall almost six miles in extent, but little of this has been preserved.

Corinth was served by two harbours: Lechaëum, less than two miles to the north, and Cenchreæ, about six miles to the east. At Lechaëum are unexplored remains of the harbour works and an early Christian basilica of the 5th century, the largest in Greece, which has been entirely cleared. At Cenchreæ some remains of the ancient harbour and associated buildings have been explored or cleared, although some of the most significant of these are submerged and inaccessible to view.

**New Corinth.** Located three miles northeast of Old Corinth, New Corinth was founded in 1858 after an earthquake that destroyed its predecessor. It is primarily a hub of communications between northern and southern Greece and is the primary point of export for local fruit, raisins, and tobacco. It is the chief town of the *nomós* of Corinth and the seat of an archbishop. As highway conditions improve, it is losing some of its advantages of location, being just 57 miles from Athens and only skirted by the finest new roads.

**BIBLIOGRAPHY.** For a condensed comprehensive account, see *The Urban Development of Ancient Corinth*, by H.S. ROBINSON (1965). For detailed reports of the excavations, see AMERICAN SCHOOL OF CLASSICAL STUDIES AT ATHENS, *Corinth: Results of Excavations (1929 et seq.)*, several volumes by various authors; and preliminary reports of work in progress in the *American Journal of Archaeology* (1885- ), and *Hesperia* (1932- ).

(R.L.S.)

## Cornales

The dogwood order (Cornales) of flowering plants encompasses 10 families, approximately 350 genera, and over 3,700 species. By far the largest family is the Umbelliferae or parsley family, also called the family Apiaceae, with about 275 genera and 2,850 species, about 80 per cent of the species in the entire order; it is practically cosmopolitan in distribution but occurs chiefly in the north temperate regions. By contrast, the second largest family, the Araliaceae, is principally tropical. The family Cornaceae is mainly north temperate; the seven remaining smaller families are from North America or eastern Asia, mostly in warm or wet regions.

### GENERAL FEATURES

**Size range and diversity of structure.** As befits an order with representatives scattered through both tropical and temperate regions, the members of the Cornales show great diversity in form. Most of the members are predominantly woody, principally consisting of shrubs but also with a fair representation of trees and a certain number of climbers, such as the ivy. Only the Umbelliferae contains any large representation of herbaceous (nonwoody) species; even within this family, the variation in life-forms is remarkable. At one extreme are low-growing, creeping species, such as the well-known

Outlying areas

marsh pennywort of Europe (*Hydrocotyle vulgaris*) and allied species in North America and elsewhere. At the other extreme are large tropical trees or bushes such as the African *Stegonotaenia araliacea*. Even in temperate regions gigantic species of the family Umbelliferae occur—notably the giant hogweed of the Caucasus (*Herculeum mantegazzianum*), which can cause painful blistering in sunlight by producing photosensitization of the skin when touched. Spine-bearing species are found in the genus *Eryngium*, some of which are grown as decorative plants because of their bright amethyst colour. No parasitic or saprophytic plants—those that obtain nourishment from living or dead organisms, respectively—occur in the order.

Figure 1: Representative plants from the two largest Cornales families.

Members of the order used as foods

**Economic importance.** Some members of the order are of widespread or local economic importance. Food-stuffs are important products of the family Umbelliferae, which yields such well-known vegetables as celery (*Apium graveolens*), carrots (*Daucus carota*), and parsnips (*Pastinaca sativa*), as well as the Andean root crop *Arracacia xanthorrhiza*. In various eastern Asiatic countries the young stems and leaves of several species of the Araliaceae are esteemed as vegetables. Plants of the family Umbelliferae also yield some well-known spices and flavourings, such as caraway seeds (*Carum carvi*). Some of these were used in biblical times; e.g., coriander (*Coriandrum sativum*), aniseed (*Pimpinella anisum*), and cumin (*Cuminum cyminum*). The last species is also employed in perfume manufacture. A few medicinal plants also occur in the order. Dill (*Anethum graveolens*), gum ammoniac (*Dorema ammoniacum*), and asafetida (from several species of *Ferula*) are products of the family Umbelliferae. The bark of *Alangium salviifolium*, an emetic, has been used as an ipecac substitute, and that of

one or two species of *Cornus* has been used as a quinine substitute. An interesting discovery has been that *Campotheca acuminata* (family Nyssaceae) yields camptothecin, which is useful in the treatment of leukemia. Ginseng, *Panax schinseng* (family Araliaceae), one of the most famous Chinese drugs, is used to treat many diseases. North American ginseng is *P. quinquefolium*.

Many species of the Umbelliferae are poisonous, including the hemlock (*Conium maculatum*) used in ancient Greece as a means of capital punishment; hemlock water dropwort (*Oenanthe crocata*), which sometimes kills livestock; and cowbane (*Cicuta virosa*).

*Tetrapanax papyrifera* (family Araliaceae) is the source of the so-called rice paper of commerce, used for, among other things, surgical dressings and artists' water-colour papers. The wood of some species of this family is used as timber. The wood of *Dendropanax arboreum* is strong and is used locally in general carpentry. The wood of *Didymopanax* species is less durable; that of *Kalopanax pictus* is very easily worked, pliable, and resonant. For this reason it has been used in China to manufacture drums. It is also suitable for furniture, in which form it has been called Japanese ash. Both *Cornus florida* (flowering dogwood) and *C. nuttallii* (western flowering dogwood) produce a close-grained wood, heavy and strong, that is suitable for turnery, wheel hubs, and similar products. The one species of the genus *Curtisia* (also of the family Cornaceae), *C. faginea*, the assegai, or Cape Lance tree, yields a valuable, red-brown durable timber that is close-grained, produces a good finish, and is valued for making furniture. Two species of *Griselinia* (*G. littoralis* and *G. lucida*) also produce heavy timber, but that of *G. littoralis* is rather brittle. The close-grained, heavy wood of *Alangium salviifolium* has been used to a limited extent in India, and some *Nyssa* species give tough but nondurable whitewoods.

Several species of *Cornus*, such as *Cornus mas* and *C. florida*, are grown as decorative shrubs because of their attractive, white petallike involucre, leaflike structures positioned just below the true flowers. *Cornus mas* also produces the cornelian cherry, which is eaten fresh or as preserves and is used in the manufacture of vin de *cornouille*, a wine. *Aucuba japonica* is a popular garden evergreen. Several genera of the family Araliaceae are grown as decorative plants, including the common ivy (*Hedera helix*), of which there are also attractive variegated forms. One or two species of *Garrya*, notably *G. elliptica*, are grown as garden evergreens, which are attractive because of their glossy, dark-green foliage and reddish-purple flower clusters. *Nyssa sylvatica*, the sour gum tree, produces beautiful foliage tints in the fall, and *N. ogeche* yields the ogeechee lime fruits; its flowers are also a valuable source of commercial honey. One or two species of *Helwingia* are also occasionally seen in gardens.

Wood products

#### NATURAL HISTORY

**Seed dispersal.** The Cornales is not among the more remarkable orders as far as seed dispersal is concerned, because most of the families produce drupes—stone-seeded fruits—or berries, and bird distribution is thus widespread. The fruit types, however, are of some interest. In some species of *Nyssa*, a genus mainly of swamp trees or shrubs, for example, the drupes may be distributed by water, but they do not germinate or establish seedlings while immersed. Seed distribution attains its greatest complexity with the family Umbelliferae. The characteristic fruit of this family is a dry compound fruit, known as a schizocarp, which splits down a septum, or wall, separating the adjacent segments of the fruit into two portions, called mericarps. These are at first anchored by a thin stalk (the carpophore), which usually divides to force the mericarps apart. In some genera the mericarps are strongly compressed and thin, with a broad, membranous wing for wind dispersal. In others, such as *Oenanthe*, the mericarps are frequently found in flood refuse and debris along riverbanks; a corky layer in the fruit presumably provides the buoyancy necessary for distribution by water. In still others the surface of the

mericarps is covered with hook- or grapple-shaped spines to facilitate distribution by attachment to animals. The efficiency of this last method is evidenced by the frequency with which an Australian species with grapple-shaped spines, *Daucus glochidiatus*, is found in European fields that have been fertilized with Australian wool refuse, or shoddy.

**Pollination.** Most families of the order produce species with a distinct nectar-secreting disk, and in correspondence with the exposed position of the nectar, pollination is usually accomplished by short-tongued insects, such as beetles, flies, wasps, and short-tongued bees. Higher bees visit plants that produce large quantities of concentrated nectar, such as are found in various genera of the family Umbelliferae.

Insects are attracted to members of the order by many-flowered open inflorescences (flower clusters) rather than by single, brightly coloured flowers. It has been suggested that the many tiny flowers of most species of the Umbelliferae, whose members have the greatest versatility of aollination mechanisms in the order, may appear to Bicker to a passing insect. Some species of *Cornus* and certain genera of the family Umbelliferae, such as *Tordylium*, have much enlarged petals in the outer rows of flowers. The central flower of the umbel (a name given to the inflorescence; typical of the Umbelliferae) of the carrot (*Daucus carota*) is often purple. The southwest Asian *Artemisia squamata* has enlarged outer petals coupled with a purple tuft of hairs in the centre of the umbel. All these variations presumably attract insects. In some inconspicuous species of the Umbelliferae, such as *Hydrocotyle*, self-fertilization apparently occurs. Self-fertilization also takes place in more conspicuous genera, particularly those with crowded heads, such as *Eryngium* and *Sanicula*, in which the elongating styles (part of the female reproductive organ) arch outward to bury themselves in the pollen of the anthers (part of the male reproductive organ); but additional insect pollination is more typical of these genera.

The distribution of the flower sexes in the inflorescences (or umbels) of the family Umbelliferae is very complex. In all cases, however, the purpose is to ensure cross-pollination by having the female organs develop in the first flowers to open and by having a corresponding reduction in the development of ones that open later. Wind pollination in the order Cornales occurs only in the genus *Garrya*.

#### EVOLUTION AND PALEONTOLOGY

**The fossil record.** Fossil remains of woody families have been well investigated. *Nyssa* is one of the many genera generally considered to be remnants of a moist-climate forest belt that extended in the Tertiary Period (about 65,000,000 to 2,500,000 years ago) throughout almost all of the Northern Hemisphere. The distribution of *Nyssa* is characteristic of such persistent remnants of otherwise extinct floras—i.e., it is centred on North America and eastern Asia. Paleobotanical evidence indicates that *Nyssa* apparently persisted in Europe into the early part of the Pleistocene Epoch (beginning about 2,500,000 years ago), when glaciation finally destroyed it, thus creating its present disjunct areas of occurrence. Tertiary remains are frequently found for the families Cornaceae (especially *Cornus*), Nyssaceae (*Nyssa*), Araliaceae, Alangiaceae, Umbelliferae, and Mastixiaceae. Records from the Cretaceous Period (136,000,000 to 65,000,000 years ago) are based upon fragmentary material and are taxonomically suspect. The Tertiary records range across the entire Northern Hemisphere from North America through Europe and Siberia to Japan and from all Tertiary divisions from the Paleocene Epoch (beginning 65,000,000 years ago) to the Pliocene (ending 2,500,000 years ago) and include fruits, pollen wood, and leaves. The genus *Nyssa* has been particularly well investigated. Its fruits, readily recognized because they have a characteristic germination valve, sometimes occur in great quantities and show considerable variation in form, as in the brown-coal deposits at Brandon, Vermont, and in those of Europe and Japan. It has been

Figure 2: Representative plants from the central family (Cornaceae) and two of the smaller families of the order Cornales.

Drawing by M. Pahl

found that the number of well-defined species of *Nyssa* was at least as great in the past as in recent times. The family Mastixiaceae, it appears, may have been considerably richer not only in species but also in genera—which may explain why the few members of this family today demonstrate such an interesting combination of features, some generally regarded as primitive and others considered more advanced.

As might be expected of generally delicate plants, Tertiary remains of members of the Umbelliferae are more scanty, consisting mostly of fruits identified with such recent genera as *Oenanthe*, *Eryngium*, and *Chaerophyllum*.

**Phylogeny.** The order Cornales is considered to have arisen from the order Saxifragales, one of the more primitive orders of the postulated central line of descent from the order Magnoliales. Definite links with the Saxifragales are indicated by morphological resemblances between genera that represent the more primitive members of the Cornales and some genera belonging to the Saxifragales—notably in the families Hydrangeaceae and Escalloniaceae, such as *Broussaisia* and *Polyosma*. It has also been demonstrated that the wood anatomy of the family Cornaceae (in its widest sense; i.e., including the Mastixiaceae, Toricelliaceae, and Helwingiaceae, here treated as separate families) closely resembles that of the wood of the family Hydrangeaceae of the Saxifragales—e.g., that of *Philadelphus*. The chief difference between these two representatives of allied orders—the families Cornaceae and Hydrangeaceae—is in the parenchyma, a type of tissue composed of simple, thin-walled, undifferentiated cells. In both families the parenchyma tissue tends to be scanty or even absent, but, when well defined, it is paratracheal (i.e., disposed around or close to the vessels) in the Hydrangeaceae and apotracheal (not asso-

Pollinat-  
ing insects

Families  
repre-  
sented in  
the fossil  
record

ciated with the vessels) in all genera of the family Cornaceae with the exception of *Aucuba*.

There has been considerable phylogenetic speculation; yet, within certain limits, the authors of most general systems of classification have been in relatively good agreement. In addition to the order Saxifragales, the orders Sapindales, Rutales, Celastrales, and Rhamnales have received considerable support as close allies of the Cornales. All of them, including the Cornales, have progressively simplified flowers, the formation of an inferior or enclosed ovary, a tendency toward the production of flowers whose basic parts occur in sets of four, the formation of a nectar-producing disk surrounding the ovary, and a reduction in the number of ovules. The cumulative effect of this evidence is impressive, but it is probably also true that the many common characters indicate a common line of descent for all of the orders rather than lines of descent from one to the other; the most likely candidate as a common ancestor remains the order Saxifragales.

Within the order, most workers agree that the Cornaceae is the basic and most primitive family and that the family Nyssaceae is derived from it. The remaining smaller families show distinct affinities with these two and, in some cases, also show links with the family Araliaceae.

As in many other plant orders, pollen morphology—form and structure of the pollen—has been of great assistance in the Cornales in helping to establish associations or divisions within the group. Pollen morphology has also provided evidence against unsatisfactory classification systems. The position of the family Alangiaceae, for example, has long been in doubt, and it has usually been compared with the Combretaceae. Evidence concerned with pollen is against this association, however. On the other hand, the pollen grains of *Alangium chinense* show some similarity to those of certain genera of the family Nyssaceae (*Nyssa*, *Camptotheca*) and of Cornaceae, thus associating a disputed link with an undisputed one (*i.e.*, that between Cornaceae and Nyssaceae). Evidence from pollen confirms the separation of *Davidia* as a family distinct from the Nyssaceae and Toricellia and Mastixia as genera not belonging to the Cornaceae. In the last two cases, however, the evidence is less conclusive, since the family Cornaceae is diverse with respect to pollen morphology. Further investigation along this and other lines of research may lead to the permanent isolation of additional families from the Cornaceae to accommodate such genera as *Aucuba* and *Kaliphora*. The distinctiveness of the family Garryaceae is no longer debated. The occurrence of pollen types of a more or less similar nature between Cornaceae and Garryaceae, and Garryaceae and certain Araliaceae provides a further confirmatory link within the order, as does the occurrence of common pollen types between the families Araliaceae and some members of the Umbelliferae.

With regard to relationships with other orders, pollen studies tend to confirm that the close association of the Cornales to the family Caprifoliaceae (order Dipsacales), specifically to the genera *Viburnum* and *Sambucus*, postulated by several authorities, may be well-founded. Below the family rank, further studies with pollen work will probably confirm other types of evidence that several natural sections occur within the genus *Cornus*.

#### CLASSIFICATION

##### Annotated classification.

##### ORDER CORNALES

Trees or shrubs, rarely herbs (except in the family Umbelliferae, then frequently herbs), rarely lianas. Leaves alternate or opposite, simple with entire (uncut, not toothed) margins or lobed in palmate or pinnate patterns (*i.e.*, the lobes radiate from a common point or from both sides of a central axis, respectively) with toothed segments. Stipules commonly absent or sometimes present and free (in the families Helwingiaceae and part of Umbelliferae). Inflorescences consist of cymes (flower clusters in which the central or topmost flower opens first and further flowers occur on lateral growing points), panicles (many-branched clusters), racemes (flower clusters with the flowers stalked and the lowest flowers opening first),

or umbels (clusters radiating from a common point), more rarely spikes or heads or flowers solitary in the leaf axils (upper angles between leaf and stem) or on the leaf surface. Flowers usually small, radially symmetrical except sometimes bilaterally symmetrical in the enlarged marginal flowers in inflorescences of some species in the Umbelliferae; bisexual, polygamous (male, female, and bisexual flowers on one plant) or dioecious (male and female flowers on separate plants), commonly 4- or 5-merous (basic parts in 4s or 5s) but occasionally with up to 10 petals and sepals. Petals free, touching at the margins or overlapped, rarely absent. Sepals commonly much reduced, sometimes absent, the bases forming a tube fused around the ovary. Stamens in 1 or sometimes 2 or more series or whorls (very numerous in *Davidia*), equal in number to or up to 4 times as many as the petals. Nectar-producing disk present, attached to upper part of ovary. Styles 1 to several, free or fused together. Ovary inferior (enclosed within the basal parts of the sepals, petals, and stamens), of fused carpels. Ovules pendulous, usually solitary, and attached to the inner walls of the ovary. Fruit a berry, drupe (stone-seeded fruit), or a dry schizocarp (splitting fruit), generally formed of two segments (mericarps), which do not always separate at maturity. Embryo small to medium in size, endosperm copious to scanty. Ten families, about 350 genera, and more than 3,700 species with worldwide distribution, but chiefly found in north temperate regions.

##### Family Cornaceae (dogwood family)

Almost entirely trees and shrubs (creeping herbs only in the small genus *Chamaepericlymenum*). Leaves opposite or alternate, simple with entire margins, often furnished with stellate (branched in star patterns) or T-shaped hairs, stipules absent. Flowers small, unisexual or bisexual. Inflorescences in axillary or terminal umbels, corymbs, or in the form of dense heads with conspicuous involucre of leafy or petallike bracts. Petals and sepals 4 or 5, the sepals small or missing. Petals commonly touching at the margins (valvate) but occasionally overlapped (imbricate). Stamens equal in number to and alternate with petals. Ovary occasionally 1- but usually 2- to 4-locular (chambered), each locule containing 1 ovule. Fruits mostly drupaceous, but bony or crustaceous pyrenes (small, hard nutlets) also occur. Eight genera and 80 species. *Cynoxylon*, *Dendrobenthamia*, *Swida*, and *Afrocrunia* are sometimes recognized as distinct from the genus *Cornus*; the number of genera is then correspondingly increased.

##### Family Garryaceae

Shrubs or small trees. Inflorescences catkin-like (pendulous elongate axes bearing numerous small flowers). Flowers dioecious; petals completely absent; sepals 4 or absent in the female flowers, very tiny, valvate. Ovary with 1 locule, 2 ovules. Stamens 4. Fruit a berry. Seeds with copious endosperm. One genus (*Garrya*) with 18 species, distributed only in the Northern Hemisphere of the New World.

##### Family Davidiaceae

Tree with deciduous, alternate, simple leaves without stipules. Flowers andromonoecious (*i.e.*, there are separate plants that contain male flowers only; others with bisexual flowers) crowded in terminal globose heads. Male flowers crowded together and each composed of 5 or 6 stamens only. Petals absent, sepals much reduced in size. Fertile flowers single in each head and placed asymmetrically, the ovary 6- to 10-locular, with a single columnar style bearing 6 to 9 stigmatic lobes. Fruit a drupe with a bony endocarp. Involucre of inflorescence of 2 very large, white, spreading bracts. One genus and species (*Davidia involucreata*), native to northern China but widely grown in gardens (commonly called the dove tree or handkerchief tree from the 2 large, white bracts).

##### Family Nyssaceae (Nyssa or gum family)

A somewhat nondescript group of trees or shrubs with simple, alternate, entire-margined or toothed leaves lacking stipules. Flowers very small, bisexual or more commonly unisexual. Male flowers in inflorescences varying from heads or spikes to racemes or umbels; female and bisexual flowers solitary or in few-flowered heads. Sepals 5 or more or absent. Petals usually 5 but occasionally from 4 to 8, imbricate; stamens 5 to 10 and typically arranged in 2 series if more than 5. Ovary constantly with 1 locule and 1 ovule. Style and stigma solitary. Seeds with scanty endosperm. Fruit a drupe in *Nyssa*, samara-like (*i.e.*, somewhat like the winged "keys" of maples) in *Camptotheca*. Two genera: *Nyssa*, with about 10 species in the Northern Hemisphere, and *Camptotheca*, with one species in China and Tibet.

##### Family Alangiaceae

Distinctive trees or shrubs with alternate, simple or lobed, often asymmetrical leaves lacking stipules. Flowers set on jointed pedicels (stalks) and disposed in axillary cymes. Sepals and petals 4 to 10, sepals generally more or less fused; petals generally free, or sometimes coherent below, very narrow and ribbonlike, valvate, frequently finally recurved, and

Related  
orders

Use of  
pollen in  
Cornales  
classification

more or less hairy on the inner surface. Stamens as many as, and alternate with, the petals, or up to 4 times as many; also hairy within. Ovary 1- or 2-locular, with 1 locule, 1 ovule, and a single style. Fruits drupaceous and crowned by the persistent sepals and disk. One genus (*Alangiurn*) with about 20 species in the Old World tropics.

#### Family Toricelliaceae

Small trees with alternate, palmately lobed or toothed leaves, broadly sheathing at the base. Flowers white, dioecious, small; disposed in lax, pendulous thyrses (contracted, compact panicle-like clusters). Petals 5, induplicate-valvate (with inrolled edges that touch but do not overlap), with elongate, inflexed tips. Stamens generally 5. Ovary 4-locular. One genus (*Toricellia*) with 3 species in the Himalayas and China.

#### Family Mastixiaceae

Trees with entire, alternate or opposite, leaves lacking stipules. Flowers small, in terminal panicles. Petals 4 or 5, valvate, but inflexed at the tip and fringed or bidentate—notched, having 2 "teeth." Stamens 4 or 5. Ovary of 2 locules; ovules 2, epitropic. One genus (*Mastixia*) with about 25 species in Southeast Asia, east to the Solomon Islands.

#### Family Helwingiaceae

Shrubs with alternate or nearly opposite, simple, toothed leaves with stipules. Stipules frequently branched. Flowers dioecious (male and female flowers are on separate plants), borne in small umbels on the upper surface of the midribs of the leaves. Male flowers clustered, females solitary or few. All flowers with 3 to 5 valvate petals and 3 to 5 stamens, alternate with the petals, inserted around a flattened, angular disk. Sepals none. Ovary 3- or 4-locular, with a single ovule in each locule. Style short, dividing into 3 or 4 stigmas. Fruit drupaceous with 3 or 4 stones. One genus (*Helwingia*) with 4 species distributed in the Himalayas and eastern Asia.

#### Family Araliaceae (ivy or ginseng family)

Mostly trees or shrubs, some climbers with aerial roots. Leaves often large, compound, usually alternate, rarely opposite or whorled. Stipules small, usually more or less fused to the leafstalks. Inflorescences usually compound umbels but sometimes spikes or racemes, or rarely with flowers solitary. Flowers typically 5-merous—petals 5, sepals 5, very small, stamens 5. Ovary inferior with 1 ovule per locule. Locules variable in number. Styles usually directly on ovary (sessile). Fruit a berry, rarely a drupe. About 55 genera and 700 species distributed mostly in Southeast Asia and tropical America.

#### Family Apiaceae (*Umbelliferae*; parsley family)

Mostly herbs with pinnately divided leaves, rarely simple, or spinous, generally having sheathing leaf bases. Flowers usually bisexual (polygamous in some genera). Sepals and petals 5. Sepals frequently small or missing. Petals frequently with a strongly inflexed apical lobe. Inflorescence an umbel or compound umbel, or flowers sometimes condensed into a tight head. Ovary bilocular, with a single ovule in each locule, surmounted by a disk, on which the styles with variously thickened style bases or "stylopodia," are set. Fruit a dry schizocarp. About 275 genera and 2,850 species distributed throughout the world, but chiefly in north temperate regions.

**Critical appraisal.** As far as the broad outline of the classification is concerned, the evidence for the unity of this order is now impressive, and it is one of the few orders that has been given attention by many disciplines. Opinions differ as to whether the family Araliaceae should be separated as an independent order (*Araliales*) from the *Cornales* in the strict sense, largely because of the differing weight of evidence given by the study of anatomy, external morphology, and other evidence.

There is much need for further serological (study of plant proteins by means of effects similar to immune reactions in animals) and comparative biochemical studies on common species and groups of species in the order and particularly for general study in the developing countries of more obscure and atypical species, which, although largely ignored because they are of no economic value, often hold the key to plant relationships.

**BIBLIOGRAPHY.** J. HUTCHINSON, "Araliales," in *The Genera of Flowering Plants*, vol. 2, pp. 41–89 (1967), includes descriptions of the genera in the families Cornaceae (under which Mastixiaceae and Toricelliaceae are also treated), Alangiaceae, Garryaceae, Nyssaceae (including Davidiaceae), and Ariliaceae (including Helwingiaceae); S. BLOEMBERGEN, "A Revision of the Genus *Alangium*," *Bull. Jard. Bot. Buitenz.*, Series 3, 16:139–235 (1939), a good revision of the larger of the two genera in the family Alangiaceae, comprising all but three of the species in the family; H. HARMS,

"Araliaceae," in A. ENGLER and K. PRANTL (eds.), *Die natürlichen Pflanzenfamilien*, 3:1–62 (1898), a good general view of the family, although out of date; R. VIGUIER, "Recherches anatomiques sur la classification des Araliacées," *Annls. Sci. Nat.*, Series 9, 4:1–207 (1906); and "Nouvelles recherches sur les Araliacées," *ibid.*, 9:305–405 (1909), two contributions forming a fairly extensive and detailed treatment of the anatomy of the family as it bears on taxonomy; W. WANGERIN, "Cornaceae," "Garryaceae," and "Nyssaceae," in A. ENGLER, *Das Pflanzenreich IV*, 229:1–110, 56a:1–17, and 220a:1–19 (1910), somewhat dated but still good treatments of these families; H. LI, "Davidia As the Type of a New Family Davidiaceae," *Lloydia*, 17:329–331 (1954), the case for treating *Davidia* as a separate family; A.S. HORNE, "The Structure and Affinities of *Davidia involucreata*, Baill.," *Trans. Linn. Soc. Lond.*, 2nd Series, 7:303–326 (1909), a classic study on the internal and external morphology of this remarkable plant; F.A. HALLOCK, "The Relationship of *Garrya*," *Ann. Bot.*, 44: 771–812 (1930), a thorough and detailed study of *Garrya*, supporting Engler's position for the Garryaceae; R.H. EYDE, "Morphological and Paleobotanical Studies of the Nyssaceae. I. A Survey of the Modern Species and Their Fruits," *J. Arnold Arb.*, 44:1–59 (1963); and with E.S. BARCHORN, "... of the Nyssaceae. II. The Fossil Record," *ibid.*, pp. 328–376 (1963), important studies involving *Mastixia* and *Davidia* as well as the family Nyssaceae in the strict sense; O. DRUDE, "Umbelliferae," in *Die natürlichen Pflanzenfamilien*, 3:63–250 (1898), an excellent review of the family, not yet superseded; H. WOLFF, "Umbelliferae (Saniculoideae, Apioideae, Ammineae)," in *Pflanzenreich IV*, vol. 228, pt. 43, 61, and 90 (1910–27), the standard work on these tribes, thorough and reliable.

(C.C.T.)

## Corneille, Pierre

Not only did Pierre Corneille produce, for nearly 40 years in all, an astonishing variety of plays to entertain the French court and the Parisian middle class: he also prepared the way for a dramatic theatre that was the envy of Europe throughout the 17th century. His own contribution to this theatre, moreover, was that of master as much as of pioneer. Corneille's excellence as a playwright has long been held to lie in his ability to depict personal and moral forces in conflict. In play after play, dramatic situations lead to a finely balanced discussion of controversial issues. Willpower and self-mastery are glorified in many of his heroes, who display a heroic energy in meeting or mastering the dilemma that they face; but Corneille was less interested in exciting his audiences to pity and fear through visions of the limits of man's agony and endurance than he was in stirring them to admiration of his heroes. Thus, only a few of his plays deal in tragic emotion. Nevertheless, because his most famous work, *Le Cid*, anticipated the tragic intensity of plays by Jean Racine, his younger contemporary, Corneille has often been referred to as the "father" of French classical tragedy; and his contribution to the rise of comedy has, in comparison, often been overlooked. From a 20th-century vantage point, however, it is as a master of drama that he appears, rather than of tragedy in particular.

**Early success.** Pierre Corneille was born in Rouen, in northern France, on June 6, 1606, of a well-to-do, middle class Norman family. His grandfather, father, and an uncle were all lawyers; another uncle and a brother entered the church; his younger brother, Thomas, became a well-known poet and popular playwright. Pierre was educated at the Jesuit school in his home town, won two prizes for Latin verse composition, and became a licentiate in law. From 1628 to 1650 he held the position of king's counsellor in the local office of the department of waterways and forests.

Corneille's first play, written before he was 20 and apparently drawing upon a personal love experience, was an elegant and witty comedy, *Mélie*, first performed in Rouen in 1629. When it was repeated in Paris the following year, it built into a steady (and, according to Corneille, surprising) success. His next plays were comedies: *Clitandre* (performed 1631), *La Veuve* and *La Galerie du palais* (1632), *La Suivante* and *La Place royale* (1634), and *L'Illusion comique* (1635). His talent, meanwhile, had come to the attention of the cardinal de

Clichee Musees Nationaux, Paris

Richelieu, France's great statesman, who included the playwright among a group known as *les cinq auteurs* ("society of the five authors"), which the Cardinal had formed to have plays written, the inspiration and outline of which were provided by himself. Corneille was temperamentally unsuited to this collective endeavour and irritated Richelieu by departing from his part (Act III) of the outline for *La Comédie des Tuileries* (1635). In the event, Corneille's contribution was artistically outstanding.

During these years, support had been growing for a new approach to tragedy that aimed at "regularity" through observance of what were called the "classical" unities. Deriving from Italy this doctrine of the unities demanded that there be unity of time (strictly, the play's events were to be limited to "the period between sunrise and sunset"), of place (the entire action was to take place in the one locus), and of action (subplots and the dramatic treatment of more than one situation were to be avoided). All this was based on a misunderstanding of Aristotle's *Poetics*, in which the philosopher attempted to give a critical definition of the nature of tragedy. The new theory was first put into dramatic practice in Jean Mairet's *Sophonisbe* (1634), a tragedy that enjoyed considerable success. Corneille, not directly involved in the call for regular tragedy of this kind, nevertheless responded to *Sophonisbe* by experimenting in the tragic form with *Médée* (1635). He then wrote *Le Cid* (performed early 1637), first issued as a tragicomedy, later as a tragedy.

*Le Cid*, now commonly regarded as the most significant play in the history of French drama, proved an immense popular success. It sparked off a literary controversy, however, which was chiefly conducted by Corneille's rival dramatists, Mairet and Georges de Scudéry, and which resulted in a bitter pamphlet war. Richelieu, whose motives are not entirely clear, instructed the then recently instituted Académie Française to make a judgment on the play: the resulting document (*Les Sentiments de l'Académie française sur la tragi-comédie du Cid*, 1637), drafted in the main by Jean Chapelain, a critic who advocated "regular" tragedy, was worded tactfully and admitted the play's beauties but criticized *Le Cid* as dramatically implausible and morally defective. Richelieu used the judgment of the Académie as an excuse for suppressing public performances of the play.

Corneille, indeed, had not observed the dramatic unities in *Le Cid*. The play has nevertheless been generally regarded as the first flowering of French "classical" tragedy. For the best French drama of the "classical" period in the 17th century is properly characterized, not so much by rules—which are no more than a structural convention—as by emotional concentration on a moral dilemma and on a supreme moment of truth, when leading characters recognize the depth of their involvement

in this dilemma. In *Le Cid*, Corneille rejected the discursive treatment of the subject given in his Spanish source (a long, florid, and violent play by Guillén de Castro y Bellvis, a 17th-century dramatist), concentrating instead on a conflict between passionate love and family loyalty, or honour. Thus *Le Cid* anticipated the "pure" tragedy of Racine, in whose work the "classical" concept of tragic intensity at the moment of self-realization found its most mature and perfect expression.

**Major tragedies.** Corneille seems to have taken to heart the criticisms levelled at *Le Cid*, and he wrote nothing for three years (though this time was also taken up with a lawsuit to prevent the creation of a legal office in Rouen on a par with his own). In 1640, however, appeared the Roman tragedy *Horace*; another, *Cinna*, appeared in 1641. In 1641 also Corneille married Marie de Lampérière, the daughter of a local magistrate, who was to bear him seven children to whom he was a devoted father. Corneille's brother Thomas married Marie's sister, and the two couples lived in extraordinary harmony, their households hardly separated; the brothers enjoyed literary amity and mutual assistance.

*Le Cid*, *Horace*, *Cinna*, and *Polyeucte*, which appeared in 1643, are together known as Corneille's "classical tetralogy," and together represent perhaps his finest body of work for the theatre. *Horace* was based on an account by the Roman historian Livy of a legendary combat between members of the Horatii and Curiatii families, representing Rome and Alba; Corneille, however, concentrated on the murder by one of the patriots of his pacifist sister, the whole case afterward being argued before the king (a "duplicity" of action admitted by Corneille himself, who otherwise seems by now to have decided to follow the classical rules). *Cinna* was about a conspiracy against the first Roman emperor, Augustus, who checkmates his adversaries by granting them a political pardon instead of dealing them the expected violent fate, boasting that he has strength enough to be merciful. The hero of *Polyeucte* (which many critics have considered to be Corneille's finest work), on adopting Christianity seeks a martyr's death with almost militaristic fervour, choosing this as the path to *la gloire* ("glory") in another world, whereas his wife insists that the claims of marriage are as important as those of religion.

These four plays are charged with an energy peculiar to Corneille. Their arguments, presented elegantly, rhetorically, in the grand style, remain firm and sonorous. The alexandrine verse that he employed (though not exclusively) was used with astonishing flexibility as an instrument to convey all shades of meaning and expression: irony, anger, soliloquy, repartee, epigram. Corneille used language not so much to illumine character as to heighten the clash between concepts, hence the "sentences" in his poetry which are memorable even outside their dramatic context. Action here is reaction. These plays concern not so much what is done as what is resolved, felt, suffered. Their formal principle is symmetry: presentation, by a poet who was also a lawyer, of one side of the case then of the other, of one position followed by its opposite.

**Contribution to comedy.** The fame of his "classical tetralogy" has tended to obscure the enormous variety of Corneille's other drama, and his contribution to the development of French comedy has not always received its proper due. The Roman plays were followed by more tragedies: *La Mort de Pompée* (1643), *Rodogune* (1645), which was one of his greatest successes, *Théodore* (1646), which was his first taste of failure, and *Héraclius* (1647). But in 1643 Corneille had successfully turned to comedy with *Le Menteur*, following it with the less successful *La Suite du Menteur* (1643–44). Both were lively comedies of intrigue, adapted from Spanish models; and *Le Menteur* is the one outstanding French comedy before the plays of Molière, Corneille's young contemporary, who acknowledged its influence on his own work. *Le Menteur*, indeed, stands in relation to French classical comedy much as *Le Cid* does to tragedy.

In 1647, Corneille moved with his family to Paris and

Corneille's  
"classical  
tetralogy"

Success of  
*Le Cid*

was at last admitted to the *Académie Française*, having twice previously been rejected on the grounds of non-residence in the capital. *Don Sanche d'Aragon* (1649), *Andromède* (1650), a spectacular play in which stage machinery was very important, and *Nicomède* (1651) were all written during the political upheaval and civil war of the period known as the Fronde (1648–53), with *Don Sanche* in particular carrying contemporary political overtones. In 1651 or 1652 his play *Pertharite* seems to have been brutally received, and for the next eight years Corneille wrote nothing for the theatre, concentrating instead on a verse translation of St. Thomas à Kempis' *Imitatio Christi* (*Imitation of Christ*), which he completed in 1656, and also working at critical discourses on his plays that were to be included in a 1660 edition of his collected works.

**Years of declining power.** Corneille did not turn again to the theatre until 1659, when, with the encouragement of the statesman and patron of the arts Nicolas Fouquet, he presented *Oedipe*. For the next 14 years he wrote almost one play a year, including *Sertorius* (1662) and *Attila* (1667), both of which contain an amount of violent and surprising incident.

Last plays

Corneille's last plays, indeed, were closer in spirit to his works of the 1640s than to his classical tragedies. Their plots were endlessly complicated, their emotional climate close to that of tragicomedy. Other late plays include *La Toison d'or* (1660), his own *Sophonisbe* (1663), *Othon* (1664), *Agésilas* (1666), and *Pulchérie* (1672). In collaboration with Molikre and Philippe Quinault he wrote *Psyché* (1671), a play employing music, incorporating ballet sequences, and striking a note of lyrical tenderness. A year earlier, however, he had presented *Tite et Bérénice*, in deliberate contest with a play on the same subject by Racine. Its failure indicated the public's growing preference for the younger playwright.

Corneille's final play was *Suréna* (1674), which showed an uncharacteristic delicacy and sentimental appeal. After this he was silent except for some beautiful verses, which appeared in 1676, thanking King Louis XIV for ordering the revival of his plays. Although not in desperate poverty, Corneille was by no means wealthy; and his situation was further embarrassed by the intermittent stoppage of a state pension that had been granted by Richelieu soon after the appearance of *Horace* in 1640. Corneille died in his house on the rue d'Argenteuil, Paris, on October 1, 1684, and was buried in the church of Saint-Roch. No monument marked his tomb until 1821.

**Assessment.** Corneille did not have to wait for "the next age" to do him justice. The cabal that had led the attack on *Le Cid* had no effect on the judgment of the public, and the great men of his time were his fervent admirers. Balzac praised him; Molière acknowledged him as his master and as the foremost of dramatists; Racine is said to have assured his son that Corneille made verses "a hundred times more beautiful" than his own. It was left to the 18th century, largely because of the criticisms of Voltaire, to exalt Racine at Corneille's expense; but the Romantic critics of the late 18th century began to restore Corneille to his true rank.

It cannot be denied, however, that Corneille signed much verse that is dull to mediocre. Molikre acknowledged this fact by saying: "My friend Corneille has a familiar who inspires him with the finest verses in the world. But sometimes the familiar leaves him to shift for himself, and then he fares very badly." But the importance of his pioneer work in the development of French classical theatre cannot be denied; and, if a poet is to be judged by his best things, Corneille's place among the great dramatic poets is beyond question.

#### MAJOR WORKS

PLAYS: *Le Cid* (published 1637); *Horace* (1641); *Cinna, ou La Clemence d'Auguste* (1643); *Polyeucte martyr* (1643); *La Mort de Pompée* (1644)—all in English in *The Chief Plays of Corneille*, trans. by Lacy Lockert, 2nd ed. (1957). *Rodogune, princesse des Parthes* (1647; *Rodogune*; or, *The Rival Brothers*, trans. by S. Aspinwall, 1765); *Nicomède* (1651; *Nicomede*, trans. by J. Dancer, 1671).

BIBLIOGRAPHY. The standard edition of the dramatist's work, *Oeuvres de P. Corneille*, ed. by CHARLES MARTY-

LAVEAUX, 13 vol. (1862–68), is still generally reliable, although a number of more recent editions—by MAURICE RAT (1962–66), and by JACQUES MAURENS (1968)—have profited from extensive work by modern scholars on dating and various historical aspects. A number of convenient one- or two-volume modern editions are available, notably *Oeuvres complètes*, ed. by ANDRÉ STEGMANN (1963). Many of the plays have also been published in critical editions (see list in ALEXANDRE CIORANESCU, *Bibliographie de la littérature française du 17<sup>e</sup> siècle*, 1965). Adequate modern translations into English have been provided by LACY LOCKERT, *The Chief Plays of Corneille*, 2nd ed. (1957) and *Moot Plays of Corneille* (1959); and more recently by SAMUEL SOLOMON, *Pierre Corneille: Seven Plays* (1969). Modern criticism of Corneille has begun to reverse the monotonous, reductionist view first set forth in Voltaire's *Commentaires sur Corneille* (1751) that had cast him chiefly as Racine's precursor in the perfecting of French classical tragedy. For a comprehensive sampling of the Corneille-Racine parallels across the centuries, see *Corneille and Racine: Parallels and Contrasts*, ed. by ROBERT J. NELSON (1966). A judicious corrective to the Voltairian bias informs both GEORGES MAY, *Tragedie cornélienne, tragédie racinienne* (1948); and OCTAVE NADAL's seminal *Le Sentiment de l'amour dans l'oeuvre de Pierre Corneille* (1948). The two-volume study by ANDRÉ SIEMANN, *L'Héroïsme cornélien—genèse et signification* (1968), offers a learned, penetrating discussion of Corneille in the religious and political setting of his own time; while, in *Corneille et la dialectique du héros* (1963), SERGE DOUBROVSKY reviews the dramatist's intellectual and political outlook in a frankly modern perspective. HENRY CARRINGTON LANCASTER, *History of French Dramatic Literature in the Seventeenth Century*, 9 vol. (1929–42), is still useful on sources, influences, editions, and theatrical history. A more compact survey of the same aspects, with greater and more thoughtful attention to problems of interpretation, may be found in PHILIP YARROW, *Corneille* (1963). For a more specialized study of Corneille's themes, particularly the dramatist's conception of tragedy and his place in the history of the genre, see ROBERT J. NELSON, *Corneille: His Heroes and Their Worlds* (1963). Finally, brilliant if controversial reevaluations of the dramatist in the larger setting of 17th-century thought and letters are contained in E.B.O. BORGERHOFF, *The Freedom of French Classicism* (1950); and in W.G. MOORE, *French Classical Literature: An Essay* (1961). Bibliographies of the author and his works include AUGUSTE-EMILE PICOT, *Bibliographie cornélienne . . .* (1876); and PIERRE LE VERDIER and EDOUARD PELEY, *Additions à la bibliographie cornélienne* (1908), which are both still useful. Also, a number of more recent general bibliographies, such as *A Critical Bibliography of French Literature*, vol. 3, *The Seventeenth Century*, ed. by NATHAN EDELMAN (1961), contain extensive, updated sections on the dramatist.

(R.J.N.)

## Corot, Jean-Baptiste-Camille

Camille Corot, as he liked to be called, was a 19th-century French painter of landscape and, to a lesser extent, of figure subjects. He began his long career as an exponent of the classical tradition of idealized Italian landscape, as exemplified by the 17th-century French masters Nicolas Poussin and Claude Lorrain, and he ended it as the contemporary and friend of the Impressionists, whose new and revolutionary landscape art he inspired and, in certain respects, anticipated.

Jean-Baptiste-Camille Corot was born of prosperous, bourgeois parents in Paris on July 16, 1796. His mother, who was Swiss born, had a fashionable milliner's shop, which Corot's father—a draper by trade—helped to manage. Camille was a poor scholar and even less adept when he tried to follow his father's trade. Finally, at the age of 25, he was given a small allowance by his father and allowed to become what he had always dreamed of being: a painter.

Like every young French artist, Corot spent much time studying the paintings in the Louvre, and he had some private instruction from Achille-Etna Michallon and Jean-Victor Bertin, who were both followers of the Neo-classical landscape painter Pierre-Henri de Valenciennes. From the beginning, however, Corot preferred to sit outdoors, sketching what he saw and learning by firsthand experience.

In the autumn of 1825 Corot went to Rome, and the three years that he spent there were the most important of his life. He painted the city and the Campagna, the

The  
Roman  
years:  
1825–28

countryside around Rome; he made a trip to Naples and Ischia; and he returned to Paris by way of Venice. He was very happy. He told a friend in August 1826: "All I really want to do in life . . . is to paint landscapes. This firm resolve will stop me forming any serious attachments. That is to say, I shall not get married." He was as good as his word and never married. Female companionship played no part in his life, which was entirely devoted to painting.

Corot, photographed by Eugene Dutiileux at Arras, France, 1871.

Back in France, Corot settled into a routine to which he kept for the whole of his life. He always spent the spring and summer months painting outside, making small oil sketches and drawings from nature. He acquired a mastery of tonal relationships that formed the basis of his art, for the balance and gradation of light and dark tones was always more important to him than the choice of colour. In the winter Corot would retire to his Paris studio to work on some much larger pictures, which he liked to have ready for exhibition at the annual Salon when it opened in May.

His first important work, "Le Pont de Narni," was shown at the Paris Salon in 1827, when he was still in Italy. In 1833 he exhibited a large landscape of the forest of Fontainebleau, which was awarded a second-class medal: this gave Corot the right to show his pictures without submission to the jury for their approval.

From May to October of 1834 Corot made his second visit to Italy. He painted views of Volterra, Florence, Pisa, Genoa, Venice, and the Italian lake district. He collected enough material in small sketches to last him the rest of his life, although he returned to Italy briefly in the summer of 1843, for the last time.

Apart from these visits to Italy, Corot had an exceptionally uneventful life. As a young man he had travelled widely in the provinces of France, sketching wherever he went. When he grew older he moved around less. Important trips were made to Avignon and the south of France in 1836, to Switzerland in 1842 and on several other occasions, to The Netherlands in 1854, and to London in 1862. His favorite regions of France were the forest of Fontainebleau, Brittany, the Normandy coast, the family property at Ville-d'Avray near Paris, and, later in life, Arras and Douai—in the north of France—where close friends lived.

Throughout his life Corot liked occasionally to paint straightforward topographical landscapes, depicting buildings such as the cathedral at Chartres (1830) or the belfry at Douai (1871) exactly as they appeared to him. But the basic division in his work was between the sketch made from nature—small, direct, spontaneous—and the

large finished picture done for the Salon. In the early 19th century the sketch was thought not to be suitable for public exhibition, and there were only a few connoisseur collectors who would buy such pictures. The finished landscapes were preferred. These were considered even more dignified and serious if they included a few small figures who could be identified with the heroic characters of legend, literature, or the Bible. Thus, Corot exhibited pictures with such titles as "Hagar in the Wilderness" (Salon 1835), "Diana Surprised by Actaeon" (Salon 1836), "Homer and the Shepherds" (Salon 1845), and "Christ in the Garden of Olives" (Salon 1849).

He was not really very interested in such subject matter, however, and, as tastes changed in the middle of the century, he bothered less about it. He was happy to introduce pretty young girls into the landscape, showing them as shepherdesses or sometimes, more daringly, as nude or half-dressed bathers, dipping their delicate feet in a pool. In the 1860s he invented a new kind of landscape, the "Souvenirs," in which he made compositions out of standardized elements—usually a lake with diaphanous trees painted in an overall silvery tonality—to evoke a mood of gentle melancholy. At the end of his life, he also painted a number of portraits and figure studies, especially of young women posed in his studio holding a flower or a musical instrument or looking at a landscape on the easel. These more private pictures Corot almost never exhibited.

During the 1830s Corot showed regularly at the Paris Salon and had some critical success. Yet he sold very few pictures and was glad of his father's allowance. Then, in 1840, the state purchased one of his exhibits, "The Little Shepherd" ("Le Petit Berger"), and, five years later, the poet and art critic Charles Baudelaire could write in his review of the 1845 Salon that "Corot stands at the head of the modern school of landscape." In 1846 he was made a member of the Legion of Honour, and, when his father died, in 1847, Corot was able to feel that he had justified the family's support of his ambition to be a painter.

By the 1850s, collectors and dealers were eagerly seeking his pictures, and Corot henceforth had no material worries. He went on sending big pictures to the salons, where they fetched high prices. At the 1855 Paris Universal Exhibition he was awarded a first-class medal for painting, and Emperor Napoleon III bought a picture from him. In 1867 he was promoted to officer of the Legion of Honour. But taste was changing, and private collectors, especially in the United States, began to buy Corot's smaller, sketchier work. Though he was a prolific artist and painted over 3,000 pictures, demand outran supply, and Corot was much imitated and faked. In the 20th century, appreciation of Corot has shifted again to show a marked preference for the earlier, more naturalistic sketches over the later, more self-consciously poetic ones. The big Salon paintings have remained firmly out of fashion, though their qualities are not negligible.

Success made little difference to Corot, who was a man of extremely conservative habits. He always worked very hard because he loved his work, and this left him little time for other things. In old age he suffered from gout, but otherwise his health was good. He never read newspapers and took no interest in politics. The revolutions and changes of regime in his time passed him by. Altogether, he read little and showed no intellectual curiosity. He was very fond of music, especially Haydn, Mozart, Gluck, and Beethoven, and he regularly attended concerts when he was in Paris. He liked to talk about the harmonies of his painting, and his late work in particular aspires to the qualities of music. He kept the modern world firmly out of his pictures: the people in his landscapes are timeless peasant figures or characters from myth and literature. There is never a sign of the vast railway network that covered France in his lifetime or of the industrial and commercial development that transformed the country.

Corot enjoyed the company of fellow painters and was a close friend of the Barbizon group of artists, especially

sionists

Jean-François Millet, Theodore Rousseau, and Charles-François Daubigny. He used his money to give unostentatious help to less successful friends, such as the cartoonist Honoré Daumier. Without going out of his way to support them publicly, Corot was sympathetic to younger painters. He gave lessons to the later Impressionists Camille Pissarro and Berthe Morisot and had many pupils and disciples. "Papa Corot" was universally loved for his unflinching kindness and generosity. He died in Paris on February 22, 1875.

Corot's place in the history of 19th-century painting is an assured one. He is no longer regarded as a major master, but his contribution was essential. If many of his larger pictures look empty and rhetorical, his unpretentious paintings are a constant delight because of the freshness of their observation and the effortless ease of technique. When he started painting, the landscape sketch was regarded primarily as raw material for more important work and was of no great artistic consequence in itself. Corot was one of the first to show that the sketch has qualities of vitality and spontaneity, a basic truth to nature that a more finished picture lacks. At the time of his death the sketch had triumphed, and any artificiality in landscape painting was regarded with suspicion. Corot helped to prepare the way for the Impressionist landscape painters, who learned much from him and who looked upon him with respect and veneration.

#### MAJOR WORKS

"Portrait de l'artiste à l'âge de vingt-neuf ans" ("Self-Portrait at the Age of 29"; 1825; Louvre, Paris); "Landscape: Le Petit Chaville, near Ville-d'Avray" (1823-25; Ashmolean Museum, Oxford); "View of the Forum from the Farnese Gardens" (1826; Louvre); "Old Man Sitting in Corot's Studio, Rome" (1826; Museum of Fine Arts, Boston, Massachusetts); "Le Pont de Narni" ("The Bridge at Narni"; 1826-27; National Gallery of Canada, Ottawa); "The Roman Campagna, with the Claudian Aqueduct" (1826-28; National Gallery, London); "Italian Monk Reading" (1827; Albright-Knox Art Gallery, Buffalo, New York); "Façade ouest de la Cathédrale de Chartres" (1830; Louvre); "View of Soissons" (1833; Rijksmuseum Kröller-Müller, Otterlo, The Netherlands); "View of Genoa" (1834; Art Institute of Chicago); "Hagar in the Wilderness" (1834-35; Metropolitan Museum of Art, New York); "Diana Surprised by Actaeon" (1836; Musée des Beaux-Arts, Bordeaux); "A View near Volterra" (1838; National Gallery of Art, Washington, D.C.); "The Little Shepherd" ("Le Petit Berger"; 1840; Musée de Metz, Metz, France); "Les Bords du Cousin" (c. 1840-45; Louvre, Paris); "Marietta 'L'Odalisque Romaine'" (1843; Musée du Petit Palais, Paris); "Homer and the Shepherds" (1845; Musée d'Art, Saint-LB, France); "The Forest of Fontainebleau" (1846; Museum of Fine Arts, Boston); "La Danse des nymphes" (1850; Louvre); "Bretonnes à la fontaine" (early 1850s; Louvre); "Le Port de La Rochelle" ("The Harbor of La Rochelle"; 1851; Yale University Art Gallery, New Haven, Connecticut); "Entree de village (environs de Beauvais du côté de Voinsinlieu)" (c. 1855-60; Louvre); "Portrait de Maurice Robert enfant" (1857; Louvre); "Macbeth and the Witches" (1859; Wallace Collection, London); "Jeune fille à sa toilette" (c. 1860-65; Louvre); "Souvenir de Mortefontaine" (1864; Louvre); "L'atelier" (1865-68; Louvre); "La Femme à la perle" (c. 1868-70; Louvre); "Le Coup de vent" ("The Gust of Wind"; c. 1865-70; Musée Saint-Denis, Reims, France); "Mademoiselle de Foudras" (1872; Glasgow Art Gallery and Museum); "La Charrette—Souvenir de Saintry" (1874; National Gallery, London); "La Dame en bleu" (1874; Louvre).

**BIBLIOGRAPHY.** The standard work is *L'Oeuvre de Corot*, 4 vol. (1905; reprinted with additional materials and documents, 5 vol., 1965), a complete catalog by ALFRED ROBAUT, with a biographical introductory volume by ETIENNE MOREAU NELATON. There are also two supplementary volumes by ANDRE SCHOELLER and JEAN DIETERLE (1948 and 1956). *Corot, raconté par lui-même et par ses amis*, 2 vol., ed. by PIERRE COURTHION and PIERRE CAILLER (1946), is a useful collection of source material and letters. No serious study of Corot exists in English. The best monograph is GERMAIN BAZIN, *Corot* (1942), in French.

(Al.Bo.)

## Corporation, Business

In terms of its size, influence, and visibility, the corporation has become the dominant business form in Western

industrial countries. Corporations may be large or small, ranging from firms having hundreds of thousands of employees to neighbourhood businesses of very modest proportions. Several hundred giant companies, however, play a preponderant economic role in the United States, Canada, Japan, and the nations of western Europe. These firms not only occupy important positions in the economy; they have great social, political, and cultural influence as well. Both at home and abroad they affect the operations of governments, influence local communities and entire societies, and help shape the values of ordinary individuals. Although in fact and in law corporate businesses are private enterprises, their activities have public consequences that are as pervasive as those of many governments. No account will be taken here of the so-called public corporations that have developed in recent decades in a number of countries. (Such government bodies, including the Tennessee Valley Authority and the Port Authority of New York and New Jersey in the United States and the National Coal Board in the United Kingdom, are discussed in PUBLIC ENTERPRISES.)

Business enterprises customarily take one of three forms: individual proprietorships, partnerships, and corporations. In the first of these, one person holds the entire firm as personal property, and, in most instances, manages it on a day-to-day basis. Of the nearly 15,000,000 businesses in the United States in the late 1970s, more than three-quarters were proprietorships, the overwhelming majority of which had annual receipts of less than \$50,000. A partnership may have from two to 50 or more members, as in the case of large law and accounting firms, brokerage houses, and advertising agencies. This form of business is owned by the partners themselves, although they may receive varying shares of the profits depending on their investment or contribution. Whenever a member leaves or a new member is added, the firm must be reconstituted as a new partnership.

The corporate arrangement is more complex. A corporation may be regarded as an association of assets, chartered under law, that is owned by individuals or institutions who have purchased shares representing fractions of the firm's holdings. Thus, a person owns part of a corporation only as long as he retains shares in the company; and a corporation maintains its independent existence even if its stock changes hands, as it often does. The degree to which stockholders participate in the operation of their company varies, usually according to the firm's size. In the late 1970s the United States had more than 2,240,000 corporations, but more than three-quarters of them did an annual business of less than \$500,000. At the other end of the spectrum, 275,000 larger corporations accounted for more than 90 percent of all corporation business, and in the late 1970s the 200 largest industrial companies in the United States accounted for almost one-half of the profits earned in manufacturing. Some relatively small firms are, in fact, corporations; for example, a local grocery store or a dry-cleaning business or even a taxicab may be incorporated, with a proportion of its shares owned by a few friends or relatives of the person who actually runs it. But the focus of this article is on the small circle of companies commanding substantial assets, sales, and earnings.

#### EARLY HISTORY OF THE CORPORATION

The corporation is a relatively recent innovation. Only since the mid-19th century have incorporated businesses risen to ascendancy over other types of ownership. Thus, any attempt to trace the forerunners of the modern corporation should be distinguished from a general history of business or a chronicle of associated activity. People have embarked on enterprises for profit and have joined together for collective purposes since the beginning of recorded history, but early enterprises are related to contemporary corporations only in the sense that new developments always embody some practices from the past. When a group of Athenian or Phoenician merchants pooled their savings to build or charter a trading vessel, their organization was not a corporation but a partnership. There is no evidence that ancient societies had laws

Forms of  
business  
enterprises

Corpora-  
tions in the  
Middle  
Ages

of incorporation specifying the scope and standards of business activity.

The corporate form itself developed in the early Middle Ages with the growth and codification of civil and canon law. Several centuries passed, however, before business ownership was subsumed under this arrangement. The first corporations were towns, universities, and ecclesiastical orders. They differed from partnerships in that they existed independently of any particular membership; but they were not, like modern business corporations, the "property" of their participants. The holdings of a monastery, for example, belonged to the order itself; no individual owned shares in its assets. The same was true of medieval guilds, which dominated many trades and occupations. As corporate bodies they were chartered by government, and their business practices were regulated by public statutes; but each guild member was an individual proprietor who ran his own establishment, and, though many guilds had substantial properties, these properties were the historic accruals of the associations themselves. By the 15th century the courts of England had agreed on the principle of "limited liability": *Si quid universitati debetur, singulis non debetur, nec quod debet universitas, singuli debent* ("If something is owed to the group, it is not owed to the individuals nor do the individuals owe what the group owes"). Originally applied to guilds and municipalities, this principle set limits on how much an alderman of the Liverpool Corporation, for example, might be called upon to pay if the city ran into debt or bankruptcy. As applied later to stockholders in business corporations, it served to encourage investment because the most an individual could lose in the event of the firm's failure would be the actual amount the person had originally paid for his shares.

Mercan-  
tilist  
corpora-  
tions

The actual incorporation of business enterprises began in England during the Elizabethan era. This was a period when businesses were beginning to accumulate substantial surpluses, and overseas exploration presented itself as an investment opportunity. This was also an age that gave overriding regulatory powers to the state, which sought to ensure that business activity was consonant with current mercantilist conceptions of national prosperity. Thus, the first joint-stock companies, while financed with private capital, were created by public charters that set down in detail the activities in which the enterprises might operate. In 1600 Queen Elizabeth I granted to a group of investors headed by the Earl of Sunderland the right to be "one body corporate," known as the Governor and Company of Merchants of London, trading in the East Indies. The East India Company was given a trading monopoly in its territories and was also given the authority to make and enforce laws in the areas it entered. The East India Company, the Royal African Company, the Hudson's Bay Company, and similar incorporated firms were semi-public enterprises acting as arms of the state, as well as vehicles for private profit. The same principle held with colonial charters in North America. In 1606 the crown vested in a syndicate of "loving and well-disposed Subjects" the right to develop Virginia as a royal domain, including the power to coin money and to maintain a military force. The same was done, in subsequent decades, for the "Governor and Company of the Massachusetts Bay in New England," and for William Penn's "Free Society of Traders" in Pennsylvania.

Much of North America's settlement was initially underwritten as a business venture. But if British investors accepted the regulations in their charters, North American entrepreneurs were apt to regard such rules as repressive and unrealistic. The American Revolution was largely directed against the tenets of the mercantilist system, raising serious questions about the idea of a direct tie between business enterprise and public policy. One result of the U.S. War of Independence, therefore, was to establish the premise that a corporation need not show that its activities advance a specific public purpose. Alexander Hamilton, the first secretary of the treasury and an admirer of Adam Smith, took the view that businesses should be encouraged to explore their own avenues of enterprise. "To cherish and stimulate the activity of the

human mind, by multiplying the objects of enterprise, is not among the least considerable of the expedients by which the wealth of a nation may be promoted," he wrote in 1791.

The corporate revolution did not occur overnight. For a long time, both in Europe and in the United States, the corporation was regarded as a creature of government and monopoly. In the United States new state legislatures granted charters principally to public-service companies intending to build or operate docks, bridges, turnpikes, canals, and waterworks, as well as to banks and insurance companies. Of the 335 companies receiving charters prior to 1800, only 13 were firms directly engaging in commerce or manufacturing. By 1811, however, New York had adopted a general act of incorporation, setting the precedent that businesses had only to provide a summary description of their intentions for permission to launch an enterprise. By the 1840s and 1850s, the rest of the states had followed suit. In Great Britain after 1825, the statutes were gradually liberalized so that the former privilege of incorporating joint-stock companies became the right of any group that complied with certain minimum conditions, and the principle of limited liability was extended to them. In France and Germany a similar development occurred.

#### DEVELOPMENT OF U.S. CORPORATIONS

Pools, trusts, and holding companies. In the United States the corporation took its present form in the late 19th century. Transcontinental railroad lines needed massive infusions of capital and depended on public stock issues. A great spur to incorporation was the Supreme Court case of *Santa Clara County v. Southern Pacific Railroad* in 1886 when the court ruled for the first time that a corporation should be construed as a "person" and was thus entitled to the protection of the Fourteenth Amendment of the U.S. Constitution, which declares: "nor shall any State deprive any person of life, liberty, or property, without due process of law." Under this interpretation, many laws seeking to govern corporate practices were declared to be violations of "due process" and hence unconstitutional.

During the 1880s and 1890s huge companies developed to serve an emerging national market; the creation of pools, trusts, and holding companies to keep prices high and competition limited; and the appearance of such industrial magnates as John D. Rockefeller, Andrew Carnegie, and James J. Hill. But many large firms remained private holdings. The Carnegie Steel Company, for example, was a partnership not open to public participation, and several of Rockefeller's Standard Oil affiliates were not incorporated. Until almost the turn of the century, corporations continued to be presided over by the generation that had originally founded them: the individual entrepreneur had not yet been replaced by formal organization.

At the very end of the 19th century, investment banks began to serve as agents for industrial mergers. The half decade from 1899 to 1904 produced United States Steel, United States Rubber, American Can, and International Harvester, along with more than 2,500 other mergers—almost six times as many as had occurred in the preceding four years. By 1904, seven out of every 10 of the country's production workers were employed by incorporated businesses. The pattern in the ensuing years was one of growth and expansion by the giant firms. Between 1919 and 1939, for example, the share of net corporate income earned by the firms in the bottom 75 percent of the industrial pyramid fell by one-half; even the larger corporations composing the next 20 percent had their share of the total earnings fall by one-quarter. Since 1916, while the nation's population has little more than doubled, the number of corporations has grown more than sixfold.

The growth of conglomerate corporations. The giant firms continued to increase their sales and assets, both by expanding their markets and by absorbing smaller companies. Another period of mergers and acquisitions occurred between 1960 and 1980. Whereas from 1948 to 1959 corporate mergers averaged only 428 per year, during the

19th-  
century  
statutes

Growth  
by merger

ensuing decade the average figure rose above 1,250. In 1969 alone, 2,307 such operations took place. Between 1955 and 1980, the top 500 corporations in the United States absorbed some 4,500 smaller companies. Generally, however, these absorptions have not involved companies in the same field. While there are exceptions, such as Atlantic's merger with Richfield in 1966 and its acquisition of Sinclair Oil in 1969, the general trend has been toward diversification. Radio Corporation of America (RCA), for example, purchased the Hertz car rental agency; Columbia Broadcasting System bought Creative Playthings; and the Greyhound bus lines absorbed the Armour meat-packing company. One reason for this branching out is that antitrust laws discourage concentration in a single field. Another incentive for diversification arises when a corporation foresees limited growth in its original area. Most corporations aspire to expand their sales and assets at a rate surpassing the overall growth of the economy; if they find that the demand for their major items cannot be increased, the alternative is to embark on new ventures, which is most easily done by buying smaller companies that have growth possibilities. Thus, the Liggett Group, the makers of Chesterfield and L&M cigarettes, anticipating a levelling off of tobacco consumption, acquired Alpo dog food, J&B Scotch whisky, Brite watchbands, and Blue Lustre cleaning products. In the early 1980s Sears diversified further by purchasing Dean Witter Reynolds, a brokerage concern, while Du Pont acted to secure its petroleum supplies through the acquisition of Conoco.

Conglomerates

Diversification carried to the extreme has led to "conglomerate" corporations, which acquire and operate subsidiaries in fields often having no palpable relation to one another. Some of the more prominent conglomerates of the early 1980s were Gulf & Western Industries, Transamerica, Borg-Warner, Boise Cascade, and Textron. Perhaps the most notable conglomerate was the International Telephone and Telegraph Corporation. From 1955 to 1982, ITT rose from the country's 80th largest corporation, with annual sales of \$450,000,000, to the 13th-ranking firm, having sales in excess of \$23,800,000,000—a rise of nearly 5,200 percent. (The corporation with the greatest growth during this period, however, was Occidental Petroleum, whose sales grew from \$3,000 in 1954 to \$9,600,000,000 in 1980—an increase of nearly 320,000,000 percent.) ITT achieved its growth by absorbing such companies as Sheraton Hotels, Avis car rentals, Bobbs-Merrill publishers, Levitt and Sons builders, Continental bakeries, and Smithfield hams, as well as firms in the cellulose, vending-machine, and fire-protection fields.

By the 1970s there were indications that the conglomerate wave had reached its crest. Mergers valued at more than \$10,000,000 peaked at 1,974 in 1968, and then fell to 99 in 1977. Between 1969 and 1980, the number of mergers declined in every year except 1972. Since a conglomerate usually acquires other firms by offering its own shares in exchange for those of the smaller companies, a fall in the market value of its stock puts it in an unfavourable position for purchasing new subsidiaries. Nevertheless, conglomerates have become a permanent part of the corporate scene, bringing financial and managerial techniques unvisited earlier.

Another path to growth for U.S. corporations has been through expansion abroad. Along with the export of U.S.-made goods to other countries, there has been a marked tendency to move production closer to the market by establishing foreign subsidiaries. The Chrysler Corporation bought Rootes Motors in the United Kingdom and Simca in France; the Celanese Corporation and Dow Chemical acquired European manufacturing firms; and Jos. Schlitz Brewing Co. bought one of Belgium's largest breweries. During the 1960s more than 1,500 U.S.-owned companies in the United Kingdom produced 10 percent of that country's manufactured goods, dominating fields such as drugs, typewriters, and razor blades. One consequence has been a large annual outflow of U.S. corporate capital to purchase foreign firms or to build new facilities abroad. This kind of international expansion has not been limited to U.S. firms; European and Japanese firms are increas-

ingly acquiring assets in other countries, including the United States.

#### CHARACTERISTICS OF U.S. CORPORATIONS

In the late 1970s the 500 largest industrial corporations in the United States accounted for more than three-quarters of the net income of all manufacturing firms. One corporation, General Electric, had 402,000 employees, or nearly as many as the state and local governments of New York and Massachusetts combined. Exxon's sales exceeded \$103,000,000,000, a figure larger than the taxes collected by New York, Georgia, Indiana, Massachusetts, Minnesota, New Jersey, California, and Texas together. Companies of this size inevitably have wide-ranging effects on the world around them. Many observers believe that large corporations are as important in modern society as governments. These corporations are not only producers of goods and services but are also agents of innovative technology, participants in the political scene, and shapers of values and behaviour.

**Separation of ownership and control.** In order to buy the capital equipment necessary for new or expanded operations, corporations have traditionally gone to the investing public for funds. Almost every day, one company or another creates new shares and offers them for sale. As a result, the legal ownership of corporations has become widely dispersed. At the beginning of 1982, for example, General Electric and International Business Machines (IBM) had 524,000 and 740,000 stockholders, respectively. General Motors had more than 1,500,000, and Exxon had more than 680,000. Although large blocks of shares may be held by wealthy individuals or institutions, the total amount of stock in these companies is so large that even a very wealthy person is not likely to own more than a small fraction of it.

Dispersion of ownership

The chief effect of this dispersion has been to give effective control of the companies to their salaried managers. Although each company holds an annual meeting open to all stockholders, who may vote on corporate policy, these gatherings in fact tend to ratify on-going policy as determined by management. Even if sharp questions are asked, the presiding officers almost invariably hold enough proxies to override outside proposals. The only real recourse for dissatisfied shareholders is to sell their stock and invest in other firms. (If enough shareholders do this, of course, the price of the stock falls markedly, perhaps impelling changes in management or in company policy.) Occasionally there are "proxy battles," when attempts are made to persuade a majority of shareholders to vote against a firm's managers, but such struggles seldom involve the largest corporations. It is in the managers' interest to keep stockholders happy, because if the company's shares are regarded as a good buy, it is easy to raise additional capital through new stock issues.

Thus, if a corporation is doing well in sales and earnings, its executives have a relatively free hand. Of course, there are government regulations, competition, negotiations with unions, and the constant need to entice the consumer. Most large firms manage to make a profit even in difficult years, just as most citizens manage to support themselves and have a little left over. If a company gets into trouble, its usual course is to merge with another corporation or to borrow money. In the latter case, the lending institution may insist on a new chief executive of its own choosing. If a corporation undergoes bankruptcy and receivership, the court may appoint someone to head the operation. But managerial autonomy is the rule. The salaried executives have the discretion and authority to decide what products and services they will put on the market, where they will locate the plants and offices, how they will deal with employees, and whether and in what directions they will expand their operation. In these respects, corporate businesses are still very much "private" enterprises. Not only does their legal ownership rest with private individuals and institutions, but also the people who run them are presumed to have the right to do so. A government can only regulate business practices by passing legislation on an area-by-area basis; it has no generalized power to interfere with business operations.

Monopolistic competition

**The problem of size.** The sheer size of the largest U.S. companies has been a subject of controversy since the end of the 19th century. The enactment of the Sherman Anti-Trust Act in 1890 was an outcome of concern over the ability of a few giant firms to dominate markets and diminish competition. Despite this and other related statutes, few significant attempts have been made to break up large corporations. Some have been forced to divest themselves of one or another of their subsidiaries, however, as when Procter & Gamble had to rid itself of Clorox. American Telephone & Telegraph has been effectively divested of its computer and more advanced transmission services, which are to be established as a wholly independent subsidiary. Likewise, ITT was prevented from acquiring the American Broadcasting Corporation (ABC). If anti-trust litigation has generally avoided broad-scale attacks on corporate bigness, one reason is the difficulty of showing that size implies monopoly or restraint of trade. Even in concentrated fields there are usually two or more firms, and competition continues to prevail, albeit among giants. Alcoa, Reynolds Metals, and Kaiser dominate the aluminum market; but customers can still choose among them, and they must vie with one another for their business. General Electric, Westinghouse, and General Telephone & Electronics make about 90 percent of the country's light bulbs; and Goodyear, Firestone, and Uniroyal produce most of the tires purchased in the United States. Many observers believe that the pricing patterns among the leading firms in such industries show a lack of competitiveness; but it has been argued that competition in quality and service are as important as in price, and that consumers often have the option of shifting to the products of another industry—for example, from steel to aluminum or from glass to plastics.

Another consequence of large size is that it may limit the entry of new firms. It seems unlikely that a new domestic competitor will arise in the U.S. automobile or copper or gypsum industries during the 20th century, because the large investment required would far exceed the potential returns. But an existing corporation may enter a new field, as when Sears, Roebuck began selling insurance and IBM began manufacturing typewriters. There have also been cases in which large companies have suffered declines. The combined sales of the major meat-packing companies—Swift, Armour, and Wilson—showed no increase between 1954 and 1964, though total industrial sales almost doubled and the nation's per capita meat consumption rose. Mansfield Tire & Rubber had far lower sales in 1979 than in 1954, dropping from \$50,400,000 to \$5,600,000. The major motion-picture studios have lost out to competing forms of entertainment, mainly television, and have themselves been joined in their own area by independent producers. Thus, it can be argued that there are still opportunities for entry. Between 1960 and 1978 the number of U.S. corporations rose from 1,100,000 to more than 2,240,000, while the number of proprietorships and partnerships grew at a much slower rate. Some of the new corporations may conceivably rise to challenge the established giants. Among the 500 largest industrial corporations in 1980, 262 had been among the 500 largest 25 years before, indicating a balance between continuity and turnover. All but four of the 238 that disappeared from the top had been absorbed by other corporations; their assets, if not their identities, remained in the top ranking.

Role of technology in corporate growth

The causes of vast corporate growth have various explanations. One theory, most prominently represented by the economist John Kenneth Galbraith, sees growth as stemming from the imperatives of modern technology. Only a large firm can employ the range of talent needed for research and development in areas such as aerospace or nuclear energy, and only companies of this stature have the capacity for innovating industrial processes and entering international markets. Just as government has had to grow in order to meet new responsibilities, so have corporations found that producing for the contemporary economy calls for the intricate interaction of executives, experts, and extensive staffs of employees. Although there is certainly room for small firms, the kinds of goods and

services that the public seems to want increasingly require the resources that only a large company can acquire.

Others hold that the optimum size of an efficient firm is substantially smaller than is generally believed. George Romney, a former president of American Motors, contended that an automobile company could prosper and be profitable while producing only 200,000 cars a year. By this reasoning, most of the divisions of General Motors could be established as separate companies: Chevrolet does not gain in efficiency because of its corporate association with Pontiac and Buick. Some research has shown that profit rates in industries having many small firms are just as high as in those in which a few big companies dominate. In this view, corporate expansion stems not from technological necessity but rather from an impulse to acquire or establish new subsidiaries or to branch out into new fields. The structures of most large corporations are really the equivalent of a congeries of semi-independent companies. In some cases, such as Procter & Gamble, these divisions compete with one another as if they were separately owned.

#### MANAGEMENT IN LARGE U.S. CORPORATIONS

Most large corporations are run by their top executives. Corporate officers have substantial power. In theory these men and women are hired to manage someone else's property; in practice, however, management regards the stockholders as simply one of several constituencies to which it must report at periodic intervals.

**Managerial decision making.** The guidelines governing management decisions cannot be reduced to a simple formula. Traditionally, economists have assumed that the goal of a business enterprise is to maximize its profits. The difficulty with this guideline is in determining which measures contribute to overall earnings. A company may spend several hundred thousand dollars on paintings and sculpture for its headquarters or may donate large amounts to charities. Perhaps such expenditures create "goodwill" and attract new customers. Executives often conduct their business over luxurious lunches and attend conventions at expensive resorts. It may be argued that such lavishness more than repays itself by establishing contacts, exchanging information, or providing incentive for more effective performance. It may be argued that every activity of a company—sooner or later, directly or indirectly—enhances its earnings, but this contention should not be pushed too far. A corporation is a social centre as well as a place of business, and employees at all levels intersperse their working hours with periods in which they waste time or simply enjoy themselves. If management seeks to maximize profits, then its efforts must be tempered by realistic expectations concerning dedication, discipline, and efficiency.

Most corporations give only about half of their earnings to stockholders as dividends. They spend the rest of their profits on the purchase of new equipment and the expansion of operations. This is closely related to management autonomy: by retaining funds within the company, a corporation's executives maintain resources that enable them to move the firm into fields of their choosing. Some observers, however, have argued that all earnings should be paid to the stockholders and that a corporation desiring capital funds should be required to approach the investing public each time it wants to embark on a new venture. Such a procedure would oblige the management to make a persuasive case to a constituency outside its own boardroom.

Whether or not managers seek to maximize profits, they undoubtedly try to maintain them at a high level. Their major motivation is to expand their operations faster than those of their competitors or at a rate exceeding the growth of the population and the economy. The usual measure of an executive is the ability to augment a company's earnings, which may be done by helping to increase sales or productivity or by achieving savings in other ways. This motivation of profit distinguishes business from other fields. The primary purpose of a drug company is not to make pharmaceuticals or to improve the health of society: it exists, first and foremost, to make

Management motivation

profits. If it found that it could make more money by manufacturing frozen orange juice, it would do so.

**The modern executive.** Much has been written about the business executive as "organization man." According to this view, the typical corporation manager no longer displays the individualism of earlier generations of entrepreneurs. Managers seek protection in committee-made decisions and tailor their personalities to please their superiors; they aim to be good "team" members, adopting the firm's values as their own. There is a germ of truth in this portrayal. Only a minority of managers have unusual qualities of initiative and imagination, and the complexities of the corporate process call for continual conferences in which information is pooled and priorities are determined. There are companies—and entire industries—that have discouraged innovative ideas. The real question, however, is whether corporations are willing to tolerate autonomy and adventuresomeness, especially among middle-level and younger managers. In many cases management has recognized and rewarded outstanding talents, even when accompanied by abrasive personalities. Certainly, most men and women who rise to high-level positions in large corporations have made some kind of individual record that sets them off from colleagues who simply go through the conventional paces. In some cases advancement involves wagering one's career prospects on what seems a risk-laden proposition; in others, it consists of encouraging subordinates to superior performance. Corporations continue to attract their share of conformists and mediocrities, but most of these remain in middle management. The real danger is when too much caution and too little creativity emerge at the top.

The managerial elite

Management in the United States is an elite but not hereditary class. Most officers of corporations begin with college degrees, and only in exceptional instances have executives worked their way up from the shop floor. But most managers by the 1960s were the first in their family to have gone to college, and no more than one-third had attended Ivy League institutions. Thus, typical executives tend to come from a middle-class background; while not wholly "self-made," they must still depend on their own accomplishments to rise in the corporate world. Those who become company presidents are apt to be Republican and Protestant; they are more likely to prefer a suburban home to a city apartment. Although top executives in large firms receive salaries and bonuses surpassing \$250,000, few retire with a net worth of much more than \$1,000,000. Most reach the high-paying brackets only toward the end of their careers; and even stock options and deferred compensation do not give them the personal fortunes amassed by many people who are self-employed. Only a handful can or do turn their positions over to their children.

**The impact of the corporation.** Although it is generally agreed that the power of corporations extends beyond the economic sphere, this influence is difficult to measure. The processes of business entail at least some effort to ensure the sympathetic enactment and enforcement of legislation, since costs and earnings are affected by tax rates and government regulations. Companies and business groups retain lobbyists in the state and national capitals and use methods such as advertising to enlist support for policies they favour. Although corporations may not legally contribute directly to candidates running for public office, their executives and stockholders may do so as individuals. Corporations may, however, pay lobbyists and contribute to committees that work to pass or defeat certain legislative proposals. In practical terms, many lawmakers look upon corporations as part of their constituency. If their districts depend on local plants, however, these lawmakers may be concerned more with preserving jobs than with protecting company profits. In any case, corporations are central institutions in society; it would be unrealistic to expect them to remain aloof from the political process when faced with the prospect of being made to do things they would prefer not to do.

The decisions made by corporate managements have ramifications for society. In effect, corporations can be important in deciding which parts of the country will

prosper and which will decline by choosing where to locate their plants and other installations. The giant companies not only decide what to produce but also help to instill in their customers a desire for the amenities they make available. To the extent that large firms provide employment, their personnel requirements determine the curriculums of schools and colleges. For these reasons, individuals' personalities are likely to reflect aspirations and dissatisfactions engendered by corporations. This does not mean that large business firms can influence the public in any way they choose; it is simply that they are the only institutions available to perform certain functions. Automobiles, typewriters, telephone service, frozen food, and electric toasters generally must come from corporate auspices if they are to be provided at all. Given this dependence, corporations tend to create an environment congenial to the conduct of their business.

The majority of the U.S. population has come to accept the corporation's presence, if only because it plays so vital a role in the nation's life. Few citizens favour the removal of the productive process from private ownership. Corporations are often criticized, particularly in times of unemployment, during labour disagreements, and whenever citizens become dissatisfied with the quality of consumer goods or concerned with the deterioration of the environment. While these attacks seldom take on political dimensions, they are evidence of some unease over the uses of concentrated power.

**The social role of the corporation.** Some corporation executives believe that their companies should act as "responsible" public institutions, holding power in trust for the community. Most companies engage in at least some public-service projects and make contributions to charities. A certain percentage of these donations can be deducted from a corporation's taxable income. In 1978, gifts by corporations amounted to approximately \$2,000,000,000, or about 1 percent of taxable income, though up to 5 percent of this income is tax deductible when donated to charities. Most of this money went to private health, education, and welfare agencies, ranging from local hospital and charity funds to civil-rights groups and cultural institutions. Eastern Airlines, for example, has contributed to the Metropolitan Opera company and McGraw-Hill to a high school in New York City. In 1979 corporate philanthropy was greater than that of foundations.

These corporate activities have been criticized. The economist Milton Friedman has asserted that corporations should reject the notion that they have public duties. Society as a whole would be better off, Friedman has suggested, if corporations maximized their profits, for this would expand employment, improve technology, raise living standards, and also provide individuals with more money to donate to causes of their own choosing. An accompaniment of this argument is that management has no right to withhold dividends: if stockholders wish to give gifts themselves, they should do so from their personal funds. On the other hand, some critics complain that large companies have been much too conservative in defining their responsibilities. Not only have most firms confined themselves to uncontroversial activities, but they also have sought to reap public-relations benefits from every dollar they donate. Very few companies, say the critics, have made a real effort to promote employees belonging to minority groups, to provide day-care centres, or to employ high-school dropouts and people released from prison. Companies have also been charged with abandoning the inner cities, profiting from military contracts, misrepresenting their merchandise, and investing in foreign countries governed by repressive regimes. A continual indictment has been that profits, prices, and executive compensation are too high, while the wages and taxes paid by corporations are too low.

In the late 1960s a new group of critics emerged who stressed the social costs of the corporation. They charged that automobiles, pharmaceuticals, and other products are badly designed and dangerous to their users. The new consumer movement, one of the leading figures of which has been Ralph Nader, has been joined by environmental

Public attitudes

Criticism from consumerists and environmentalists

critics who want to reduce the quantities of waste products released into the water and the air. State and federal laws have been passed in an effort to set higher standards of safety and to force companies to install antipollution devices. The costs of these measures, however, are ultimately passed on to the consumer. If a nuclear power plant must have cooling towers so that it does not discharge heated water into an adjacent lake, the extra equipment results in higher electricity bills. Most companies are hesitant to take such steps on their own, fearing that the need to raise their prices would reduce their sales. But consumers are already paying for the costs of traffic congestion, trash removal, and nutritional deficiencies. The prices charged by corporations are far from reflecting the total impact that the manufacture and consumption of their products have on the lives of the country's people.

(A.Ha.)

#### THE LARGE BUSINESS CORPORATION IN EUROPE

Inter-  
national  
similarities

In many respects the corporation has become a social organization that transcends national differences. As modern business has grown more and more international in outlook, its methods of operation have everywhere come to resemble each other in structure and management. In most countries of western Europe, firms have shown a tendency to grow larger since the 19th century. The giant firm has become particularly prominent in the United Kingdom, West Germany, The Netherlands, and Belgium. It is less predominant in France, Italy, and Sweden, though its relative importance in France is demonstrated by the fact that in 1963 some 50 firms accounted for 65 percent of the output of the largest 500 firms. In Belgium in the late 1970s, one firm, the *Société Generale*, owned very large proportions of the deposit-banking, insurance, metallurgical, coal, and electric-power industries, and was the sixth largest bank outside the United States. In the United Kingdom in 1955-56, companies comprising only 0.12 percent of all concerns received 45 percent of the gross income.

**The tendency toward growth.** The process of growth in size has generally persisted since 1870, though it has been far from continuous. There have been periods of cumulative leaps and periods of reversal. In Germany in the 1920s a wave of amalgamations occurred in the heavy industries, spurred on by foreign investment. After the German defeat in World War II, the victorious Allies attempted to break up the large combines. These later tended to reappear, however, and in 1960 the 100 largest West German firms accounted for 40 percent of the country's industrial output and employed one-third of its industrial labour force. In France, where a large stratum of small firms remained, government policies after World War II attempted to encourage the growth of large firms as well as certain forms of cooperation among them. A unique development has taken place in Yugoslavia, where the reforms carried out under President Tito from the 1950s through the 1970s created large Socialist enterprises nominally owned by the state but run by workers' councils, some of them resembling private Western corporations. One of the largest of these in the early 1980s was *Energo-invest*, a confederation of 125 factories with 40,000 employees that produces electrical equipment, aluminum, processing equipment, and a wide range of metals, minerals, and household appliances.

The tendency of large corporations to become larger does not necessarily mean that they become more dominant in their markets or control a larger proportion of total assets. In the United Kingdom and Germany, over a period of several decades, there was little evidence of a long-term trend toward greater monopoly by the largest companies. The degree of concentration in the German iron-and-steel, chemical, and electrical industries was not as great in the 1950s and 1960s as it had been in the 1930s; according to a study by the West German government, in the late 1930s eight trusts produced 95 percent of the nation's output of crude steel and 57 percent of the coal, while in 1958 the eight largest trusts produced 76 percent of the steel and 30 percent of the coal. The ex-

pansion of large corporations partly resulted from the growth of the economy as a whole; firms grew larger along with their industries. It was also partly the result of firms diversifying by expanding into a number of different industries. This latter trend was especially pronounced in the decades after World War II, and it has produced such mammoth corporations as Michelin and Renault in France; Fiat and Olivetti in Italy; Volvo in Sweden; Unilever, EMI, and Courtaulds in the United Kingdom; and Philips' in The Netherlands, each of which is engaged in a number of different industries.

**The business manager.** As in the United States, the large European corporations are increasingly controlled by professional managers rather than by stockholders or owners. While relatively more of the large European corporations continue to be controlled by individuals or families, the number seems to be steadily declining. The divorce of ownership from control, largely the result of increased stock ownership among the general public, has not gone as far as in the United States. In the United Kingdom, however, the number of large companies in which the 20 largest stockholders owned 30 percent of the total voting stock declined markedly between 1936 and 1951. There has been a similar trend in other countries. Even in companies that continue to be owned by a small group of stockholders or a family, the everyday operations are often the responsibility of managers who act independently.

These managers are predominantly university-educated and of middle-class background. They come more from the upper strata of the middle class than is the case in the United States. Studies made in the 1950s and 1960s showed that in the United Kingdom nearly half of the managers had parents in the highest occupational groups. In France the top managers were recruited largely from the families of business executives, civil servants, and members of the professions. In Sweden and Denmark, in the 1940s and 1950s, the upper middle class background of managers was even more pronounced. The democratic social climate was thus not reflected in the upper echelons of the large European corporations, and the inequality of selection seems to be increasing rather than decreasing.

(Ed.)

#### THE LARGE BUSINESS CORPORATION IN JAPAN

**Ownership and control. The zaibatsu.** Before World War II the large Japanese companies in heavy industry and finance were controlled by holding companies. For the most part, these holding companies were family-owned businesses known as *zaibatsu*. They differed from Western cartels or trusts of the time in two chief ways: usually they were organized around single families, and each *zaibatsu* controlled companies that encompassed a wide range of economic activities. Mitsui, for example, controlled companies in banking, foreign trade, mining, insurance, textiles, sugar, food processing, machinery, and other fields. The four largest *zaibatsu* were Mitsui, *Mitsubishi*, Sumitomo, and Yasuda. They had developed after the Meiji restoration of 1868, expanding rapidly during World War I and afterward.

After the defeat of Japan in World War II, the Allied occupation authorities undertook to dissolve the *zaibatsu* on the ground that their close relations with the military establishment had contributed to Japan's involvement in the war. Their stock was put up for sale, and individual companies were freed from the control of the parent organizations. The amount of stock held by *zaibatsu* families in the holding companies before divestiture was as follows: Mitsui, 64 percent; Iwasaki (Mitsubishi), 50 percent; Sumitomo, 83 percent; and Yasuda, 90 percent. These families also had substantial stock holdings of individual companies in their empires. The influence of the *zaibatsu* organizations is demonstrated by the fact that the four largest groups accounted for about one-fourth of the total paid-up capital in Japanese industry; including the six next largest groups, the figure was more than one-third.

An antitrust law was enacted, patterned after U.S. legislation, that prohibited the establishment of holding com-

Holdings  
of British  
managers

The  
family  
groups

panies of the *zaibatsu* type, limited stock ownership by banking institutions, and restricted corporate mergers and acquisitions. Japan then entered its long postwar boom, during which the economy grew at a rate surpassing that of any other country. Large enterprises have continued to increase their capital investments, but ownership is no longer in the hands of a few individual or institutional stockholders. Even in the cases of such successful postwar enterprises as Matsushita, Sony, and Honda, which were built up by a few talented entrepreneurs, the founders owned approximately 5 percent of the stock in their companies in 1970.

**The role of banks.** During the period of rapid industrial growth after 1955, corporations sought to diversify their activities and acquire sophisticated technology. Part of the intensified demand for capital was met through the capital markets; but the sale of securities to the public was far from enough, and enterprises became more and more dependent upon financing by banks. The importance of banking institutions continued to increase until they supplied as much as three-fourths of the total capital of industrial firms.

Among large banks there arose a strong competition for new customers, leading them to encourage diversification among their business clientele. The approach of banks to diversification is known among Japanese economists as the one-set doctrine, meaning that each bank endeavours to obtain customers that represent a complete set of industries. To the banks, which have invested heavily in industry, the expansion of corporations offers a chance to increase their capital, with the result that banks have taken an important role in Japanese industrial expansion. By the late 1970s, however, Japanese companies were borrowing less and less from banks, and were generating much of their capital from profits and stock issues. Electronics and computer companies, for example, met nearly 75 percent of their capital needs from profits and 11 percent from stock issues.

The banks have shown no inclination to use their financial power to take over control of management as long as the performance of the managers is adequate. Since the end of the 1960s, the separation of ownership and management has been almost complete among large Japanese corporations.

Corporations have tended to avoid a concentration of control by any one bank or enterprise; stocks have generally been widely held by a large number of shareholders, many of them being other corporations in the same group. An example is the giant Nippon Steel, comparable in size to the United States Steel Corporation. In the late 1970s its shares were held by some 514,000 shareholders, less than 15 percent of whom represented financial institutions; but these financial institutions owned a considerably higher percent of the equity capital, while individuals, representing more than 85 percent of the shareholders, owned a proportionately lower percent of the equity capital.

Another role of banks in postwar Japanese economic history developed in the 1960s, when Japanese businesses became concerned that foreign capital might try to take control of their organizations. To avoid this potential danger, some large firms began to seek ties with banks and other institutional investors in order to keep a large proportion of their stock off the market. In the early 1980s, however, Japan began encouraging foreign investment.

Professionalization of management. **The modern role of management.** The characteristics and aspirations of managers have undergone a profound alteration during the postwar years. In the prewar industries controlled by the *zaibatsu* families, the management of operations was delegated to professional managers employed for their skills and abilities. Many of these *bantō* had political connections and were influential in political and economic affairs, though their primary loyalty was to the families that employed them. At the end of World War II they were purged by the occupation authorities and replaced by new personnel promoted from among the middle-level managers, who felt allegiance to the corporation rather than to any particular master. Most managers in present-day Jap-

anese corporations have risen through the ranks of a single company. Since they do not own substantial amounts of stock, they have come to be known as "salary men." In some of the newer corporations, however, such as Matsushita, Sony, and Honda, management has been substantially retained by the founders.

According to Japanese commercial law, there are three main legal organs in a corporation: the stockholders at general meetings, the boards of directors, and the company auditors. In practice, however, all three of these have been reduced to a purely nominal status. Meetings of stockholders, as in other countries, are merely rituals; the real decisions have already been made in private negotiations among the large shareholders. The function of the auditors is limited to formal duties only; the actual accounting is carried out by independent certified public accountants, institutionalized after the war in accordance with the U.S. system. The boards of directors consist mainly of company personnel and rarely include outsiders. As the number of directors has increased with the growth of large companies, functions nominally in the province of the boards are actually carried out by "committees of senior executives," or *jomu-kai*, composed of senior members of the boards. The *jomu-kai* discuss and decide key issues, and since the general stockholders and the auditors have no substantial influence, the *jomu-kai* are left as the top decision-making bodies. The head of the *jomu-kai* is usually also the president of the company, with all the corresponding power and authority.

The guiding objectives of management in the Japanese corporation are too complex to describe in simple terms. They do not necessarily seek to maximize profits, as did the prewar *zaibatsu*. Their major objectives seem to be the maximization of sales volume, the expansion of their corporations, and the increase of their own social prestige, as well as the avoidance of criticism from stockholders, trade unions, and consumers.

**Employee advancement.** The employees of large Japanese corporations tend to remain with the same employer throughout their working lives, advancing gradually on the basis of seniority. Employees who show superior ability and potential advance rapidly to higher ranks within the company, while those who show less promise advance along standard lines. When the need arises to choose between an employee and an organization, in most cases the latter will be protected. Most employees, however, welcome the advantages of the corporation; they devote their lives to the organization and accept their positions in their vertically structured companies.

The corporations recruit young people upon their graduation from the universities and train them as company cadets. Those cadets who demonstrate ability and a personality compatible with the organization are later selected as managers. Because of the seniority system, many are well past middle age before they achieve high status. There have been occasional efforts to get around the seniority system by lifting promising young men and women out of their low-echelon positions; many have urged that less emphasis be placed on educational background as a criterion for advancement. Such criticism of tradition has been stimulated by the example of some of the new postwar corporations and of those owned by foreign capital.

The few individuals in the Japanese business world who have emerged as personalities are either founders of corporations, managers of family enterprises, or owners of small businesses. They share a strong inclination to make their own decisions and to minimize the role of directors and boards. But many of these individualists have competent managers to assist them, resulting in a peculiar form of leadership that the Japanese call the "three-legged race."

**Industrial concentration.** The concentration of ownership in Japanese industry increased during the decades after World War II. In 1967 a study of 586,000 companies by the Fair Trade Commission (excluding the fields of finance and insurance) showed that those having a capital of less than 5,000,000 yen (360 yen = \$1 U.S.; 864 yen = £1 sterling, on April 1, 1964) comprised 86 percent of the total number but had only 7.7 percent of the total

Company  
cadets

*Bantō*  
and  
"salary  
men"

capital. On the other hand, those companies with more than 10,000,000 yen capital, comprising 0.2 percent of the total, had 64 percent of the total capital. The 100 largest companies had 36 percent of the total capital. The degree of concentration was similar when total assets and profits were used as the basis for comparison.

The highest concentration was found in the iron-and-steel, shipbuilding, automobile, electrical-machinery, and domestic-appliance industries. Concentration was also high in fishing, chemicals, and shipping. It accelerated in the period from 1955 to 1965 and levelled off or even declined slightly in some areas between 1965 and 1970. The list of the 100 largest corporations changed frequently from 1955 to 1965; for example, of those belonging to the list in 1963, some 39 were replaced the following year.

**Public** attitudes toward corporations. Since the 1960s the Japanese corporation has encountered criticism from most sectors of the public, particularly from the younger generation whose goodwill is so important to its future. The criticism centres on four basic problems: the pollution of air and water by large-scale industry; the destruction of the natural environment; the infringement of the rights of consumers; and the demoralizing effects of work in large organizations.

The most urgent problem seems to be that of pollution. In earlier days, when the scale of industry was relatively small, firms were able to improvise their own solutions. At the end of the 19th century, for example, the Sumitomo copper refinery was moved to Shisaka Island in the Inland Sea, away from populated areas. Similarly, during the second decade of the 20th century, the Hitachi company constructed an extraordinarily high smokestack at one of its mines in order to prevent smoke damage to the surrounding community. But from the 1930s onward, little was done to counter the damaging effects of industrial expansion, and as a result urban areas began to suffer from air pollution on a large scale. Several new diseases were added to Japanese medical terminology. The Minamata disease was poisoning caused by a mercury compound in factory waste discharged into Minamata Bay. The "Itai-itai disease" was caused by cadmium discharged from refineries in Kamioka and Annaka. The local and national governments were slow to take effective measures against pollution caused by industrial wastes. In the early 1970s a movement was started by people who had suffered some of the effects of such pollution and were able to find public support for their cause. They brought legal action against certain companies; they also attempted to take their cases directly to the boardrooms by purchasing stock and attending stockholders' meetings. These efforts, combined with a campaign by influential newspapers, has made pollution a political issue in Japan.

The phenomenal growth of Japanese industry has also pressed upon the supply of land. The resulting increase in land values has been felt in the housing market, as adequate housing becomes more difficult and expensive to obtain. Many critics argue that investment in social capital has not kept pace with the building of roads, railways, airports, and other land-consuming facilities.

Consumer groups have also protested against poor quality goods and improper selling practices. In response to their demands, the government's Fair Trade Commission undertook to enforce higher standards in the production and sale of durable goods, such as automobiles and television sets, as well as in soft goods, such as cosmetics, toothpaste, and processed foods.

The effect of large automated factories on those who work in them has become a popular subject in the Japanese press. Increasing numbers of workers are reported to be alienated from their work and from life, particularly in the areas of steel and petrochemical processing, automobile assembling, and the production of home appliances. Some are leaving these industries for smaller ones in the hope of establishing a better working identity for themselves.

*Early history of the corporation:* JOHN P. DAVIS, *Corporations: A Study of the Origin and Development of Great Busi-*

*ness Combinations and Their Relation to the Authority of the State*, 2 vol. (1905, reprinted 1971), remains one of the best historical accounts of the corporate form in the medieval and mercantile periods. EPHRAIM LIPSON, *The Economic History of England*, 12th ed., vol. 1 and 6th ed., vol. 2-3 (1959-61), provides a full exposition of the joint-stock companies and the chartered companies. LOUIS M. HACKER, *American Capitalism, Its Promise and Accomplishment* (1957), traces the rise of corporations in the United States in the 19th century.

**United States:** The separation of ownership and management is analyzed in ADOLPH A. BERLE and GARDINER C. MEANS, *The Modern Corporation and Private Property*, rev. ed. (1968); and the implications of this development are treated in JOHN KENNETH GALBRAITH, *The New Industrial State*, 3rd ed. rev. (1979). WILBERT E. MOORE, *The Conduct of the Corporation* (1962, reprinted 1975), centres on internal operations; RICHARD J. BARBER, *The American Corporation: Its Power, Its Money, Its Politics* (1970), concentrates on external aspects. FRANCIS W. STECKMEST, *Corporate Performance: The Key to Public Trust* (1982), studies the role of the corporation in U.S. society; JAMES S. COLEMAN, *Power and the Structure of Society* (1974), examines how corporations exercise power and discusses ways of controlling it. JOSEPH LIVINGSTON, *The American Stockholder* (1958), evaluates the impact of the individuals and institutions that own corporate shares. MILTON FRIEDMAN, *Capitalism and Freedom* (1963), is an argument for non-interference by public agencies; while ESTES KEFAUVER, *In a Few Hands: Monopoly Power in America* (1965), supports further regulation and antitrust action by government. ANDREW HACKER (ed.), *The Corporation Take-Over* (1964), is a collection containing both theoretical analyses and research findings.

**Europe:** Recent studies of the corporation in European countries are few. Some of them are discussed in MICHAEL M. POSTAN, *An Economic History of Western Europe, 1945-1964* (1967), in which several chapters are devoted to the organization and management of industry. LESLIE HANNAH, *The Rise of the Corporate Economy* (1976), studies the development of large corporations in the United Kingdom from 1880 to 1973. French policies toward industry are studied in JOHN SHEAHAN, *Promotion and Control of Industry in Postwar France* (1963). An informal survey of managers is DAVID GRANICK, *The European Executive* (1962, reprinted 1979). N. MARCH HUNNINGS (ed.), *Antitrust Cases from Common Market Law Reports: Restrictive Agreements* (1976), documents restrictions placed on corporate mergers by the European Economic Community.

**Japan:** For the historical development of the Japanese economy, see WILLIAM W. LOCKWOOD, *The Economic Development of Japan*, expanded ed. (1969); and HENRY ROSOVSKY, *Capital Formation in Japan, 1868-1940* (1961), which cover the period from the Meiji restoration to World War II; and RYUTARO KOMIYA (ed.), *Postwar Economic Growth in Japan* (1966; orig. pub. in Japanese, 1963), for the postwar period. For a statistical analysis of Japan's economic growth since the 1860s, LAWRENCE KLEIN and KAZUSHI OHKAWA (eds.), *Economic Growth: The Japanese Experience Since the Meiji Era* (1968), are useful. The characteristics of entrepreneurs in the early Meiji period when modern capitalism rose in Japan are given in JOHANNES HIRSHMEIER, *The Origins of Entrepreneurship in Meiji Japan* (1964). KAZUO NODA, "The Postwar Japanese Executive," in RYUTARO KOMIYA (ed.), *op. cit.*, explains the role of business executives in the post-World War II period. Some aspects of Japanese industrial labour are described in EZRA F. VOGEL, *Japan's New Middle Class: The Salary Man and His Family in a Tokyo Suburb*, 2nd ed. (1973); and in a comparative study by ARTHUR M. WHITEHILL, JR. and SHIN-ICHI TAKEZAWA, *The Other Worker: A Comparative Study of Industrial Relations in the United States and Japan* (1968). Regarding the Japanese industrial structure, JOE S. BAIN, *International Differences in Industrial Structure: Eight Nations in the 1950's* (1966, reprinted 1980), is recommended, though the data are rather outdated. Japan's bureaucratic establishment is described in MARSHALL E. DIMOCK, *The Japanese Technocracy* (1968), one of the few books covering this aspect of Japanese society. For a view of Japan's management system, see MICHAEL Y. YOSHINO, *Japan's Managerial System: Tradition and Innovation* (1968); THOMAS F.M. ADAMS and NORITAKE KOBAYASHI, *The World of Japanese Business* (1969); and ROBERT J. BALLON (ed.), *Doing Business in Japan*, 2nd ed. rev. (1968). In addition, JAMES C. ABEGLIN, *The Japanese Factory* rev. ed. (1981); and SOLOMON B. LEVINE, *Industrial Relations in Postwar Japan* (1958), are considered semiclasses in the management field. RODNEY CLARK, *The Japanese Company* (1979), analyzes the Japanese corporation and its place in Japanese society.

## Correggio

One of the greatest masters of painting of the 16th century High Renaissance style in Italy, Antonio Allegri, universally known as Correggio, was in his late works a forerunner of the 17th-century Baroque style. In the 16th century he was already known as "the painter of the Graces," and, although his works were concentrated in Parma and in a few neighbouring Italian cities, he was early considered worthy of being named in the company of such illustrious contemporaries as the artists Raphael, Michelangelo, and Titian.

"Jupiter and Io," oil painting by Correggio, c. 1530. In the Kunsthistorisches Museum, Vienna. 163.5 X 74 cm.

His father was Pellegrino Allegri, a tradesman living at Correggio, a small city in the territory of Modena. Antonio was born at Correggio, the town that gave him his name, probably not long before August 30, 1494, and died there on March 5, 1534. He was not, as it is often alleged, a self-taught artist. His early work refutes the theory, for it shows an educated knowledge of optics, perspective, architecture, sculpture, and anatomy. His initial instruction probably came from his uncle, Lorenzo Allegri, a painter of moderate ability, at Correggio. About 1503 he probably studied in Modena and then went to Mantua, arriving before the death in 1506 of the famed early Renaissance painter Andrea Mantegna. It has traditionally been said that he completed the decoration of Mantegna's family chapel in the Church of S. Andrea at Mantua after the artist's death. It seems certain the two round paintings, or tondi, of the "Entombment of Christ" and "Madonna and Saints" are by the young Correggio. Although his early works are pervaded with his knowledge of Mantegna's art, his artistic temperament was more akin to that of Leonardo da Vinci (1452–1519), who had a commanding influence upon almost all of the Renaissance painters of northern Italy. Where Mantegna uses tightly controlled line to define form, Correggio, like Leonardo, prefers chiaroscuro, or a subtle manipulation of light and shade creating softness

of contour and an atmospheric effect. It is also fairly certain that early in his career he visited Rome and came under the influence of the Vatican frescoes of Michelangelo and Raphael.

Leaving Mantua, Correggio's time was divided between Parma and his hometown. His first documented painting, an altarpiece of the "Madonna of St. Francis," was commissioned for S. Francesco at Correggio in 1514. The best known works of his youth are a group of devotional pictures that became increasingly luscious in colour. They include the "Nativity" (Brera, Milan), "Adoration of the Kings," and "Christ Taking Leave of His Mother."

Correggio's mature style emerged with his first commission—for Parma, the ceiling of the abbess' parlour in the convent of S. Paolo, which was probably executed about 1518–19. Although there are echoes in this work of Mantegna's murals in the Castello at Mantua (1494), it was wholly original in conception. The abbess Giovanna de Piacenza secured for Correggio another important appointment, to decorate the dome of the Church of S. Giovanni Evangelista at Parma. The dome fresco of the "Ascension of Christ" (1520–23) was followed by the decoration of the apse of the same church, of which only the segment entitled "Coronation of the Virgin" survives (Galleria Nazionale, Parma), the remainder having been destroyed in 1587. This work was still in the High Renaissance tradition and owed much to Michelangelo.

The fresco of the "Assumption of the Virgin" in the dome of the Cathedral of Parma marks the culmination of Correggio's career as a mural painter. This fresco (a painting in plaster with water-soluble pigments) anticipates the Baroque style of dramatically illusionistic ceiling painting. The entire architectural surface is treated as a single pictorial unit of vast proportions, equating the dome of the church with the vault of heaven. The realistic way the figures in the clouds seem to protrude into the spectators' space is an audacious and astounding use for the time of foreshortening.

The remainder of Correggio's most famous works, the dates of few known with certainty, fall into three groups: the great altarpieces (and a few other large religious compositions); exquisite small works of private devotion; and a handful of mythological subjects of a lyrically sensuous character. Many of the altarpieces became so well known that they acquired nicknames. The "Adoration of the Shepherds" (c. 1530; Gemäldegalerie, Dresden) is called "Night" ("La Notte"), and the "Madonna of St. Jerome" (Galleria Nazionale, Parma) is popularly known as "Day" ("Il Giorno"). The late altarpieces are generally characterized by an intimate and domestic mood sustained between idealized figures. This intimate and homely poetry also distinguishes the small devotional works, such as "The Madonna of the Basket" or "The Virgin Adoring the Child Jesus" (Uffizi, Florence), while the "Mystic Marriage of St. Catherine" is a visual essay in the mid-16th-century aesthetic of ideal feminine beauty. In these late works Correggio fully exploited the medium of oil painting. He was intrigued with the sensual beauty of paint texture and achieved his most remarkable effects in a series of mythological works, including the "Danae" (Borghese Gallery, Rome), "The Rape of Ganymede," and "Jupiter and Io" (both in the Kunsthistorisches Museum, Vienna). The sensuous character of the subject matter is enhanced by the quality of the paint, which seems to have been lightly breathed onto the canvas. These pictures carry the erotic to the limits it can go without becoming offensive or pornographic.

Although his influence can be detected in later Parmese painting, especially in the Mannerist style of Parmigianino (1503–40), Correggio had many imitators but no direct pupils who deserve mention. His decorative ideas were taken up by the Baroque painters of the 17th century, particularly in the ceiling painting of Giovanni Lanfranco (1582–1647), himself a native of Parma. Correggio became almost a tutelary deity of the French Rococo style, and his great altarpieces were among the works most abundantly copied by the travelling artists of the 18th century during their years of study in Italy.

Sensual quality of paint

## MAJOR WORKS

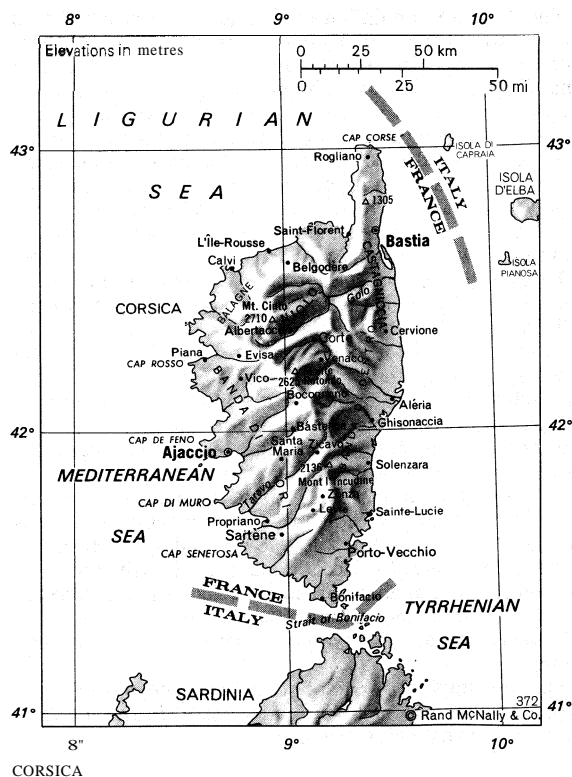

**PAINTINGS:** "The Mystic Marriage of St. Catherine" (1510–14; National Gallery of Art, Washington, D.C.; Detroit Institute of Arts); "Madonna of St. Francis" (1514; Gemäldegalerie, Dresden, East Germany); "Adoration of the Kings" (c. 1514; Brera, Milan); "Madonna" (Art Institute of Chicago); "Four Saints" (1514–17; Metropolitan Museum of Art, New York); "Christ Taking Leave of His Mother" (1514–17; National Gallery, London); "Campori Madonna" (1514–17; Galleria e Museo Estense, Modena); frescoes (1517–20; Camera di S. Paolo, Parma); frescoes (1520–23; cupola of S. Giovanni Evangelista, Parma); "Mystic Marriage of St. Catherine" (1520–26; Louvre, Paris); "The Sojourn in Egypt" (1520–26; Uffizi, Florence); "The Madonna of the Basket" (1520–26; National Gallery, London); "Noli Me Tangere" (1520–26; Prado, Madrid); "Ecce Homo" (1520–26; National Gallery, London); "Madonna of St. Sebastian" (1520–26; Gemäldegalerie, Dresden); "Madonna of St. Jerome," "Il Giorno" (1523; Galleria Nazionale, Parma); "Madonna of the Bowl" (c. 1525; Galleria Nazionale, Parma); "Holy Family with St. James" (c. 1525; Hampton Court, Middlesex); "Assumption of the Virgin" (1526–30; cupola of Cathedral, Parma); "The School of Love" (c. 1532; National Gallery, London); "The Virtues" (c. 1530s; Galleria Doria-Pamphili, Rome); "The Virtues" (c. 1530s; Louvre); "Leda" (c. 1530s; Staatliche Museen Preussischer Kulturbesitz, Berlin).

**BIBLIOGRAPHY.** c. RICCI, Correggio (Eng. trans. 1930), out of date but the fullest available account; A.E. POPHAM, Correggio's Drawings (1956), definitive and with catalog; SILVIA DE VITO BATTAGLIA, Correggio *Bibliografia* (1934), definitive bibliography up to 1934; for later works of consequence, see A. BEVILACQUA and A.C. QUINTAVALLE, *L'opera completa del Correggio* (1970), the only book that reproduces everything plausibly ascribed to Correggio (in Italian); E. PANOFSKY, *The Iconography of Correggio's Camera di San Paolo* (1961), the most stimulating book written about Correggio.

(E.K.W.)

## Corsica

The fourth largest island in the Mediterranean (after Sicily, Sardinia, and Cyprus), Corsica lies just over 100 miles from the southeast of France, about half that distance westward from the mainland of Italy, and less than ten miles from its southern neighbour, Sardinia. Oval-shaped, it has an area of 3,352 square miles (8,681 square kilometres) and a maximum width of about 50 miles. It is characterized by an almost wholly mountainous territory, more than half of which lies above 1,300 feet.

Corsica (French Corse) became a part of France in 1769 after nearly four centuries of unconstructive colonial rule by the Genoese Republic. In 1789, at the request of its inhabitants, the island was made a French *département*. Yet political integration brought no rapid change in local conditions; living standards lagged well behind those of continental France until after 1957, when significant programs were put in hand to develop the island's most promising sources of revenue: agriculture and tourism.

**History.** The evolution of Corsica has been shaped by two factors: proximity to prosperous mainland areas and a rugged interior resistant to foreign penetration. The strategic value of Corsican ports was recognized from early times by the rival Mediterranean maritime powers, with the result that the island was often fought over and continually subjected to foreign overlords. Foreign control, however, was concentrated in coastal urban centres: the interior remained backward, while retaining a measure of independence that permitted the development of original social and political institutions.

Greeks, Etruscans, and Carthaginians had battled for control of the eastern seaboard before the Roman conquest in 259 BC. The Romans built towns and implanted agricultural colonies on the coasts but exercised much less influence over the interior. A sequence of invasions and partial occupations between c. 450 and 1050—by Vandals, Lombards, and Saracens—impelled a reversion to the indigenous way of life: the towns were destroyed, their inhabitants driven inland, and the coastal agricultural lands were abandoned, as they remained until modern times.

During the long medieval period of political insecurity and of interrupted contacts with the European mainland, the Corsicans forged an enduring social structure based on the extended family and the rural community. The rural communities, virtually autonomous units, exploited the land through a collective system and elected their own magistrates. These, and other leaders, often assumed hereditary feudal privileges and came to constitute a class of nobles recurrently embroiled in internecine conflict. The struggles for the control of Corsica (between Pisa and Genoa till 1284 and between Genoa and Aragon from 1297 to 1434) were used by the conflicting forces in Corsican society to further their particular interests. In 1358 the nobles in the northeast of the island were overthrown in a popular revolution supported by the Giovannali, heretics in the Franciscan Third Order who appealed to the Genoese who, at their request, assumed sovereignty of the island, and who, in their own defense, completed the ruin of the Corsican nobility by the early 16th century.

The Genoese centred their occupation in six coastal fortress towns; though they were corrupt and despotic rulers, they left the rural communities to administer themselves under their elected officers. Village affairs were settled in plenary assemblies: collective exploitation of the land subsisted alongside a gradual increase of private property. Corsican resentment against the Genoese regime facilitated a rapid conquest of the island by Henry II of France in 1553. Popular discontent increased after the island was returned to Genoa in 1559 and persisted throughout the 17th century, while Genoese trade monopolies antagonized a new class of relatively prosperous rural notables.

A national rebellion of 1729–69 was a spontaneous mass movement, directed by the notables, and as a result, the Genoese were driven from the interior almost immediately. Corsican experiments in self-government culminated in a written constitution of 1755. A General Diet, or national legislature, was instituted, with the majority of its members elected by universal suffrage. The Diet elected an executive council, which was responsible to it; Pasquale Paoli, a national leader and author of the constitution, became life-president of the council. The constitution operated until the French annexation in 1769.

After 1769, Corsica was a province of France, except

Strategic importance

The rise and fall of the nobility

during a brief period that saw the establishment of the Anglo-Corsican kingdom (1794–96). The ascendancy of Napoleon put an end to separatist movements and consolidated links between continental France and his homeland. In the two World Wars the Corsicans proved themselves conspicuously loyal citizens.

Dramatic  
terrain

**The landscape.** The Corsican landscape gives an overall impression of magnitude and untamed exuberance. About two-thirds of the island is composed of an ancient crystalline massif, subsequently worn down and then re-elevated. Dividing the island on a northwest to southeast axis, it rises to a cluster of 20 peaks exceeding 6,500 feet. Mont Cinto attains a height of 8,890 feet (2,710 metres). Lakes, scooped out by Ice Age glaciers, lie at the higher altitudes. The spiked and turreted mountain silhouettes are everywhere dramatic, with the rocks—especially the crimson, rose, and violet granites—varied and vivid. The mountains descend steeply in parallel ranges to the west, where the coast is cut into deep gulfs, with high cliffs and headlands. Rocky islets mark submerged former coastlines offshore. On the east the massif falls in broken escarpments to extensive alluvial plains, and a lagoon-indented coast has, in contrast, risen from the sea. In the northeast, a less spectacular younger formation of rocks has been folded against the ancient crystalline structure. Its rounded summits do not exceed 5,792 feet (1,766 metres). Erosion has cut a depression between the two mountain systems.

The eastern and western watersheds are drained by seasonally torrential rivers that rise in the crystalline centre and cleave their way through impressive gorges in their upper reaches. Soil types, which show multiple local variations, have in common a high acidity caused by calcium deficiency. Lack of humus is general, owing to the scarcity of organic matter and its rapid disintegration in warm, light soils.

The typical sunny Mediterranean climate of the coasts—where the average temperature is 59.9° F (15.5° C) throughout the year, and 51.1° F (10.6° C) in winter—is modified, in the interior, by altitudinal factors. The climate is cooler from 2,000 feet, and, from 3,000 feet, has alpine characteristics: the average summer temperature in coastal Ajaccio is 70.2° F (21.2° C); it is only 64° F (18° C) at Albertacce, at 3,525 feet, where it falls to an average 36° F (2.2° C) in winter.

The prevailing winds are westerly (121 days a year) and northeasterly. Precipitation is heavy, averaging 35 inches (880 millimetres) a year, 80 percent of which falls in storms between November and April, when the island is exposed to cyclonic depressions that form in the Atlantic and the Gulf of Genoa. The area above 3,000 feet, about a third of the whole, receives over 39 inches (one metre) of rain, and is normally snow-covered from December until April.

Vegetation is luxuriant. The characteristic maquis proliferates at low and medium altitudes; it is composed of aromatic shrubs, together with holm oak and cork oak in the south. Chestnut forests appear between 1,600 and 2,600 feet; the trees were planted from the 16th century onward for human and animal nutrition. The laric pine (*Pinus corsicanus*), which may grow to 160 feet, reigns in the higher forests, interspersed locally with beech and silver birch. Alders are found by the high mountain streams. Forests, in fact, cover 20 percent of the island. The Parc Naturel Régional of 370,000 acres was created in 1971 for the preservation of the natural environment. Boar and foxes are numerous, and about 150 strictly protected moufflons (wild, curly horned sheep) inhabit the crystalline heights.

Regional  
develop-  
ment

Several Corsican regions may be characterized on the basis of distinctive local traditions and scenery. The Balagne is covered with ancient olive groves, the Castagniccia, marked by its planted chestnut forests, the Sartenais is a wild country of rocks and holm oak, and the Niolo plateau is the home of sturdy shepherds.

Though the coastal plains were freed of malaria in 1943, their development is uneven. While some stretches of the seaboard are being built up to accommodate tourists, others are almost deserted. Only the east coast

is continuously cultivated and inhabited: this achievement is largely due to the state-financed Somivac (*Société pour la Mise en Valeur Agricole de la Corse*), and to 280 or so French families repatriated from North Africa in the years following 1957. New houses are scattered in thriving farmlands where vines—and, with irrigation, citrus fruit—are cultivated for export.

The traditional rural communities are nucleated villages, mostly situated in a band lying between about 650 and 2,600 feet. Emigration has depleted their populations, and 255 out of the 364 Corsican communes had fewer than 300 inhabitants by the early 1970s. Ownership by the communes of a quarter of the island's territory is a survival of the ancient collective system; but there are few remnants of the traditional agriculture of the interior except for small family vegetable gardens and vineyards. Practically no cereals are grown, and olives and chestnuts are rarely harvested.

The coastal towns, Ajaccio and Bastia, each with over 40,000 inhabitants by the 1970s, have drawn to themselves more than a third of the island's population. Without noteworthy industries, they serve as commercial and distributing centres, Bastia for the east and north, Ajaccio—the administrative capital—for the west and south. Sartène, Porto-Vecchio, and Corte have each more than 5,000 inhabitants.

**The people.** French, the official language, is spoken by virtually all Corsicans, most of whom also use the Corsican dialect, which is thought to have evolved from Latin in the Middle Ages. The majority of the population is Corsican-born. The wide variety of physical types, ranging from tall, fair-haired people to smaller people with dark colouring, is a reminder that Corsica has been repeatedly invaded since prehistoric times. Continental French residents are most numerous in the towns. Since 1957 some 17,000 French citizens from North Africa have found homes in the island, followed by Arab, Spanish, and Portuguese workers constituting a fluctuating labour force of about 8,000. Nearly 10,000 Italians also make a living in Corsica, while other nationalities are represented in small numbers.

Roman Catholicism is the dominant religion; the island forms a single diocese of 150 parishes with a bishop resident in Ajaccio. French Protestants number about 100; a smaller Eastern Catholic congregation, at Cargèse, consists of descendants of Maniate Greeks who settled in Corsica in 1676.

The de facto population of Corsica in the early 1970s was a little over 200,000, about 80,000 less than it was at the end of the 19th century. The decline has been due to massive emigration to mainland France and the French colonies, provoked by the failure of the traditional agricultural economy to support increasing numbers: births have exceeded deaths throughout this period. Corsicans still emigrate at the rate of about 2,000 a year, although many Corsicans retire to the island after careers overseas. As a result, 16 percent of the population is over 64, compared with some 12 percent in France as a whole. The aging of the population has affected the birthrate, which is 1.61 percent, as compared with 1.74 percent for all France, although births still exceed deaths.

In 1954 the population was down to about 170,000. The ensuing gain of some 50,000 inhabitants was due to the influx of French families from North Africa, accompanied by an economic revival that has attracted foreigners and reduced emigration. The process has been accompanied by a demographic shift from interior to coasts and country to town. The urban population, approximately a third of the whole in 1954, was about two-thirds by the 1970s, and there was a low population density in many rural areas. Corsica's population is still too small to ensure an expanding prosperity. Its increase depends on the economic inducements that can be offered to keep Corsicans in the island and attract non-Corsican residents.

**The economy.** In spite of striking recent progress, the Corsican standard of living, particularly in the interior, is still somewhat below that of continental France.

Corsica's exploitable natural resources are agricultural;

The role of  
emigration

it contains various minerals, including anthracite and asbestos, but in such small deposits that mining has been abandoned. The only power resources are two medium hydroelectric plants and four small, fuel-powered plants.

The need to import fuel and equipment has prevented significant industrial development, but a canning factory, completed in 1970, is equipped to treat 33,000 tons of fruit and vegetables per annum. The principal Corsican exports are cheese (about 1,900 tons a year); citrus fruit; cork; cigarettes (from homegrown tobacco); and wines and liqueurs, which together represent almost half of the total export value. Imports include cereals, meat, and various fresh foods as well as manufactured goods.

Retirement pensions, state salaries, and social security benefits make up 46 percent of the island's revenue. Agriculture (including stockbreeding) contributes no more than 11 percent, while engaging about 16,000 people full or part time. Only the new farms on the coasts are reliably profitable; most farmers of the interior depend upon pensions or social aid. Traditional agriculture has been ruined by emigration, loss of lives in the two World Wars, failure of markets (olive oil has been undersold by peanut oil), the importation of low-priced cereals, archaic methods, and the division of properties by inheritance (only 34 percent of the Corsican farms exceed 25 acres). Stockbreeding, well adapted to the mountain areas, is in decline. Though the 1,200 owners of some 120,000 sheep make an adequate living selling ewes' milk to the cheese making centres established by the *Sociétés de Roquefort*, the pastures are critically impoverished by uncontrolled grazing, and the flocks dwindle year by year.

As a tourist resort, Corsica has outstanding assets in its climate, its scenery, and its magnificent coastline. Yet tourism, handicapped by lack of capital, publicity, and experience, provides, at most, 16 percent of the island's revenue. Yearly numbers of holidaymakers increased from 50,000 in 1948 to about 500,000 in 1970; but there is room for many more. The majority come in summer and cluster on the seaboard, and more than three-quarters are French.

The state provides advice and subsidies, and has taken the lead in large-scale investment in the Corsican economy since 1957, through Somivac and through Setco (*Société pour l'Équipement Touristique de la Corse*). Management of the farms and hotels created by these organizations is in private hands. The example of the state has attracted private capital from overseas.

Taxation is the same as in continental France, except for certain concessions in indirect taxation. A proportion of taxes is allocated to a *Fonds d'Expansion de la Corse* (Corsican Expansion Fund). In 1968 this sum was equivalent to 10 percent of the normal budget of the *département*.

The small number of French salaried workers minimizes the influence of the trade unions, but increasingly useful functions are performed by 38 recently constituted agricultural cooperatives.

The French market for Corsican wines seems fully assured, and the export of citrus fruit is considered to be capable of a large extension. Agricultural prospects are none the less prejudiced by the small extent of land (about 22 percent of the whole) suited to mechanical cultivation; by a small local consumption, unevenly distributed through the year; and by high transport charges to the mainland. Stockbreeding could certainly provide a larger revenue if methods were modernized as planned. The possibilities of tourism appear almost unlimited, especially if steps are taken to exploit the mountain sites and improve facilities for outdoor and winter sports.

Transportation. There is reliable air and sea transport between Corsica and continental France, both operating with monopoly and state subsidy. Italian shipping lines run service to and from Sardinia and summer services between Bastia, Leghorn, and Genoa. Internal transport is provided by a state-subsidized railway and numerous privately owned road transport companies.

The network of 3,700 miles of tarred roads is adequate in extent—its upkeep engages 12 percent of the island's

budget—while a railway links Ajaccio, Bastia, and Calvi, the principal ports, for air and sea travel. Plane and boat services to and from continental France run at a loss in winter but are barely sufficient during the peak summer tourist season.

Administration and social conditions. Corsica is administered by the same system as the *départements* of continental France. Ajaccio is the seat of the prefecture; there are four other *arrondissements*. In January 1970 Corsica was detached from the *Région* Marseilles-Cote d'Azur-Corse and constituted as a separate *région*.

The *Conseil Général* is elected by 62 *cantons*; the 364 *communes* elect municipal administrations. A long tradition of local self-government makes elections acrimonious and sometimes turbulent; yet the Corsicans are moderate in their political views; the Communist party, for example, attracts the support of only about 6 percent of the electorate, in contrast to its strong overall showing in southern France and in Italy. At the start of the 1970s, the majority in the *Conseil Général* was radical, supported by a small Socialist group (*SFIO* [*Section Française de l'Internationale Ouvrière*]); the opposition was centrist. Party labels count for less than family allegiances to political power groups and their leaders; but in national elections voters feel less bound by these traditional loyalties; Corsica entered the 1970s with two radical senators, while the three deputies were *UDR* (*Union Démocratique Républicaine*) members of the Corsican political minority.

Justice is administered as it is in the continental *departements*. The capital of the judiciary is Bastia, seat of the courts of assizes and of appeal. The military command is stationed in Bastia, while in Ajaccio the army is represented by a small detachment, and the navy by a naval air base. The Foreign Legion, repatriated from North Africa, has a parachutist regiment at Calvi and training units at Corte and Bonifacio. There is a military air base on the east coast.

Educational facilities, under the direction of a *vice-recteur* of the Academy of Nice, had much improved by the early 1970s to meet the aspirations of a people who value professional qualifications: nearly 40,000 students are accommodated in more than 450 primary, and 41 secondary schools and in three technical colleges. A public demand for a university has so far been disallowed because of small numbers of prospective students. Up to 600 students a year enter universities in France.

Thanks to the national social security system and well-equipped medical services (250 doctors, 20 hospitals and clinics, a sanatorium, and a psychiatric hospital), public health is on a level with the national standard.

New homes have been built since 1963 at the rate of 2,000 a year, two-thirds of them in Ajaccio and Bastia, where there is still a demand for inexpensive housing. In the country houses are plentiful but under-equipped.

Though Corsica is still underdeveloped in relation to its economic potential, there is no malnutrition and little sign of poverty: more cars per capita are, in fact, owned by the inhabitants than in France as a whole. Corsicans assess their position by middle class criteria; aim at making careers in the professions, the administrative services, or the armed forces; and leave most manual work to foreign labourers. The latter enter the island poor but, because of social security and wages that conform to the national scale, soon improve their conditions.

Cultural life and institutions. Cultural life has suffered from the emigration of the most gifted Corsicans, and there is little contemporary artistic or literary creation. Much intelligent effort is, nevertheless, devoted to the study and conservation of the insular cultural heritage. The *Conseil Général* votes yearly funds from its budget for archaeological research, which is entrusted to qualified experts, enthusiastically followed by the population, and publicized by the Association *Archéologique de la Corse*. The outstanding megalithic monuments discovered during the 1960s and the remarkable Greek ceramics excavated at Aléria attract many savants and tourists. Learned journals of a high quality are published, including the *Bulletin de la Société des Sciences historiques et*

Political  
framework

Decline of  
agriculture

*naturelles de la Corse*, founded in 1881. Works on Corsican history find a responsive public.

Corsica has many museums for its size: the Centre de la Préhistoire Corse (Sartène); Musée Jérôme Carcopino (Aléria); a Musée d'Ethnographie Corse (Bastia); a Musée d'Histoire Corse (Corte); and the Musée Pasquale Paoli at Paoli's birthplace, Morosaglia. Souvenirs of Napoleon Bonaparte and his family are exhibited in the Maison Bonaparte and the Musée Napoléonien in Ajaccio, where the Musée Fesch contains a fine collection of old masters assembled by Cardinal Joseph Fesch, Napoleon's step-uncle.

Traditional folk music is performed by groups in the towns and can still be heard in its rural setting, and traditional handcrafts are being revived. The much-studied Corsican dialect is the language of a literary periodical, *U Muntese*. The Maison Itinérante de la Culture de la Corse, founded in 1968, brings classical and modern theatre and concerts, with performers from overseas, to towns and villages and organizes art exhibitions and a summer music and drama festival. Two daily papers in Nice and Marseille carry several pages of Corsican news; and about a dozen papers and periodicals are published in Corsica. Radio and television programs are regularly broadcast from the island.

Problems and prospects. Since the 1960s, Corsica has been emerging with startling rapidity from an archaic, traditional pattern of life. But the transformation is incomplete and insecure: the impetus given by the return of French families from North Africa may be spent, and it is uncertain if the population will continue to increase or the standard of living to rise.

Questions crucial in relation to Corsica's future are whether the coastal monocultures will hold their own in the French market, and, indeed, in the Common Market as a whole, and whether the interior can be revived by a modernization of stockbreeding and a geographical extension of tourism. Continental France, meanwhile, still offers a living to almost every Corsican who emigrates, and Corsican problems appear much less acute when placed in a national rather than in an insular context.

**BIBLIOGRAPHY.** PAUL ARRIGHI (ed.), *Histoire de la Corse* (1971), is a modern treatment by a team of experts. The following studies illuminate specifically Corsican institutions: A. CASANOVA, "Essai sur la seigneurie banale en Corse," *Etudes Corsea* (1959-60); PIERRE EMMANUELLI, *Recherches sur la Terra di Comune* (1958); FRANCIS POMPONI, *Essai sur les notables ruraux en Corse au XVII<sup>e</sup> siècle* (1962); and DOROTHY CARRINGTON, "The Corsican Constitution of Pasquale Paoli, 1755-69," in the proceedings of the *International Commission for the History of Representative and Parliamentary Institutions* (1971). JANINE RENUCCI, *Corse traditionnelle et Corse nouvelle* (in prep.), is a comprehensive analysis of Corsican demography and economy. *Corse, Ile d'Elbe, Sardaigne*, 22nd ed. (1968, revised periodically), is a guide (Guide bleu) offering reliable general information.

(D.V.C.)

## CortCs, Hernan

Hernán (or Hernando) Cortés, the Spaniard who conquered Mexico early in the 16th century, was—with Francisco Pizarro, conqueror of Peru—the greatest of the Spanish conquistadors. Cortés was 33 years old when he set out in February 1519 to do what two previous Spanish expeditions under Francisco Hernandez de Córdoba (1517) and Juan de Grijalva (1518) had failed to do: colonize the mainland of America. By 1521 the Aztec Empire in Mexico had been destroyed; the Aztec priest-king Montezuma (Moctezuma II) was dead; the Aztec capital of Tenochtitlán was in ruins; and Cortés had founded New Spain, the first of the great Spanish American possessions. His conquest, achieved initially with barely 400 Spanish soldiers, represented the peak of his extraordinary career. It set the pattern for Pizarro's later conquest of the Incas of Peru and remains to this day one of the most fascinating and colourful campaigns in history. (For a detailed account of the Spanish conquest of Mexico, see MEXICO, HISTORY OF.)

Early years. Cortés was born in the Spanish town of Medellín in 1485. Thus, like Pizarro, who was vaguely

Cortés, oil painting by an unknown artist. 1530. In the Hospital de Jesús, Mexico City.  
By courtesy of the Hospital de Jesús, Mexico City

related to him, he was reared in the Estremadura province of Spain at a time when the centuries-old crusade against the Moorish invader was drawing to a close. There, in harsh upland country, both men developed an exceptional hardiness; there, too, they recruited many of their toughest soldiers of fortune. Born to the sword and the saddle, the peasant world of their upbringing combined with the background of religious warfare to give them a blend of greed for gold and a religious fervour that was to carry them with fanatical courage into a new world.

In the little town of Medellín, below its large castle, there are still some traces of the Cortés family home. He was the son of Martín Cortés de Monroy and of Doña Catalina Pizarro Altamarino—names of ancient lineage. "They had little wealth, but much honour," according to Cortés' secretary, Francisco López de Gómara, who tells how, at the age of 14, the young Hernán was sent to study at Salamanca, in west central Spain, "because he was very intelligent and clever in everything he did." Gómara went on to describe him as ruthless, haughty, mischievous, and quarrelsome, "a source of trouble to his parents." Certainly he was "much given to women," frustrated by provincial life, and excited by stories of the Indies Columbus had just discovered. He would have sailed with Nicolás de Ovando, royal governor of the Spanish Indies from 1501 to 1509, but was injured by a falling wall while escaping from the house of a married woman. He then set out for the east-coast port of Valencia with the idea of serving in the Italian wars, but instead he "wandered idly about for nearly a year." Clearly Spain's southern ports, with ships coming in full of the wealth and colour of the Indies, proved a greater attraction. He finally sailed for the island of Hispaniola (now Santo Domingo) in 1504. He was then 19.

Years in Hispaniola and Cuba. In Hispaniola, he became a farmer and notary to a town council; for the first six years or so, he seems to have been content to establish his position. He contracted syphilis and, as a result, missed the ill-fated expeditions of Diego de Nicuesa and Alonso de Ojeda, which sailed for the South American mainland in 1509. By 1511 he had recovered, and he sailed with Diego Velázquez to conquer Cuba. Velázquez

Upbringing and study in Salamanca

was appointed governor, and Cortés clerk to the treasurer. Cortés received a *repartimiento* (gift of land and Indian slaves), and the first house in the new capital of Santiago. He was now in a position of some power and the man to whom dissident elements in the colony began to turn for leadership. This, and his affair with Catalina Juárez, when Velázquez was courting her sister, led to a whole series of farcical episodes—breach of promise, imprisonment, escape into sanctuary, being put in irons on board a ship, a second escape (disguised as a servant boy), swimming the river to sanctuary. In the end, Cortés married Catalina and made his peace with Velázquez.

Appointment from Velázquez to lead an expedition to Mexico

Cortés was twice elected *alcalde* ("mayor") of the town of Santiago and was a man who "in all he did, in his presence, bearing, conversation, manner of eating and of dressing, gave signs of being a great lord." It was therefore to Cortés that Velázquez turned when, after news had come of the progress of Grijalva's efforts to establish a colony on the mainland, it was decided to send him help. An agreement appointing Cortés captain general of a new expedition was signed in October 1518. Experience of the rough and tumble of New World politics advised Cortés to move fast, before Velázquez changed his mind. He went about with a large armed following and had banners that proclaimed: "Brothers and Comrades, let us follow the sign of the Holy Cross in true faith, for under this sign we shall conquer." His sense of the dramatic, his long experience as an administrator, the knowledge gained from so many failed expeditions, above all his ability as a speaker gathered to him six ships and 300 men, all in less than a month. The reaction of Velázquez was predictable; his jealousy aroused, he resolved to place leadership of the expedition in other hands. Cortés, however, put hastily to sea to raise more men and ships in other Cuban ports.

**The expedition to Mexico.** When he finally sailed for the coast of Yucatán on February 18, 1519, he had 11 ships, 508 soldiers, about 100 sailors, and—most important—16 horses. He had also incurred the undying enmity of Velázquez. As a result, there was an element of disaffection within his fleet. The immediate solution was to send Diego de Ordaz, who commanded a Velázquez ship, away on a foraging expedition. On the mainland Cortés did what no other expedition leader had done: he exercised and disciplined his army, welding it into a cohesive force. But the ultimate expression of his determination to deal with disaffection was when he burned his ships. By that single action he committed himself and his entire force to survival only through conquest.

The key to that conquest lay in the political crisis within the Aztec Empire. The ability of Cortés as a leader is nowhere more apparent than in his quick grasp of the situation—a grasp that was ultimately to give him more than 200,000 Indian allies. He was also fortunate in being presented at the outset with a captured princess who spoke Nahuatl, the language of the Aztecs. She became his "tongue," his adviser on Indian affairs, and, later, his mistress. It was she who worked on the complicated enigmatic mind of Montezuma so subtly that he finally became the voluntary prisoner of her master. Any assessment of Cortés' two campaigns against the Aztecs must take account of his ability to attract and retain the loyalty of this extraordinary woman. She was given the title Doña Marina by the Spaniards, hut, to the Aztecs, Cortés and his "tongue" were one—"Malinche."

The role of the captured princess Doña Marina

Spanish politics and envy, however, were to bedevil Cortés throughout his meteoric career. At the outset his problem concerned Velázquez, and he dealt with it by having his newly founded town of Veracruz on the coast of Mexico elect him captain and chief justice—a simple expedient that only a man trained in law and civic affairs would have appreciated. His power then rested on the civic rights of a town under the Spanish crown, not on his appointment by the Governor of Cuba. But this legal safeguard did not prevent Cortés from being threatened by a Spanish force from Cuba, led by Pánfilo Narváez, at a time (mid-1520) when he held the Aztec capital of Tenochtitlán by little more than the force of his personality. He defeated Narváez in a night attack, but

his forced march to the coast, leaving his most reckless captain Pedro de Alvarado in control of Tenochtitlán, led directly to the *noche triste* (the nearly disastrous Spanish retreat from the city). Cortés, however, could face and contend with such disaster.

More insidious was the political attack Velázquez mounted in Spain through Bishop Juan Rodríguez de Fonseca and the Council of the Indies. Thus, in 1521, when Cortés had finally destroyed Tenochtitlán, conquering it street by street, canal by canal, and was absolute ruler of a huge territory that extended from the Caribbean to the Pacific, it was the politics and bureaucracy of Spain itself that began the slow, corrosive work of destroying him. Fully conscious of the vulnerability of a successful conqueror whose field of operations was almost 5,000 miles from the centre of political power, he countered with lengthy and detailed dispatches—five remarkable letters addressed to Charles V. His acceptance by the Indians and even his popularity as a relatively benign ruler was such that he could have established Mexico as an independent kingdom. Indeed, this is what the Council of the Indies feared. But his upbringing in a feudal world in which the king commanded absolute allegiance was against it.

**The Honduran expedition and last years.** In 1524, his restless urge to explore and conquer took him south to the jungles of Honduras. The two arduous years he spent on this disastrous expedition damaged his health and his position. His property was seized by the officials he had left in charge, and reports of the cruelty of their administration and the chaos it created aroused concern in Spain. His fifth letter to the Emperor attempts to justify his reckless behaviour and concludes with a bitter attack on "various and powerful rivals and enemies" who have "obscured the eyes of your Majesty." But it was his misfortune that he was not dealing simply with a king of Spain but with an emperor who ruled most of Europe and who had little time for distant colonies, except insofar as they contributed to his treasury. The Spanish bureaucrats sent out a commission of inquiry under Luis Ponce de León, and, when he died almost immediately, Cortés was accused of poisoning him and was forced to retire to his estate.

In 1528 Cortés sailed for Spain to plead his cause in person with the Emperor. He brought with him a great wealth of treasure and a magnificent entourage. He was received by Charles at his court at Toledo, confirmed as captain general (but not as governor), and created *Marqués del Valle*. He also remarried, into a ducal family. He returned to New Spain in 1530 to find the country in a state of anarchy and so many accusations made against him—even that he had murdered his first wife, Catalina, who had died that year—that, after reasserting his position and re-establishing some sort of order, he retired to his estates at Cuernavaca, about 30 miles south of Mexico City. There he concentrated on the building of his palace and on Pacific exploration.

Reception in Spain

Finally a viceroy was appointed, after which, in 1540, Cortés returned to Spain. By then he had become thoroughly disillusioned, his life made miserable by litigation. All the rest is anticlimax. "I am old, poor and in debt. . . again and again I have begged your Majesty. . . ." In the end he was permitted to return to Mexico, but he died before he had even reached Seville—on December 2, 1547.

**BIBLIOGRAPHY.** The three prime sources are Cortés himself, his secretary Gómara, and Bernal Díaz. *Hernando Cortés: Five Letters, 1519-1526*, trans. by J. BAYARD MORRIS (1928), covers the period of conquest and the immediate aftermath and is the most reliable source on facts, dates, and numbers of men involved in battle between these years. BERNAL DÍAZ, *Historia verdadera de la conquista de la Nueva España* (first published in 1632; Eng. trans., *The Conquest of New Spain*, 1963), a classic work, covers much the same period, but the author began it when he was 70 years old, and though his memory is astonishing and very vivid, it cannot be compared for accuracy with the *Letters*, which were written at the time and on the spot. FRANCISCO LOPEZ DE GOMARA, *Historia de la conquista de Mexico* (1553; Eng. trans., *Cortés: The Life of the Conqueror by His Secretary*, 1964), is the only real

source for Cortés' early life and is probably reasonably accurate. The works of later Spanish writers tend to be politically biased and should all be treated with caution—and particularly the work of Las Casas, though he was a contemporary of Cortés. The best academic source remains W.H. PRESCOTT, *History of the Conquest of Mexico*, 3 vol. (1843, with many later reprints), a work so thorough that no scholar or traveller has since been able to fault him other than in very minor details. Of the modern studies, SALVADOR DE MADARIAGA, *Hernán Cortés, Conqueror of Mexico* (1941, reprinted 1979), is both scholarly and readable; HAMMOND INNES, *The Conquistadors* (1969), covering the whole sweep of Spain's New World involvement, demonstrates the duality of Cortés' conquest of the Aztecs and Pizarro's later conquest of the Incas.

(R.H.I.)

## Cosmetics Industry

The cosmetics industry includes not only preparations (other than soaps) designed to clean or beautify the body, which are normally associated with the word cosmetics, but also perfumes, dentifrices, and other toilet preparations, some of which are treated in some countries as nonprescription drug products. In general, the term is used to cover all products applied to the body that help the user look or feel more attractive, acceptable, and desirable to others. Such products also deal with the abnormalities caused by normal daily stresses but not with those abnormalities that are the proper field of medicine.

The industry contains several major companies operating internationally, in addition to smaller local manufacturers and distributors. A similarly structured supply industry provides chemicals, perfume essences, and packing materials used by the industry. The size of the market tends to be underestimated. It is actually as large as the detergents market, though much more fragmented. In the late 1970s, world consumption of cosmetics was valued at about \$40,000,000,000, of which western Europe represented about \$12,000,000,000 and Japan \$5,000,000,000. Consumption patterns in the United States, where more than one-fourth of the total sales occurred, were 42 percent in hair care products, 13 percent in antiperspirants and deodorants, 12 percent in dentifrices, 11 percent in creams and lotions, and 22 percent in other items, including bath products, shaving creams, and fragrances.

### HISTORY

The use of cosmetics is an ancient practice. Evidence of the use of eye makeup and aromatic ointments has been found in Egyptian tombs dating to 3500 BC. Perfumes of natural origin were greatly prized and hence associated with priestly functions. Oils were used in bathing, possibly because of the drying Mediterranean climate, and this practice was evidently widespread in ancient Greece.

By the 1st century AD the Egyptian, Roman, Greek, and Middle Eastern cultures had developed such cosmetics as powders to whiten the skin; kohl to darken the eyelids, eyelashes, and eyebrows; rouge for the cheeks; abrasive products to clean the teeth; perfumed cleansers and unguents; and oils for the bath. The oils used were natural products such as those obtained from almonds and olives; the perfumes were floral or spicy, with natural gums employed as vehicles and fixatives.

Similar cosmetics were used throughout the centuries. They were not very different from those employed today. Cosmetics for the face, dyes for the hair, perfumes for adornment, and environmental health and bath aids were all common in western Europe from the 13th century. Less developed civilizations also applied cosmetics; facial decoration has been associated with both magic and war in cultures as far removed geographically as that of the North American Indian and of the indigenous African. The African continent, particularly, developed the art of hairstyling, and the East contributed much to perfumery.

The significant technical developments that form the basis of the modern cosmetics industry, however, are much more recent in origin. In addition to new and improved products, improved packaging and promotional advertising played a role. Among important innovations of the last hundred years are the collapsible tube (1890s); chemicals in hair-waving (1920s); soapless shampoos and

the cold permanent wave (1930s); the aerosol container (1940s); and improved, less hazardous hair colorants and the fluoride toothpaste (1950s).

### COSMETICS AND RELATED PREPARATIONS

**Skin-care preparations.** The skin consists of a series of outer layers collectively called the epidermis, and the underlying true skin, or dermis (see also SKIN, HUMAN). The fact that skin creams and similar products are normally associated with the word cosmetics reflects a change in public attitudes. The basic step in facial care is cleansing, and soap and water is still one of the most effective means.

**Cleansing creams and lotions.** Cleansing creams and lotions are useful if heavy makeup is to be removed or if the skin is sensitive to soap. Their active ingredient is essentially oil, which acts as a solvent, presented in an emulsion (a mixture of liquids in which one is suspended in droplets in another) with water. Consistency ranges from the thick cold-cream types, made from an emulsion of water suspended in oil, to the relatively thin oil-in-water emulsions called cleansing milks. Cold cream, one of the oldest beauty aids, originally consisted of water beaten into relatively hard mixtures of such natural fats as lard or almond oil. But modern preparations use mineral oil with a suitable emulsifier to aid and maintain the uniform dispersion of oil in water, and their cooling effect is produced by delayed evaporation of the water.

**Emollients.** Emollient, or softening, creams; night creams; and nourishing creams are heavier derivatives of cold cream. They are usually formulated to encourage a massaging action in application and often leave a thick film on the face overnight, minimizing water loss during that period when natural metabolism is at work. This process is possibly aided by the creams' special ingredients, such as humectants (moisturizers) and herbal extracts. Among such ingredients, the hormones (substances naturally secreted by the endocrine glands and affecting metabolism) are almost unique in having some proved physiological action. At the low levels at which they must be used for safety, however, their effect is minimal.

**Hand creams and lotions.** Hand creams and lotions are used chiefly to prevent or reduce the roughness and dryness arising from exposure to household detergents, wind, and dry atmospheres. Like the analogous facial products, they act largely by replacing lost water and laying down an oil film to reduce subsequent moisture loss while natural processes repair the damage. To avoid a greasy layer on the hands, such creams are generally creamy, oil-in-water emulsions.

**Other skin-care products.** Many specialized products are used for skin care, particularly products called tonics and fresheners—dilute alcoholic lotions that contain some astringent and, especially for use by children and young adults, some germicide usually to deal with the secondary infection of acne. Many products claim some skin-lightening effect, but this is only appreciable when they contain those chemicals that have a real action on the melanin (a dark brown pigment in the skin), such as hydroquinone or related chemicals.

**Makeup preparations.** **Foundations, face powder, and rouge.** The classic foundation is vanishing cream, essentially an oil-in-water emulsion that contains approximately 15 percent stearic acid (a solid fatty acid), a small part of which is saponified, thus converting the stearic acid to the crystalline form that provides sheen. Such creams spread easily and leave no oily finish, though they provide an even, adherent base. Hence, lacking pigment, the cream "vanishes." Variations are provided by oilier products for dry skin, which have nonionic emulsifiers and contain colouring matter. Liquid foundations, also oil-in-water emulsions but with less oil, are more heavily pigmented and can replace the classic combination of foundation cream and face powder. Face powder dusted on top of a foundation provides a peach-skin appearance. Many ingredients are needed to provide the characteristics of good powder. Talc helps it spread easily; chalk or kaolin gives it moisture-absorbing qualities; magnesium stearate helps it adhere; zinc oxide and titanium dioxide permit it to

Vanishing cream

The market for cosmetic products

Early cosmetics

cover the skin more thoroughly; and various pigments add colour.

Heightened colour and texture can be provided with rouge, in compressed powder or in cream form, used for highlighting the cheekbones; the more modern version is the blusher, used to blend more colour in the face. Make-up in compressed cake, cream, or gel form and compressed powders are popular as a more or less complete facial make-up and are particularly useful for carrying in the handbag.

*Eye makeup.* Eye makeup, usually considered indispensable to a complete maquillage (full makeup), includes mascara to emphasize the eyelashes, either in cream form or as a soap-based block; eye shadow for the eyelids, available in many shades; and eyebrow pencils and eyeliner to pick out the edges of the lids. Because eye cosmetics are used adjacent to a very sensitive area, innocuity of ingredients is essential.

*Lipstick and lipsalve.* Lipstick is an almost universal cosmetic since, together with the eyes, the mouth is a leading feature, and can be attractively coloured, textured, and seemingly changed in size to meet the needs of beauty and fashion. Lipstick has a fatty base that is firm in itself and yet spreads easily when applied. The colour may be provided by pigments—usually reds but also titanium dioxide, a white compound that gives brightness and cover—or by stains that dye the surface of the lips. The stains are always eosin, a red crystalline fluorescent dye, or derivatives of fluorescein, a yellow granular or red crystalline dye. Being only slightly soluble in the wax base, these dyes need a further solvent to render them effective. Because lipsticks are placed on a sensitive surface and ultimately ingested, they are made to the highest safety specifications, considerably restricting the materials available and especially the colours.

Products similar to lipsticks but with little or no colour are also sold as lipsalves to lay a thickish protective coating on the lips against the ravages of wind, sun, and extremely low humidities, or to provide a glossy finish.

*Suntan preparations.* Further protection by suntan preparations is needed when tanning of the face or body is to be achieved from natural sources without further damage. Products corresponding to most of the cosmetic range, such as vanishing creams, general-purpose creams, and cleansing milks, together with oils and foams, are used to apply the necessary film that also contains a specific sunscreen ingredient, such as ethyl paradimethylaminobenzoate, designed to transmit enough of the sun's spectrum to produce tanning but not the short ultraviolet rays that burn.

*Hair preparations.* *Shampoos.* Shampoos must clean the hair adequately and leave it in manageable condition. The use of soap as the sole detergent risks scum production; the basis of retail shampoo is usually an anionic (negatively charged) detergent of good solubility, insensitivity to hard water, and with high grease-removal powers, such as triethanolamine lauryl sulfate in a concentration of about 15 percent. Perfume and additions to control viscosity are essential to an acceptable product, but shampoos may also contain ingredients to meet the special requirements for dry or greasy hair or to combat dandruff. Such products are usually in an opaque or cream form. The firmer varieties can be packed in tubes or jars; other types are bottled.

The job of shampooing is basically that of removing greases, such as sebum and hairdressing, that bind particulate dirt to hair and scalp. This is an easy task for detergents when used in warm water, and the choice of a shampoo usually is based on the secondary requirement of leaving the hair not only clean but as the user requires; e.g., more manageable or freer of dandruff.

*Hairdressings, sets, and sprays.* Hairdressings, sets, and sprays are useful in grooming when the hair is to be fixed in a desired style, possibly with added gloss and certainly without loss of natural lustre. The aerosol spray is widely accepted by women and permits significant choice of permanence from a very light hold to a virtual varnishing occasionally used for special purposes. Hair sprays are composed of a suitable resin that may be nat-

ural (e.g., shellac) or synthetic (e.g., polyvinylpyrrolidone). They also include perfume and possibly a plasticizer, a chemical substance imparting workability, dissolved in a volatile solvent such as alcohol, and delivered in fine-spray form by the aerosol propellant (see below). Hair sprays for use by men were gaining acceptance in the early 1970s.

Before the arrival of the aerosol can, hair was set in position by use of fairly simple gum solutions, usually tragacanth, and these are still employed because of their effectiveness and cheapness; use of "gominas" by men is particularly popular in South America.

Oily dressings, either as brilliantines that are nearly 100-percent oily matter, or as emulsions, usually of water-in-oil, provide an acceptable gloss, particularly on dark hair, and some measure of fixation. The emulsion products also provide the water necessary to make the hair initially more capable of being reformed into the required position. Brilliantines, which cannot do this, are most used by both sexes in hot climates where the hair is straight, as in India, or short and not in need of restyling, as in West Africa. Locally used oils are usually natural (e.g., coconut oil in India), but heavy brilliantines and pomades are based on petroleum oils and jellies. In tropical climates particularly, these brilliantines are also used as a means of positive perfuming.

Alcoholic lotions, especially popular in Europe and South America, provide a fresh stimulus to the scalp and are excellent vehicles for treatment ingredients and perfumes.

Increased attention to the hair results in more work being done on it by combing, setting, bleaching, and colouring; and this, together with environmental pollution and the consequent need for frequent shampooing, makes "out-of-condition" hair a common complaint. This condition relates largely to surface damage to the scales, which can be treated with suitable surface-active compositions normally made up as emulsions for after-shampoo treatments and sold as hair conditioners or strengtheners.

*Permanent waving.* Permanent waving can be effected in various ways by altering the shape of the hair into the desired configuration under the influence of heat or chemicals that cause an irreversible change. Straight-haired people frequently would like a wave; others with tightly curled hair may want the tightness released to make the hair more controllable. The process is essentially the same. Heat can be used, as in traditional curling processes or hot-comb straightening, but the more common process is to use ammonium thioglycollate to release the bonds in hair by chemical means, permitting it to be reset in its new form by oxidation. This process is also used in milder form to add a small amount of wave to give the hair more lift and body.

*Hair colorants and bleaches.* Hair colorants and bleaches are used to add "life" to dull or mousy-coloured hair or to cover gray. Dyes were once harsh and drastic and their use confined to theatrical performers and others whose professions required youthful hair colour. Today both permanent colouring, remaining until it grows out, and semipermanent colour, removable after a small number of shampoos, are available for home use. Permanent dyes act by letting a small, colourless, dye precursor (a substance that becomes a dye when polymerized) penetrate the hair and then polymerizing it by oxidation in place, usually with hydrogen peroxide, to a large coloured molecule. Semipermanent types dye directly by incorporating a small-molecule dye of the textile-disperse type in a special shampoo base; some products combine both principles. There are also strictly temporary coloured lacquers and setting lotions that put a coloured film on the hair.

Perfumes and other fragrance products. Perfumes are used in practically every cosmetic and toiletry item, sometimes subsidiary to the main function of the product but often solely to provide fragrance. The fragrance must be formulated for its specific use, and its chemical stability in the particular system must be considered. Various ingredients are used to obtain so-called top

Brilliantines and emulsions

Sunscreens

notes, providing the more volatile, immediate odours; middle notes, adding the full, solid character; and base notes, responsible for less volatile, persistent odours. The ingredients making up the fragrance may be of vegetable, animal, or chemical origin. A simple essence, such as for a toilet soap, may have some 20 ingredients and a fine handkerchief perfume, more than 100 (see also OILS, FATS, AND WAXES).

The simplest fragrances are the toilet waters and eau de colognes, which are aqueous alcoholic solutions of low persistence, containing a fairly small proportion of the fragrance-producing ingredients, designed to be reasonably fugitive and fresh in impact. Handkerchief perfumes are more concentrated and essentially alcohol solutions of the essence; the creation of these perfumes is an art form as well as a science, and its leading practitioners are recognized as artists of the highest calibre. Solids and semisolids can also be used as fragrance vehicles. Products of this type include cologne sticks, in which the alcohol is gelled with soap.

#### HYGIENE AND OTHER PREPARATIONS

**Dentifrices.** Regular brushing of the teeth is effective in combatting gum problems and limiting bacterial attack on teeth. Dentifrices assist these processes by providing an abrasive, which may be very mild or quite hard, and a detergent; in toothpastes, these are put together with a substance serving as a vehicle and a suitable flavour. Typical formulae include abrasive (*e.g.*, calcium phosphate dihydrate, chalk, alumina), 40 percent; glycerine, 20 percent; detergent (*e.g.*, sodium lauryl sulfate), 1.5 percent; thickener (*e.g.*, sodium carboxymethyl cellulose), 1 percent; flavour, 1 percent; and water.

A significant advance in oral hygiene was made when, following the discovery of the effect of the fluoride ion in water in reducing dental decay (caries), it was shown to be possible also to reduce the incidence of caries by topical treatment with fluorides (salt of hydrofluoric acid) or fluorophosphates in dentifrice formulations. The efficiency of such products depends very much on the assiduity of use and the skill of the formulator in preserving the activity of the fluorine compound.

**Mouthwashes.** Mouthwashes are sometimes considered helpful in oral hygiene, although their widespread use is largely confined to the United States. These are usually based on a mild germicidal action, plus some astringency and appropriate flavour.

**Antiperspirants and deodorants.** A rising consciousness of personal hygiene has been brought about in much of the world by a general improvement in living standards, population density in the cities, and increased promotion and advertising of products intended to improve the impact of the individual on the senses of others. Antiperspirants, deodorants, and deodorant soaps have made especially rapid strides since the introduction of aerosol sprays. The first antiperspirants were dilute alcoholic solutions of aluminum chlorhydrate applied with a sponge, later developed into cream and stick formulae but all suffering from the unaesthetic nature of the operation. Many other materials have been tried, but aluminum derivatives remain the safest and most effective. Deodorants, essentially mild germicides with a good perfume, combat the odours developed by bacterial or enzyme activity from the initially odourless sweat. The combination of an antiperspirant to reduce the excretion of moisture, a deodorant to reduce odour, and perfume is the attraction of the popular sprays and roll-ball applicators.

**Bath preparations.** Bath preparations have risen rapidly in popularity, with extended use of germicidal soaps, bath oils, and preparations that add perfume and a pleasant feel to the skin. Bath crystals, in the form of the original bath salts (usually perfumed and coloured sodium sesquicarbonate) or as compressed tablets supply an additional benefit in softening the water and reducing scum from the soap. Bubble baths also provide a touch of luxury with their abundant foam, produced by the action of the stream of water from the tap, whipping it up with the aid of a high content of surfactant (a substance aiding

in wetting and dispersion) and foam stabilizer. Other foam baths contain specific additives to promote a feeling of well-being.

Talcums, *dusting powders*, and other after-bath preparations. In hot climates, extensive use is made of talcum and dusting powders as after-bath aids to freshness. The pleasant feel of the powdered skin is also appreciated in temperate climates. In the tropics, alcoholic lotions and colognes are used as much for normal hygiene purposes as for perfume. The difference in the scale of use is vividly displayed in the sizes of the unit containers sold in the tropics compared with those for the same class of product in Europe; *e.g.*, for powders, 16 ounces as against four ounces. These products may also include a small amount of germicide to assist in deodorizing perspiration.

**Depilatories.** Depilatories are used to remove hair, particularly from the legs and underarms. Removal of underarm hair also permits more effective use of antiperspirant deodorants. The active ingredient in such products is usually calcium thioglycollate made into a cream or paste. This reacts with hair in the same way as do waving lotions, by breaking chemical bonds in the structure. Instead of controlling and then reversing the process, however, as in waving, the depilatory action is allowed to go to completion, weakening the hair so that it can be removed at skin level with minimal effort. Other methods of depilation include application of waxes that set around the hair, pulling the hairs out of the follicle when the wax is pulled off; and, of course, shaving.

**Miscellaneous preparations.** Shaving preparations. Shaving preparations are designed to make the task of shaving easy and pleasant. The beard must be moistened to soften it, and full saturation of a hair with water takes some three to four minutes, so that the shaving soap, cream, or foam must have a consistency or lather to hold water in contact this long. Hence, shaving soaps, sticks, and lather creams produce a tight, slow-to-collapse foam; brushless cream and aerosol creams perform the same task without lathering. The brushless cream is similar to a foundation vanishing cream in being an oil-in-water emulsion containing some 15–20 percent of oily matter, essentially stearic acid. The lather products are always based on stearic-acid soaps, to produce close lather, saponified with a mixture of soda and potash to provide adequate solubility or speed of lather. Aerosol foams are produced by the expansion of propellant in a cream.

Other shaving aids include preshave lotions and powders to prepare the face for dry shaving with electric shavers and after-shave lotions, creams, and powders to provide a smooth, soothed finish to the operation. After-shave lotions are alcoholic, similar to colognes but less strongly perfumed, and may include an additional astringent.

**Manicure preparations.** The nails, particularly of the hands, also receive care and adornment, and many specialized manicure preparations exist. Chief among these is the nail lacquer, or varnish, and its associated remover. Nail polish is basically a solution of nitrocellulose lacquer, with a plasticizer to make it spread, and appropriate colouring matter. Removers are made from such solvents as acetone and ethyl acetate.

**Baby preparations.** Preparations used for babies are technically similar to the corresponding adult products, but in a milder and less strongly perfumed form. Avoidance of irritant material is essential, and many adult users buy baby products for the implied characteristics of mildness.

#### TECHNICAL ASPECTS

**Manufacturing.** The manufacture of cosmetics and toilet preparations does not generally require heavy capital investment, nor is it excessively labour intensive, and the added value of the resulting products is high in relation to the direct manufacturing costs. Most of the processes are basically those of mixing and blending. Because of the variety of shades, types, and packs necessary to provide the wide choice to the consumer that is intrinsic to the industry, it is usual to employ the batch process, in which a specific quantity is completely pro-

Fluorides  
added to  
toothpaste

Batch  
processing

cessed at one time (unlike continuous processing). This type of processing demands ready convertibility and cleaning; cosmetic factories have standards of good housekeeping that approach and often equal those of the pharmaceutical industry.

Packaging is of the highest importance because the function of a cosmetic product is indissolubly linked to its container. The most extreme instances of functional packaging are probably the aerosol and the roll-on ball, but every product needs its appropriate pack. Especially for cosmetics carried in the handbag or used at the dressing table, packaging requires design of high aesthetic quality, in addition to functional and protective qualities. Fully automated packing lines are used by larger manufacturers for their main lines, particularly for toothpastes, aerosol hair sprays, and shampoos.

Aerosols were introduced in 1943 for insecticidal sprays for use by the U.S. armed forces. Aerosols have since shown a phenomenal growth in use for such products as hair sprays, room deodorants, insecticides, and antiperspirants and deodorants.

In addition to the requirement for the plant to produce an uncontaminated product, care must be taken to maintain such conditions throughout the storage and use of the product. Adequate preservatives must always be included in products that are not self-preserving.

Evaluation and testing. Safety testing. Laws relating to cosmetics manufacturing vary from country to country, but generally no manufacturer deliberately would subject customers to unknown risks. Products must be tested before sale. Use of chemicals or other ingredients of known hazard is limited or excluded; products containing such ingredients are subject to labelling regulations.

New products or ingredients are usually screened first on animals. The main tests are for: (1) primary irritation, (2) sensitization, (3) eye damage, (4) acute toxicity, and (5) chronic toxicity. Primary irritation is determined by patching (applying to a small area) on rats, mice, or guinea pigs. Sensitization, a reaction that may be peculiar to the individual, differs from a primary irritation in that the subject becomes sensitized to the chemical, or one closely related to it, by a prior use that may provoke no reaction, while subsequent use provokes an allergic response involving inflammation, swelling, or reddening not necessarily at the site of application.

For shampoos and other products likely to reach the eyes, animal tests are used to determine the possibility of eye damage. The product is dropped into a rabbit's eye and the nature of any damage or inflammation and rate of recovery after specified periods of time are observed. It is accepted that soap may sting a bit if it goes into the eyes, but there must be no permanent damage; some highly functional products may carry a warning.

Animal testing has been under intense criticism from animal protection groups for some time. Since 1981 alternatives to animal testing have been explored at the Rockefeller University, New York City, under a grant from Revlon, and at Johns Hopkins University, Baltimore, under a grant from the cosmetic industry.

Products destined or likely to be swallowed are assessed for toxicity, employing established standards based on the size of the dose versus the weight of the test animal. There is little difficulty in measuring acute toxicity, although chronic toxicity—the effect of ingesting small amounts over a long time—is more difficult to measure. Some functional products, such as cold permanent-waving solution, are required to carry labels stating "do not drink" or "not for internal use."

Assuming that potential hazards have been adequately assessed on prior evidence or animal tests, it must still be confirmed that undesired human reactions do not take place. Because of its idiosyncratic nature, reactions produced by sensitization may remain undetected prior to marketing, even when extensive testing is done. Skin tests can at least assess the level of any primary irritation and can determine if widespread sensitization is a risk. Such tests involve applying the product to the skin of volunteers, usually on their forearms, and covering the patch to intensify the reaction. A final test is made when a suitable

period has elapsed after the initial patch applications.

Despite having previously determined a product's safety through pre-market testing, the manufacturer keeps particularly close watch on any consumer complaints during early sales. During a test-market operation in a restricted area, for example, the manufacturer may alert nearby hospitals and clinics to report any unusual occurrences that may be linked to the product. A sensitization that occurs only in one person out of 50,000 might not be detected in preliminary tests but could be recognized through use by millions of people.

Performance and preference testing. The actual functionality of a product can be tested only through use by human subjects. Performance claims must be verified before they are advertised. Testing may range from relatively simple panel or salon tests to three-year clinical trials.

Modern preference testing has reached high levels of sophistication. In such highly subjective matters as perfume and flavour, statistically based techniques, largely originating in the food industry, are used to establish a straightforward preference between like items. In products judged largely on function, there may be an optimum or a maximum performance—for example, permanent waves can give either too tight or too loose a curl. In attributes difficult to quantify, mathematical techniques can now handle rank decisions, arranged in order of preference and based on paired comparisons. Modern consumer testing is a substantial part of cosmetics research and development. In addition, actual market research is employed to establish facts about the nature of the market as a whole.

#### LEGAL CONSIDERATIONS

Most legal codes recognize the duty of the manufacturer to take care not to harm the population at large. This duty is reinforced in most countries by more detailed legislation directed at specific types of products, and controlling some or all of the ingredients, labelling, packaging, and advertising. Some governments maintain regulatory bodies responsible for counselling and enforcement. The most highly developed system is that in the United States, where the Food and Drug Administration (FDA) and the Federal Trade Commission (FTC) both regulate drugs, cosmetics, and food products. The FDA requires that industry use certified dyestuffs for particular uses, and that toiletry items with therapeutic claims show heavily documented proof of performance and safety, such toiletries being treated as drugs.

By contrast, the United Kingdom has no specific cosmetic legislation, relying largely on the common law but reinforcing it by the Pharmacy and Poisons Act, with negative and restricted lists common to the drug industry; and by the Medicines Act of 1968 and the Trade Descriptions Act, with general laws on claims and performance. Toiletries that make substantial curative claims are treated as drugs.

In the early 1970s the European Economic Community engaged in harmonizing the separate laws of the member countries, and it seemed likely that legislation would emerge that treated toiletries separately from drugs and foodstuffs and that incorporated negative and restricted lists of ingredients. Similar patterns apply to many other countries, but there are variable patterns of control at the sales point. In France, for example, a physiologically active product must obtain a "visa" and can be sold only through pharmacies.

Most countries call for special labelling on products that, in order to achieve their performance standards, require ingredients of possible but acceptable hazard—e.g., certain hair colorants instruct the buyer to perform a patch test before making general application, and certain anti-dandruff shampoos instruct users to keep the product away from the eyes.

**BIBLIOGRAPHY.** Comprehensive single-volume references in English include R.G. HARRY, *Harry's Cosmetics*, rev. by J.B. WILKINSON et al., 6th ed. (1973); and M.S. BALSAM and EDWARD SAGARIN (eds.), *Cosmetics: Science and Technology*, 2nd ed., 3 vol. (1972-74), containing a helpful section on the history of cosmetics. M.G. DE NAVARRE (ed.), *Chemistry and Manufacture of Cosmetics*, 2nd ed., 2 vol. (1962), is another

Allergic response

comprehensive work. H.W. HIBBOTT (ed.), *Handbook of Cosmetic Science* (1963), produced for students of the Diploma Course of the Society of Cosmetic Chemists of Great Britain, is highly recommended as an elementary text. J. STEPHAN JELLINEK, *Kosmetologie*, 3rd ed. (1976; Eng. trans. of 2nd ed., *Formulation and Function of Cosmetics*, 1970), presents background and formulation aspects in relation to function in use.

F.V. WELLS and I.I. LUBOWE, *Cosmetics and the Skin* (1964), links the views of cosmetic scientist and dermatologist. In French, EDWIN SIDI and CHARLES ZVIAK, *Problèmes capillaires* (1966), does the same task for hair products and offers excellent discussions on hair coloration. A. HERZKA (ed.), *International Encyclopaedia of Pressurized Packaging: Aerosols* (1966), is a most comprehensive text specializing in aerosols.

Leading trade journals published in English include (all issued monthly): *Cosmetics and Toiletries* (U.S.); *Drug and Cosmetic Industry* (U.S.); *Soap, Perfumery and Cosmetics* (U.K.); and *Manufacturing Chemist and Aerosol News* (U.K.). There are similar journals in many countries. An excellent source of original scientific information is the bimonthly *International Journal of Cosmetic Science* (U.S., U.K., and West Germany).

## Cosmic Rays

In the early 1900s investigators discovered that the Earth is continually bombarded by highly energetic and extremely fast-moving particles that are now known to have originated far beyond the atmosphere. These incoming particles are known as "primary" cosmic rays. When these rays interact with the atoms and ions of the air, the Earth's magnetic field, recording instruments, and the ground, they produce "secondary" cosmic rays with much lower energy, which differ from the primaries in composition. The primary cosmic rays consist of atomic nuclei—mostly protons (nuclei of hydrogen atoms) with appreciable numbers of nuclei of other kinds of atoms—and some electrons. Secondary cosmic rays consist mainly of subatomic particles that are short-lived (they change within fractions of a second into other types of particles); they cannot have come far and are thus known to have been produced within the atmosphere.

For many years cosmic radiation, as the only source of high-energy particles, was of critical importance in the discovery of new elementary particles; the unravelling of the complicated chain of interactions initiated by high-energy cosmic rays in the atmosphere was accomplished by the efforts of several generations of scientific research. An observer situated within the Earth's atmosphere has only an obstructed view of the primary cosmic rays, but the modifying effect of the atmosphere was deduced in some detail by comparing data from balloons and from observing stations on mountains, near sea level, and underground. Cosmic-ray studies, particularly those regarding details of the composition and energy distribution of the primary radiation, have become part of astronomy and astrophysics. Results of these studies have contributed to the understanding of supernovae (exploding stars, now regarded as the most probable ultimate sources of the rays); of nuclear synthesis in stars; and of the properties of the Galaxy, the Sun, and the solar system. Investigations of the radioactive elements produced by cosmic-ray bombardment of the Earth, of meteorites, and of the lunar surface have added much information about the history of these objects. The isotopic composition of cosmic rays, particularly of the radioactive isotopes, promises to reveal much about the nature of cosmic-ray sources and of the particle interactions in interstellar space; cosmic-ray neutrinos and solar neutrinos are being studied in the hope that they will provide further clues toward new fundamental discoveries.

### HISTORICAL SURVEY

Discovery of cosmic rays. Around 1900, investigators of natural radioactivity—using ionization chambers in which the ionization of a gas by fast, charged particles is measured—found that there is residual ionization even in the absence of all radioactive material. Since such radiation could not be eliminated by heavy shielding, workers hypothesized the phenomenon was likely due to a penetrating radiation of unknown origin. In 1911 and 1912,

balloons carrying detection instruments to altitudes of about 5,000 metres led to the discovery that the intensity of radiation drastically increases with altitude. From this it was concluded that radiation originated outside, or within, the upper atmosphere. The fact that the radiation persisted day and night with the same intensity led to the conclusion that the Sun was not its direct source.

The first decades of analysis. In the 1920s progress came from the work of several investigators. One of these, Robert A. Millikan, was the first to show that the atmosphere acts only as a mass of absorbing material, and that it is not the producer of primary cosmic rays. He showed that the radiation is absorbed in the water of mountain lakes to the same degree as under an equivalent weight of air at lower altitudes, consistent with an extra-terrestrial origin of the cosmic rays. Since at that time the most penetrating radiations known were the gamma rays (electromagnetic radiation of very short wave length), it was assumed that primary cosmic radiation consisted of these rays. Later it was discovered that the intensity of the rays is less near the Earth's Equator than it is toward the polar regions. This phenomenon can be adequately explained if the radiation is assumed to consist of electrically charged particles that, as they move through the magnetic field of the Earth, encounter greater difficulties in reaching Earth near the Equator, where the lines of magnetic force are nearly parallel to the surface, than they do at the poles where the lines emerge almost vertically.

In the late 1920s two new research techniques became available. The first cloud chamber pictures of cosmic rays were made, and the use of multiple Geiger counters to record simultaneous pulses from different counters proved that very fast and, therefore, very energetic charged particles must be a dominant constituent of cosmic radiation at sea level. (The extremely short time between the arrival of signals showed that the speed of the particles was enormous.)

During the 1930s scientists developed their understanding of the complicated phenomena that occur in Earth's atmosphere under cosmic-ray bombardment. Ground and balloon observations were extended, and the absorption of cosmic radiation deep underground was measured. Two components of secondary cosmic rays were distinguished. A "hard" component, capable of penetrating deep underground and today known to consist mainly of muons (see below *Muons*), was separated from a "soft" component, now known to consist of electrons and photons, which could be absorbed in a few centimetres of lead. High-altitude balloon flights established that the total cosmic-ray intensity reaches a maximum at around 12 kilometres above sea level and declines at higher altitudes, showing that many of the particles must be produced well within the atmosphere and demonstrating the secondary nature of much of the cosmic radiation within the atmosphere. The same decade brought the discovery of extensive air showers, large numbers of secondary particles clearly produced by a single primary particle of extremely high energy (greater than  $10^{16}$  electron volts). (An electron volt, symbol eV, is a unit of energy, namely the energy acquired by an electron or proton falling through a difference in potential of one volt. The units kiloelectron volt [keV], megaelectron volt [MeV], and gigaelectron volt [GeV] represent  $10^3$ ,  $10^6$ , and  $10^9$  eV, respectively.)

In the early 1940s it was demonstrated that most primary particles are protons—positively charged hydrogen nuclei. Later during that decade photographic emulsions that proved sensitive to nuclear particles were produced; the scintillation counter was invented; sophisticated electronics systems emerged; and high-altitude balloons became reliable tools for cosmic-ray research. The nuclear emulsion technique—in which ionized tracks, formed in the emulsion as a result of cosmic rays passing through thick photographic emulsion, are rendered visible—led the way to many discoveries, the most important of which was the detection of the pi-meson, or  $\pi$ -meson, and the muon. With the discovery that many  $\pi^+$ ,  $\pi^-$  and  $\pi^0$  mesons are created in high-energy nuclear collisions,

Significance of cosmic-ray studies to astronomy

Secondary particles

the missing link necessary to account for the large flux of photons and electrons in atmospheric cosmic rays (see below) was found. A large number of other unstable particles were subsequently discovered, most of them through the use of nuclear emulsions, and some in cloud chambers developed to a high degree of sophistication.

**Developments after 1950.** Unmanned spacecraft, used since the late 1950s, have made possible the investigation of primary cosmic radiation free of terrestrial influences; with the development of solid state electronics the scientist was able to put small, sophisticated instruments into orbit around the Earth and the Sun. There followed the discovery of the Van Allen radiation belts, the configuration of the outer geomagnetic field (the magnetic field that surrounds the Earth), the solar wind, and interplanetary magnetic fields, all phenomena closely connected with cosmic-ray research.

In the 1950s cosmic-ray research rapidly evolved into a branch of astrophysics, joining with other branches of astronomy in probing galactic phenomena. It became clear that high-energy particles play an important role in the physics of most astronomical objects (planets, satellites, stars and galaxies, etc.), as well as in interstellar space. The acceleration of particles to high energies, so difficult on Earth, appears to occur readily and frequently in some astronomical environments. The distribution of energy in galactic cosmic rays contains information about the acceleration mechanisms. The elemental composition of the particles carries information about the objects from which they originate, may reveal the degree to which they interact with the interstellar medium, and, indirectly, provides evidence about the length of time the particles spend in the Galaxy.

#### METHODS OF DETECTION

Principles and types of detecting instruments. **Counters.** The Geiger counter, the oldest of the cosmic-ray-detection instruments, produces an electrical pulse whenever an ionizing particle passes through its gas-filled chamber. Though it played a vital role in early investigations of cosmic rays, it has now been largely superseded by other detectors. Both the scintillation counter and the Cerenkov counter make use of the light produced by the passage of charged particles through transparent materials, and require light-sensing devices, generally photomultipliers—electron tubes that convert weak light signals to electronic signals and amplify them. Scintillation counters work because some transparent materials used in them emit light in proportion to the energy transferred from the ionizing particles, and the output of the photomultiplier yields a measure of this energy. If a particle is stopped within the scintillator, the electric pulse from the photomultiplier is a direct measure of its energy. If a particle penetrates through a slab of scintillation material, its energy loss is proportional to the square of its charge and inversely proportional to the square of its velocity. Measurements of the energy loss and of the total energy together yield the charge as well as the energy of the particle. The method of simultaneous observation of the energy loss and total energy of a cosmic-ray particle is the basis of most composition measurements using particle counters.

The operation of the Cerenkov counter is based on the emission of an electromagnetic-shock wave by a charged particle moving through a transparent medium with a velocity faster than the speed of light in the medium. A mechanical analogue to this process is the bow wave emitted by a boat moving through water at a speed greater than the velocity of the water waves. The Cerenkov light created by the particle moves closely along the path of the particle and can therefore be used to determine the direction of incidence. Many studies of cosmic-ray electrons and gamma-rays rely on the counter's ability to discriminate against particles of low velocity.

The semiconductor detector, a counter device that has found wide application in satellite-borne cosmic-ray detectors, consists of a thin wafer of silicon, made into a solid-state electronic diode. When an ionizing particle traverses the device, the size of the resulting output

pulse is proportional to the particle's energy loss by ionization; this type of counter can therefore replace a scintillation counter and photomultiplier. Its small-weight and low-voltage requirements make it extremely useful for space experiments, the only drawback being the limited range of sizes of semiconductors available.

**Visual detectors.** Foremost in this group is the nuclear emulsion, a supersensitive photographic emulsion in which charged particles produce a track of developable grains, whose density is proportional to the ionization-energy loss of the particle. A measure of the energy loss can therefore be obtained by counting the number of grains per unit length of the track. If the particle should be stopped within the emulsion, its penetration distance, called "range," can also be obtained. The range of a particle in matter is proportional to its mass, inversely proportional to the square of its charge, and depends also on its initial velocity. A further important parameter of the particle track that can be measured in the emulsion is the scattering; *i.e.*, the random deviations of the trajectory from a straight line. Determination of the scattering factors provides a method of identification of mass, charge, and energy of the particle. The mass identification by this method led to the first determination of the contribution of nuclei heavier than hydrogen to the primary cosmic rays. Interaction of the cosmic-ray particle with the constituents of the emulsion can often be observed as a "star" in the emulsion; *i.e.*, a spot from which secondary particles are emitted. These secondary particles are frequently nucleons, but if the interaction takes place at sufficiently high energy, unstable mesons are created. The first observation of the creation of  $\pi$ -mesons, decaying into muons, then further decaying into electrons, was a triumph of the emulsion technique. Subsequently many other unstable particles were discovered with the help of nuclear emulsions, as were, most recently, primary cosmic-ray nuclei of elements between iron and uranium.

The cloud chamber, a visual detector, the first for charged particles, consists of a vessel containing a gas and saturated vapour (vapour on the point of condensation). The vessel is suddenly expanded, supersaturating the vapour so that droplet formation takes place along the ionizing particle's track, which can then be photographed. Importantly, the cloud chamber may be triggered by counters (see above), giving assurance that it will be expanded whenever it is traversed by cosmic-ray particles. The tracks of cosmic-ray-produced muons and positrons were first observed in cloud chambers, and several unstable elementary particles were discovered. The insertion of plates of heavy material in the chamber allowed observation of nuclear interactions, of electron-photon showers, and of meson showers.

Spark chambers also have applications in cosmic-ray research. These chambers consist of layers of metal plates usually in a mixture of neon and helium gas. After the passage of a charged particle through the assembly, which can be indicated by the triggering of an appropriate counter arrangement similar to that mentioned in the previous paragraph, a fast high-voltage pulse is put on alternate plates, causing sparks between the plates where the ionizing particle has left a track of gas ions. The set of sparks reproduces the particle track and can be photographed. In a digitized spark chamber the metal plates are replaced by grids of wires and sensors that indicate which of the wires has been fired by the spark. This method eliminates the need for an optical system and cameras and yields the information immediately in digital (directly counted) form. It is used in spark chambers on unmanned spacecraft from which the retrieval of film is not possible. Spark chambers employed on high-altitude balloons made possible the discovery of primary cosmic-ray positrons (particles with the mass of an electron but with a positive electric charge).

In 1962 it was found that ionizing particles leave tracks that can be made visible by chemical etching in many insulating solid materials. The importance of the track-detection method to cosmic-ray investigations is twofold. First, it yields information on the composition, energy distribution, and intensity of cosmic rays from past ep-

Galactic  
cosmic  
rays

Particle  
tracks

Use of  
spark  
chambers

ochs through the study of old particle tracks in natural crystals from meteorites and from the lunar surface. Second, it is a powerful tool with which to investigate the rare contemporary very heavy cosmic rays through exposure of large areas of plastic sheets on balloons and spacecraft. It is probably the least expensive large-area particle detector. The first observations on such particle tracks were made in natural crystals from meteorites that had been subjected in space to a long bombardment by cosmic rays; these observations yielded the first indication that nuclei of elements much heavier than iron are present in primary cosmic rays. It was soon found that mica, plastics, and glasses are all capable of registering cosmic-ray tracks. Sheets of special plastics sent up in balloons are now used to investigate the heavy nuclei of primary cosmic rays. The properties of the track and subsequent etch pattern depend on the energy loss of the particles, hence distinction between particles of different nuclear charges is possible by methods similar to those employed with nuclear emulsions.

**Observational methods.** *Investigations at the Earth's surface.* These are restricted to the study of effects caused by primary particles with energies in excess of several times  $10^6$  electron volts, because atmospheric absorption prevents significant observations of lower energy primary particles. Continuous monitoring over long periods is possible at the surface and can provide a long-term record of cosmic-ray intensity but without discrimination between the various primary components. Recording ionization chambers were first installed in the 1930s and several are still operating. The secondary meson component (the mesons produced as secondary particles after collisions between primary cosmic rays and other particles in the Earth's atmosphere or underground; see above) can be monitored with Geiger counters and scintillation counter telescopes, often placed underground to eliminate effects from lower-energy particles. Lower primary energies can be investigated indirectly with neutron monitors, which record secondary neutrons from the atmosphere. Networks of such monitors exist throughout the world. Some evidence on the energy of primary cosmic-ray particles is obtained by comparing the monitor responses at different geomagnetic latitudes (see below). Cosmic-ray monitors led to the discovery of substantial cosmic-ray intensity variations associated with solar phenomena.

There is about one chance in a thousand that a very high-energy primary cosmic-ray proton will reach a mountain altitude detector without first undergoing a collision with an atom in the atmosphere. Since such high-energy particles cannot be produced by artificial accelerators, high-altitude mountain laboratories are the only sites where they are investigated.

To investigate individual, very rare, cosmic-ray particles with energies exceeding  $10^{15}$  eV would require detectors of unmanageable size. Such particles, however, produce extensive air showers; that is, large numbers of electrons and photons that simultaneously reach points at mountain altitudes or sea level. Studies of large air showers, therefore, extend knowledge of the cosmic-ray spectrum to the highest energies. To investigate the structure and size of the shower, some observers use detectors distributed over many square miles of the surface of the Earth that record the simultaneous arrival of the particles and measure their density. Measurements of extensive air showers have demonstrated the existence of individual cosmic-ray particles with the incredible energy of  $10^{19}$  eV (that is, almost the amount of energy required to raise a mass of one kilogram one metre) concentrated in one nuclear particle. A further important observation available through air-shower measurements is the incidence of high-energy particles in more or less equal numbers from all directions (see below).

*Observations from high-altitude balloons, satellites, and space probes.* High-altitude balloons have been extensively used in the past decades, and all known primary cosmic-ray components have been discovered with balloon-borne apparatus that carry instruments to a height where there are only two to three grams per square cen-

timetre ( $\text{g}/\text{cm}^2$ )—that is, practically no residual atmosphere above the apparatus. The unit gram per square centimetre is used as a measure of the material traversed. The average mass of the entire atmosphere per square centimetre in the vertical direction above a point at sea level is 1,030 grams; this mass decreases by a factor of almost 2 for each 5 kilometres (16,000 feet) of elevation. At 16 kilometres (10 miles), the residual atmosphere is  $100 \text{ g}/\text{cm}^2$  and a balloon floating under 2 to  $3 \text{ g}/\text{cm}^2$  is 130,000 to 140,000 feet high. The shortcomings of balloon experiments are: (a) the limited time of exposure, normally 10 to 15 hours; (b) the presence of a layer of atmosphere above it in which various undesirable processes can occur. These include the production of secondary particles that may be confused with the primaries and the slowing down or stoppage of very-low-energy primaries. Heavy primary particles may undergo collision and subsequent spallation (flaking or breaking) resulting in a changed chemical composition. The advantages of the balloon technique are: (a) ability to carry relatively heavy payloads; (b) recoverability of the payload permitting reuse of the instrument, an indispensable requirement for all visual detectors; (c) relatively low cost.

Complete freedom from terrestrial influences is provided by Earth satellites in highly eccentric orbits and deep space probes. Instruments on such spacecraft are the source of the most important and reliable information on several aspects of cosmic radiation. Notable among many scientific advances made with satellites are the following: (1) An extension of the knowledge of the primary cosmic-ray energy spectrum to as low an energy as several times  $10^6$  electron volts, which allows detailed investigations of the solar influence on the cosmic ray flux (rate of flow past a unit of area at the measuring point), an effect that is most pronounced at low energies and provides evidence about electromagnetic conditions in interplanetary space; (2) discovery of the frequent emission of energetic particles by the Sun, associated with other solar phenomena; (3) detailed determination of the chemical composition of primary cosmic rays for elements from hydrogen through iron, which reveal the character of the cosmic-ray sources and also contain clues regarding cosmic-ray propagation in interstellar space; (4) study of the isotopic composition of primary cosmic rays including hydrogen–deuterium, helium isotopes of atomic weights 3 and 4, and beryllium isotopes of atomic weights 7 and 9 or 10; (5) the spatial distribution of the intensity of cosmic rays, both solar and galactic, in the solar system. The intensity of galactic cosmic rays in interplanetary space depends on the distance from the Sun. Space probes flown in the future to Jupiter and beyond may reveal the extent of the volume of space under solar influence and lead to a measurement of the cosmic-ray intensity in interstellar (galactic) space, free of the Sun's influence.

#### PROPERTIES OF GALACTIC COSMIC RAYS

**Composition.** By far the most abundant nuclei in galactic cosmic rays are protons (about 83 percent). Next are helium nuclei with an abundance of around 16 percent. The remainder are heavier nuclei from the entire periodic table of the elements. Figure 1 shows the relative abundance of some low-energy nuclei (measured at  $150 \text{ MeV}/\text{nucleon}$ ) from helium to the iron group. This distribution of the elements exhibits some striking features. With some notable exceptions, it greatly resembles the estimated cosmic-abundance distribution of the elements, indicating that cosmic rays originate from objects containing the element distribution consistent with evolution through thermonuclear processes. A characteristic feature of this distribution is the considerably larger abundance of elements with even-charge number compared to those with odd charge, a feature that is clearly displayed in Figure 1 and which is a consequence of the greater stability of atomic nuclei with even charge. The element distribution also demonstrates that cosmic-ray particles have undergone interactions in their travel between source and observer. This is most clearly seen in the relatively high cosmic-ray abundance of the elements

Production of lithium, boron, and beryllium in interstellar space

lithium, beryllium, and boron, which are practically absent in stellar objects. These elements must therefore have been produced in interstellar space, and there exists good evidence that they are the product of collisions and subsequent spallation (ejection of the light nuclei), mostly of carbon and oxygen, with particles present in the tenuous interstellar gas. Their abundance has led to the estimate that cosmic rays on the average encounter 3 to 5 g/cm<sup>2</sup> of interstellar matter.

Until 1967 no nucleus heavier than iron was known to exist in the cosmic radiation. The discovery in meteoritic crystals of particle tracks produced by primaries heavier than iron, and subsequent observations of cosmic rays of high nuclear charge, changed this situation. The frequency of these very heavy nuclei is extremely low; for each nucleus with a nuclear charge in excess of 31, 10<sup>4</sup> nuclei in the iron group (nuclear charge around 26) are found. Their presence, however, is important in determining the nature of the source of the cosmic rays. It is most likely that they originate in violent events, such as supernova explosions, in the Galaxy. Though there is interest in whether elements heavier than uranium may be present in the cosmic rays, this has not been proved.

Cosmic-ray electrons and positrons

Cosmic-ray electrons were discovered long after most of the other nuclear components, and the first evidence for their existence came from observation of an emission of radio waves distributed over a wide range of frequencies and having apparently the entire Galaxy as their

source. These radio waves were interpreted as being due to high-energy electrons moving in galactic magnetic fields. Electrically charged particles that move on curved paths due to the presence of magnetic fields emit radio waves that become particularly strong if the particle velocity closely approaches the speed of light. This emission is called synchrotron radiation. This evidence for the presence of electrons in cosmic radiation was confirmed in 1961 with the discovery of primary cosmic-ray electrons having an intensity about 1 to 2 percent that of the protons. Later, it was shown that the electron component contains an admixture of around 10 percent positively charged particles (positrons). Positrons (see above) are the antiparticles of electrons, and in the laboratory they quickly combine with electrons in mutual annihilation. In interstellar space, where the density is low, as long as the positron has a high velocity it runs little risk of annihilation and survives for a long time. Cosmic-ray positrons originate in collisions between high-energy cosmic-ray protons and interstellar hydrogen nuclei. This source provides about equal numbers of electrons and positrons, but the observed large electron excess in the composition of cosmic rays may be explained as due to electrons of supernova origin.

Detailed information on the composition of the primary cosmic radiation exists for energies of up to 10<sup>10</sup> eV per nucleon; beyond that, knowledge is fragmentary.

**Energy distribution.** One striking feature of the cosmic-ray energy distribution is the similarity of the energy distribution of all nuclear components, suggesting an acceleration mechanism that does not discriminate between them. Figure 2 shows measurements for the two most abundant components, protons and helium nuclei. Below

Figure 2: Flux of primary cosmic-ray protons and helium nuclei as a function of their kinetic energy. The different symbols indicate measurements by different workers, and the flux is measured in nucleons per square metre per second per steradian per megaelectron volt.

1,000 MeV/nucleon these distributions do not represent the true interstellar energy spectrum but include the effects of solar modulation. Above that energy, solar modulation has little influence (see below).

The energy spectrum of the total cosmic radiation is known to much higher energies than those of individual components. It follows a "power law" where the flux of particles of energy greater than  $E$  is proportional to  $E^{-\gamma}$  with  $\gamma = 1.6$  up to an energy of 10<sup>16</sup> eV. Between 10<sup>16</sup> eV and 10<sup>18</sup> eV the spectrum becomes slightly steeper

( $y = 2.2$ ) and beyond  $10^{18}$  eV it appears to resume its former slope up to the highest energies, though there is considerable uncertainty about this. Only two particles with energies above  $10^{19}$  eV arrive in a year at every square kilometre of surface, and extensive air-shower measurements are the only tool to observe these particles, which in spite of their scarcity are of great importance as their very existence contains important clues concerning cosmic-ray origins.

**Isotropy.** An obvious way to identify the source of cosmic rays might be to determine the direction from which the radiation comes. This, however, is not possible since these electrically charged particles are deflected by magnetic fields. In the galactic field, a proton of 1 GeV would move on a circle or spiral with radius of about  $10^{12}$  cm, a length that is extremely small compared to the thickness of the galactic disc ( $\sim 400$  light-years or  $10^{20}$  cm). These particles move along tightly wound spirals around the magnetic field lines. As a result, low-energy cosmic rays arrive from all directions in the Galaxy and give no directional information regarding their origin. Small anisotropies in distribution are found, which have their origin in features of the solar system.

The situation becomes different at higher energies. The path of a proton with  $10^{17}$  eV energy or above has a radius of curvature comparable to or larger than the thickness of the galactic disc. At such energies, if the particles originate in the disc, more of them should appear to come from the general direction of the galactic centre. All experimental results, however, have so far shown an isotropic distribution of incidence. This forces acceptance of the notion that very high energy cosmic rays are likely to be of extragalactic origin.

**Energy density.** From the observed flux of energy carried by the cosmic rays ( $\sim 10^{-2}$  erg per square centimetre per second) the energy density of cosmic rays in nearby interstellar space can be calculated to be about  $10^{-12}$  erg per cubic centimetre (erg/cm<sup>3</sup>). The amount of energy impinging on the Earth in the form of cosmic rays is therefore almost the same as that of starlight (with the exception of the Sun), a coincidence that seems to have no particular physical significance. More interesting is a comparison with the energy density of the galactic magnetic fields that prevent cosmic rays from leaving the Galaxy along straight-line paths. That their energy density is found to be of the same magnitude as that of the cosmic ray is probably not due to chance. If the fields are capable of holding the cosmic rays in the Galaxy, their energy density must somewhat exceed that of the cosmic rays. Otherwise, the hot "cosmic-ray gas" would blow the field apart.

From the estimate (see above) that cosmic rays traverse about 3 to 5 g/cm<sup>3</sup> of interstellar material in their lifetime and that the density of gas in interstellar space is about 1 to 2 hydrogen atoms per cm<sup>3</sup>, it can be deduced that the dwelling time of a cosmic-ray particle in the Galaxy is about  $10^6$  years on the average. To maintain the energy density of cosmic rays, a continuous input of  $5 \times 10^{-26}$  erg/cm<sup>3</sup>-second is therefore required from cosmic-ray sources in the Galaxy.

This estimate is based on the assumption that most cosmic rays originate in the Galaxy. There is an alternate view that cosmic rays exist throughout extragalactic space with a density similar to that observed near the Earth. While such a proposal can not be ruled out experimentally, it encounters considerable difficulties. To maintain a flux of cosmic rays throughout the universe with an energy density of  $10^{-12}$  erg/cm<sup>3</sup> requires the generation of cosmic rays at a rate of  $5 \times 10^{-30}$  erg/cm<sup>3</sup>-sec. Since as a consequence of the expansion of the universe intergalactic cosmic rays have to fill an ever-increasing volume of space, their intensity would continuously decline unless they are supplied at the enormous rate mentioned above; a rate very much larger than the energy emitted by extragalactic objects in any form. The present point of view on this question may be summarized as follows: The bulk of cosmic radiation is most likely accelerated within the Galaxy. The observed isotropy of cosmic rays of highest energy indicates, however, that a

small fraction of the cosmic radiation has its origin elsewhere.

#### PROPERTIES OF SOLAR COSMIC RAYS

The Sun is the only stellar object whose emission of cosmic-ray particles can be directly observed at the Earth. In 1942 ground-based cosmic-ray detectors for the first time showed a large, temporary increase in cosmic-ray intensity following a major solar flare. This type of event can be observed once every three to four years, with varying degree of intensity, and is always associated with a solar flare. Clearly, high-energy particles are accelerated and emitted from the solar surface in the flare process.

While ground-based detectors are capable of observing the rare events when solar particle energies exceed several GeV, detectors on satellites and space probes permit a study of solar cosmic rays at lower energy and provide evidence that low-energy particle acceleration and emission frequently accompanies a solar flare. Depending on the general level of solar activity, there are one or two solar-flare events per month in which the particles reach energies up to a few hundred MeV.

Solar particle emission offers the possibility of studying in some detail particle-acceleration processes on astronomical scales. Though the detailed mechanism of acceleration is by no means fully understood, it is clear that the large concentration of energy at the flare site must be found in magnetic fields. Altogether, energies of the order of  $10^{11}$  erg can be released in a short time in the form of various radiations. The rapidly changing magnetic fields, including electric fields, are likely to cause the particle acceleration. In a typical solar-flare event, the cosmic-ray intensity observed at the Earth increases to a maximum within 30 minutes to an hour following the visual eruption on the solar surface. The maximum intensity of the solar particles can be many times the value of the normal galactic cosmic-ray flux. In some of the largest events the flux of particles with energy in excess of several GeV has been observed to increase by a factor of 30, and it is not uncommon to see an increase by a factor of  $10^3$  for particles of about 100 MeV. The occurrence of such high-intensity particle fluxes is of concern for manned space flight and for airplanes travelling at extremely high altitudes. Without the protection of Earth's atmosphere, passengers in such vehicles may be exposed to excessive radiation.

While the maximum intensity of flare particles is reached in an hour or less, the decay in intensity occurs slowly over a day or two, indicating that the particles in interplanetary space must be temporarily stored since there are good reasons to believe that their emission at the Sun occurred within a time span of 10 to 30 minutes. Magnetic fields within the solar system prevent the particles from leaving along straight paths and force them to diffuse slowly out of the interplanetary medium. Further, the particles, while initially coming mainly from the direction of the Sun, will, after reaching maximum intensity, impinge nearly isotropically upon the Earth.

The energy distribution of solar cosmic rays is considerably more complex than that of galactic particles. Solar cosmic rays show a much steeper energy spectrum, which further steepens as the flare event progresses. This indicates differences in the rate of diffusion in the interplanetary medium for particles of different energy and qualitatively shows, as would be expected, that high-energy particles can leave the solar system more readily than those of lower energy.

By far the most abundant component of solar-flare particles are protons. There exists, however, a significant admixture of heavier nuclei, intensively studied because their composition provides direct evidence regarding the composition of solar matter. This composition closely resembles that of the visible layers of the Sun as determined spectroscopically. The solar abundances of the noble gases, helium and neon, were first determined through solar-particle studies since it is not possible to obtain estimates for them spectroscopically. The composition of solar particles is distinctly different from that of

Solar flare energies

Very high energies

Energy distribution of solar cosmic rays

galactic cosmic rays. Recent evidence has indicated that electrons, also, are frequently ejected during flare events.

Aside from individual flare events, the Sun contributes energetic particles on a more continuous basis. Some of its active regions emit streams of particles with low energy, around 10 to 50 MeV, for several months. This continuous solar production makes it difficult to distinguish between particles of solar and of galactic origin at low energies.

Neutrinos

Extremely interesting solar components are the neutrinos (particles that, since they have no mass or charge, can penetrate undisturbed through large amounts of matter). As solar energy is provided by nuclear reactions, a copious flux of neutrinos must be steadily emitted by the Sun. Attempts have been made to detect this neutrino flux at the Earth. So far, however, the effect of solar neutrinos has not been detected although the sensitivity of the apparatus used should be adequate to do so.

Attempts to detect the emission of neutrons from the Sun have not yet been successful.

#### THE ORIGIN OF COSMIC RAYS

The Sun is only a minor contributor to the total cosmic-ray flux observed at Earth. Early hypotheses that cosmic radiation was a local solar phenomenon were soon abandoned. As major sources of the high-energy particles, the following possibilities remain: (1) acceleration of cosmic rays in interstellar space, (2) acceleration by stars, (3) violent phenomena in the Galaxy (which appears to be the most promising choice), (4) extragalactic origin.

**Interstellar origin.** In 1949 Enrico Fermi (best known for his development of controlled nuclear fission) first suggested an ingenious mechanism in which cosmic rays are accelerated in interstellar space by bouncing from moving clouds of ionized gas containing irregular magnetic fields. In this way the particles may gain energy in head-on collisions as a ping-pong ball gains energy from moving paddles. This mechanism can explain the energy distribution of the cosmic rays but is too inefficient to account for all the observed cosmic rays and the required rate of production.

**Stellar origin.** The flare phenomenon is not restricted to the sun. Stars exist in which flares occur on a much larger scale, but while flare stars are likely to contribute some cosmic rays, they cannot provide all because the energy required is too great.

**Supernova origin.** The most likely sources of the bulk of the cosmic rays are violent phenomena in the Galaxy, in particular, supernova explosions. The most famous remnant of a supernova is the Crab Nebula, a continuously expanding nebulosity found today where a supernova explosion was observed by Chinese astronomers in the year 1054 AD. Many interesting phenomena observed in the Crab may have a direct bearing on its potential as a high-energy particle source. Estimates of the energy of electrons present in the nebula reach up to  $10^{11}$  or even  $10^{13}$  eV. There is no direct evidence for the acceleration of atomic nuclei in supernova remnants, but it is likely that such nuclei are accelerated with high efficiency. A strong source producing the high-energy electrons is needed in the supernova remnant, to replenish particles that rapidly lose their energy by synchrotron emission. Calculation of the time for an electron to lose about half of its energy by synchrotron radiation reveals that electrons of  $10^{11}$  eV energy live about 100 years if the magnetic field in the Crab is  $10^{-3}$  gauss and the time decreases rapidly for particles of increasing energy. Since these times are considerably below the age of the supernova, electrons must therefore be accelerated in the supernova shell long after the initial explosion. The recent discovery of a pulsar at the centre of the Crab Nebula has revealed a potentially powerful source of energy for particle acceleration. Many if not all supernova remnants may contain pulsars. The properties of pulsars suggest that efficient particle acceleration may take place.

The energy output per supernova, if supernova explosions occur at the rate of one or two per century, can just about suffice to provide the energy input of  $5 \times 10^{46}$  erg/cm<sup>2</sup>-sec required to maintain the galactic cosmic-ray

density. It is estimated that on the average,  $10^{51}$  ergs of energy are released by each supernova explosion, an energy production of  $10^{42}$  ergs/sec, or, taking the volume of the galactic disc as  $3 \times 10^{66}$  cm<sup>3</sup>, an energy production per unit volume of about  $10^{-25}$  erg/cm<sup>3</sup>-sec, which is approximately 10 times larger than the requirement for cosmic rays. If these supernova remnants are the major source of cosmic-ray particles, particle acceleration must be quite efficient.

**Extragalactic origin.** In spite of its appeal, the supernova hypothesis cannot answer all problems of cosmic-ray origin. For example, a supernova origin cannot account for the isotropic distribution of very high energy particles,  $10^{18}$  to  $10^{20}$  eV. This situation led to the assumption that the sources of very high energy cosmic rays are possibly extragalactic objects. It is likely that 1 percent to 10 percent of cosmic radiation originates outside the Galaxy, in objects where incredibly high fluxes of energetic electrons are present, as shown by observations of the synchrotron radiation (see above).

Possible sources of very high energy cosmic rays

#### INTERACTIONS OF COSMIC RAYS

**Interstellar medium.** A cosmic-ray particle spends an average of  $10^4$  years in the galactic disc before being expelled into extragalactic space. During this time it traverses 3 to 5 g/cm<sup>2</sup> of very dilute interstellar matter, mostly hydrogen, while following a complicated trajectory, spiralling around magnetic lines of force. The cosmic ray nuclei occasionally collide with the nuclei of the interstellar gas. For example, since cosmic-ray protons can, on the average, traverse 60 g/cm<sup>2</sup> hydrogen before colliding, 6 percent of them will undergo a nuclear collision before they can escape from the galactic disc. If the energy of the colliding proton is greater than about 1 GeV, positive pi-mesons ( $\pi^+$ -mesons), negative pi-mesons ( $\pi^-$ -mesons), and neutral pi-mesons ( $\pi^0$ -mesons) are created in the collision process. The  $\pi^\pm$  mesons decay into muons and neutrinos, and the negative and positive muons, in turn, decay into electrons or positrons, respectively. This latter decay is also accompanied by the emission of neutrinos and antineutrinos. The high-energy electrons and positrons survive for a long time and contribute to the primary cosmic-ray electron component. The collision process appears to be the source of all cosmic-ray positrons observed near Earth. The  $\pi^0$ -mesons decay very rapidly into two gamma rays ( $\gamma$ -rays). The cosmic rays and this  $\gamma$ -ray source should be similarly distributed.

Nuclei heavier than protons have larger cross sections for collision than do protons and the heavier the nucleus, the more probable is a collision. The collision, aside from producing mesons, leads to spallation (see above) of the arriving nucleus after which the fragments proceed with almost undiminished speed. The energy spectrum of the cosmic radiation is not much influenced by the collision process but the chemical composition, as discussed above and shown in Figure 1, certainly is. Most elements, from calcium through manganese, in cosmic rays appear to be produced by the spallation of iron-group nuclei. The chemical composition points to characteristics of the cosmic-ray source and also reveals the importance of nuclear interactions in interstellar space. Magnetic fields in the Galaxy determine the trajectory of the nuclear particles but do not change their energy unless they reach extremely high energies.

Electrons, on the other hand, are not much influenced by interstellar matter. Magnetic fields and photons, however, cause large energy losses to cosmic-ray electrons and positrons, as discussed above. The electron energy spectrum observed near Earth therefore will differ from the source spectrum, in ways dependent on the interstellar photon density, on the lifetime of individual cosmic-ray particles in the galactic disc, and on the distribution of cosmic-ray sources. Knowledge of the electron spectrum can provide information on these important quantities and extensive studies have therefore been undertaken.

**Cosmic-ray modulation by the Sun.** Before approaching Earth, the cosmic radiation is modified by solar influ-

Spallation

## Solar wind

ences. The Sun continuously emits very hot highly ionized gas (about one million tons per second) which moves away from the Sun with an average speed of **400 km/sec**. This "solar wind" carries with it solar magnetic fields whose lines of force therefore tend to point radially away from the Sun. Since the Sun rotates, the lines of force are bent into an Archimedes spiral. Superimposed on this general field configuration are local irregularities that also move outward with the solar wind speed. Galactic cosmic radiation is scattered by the irregularities and at the same time continuously swept out by the wind. The net result is a depression of the cosmic-ray intensity in interplanetary space, especially of the low-energy portion of the spectrum. This cosmic-ray modulation manifests itself most clearly in an 11-year intensity variation of cosmic rays, closely correlated to the 11-year activity cycle of the Sun. Cosmic-ray intensity is high in the years of low solar activity, because the solar wind is not blowing so strongly, and low in years of enhanced solar activity. Figure 3 shows this behaviour of the cosmic-ray intensity as measured by a neutron monitor from **1952 to 1969**, years of minimum solar activity indicated by arrows. The properties of interplanetary magnetic fields

Figure 3: Total cosmic-ray intensity as a function of time, measured over about two solar cycles at Climax, Colorado (altitude 11,800 feet). The ordinate is expressed as a change from the intensity at solar minimum, 1954.

and the solar wind that lead to this modulation were first deduced indirectly through interpretation of cosmic-ray data and related evidence. More recently they have been directly observed using instruments on satellites and deep space probes. The modification of the cosmic-ray energy spectra as observed at the Earth can also be seen in Figure 2. An extrapolation out of the interplanetary medium is necessary in order to picture the interstellar spectra.

Aside from the 11-year cycle intensity variation of cosmic rays other short-term fluctuations are observed. All can be traced to changes of the interplanetary medium induced by the solar wind. Active regions on the Sun occasionally greatly enhance the solar wind.

The geomagnetic field. All ground-based cosmic-ray measurements, balloon observations, and near-Earth satellite work are affected by the geomagnetic field. The first hint of this influence came when the cosmic-ray intensity was found to be lower in the vicinity of the Earth's Equator than at higher latitudes.

Depending on their charge, their direction with respect to the geomagnetic field, and their momentum, cosmic-ray particles are to some degree deflected in the Earth's field. The observed particle flux therefore depends on the location of the observer on the surface of the Earth, and for any given location it depends also on the direction of incidence. Under the simplifying assumption that the Earth's magnetic field may be represented as due to a magnetic dipole at the Earth's centre, the orbits of particles of any momentum or direction of incidence can be calculated. This type of calculation, first carried out in studies of the aurora borealis, has been applied to cosmic-ray particles. The calculations are complex in detail,

particularly when realistic models of the geomagnetic field are used and when deformations of the field under the impact of the solar wind are taken into account. Modern computers are used. The most important effects of the geomagnetic field may be summarized as follows. For each geomagnetic latitude (measured from the magnetic poles) there exists a cut-off energy below which vertically incident primary cosmic-ray particles cannot reach the top of the atmosphere. For protons this energy is about **14 GeV** at the geomagnetic equator; **4 to 5 GeV** in Texas; less than **1 GeV** in Minnesota, and of course zero at the magnetic pole. The Earth therefore serves as a magnetic spectrometer for the determination of the energy spectrum of primary cosmic-ray particles and of solar-flare particles. Changes of cosmic-ray spectrum under solar modulation were first discovered using airplanes equipped with cosmic ray detectors that could rapidly move between places of widely different latitude.

Many studies of low-energy cosmic rays with balloon-borne apparatus are carried out at high geomagnetic latitudes, for example, at Ft. Churchill, Manitoba.

## PARTICLES DISCOVERED IN SECONDARY RAYS

All known types of elementary particles occur in secondary cosmic rays. They are produced by interactions between extremely fast-moving primary particles and nuclei in the air and by subsequent nuclear interactions or radioactive decay of the initial products. Many particles are found in nature only when created by cosmic rays, because of their instability against radioactive decay and the concentration of energy required to create their masses. Many were first seen among cosmic rays, because high energies were available in cosmic rays before powerful man-made accelerators were built, and because of the exploratory rather than selective nature of cosmic-ray experiments.

Several of the elementary particles first discovered among cosmic rays are:

**Positrons.** Positrons (see above) are often produced in cosmic rays by pair production, a process in which a high-energy photon interacts with the nuclear field of a nucleus and is absorbed, while an electron and a positron are created, sharing the energy of the photon. A second means of production is in the decay of positive muons, discussed below. Almost as numerous as electrons, positrons constitute about **10 percent** of the charged cosmic rays at sea level, and **20 percent to 30 percent** at mountain or airplane altitudes.

**Muons.** The existence of positive and negative muons (formerly called mu-mesons) was proven between **1933** and **1938** by the combined weight of evidence from many experimenters. Muons have the longest ranges of any particles except neutrinos; they constitute three-fourths of the charged cosmic rays at sea level, and are the only charged cosmic rays that penetrate more than a few metres into the ground. Some have been detected after passage through as much as two miles of rock. Some decay in the atmosphere, producing most of the positrons and electrons among the cosmic rays at sea level. For muons of **3 GeV** energy, however, the average range before decay is **18 km**, and many reach sea level even though they are produced at high altitudes.

**Positive and negative  $\pi$ -mesons.** Positive and negative  $\pi$ -mesons were discovered in 1947, when a  $\pi^+$ -meson came to rest in a nuclear emulsion and underwent radioactive decay. In the air, both  $\pi^+$  and  $\pi^-$  mesons decay before being captured. The mean lifetime is  $2.56 \times 10^{-8}$  sec, and the decay products are a muon and a neutrino.

Abundant  $\pi^+$ -mesons are created in cosmic rays by collision of primary and secondary protons and neutrons and other  $\pi^+$ -mesons with atmospheric nuclei; a few are created by the nuclear absorption of photons. When produced in the air,  $\pi^+$ -mesons soon decay, unless their energies are exceptionally high, in which case they are mostly absorbed by interacting with nuclei. As a result,  $\pi^+$ -mesons constitute less than 1 percent of charged cosmic rays at sea level, and their decay is the principal source of the muons appearing in sea-level cosmic radiation.

Production of elementary particles

**Neutral  $\pi$ -mesons.** The existence of the neutral  $\pi$ -meson was predicted two years before its experimental discovery. Its very short lifetime is followed by decay into two photons, which in turn create electrons and positrons by pair-production. The theory explained two anomalies regarding cosmic rays: the abundance of positrons and electrons at high altitudes despite their scarcity in primary radiation, and their observed creation near nuclear interactions in which charged  $\pi$ -mesons were also created. The mass of the  $\pi^0$ -meson was determined from the energy spectrum of photons in the upper atmosphere, although because  $\pi^0$ -mesons exist so briefly and are neutral, they could not be detected directly in nature but were discovered in 1950 by means of the cyclotron and synchrotron. The mean lifetime of the  $\pi^0$ -meson is about  $10^{-16}$  seconds.

**Neutrinos.** The decay of  $\pi^\pm$  mesons and muons in the atmosphere leads to a large flux of neutrinos. Muon neutrinos induce reactions in which further muons are produced. This reaction can, with great care, be used to detect cosmic ray neutrinos.

#### TRANSITIONS IN THE ATMOSPHERE

Because they are comparatively rare, unstable particles heavier than  $\pi$ -mesons will be neglected here and their brief existence, before decaying into the various components to be discussed, is unimportant to the major transitions in the atmosphere. Antinucleons (antiprotons and antineutrons) will be neglected too, because of their infrequent production.

**Fate of heavy primaries.** Heavy primary nuclei lose energy by ionization faster than do protons, in proportion to the square of their charge; hence, most of them are stopped near the top of the atmosphere. The more energetic interact with other nuclei and break up into protons and neutrons, which behave thereafter like the more numerous primary protons. The larger the nucleus, the shorter the mean path-length traversed before breakup; it varies from 45 g/cm<sup>2</sup> for alpha particles to 20 g/cm<sup>2</sup> for primary silicon nuclei and 14 g/cm<sup>2</sup> for iron. This explains why heavy primary nuclei are detected only at very high altitudes.

**Interactions of primary protons.** The typical first interaction of a primary proton in the atmosphere is its collision with a nucleus of nitrogen or oxygen. The immediate effects are: (1)  $\pi^\pm$ - and  $\pi^0$ -mesons are produced, in the approximate ratio of 2 to 1, the total number depending on the primary energy but being typically between 2 and 10; (2) the original proton continues with reduced energy, together with one or two nucleons of the struck nucleus that were given high velocities by the collision; and (3) the residual nucleus is left in an excited state, from which it recovers by emission of slower protons and neutrons in any direction, or by breaking up into deuterons, tritons, and alpha particles all positively charged. These fragments, called evaporation products, typically have energies on the order of 10 MeV.

**Absorption of evaporation products.** The charged evaporation products lose all their energy in less than 1 g/cm<sup>2</sup> of air. The neutrons lose no energy by ionization and travel through 5 percent to 10 percent (by weight) of the atmosphere before absorption. They are gradually slowed down by collisions with atoms of oxygen and nitrogen; and with decreasing velocity, their chance of being captured in a collision increases. Most reach energies of about  $\frac{1}{4}$  eV before being captured by a nitrogen nucleus, which then emits a proton and becomes radioactive carbon, carbon-14.

**Interactions of secondary nucleons.** Secondary protons or neutrons of energy very much greater than a GeV behave like primary radiation, undergoing nuclear collisions from which further mesons, fast secondary nucleons, and evaporation products emerge. This step-like multiplication of mesons and nucleons through successive nuclear interactions is known as a nuclear cascade. The average distance between steps is about  $\frac{1}{13}$  of the vertical atmosphere by weight, or 80 g/cm<sup>2</sup>. The number of steps depends on the primary energy. How low a cascade reaches depends also on chance variations of the distance

between steps. The number of cascades still proceeding decreases rapidly as sea level is approached, changing by a factor of 2 in every 80 g/cm<sup>2</sup>, or by a factor of 13 in the last 10,000 feet.

Secondary nucleons of energy less than a GeV usually undergo nuclear interactions that yield only charged nuclear fragments of rather short range, plus neutrons that in turn interact until only evaporation products are emitted.

**Fate of positive and negative  $\pi$ -mesons.** Primaries of extreme energy, more than  $10^{13}$  eV, may produce  $\pi^\pm$ -mesons of more than  $10^{11}$  eV. The slowing down of time for these particles, in accordance with the theory of relativity, is so great that they may travel far enough to experience nuclear collisions instead of decaying. Like the high-energy secondary nucleons, these mesons contribute to the nuclear cascade, producing further  $\pi^\pm$ - and  $\pi^0$ -mesons and fast secondary nucleons as well as evaporation fragments.

Much more common are  $\pi^\pm$ -mesons of energy less than 100 GeV. These usually decay without further interactions into muons and neutrinos.

**Fate of muons.** Muons retain about 80 percent of the energy of the  $\pi^\pm$ -mesons, and very seldom lose it by nuclear collisions. Instead, there is a gradual loss of energy by ionization, amounting on the average to about 2 GeV before a muon reaches sea level, since most of them are produced in the uppermost 200 g/cm<sup>2</sup> of the atmosphere.

Many muons, including a few having energy of tens of GeV, decay during flight through the atmosphere. About two-thirds of the energy and momentum of such a muon is taken away by neutrinos, and the rest by a high-energy electron or positron. Fast muons also generate a minor fraction of the high-energy electrons in the atmosphere by occasional close collisions with electrons belonging to atoms in the air. The particles so produced are called "knock-on electrons."

Most muons of many GeV energy survive, however, until they reach the ground, where they dissipate the remainder of their energy by ionizing atoms along their paths into the Earth. The rate of energy loss is about 2.2 MeV per g/cm<sup>2</sup>, and the density of the Earth's surface is about 2.7 g/cm<sup>3</sup>; a muon of 20 GeV, for instance, will, thus, penetrate 110 feet before coming to rest.

**Fate of neutral  $\pi$ -mesons; cascade showers.** The  $\pi^0$  mesons produced in primary and secondary collisions have such short lifetimes that they travel only negligible distances before decaying, each into two photons, which share the rest energy and kinetic energy of the mesons. Each photon travels on the average only 48 g/cm<sup>2</sup> in air before undergoing pair-production while passing near an atomic nucleus. The positron and electron thus produced generate new photons along their paths by radiation as they pass near nuclei; in travelling about 40 g/cm<sup>2</sup>, each radiates a photon of about half its own energy, plus numerous photons of lesser energy. The new photons in turn make new pairs of electrons and positrons, and these radiate additional photons. Thus a cascade shower or electronic cascade develops, the average energy per particle decreasing as the number grows. This is the principal means by which secondary photons, electrons, and positrons are created. Ultimately the energies of the photons become too small to make pairs, while the energies of the electrons are too low to permit radiation of further high-energy photons; the remaining photons then lose energy (a reduction in frequency) through interaction with electrons by the process known as Compton scattering and are ultimately absorbed by the photoelectric process, while the energy of the electrons is absorbed by ionization.

Charged particles other than electrons and positrons directly initiate electronic cascades infrequently; the radiation process requires sudden acceleration in the electric field of a nucleus and only electrons and positrons are light enough to be accelerated sufficiently. Their ratio of charge to mass is 207 times greater than that of their nearest competitor, the muon. Cloud chambers and spark chambers are often equipped with lead plates, one of the

chief purposes of which is to make possible the detection of photons and the recognition of positrons and electrons by their unique ability to produce cascade showers.

In a heavy, condensed material such as lead, the mean distance between successive generations (called the "radiation length") is only 0.5 cm; hence, electronic cascades develop rapidly and are usually absorbed within 5 to 10 cm. In contrast, the distance per generation in nuclear cascades or penetrating showers is 14 cm in lead, and the total range is on the order of 1 m. Typical ranges of muons are even longer. Therefore electronic cascades are called "soft showers."

"Soft  
showers"

Transition curves. Graphs of the counting rates of the various kinds of particles as functions of depth in the atmosphere are called atmospheric transition curves. The transition curve of the total number of charged particles reflects the combined effect of all the processes discussed above.

The maximum in the atmospheric transition curve is due to the multiplication of particles through the mechanisms of multiple meson production, nuclear cascades, and cascade showers. At the top of the atmosphere the number of new particles produced exceeds the number of primaries absorbed, because the average energy is high. Lower in the atmosphere the number of particles capable of the multiplicative processes is much smaller, and absorption predominates over new production. Near the maximum in the transition curve, the most abundant charged particles are positrons and electrons, while photons and slow neutrons are present in comparable number. At the top of the atmosphere the particles are all primary protons, heavier nuclei, and some electrons. Near sea level, the primaries are gone, the soft component has been mostly absorbed, and the most abundant remaining particles are muons.

The relative counting rates (see above) at the top of the atmosphere, at the maximum of the transition curve, and at sea level reflect the total multiplying power of the primaries and the penetrating power of their secondaries. The ratios therefore are indicative of the average primary energy and vary with latitude.

Extensive air showers. An extensive air shower is the most complex of all cosmic-ray phenomena. It occurs when a primary of extremely high energy,  $10^{14}$  eV or more, enters the atmosphere. The primary energy is so high that the cascade creation of particles can go on and on until huge numbers have been produced. All kinds of elementary particles have been found in extensive air showers, but by far the most numerous are photons, electrons, and positrons. In some instances, the number in a single shower exceeds  $10^{10}$ .

Not all particles in air showers proceed in exactly the same direction. Although there is a core near which many are clustered, particles in single air showers have been detected more than 1,000 m apart. The majority, however, land in an area 70 m in radius (at sea level), and within about  $10^{-7}$  sec of each other. Measurement of the energy contained in the biggest showers is a challenging experimental problem, and the acquisition of such energies by submicroscopic particles is difficult to explain.

#### EFFECTS OF COSMIC RAY BOMBARDMENT

Production of radioactive isotopes. Wherever cosmic-ray particles strike matter, nuclear collisions produce substantial amounts of radioactive isotopes.

Perhaps the most important isotope produced by cosmic rays is carbon-14, created by the capture of slow secondary neutrons in nitrogen-14 nuclei. Carbon-14, with a half-life of about 5,600 years, is employed in the carbon-dating technique that has played an important role in archeological and geological studies. When applied to objects of known age, it reveals that the average cosmic-ray intensity has been very nearly constant for the past 30,000 years. An isotope of hydrogen produced by cosmic radiation in the atmosphere is tritium, which has a half-life of about 12 years and can therefore serve for accurate dating of more recent events. A variety of other cosmic-ray produced radioactive isotopes of widely dif-

ferent half-lives are observed at the Earth. They add only insignificantly to the natural radioactivity of terrestrial origin.

Stable as well as radioactive isotopes of cosmic-ray origin are found in meteorites and on the lunar surface. Their abundance provides insight into the history of the solar system as well as evidence indicating that the average cosmic-ray intensity has been constant within 10 percent for the past  $10^7$  years and within a factor of 2 for the past  $10^9$  years.

Average  
cosmic-ray  
intensity

Cosmic ray exposure age. The effective duration of cosmic-ray bombardment of a meteorite, called the cosmic-ray exposure age, can be measured by determining the concentration and production rate of both radioactive and stable nuclides it has produced. Cosmic-ray bombardment is assumed to begin at a specific time, at the breakup of a mass of material sufficiently large to shield most of its volume from cosmic radiation. This assumption seems to be borne out since the exposure ages of many iron meteorites, for example, cluster around 630 and  $900 \times 10^6$  years, indicating that the parent bodies of these meteorites broke up in catastrophic collisions at those specific times in the past. Other ages found range from  $1.5 \times 10^8$  to  $2 \times 10^9$  years. These investigations have provided information regarding the origin of meteorites and of the solar system. Study of lunar material promises to provide data on the history of the Moon.

(P.M.)

## Costa Rica

A republic of Central America, Costa Rica is located on the great isthmus that joins North and South America, between Panama, situated on its eastern border, and Nicaragua, on its northern border. Costa Rica's greatest length, between the two neighbouring countries, is 288 miles, and its narrowest width, between the Pacific Ocean and the Caribbean Sea, is 74 miles, the shortest coast-to-coast distance on the isthmus outside of Panama. Its total area is approximately 19,650 square miles (50,900 square kilometres).

Costa Rica played a role in the federation of Central American states from 1823 to 1838 and is a member of the Organization of Central American States founded in 1951. Of the five states that have been partners in these two enterprises, Costa Rica is the most Spanish in character and has the highest percentage of literacy, the largest gross domestic product per capita, and the longest experience with democracy. Its well-populated and highly civilized heartland, dedicated to quality harvests of coffee, has long been admired by both its own citizens and visitors from outside. Its outlying reaches, good for stock raising and banana cultivation, have only recently, with the building of new roads, become readily accessible to visitors.

#### THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Physical geography.* Three mountain chains run almost the entire length of Costa Rica, from southeast to northwest; they are divided into the Cordillera Central, the Cordillera de Guanacaste to the northwest, and the Cordillera de Talamanca to the

Mountain  
ranges and  
drainage  
patterns

southeast. The highest peak is Chirripó Grande in the Talamanca system, at 12,529 feet (3,819 metres). Two of the four volcanoes in the Cordillera Central, Irazú (11,260 feet) and Poás (8,875 feet) have paved roads to the rims of their active craters. The Guanacaste range also contains four major volcanoes, the highest of which is Miravalles (6,627 feet).

The southern side of the Cordillera Central overlooks the Valle Central, often called the Meseta Central, the heartland of the country that includes San José, the capital, at 3,809 feet. The Valle Central is drained by the Rio Reventazón to the Caribbean and by the Rio Grande de Térrones to the Pacific. To the north and east of the mountain ranges lie the Caribbean lowlands, about one-fifth of the country and less than 400 feet in altitude.

Roughly half of the land is too rocky for farming. Other portions are too completely leached or have too poor drainage or (on the Caribbean shore) consist of sand and bogs. The best agricultural areas are the Valle Central, river bottoms, and areas where the older alluvium of the northern lowlands is well drained.

**Climate.** Thermal-heating and shore-breeze patterns bring abundant precipitation to the Pacific coast in the wet season, generally May to October in the north, April to December in the south. Northeasterly winds on the Caribbean coast provide plentiful rain all the year round. The Central and Talamanca ranges have warm temperate climates with the southern side of the mountains both wet and dry, the northern side always wet.

San José weather records show monthly averages of rainfall from well under one inch in February to nearly 14 inches in September, with over 75 inches the average for a year. Temperatures vary with the altitude, San José reporting a mean of 69° F (21° C), a nearby station at 7,665 feet, a mean of 59° F (15° C), and another at 682 feet, a mean of 80° F (27° C).

**Vegetation and animal life.** Dense broadleaf evergreen forest, which includes mahogany and tropical cedar trees, covers about half the landscape. On the Talamanca range, there are many evergreen oaks and, above the timberline, mountain scrub and grasses. The northwest, with the most pronounced dry season, contains open deciduous forest. Palm trees are common on the Caribbean coastline, and mangroves near the Pacific where peninsulas are attached to the mainland, both the palms and mangroves growing in swampy ground.

Mammalian life is both abundant and varied. It has major ties to both South and North American animal populations. The former tie includes monkeys, anteaters, sloths; the latter, deer, wildcats, weasels, otters, coyotes and foxes, and many other species and genera.

**Character of human settlement.** Almost everywhere in Costa Rica the family unit is tight knit, with sharply defined male, female, and child roles. In the Valle Central, rural men are employed in the coffee, sugarcane, or dairying industries, while some of those in urban areas work in manufacturing. The very Spanish atmosphere of the Valle Central, even though patterns of life are changing, is the milieu of which most outsiders speak when they refer to Costa Rica. The Pacific northwest, where many men work on large cattle ranches, or haciendas, and also maintain small agricultural plots of their own, is more typically Central American. From this district came the national dance, the *punto guanacasteco*. The Pacific south contains two banana zones, developed in the 1930s, and significant new settlement in the Valle del General that followed the construction of the Inter-American Highway. The Caribbean side contains many reminders of an older banana industry, abandoned in the 1930s, with railroads instead of roads (children even go to school on the trains) and with houses built on stilts and, under each one, large drawers for drying cacao. The San Carlos Plains, part of the northern lowlands, are attracting new settlers, who live like pioneers. The typical Costa Rican house has wooden walls and floors and roofs made of corrugated metal. Earthen floors predominate over wooden ones only in the Pacific northwest.

The built-up portion of the San José metropolitan area had an estimated population of almost 409,000 in the

## Costa Rica, Area and Population

	area*		population†

\*Approximate; subject to revision. †De jure. ‡Includes islands totaling 100 sq km or 38 sq mi. Figures do not add to total given because of rounding.

Source: Official government figures.

early 1970s. Deep gullies line the city proper on the north and south; some suburbs are built in irregular patterns, following the terrain. The city has an unhurried appearance: its life is congested only in a small area in which the larger stores and offices are located and, recently, the first modern edifices have been erected.

Outside the capital urban life is similar. Cartago offers a colonial flavour, being much older than any of the other cities. It and Heredia and Alajuela, each near 20,000 in population and very near San José, all cater to the outlying provinces they head. Limón and Puntarenas are the chief Caribbean and Pacific ports; Puntarenas (situated on a sandspit) serves also as a warm resort centre. Golfito, on the Pacific, has a life based on banana export.

Character  
of San  
José

## THE PEOPLE OF COSTA RICA

**Ethnic and religious groups.** The Valle Central, with over half of Costa Rica's population, is predominantly European, or, more specifically, Spanish, in both its manner of living and its ancestry. In this district, minority Indian and Negro strains have been absorbed into the general European population. Spanish is spoken, though with distinctive national accents and usages. In Central America, a Costa Rican is called a *tico*; Costa Ricans replace the diminutive ending *tito* with *tico*, a practice known elsewhere but uncommon in Central America.

Catholicism, the religious faith of most of the people in the Valle Central, generally is adhered to very seriously. Roman Catholicism is also the official religion of the country, receiving a small part of the national budget. There is a Catholic archdiocese centred in San José, with suffragan bishops in Alajuela, Tilarán (for the Pacific northwest), and San Isidro (for the Pacific south), as well as an apostolic vicar in less Catholic Limón. Though priests are forbidden to bring politics into the pulpit, the church maintains an interest in social conditions.

The racial  
and  
religious  
mix

Protestant evangelical activity is also strong in the Valle Central, although only a small minority of the Costa Rican people are Protestants. There is a language school, in which beginning missionaries study Spanish, and a seminary attended by Spanish American young people from many countries.

Nearly one-fifth of the population of the country is found in the Pacific northwest, often called Costa Rica's "brown" province. These people are a three-way blend of colonial Spanish, Indian, and Negro, whose Spanish is more like that of Nicaragua than that of the Valle Central. Their adherence to Catholicism is often nominal.

African ancestry is the strongest in the eastern Caribbean lowlands, which contain only about 6 percent of the population. The Negro people who live there are descendants of those brought from the West Indies to build railroads and raise bananas. Most of them speak both Spanish and a Jamaican style of English, a predominant number having come from that island. Protestantism is the most widespread faith in this district, some of the people of which are now moving to the Valle Central.

The Pacific south, with about 15 percent of the people, and the San Carlos Plains, with about 6 percent, are drawing upon the human resources of the other districts

in Costa Rica, and of Panama and Nicaragua as well. Language and religious preferences of these districts are thus a *mélange*, though basically Spanish and Catholic.

In the far south, a few thousand Indians are left. The Bribri and Cabecar tribes inhabit valleys on both sides of the Cordillera de Talamanca, the Boruca group the Pacific side only. There are also a few hundred Guatuso Indian people on the northern plains. The languages of all four groups are related to the Chibcha speech of Colombia. Those on the Pacific side in the south and the Guatusos in the north are slowly losing their languages and becoming assimilated in every way. Those on the Caribbean side in the southern Talamanca district maintain their separate ways, including their animistic religions. The only pre-Columbian group oriented toward Mexico, the Orotina of the Pacific northwest, contributed strongly to the district's population, but already they have lost their language, and only a few of their customs remain.

**Demographic trends.** The total population of Costa Rica was estimated at more than 1,811,000 in the early 1970s. Although Costa Rica is often cited as a nation whose population growth rate is high, it is not on the brink of becoming overpopulated. As general prosperity has increased, the population growth rate has gone down despite a drop in both the general and the infant mortality rates. In recent years the general mortality rate dropped from 8.6 to 6.6 deaths per 1,000 inhabitants; the infant mortality rate dropped in the same three years from 76 to about 60 deaths within the first year per 1,000 infants; and the annual growth rate dropped in four years (1965-69) from 3.5 percent to 2.7 percent. Life expectancy is 66.8 years, compared with an average of 51.1 years for the other four Central American nations.

Costa Rica's net loss of population by migration is of minor importance in explaining the drop in the growth rate. Of greater significance is a diminution of the birth rate, which, in 1965, stood at 42.3 births per 1,000 inhabitants but, in 1970, had dropped to 33.8. European immigration and life styles have molded Costa Rican history and influenced its character. The 1963 census counted 1,334 persons born in Spain and 2,597 in the remainder of Europe. Immigration from American countries, however, is much heavier. With 92 inhabitants per square mile at the beginning of 1972, Costa Rica had ample room to contain an expansion of the population.

## THE NATIONAL ECONOMY

Costa Rica is neither rich, as its name ("rich coast") im-

plies, nor as poor as many of its neighbours. Its gross domestic product per capita is the highest in Central America and comparatively is better distributed among all social classes—though this does not mean that the wealth is shared as much as it might be, or that even if it were the Costa Rican family would be living well by European or North American standards. Recent economic growth rates, however, suggest that Costa Rica may develop an economy characterized by a highly active and productive work force earning a decent livelihood, though continuing to depend heavily upon the nation's exports.

**Natural resources.** Costa Rica has some mineral resources, though because of small quantity or relative inaccessibility they may be disappointing commercially. The most important are bauxite deposits in the General and Coto Brus valleys. There is manganese also, in and near the Nicoya Peninsula; some gold in the Osa Peninsula; and magnetite sand on scattered beaches, particularly on the southern Caribbean coastline. Timber reserves, already used domestically, have considerable commercial potential. Hydroelectric sources of power, now being developed, have capacity enough to support a great expansion of industry in the Valle Central. The greatest of the reservoirs is at Cachi, on the Rio Reventazón at the eastern edge of the Valle Central. Elsewhere most electricity is generated by diesel plants, and many rural areas have no electricity at all.

**Agriculture.** Agriculture occupies almost half of Costa Rica's economically active people and contributes nearly one-fourth of the national income. Maize (corn) is grown less widely than in other Central American lands, but corn and beans remain the most significant crops for home consumption. Both of them, and rice as well, are raised chiefly on the Pacific side of the mountains. Coffee and bananas vie for first place among the nation's valuable exports. Coffee of high quality comes from the Valle Central and a few outlying areas. Bananas are grown commercially on both shores, though in larger quantity along the southern coast of the Pacific. Three lesser but important exports of food are beef, chiefly from the Pacific northwest; sugar, from cane grown mainly in the lower altitudes in the vicinity of the Valle Central; and cacao, from the eastern Caribbean lowlands.

**Manufacturing and services.** Manufacturing, contributing nearly one-fifth of the national income in recent years, involves little more than one-tenth of the economically active population. Most of it is concentrated in the Valle Central, with a few new plants in Puntarenas and Limón. For domestic consumption, the processing of food and beverages and the making of textiles, shoes, and furniture are important. The main items for export, chiefly to other Central American nations, are fertilizers, rubber tires, cotton fabrics, sheets of galvanized iron, plywood, medicines, electric batteries, and metal containers (in rough order of importance).

The number of Costa Ricans employed in providing services is greater than the number in manufacturing. A third of those contributing services are domestic help, and another third are teachers and government employees. Commerce, construction, transport, utilities, and mining follow manufacturing as branches of activity.

**Foreign trade.** To round out its food supply, Costa Rica imports wheat from the United States and both maize and beans from isthmian neighbours. The larger values in nonfood imports, by country in 1970, were paper from the U.S., partially refined petroleum from Venezuela, excavation machinery from the U.S., iron sheets from Japan, cottonseed oil from Nicaragua, and insecticides from the United States, in decreasing order.

Coffee is shipped extensively but in greatest quantity to the U.S., seven countries of Western and Central Europe, the Soviet Union, and Saudi Arabia. The bananas go chiefly to the U.S., Italy, West Germany, and Belgium. The U.S. buys most of the beef, sugar, and cacao.

**Economic organization.** There are three trade union associations. The Costa Rican Confederation of Democratic Workers is affiliated with the International Confederation of Free Trade Unions, the Costa Rican General Confederation of Workers with the Communist-led

Principal  
crops

The Indian  
population

Private  
and public  
sectors of  
the  
economy

World Federation of Trade Unions, and the Costa Rican Christian Confederation of Workers and Farmers with the World Confederation of Labour. There are also a number of independent unions and a few nationwide employer associations.

Private industry has retained its place in Costa Rica even though there is much sentiment for a larger public investment role. Individual autonomous agencies created by the government cover the entire insurance field, operate one railroad, provide low-cost public housing, develop sources of electricity, hasten economic growth on the Caribbean coast, and operate many of the country's banks. Small national budgets, however, have made it difficult for the government to go much further, so that stress has been placed on new private investment instead.

Costa Rica is one country that made effective use of assistance granted under the United States aid program, which formed part of the Alliance for Progress. Despite temporary balance of payment difficulties, it has benefited also by its membership in the Central American Common Market.

**Transportation.** The hub of almost all Costa Rican transportation is the Valle Central. From San José, Cartago, Heredia, and Alajuela, all very close together, fan out narrow, often tortuous, paved routes with little interconnection, that reach the many valley and mountain communities in the immediate area. From this centre of human activity there extend two narrow-gauge railways—an electrified, government-operated line to Puntarenas and a British-operated, diesel-engine line to Limón. Three lesser lines are maintained by a fruit company.

The Inter-  
American  
Highway

The Inter-American Highway has since 1955 made Costa Rica far more accessible for trade. The provincial capitals of Puntarenas and Liberia are now reached with ease from the Valle Central. So are Nicaragua and the Central American countries beyond, with freight vans hauled by land even as far as Guatemala's ports on the Caribbean. There is also steady traffic to Panama, the obstacles being greater distance, a difficult crossing over the Talamanca range, and a lack of pavement on the road until very recently. Of the seven provincial capitals, only Limón remains without a paved highway from San José, and that connection entered the construction stage in 1971.

Limón has two piers, and Puntarenas and Golfito one each, to handle freight transported by railway. Limón's traffic is heavier than that of the other two combined, despite Golfito's status in the banana industry. El Coco, near San José, is the only international airport used by jet planes. Paved runways exist at Limón and Golfito and gravel strips at a few other airports offering local service by Líneas Aéreas Costarricenses, known as LACSA.

#### ADMINISTRATION AND SOCIAL CONDITIONS

Costa Rica is governed by its constitution of November 1949, the tenth in its history. A president, two vice presidents, and a unicameral legislative assembly are elected at one time for a term of four years, the assembly by proportional representation. Magistrates of the Supreme Court are chosen by the assembly for eight-year terms, being then automatically continued in office unless removed by a two-thirds vote.

**Local government.** The nation's seven provinces are ruled by governors appointed by the president. Guanacaste, the "brown" province, lies in the Pacific northwest. Puntarenas contains two areas, that in the vicinity of its capital and another in the Pacific south, connected by a narrow strip of territory along the sea. Limón contains all the Caribbean coastland. The other four, though they include much of the untamed territory, are governed at, and have the same names as, the four cities of the Valle Central. Each province is divided into cantons, and each canton into districts. Councilmen for the cantons are elected locally, but budgets for all are approved by the national government.

**Government finance.** Import duties, until the 1960s the biggest source of government revenue, have been reduced to about one-half their former level. Other government revenue comes from a graduated income tax that

runs from 1 to 30 percent of net income, a similarly progressive real estate tax, rather heavy consumption taxes on a variety of nonfood items, a new general sales tax of 5 percent, and a number of other levies.

**Political parties.** The fairness of national elections in recent decades has been indicated by the fact that every four-year period has seen a change in the party winning the presidency. In effect, the political situation since 1949 has been a struggle between the Party of National Liberation (Partido de Liberación Nacional) and its enemies. This organization, founded by the moderate Socialist José Figueres and friends, has impelled the nation into cooperative activity of various kinds, in the belief that good fortune should be shared by all Costa Rica's inhabitants. Opposition groups, highly personalist in nature and oriented toward the liberal left as well as the conservative right, generally unite behind one presidential candidate. Small parties, devoted to Marxism or the Christian Democratic movement, have not taken firm hold in the minds of the people, their role as left-wing reform groups already having been appropriated by the Party of National Liberation.

**Police and judiciary.** Costa Rican people were once proud of the fact that their country had more schoolteachers than army personnel. They now cite the fact that there is no army at all but only a nonconscripted civil guard that has police duties. There are district police also. A person accused of a crime will have his case decided by a single judge or, on appeal, by a panel of judges, without the use of a jury. Capital punishment is banned, and sentences to the penitentiary must be for a stated number of years.

**Education.** For two decades, the government has been taking vigorous action to see that all children attend school, that health standards are raised, and that adequate housing is available in urban zones. Education occupied 27.8 percent of the nation's budget in 1969. The census of 1963 showed a literacy count of 85.7 percent of the population ten or more years old, reaching to 94.8 percent in urban zones. Less than half of the people ten or more years old had, however, completed fourth grade. School attendance figures since then indicate a marked prolongation of the years spent in learning, especially in the cities. The University of Costa Rica has a well-planned, functional campus in San Pedro, very near San José, with an enrollment of more than 11,000 in 1970. More than one-third of the students were women.

**Health and welfare.** The greatest health problem for the Costa Rican people is protein-calorie malnutrition. Vitamin A deficiencies and goitre are common, as are infectious and parasitic diseases.

Though the break between the wealthy and the manual worker is less sharp in Costa Rica than in other Central American lands, there remains a large number of employees who are paid a very small wage. In the entire country, at the beginning of 1969, a sampling study showed that, of the urban working force receiving its compensation only in money (over three-fourths of whom worked more than 40 hours a week), 76 percent received less than 175 colones (about \$26) a week, while only 6 percent received 400 colones (about \$60) or more per week. At the same time, in the San José metropolitan area, black beans cost 12.1 cents per pound in United States currency, first-class rice 13.6 cents per pound, and workingman's shoes \$4.63 per pair.

#### CULTURAL LIFE AND INSTITUTIONS

Tourist impressions of Costa Rica may include the national dance, called the *punto guanacasteco*, the gaily painted oxcarts now made in miniature for the tourist market, or the baiting of the bulls, which is done by amateurs during the week's holiday from Christmas to the New Year. Altogether, however, most Costa Rican diversions are cosmopolitan rather than nationalistic in nature. The people attend film shows with great frequency, enjoying international cinema. They listen to an extraordinary variety of music, especially from the more than 50 radio transmitters in the country. Residents of the Valle Central attend the national theatre, where the

The Party  
of National  
Liberation

music played and the drama performed may come from any part of the world.

Costa Ricans take an interest in their pre-Columbian art, which includes large statues from the Pacific northwest, smaller examples of carved relief in stone from other districts, and some very fine work done in the form of small objects of gold. Samples of all of these may be seen in the national museum. Genuine colonial architecture is little found, the most famed example being a 17th-century mission in Orosi. Cartago's older buildings, destroyed by earthquake, have in some cases been restored; new ones have also been built like them. Painting and sculpting have re-entered the Costa Rican scene only in recent decades. In the early 1970s a new art centre was being constructed in San José near the national theatre.

Costa Ricans are not inactive in the field of literature. *El Repertorio Americano*, edited in San José from 1919 to 1958 by Joaquín García Monge, was heralded throughout the Western Hemisphere as a magazine of high intellectual and literary value. Roberto Brenes Mesén and Ricardo Fernández Guardia were widely known as independent thinkers in the fields of education and history, respectively. Fabián Dobles has attracted international attention as a writer of novels on social-protest themes.

*La Nación*, independent but conservative, is the most widely read of Costa Rica's newspapers. A combination of *La Nación* with either *La República* or *La Prensa Libre*, which lean more toward reform ideas, would provide the subscriber with a fairly full account of Costa Rican news. Television programming, which relies heavily upon productions from the United States and Mexico, is only slowly becoming part of the life of the majority of the people. Residents of the Valle Central have a choice of stations, while other areas receive only the relayed transmissions of the one national network.

#### PROSPECTS

The character of present-day Costa Rica was set in 1943 in a letter written by José Figueres, who three times since then has been the country's leader (as chairman of a ruling junta, 1948–49; and president 1953–58, 1970–74). In setting goals for the nation, Figueres listed (1) honesty in government; (2) liberty for the people; (3) professionalism in public administration; and (4) a distinct social orientation, the state gradually assuming the direction of all economic activity, so that there might be a greater production of wealth and more equity in its distribution.

All four of these goals have been pursued vigorously by the Party of National Liberation while in power (1962–66 and the three periods with Figueres), without their being negated by National Liberation's opponents while they held the presidency (1949–53, 1958–62, 1966–70). This was true even though some of the opponents denounced the prospect of complete governmental control of economic activity.

**BIBLIOGRAPHY.** JAMES L. BUSEY, *Notes on Costa Rican Democracy* (1962), provides a brief but in-depth study of the social and economic conditions that provide the bases for democracy in Costa Rica. DONALD E. LUNDBERG, *Costa Rica* (1968), is an informal guide for tourists and prospective immigrants. HOWARD I. BLUTSTEIN et al., *Area Handbook for Costa Rica* (1970), is a comprehensive fact book for government personnel. FRANKLIN D. PARKER, *The Central American Republics* (1964), gives historical background and a Spanish-language bibliography.

(F.D.P.)

## Counterpoint

A peculiarly Western phenomenon, counterpoint is the art of combining different melodic lines in a musical composition. It is the most characteristic element in Western music and a major distinguishing feature between the music of the West and that of the Orient and of primitive peoples.

The term counterpoint is frequently used interchangeably with the term polyphony. This is not properly correct since polyphony refers generally to music consisting of two or more distinct melodic lines, while counterpoint refers to the compositional technique involved in the handling of these melodic lines. Good counterpoint requires

two qualities: (1) a meaningful or harmonious relationship between the lines (a "vertical" consideration—i.e., dealing with harmony), and (2) some degree of independence or individuality within the lines themselves (a "horizontal" consideration, dealing with melody). Musical theorists have tended to emphasize the vertical aspects of counterpoint, defining the combinations of notes that are consonances (euphonious combinations, implying musical repose) and dissonances (clashing combinations, implying musical tension) and prescribing where consonances and dissonances should occur in the strong and weak beats of musical metre. In contrast, composers, especially the great ones, have shown more interest in the horizontal aspects: the movement of the individual melodic lines and long-range relationships of musical design and texture, the balance between vertical and horizontal forces, existing between these lines. The freedoms taken by composers have in turn influenced theorists to revise their laws.

The term counterpoint is occasionally used by ethnomusicologists to describe aspects of heterophony—duplication of a basic melodic line, with certain differences of detail or of decoration, by the various performers. This usage is not entirely appropriate, for such instances as the singing of a single melody at parallel intervals (e.g., one performer beginning on C, the other on G) lack the truly distinct or separate voice parts found in true polyphony and in counterpoint.

Finally, contemporary theorists generally use the term counterpoint in a narrow sense for musical styles resembling those of Palestrina or Bach and emphasizing clear melodic relationships (e.g., melodic imitation) between the voice parts.

In the present article, counterpoint will be considered more broadly, as an essential element in many styles within Western music. Composers in different periods have used counterpoint differently: in the Middle Ages they used it for the superimposing of different rhythmic groupings, in the Renaissance for melodic imitation, in the Baroque for contrasts between groups of instruments or voices, in the Classical period in conjunction with tonality, the organization of music in terms of key (a specific group of interrelated notes and chords), in the Romantic in the combining of leitmotifs, or short melodic fragments, and in contemporary music in the arrangement of isolated components of sound.

**Historical survey.** *The Middle Ages.* The earliest examples of actual written counterpoint appear in the late-9th-century treatise *Musica enchiriadis*. Here a Gregorian

Figure 1: Early organum; from *Musica enchiriadis* (c. 859).

chant melody, or "principal voice" (*vox principalis*), is combined with another part, "organal voice" (*vox organalis*), singing the same melody in parallel motion a perfect fourth or fifth below (e.g., G or F below C). Such music was called organum, probably because it resembled the sound of contemporary organs. In the early 11th century the teacher and theorist Guido of Arezzo in his *Micrologus* described a variety of organum in which the accompanying or organal voice had become more individualized. In addition to moving parallel to the main voice, it included oblique (diverging or converging) motion and contrary (opposite) motion. In this period the organal voice remains melodically awkward and subservient to the chant voice, as though it were composed one note at a time simply to colour or ornament each note of the chant. Early organum is thus not far removed from heterophony. Until the end of the 11th century organum was written entirely in note-against-note style, described, in

point

Counter-  
point and  
polyphony  
disting-  
uished

1336, as *punctus contra punctum* (point against point—*i.e.*, note against note), hence the name counterpoint (see Figure 1).

In the 12th century true polyphony comes into being; the melodic lines become individualized mostly by being given different rhythms. There emerges a hierarchy between the voice parts. The emphasis is upon the chant voice, which now becomes the lower part. Its notes are prolonged, or "held," and this part is now called the tenor, from the Latin *tenere*, to hold. The contrapuntal genius of the Middle Ages realizes itself mostly through the use of rhythmic contrasts between the different voice parts, and such contrasts gradually increase in complexity from c. 1100 to c. 1400. Around 1200 Pérotin, composer at Notre Dame in Paris who wrote some of the earliest music in three and four parts, superimposed different rhythmic modes (short fixed rhythmic patterns) in the voice parts. In his three-part Alleluia Nativitas (see Fig-

Medieval  
rhythmic  
complexity

Figure 2: From *Christmas Alleluia* by Pérotin

ure 2), the voices are in different rhythmic modes, and they are also distinguished by different phrase lengths, consisting of more or fewer repetitions of the rhythmic pattern. During the 13th century such contrasts were carried still further in the motet, a musical form usually in three voice parts, each in a different rhythmic mode. The theorist Franco of Cologne advocated the use of consonance at the beginning of each measure; such consonances (usually a chord made up of the unison, fifth, and octave, such as C-G-C') served as fixed pillars in terms of which the horizontal extensions of different rhythmic lengths were like soaring arches of sound. The tenor voice part in the motets of the 14th and early 15th centuries was organized by huge rhythmic recurrences known as isorhythm (*i.e.*, the return throughout the piece of a complex rhythmic pattern, not necessarily in conjunction with the same pitches of the melody). During the 14th century, particularly in the works of Guillaume de Machaut, the upper voice part was sometimes displaced by a beat or more in respect to the other parts, giving it further rhythmic independence. In the late 14th century complicated syncopations (displaced accents) and the simultaneous use of different metres characterized some of the most complex counterpoint in history.

The *Renaissance*. If the medieval composer explored mostly the possibilities of rhythmic counterpoint, the Renaissance composer was concerned primarily with melodic relationships between the voice parts. The predominant technique used was that of imitation; *i.e.*, the successive statement of the same or similar melody in each of the voice parts, so that one voice imitates another.

Imitation had appeared earlier in the Italian caccia and French chace, roundlike vocal forms of the 14th century, and in England in the 13th-century round, *Sumer is icumen in*. These compositions anticipate the Renaissance and also emphasize the rhythmic relationships typical of medieval counterpoint.

During the Renaissance the technique of imitation contributed to a new unity between the voices, as opposed to the hierarchy found in medieval counterpoint. Renaissance composers strove also for clear melodic relationships between voices; consequently imitations usually began on the same beat of a measure and were separated in pitch by simple intervals such as the fifth (as, c-g) or octave (as, c-c'). The Renaissance theorists, among them Johannes Tinctoris and Gioseffo Zarlino, categorized dissonances according to type and governed each type by definite rhythmic and melodic restrictions.

What is often proclaimed as the "golden age" of counterpoint—meaning melodic counterpoint—stretches from the late 15th to the late 16th centuries, from the Flemish-French master Jean d'Okeghem to the Spanish Tomás Luis de Victoria and the Elizabethan William Byrd. Its leading masters were Josquin des Prez, Giovanni Pierluigi da Palestrina, and Orlando di Lasso. The northern composers in particular showed a penchant for complex melodic relationships. Okeghem's *Missa prolationum* (*Prolation Mass*), for example, involves simultaneous canons in two pairs of voices. (In a canon, one melody is derived from another. It may be identical, as in a round, or it may be given various alterations, as of speed, or metre or omission of certain notes.) The most versatile craftsman of the Renaissance was Josquin, whose music displays a continual variety of contrapuntal ingenuities, including melodic imitation. His use of successive imitation in several voices, as in his *Missa da pacem* (see Figure 3) based on the chant melody "Da pacem" ("give peace"), is coupled with melodic smoothness and rhythmic vitality. The imitative style came to its fullest flowering in the late 16th century, not only in the masses and motets of Lasso and Palestrina but also in secular songs such as the French chanson and Italian madrigal. It also flourished in instrumental music in such contrapuntal forms as fantasias, canzonas, and ricercares.

Golden  
age of  
melodic  
counter-  
point

Figure 3: From *Missa da Pacem* by Josquin des Prez

The Baroque period. During the 17th and early 18th centuries the pure linear—*i.e.*, melodic—counterpoint of the Renaissance, now called the first practice, was retained alongside the newer type of counterpoint known as the second practice. This latter type was characterized by a freer treatment of dissonances and a richer employment of tone colour. The new liberties with dissonance disturbed the conservative theorists of the time; but they were justified by their proponents on the ground that they allowed a more expressive treatment of the text. Still more distinct was a new use of tone colour. Although the individual melodic lines often resembled those of the Renaissance, they were intensified and made to stand out through differences of scoring or instrumentation. In figured bass compositions (in which a keyboard instrument improvised the harmonies over a given bass melody) the counterpoint was between the upper melody and the bass line. These stood out clearly from one another because of their differences of instrumental or vocal tone colour. Also significant at this time was the development of concerto-like scoring. In a concerto a soloist or group of instruments is contrasted with the entire orchestra. Hence concerto style emphasized contrasts between the numbers of performers, the high and low registers, and the tone colours of two or more performing groups. This was anticipated in some of the madrigals (Italian part-songs) of the late Renaissance, especially those of Luca Marenzio (1553–99) and Don Carlo Gesualdo, in which two or three voice parts in a high or low register were immediately answered by parts in a contrasting register. Giovanni Gabrieli of Venice expanded this principle in his *Symphoniae Sacrae* (Sacred Symphonies) by setting off choirs of voices or instruments, thus achieving a counterpoint of contrasting sonorities. Such concerto-like effects became an essential part of the later madrigals and operas of Claudio Monteverdi. In his madrigal *Lament of the Nymph* (see Figure 4), a single soprano voice is pitted against three male voices, and both in turn against an instrumental continuo (figured bass played, for example, by cello and harpsichord) in the background. This type of counterpoint was ideal for emphasizing dramatic con-

Influence  
of the  
concerto

Figure 4: From *Lament of the Nymph* by Claudio Monteverdi.

trasts in the new forms of the opera and the oratorio. In these forms soloists, ensembles, and instrumental parts were opposed and combined in a great variety of ways by composers like Heinrich Schütz, Giacomo Carissimi, and Henry Purcell. In the late Baroque Arcangelo Corelli and Antonio Vivaldi added this style of dramatic contrasts to the purely instrumental contrasts of the concerto. The Baroque concerto culminated in the *Brandenburg Concertos* of J.S. Bach, which are characterized by a remarkable fusion of contrapuntal lines and instrumental colours (see Figure 5).

Figure 5: From *Brandenburg Concerto No. 5* by J.S. Bach

Bach's counterpoint has a retrospective side, which uses a mainly melodic approach. The fugue, a composition using the technique of melodic imitation, became highly developed in Bach's hands—e.g., the fugues of the *Well-Tempered Clavier*, and his final compendium of contrapuntal devices, *The Art of the Fugue*. A similar melodic, rather than tone-colour, approach occurs in works such as the *Inventions* and in the canons of the *Musical Offering*. These works are akin to "the first practice," the melodic counterpoint of the Renaissance, although in their use of dissonance and harmony they go considerably beyond Renaissance convention.

*The Classic period.* The turn from the Baroque to the Classic period in music was marked by the change from a luxuriant polyphonic to a relatively simple homophonic texture—i.e., a texture of a single melodic line plus chordal accompaniment. Composers of the early Classic period (c. 1730–70) largely eschewed counterpoint altogether, drawing on it only when preparing church music in the "learned style," as the Renaissance style was then called. Many of the keyboard sonatas of Domenico Scarlatti and Carl Philipp Emanuel Bach, despite a basically homophonic approach, reveal a skillful interplay between the main melody and accompaniment. In the late Classic period (c. 1770–1820), especially in the music of the Viennese school of Haydn, Mozart, and Beethoven, there was an ever-increasing penetration of counterpoint into musical forms based on this homophonic style and its contrasts of tonality, or key (the particular notes and chords related to a given keynote). This counterpoint in turn was tempered by the Classical style and musical forms. For example, although combined melodic lines are heard as counterpoint, together they can also be heard as a series of harmonies. In this way they form unified phrases in the homophonic style. This satisfied demands for symmetrical phrase lengths and clear-cut cadences, or stopping points, necessary to mark the sections of Classical forms such as the sonata.

Haydn underwent his contrapuntal "crisis," or movement toward counterpoint, during the 1770s, the period of "Storm and Stress" in German literature, which had a deepening effect on other arts as well. Three of his *Sun Quartets* (1772) had fugues as final movements, and in the *Russian Quartets* (1781) Haydn proclaimed "an entirely new manner," in which the thematic material was to be more equally shared by all of the string instruments instead of being given to a single principal melody instrument.

Haydn heard Handel's oratorios in London, which inspired him to write his own richly contrapuntal late oratorios, *The Creation* and *The Seasons*.

Mozart's discovery of the contrapuntal art of Bach and Handel impressed him so deeply that almost all of his later works were affected. The ensembles of the operas—e.g., *Don Giovanni* and *Così fan tutte*—with their clear delineation of several characters through their vocal lines, only became possible because of his new feeling for counterpoint. And at one point in his *Jupiter Symphony* five different themes are stated simultaneously, singly, or in combination. Nevertheless the counterpoint is kept entirely subservient to the harmonies of the symphony's tonal design, or its use of keys. Each voice is also governed by an underlying phrase structure applied to all of them, so that the combined parts form unified musical phrases (see Figure 6).

Figure 6: From *String Quartet (K. 490)* by W.A. Mozart.

Beethoven began his career in Vienna under the tutelage of the noted contrapuntal theorist Johann Albrechtsberger, and this, coupled with his admiration for Handel, probably accounts for his lifetime interest in counterpoint. He drew upon counterpoint to create musical intensity, especially in the development section of sonata (q.v.) form (the form prominent in Classical symphonies and chamber music), as in the first movement of the *Razumovsky Quartet*, Opus 59, No. 1, for example. In his late sonatas and quartets, except for obvious fugal works such as the first movement of Opus 131, or the *Great Fugue*, Opus 133, almost every movement shows the interpenetration of the principles of counterpoint, which deals with melodic lines, and tonality, which deals with harmonies.

*The Romantic period.* Counterpoint in the 19th century had a retrospective side in addition to a characteristically Romantic style. Richard Wagner admired the counterpoint of Palestrina, and Johannes Brahms revered the Baroque masters. Felix Mendelssohn revived Bach's *St. Matthew Passion* in 1829, and this led to numerous Bach-like works, such as the organ sonatas of Mendelssohn and numerous organ works by Max Reger, as well as arrangements of Bach's works by Franz Liszt. Yet the true bent of Romantic composers was toward combinations of motives (small melodic fragments), use of mo-

Use of counterpoint by Haydn, Mozart, and Beethoven

Combina-  
tions of  
motives  
and  
leitmotifs

tivic accompaniments against themes, and later, of the combination of leitmotifs, or motives with significance beyond the music itself. The lieder (songs) of Franz Schubert were highly innovative because of their motivic accompaniments, which balance in interest the vocal part itself and contrapuntally interact with it. This technique is still more pronounced in the songs of Robert Schumann and Hugo Wolf. It is also the tendency in 19th-century opera. In the later operas of Giuseppe Verdi the voices often have a parlante character (imitating speech through music) while the orchestra defines the dramatic substance. This, too, is the principle of the Wagner music dramas, with their "speech-song" (*Sprechgesang*) in the voice balanced contrapuntally by the leitmotifs of the accompaniment. In *Tristan und Isolde* Wagner set the leitmotifs in counterpoint against one another. Similarly, in the Prelude to Act III of *Siegfried*, a motif known as the

Figure 7: From *Siegfried* (Act III) by Richard Wagner.

"Need of the Gods" is cast against one associated with the "Valkyries." This results in a "counterpoint" of connotations and of emotions as well as in a musical counterpoint (see Figure 7). In purely instrumental music a similar joining of motives previously heard separately is encountered in the finale of Hector Berlioz's *Symphonie fantastique* when the plainchant melody "Dies Irae" ("Day of Wrath") is heard together with the theme called "Round of Sabbath." Richard Strauss, in his tone poem *Ein Heldenleben* (*A Hero's Life*), skillfully combines several themes taken from his earlier tone poems. And in the late symphonies of Gustav Mahler there is sometimes a complex of interwoven motives, each of which stands out contrapuntally through its presentation by a solo instrument.

In the 20th century Arnold Schoenberg carried this technique further, especially in his 12-note works, which are based on a 12-tone row, or specific ordering of the 12 notes of the chromatic scale, arranged in such a way as to avoid a sense of tonality. In some 12-note operas—e.g., *Moses und Aron* by Schoenberg and *Lulu* by Alban Berg—there is but one tone row used in the entire work; nonetheless, several hours of music are spun out of it through a continual variety of thematic shapes and contrapuntal combinations.

*The contemporary period.* The 20th century, like the 19th, has had its counterpoint inspired by earlier music. Anton Webern, for example, advocated a return to the forms of counterpoint used by Renaissance composers such as Heinrich Isaac, and in numerous of his own works (e.g., *Symphonie*) he makes use of Renaissance contrapuntal devices such as simultaneous canons and retrograde movement between the voice parts—i.e., one voice using the other's melody but with the notes in reverse order. Out of a similar return to Baroque forms came musical works such as the double fugue (a fugue based on two themes) that forms the second movement of the *Symphony of Psalms* by Igor Stravinsky.

But the use of older musical forms is no more of the essence of 20th-century counterpoint than it was of the 19th. A basic characteristic of 20th-century counterpoint is the separation of the voice parts into isolated entities of sound that are of themselves rather static. This may take the form of polytonality (the simultaneous use of two or more keys), using as static entities the notes of each key. It may also take the form of contrast of individual tone colour effects rather than of melodies, found in much electronic music. (This use extends beyond the original

definition of counterpoint simply as the combination of melodies.)

Richard Strauss's *Elektra* (1909) was one of the earliest works to make use of polytonality; in certain passages the instruments and voice parts are grouped into layers, each of which defines a different tonality, or key, although in this case all of the keys can also be interpreted as complicated aspects of the basic key. Stravinsky's *Three Pieces for String Quartet* suggests four keys at the same time: G, B, D, and A $\flat$ . In this particular work each instrument is limited throughout the piece to a few notes assigned to it. Thus each part is absolutely individual and, except for the viola, consists of an ostinato melodic and rhythmic pattern. The coming together of these ostinato patterns at different times and in continually shifting arrangements suggests the effect of a mobile (see Figure 8).

Figure 8: From *Three Pieces for String Quartet* (No. 1) by Igor Stravinsky.

Béla Bartók carried out a similar procedure in many of the short piano pieces of his *Mikrokosmos*, and in his *Fourth Quartet* (1928) he set apart tone clusters (chords built up in seconds, as C–D–E–F–G) in this way.

Turning now to a counterpoint purely of tone colours, *Intégrales* (1925) by Edgard Varese presents 11-note "sound-clouds" in the wind instruments in opposition to the sounds of a large battery of percussion instruments. This approach probably grew directly out of earlier experiments with polytonality, but here tone colours, rather than keys or tones, are differentiated. Elliott Carter in his *Double Concerto* (1961) set apart two groups of instruments, one around a piano, another around a harpsichord, each with its distinctive tone colours and its own distinctive harmonic intervals or note combinations. In György Ligeti's *Atmospheres* every instrument in a symphony orchestra, including every string part, plays its own unique, melodic pattern; all of these parts coalesce into gigantic bands or spectra of tone colour that contrast with one another. In later experiments, the sound-producing groups are further set off by visual or spatial contrasts in the physical placement of performers; e.g., Ramon Zupko's *Third Planer from the Sun*, 1970.

Evaluation and discussion of writings on counterpoint. Most of the writings on counterpoint have sought to increase the student's skill in musical composition. From the 18th century onward, textbooks of counterpoint have recommended as a model usually Palestrina or Bach, and in some recent cases 20th-century composers. Medieval and Renaissance treatises also were originally intended for student guidance and reflect the taste and attitudes of their own time. Several 20th-century studies deal with the contrapuntal technique of a particular composer or group of composers. At present there is no comprehensive study analyzing both the actual practices of composers and the theoretical writings on counterpoint throughout history.

## Couperin Family

For over 200 years, beginning in the early 17th century members of the Couperin family, one of the outstanding dynasties of music, worked in and around Paris as composers, performers, and teachers. Their name is linked inseparably with the church of Saint-Gervais, where for 173 years the post of organist was held by a Couperin.

The family is first heard of in the district of Brie, about 30 miles southeast of Paris. There, in the little walled town of Chaumes-en-Brie, between 1626 and 1638, three brothers were born. Their father, a merchant and small landowner, was also the organist of the local abbey church, and all three learned to play respectably on the violin, viol, harpsichord, and organ. Still, they might have remained provincial musicians but for a gesture of friendly respect. One summer, around 1650, Jacques Champion de Chambonnières, the best harpsichordist in France, was celebrating his name day at his house near Chaumes-en-Brie. The Couperin brothers and some friends honoured the great man with a serenade. The delighted Chambonnières, learning that it was Louis (c. 1626-61), the eldest, who had composed the music, insisted that he go to Paris.

In 1653 Louis had become the first Couperin to occupy the post of organist at Saint-Gervais, on the right bank of the Seine, across from Notre-Dame Cathedral. He also

held a court appointment as a treble viol player, but it was for his performing ability as a harpsichordist that he was best known. Until about 1960 when a collection of 70 organ pieces was discovered, his known compositions had consisted of 123 pieces for harpsichord and a handful for viol and organ. This small surviving sample of his life's work suggests that when he died in 1661, at only 35, the 17th century lost one of its greatest musical talents. Into conventional forms he crowded invention, learning, and passion in a measure surpassing even Chambonnières.

François Couperin le Grand, portrait by an unknown French artist, 18th century. In the Musée de Versailles.

The two younger brothers followed Louis to Paris and, although less illustrious, became successful musicians. François was described as a "great musician and great drunk"; no compositions are known, but his line of the family carried the name of Couperin into the 19th century. Charles succeeded Louis at Saint-Gervais, styled himself *Sieur de Crouilly* after some land inherited from his father, and, in 1668, produced an only child, François Couperin le Grand (1668-1733), who stands far above all the other Couperins with the exception of Louis, his equal in genius.

Although François was only 11 when his father died, the wardens of Saint-Gervais reserved the office of organist for him until he was 18. The organist Jacques Thomelin acted as a "second father" to François, and his mother went to considerable expense to provide teachers of "music, harpsichord, and organ" so that François would be ready at 18 to assume his father's position. The boy took over before his 18th birthday and in 1693 became one of the four organists of the royal chapel. One honour followed another: harpsichord teacher to the royal children (1694), *chevalier de l'ordre du Lateran* (1702), and the *survivance* (right to succeed) of Jean-Henri d'Anglebert as court harpsichordist (1717).

By 1723 Couperin's health obliged him to bestow the *survivance* at Saint-Gervais upon his cousin Nicolas, and in 1730 the d'Anglebert *survivance* went to his daughter Marguerite-Antoinette. François had married in 1689, and of his four children none gave him a grandchild. Only Marguerite-Antoinette remained to carry on his work, until ill health forced her, too, to desist. Despite his poor health, Couperin composed, collected, and edited at a furious rate, bringing out major publications in 1724-26, 1728, and 1730—half of all his surviving works. Like Louis, François is known above all for his harpsichord music. It carried his name across Europe and passed for the quintessence of civilized elegance. J.S. Bach knew it and copied it. Most of his 254 harpsichord pieces have titles and were written with some person or thing in mind, now often impossible to identify; all are alive with colours of the age captured in the cool, luminous precision of harpsichord sound.

François  
Couperin

Nicolas  
Couperin

Nicolas, who had been acting organist at Saint-Gervais, took over the full title at the death of François in 1733. No music can be definitely attributed to Nicolas, and he seems not to have been much talked about as a performer. He died in 1748, and the post went to his only son, Armand-Louis, who kept it until his death in a traffic accident in 1789. The surviving music of Armand-Louis, the last of the Couperins to enjoy an international reputation, reflects the cosmopolitan ferment of mid-18th century Paris and shows a strong experimental vein. His son Pierre-Louis took over at Saint-Gervais but died the same year and was succeeded by his brother, Gervais-François, last male of the line.

In Revolutionary Paris in 1793, all the churches were closed; but Gervais-François bent with the political winds of the next 30 years, celebrating in music the Republic, the Empire, and the restored Monarchy, all with impartial loyalty. He ended his days in 1826 in the same organ loft at Saint-Gervais that his great-great-uncle had entered 173 years before. The surviving music by both brothers is mostly for piano.

In 1830 Gervais-François's daughter Céleste and her mother retired to Beauvais, where Céleste gave lessons until 1843, when they returned to Belleville, near Paris. In 1848 the mother sold the family portraits to the state for a pittance. Celeste died in 1860 survived by her mother, with whom the dynasty perished in 1862.

#### MAJOR WORKS

**François Couperin** ("le Grand")

THEORETICAL WORK: *L'Art de toucher le clavecin* (1716 and 1717).

CHURCH MUSIC: 3 *Leçons de ténèbres* (c. 1714–15); *Élévations*; various motets.

CHAMBER MUSIC: 4 *Concerts royaux* (published 1722); *Les Goûts réunis* (1724); *Le Parnasse ou l'Apothéose de Corelli* (1724); *Apothéose de Lully* (1725); *Les Nations* (1726).

HARPSICHORD: *Livres de clavecin*: these works were published in four books in 1713, 1717, 1722, and 1730, arranged in 27 *Ordres* each comprising pieces in the same key, major or minor.

ORGAN: *Pièces d'orgues consistantes en deux messes: Messe pour les paroisses et Messe pour les couvents* (1690).

**Louis Couperin**

INSTRUMENTAL MUSIC: 123 pieces for harpsichord, including unmeasured preludes and dances: allemandes, courantes, sarabands, etc.; 70-plus organ pieces including fantasies, fugues, and versets.

**Armand-Louis Couperin**

A book of harpsichord pieces; 9 sonatas for harpsichord with the accompaniment of violin and violin and cello; 2 sonatas for two harpsichords with expressive devices.

**BIBLIOGRAPHY.** Owing to the enormous richness of French archives and the continuing researches of musical archivists, each year brings new discoveries about the Couperins, so that opinions about even such basic matters as how many Couperins there were are being continually revised. This is why there is so little agreement among the most recent articles in reference works. The following studies, however, are particularly recommended: MAURICE CAUCHIE, *Thematic Index of the Works of François Couperin* (1949); "Bibliographie chronologique des Couperin," *Mélanges François Couperin*, pp. 132–136 (1968); WILFRED MELLERS, *François Couperin and the French Classical Tradition* (1950), the most comprehensive study to date; CHARLES BOUVET, *Les Couperin* (1919), the first and most detailed work (copiously documented) on the entire family; *Nouveaux documents sur les Couperin* (1933); JULIEN TIERSOT, *Les Couperin* (1926); GUY OLDHAM, "A New Source of French Keyboard Music of the Mid-17th Century," *"Recherches" sur la musique française classique*, vol. 1, pp. 51–59 (1960).

(D.Fu.)

## Courbet, Gustave

Gustave Courbet founded and dominated the school of Realism in mid-19th century France in opposition to the academic art that had dominated French painting since 1800. His paintings, demonstrations of his belief that art should render reality unadorned and unaltered, shocked a society that had long been accustomed to an art that prettified life.

**Early life and work.** Courbet was born at Ornans, in eastern France, on June 10, 1819, the son of Eléonor-

Régis, a prosperous farmer, and Sylvie Courbet. After attending both the Collège Royal and the college of fine arts at Besançon, he went to Paris in 1841, ostensibly to attend law school. He devoted himself more seriously, however, to studying the paintings of the masters in the Louvre. Father and son had great respect for each other, and, when Courbet told his father of his intention to become a painter rather than a provincial lawyer, his father consented, saying, "If anyone gives up, it will be you, not me," and adding that, if necessary, he would sell his land and vineyards and even his houses.

Freed from all financial worry, young Courbet was able to devote himself entirely to his art. He gained technical proficiency by copying the pictures of Diego Velázquez, Ribera, and other 17th-century Spanish painters. In 1844, when he was 25, after several unsuccessful attempts, his self-portrait "Courbet with a Black Dog," painted in 1842, was accepted by the Salon—the only annual public exhibition of art in France, sponsored by the Royal Academy. When in the following years the jury for the Salon thrice rejected his work because of its unconventional style and bold subject matter, he remained undaunted and continued to submit it.

**The development of Realism.** The revolution of 1848 ushered in the Second Republic and a new liberal spirit that greatly affected the arts. The Salon held its exhibition not in the Louvre itself but in the adjoining galleries of the Tuileries. Courbet exhibited there in 1849, and his early work was greeted with considerable critical and public acclaim.

In 1849 he visited his family at Ornans to recover from the hectic life in Paris and, inspired again by his native countryside, produced two of his greatest paintings: "The Stone-Breakers" and "Burial at Ornans." Painted in 1849, "The Stone-Breakers" is a realistic rendering of two figures doing menial labour in a barren, rural setting. The "Burial at Ornans," from the following year, is a huge representation of a peasant funeral, containing more than 40 life-size figures. Both works depart radically from the more controlled, idealized pictures of either the Neoclassic or Romantic schools; they portray the life and emotions not of aristocratic personages but of humble peasants, and they do so with a realistic urgency. The fact that Courbet did not glorify or ennoble his peasants but presented them boldly and starkly created a violent reaction in the art world.

**Leader of the new school of Realism.** Courbet, an intimate of many writers and philosophers of his day, including the poet Charles Baudelaire and the social philosopher Pierre-Joseph Proudhon, became the leader of the new school of Realism, which in time prevailed over other contemporary movements. One of the decisive elements in his development of Realism was his lifelong attachment to the traditions and customs of his native province, the Franche-Comté, and of his birthplace, Ornans, one of the most beautiful towns in the province. After a brief visit to Switzerland, he returned to Ornans and in late 1854 began an immense canvas, which he completed in six weeks, "The Artist's Studio," an allegory of all the

Early  
realistic  
works

Giraudon

"L'Atelier du peintre, Allégorie réelle" ("The Artist's Studio"), with Courbet at the easel; oil on canvas, 1855. In the Louvre.

influences on Courbet's artistic life, portrayed as human figures from all levels of society. Courbet himself presides over all the figures with ingenuous conceit, working on a landscape and turning his back to a nude model. When the painting was refused by the jury for the 1855 Exposition Universelle, Courbet, with the financial support of a friend, opened his own pavilion of Realism to exhibit his works close to the exposition. His show provided the first group exhibition of Realistic paintings. The enterprise failed; the painter Eugène Delacroix alone, in his journal, praised the audacity and talent of Courbet, who made another attempt in 1867 but was again unsuccessful.

In 1856 Courbet visited Germany, where he was warmly welcomed by his fellow artists. Three years later, at the age of 40 and still working in defiance of severe criticism in his own country, he was the undisputed master and leader of a new generation of painters that had turned away from the traditional schools of painting, which they considered only barriers to artistic inspiration. Courbet worked in all genres. A lover of women, he glorified the female nude in paintings of stunning warmth and sensuality. He executed admirable portraits, but above all he celebrated the *Franche-Comté*, the forests, springs, rocks, and cliffs of which were immortalized by his vision. In 1865 he set up his easel before the cliffs of *Étretat*, Deauville, Trouville, and other resorts fashionable during the Second Empire. Carefully observing air currents and storm skies, he successfully depicted the architecture of a tempest in a series of seascapes. These pictures were an extraordinary achievement that amazed the world of art and opened the way for Impressionism, which was to achieve an even greater sensualism by reproducing the colour and light reflected by an object rather than its strict linear shape.

Political activist. The Franco-Prussian War broke out in 1870, the Second Empire collapsed, and the Third Republic was proclaimed. On March 18, 1871, the republican Paris Commune was established to fight the Germans in France as well as to fight the Army of Versailles, which had remained loyal to Napoleon III and had concluded an armistice with the Germans that was judged to be dishonourable by the members of the Commune. Courbet, who had been recently elected president of the artists' federation and was charged with reopening the museums and organizing the annual Salon, took part in the revolutionary activities of the Commune. Instead of opening the museums, he decided to protect the major public monuments, especially the *Sèvres* china factory and the palace at Fontainebleau, for Paris had been under constant bombardment by the Germans. Alarmed by the excesses of the Commune, he resigned May 2.

The Commune had voted to destroy the column in the Place Vendôme commemorating the Grand Army of Napoleon Bonaparte, and it carried out the decision on May 16. But on May 28 the Commune was crushed by the Army of Versailles, and on June 7 Courbet was arrested at the home of a friend. Because he was thought to be responsible for the demolition of the column, he was brought before a military court. As he had often made known his disgust of the militarism represented by the monument, he was charged with having been the instigator, although he had in no way participated in its destruction. A scapegoat was needed, and Courbet was arbitrarily chosen, despite his protests and those of the persons actually responsible for the demolition, who had fled to England. He was sentenced to six months in prison, and, thank, to the intervention of Adolphe Thiers, head of the provisional government of the French Republic, he was given a minimum fine of 500 francs. He served his sentence first at the *Sainte-Pélagie* prison, and, when he became seriously ill, he was moved to a clinic near Paris. Once freed, he hastened to Ornans in the hope of regaining his strength.

When Thiers resigned in 1872, the Bonapartist deputies reopened Courbet's case and sued him for the cost of rebuilding the column. His entire personal property and all his paintings were seized, and he was fined 500,000 gold francs. Having no other alternative but to leave

France because he could not pay the fine, he crossed the border into Switzerland on July 23, 1873, and settled in the small town of Fleurier. He set to work again, but, feeling unsafe so close to France, he first went to Vevey and then to La Tour-de-Peilz, where he bought an old inn, appropriately named the *Bon-Port* (Safe Arrival). There he died on December 31, 1877, at the age of 58, physically and morally exhausted by illness and disappointment.

Courbet's reputation has continued to grow since his death. His detractors often judge his art only on the basis of his Socialism, ignoring the fact that his political beliefs grew out of his generosity and compassion. His work, however, exerted much influence on the modern movements that followed him. He offered succeeding generations of painters not so much a new technique as a whole new philosophy. The aim of painting was not, as previous schools had maintained, to embellish or idealize reality but to reproduce it accurately. Courbet succeeded in ridding painting of its artistic clichés, contrived idealism, and timeworn models.

#### MAJOR WORKS

"Courbet au chien noir" ("Courbet with a Black Dog," 1842; Musée du Petit Palais, Paris); "Juliette Courbet" (1844; Musée du Petit Palais, Paris); "L'Homme à la pipe" ("Man with a Pipe," c. 1846; Musée Fabre, Montpellier France); "St. Nicolas ressuscitant les petits enfants" (1847; Bglise de Saules, near Ornans, France); "L'Après-dînée à Ornans" ("After Dinner at Ornans," 1849; Musée des Beaux-Arts, Lille, France); "Un Enterrement à Ornans" ("Burial at Ornans," 1849; Louvre, Paris); "Les Paysans de Flagey revenant de la foire" ("The Peasants of Flagey Returning from the Fair," 1850; Musée des Beaux-Arts et d'Archéologie, Besançon, France); "Young Ladies from the Village" ("Les Demoiselles de village," 1851–52; Metropolitan Museum of Art, New York); "Les Baigneuses" (1853; Musée Fabre, Montpellier, France); "Portrait de Bruyas" (1854; Musée Fabre, Montpellier, France); "La Rencontre ou bonjour, Monsieur Courbet" (1854; Musée Fabre, Montpellier, France); "La Roche de dix-heures" (c. 1854; Louvre); "Les Cribleuses de blé" ("The Winnowers," 1854; Musée des Beaux-Arts, Nantes); "L'Atelier du peintre, Allégorie réelle" ("The Artist's Studio, a Real Allegory of a Seven-Year Long Phase of My Artistic Life," 1855; Louvre); "Mère Grégoire" (1855; Art Institute, Chicago); "Les Demoiselles des bords de la Seine" ("Young Women on the Banks of the Seine," 1856; Musée du Petit Palais, Paris); "La Toilette de la mariée" ("The Bride at Her Toilet," 1859; Smith College Museum of Art, Northampton, Massachusetts); "La Diligence dans la neige" (1860; National Gallery, London); "Combat de cerfs. Le Rut du printemps" ("Battle Between Two Stags," 1861; Louvre); "The Trellis" (c. 1863; Toledo Museum of Art, Toledo, Ohio); "Proudhon et ses enfants" ("Proudhon and His Family," 1865; Musée du Petit Palais, Paris); "La Remise de chevreaux" ("Roe-Deer in Cover by the Plaisir-Fontaine Stream," 1866; Louvre); "The Woman with a Parrot" ("La Femme au Perroquet," 1866; Metropolitan Museum of Art, New York); "Les Dormeuses" ("Sleeping Women," 1866; Musée du Petit Palais, Paris); "La Source ou baigneuse à la source" (1868; Louvre); "Falaise d'Étretat après l'orage" ("The Cliffs at Étretat," 1870; Louvre); "Mer orageuse" ("La Vague," 1870; Louvre); "Portrait de Régis Courbet" (1874; Musée du Petit Palais, Paris).

**BIBLIOGRAPHY.** G. CASTAGNARY, *Gustave Courbet et la colonne Vendôme* (1883), was a courageous attempt of the author to absolve Courbet of the unjust charge that he took part in the demolition of the Vendôme column. GEORGES RIAT, *Gustave Courbet, peintre* (1906), written in collaboration with JULIETTE COURBET, who made important documents available to the author, is the definitive work upon which most later studies were based. BELA LAZARE, *Courbet et son influence à l'étranger* (1911), is a detailed analysis of Courbet's influence on the painters of central Europe. CHARLES LEGER, *Courbet* (1929), is an abundantly illustrated volume published on the 50th anniversary of Courbet's death (in French) that often sheds new light on the art of the painter. MARCEL ZAHAR, *Gustave Courbet* (1950), analyzes with rare perception the character of the man and the genius of the painter (in French). GERSTLE MACK, *Gustave Courbet* (1951), is a meticulously and heavily documented study of the artist (in English). ROBERT FERNIER, *Gustave Courbet* (Eng. trans. 1969), analyzes Courbet the craftsman; it is written as an homage to the genius of the painter whom the author greatly admired. The Société des "Amis de Gustave Courbet" *Bulletin* (issued twice a year since 1947) describes the society's

Flight to  
Switzer-  
land

Portraits,  
landscapes,  
and  
seascapes

Arrest  
and im-  
prisonment

activities and records all new information on Courbet's life and work.

(R.J.F.)

## Courts and the Judiciary

This article deals with the operations of the judicial branch of government. It explores some of the fundamental relationships of this branch with legislative and executive branches and analyzes the functions, the structure and organization, and finally, the key personnel of courts: the judges.

The approach is comparative, contrasting and comparing the systems of the two predominant legal traditions of the contemporary world: first, that of the common law, represented by England, the United States, Canada, Australia, and other nations deriving their legal systems from the English model; and second, that of the civil law, as represented by nations of western Europe and Latin America and certain Asian and African nations that have modelled their legal systems on western European patterns. Reference is made to the legal institutions in the Soviet Union and other Communist nations that display distinctive characteristics different from those of the civil-law tradition, from which, basically, they developed. Furthermore, at the end of the article there has been appended a section dealing more specifically with systems in Communist countries.

### FUNCTIONS OF COURTS

**Keeping peace.** The primary function of any court system in any nation—to help keep domestic peace—is so obvious that it is rarely considered or mentioned. If there were no agency to decide impartially and authoritatively whether a man had committed a crime and, if so, what should be done with him, other persons offended by his conduct would take the law into their own hands and proceed to punish him according to their uncontrolled discretion. If there were no agency empowered to decide private disputes impartially and authoritatively, self-help, quickly degenerating into physical violence, would prevail and anarchy would result. Not even a primitive society could survive under such conditions. All social order would be destroyed. In this most basic sense, courts constitute an essential element in society's machinery for keeping peace.

**Deciding controversies.** In the course of helping to keep the peace, courts are called upon to decide controversies. If, in a criminal case, the defendant denies committing the acts charged against him, the court must choose between his version of the facts and the prosecution's; and if he asserts that his conduct did not constitute a crime, the court must decide whether his view of the law or the prosecution's is correct. In a civil case, if the defendant disputes the plaintiff's account of what happened between them—for example, whether they entered into a certain agreement—or if he disputes the plaintiff's view of the legal significance of whatever occurred—for example, whether the agreement was legally binding—the court again must choose between the contentions of the parties. The issues presented to, and decided by, the court may be either factual, legal, or both.

It would be a mistake, however, to assume that courts spend all of their time deciding controversies. Many cases brought before them are not contested. They represent potential, rather than actual, controversies in which the court's role is more administrative than adjudicatory. The mere existence of a court renders unnecessary any very frequent exercise of its powers. The fact that it operates by known rules and with reasonably predictable results leads those who might otherwise engage in controversy to compose their differences.

Most people arrested and charged with crime in the common-law world plead guilty. If they do so understandingly and without coercion of any sort, there is no need to determine guilt, for the sole question is whether the defendant should go to jail, pay a fine, or be subjected to other corrective treatment. In civil-law countries some judicial inquiry into the question of guilt or innocence is

required even after a confession. But the inquiry is brief and tends to be perfunctory. The main problem to be resolved, usually without contest, is what sentence should be imposed.

The vast majority of civil cases are also uncontested or, at least, are settled before trial. The court keeps the calendar moving, sometimes encouraging settlement, and decides such questions of law or fact as are presented by the parties; but the number of cases actually tried is small compared to the number settled.

Most divorce cases are uncontested, both parties usually being anxious to terminate the marriage and often agreeing on related questions concerning support and the custody of children. All the court does in such cases is to review what the parties have agreed upon and give its official approval.

Many other uncontested matters come before courts, such as the adoption of children, the distribution of assets in trusts and estates, and the setting up of corporations. Occasionally questions of law or fact arise that have to be decided by the court, but normally all that is required is judicial supervision and approval.

**Judicial lawmaking.** As courts decide controversies they create an important by-product beyond the peaceful settlement of disputes; that is, the development of rules for future cases. Law is thus made not only by legislatures but also by the courts.

To an extent that varies greatly between common-law and civil-law nations, all courts apply pre-existing rules formulated by legislative bodies. In the course of doing so, they interpret those rules, sometimes distorting them, sometimes transforming them from generalities to specifics, sometimes filling gaps to cover situations never considered by the original lawmakers. The judicial decisions embodying these interpretations then become controlling for future cases, sometimes to the extent of virtually supplanting the legislative enactments themselves.

This is one aspect of the doctrine of precedent, or, as it is sometimes called, *stare decisis* (literally, "to stand by decided matters"). Judges follow earlier decisions, not only to save themselves the effort of working out fresh solutions for the same problems each time they recur but also, and primarily, because their goal is to render uniform and stable justice. If one individual is dealt with in a certain way today, the theory is that another individual engaging in substantially identical conduct under substantially identical conditions tomorrow or a month or year hence should be dealt with in the same way. This, reduced to its essentials, is all that precedent means.

In civil-law nations all judicial decisions are, in theory, based upon legislative enactments, and the doctrine of judicial precedent does not apply. Practice, however, departs from theory. While there are comprehensive legislative codes in these countries, supposedly covering almost every aspect of human conduct and supplying ready-made answers for all problems that can arise, in fact many of the provisions are exceedingly vague and are sometimes almost meaningless until applied to concrete situations, when judicial interpretation gives them specific meaning. Furthermore, the legislative codes cannot anticipate all situations that may arise and come before the courts. The gaps in legislative schemes must be and are filled by judicial decisions, for no court in any nation is likely to refuse to decide a case on the ground that it has not been told in advance the answers to the questions presented to it. Decisions dealing with circumstances unforeseen by the codes and giving specific meaning to vague legislative provisions are published in most civil-law countries and are frequently referred to by lawyers and relied upon by judges. They are not considered "binding," but neither are they forgotten or disregarded. In actual practice, they have almost as much influence as statutory interpretations in nations that formally adhere to the doctrine of *stare decisis*.

It remains true that in common-law countries judicial lawmaking is more pervasive and more frankly acknowledged than in civil-law countries. In addition to rendering decisions that authoritatively interpret statutes, the courts

The uses of experience in the law: *stare decisis*

The court's administrative role

of these nations have created a vast body of law without any statutory foundation whatever. Centuries ago, when there was no legislation to guide them, judges began to decide cases in accordance with their own conceptions of justice. Later judges followed them, deciding like cases in the same manner but distinguishing earlier cases when dissimilar factors were discovered in the cases before them. The later cases also became precedents to be followed in still later cases presenting substantially similar fact patterns. So the process has continued over centuries and is still continuing. The total accumulation of all these judicial decisions is what constitutes "the common law" —the by-product of judges deciding cases and setting forth their reasons. In the common-law nations, legislation is, as a result, more limited in scope than in the civil-law countries. It does not purport to provide for all possibilities but leaves large areas of conduct to be governed solely by judge-made law.

To speak of precedent as "binding" even in common-law systems is misleading. As already noted, earlier decisions can be and are distinguished when judges conclude that they are based upon situations different from those before the court in later cases. Even more significant, earlier decisions can be overruled by the courts that rendered them (not by courts lower in the judicial hierarchy) when the judges conclude that they have proved to be so erroneous or unwise as to be unsuited for current or future application. The Supreme Court of the United States has overruled many of its own earlier decisions, to the consternation of those who yearn for a rigid separation of powers and who are unable to accept the inevitability of judicial lawmaking. Many of these overrulings are in the field of constitutional law, in which legislative correction of an erroneous judicial interpretation of the Constitution is impossible and in which the only alternative is the exceedingly slow, cumbersome, costly, and difficult process of constitutional amendment. Nevertheless, the power to overrule decisions is not restricted to constitutional interpretations. It extends to areas of purely statutory and purely judge-made law as well, areas in which legislative action would be equally capable of accomplishing needed changes. Even in England, which has no written constitution and which has traditionally followed a far more rigid doctrine of stare decisis than the United States, the House of Lords, in its role as the highest court, has announced its intention of departing from precedent "in appropriate cases."

Conflicting  
views  
of the  
court's  
role

The desirability of judicial lawmaking has long been the subject of lively debate in both civil- and common-law countries. That courts should not arrogate to themselves unrestricted legislative power is universally accepted. But when existing statutes and precedents are outmoded or barbarous as applied to specific cases before the courts, should not judges be able to change the law in order to achieve what they conceive to be just results or, stated differently, to avoid what they consider unjust results?

The extent to which the judges should be bound by statutes and case precedents as against their own ethical ideas and concepts of social, political, and economic policy is an important question as is the matter of which should prevail when justice and law appear to the judges to be out of alignment with each other. These are questions upon which reasonable men disagree vigorously even when they are in basic agreement on the proposition that some degree of judicial lawmaking is inevitable. What is mainly at issue is the proper tempo and scope of judicial change. How quickly should judges act to remedy injustice and when should they consider an existing rule to be so established that its alteration calls for constitutional amendment or legislative enactment rather than judicial decision? As many dissenting opinions attest, judges themselves disagree on the answers to these questions, even when they are sitting on the same bench hearing the same case.

Constitutional decisions. In some nations courts not only interpret legislation but determine its validity and in so doing sometimes render statutes inoperative. This happens only in nations that have written constitutions

and have developed a doctrine of "judicial supremacy." The prime example is the United States and the classic statement of the doctrine is the Supreme Court's decision in *Marbury v. Madison* (1803), in which Chief Justice Marshall said:

The powers of the legislature are defined and limited; and that those limits may not be mistaken, or forgotten, the Constitution is written. To what purpose are powers limited, and to what purpose is that limitation committed to writing, if these limits may, at any time, be passed by those intended to be restrained? The distinction between a government with limited and unlimited powers, is abolished, if those limits do not confine the persons on whom they are imposed, and if acts prohibited and acts allowed, are of equal obligation. It is a proposition too plain to be contested, that the Constitution controls any legislative act repugnant to it. . . . It is emphatically the province and duty of the judicial department to say what the law is. Those who apply the rule to particular cases, must of necessity expound and interpret that rule. If two laws conflict with each other, the courts must decide on the operation of each.

Armed with the authority asserted at this early date, the Supreme Court of the United States has held many statutes, federal as well as state, unconstitutional and has also invalidated executive actions that violated the Constitution. Even more surprising is the fact that lower courts also possess and exercise the same powers. Whenever a question arises in any U.S. court at any level as to the constitutionality of a statute or executive action, that court is obligated to determine its validity in the course of deciding the case before it. The case may have been brought for the sole and express purpose of testing the constitutionality of the statute or it may be an ordinary civil or criminal case, in which a constitutional question incidental to the main purpose of the proceeding is raised. Of course, when a lower court decides a constitutional question, its decision is subject to appellate review, sometimes at more than one level. When a state statute is challenged as violating the state constitution, the final authority is the supreme court of that state; when a federal or state statute or a state constitutional provision is challenged as violating the Constitution of the United States, the ultimate arbiter is the Supreme Court of the United States.

In a few American states, questions as to the constitutional validity of a statute may be referred in abstract form to the state's highest court by the chief executive or the legislature for an advisory opinion. This, however, is unusual and, in any event, supplementary to the normal procedure of raising and deciding constitutional questions. The normal pattern is for a constitutional question to be raised at the trial-court level in the context of a genuine controversy and to be decided finally on appellate review of the trial-court decision.

The U.S. pattern of constitutional adjudication is not followed in all nations that have written constitutions. In some, such as Germany, there is a special court at the highest level of government that handles only constitutional questions and to which all such questions are referred as soon as they arise. A constitutional question may be referred to the special court in abstract form for a declaratory opinion by a procedure similar to that prevailing in the minority of U.S. states that allow advisory opinions.

Other  
methods of  
constitu-  
tional  
adjudica-  
tion

In other nations, written constitutions may be in effect but not accompanied by any conception that their authoritative interpretation is a judicial function. Legislative bodies, rather than courts, act as the guardians and interpreters of the constitution, being guided by their provisions but not bound by them in any realistic sense.

Finally, there are some nations, such as England, that have no written constitutions. Here parliamentary supremacy clearly prevails. The courts have no power to invalidate statutes, although they can and do interpret them.

Procedural rule making. Distinct from the type of lawmaking just described is a more conscious and explicit type of judicial legislation and one that is less controversial. It is directed toward the rules of procedure by which

the courts operate. This is a technical area in which expert knowledge of the type possessed by judges and lawyers is needed; in which constant attention to detail is required; and in which major problems of social, economic, or political policy are seldom encountered. Some legislative bodies, able or willing to devote only sporadic attention to the day-to-day problems of the management of litigation, have delegated the power to regulate procedure to the courts themselves. This is not *ad hoc* judicial lawmaking as a by-product of deciding cases but openly acknowledged promulgation of general rules for the future, in legislative form, by courts rather than legislatures.

An outstanding example of judicial rule making is found in the United States where Congress has delegated to the Supreme Court broad power to formulate rules of civil, criminal, and appellate procedure for the federal courts. The Supreme Court also has and exercises the power to amend the rules from time to time as experience indicates that changes are desirable. Congress reserves the power to veto the rules so promulgated but has felt no need to exercise it.

Other legislative bodies, including those of some American states and most of the nations of continental Europe, have been unwilling to repose equal trust in the courts and have retained for themselves the power to regulate procedure. The results have been varied. Courts sometimes become so immersed in day-to-day decision making that they fail to pay adequate attention to the proper functioning of the judicial machinery and so perpetuate rules that are unduly rigid, unrealistic, and unsuited to the needs of litigants, which was the case in England and the American colonies during the 18th and first part of the 19th century. When such a condition occurs, reform through legislative action is indicated. Apart from the occasional necessity of major sweeping changes, however, experience in the common-law countries, at least, indicates that procedural rule making is better vested in the courts than in legislative bodies.

Review of administrative decisions. Existing alongside the courts in any nation are administrative agencies of various kinds. Some do substantially the same kind of work as is done by courts and in substantially the same manner; some have quite different functions such as the issuing of licenses and the payment of welfare benefits.

The relationship between such agencies and regular courts differs markedly between common-law countries and civil-law countries. In common-law countries the actions of administrative agencies are subject to review in the ordinary courts. If the agency is one that decides controversies in substantially the same manner as a court, but in a different and more limited area, judicial control takes much the same form of appellate review as is provided for the decisions of lower courts. The objective of reviewing the record of proceedings is to determine whether the administrative agency acted within the scope of its jurisdiction, whether there was any evidence to support its conclusion, and whether the governing law was correctly interpreted and applied. Administrative decisions are **seldom upset** by the courts because of a belief on the part of most judges that administrative agencies have special expertise in the area of their specialty. However, they can be and occasionally are upset, thus underscoring the large degree of judicial control over other agencies of government that characterizes common-law systems. If the administrative agency does not engage in formal adjudication, it produces no record of proceedings for judicial review. Nevertheless its action can be challenged in court by way of trial rather than appeal. The same problems are presented for judicial determination: did the agency act within its jurisdiction, did it correctly follow the law, and was there any rational or factual basis for its action?

In many civil-law countries, the ordinary courts have no control over administrative agencies. Their decisions are reviewed by a special tribunal that is engaged exclusively in that work and that has nothing to do with cases of the type that come into the courts. Its function is solely ap-

pellate and solely within the specialized areas entrusted to the administrative agencies. The prototype of this type of tribunal is the Conseil d'État of France.

Enforcement of judicial decisions. The method of enforcing a judicial decision depends upon its nature. If it does nothing more than declare legal rights, as is true of a simple divorce decree (merely severing marital ties, not awarding alimony or the custody of children), or a declaratory judgment (for example, interpreting a contract or a statute), no enforcement is needed. If a judgment orders a party to do or refrain from doing a certain act, as happens when an injunction is issued, the court itself takes the first step in enforcing the judgment by holding in contempt anyone who refuses to obey its order and sentencing him to pay a fine or go to jail. Thereafter, enforcement is in the hands of the executive branch of government, acting through its correctional authorities.

In routine criminal cases and in civil cases that result in the award of money damages, courts have little to do with the enforcement of their judgments. That is the function of the executive branch of government, acting through sheriffs, marshals, jailers, and similar officials. The courts themselves have no machinery for enforcement.

Some judgments are extremely controversial, as was the case with the decision of the Supreme Court of the United States ordering racial desegregation of the schools. When voluntary compliance with such a judgment is refused, forcible methods of enforcement are necessary, sometimes even extending to the deployment of armed forces under the control of the executive branch of the government. The withdrawal of executive support seldom occurs, even when decisions are directed against the executive branch of government itself; but when such executive support is withheld, the courts are rendered impotent. Judges, being aware of their limited power, seldom render decisions that they know to be so lacking in support that they will not be enforced.

The limits  
of judicial  
Power

#### COURT STRUCTURE AND ORGANIZATION

There are many different types of courts and many ways to classify and describe them. Basic distinctions must be made between civil and criminal courts, between courts of general jurisdiction and those of limited jurisdiction, and between trial and appellate courts.

Criminal courts. Criminal courts deal with persons accused of crime, deciding whether they are guilty and, if so, determining the consequences they shall suffer. Prosecution is on behalf of the public, represented by some official such as a district attorney, procurator, or a police officer. Courts are also public agencies, but in this instance they stand neutral between the prosecution and the defense, their objective being to decide between the two in accordance with law.

In civil-law countries a more active role is assigned to the judge and a more passive role to counsel than in common-law countries. In the common-law courts, in which the "adversary" procedure prevails, the lawyers for both sides bear responsibility for producing evidence and they do most of the questioning of witnesses. In civil-law countries, "inquisitorial" procedure prevails, with judges doing most of the questioning of witnesses and having an independent responsibility to discover the facts. This difference pertains more to procedure rather than function.

If a man has been found guilty, he is sentenced, again according to law and within limits fixed by legislation. The objective is not so much to wreak vengeance upon the offender as to rehabilitate him and deter others from following his example. Hence the most common sentences are fines, short terms of imprisonment, and probation (which allows the offender to remain at large but under supervision). In extremely serious cases, the goal may be to prevent the offender from committing further crimes, which may call for a long term of imprisonment or even capital punishment. The death penalty, however, is gradually disappearing from the criminal codes of civilized nations.

Criminal proceedings in any nation inevitably have

some educational impact on defendants and upon members of the general public. In Communist nations education is a conscious and primary goal. A basic provision of Soviet law declares:

By all its activities the court shall educate the citizens of the U.S.S.R. in the spirit of devotion to the Motherland and the cause of communism in the spirit of strict and undeviating observance of Soviet laws, of care for socialist property, of labor discipline, of honesty toward public and social duty, of respect for the rights, honor and dignity of citizens, for the rules of socialist common-life.

**Civil courts.** Civil courts deal with "private" controversies, as where two individuals (or corporations) are in dispute over the terms of a contract or over who shall bear responsibility for an auto accident. Ordinarily the public is not a party as in criminal proceedings, for it has no interest beyond providing just rules for decision and a forum where the dispute can be impartially and peacefully resolved.

It is possible, however, for the government to be involved in civil litigation if it stands in the same relation to a private party as another individual might stand. Thus, if a postal truck should run down a pedestrian, the government might be sued civilly by the injured man; or if the government contracted to purchase supplies that turned out to be defective, it might sue the dealer for damages in a civil court.

The objective of a civil action is not punishment or correction of the defendant or the setting of an example to others but rather to restore the parties so far as possible to the positions they would have occupied had no legal wrong been committed. The most common civil remedy is a judgment for money damages but there are others, such as an injunction ordering the defendant to do or refrain from doing a certain act or a judgment restoring property to its rightful owner.

Civil claims do not ordinarily arise out of criminal acts. A man who breaks his contract with another or who causes him a physical injury through negligence may have committed no crime but only a civil wrong for which he may not be prosecuted criminally by the public.

There are, however, areas of overlap, for a single incident may give rise to both civil liability and criminal prosecution. In some nations, such as France, both types of responsibility can be determined in a single proceeding under a concept known as *adhesion* by which the injured party is allowed to assert his civil claim in the criminal prosecution, agreeing to abide by its outcome. This removes the necessity of two separate trials. In common-law countries there is no such procedure, even though civil and criminal jurisdiction may be merged in a single court. Two separate actions must be brought, independent of each other.

**Courts of general jurisdiction.** Although there are some courts that handle only criminal cases and others that handle only civil cases, a more common pattern is for a single court to be vested with both civil and criminal jurisdiction. Such is the High Court of England and such are many of the trial courts found in U.S. states. Often these tribunals are called courts of general jurisdiction, signifying that they can deal with almost any type of controversy, although in fact they may not have jurisdiction over certain types of cases assigned to specialized tribunals. Often such courts are also described as superior courts, because they are empowered to handle serious criminal cases and important civil cases involving large amounts of money.

Even if a court possesses general or very broad jurisdiction, it may nevertheless be organized into specialized branches, one handling criminal cases, another handling civil cases, another handling juvenile cases, and so forth. The advantage of such an arrangement is that judges can be transferred from one type of work to another, and cases do not fail to be heard for having been instituted in the wrong branch since they can be transferred administratively with relatively little effort.

**Courts of limited jurisdiction.** Specialized tribunals of many kinds exist, varying from nation to nation. Some

deal only with the administration of the estates of deceased persons (probate courts), some only with disputes between merchants (commercial courts), some only with disputes between employers and employees (labour courts). All are courts of limited jurisdiction. Deserving of special mention because of their importance are juvenile courts, empowered to deal with misconduct by children and sometimes also with the neglect or maltreatment of children. Their procedure is much more informal than that of adult criminal courts, and the facilities available to them for the pretrial detention of children and for their incarceration, if necessary after trial, are different. The emphasis is on salvaging children, not punishing them.

Traffic courts also deserve mention because they are so common. They process motor vehicle offenses such as speeding and improper parking. Their procedure is summary and their volume of cases heavy. Contested trials are relatively infrequent.

Finally, in most jurisdictions there are what are called, unfortunately and for want of a better term, "inferior" courts. These are often manned by part-time judges who are not trained in the law. They handle minor civil cases involving small sums of money, such as bill collections, and minor criminal cases carrying light penalties, such as simple assaults. In addition to finally disposing of minor criminal cases, such courts may handle the early phases of more serious criminal cases—fixing bail, advising defendants of their rights, appointing counsel, and conducting preliminary hearings to determine whether the evidence is sufficient to justify holding defendants for trial in higher "superior" courts.

**Appellate courts.** The tribunals described thus far are trial courts or "courts of first instance." They see the parties, hear the witnesses, receive the evidence, find the facts, apply the law, and determine the outcome.

Above them, to review their work and correct their errors, are appellate courts. These are usually collegiate bodies, consisting of several judges instead of the single judge who usually presides over a trial court. The jurisdiction of the appellate courts is usually general; specialized appellate tribunals handling, for example, only criminal appeals or only civil appeals are rare, although not unknown. The *Conseil d'État* of France and the Constitutional Court of Germany have already been mentioned as examples of specialization.

Appellate review is not automatic. It must be sought by some party aggrieved by the judgment in the court below. For that reason, and because an appeal may be both expensive and useless, there are far fewer appeals than trials and, if successive appeals are available, as is often the case, far fewer second appeals than original appeals. Judicial systems are organized on a hierarchical basis: at the bottom are numerous trial courts scattered throughout the nation; above them are a smaller number of first level appellate courts, usually organized on a regional basis; and at the apex is a single court of last resort.

There are three basic types of appellate review. The first consists of a retrial of the case, with the appellate court hearing the evidence for the second time, making fresh findings of fact, and in general proceeding in much the same manner as the court that originally rendered the judgment under attack. This "trial de novo" is used in common-law countries for the first stage of review but only when the trial in the first instance was conducted by an "inferior" court—one typically manned by a part-time judge or two or more such judges, empowered to try only minor cases and keeping no adequate record of its proceedings.

The second type of review is based in part on a "dossier," which is a record compiled in the court below of the evidence received and the findings made there. The reviewing court has the power to rehear the same witnesses again or to supplement their testimony by taking additional evidence, but it need not and frequently does not do so, being content to rely on the record already made in reaching its own findings of fact and conclusions of law. This type of proceeding prevails generally in civil-

Distinction  
between  
civil and  
criminal  
actions

Varieties  
of appel-  
late review

law countries for the first stage of appellate review, even when the original trial was conducted in a superior court, staffed by professional judges, and empowered to try important or serious cases.

The third type of review is based solely on a written record of proceedings in the court or courts below. The reviewing court does not itself receive evidence directly but concentrates its effort on discovering from the record whether any errors were committed of such a serious nature as to require reversal or modification of the judgment under attack or a new trial in the court below. The emphasis is on questions of law (both procedural and substantive) rather than on questions of fact. This type of review prevails both in civil-law nations and common-law nations at the highest appellate level. It is also used in common-law nations at lower levels when the judgment of a superior court is under attack. The purpose of this type of review is not merely to assure that correct results are reached in individual cases but also to clarify and expound the law in the manner described earlier. Lower courts have little to do with the development of the law, for they ordinarily do not write or publish opinions. The highest appellate courts do, and it is their opinions that become the guidelines for future cases.

**Courts in federal systems.** Many nations, such as England, France, and Japan, have unitary judicial systems with all courts (that is, regular courts as distinguished from administrative bodies) fitting into a single national hierarchy of tribunals along the lines just described. Other nations, organized on a federal basis, tend to have more complicated court structures, reflecting the fragmentation of governmental powers between the central authority and the local authorities. In the United States, for example, there are 51 separate judicial systems, one for each state and another for the federal government. To a limited extent, the jurisdiction of the federal courts is exclusive of that exercised by the state courts, but there are large areas of overlap and duplication. At the top level is the Supreme Court of the United States, hearing appeals not only from the lower federal courts but also from state courts insofar as they present federal questions arising under the Constitution of the United States or under federal statutes or treaties. If a case in a state court involves only a question of state law—for example, the interpretation of a state statute—the ultimate authority is the state supreme court, and no appeal is possible to the Supreme Court of the United States.

Court structure in a federal form of government need not be as complicated as that in the United States. It is possible to have only one set of courts for the nation, operated by the central government and handling all cases that arise under state law as well as federal law.

Another possibility is for each state or province to have its own system of courts, handling all questions of federal as well as state law, and for the central government to maintain only a single supreme court to decide questions as to the relationship of the central authority and the local authorities or as to the relationship among the local authorities themselves. This is the pattern in Canada and Australia.

Another complication resulting from a federal form of government is that questions involving conflict of laws arise with great frequency. Such questions concern the choice to be made between the law of one jurisdiction and another as the rule for decision in a particular case. Even in a unitary system, such problems cannot be avoided, for an English court may be called upon to try a case arising from a transaction that took place in France and to decide whether English or French law should govern. Such problems arise much more often, however, in federal systems, where laws differ from state to state and people move about very freely. Their activities in one state sometimes become the subject of a lawsuit in another, requiring the court to decide which law should apply.

#### JUDGES

A court is a complex institution whose functioning depends upon many people: not only the judge but also the

parties, their lawyers, witnesses, clerks, bailiffs, probation officers, administrators, and many others, including, in certain types of cases, jurors. Nevertheless, the central figure in any court is the judge.

Judges vary enormously, not only from nation to nation but often within a single nation. For example, a rural justice of the peace in the United States—untrained in the law, serving part-time, sitting alone in his work clothes in a makeshift courtroom, collecting small fees or receiving a pittance for salary, trying a succession of routine traffic cases and little else—obviously bears little resemblance to a justice of the Supreme Court of the United States—a full-time, well-paid, black-robed professional, assisted by law clerks and secretaries, sitting in a marble palace with eight colleagues and deciding at the highest appellate level only questions of profound national importance. Yet both men are judges.

**Lay judges.** In some civil-law countries, judges at all levels are professionally trained in the law, but in many other nations they are not. In England, part-time, lay judges outnumber full-time professional judges by about 60 to 1. Called magistrates or justices of the peace, they dispose of about 97 percent of all criminal cases in that nation and do so with general public satisfaction and the approbation of most lawyers. Professional judges deal only with the most serious crimes, which are relatively few in number; most of their time is devoted to civil cases. England places unusually heavy reliance on lay judges, but they are far from unknown in the courts of many other nations, particularly at the lowest trial level. This is as true in the U.S.S.R. as it is in the United States. There is considerable diversity in the way laymen are chosen and used in judicial work. In the U.S.S.R. and the United States, for example, lay judges are popularly elected for limited terms, whereas in England they are appointed by the lord chancellor to serve until retirement or removal. In the U.S.S.R. and England the lay judges serve intermittently in panels on a rotating basis for short periods, whereas in the United States they sit alone and continuously. In the U.S.S.R. lay judges (who are called assessors) always sit with professional judges; in England, they sometimes do; and in the United States, they never do. In some underdeveloped nations, few judges at any level are legally trained. They are more likely to be priests, for the law they administer is mainly derived from religious teaching, and religion and secular government are often not sharply differentiated. The vast majority of nations that use lay judges at the lowest trial level, however, insist upon professionally trained judges at higher levels: in trial courts of general jurisdiction and in appellate courts.

**Professional judges in the civil-law tradition.** Professional judges in civil-law countries are markedly different in background and outlook from professional judges in common-law countries. Both are law trained and both perform substantially the same functions, but there the similarities cease. In a typical civil-law country, a man graduating from law school makes a choice between a judicial career and a career as a private lawyer. If he chooses the former and is able to pass an examination, he is appointed to the judiciary by the minister of justice (a political officer) and enters service in his early 20s. His first assignment is to a low-level court; thereafter, he works his way up the judicial ladder as far as he can until his retirement on a pension. His promotions and assignments depend upon the way his performance is regarded by a council of senior judges, or sometimes upon the judgment of the minister of justice, who may or may not exercise his powers disinterestedly and on the basis of merit. The civil-law judge, in short, is a civil servant.

**Professional judges in the common-law tradition.** In common-law nations, the path to judicial office is quite different. Upon completion of his formal education, a man typically spends 15, 20, or 25 years in the private practice of law or, less commonly, in law teaching or governmental legal service; then, at about age 50, he becomes a judge. He takes no competitive examination but is appointed or elected to office. In England the appoint-

The levels of legal training

Conflict of laws problems

ive system prevails for all levels of judges, including even lay magistrates. Appointments are primarily under the control of the lord chancellor, who, although a cabinet officer, is also the highest judge of the realm. They are kept surprisingly free from party politics. In the United States, the appointive method is used in federal courts and some state courts, but it tends to be highly political. Appointments are made by the chief executive of the nation or state and are frequently subject to legislative approval. In many states, judges are popularly elected, sometimes on nonpartisan ballots, sometimes on partisan ballots with all the trappings of traditional political contests. In an attempt to de-emphasize political considerations and yet maintain some measure of popular control over the selection of judges, a third method of judicial selection has been devised and is slowly growing in popularity. Called the Missouri Plan, it involves the creation of a nominating commission that screens judicial candidates and submits to the appointing authority a limited number of names of men considered qualified. The appointing authority must make his choice from the list submitted. The man chosen as judge then assumes office for a limited time, and, after the conclusion of this probationary period, he stands for "election" for a much longer term. He does not run against any other candidate but only "against his own record."

In common-law countries, a man does not necessarily enter the judiciary at a low level; he may be appointed or elected to his nation's highest court or to one of its intermediate courts. He does not look forward to any regular pattern of promotion, nor is he necessarily assured of long tenure with ultimate retirement on a pension. In some courts, life tenure is provided, usually subject to mandatory retirement at a fixed age. In others, tenure is limited to a stated term of years. At the conclusion of his term, if not mandatorily retired earlier, the judge must be re-elected or re-appointed if he is to continue.

While in office, the common-law judge enjoys greater power and prestige and more independence than his civil-law counterpart. He occupies a position to which most members of his profession aspire. He is not subject to outside supervision and inspection by any council of judges or by a minister of justice; nor is he liable to be transferred by action of such an official from court to court or place to place. The only administrative control over him is that exercised by judicial colleagues, whose powers of management are generally slight, being limited to such matters as requiring periodical reports of pending cases and arranging for temporary (and usually consensual) transfers of judges between courts when factors such as illness or congested calendars require them. Only if a judge misbehaves very badly is he in danger of disciplinary sanctions and then usually only by way of criminal prosecution for his misdeeds or legislative impeachment and trial, resulting in removal from office—a very cumbersome, slow, ill-defined, inflexible, ineffective, and seldom used procedure. In parts of the United States, newer and more expeditious methods of judicial discipline are developing in which senior judges are vested with power to impose sanctions ranging from reprimand to removal from office of erring colleagues. They are also vested with power to retire judges who have become physically or mentally unfit to discharge their duties.

Except at the very highest appellate level, common-law judges are no less subject than their civil-law counterparts to appellate reversals of their judgments. But appellate review cannot fairly be regarded as discipline. It is designed to protect the rights of litigants; to clarify, expound, and develop the law; and to help and guide rather than reprimand lower court judges. (D.K.)

**Other judicial officials.** In most countries there are other officials who serve the court. Court clerks, who are responsible for case records and documents, and bailiffs, who are in charge of keeping order, are found in most judicial systems. Also prevalent are officers who prosecute cases in the government's name: states attorneys and district attorneys in the United States, *procurators-general* in the U.S.S.R., and *procureurs généraux* in France.

Probation officers are found in many countries including the U.S. and Japan. Notaries in France, Italy, and the U.S.S.R. have greater powers than their counterparts in the U.S. In fact, they perform many services carried out by lawyers in the common-law system such as drafting and verifying wills and contracts and preparing petitions for presentation in court.

Certain countries have officials that are particularly indigenous to their country or legal system. France, for example, has a *juge d'instruction*, who is responsible for the preliminary investigative proceedings prior to a criminal trial.

#### THE STRUCTURE AND STATUS. OF THE JUDICIARY UNDER COMMUNISM

Although the essential legal institutions of the Soviet Union and other Communist countries are based on the civil-law system, certain features are unique. These characteristics are partly the result of the Soviet Union's attitudes toward law that antedate the Soviet system, but mostly they result from the attempt to reconcile Marxist theory with the institutional needs of a modern society.

According to Marx and his followers the legal system, like all other governmental structures and instruments of class oppression, would "wither away" in a Communist society; thus the courts that existed after the Revolution were considered temporary institutions, required only during the transition to Communism. The ordinary and traditional business of the courts was carried on by the so-called people's courts, while "revolutionary tribunals" dealt with individuals the government considered to be political opponents. A nonjudicial body in the hands of the secret police (at first called Cheka, later OGPU and NKVD), operating in the style of an administrative agency, also heard cases and handed out sentences—usually of the severest kind.

In 1921 some capitalist measures were temporarily introduced to revive the economy, and this necessitated some stabilization of the legal system and its institutions. A three-level system of courts with civil and criminal jurisdiction was established in 1922 for the Russian Republic, which in the same year formed a federation with the other soviet republics under its jurisdiction, making up the Union of Soviet Socialist Republics. A new constitution created a federal court—the U.S.S.R. Supreme Court—and a federal judiciary act of 1924 established uniform principles for the judiciary throughout the republics, patterned largely after the system adopted by the Russian Republic. The basic structure of the courts laid down at that time has remained essentially the same to the present, with some minor changes and reforms.

The "people's courts" on the local level are courts of original jurisdiction for minor criminal cases and a large number of civil cases. The next level, the provincial courts, receive appeals from the people's courts and have original jurisdiction over political and serious civil and criminal cases. The highest level in each republic is its supreme court, which hears appeals from the provincial courts, disciplines lower courts, and has some original jurisdiction over extremely serious cases.

On all three levels, appellate cases are tried by a court consisting of three full-time judges, whereas one judge and two lay judges, or assessors, preside over cases on first hearing. Judges of the people's courts are popularly elected every five years and judges on the other two levels are "elected" by soviets (bodies combining legislative and executive functions) of the corresponding levels of government. All judges may be recalled before the expiration of their terms by those who elected them.

The federal court system is twofold. There are courts called military tribunals that deal with charges against men in the armed forces and with charges of espionage brought against civilians. The other federal body is the U.S.S.R. Supreme Court—the highest judicial body—which has original jurisdiction in a few special cases relating to the survival of the regime, appellate power over the decisions of the supreme courts of the republics or decisions of the military tribunals, and the right to issue

The Soviet  
three-level  
court  
system

The status  
of judges

directives to all inferior courts in matters of administration of justice on the basis of its decisions. Although Soviet legal theory is patterned after that of civil-law countries in that it does not recognize judicial law-making, these Supreme Court directives function as a source of law and are binding on all courts. The status of the judiciary in the Soviet Union has undergone some changes that parallel the institutional changes since the early days of the Revolution. The system organized in 1922 had the stated purpose of safeguarding the conquests of the Revolution and establishing the dictatorship of the proletariat. Judges were called upon to use their "revolutionary conscience" in deciding cases, and the doctrine of impartiality and independence of the judiciary was repudiated. With the passage of time, however, the Soviet rulers found the need for legal institutions of a stable nature increasing rather than decreasing, and the goal of the legal system was changed from protection of a particular class to protection of the Socialist order and the rights of all citizens. Although the role of the judiciary is still conceived of as a political task, there is some acceptance of the idea that judges should be independent and impartial. Marxist philosophy notwithstanding, the Soviet Union and other Socialist countries are confronted with a growing need for legal institutions to fulfill many of the same functions as those in the West. One attempt to fill this need has been the appearance of "social organizations," such as the "comrades' courts," which are described as voluntary organizations using persuasion and social influence to deal with matters that would otherwise come before a court. But these organizations are party controlled, have only limited power to impose sanctions, and do not appear to offer an effective alternative to the type of legal institutions that have been developing within Soviet society.

The other Communist countries, both in eastern Europe and Asia, adopted legal institutions largely patterned after the Soviet model. Since Stalin's death, however, there have been some modifications in the eastern European countries, coinciding with the reforms in the civil and criminal codes adopted by the Soviet Union in the late 1950s and early 1960s. Chinese leaders, however, have resisted efforts to codify their laws, preferring flexibility in their courts, and they have abandoned the policy of copying Soviet legal patterns.

## Covenant

The concept of covenant—that is, a binding promise—is of far-reaching importance in the relations between individuals, groups, and nations. It has social, legal, religious, and other aspects. This article is concerned primarily with the term in its special religious sense and especially with its role in Judaism and Christianity.

### NATURE AND SIGNIFICANCE

Covenants in the ancient world were solemn agreements by which societies attempted to regularize the behaviour of both individuals and social organizations, particularly in those contexts in which social control was either inade-

quate or nonexistent. Although ancient pre-Greek civilizations apparently never developed a descriptive theory of covenants, analysis of covenant forms and the ancient use of language yields a definition that essentially is the same as that which is found in modern law. It is a promise or agreement under consideration, usually under seal or guarantee between two parties, and the seal or symbol of guarantee is that which distinguishes covenant from modern contract.

The concept of covenant has been of enormous importance in the biblical tradition; from it there is derived the long traditional division of the Bible into the Old and New Testaments (Covenants). In post-biblical Judaism and sporadically in Christianity, the concept of covenant has been a major source and foundation of religious thought and especially of the concept of the religious community, but the nature and content of covenant ideas have undergone an extremely complex history of change, adaptation, and elaboration.

Though both covenant and law in the ancient world were means by which obligation was both established and sanctioned, and are often virtually identified with each other in modern scholarly literature, there are, nevertheless, very important contrasts between the two that should not be obscured. A covenant is a promise that is sanctioned by an oath. This promise in turn was accompanied by an appeal to a deity or deities to "see" or "watch over" the behaviour of the one who has sworn, and to punish any violation of the covenant by bringing into action the curses stipulated or implied in the swearing of the oath. Legal procedure, on the other hand, may be entirely secular, for law characteristically does not require that each member of the legal community voluntarily swear an oath to obey the law. Further, in ordinary legal procedure the sanctions of the law are carried out by appropriate agencies of the society itself, and not by transcendent powers that are beyond the control of man and society.

Because a person swearing an oath can bind only himself by that oath, covenants in the ancient world were usually unilateral. In circumstances in which it was desirable to establish a parity (equivalence) treaty, such as in rare cases in political life, the parity was obtained by the simple device of what might be termed a double covenant, in which both parties would bind themselves to identical obligations, and neither one of them was therefore subjected to the other.

The oath was usually accompanied by a ritual or symbolic act that might take any of an enormous range of forms. One of the most frequent of these was the ritual identification of the promisor with a sacrificial animal, so that the slaughter and perhaps dismemberment of the animal dramatized the fate of the promisor if he were to violate the covenant.

### ORIGIN AND FUNCTION OF COVENANTS

**Origins.** That covenants probably originated in remote prehistoric times is indicated by the fact that they were already well-developed political instruments by the 3rd millennium BC. To judge from later parallels and from the modern observations of anthropologists, covenants may very well have developed, at least in part, from marriage contracts between exogamous tribes or bands; *i.e.*, those groups that stayed within the required patterns of intermarriage. Whether or not this was the case, the most important functions of covenants for 1,000 years before the 13th-century BC Sinai covenant (see below) had to do with the creation of new relationships, both familial and political. Though the old theory of "social contract"—*i.e.*, the basic agreement about the social and political order—as the basis of large social organizations has not for some time been much in favour among social scientists, very early historical evidence increasingly suggests that covenants may have been much more instrumental in society than has been realized.

Typically, so far as existing sources now reveal, a covenant between social groups regularized in advance the relationships between two societies after one had been subjugated by a superior coercive force, usually by mili-

of  
covenants

tary action or the threat thereof. In the Mari documents (18th-century-BC archives from the palace at Mari in Syria), such a covenant was called a *salimum*, a "peace," probably because the promises made by the vanquished brought to an end the necessity of military operations against the vassal ruler or state. As is the case throughout so much of human history, ancient states characteristically seem to have regarded their neighbors as either enemies or vassals. Thus it is not surprising that covenants made under duress had little vitality, particularly when the terms of the covenant called for a considerable annual tribute to the overlord state.

Late Bronze Age developments. About the beginning of the late Bronze Age (c. 1500 BC), there occurred a major step forward in both the form and the concept of political covenants as is attested by treaties of the Hittite Empire of Asia Minor. Though the realities of political life were probably little changed, since the foreign policy of the Hittite Empire was primarily military, the structure of suzerainty treaties from this time on included rather strenuous efforts to demonstrate that the vassal's obligations to the Hittite overlord were really founded upon the former's self-interest, not merely upon the brute military force of the latter.

Hittite  
treaties

By far the most evidence for international treaties in the ancient world comes from Hittite sources, which were contemporary with the events that preceded and led up to the formation of the ancient Israelite federation of tribes in Palestine. The treaty form in written texts was highly developed and flexible but usually exhibited the following structure: preamble, historical prologue, stipulations, provisions for deposit and public reading, witnesses, and curses and blessings formulas. (1) The preamble names the overlord who grants the treaty-covenant to the vassal. The titles and laudatory epithets of the Great King are also given. (2) The historical prologue describes the previous relationships between the two parties in some detail, usually emphasizing the benevolent acts of the Great King toward the vassal. Thus the covenant is based upon the demonstrated benefits that have already been received and therefore holds out the expectation of continuing advantage for faithful obedience to the covenant. There is an implication that obedience to obligations is based upon gratitude. (3) The stipulations, which in form are much like those of the ancient Mesopotamian law codes (case law), define in advance the obligation of the vassal in certain circumstances. In addition, there are also generalized statements of obligation of a type that has been called "apodictic law" (regulations in the form of a command). The obligations deal particularly with military assistance, the treatment of fugitives, and foreign policy. Treaty relationships with other independent states are a violation of covenant. (4) Provision is made for deposit of the treaty in the temple and for periodic public reading. Because the temple is the "house of the god," the written document was placed there for the watchful attention of the deity. The treaty obligations, however, were also binding upon the vassal's citizenry, and so at stipulated intervals the text was read to the assembly, both as a reminder and a warning. (5) The list of witnesses included, in addition to the major deities of both states, deified elements of the natural world, such as mountains, rivers, heaven and earth, winds, and clouds. The witnesses were those powers that were believed to be beyond human control and upon which man and society were regarded as completely dependent. They were invoked to apply the appropriate sanctions of the covenant. (6) The curses and blessings formulas are the sanctions that furnish not only negative but also positive motivations for obedience. They include the natural and historical calamities beyond human control, such as disease, famine, death without posterity, and destruction of the society itself. The blessings are of course the opposite: prosperity, peace, long life, continuity of kingship and society.

In view of the obsession with rituals that characterized Hittite culture, some elaborate ceremony probably accompanied the ratification of covenant, such as the account of one preserved in the document known as "The

Soldiers' Oath," but it is not described in existing covenant texts.

Scholars in Europe and America in the 20th century have seen an astounding similarity between this treaty structure and the biblical traditions of the Sinai covenant. Publication of texts in the mid-1950s was followed by an enormous amount of scholarly discussion, but as yet no conclusions can be said to represent a scholarly consensus. The formal similarity to biblical traditions cannot be denied, but the problem of what historical conclusions can be drawn from the formal similarities is highly sensitive and controversial. While the following synthesis is a probable, and historically plausible, interpretation, it must be admitted that other possibilities can by no means be excluded.

#### THE ORIGIN AND DEVELOPMENT OF BIBLICAL COVENANTS: JUDAISM

The **Sinai** covenant. *Historical background.* The 100 years between 1250 and 1150 BC saw the complete destruction, or reduction to virtual impotence, of every major political state in the eastern Mediterranean region and the beginning of a "dark age" that has yielded very few written materials from which historical conclusions can be drawn. The reasons for the universal catastrophe are far from clear, but the reversion of society to communities of peasants and shepherds with a subsistence level economy can be well illustrated archaeologically. The earliest biblical traditions illustrate the conditions in Palestine at this time, though it is a difficult task to distinguish genuine ancient traditions from the use of the past by biblical writers to give religious validity to social realities or institutions of much later date.

In view of the highly elaborate social structure of the old Bronze Age states—with its apex in the military aristocracy, a highly complex priesthood, and ritual—and the equally complex social structure of the many local enclaves and tribes—each with its particular god—the monotheistic and ethically centred religious ideology of early Israel has been regarded for millennia as a miracle of "revelation," which cannot be explained on the basis of usual historical principles and concepts. Yet, ancient Israel was an historically existent community created, and precariously maintained, by a unity of which the religious ideology was the foundation for two centuries, until military considerations resulted in the formation of a political centralization of power about 1000 BC. The covenant tradition is the only instrument by which the effective functioning of that unity can be understood, and its importance is underlined by the biblical traditions themselves. The structure of the Hittite treaties now makes available an historical precedent that enables scholars to understand the structure of early Israelite thought and consequently its functional operation in history.

*The covenant at Sinai.* The Decalogue (The Ten Commandments) given by Yahweh, the God of the Israelites, at Sinai, plus the various traditions associated with earliest Israel yield all of the important elements of the Hittite treaty form but in an extremely succinct and simple form. Yahweh is identified as the covenant giver, and the historical prologue is the only possible one according to the ancient traditions: the announcement that it is this God who delivered the assembled group from bondage in Egypt (in the 13th century BC). This delivery is a free, voluntary act of the deity that forms the basis of the obligations that the community can either accept together with a lasting relationship to that God or reject, thus entailing a permanent hostility (hatred) between the God and human beings. It is the common relationship to a single sovereign God that furnished the basis for a radically new kind of community, which grew with rapidity first in Transjordan, then in Palestine proper, until it included virtually all the nonurban population of the region.

The new community was the answer, temporarily at least, to the old dilemma of civilization: how to maintain peace among a large and diverse population, perform the necessary social functions of cooperation and protection, and control individual attacks upon the security and

The  
covenant  
tradition  
as an  
instrument  
of unity

property of others without the enormous and expensive paraphernalia of political bureaucracy, military machine, and the ruinous tax collector. It was, for all functional purposes, the Kingdom (or Rule) of Yahweh, which excluded the deification of any other factor in human history or nature that was of importance to human life and well-being. The Sinai covenant marked the beginnings of nearly all the various theological themes that were to be so greatly elaborated upon in the following millennia: the Providence, or Grace, of God; the Kingdom of God; the sin of man and the wrath of God; the Holy People as the community of God; the rewards and punishments of the obedient and the disobedient respectively; and above all, the ethical norms as the essence of divine command over against the universal pagan obsession with proper ritual as the normative expression of man's subjection to the divine will.

Modern functional equivalents of the Ten Commandments

The Sinaitic covenant stipulations may be expressed in modern functional terms in the following manner: (1) The commandment to have no other gods involves the obligation to refuse subjection to all other social and human concerns and their symbolization in art forms so as to give them a position of parity or superiority to Yahweh and his commands. (2) The commandment not to take the name of God in vain emphasizes the unconditional sanctity of oaths that Yahweh was called upon to guarantee and enforce. (3) The commandment to observe the sabbath, the seventh day, the original social function of which is still unknown, could very well have grown out of a common village custom, for even in Rome in the 1st century BC, good farming practice permitted work animals and slaves to rest every eighth day—and this is precisely the interpretation given in Deut. 5:14. (4) The commandment to honour father and mother emphasizes the treatment of parents with respect and deference, which must have been of particular importance in a time of social upheaval and polarization. (5) The commandment not to kill meant that killing of persons by persons, even by accident if it involved negligence, was a usurpation of the divine sovereignty over persons. Contrary to modern reinterpretations, among opponents of capital punishment and pacifists, this could not include execution of persons for crime or killing of the enemy in warfare, for in both cases human beings were acting as the agents of Yahweh under divine command, just as the various officials of states have long carried out similar functions without incurring personal guilt for their acts. (6) Other commandments against theft, adultery, and false witness categorically prohibit acts that call into question the security of property, of family relationships and true lineal succession, and the integrity and therefore the justice of juridical procedures in society. (7) Finally, the prohibition of coveting what one's neighbour has excludes an enormous range of social attitudes and motivations that modern man now takes for granted as normal, if not essential.

The Ten Commandments as ethical obligations

Most, if not all, of the Ten Commandments are ethical obligations of which violations are very difficult if not impossible for society to detect, much less to enforce or punish. The Sinai covenant, therefore, marked the beginnings of a systematic recognition that the well-being of a community cannot be based merely upon socially organized force, nor can the political power structure be regarded, as in ancient pagan states, as the manifestation of the divine, transcendent order of the universe.

Post-Sinai covenants. Traces remain in the biblical traditions to indicate that the new community formed from a "rabble" at Sinai was in very short time joined by a considerable part of the population of Transjordan and Palestine proper. After the destruction (in the late 13th century) of the military chiefdoms ruled by Sihon and Og in the area east of the Jordan River, the Hebrews held a covenant ceremony at Shittim (northeast of the Dead Sea), which has been greatly elaborated upon in tradition as the "second giving of the Law," Deuteronomy. Though it is true that the Book of Deuteronomy from the 7th century BC exhibits the same basic structure as that of the old covenant form, it is at present impossible to reconstruct the original form or content of the Shittim

covenant. It may be presumed that entry into the community by covenant was followed by the allotment of land as tenured fiefs from Yahweh and the organization of the population into "tribes." This organization probably was the last event of the Hebrew leader Moses' life, and the sequel in the more important covenant at Shechem (northwest of the Dead Sea) took place under the leadership of Joshua, the successor of Moses.

Shechem evidently had had an important covenant tradition long before Israel existed. The name of its god, Baal Berit ("Lord of the Covenant"), presupposes some kind of covenant basis for the local social structure, just as a considerable segment of the population can be shown to have originated from Anatolia.

The Shechem covenant narrative has been preserved at least in part in Joshua, in which Joshua appeals to the family and clan heads to choose between the new dominion of Yahweh and the continuation of the old ancestral cults of the Amorite tradition "beyond the River." As in the case of the Transjordan covenant at Shittim, this covenant followed the defeat of a coalition of petty kings and evidently the removal of many others according to the list of Joshua. Again, there ensued an allotment of fields and an organization of the population into administrative units called "tribes," each under a nasi (literally, "one lifted up").

The entire process from the covenant at Sinai to the unification of perhaps a quarter of a million people by a covenant involving a religious loyalty to a single deity took only a little over one generation. It began with a group of probably considerably less than 1,000 people who left Egypt with Moses.

The subsequent history of the Sinai covenant tradition is very complex. The Book of Deuteronomy preserves slight traces of a covenant-renewal ceremony held every seven years, which is inherently plausible and which would function as a means for obtaining the oath-bound loyalty to Yahweh and his dominion of those who had come into the community from the outside or who had come of age in the intervening period.

The covenants of the Israelite monarchy. (1020–587/586 BC). Since early Israel was a religious confederacy of tribes that bitterly rejected the old military chiefdoms and their religious ideology, which elevated a Baal, or local agricultural deity—the god with the club as a symbol of the supernatural power undergirding the king—to a position of preeminence in the pantheon, it follows that the authentic Yahwist traditions stemming from Moses could not furnish a religious ideology to legitimize the monarchy when it was finally established first under Saul (reigned c. 1020–1000 BC) and then successfully under David (reigned c. 1000–962). Furthermore, early in David's reign, he had incorporated by military force most of the existing city-states of Palestine and Transjordan into his empire, and that population had never given up the old Bronze Age cults.

It is not surprising, therefore, that this double dilemma of the new political structure should have driven the royal bureaucracy to pre-Mosaic sources as a solution to the problem. One result was the reintroduction of the age-old pagan concept of the king as the "chosen" one of the gods and a radically different—and opposite—concept of covenant, in which it was now Yahweh, not the king or the people, who bound himself by oath. Possibly modelled after old royal covenants by which ancient pagan kings made a grant to their faithful retainers, the Davidic covenant introduced a radically different (and thoroughly pagan) element into the Mosaic tradition, and the two traditions contended with one another for the next 1,000 years.

Since the old Israel-Jacob (pre-Mosaic) traditions also could not furnish an ideological base for unifying the old Israelite and non-Israelite populations under the monarchy, pre-Mosaic epic traditions of Abraham (perhaps 19th–18th centuries BC) were appealed to to furnish the "common ancestor" symbol of unity, and the covenant tradition—no doubt, already a part of that epic—was re-adapted to bring it up to date. The deity (now identified with Yahweh) bound himself by oath to fulfill certain

The Shechem covenant

promises to Abraham, though the content of the promise, in the form now received, was by and large a description of the historical situation of the Davidic empire. Though it is difficult to see what the social or ideological function may have been, the covenant with Noah (the hero of the Flood) in Genesis exhibits the same structure. The result of all these radical changes in a very short time was a complete confusing of the religious tradition and structure and a permanent deposit of the pre-Mosaic pagan religious ideology into the biblical tradition. It seems virtually certain that the Sinai tradition was itself systematically reinterpreted in the so-called ritual decalogue of Exodus in which it is dogmatically stated that the Sinai obligations were entirely ritual in nature, rather than ethical-functional. The first tables of stone of the Ten Commandments, after all, had been "broken," which in the ancient world was a customary phrase used to indicate the invalidation of binding legal documents.

The next several centuries illustrate the constant battle between the Mosaic and the reintroduced pagan elements. The prophets proclaimed and supported the disintegration (c. 922 BC) of the Solomonic empire into a northern (Israel) and a southern (Judah) kingdom as the divine chastisement of Yahweh for gross disobedience. Particularly in the north, which did not retain the Davidic dynasty, the prophets periodically proclaimed the necessity and inevitability of wiping out one royal dynasty after another. Elijah, a 9th-century BC rustic prophet, ridiculed the idea that the Israelites could limp along on both legs—*i.e.*, observe loyalty to both the Yahwistic and the Baal cults. Reforms were carried out occasionally, but not until the time of Josiah, the young king of Judah (late 7th century BC), and the discovery of an old copy of the Mosaic legal-ethical tradition (the Deuteronomistic code) in c. 621 BC was serious reform undertaken—and there with little permanent success. The preservation of the Mosaic tradition was a function of the destruction of the monarchical state and its religious symbol, the temple, which nearly all the pre-exilic (before 587/586 BC) prophets had predicted.

**The post-Exilic covenant tradition.** Though the prophet Jeremiah (late 7th century BC) had predicted a "new covenant" written upon the heart (Jeremiah), not until the time of the prophets Ezra and Nehemiah in the 5th century is there another biblical narrative of covenant making, this time one of incalculable importance for the future of both postbiblical Judaism and Christianity and perhaps even for certain aspects of political theory or practice in the West (*e.g.*, "Covenant" of the United Nations, Mayflower Compact, and constitutions).

The account in Nehemiah is not so much that of a covenant as it is of a constitutional convention, the purpose of which was to establish as binding law the complex of traditions that had been preserved and recorded as the "law of God" which was given by Moses, the servant of God" (Nehemiah). It is a one-party enactment by the authorities and representatives of the community, in which Yahweh appears only as the deity addressed in the long historical prologue in the form of a prayer. The content is a recapitulation of the Deuteronomistic history (interpretations of the 7th-century BC document), narrating the benevolent acts of Yahweh and the sin and punishment of the people. In order to avoid the curses, and obtain the blessings, the community resolved henceforth to observe the "law of God." From this time on, the dominant concept of covenant in Judaism identifies it with circumcision, the ritual by which on the eighth day of his life, the male Jew becomes obligated to obey the law of Moses, the *berit* (covenant). The Sinai covenant had become permanently identified with the accumulation of legal-ritual tradition, and the community was identified not as the complex variety of all those who wished and accepted the rule of God but as the ethnic group of those who were heirs of the promise to Abraham in direct lineal (and fictitious) descent.

#### ORIGIN AND DEVELOPMENT OF COVENANT: CHRISTIANITY

**The New Testament tradition of the covenant.** The cup of wine at the Last Supper of Jesus and his disciples

before Jesus' crucifixion is identified in all New Testament sources as the (new) covenant by Jesus himself, but in spite of millennia-long controversy, theological elaboration, and discussion, the nature and meaning of the covenant has never been adequately understood historically, and the variety of interpretations regarding covenant in the New Testament itself indicates that very early in the tradition it had become a problem. Here it is possible only to indicate some significant associations that might explain why it was called a "covenant" and how the ancient Sinaitic tradition was radically renewed but the basic structure retained.

First, it has been noted that a most important aspect of covenant traditions common to most ancient cultures was the ritual identification of the oath taker with the sacrificial victim. The identification of the bread and the wine with the body and blood of Christ at the Last Supper apparently was interpreted in this sense, so that the subsequent death of the victim entails the symbolic death—the ultimate curse for breach of covenant—of all those who were thus identified with the victim. Consequently, the curses of the law were nullified. The death of Jesus thus becomes in the Christian proclamation the centre of the historical narrative—the historical prologue of the covenant—leading up to the covenant enactment, or the sacramentum, to use the Latin term of the early church, which in secular use at that time meant primarily the soldier's oath of loyalty to the emperor (see above Late Bronze Age developments). The Christian covenant was thus a highly complex historical act that brought about a relationship of the believer to Christ whose (normally) unseen Glory was identified with that of God himself, whose Lordship was viewed as operational in history, and whose community (of believers) was identified with the Kingdom (Dominion or Rule) of God. If God in the Old Testament could rule without kings, God could, for the New Testament writers, rule without the elaborate structure of the accumulated legal traditions. They were regarded as valuable for edification and for warning but no longer as having binding validity. The anathema, or curse, was no longer tied to the definitions of legal violation but rather to rejection of God's rule in Christ. The community in turn was no longer the lineal descent group with a parochial ritual tradition but the assembly (*ekklesia*) of those who had through the covenant accepted a relationship to the dominion of Christ.

The obligations could not, in the New Testament viewpoint, be again defined in legal terms, nor could they be enforced by social power structures, which could deal only with external formal acts, not with the basic springs of behaviour, such as love or hate. The content of obligation was thus not defined; instead, in the Sermon on the Mount (Matthew) and other New Testament literature, it is the criteria (motivations, ethical norms, personality traits) by which the rule of God is recognized upon which the emphasis falls. The presumption is that anyone who is capable of recognizing the rule of God in his experience in society will also be capable of understanding what the nature of his obligation will be in specific circumstances. The curses and blessings alike are then postponed until the final judgment. The motivations of fear of punishment and hope of reward are irrelevant to the daily routine of ethical choice, which is thus not only possible (*i.e.*, not prescribed in advance by legal definition) but unavoidable and also necessary to make responsible ethical decisions in a world that is characterized by cultural diversity and change.

**The post-apostolic church.** Covenant concepts in early Christian theology apparently centred on the transference of the Davidic covenant to the Messianic figure—*i.e.*, Christ. The fundamental theological problem of the early church was to validate the authority of Christ against both paganism and Judaism and to maintain the authority of the new religious community. After the great theologian Augustine (354–430), little attention was given to covenants until the Reformation in the 16th century. Though Luther (1483–1546) referred to and discussed the biblical covenants, it was never of particular importance to his theology. It is rather in Reformed the-

The death  
of Jesus in  
relation to  
the  
covenant

ology, particularly that of John Calvin (1509–64) and the later Puritans of the 17th century, that its further elaboration took place. One aspect of the use of covenant may be cited in the famed Mayflower Compact of Nov. 11, 1620 (drawn up by the Pilgrims, Separatists from the Church of England) by which a "civil body politic" was formed that would in turn enact laws and offices for the general good.

The theological elaboration of covenant in Puritan and Separatist theology centred on the themes of election, grace, and Baptism. It is curiously ironic that covenant enactment, such as the Mayflower Compact, became historically operative but remained essentially secular, while the religious covenant became predominantly a theological concept associated particularly with Baptism—the ritual means by which a person became a participant in the covenant of grace. The essential elements in the biblical covenant—i.e., that of free, voluntary acceptance of ethical obligation on the basis of and as response to past experience—has virtually always given way to covenant as fixed religious dogma that legitimizes the social structure. Covenant historically has been a means by which new communities are formed, particularly in times of rapid change, social dislocation, or political breakdown. Covenants have rarely been the actual instruments by which societies actually functioned for long, but they are extremely frequent as ideological foundations for sociopolitical legitimacy.

#### COVENANT IN OTHER RELIGIONS

**Islām.** Covenants (*mīthāq*, 'ahd) were of great importance in the formative period of Islām (7th century AD, or 1st century AH—after the Hegīra, Muhammad's flight from Mecca to Medina). More than 700 verses of the Qur'ān, the Muslim sacred scripture, have to do with various aspects of covenant relationships. As one recent Muslim writer, Sayyid Qutb, states, Islām combines both the Old and the New Testaments (covenants) and the Last Covenant, of Islām, as well. All revelation from Adam to Muhammad is regarded by Muslims as a unit, mediated through a series of prophets, or messengers, with whom God made a covenant: Noah, Abraham, Moses, and Jesus. Though the concept is difficult, it seems that the prophet in each case was given a revelation and a religion to which he covenanted with God to witness faithfully. This concept of a covenant of the prophets conveys the conviction of the unity of revelation as well as the unity of God in past history.

On the second level, the Muslim community itself is often regarded as being composed of those who have accepted the covenant with God. In this connection, the grace, or providence, of God in nature or creation is of great importance. In addition to this view is the repeated emphasis upon the doctrine that God alone is man's sole benefactor, and for these reasons the response of gratitude is an important element in the structure of the covenant. It is also necessary that rewards and punishments are included. These are predominantly, as in the Christian concepts, focussed upon the hereafter, paradise, and hell, though not exclusively so. The recipients of the rewards and punishments are described as those who obey or disobey Allāh's (God's) commands, which include prayer, paying the *zakāt* (head tax: an obligatory charity), belief in the messengers of Allāh, fearing God alone, and refraining from theft, adultery, murder, and false witness. They are further obligated to show kindness to parents and to strive in the cause of God with their persons and property.

On the historical and social level, it seems quite certain that the community of the formative period in Islām was based on covenant acts, in which persons or groups formally proclaimed their acceptance of Muhammad's message and swore an oath of loyalty, accepting the obligations outlined above. References to the clasp of hands indicate that this was probably regarded as the formal act of commitment and acceptance by the community. In later Muslim theology, as in Christianity, the covenant idea seems to have been of comparatively little importance.

**Other religions.** It seems that only in the religions stemming from the biblical tradition is covenant of central importance. Though gods are often invoked as guarantors of promises sworn to in Iranian and Indic (Hindu) religious traditions, the covenant with a deity or the community as a covenant-bound one apparently was of relatively little importance, or possibly the concept has not been recovered by modern scholarship. The great importance of Mithra in early Iranian religion as god of the covenant, and Mitrā-Varuṇa in Indic (Hindu) religion suggests that such concepts may have been more important than is now realized. Thus, modern scholarship has yet to indicate the importance of the covenant concept in Indo-Iranian and other religions.

#### Covilhã, Pêro da

A Portuguese traveller, Pêro da Covilhã was the first European known to have explored both western India and East Africa. Born at Covilhã in Beira c. 1460, he served the duke de Medina-Sidonia in Seville for six or seven years, returning to Portugal with the duke's brother late in 1474 or early in 1475, when he passed into the service of King Afonso V, first as a junior squire and then as squire, serving with horse and arms. He accompanied the king when he claimed the Castilian throne and was proclaimed at Plasencia, and he was present at the Battle of Toro. He also escorted the King on a fruitless journey to France to seek aid from Louis XI. On Afonso's death, Pêro served his son John II as a squire of the royal guard and was employed as a confidential messenger to Spain. He was also sent on two missions to North Africa, one, in the guise of a merchant, to seek the friendship of the ruler of Tlemcen, and the other to Fez to buy horses for Dom Manuel, later king.

John II hoped to profit from the spice trade of India and to make contact with the Christian ruler of Abyssinia, identified with the semimythical Prester John. Abyssinians had already visited Rome and even the Iberian Peninsula. John had sent Diogo Cão (Diogo Cam) down the west coast of Africa, and he had discovered the Congo and sailed beyond, but his belief that he had reached or was about to reach the cape proved unfounded. John then ordered Bartolomeu Dias (q.v.) to pursue Cão's explorations. He also decided to send travellers by land to report on the location and trade of India and Abyssinia. This move may have resulted from reports received in 1486 in Benin (a kingdom on the west coast of Africa), referring to a great ruler far to the east. Pêro was chosen for the mission to India, and Afonso de Paiva, a squire who spoke Arabic, was to seek Prester John and discover a route from Guinea to Abyssinia. The men left Portugal in May 1487 with letters of credit on Italian bankers; they reached Barcelona and sailed to Naples and Rhodes, where they assumed the guise of honey merchants and sailed to Alexandria. They became ill, and their wares were seized, but they bought other goods and went to Cairo, joining a group of North Africans travelling to

Attempt to find Prester John

Aden. There they separated, **Pêro** going to India, reaching Cannanore, Calicut, and Coa. He then returned to Ormuz, in Persia, sometime between October 1489 and March 1490. Meanwhile, Afonso de Paiva had reached Abyssinia. The two had proposed to meet at Cairo. **Pêro** arrived there about the end of 1490 or early 1491 and received news of his companion's death. Meanwhile, John II had sent two messengers to Cairo to instruct **Pêro** to return when the mission was completed. **Pêro** wrote a letter to John about his experiences and continued on to Abyssinia. One of the messengers accompanied him to Ormuz, where they separated. **Pêro** made his way to the Red Sea. Disguised as a Muslim, he visited Mecca and Medina. He also saw Mount Sinai, reaching Zeila in 1492 or 1493, whence he passed by caravan to Abyssinia, where he was destined to spend the rest of his life.

**Pêro** was received by the Abyssinian ruler Emperor Eskender and was well treated and made governor of a district. He was not, however, allowed to leave the country. Some years later the Abyssinian regent, Queen Helena, sent an Armenian named Matthew to Portugal. He reached Afonso de Albuquerque at Goa in 1512 and was in Portugal in 1514. It was then decided to send a Portuguese embassy to Abyssinia. The first ambassador died, and his successor, Dom Rodrigo de Lima, and his party left from India in 1517 and finally reached the Emperor's camp in December 1520. They found **Pêro** old but robust, and he served them as guide and interpreter. When they returned in 1524, **Pêro** and his wife and family accompanied them for part of the way, and he sent his 23-year-old son with Dom Rodrigo to be educated in Portugal. **Pêro** died sometime after 1526.

**BIBLIOGRAPHY.** Most of what is known of **Pêro da Covilhã** derives from the account of FRANCISCO ALVARES, chaplain to the embassy. His *Verdadera informaçam das terras do Preste Joam* was printed (1540), and also in a different version in Ramusio's collection (1550). See also Alvares' *Prestre John of the Indies*, rev. and ed. by C.F. BECKINGHAM and G.W.B. HUNTINGFORD, 2 vol. (1961); and GASPAR CORREA, *Lendas da India*, 4 vol. (1858–64).

## Craig, Edward Gordon

The life and work of Edward Gordon Craig were clearly and closely interwoven. The son of an actress, and "of" the theatre from birth, he worked in three distinct yet overlapping areas of artistic endeavour: as actor, as director-designer, and, most important, as dramatic theorist. Critics often labelled him an idealistic scene designer whose work was impractical in terms of existing theatre architecture. Certainly his visions were incapable of realization at the time of conception because of limited technology and lack of appropriate materials. But most of his life was devoted to a "theatre of the future," and the inspiration behind much of today's theatre practice and theory clearly stems from Craig's pioneering work.

Born in Stevenage, Hertfordshire, in England, on January 16, 1872, Craig was the second child of a liaison between Ellen Terry, who was to become one of England's most celebrated actresses, and Edward William Godwin, architect, theatre critic, and designer. Like Edith (the other child of Godwin and Ellen Terry), their son was given the name Craig, which he adopted as a surname. He made his official debut as an actor on September 28, 1889, as a member of Henry Irving's company at the Lyceum Theatre in London. During his nine-year association with Irving, Craig appeared in a variety of roles, and he also worked in touring companies between Lyceum seasons, all of which theatrical experience was of inestimable value in the formulation of his aesthetic theories.

Craig was a handsome young man with somewhat delicate features. Consequently, he was cast in such roles as Romeo, Cassio, Hamlet, Lorenzo, and Malcolm. He complained that he "looked like an actor" and noted with relief that, when he left off acting, he began to lose the "girlish face which I dislike so much . . . and by 40 I had improved it a bit more." As well as performing, Craig

also began to try his hand at directing. His early efforts clearly revealed a debt to Irving (who by the 1890s had become the foremost exponent of an historical-archaeological approach to the visual elements of dramatic production). In 1893 he married May Gibson, who bore him four children, but the marriage did not last.

Meanwhile, however, Craig became friends with other creative artists, among them the painters William Rothenstein, James Pryde, and William Nicholson; the two last, known as the Beggarstaff Brothers, taught Craig how to use wood-engraving tools. Also among his friends were literary men such as Max Beerbohm, and the musician Martin Shaw. These new friends helped to widen Craig's interest in the theatre to embrace other arts. Shaw, for example, introduced Craig into the Purcell Operatic Society, under whose aegis he produced *Dido and Aeneas* in 1900. This production caused a stir by its new approach to theatre art, for Craig avoided both historical-archaeological scenography and the flat, unimaginative use of electric stage lighting. His keynote was one of simplicity: in setting, costume, lighting, and movement. *Dido*, repeated in 1901 with *The Masque of Love*, was followed in rapid succession by Handel's *Acis and Galatea* (1902), Laurence Housman's nativity play, *Bethlehem* (1902), and, under his mother's management, Henrik Ibsen's *Vikings* and Shakespeare's *Much Ado About Nothing*, both in 1903. (It was the last time he was to work with Ellen Terry. In 1875 she had parted from Godwin; much later Craig was to speculate what the three of them together might have achieved in the theatre.)

These productions, too, were marked by simplicity and unity of concept, with the emphasis being placed on the movement of actors and of light. Soon to come was the idea of moving scenery, which ultimately led to Craig's vision of a theatre without actors or words, in which the movement of scenery and of light would engender an emotional response in the audience. But these productions, despite their artistic impact, were commercial failures; the financial support that would have permitted Craig to develop his ideas and to experiment was not forthcoming in England. Therefore, toward the end of 1904, he took up an earlier invitation from Count Harry Kessler—the arbiter of taste at the influential Weimar Court—to visit Germany. In December of the same year, in Berlin, he met the dancer Isadora Duncan and began a short love affair with her. In a necessarily subjective and often fictitious account of their relationship, Duncan stressed Craig's restless dedication to his work, and the obsession she unwittingly describes has the ring of truth. He never ceased to admire her dancing, however, recognizing in it the pure movement that was for him an essential ingredient of theatre art.

The following few years were a particularly fruitful pe-

Success of  
his *Dido*  
and  
*Aeneas*

Debut as  
an actor

riod for Craig. In 1905 the first statement of his developing theories, *The Art of the Theatre*, was published; in 1906 he designed a production of Ibsen's *Rosmersholm* for Eleonora Duse, the world-renowned Italian actress; and in 1907 he returned to his earlier thoughts about movement. By this time he was able to record those ideas through the medium of etching; fascinated by the new technique, he etched some 15 metal plates within two months. His new theatrical concept was that the entire "scene" should be movable in all parts; both the floor and ceiling were to be composed of squares that, under the control of the artist, could be moved up and down independently or in groups within a constantly changing pattern of light. Thus an emotional response might arise in the audience through the abstract movement of these plastic forms. The etchings illustrating these scenographic concepts were exhibited in 1908 in Florence (*Portfolio of Etchings*; 1908, 1910) and collected, with an essay, in *Scene* (1923). They depicted frozen motion rather than a series of individual, separate stage designs.

Although the vision of the "moving scene" with its vertical movement was clear in Craig's imagination, he could find no way to translate the theory into practice because of his limited technical knowledge. With a growing fear of having his idea stolen, he suppressed any further public display of it and substituted a compromise—screens that moved horizontally. After several years of experiments with models using these screens, he allowed the Irish poet and dramatist William Butler Yeats to construct a screen set in 1911 for his Abbey Theatre in Dublin, a set that was used until 1951. In 1912 Craig co-produced *Hamlet* with the Russian director Konstantin Stanislavsky at the Moscow Art Theatre. This was the first and only use of the moving screens under Craig's own supervision. It also was the last time Craig tried to put his pioneer theories into practice.

Because commercial theatre managers, conservative and traditional, ignored Craig's advanced thinking, he received no financial support for productions other than those few sponsored by noncommercial managements. Such rejection proved to be an advantage, however. It provided more and more a limitless stage—his own fertile imagination—upon which to create his theatre magic. To find expression for the ideas and to disseminate them, he turned increasingly to the graphic arts and the written word. His wood engravings and etchings in *Woodcuts and Some Words* (1924) and *Nothing; or, The Bookplate* (1925) are eminently theatrical. He cut dramatic light into the wood blocks and metal plates from which the illustrations were printed as he would into the black void of the stage. Early in his experience as a graphic artist, from 1898 to 1903, he had published *The Page*, a journal devoted to all the arts paralleling his own discovery of them. Following the successful appearance of *The Art of the Theatre*, expanded and retitled *On the Art of the Theatre* (1911–69), Craig discovered his gift for writing.

A particularly fecund period commenced that lasted almost to the very end of his life. In addition to writing a number of books (*Towards a New Theatre*, 1913; *The Theatre Advancing*, 1919) and hundreds of periodical articles, he founded *The Mask* in 1908, which, until its demise in 1929, became not only the first theatre journal but a platform for Craig's rebellious ideas. Using almost 100 pseudonyms in addition to his own name, Craig wrote controversial pieces on the theatre of the future in all its aspects, as well as editorials, historical pieces, and book reviews. Among his many avant-garde ideas were the rejection of the academic mannerisms of the actor and the decorative trappings of both costumes and settings. These rejections, Craig argued, would restore art to the theatre so that it could take its proper place with its sister arts. To accomplish these goals he established a school in 1903 to study the art of the theatre. Unsuccessful at first, the school was reopened in 1913 in Florence but closed the following year with the outbreak of World War I. The function of Craig's school was not only to plan for a new theatrical future but, as part of the training program, to study theatre history to promote greater insight and understanding. In terms of physical

play production, only one man was to be in artistic control of the production; the visual emphasis was to be on form, colour, the plastic use of light, and, most important, movement; the last was to be achieved through the use of the horizontally moving screens, for Craig never had managed to find the solution to a stage movable in all parts.

After 1914 he lived chiefly in Italy, moving from city to city with Elena Meo (whom he had met in 1900) and their two children. He designed a production of Ibsen's *Pre-tenders* in 1926 at the invitation of the Royal Theatre in Copenhagen, for which King Christian X of Denmark conferred on him the Order of the Knights of the Dannebrog for his services to the Danish theatre. Craig's last production was Shakespeare's *Macbeth*, produced in New York in 1928. He refused to go to the United States, however, and the execution of his designs and lighting was carried out by others. Neither of these plays involved Craig's earlier, creative use of stage space.

In 1931 Craig went to live in France and in 1948 made his home in the south of that country, where he wrote his memoirs of the years 1872 to 1907, entitled *Index to the Story of My Days* (1957), and continued to arrange and correct his various papers. He died at Vence, France, on July 29, 1966.

Many of Craig's "impractical" ideas have since become common practice; once a "rebel," he is now seen as a prophet. Even in those areas where modern technology has improved upon Craig's vision, the underlying aesthetic concept is still relevant. One measure of recognition for his life-long, singleminded pursuit of theatre art came in 1956 when Queen Elizabeth II conferred upon him the privilege of being named a Companion of Honour.

**BIBLIOGRAPHY.** EDWARD CRAIG, *Gordon Craig: The Story of His Life* (1968), is the definitive work; an earlier study, based largely on the Craig collection in the Bibliothèque Nationale, Paris, is DENIS BABLET, *Edward Gordon Craig* (1962; Eng. trans., 1966). Important because of the chronology by Craig himself is JANET LEEPER, *Edward Gordon Craig: Designs for the Theatre* (1948). IFAN KYRLE FLETCHER and ARNOLD ROOD, *Edward Gordon Craig: A Bibliography* (1967), records Craig's written and graphic work. ARNOLD ROOD, "After the Practise the Theory," *Gordon Craig and Movement*, *Theatre Research/Recherches Théâtrales*, 11:81–101 (1971), traces the development of Craig's theories regarding movement.

(A.Ro.)

## Cranach, Lucas, the Elder

A painter, draftsman, and illustrator, Lucas Cranach the Elder was one of the most important and influential artists in the 16th-century flowering of German painting and graphic arts. Admired by his contemporaries for the speed with which he executed commissions, Cranach, with the help of assistants, worked with such unremitting industry that, despite many losses, some 400 of his paintings have been preserved. The striking individuality of his works and his skill as a portraitist have made him one of the most popular German artists of the period. He exerted a lasting influence on the art of northern and northeastern Germany through his own work, through his numerous pupils, and through his son Lucas Cranach the Younger, himself a famous painter.

The elder Cranach was born in 1472 in Kronach, some 55 miles (90 kilometres) north of Nurnberg. Although only a year younger, he survived Albrecht Diirer, the great genius of German art, by 25 years and, in fact, outlived all the significant German artists of his time.

Cranach's teacher was his father, the painter Hans Müller of Kronach, with whom he worked from 1495 to 1498. He is known to have been in Coburg in 1501, but the earliest of the works that have been preserved date from c. 1502, when he was already 30 and ill in Vienna. It was there that he dropped the surname of Müller, calling himself Cranach after his home town, which was then spelled that way. In 1504 he signed "Rest on the Flight into Egypt" with "LC" (Lucas Cranach).

Through his pictures and woodcuts he made an important contribution to the painting and illustrations of the Danube school, the art of the Austrian Danubian region

Cranach, self-portrait, tempera on panel, 1550. In the Uffizi, Florence. 66.36 cm X 48.9 cm  
Alinari

Contributions to the Danube school

around Vienna, Passau, and Ratisbon, as well as **Salzburg** and **Innsbruck**. In Vienna, then flourishing under the patronage of Emperor Maximilian I, Cranach came in contact with the Humanists teaching at the university, doing portraits of the scholars Dr. Johannes Stephan Reuss (1503, Germanisches Nationalmuseum, Nürnberg) and Dr. Johannes Cuspinian (c. 1502–03, **Sammlung Oskar Reinhart**, Winterthur).

**Wittenberg period.** Presumably while Cranach was still in Vienna, he received news of his appointment as court painter to the elector Frederick the Wise of Saxony; he must already have been a famous artist, for he was given two-and-a-half times the salary paid to his predecessor. In spring 1505 he arrived in Wittenberg, a university town on the **Elbe** River and seat of the electoral court, where he remained for 45 years, until July 1550. Through Cranach, who received important commissions from three successive electors and caused many young artists to come to Wittenberg, the town became an art centre.

Beginning with a Latin panegyric for him that the schoolmaster Georgius Sibutus published in 1507, Cranach's name is often found in the records, sometimes without commentary presumably because he was so well-known to the public. Dr. Christoph Scheurl, a jurist in the university, prefaced his *Oratio*, published in 1509, with a Latin introduction dedicated to the artist in which he tells of his life and works, characterizing the man Cranach as "friendly, talkative, generous, and obliging" and mentioning his uncommon industriousness that did not let him spend an idle hour. Such qualities made Cranach not only a popular court painter, who maintained himself in the Elector's favour and in that of his two successors, but also an artist who was highly esteemed by the nobility, the wealthy bourgeoisie, and the university professors. It is a further measure of his skill in handling people of all classes and faiths and a token of the popularity of his art that he continued to receive commissions from Catholics even after the onset of the Protestant Reformation.

The Reformation had begun in 1517 in Wittenberg with Martin Luther's Ninety-Five Theses. Being on friendly terms with Luther, who had been a teacher at Wittenberg University since 1508 and a doctor and professor of Bible exegesis since 1512, Cranach designed, among other things, ornamental vignettes for Luther's writings (1518–19). He also left portraits of Luther, his wife Katherina von Bora, and his parents. Through these and other portraits, Cranach helped form today's image of Luther's circle. Having already created a court art, the portraitist of the leaders of the Reformation thus became also the initiator of a new religious art, the painting of Lutheran-ism. As such, Cranach did altarpieces and paintings for Lutheran churches.

Vignettes for Luther's writings

The output of Cranach's large studio ranged from mere artisan's painting through gilding and decorative work to paintings on building façades and in palace halls. He also designed tapestries, medals, coins, court dresses, escutcheons, decorations on cannon, and painted glass. What was and continues to be important are his altarpieces for Catholic and Protestant churches, his panels with religious and lay scenes, and his portraits. Aside from his numerous paintings, there are more than 100 separate woodcuts by him, as well as woodcuts in the form of book illustrations, and six engravings.

For many years, Cranach's life in Wittenberg ran an even course. In 1508–09 he was at Antwerp, in Flanders, possibly on a diplomatic mission. Cranach probably did not marry until about 1512, when he had reached 40; in 1513, at any rate, he purchased a corner house on the market square that carried with it the lucrative privilege of selling wine. The property was so stately that King Christian II stayed there in 1523. Like a typical entrepreneur in the early days of capitalism, Cranach was active far beyond his duties as court painter. He not only derived an income from the sale of wine but in 1520 bought a pharmacy, which he leased to pharmacist's assistants; he also was, at least temporarily, the owner of a printing press and a book and stationery shop (c. 1524). By 1528 he was, after the chancellor Brück, the richest man in Wittenberg.

Success as an entrepreneur

Furthermore, Cranach, whose works were sought after by Protestant and Catholic patrons alike, not only enjoyed the confidence of princes and leaders of the Reformation but was also so highly regarded by his fellow citizens that he sat on the town council from 1519–20 on and served as burgomaster of Wittenberg in 1537–38, 1540–41, and 1543–44.

Fate struck him a few blows, nonetheless. His son Hans, also a painter, died in 1537 in Bologna, and his wife Barbara died in 1541.

East years. In 1547 the palmy days of Wittenberg came to an end with the defeat of the Protestant princes by the emperor Charles V in the Schmalkaldic War, a religious conflict in which the Elector of Saxony was taken prisoner. The Emperor, who owned one of Cranach's paintings, had sat in 1508 as a child in Flanders for a Cranach portrait. He now had the artist summoned to his headquarters, near occupied Wittenberg, in order to renew acquaintance with him.

Summoned by his own sovereign who was held captive by the Emperor, Cranach joined the Elector in July 1550 at Augsburg, accompanying him the following year to Innsbruck, where he painted continually in order to keep him in good humour. In Innsbruck Cranach met Titian, whom he painted in 1551 (now lost). When John Frederick the Magnanimous was finally able to return to his diminished country in 1552, he established his court in Weimar, where Cranach, at 80, was given a new contract as court painter. He died in Weimar on October 16, 1553, at the age of 81.

**Assessment.** Cranach did not acknowledge his works with his name. The early ones, before 1504, were unsigned; from 1504 to 1506 his signature consisted of an entwined "LC"; from 1506 to 1509, it consisted of the separated initials "LC"; from 1509 to 1514, it consisted of these spaced initials and his coat of arms, the winged serpent, which became his sole signature in 1515. All works, even those that had issued from his large workshop or studio (in which he often employed ten or more assistants) and had only been checked out by him, henceforth carried this device, which was also used by his son Lucas the Younger, until his death in 1586. This gave rise to many problems of attribution that still remain unsolved. The fact that so few works bear any date further complicates the establishment of a Cranach chronology. The works of the 30-year-old artist were paintings of a profoundly devotional kind set in the emotion-laden landscapes of the Alpine foothills, with ruins and wind-swept trees. Later, too, he remained as it were a teller of fairytales, even when depicting scenes from classical mythology, sensuous nudes, and very slender figures in the proportions of Mannerism. Along with such paintings as

Painterly style

"Reclining River Nymph at the Fountain," "Adam and Eve," and "Hercules and Antaeus," he painted Biblical beauties, such as Salome or Judith, and such classical themes as Lucretia and the judgment of Paris, subjects to which he returned time and again. He represented female saints as beautiful and elegant ladies in fashionable dress and covered with jewelry. In his works, the borderline between sacred and mundane art is blurred.

Drawing played a minor role in the production of this inventive artist. Only a handful of his drawings are autonomous works, "master drawings" like the eight border drawings of 1515 for the emperor Maximilian's prayer book. The others are sketches for murals, altarpieces, portraits, or preliminary outlines of new projects.

*Pictor celerrimus* (swiftest of painters) is what Cranach is called on his tombstone, and his contemporaries never ceased to marvel at the speed with which he worked. But this very speed also suggested the limitations of his art, for his strength lay not in reflection, composition, and construction but in an impulsive creativity that was nourished by his imagination and fancy, particularly in unheroic and idyllic scenes. His art was especially popular in that period of great political upheavals, and for good reason: his success may well be due to the fact that his contemporaries, in public life the protagonists of embattled ideologies, yearned for beauty in man and in nature and for a peaceful refuge from the world's turmoil.

No other German painter was given the honour that came to Cranach after his death, when Lucas Cranach the Younger finished in 1555 a large altar in triptych form for the parish church of Wittenberg. On the side panels, the ducal family is shown kneeling; in the centre (an allegory on redemption through Christ's expiatory death), John the Baptist stands below the cross, and between John the Evangelist and the reformer Martin Luther, life-size, the painter Lucas Cranach the Elder, onto whose head Christ's redeeming blood flows from the wound. It is a memorial by which the reigning family immortalized not only itself but also its reformer, Luther, and its confidant Cranach, the court painter who had served it faithfully for almost 50 years.

#### MAJOR WORKS

"St. Francis Receiving the Stigmata" (c. 1502; Gemäldegalerie der Akademie der Bildenden Künste, Vienna); "St. Jerome in Penitence" (1502; Kunsthistorisches Museum, Vienna); "Christ on the Cross" (1503; Alte Pinakothek, Munich); "Rest on the Flight into Egypt" (1504; Staatliche Museen Preussischer Kulturbesitz, Berlin); "St. Catherine Altarpiece," right wing (1506; Gemäldegalerie, Dresden); "The Holy Kinship" (c. 1510–12; Gemäldegalerie der Akademie der Bildenden Künste, Vienna); "Duke Henry the Pious" and "Duchess Katharina von Mecklenburg" (1514; Gemäldegalerie, Dresden); "Virgin and Child with St. Anne" (c. 1515–20; Alte Pinakothek, Munich); "The Nativity" (c. 1515–20; Gemäldegalerie, Dresden); "A Prince of Saxony" and "A Princess of Saxony" (c. 1516–18; National Gallery of Art, Washington, D.C.); "Reclining River Nymph at the Fountain" (1518; Museum der Bildenden Künste, Leipzig); "Martin Luther As St. George" (c. 1521; Kunstsammlungen, Weimar); "David and Bathsheba" (1526; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Cardinal Albrecht of Brandenburg as St. Jerome" (1526; John and Mable Ringling Museum of Art, Sarasota, Florida); "Adam and Eve" (1526; Courtauld Institute Galleries, London); "Portrait of Dr. J. Scheyring" (1529; Musée Royaux des Beaux Arts, Brussels); "The Stag Hunt of the Elector Frederick the Wise" (1529; Kunsthistorisches Museum, Vienna); "Paradise" (1530; Kunsthistorisches Museum, Vienna); "The Close of the Silver Age (?)" (c. 1530; National Gallery, London); "Apollo and Diana in a Wooded Landscape" (1530; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Venus and Cupid" (c. 1530; Staatliche Museen Preussischer Kulturbesitz, Berlin); "The Judgment of Paris" (1530; Kunsthalle, Karlsruhe); "Hercules and Antaeus" (c. 1530; private collection, Garmisch-Partenkirchen, Germany); "Feast of Herod" (1531; Wadsworth Atheneum, Hartford, Connecticut); "The Old Lover" (1531; Gemäldegalerie der Akademie der Bildenden Künste, Vienna); "The Payment" (1532; Nationalmuseum, Stockholm); "Venus" (1532; Städtisches Kunstinstitut, Frankfurt); "Self-Portrait" (1550; Uffizi, Florence).

## Crane, Stephen

Although Stephen Crane died at the age of 28, he left enough outstanding fiction to place him solidly among the half-dozen best U.S. novelists and short-story writers of the 19th century. He first broke new ground in *Maggie: A Girl of the Streets* (1893), which evinced an uncompromising (then considered sordid) realism that initiated the literary trend of the next generation—i.e., the sociological novels of Frank Norris, Theodore Dreiser, and James T. Farrell. In the social realism of "The Monster" (1898), Crane anticipated Ralph Ellison's *Invisible Man* (1952) and other writers on the plight of the Negro in society. Crane intended *The Red Badge of Courage* to be "a psychological portrayal of fear," and reviewers rightly praised its psychological realism. The first non-romantic novel of the Civil War to attain widespread popularity, *The Red Badge of Courage* turned the tide of the prevailing convention about war fiction and established a new, if not unprecedented, one. The secret of Crane's success as war correspondent, journalist, novelist, short-story writer, and poet lay in his double point of view, by which he achieved tensions between irony and pity, illusion and reality, or the double mood of hope contradicted by despair. A great stylist, Crane was a master of the contradictory effect.

Methodist  
heritage  
and  
education

Born on November 1, 1871, in the parsonage of the Central Methodist Church in Newark, New Jersey, Stephen was the 14th child of Mary Helen Peck and the Reverend Dr. Jonathan Townley Crane. The year they were married Dr. Crane published his *Essay on Dancing* (1848)—~~he~~ was against it. "Upon my mother's side," Stephen once remarked, "everybody as soon as he could walk became a Methodist clergyman—of the ambling-nag, saddle-bag, exhorting kind." Mrs. Crane, the daughter of the Reverend George Peck, an eloquent minister and editor of the Methodist *Christian Advocate*, was the niece of Bishop Jesse Truesdell Peck, one of the founders of Syracuse University and author of *What Must I Do To Be Saved?* (1858). A woman of broad culture, although not university educated, Mrs. Crane was active in temperance programs, served as vice president of the Women's Christian Temperance Union in New Jersey, and reported Methodist revivalist meetings in the *New York Tribune*.

Stephen's ancestors included not only clergymen but also soldiers, including the four sons of the Stephen Crane who served in the Continental Congress (1774–89). As one of Stephen's friends declared in 1896, "It is an interesting study in heredity to note the influence of these two professions in Mr. Crane's literary work, the one furnishing the basis of style, the other of incident."

Stephen grew up in full rebellion against the dogmas of his clerical forebears and came to revel in all the vices his father had preached against in *Popular Amusements* (1869) and *The Arts of Intoxication* (1870)—~~the~~ vices of the novel, the theatre, baseball, tobacco, and alcohol. Stephen not only read novels but also wrote them. Admonished by his father to "Read your Bibles," Stephen was intimately versed in the Bible, and his writings are haunted by his religious background.

Stephen attended school in Asbury Park, New Jersey, where his brother Jonathan Townley operated a news agency from 1882 to 1892, when the *New York Tribune* fired him because of an article Stephen wrote for his column, "On the New Jersey Coast." The Junior Order of United American Mechanics took offense at Crane's description of their Asbury Park parade. From September 1885 to December 1887, Stephen attended the Pennington Seminary, of which his father had been president from 1849 to 1858. He next attended Claverack College (from January 1888 to June 1890), a semi-military and coeducational school, where he was a strict disciplinarian as drillmaster, though he pretended not to like drilling. The school's leading tenor, he pretended not to like singing. Gambling, drinking, smoking, he had "a bully time," the happiest in his life; the faculty thought he would come to a bad end. Yet he was a voracious reader of all 19th-century English writers, Shakespeare, Plutarch's *Lives of Noble Grecians and Romans*, and the classics of Greece and Rome.

Military drill at Claverack accelerated his interest in warfare, as did the Civil War reminiscences of his history teacher, the Rev. Gen. John Bullock Van Patten, who as true Christian and brave soldier personified the two strands of Crane's heredity. They are fused again in Jim Conklin of *The Red Badge of Courage*. Although Stephen took pride in his military ancestors, he was "bitterly ashamed" to be named after the biblical martyr.

Crane next attended Lafayette College (fall 1890). Flunking out, he then survived one semester (spring 1891) at Syracuse University, where again he spent more time on the baseball diamond than in the classroom. Although he was acclaimed by his teammates as the best catcher and infield man of his time, he decided against being a professional baseball player in favour of a literary career. While at Syracuse he wrote his first draft of *Maggie* and "Great Bugs in Onondaga," his first but not his last literary hoax.

To write *Maggie* Crane explored the Bowery (where he claimed to have received his "education"), bumming beds in studios of artist friends, which he described in his fourth novel, *The Third Violet*. These friends acquainted him with the French Impressionists and Neo-Impressionists, which may account for the prose pointillism

of his *Red Badge of Courage*, which is composed of seemingly disconnected images that coalesce like the blobs of colour in French Impressionist paintings. Strikingly opposite in style is the sober realism of *George's Mother*, a study of fear in the squalor of the Bowery. He began this novel after publishing *Maggie* and wrote it (simultaneously with *The Red Badge of Courage*) on the back sides of sheets of "The Holler Tree" in May–June 1893. The *Tribune* in 1892 had published a dozen of his Sullivan County tales and sketches. The fact that these writings were all composed within a span of two or three years (1892–94) and that the styles differed from one another prompted the influential critic William Dean Howells to remark, "Here is a writer who has sprung to life fully armed."

Crane published *Maggie* at his own expense by selling his brother William shares of coal-mine stock inherited on the death of their mother in 1891; the unknown printers did him in for \$869. Rejected by editors as "not nice," Crane issued *Maggie* under the pseudonym "Johnston Smith." Reform ministers ignored the novel, and it did not sell; but *Maggie* did win Crane the friendship of Howells, and Hamlin Garland, who was already forceful in literary affairs, favourably reviewed it. He urged Crane to explore the demimonde of the city, which Crane did in the New York *Press* sketches and stories from 1894. Curiosity was Crane's ruling passion.

Early in 1895 Crane journeyed to the West and Mexico, writing sketches for the Bachelier and Johnson Syndicate. His best western stories, however, were to be written in England. Late in 1895 Irving Bachelier, who had syndicated *The Red Badge of Courage* in a shortened newspaper version in 1894, sent Crane to Jacksonville, Florida, with \$700 in gold to report the insurrection in Cuba. But, on New Years' Day 1897, the filibustering "Commodore" sank with \$5,000 worth of ammunition, and Crane—reported drowned—finally rowed into shore in a dinghy with the captain, cook, and oiler, Crane scuttling his money belt of gold before swimming through dangerous surf. The result was one of the world's great short stories, "The Open Boat."

Unable to get to Cuba, Crane went to Greece to report the Greco-Turkish War for the New York *Journal*, accompanied by Cora Taylor, the madame of the Hotel de Dream in Jacksonville who had fallen in love with the famous author and had sold her "house of joy" to become the "first" woman war correspondent. At the end of the war, they settled in England in a villa at Oxted, Surrey, and in April 1898 Crane departed to report the Spanish–American War in Cuba, first for the New York *World* and then for the New York *Journal*. When the war ended, Crane hid out in Havana, writing the first draft of *Active Service*, a novel of the Greek war. He finally returned to Cora and England nine months after his departure and settled in an almost uninhabitable and costly to maintain 14th-century manor house at Brede Place, Sussex. Here Cora, a silly woman with social and literary pretensions, contributed to Crane's ruin by encouraging his own social ambitions. Financially they bled themselves to death by entertaining hordes of spongers, as well as close literary friends—including Joseph Conrad, Ford Madox Ford, H.G. Wells, Henry James, and Robert Barr, who completed Crane's Irish romance *The O'Ruddy*.

Crane lived in desperation against time and debts (they totalled \$5,000 at his death). His indifference to money coupled with his constant need of it patterned his life and also Cora's. On borrowed money, Cora deposited the dying Crane in a sanitarium at Badenweiler, Germany, where he died on June 5, 1900, of tuberculosis compounded by the recurrent malaria fever he had caught in Cuba. Crane's body, after lying in a London horse stall, was brought back to New York City for services and then internment at Hillside, New Jersey.

#### MAJOR WORKS

NOVELS: *Maggie: A Girl of the Streets* (privately printed 1893, published 1896); *The Red Badge of Courage* (1895); *George's Mother* (1896); *The Third Violet* (1897); *Active Service* (1899); *The O'Ruddy* (1903).

Recognition as a writer

War correspondent in Cuba and Greece

Friendship with Conrad, James, and Wells

SHORT STORIES: *The Little Regiment, and Other Episodes of the American Civil War* (1896); *The Open Boat, and Other Tales of Adventure* (1898); *The Monster and Other Stories* (1899); *Whilomville Stories* (1900); *Wounds in the Rain: A Collection of Stories Relating to the Spanish-American War of 1898* (1900); *Last Words* (1902).

POETRY: *The Black Riders and Other Lines* (1895); *War Is Kind* (1899).

BIBLIOGRAPHY. Three biographical works, all entitled *Stephen Crane*, are those by R.W. STALLMAN (1968), which locates Crane in his historical background; THOMAS BEER (1923); and JOHN BERRYMAN (1950), similar in style and theme to Beer. LILLIAN GILKES, *Cora Crane* (1960), defends Cora by denigrating Crane. R.W. STALLMAN, *Stephen Crane: A Critical Bibliography* (1972), incorporates and extensively enlarges the Crane bibliography by AMES W. WILLIAMS and VINCENT STARRETT (1948), and reports contemporary reviews in quotation and critically annotates more than 2,000 writings on Crane. See also THEODORE L. GROSS and STANLEY WERTHEIM, *Hawthorne, Melville, Stephen Crane: A Critical Bibliography*, pp. 210–295 (1971).

The definitive texts are collected in *The Works of Stephen Crane*, ed. by FREDSON BOWERS (1969– ). Comprised of tampered texts, *The Works of Stephen Crane*, ed. by WILSON FOLLETT, 12 vol. (1925–27), remains useful solely now for its introductions, notably by HERGESHEIMER, AMY LOWELL, and WILLA CATHER. *Stephen Crane: Letters*, ed. by R.W. STALLMAN and LILLIAN GILKES (1960), contains 184 new letters by Crane, Cora, and their friends. *Uncollected Writings*, ed. by OLOV W. FRYCHKSTEDT (1963), does not include new Crane manuscripts; *The War Dispatches* (1964), and *The New York City Sketches* (1966), ed. by R.W. STALLMAN and ER. HAGEMAN, do contain some new ones. *The Collected Poems*, ed. by JOSEPH KATZ (1966), supersedes Follett's 1930 edition. *The Complete Short Stories and Sketches* (1963), and *The Complete Novels* (1967), were edited by THOMAS A. GULLASON; the former book lacks 40 pieces and thus is not complete, nor are its texts the first periodical publication as claimed. *Sullivan County Tales and Sketches*, ed. by R.W. STALLMAN (1968), adds seven new pieces to MELVIN SCHÖBERLIN, *Sullivan County Sketches* (1949). Stallman's *Stephen Crane: An Omnibus* (1952), presented the first collection of Crane letters, brought together for the first time the manuscripts of *The Red Badge of Courage*, and critically scrutinized Crane's best works.

Among the best short scrutinies ever written on Crane are the essays by JAMES B. COLVERT and SERGIO PEROSA in *A Collection of Critical Essays*, ed. by MAURICE BASSAN (1967); and Daniel Knapp, "Son of Thunder," in *Nineteenth Century Fiction*, 24:253–291 (1969). A landmark in Crane criticism was the Crane number of *Modern Fiction Studies*, vol. 5 (1959). Other collections of criticism include: SCULLEY BRADLEY (ed.), *The Red Badge of Courage: Text and Essays in Criticism* (1962); M. BASSAN (ed.), *Maggie: Text and Context* (1966); J. KATZ (ed.), *The Blue Hotel* (1969); STANLEY WERTHEIM (ed.), *Studies in Maggie and George's Mother* (1970); and R.W. STALLMAN (ed.), *The Art of Stephen Crane: A Critical Symposium* (1974).

An excellent study of the poetry is DANIEL G. HOFFMAN, *The Poetry of Stephen Crane* (1957). Other studies of Crane and his works are EDWIN CADY, *Stephen Crane* (1962); and JEAN CAZEMAJOU, *Écrivain journaliste* (1969). His pamphlet *Stephen Crane* (1969), is an excellent short introduction. ERIC SOLOMAN, *Stephen Crane in England* (1964), refashions Crane's literary relationships, which were outlined in *Letters* and narrated in *Cora Crane* (1960); and which obtain rather exhaustive portraits in *Stephen Crane: A Biography* (1968). Solomon's *From Parody to Realism* (1966), reduces Crane's works to parodies of popular romantic literature. DONALD B. GIBSON, *The Fiction of Stephen Crane* (1968), is at its best on "The Blue Hotel." The best short studies of Crane's poetry are HARLAND S. NELSON, "Stephen Crane's Achievement As a Poet," *Texas Studies in Literature and Language*, 4: 564–582 (1963); MAX WESTBROOK, "Stephen Crane's Poetry: Perspective and Aitrogance," *Bucknell Review*, 11:24–34 (1963); and RUTH MILLER, "Regions of Snow: The Poetic Style of Stephen Crane," *Bulletin of the New York Public Library*, 72:328–349 (1968).

(Ro.W.S.)

## Cranmer, Thomas

Thomas Cranmer was the English prelate who found in canon law a rationale that enabled King Henry VIII to justify invalidating his marriage to Catherine of Aragon without recourse to the Pope and who subsequently was made the first archbishop of Canterbury of the reformed Church of England. As archbishop, he put the English Bible in parish churches, drew up the Book of Common

Prayer, and composed a litany that remains in use today. His belief in the divine right of kings to rule the clergy as well as the people and his emphasis on the Bible made him the characteristic Anglican of his day. Denounced for promoting Protestantism by the Catholic Mary I, he was tried for treason, convicted of heresy, and burned at the stake.

Born at Aslacton, Nottinghamshire, on July 2, 1489, he was the second son of Thomas Cranmer and Agnes (née Hatfield). His father seems to have belonged to the lowest rank of the gentry; at any rate, he had only enough property to endow his eldest son, John, so that Thomas and his younger brother, Edmund, were destined for the church. After experiencing the teaching of a "marvellous severe and cruel schoolmaster," whose ministrations Cranmer later maintained instilled in him a permanent uncertainty and pliability, the boy went on to Cambridge in 1503. In 1510 or 1511 he was elected to a fellowship at Jesus College but was soon compelled to vacate because he married a relative of the landlady of the Dolphin Inn. During this time he earned his living by teaching at Buckingham (later Magdalene) College, leaving his wife to lodge at the Dolphin; out of this arrangement grew a later story that he had started out in life as a hostler.

His wife died in childbirth soon after their marriage, however, and Jesus College restored Cranmer to his fellowship. He now entered the church and threw himself into his studies, becoming one of the outstanding theologians of his time, a man of immense, though not very original, learning. From about 1520 he belonged to a group of scholars who met regularly at the White Horse Inn to discuss the theological and ecclesiological problems raised by Luther's revolt; known to be inclined to the new way of thinking, they were dubbed "Little Germany." Among the group that was to lead the first generation of the English Reformation were William Tyndale, Robert Barnes, Thomas Bilney, and, above all, Cranmer, who by 1525 included among his prayers one for the abolition of papal power in England.

**Entry into royal service.** Cranmer's ambitions for reform would have remained academic had it not been for the political events into which he was soon drawn, however contrary they were to his upbringing and tastes. From 1527 onward, Henry VIII pursued his desire to be freed from his first wife, Catherine of Aragon, in order to marry Anne Boleyn, and in 1529 the wheels of the "divorce" seized also upon Cranmer. In August a plague known as the sweating sickness swept the country and was especially severe in Cambridge; to escape the sickness, Cranmer left the town with two of his pupils, named Cressy and related to him through their mother, and went to their father's house at Waltham in Essex. The King was visiting in the immediate neighbourhood at the time, and two of his chief councillors, Stephen Gardiner and Edward Fox, soon afterwards met Cranmer in those lodgings. Not surprisingly, they were led to discuss the King's meditated divorce. The old idea that Cranmer suggested consulting the canonists and the universities about the legality of a marriage with a deceased brother's widow was mistaken, but he evidently demonstrated his belief that the King had the right of it and advocated reliance on the services of home-bred theologians. Henry, who was willing to secure the help of any likely head and hand, however obscure, summoned Cranmer for an interview and commanded him to lay aside all other pursuits in order to devote himself to the question of the divorce. Cranmer accepted a commission to write a propaganda treatise in the King's interest, stating the course he proposed and defending it by arguments from Scripture, the Fathers, and the decrees of general councils. His material interests certainly did not suffer by compliance. He was commended to the hospitality of Anne Boleyn's father, the Earl of Wiltshire, in whose house at Durham Place he resided for some time; was appointed archdeacon of Taunton; became one of the King's chaplains; and also held a parochial benefice, the name of which is unknown. When the treatise was finished, Cranmer was called upon to

The divorce question

defend its argument before the universities of Oxford and Cambridge; but in the end the debates, which on the whole endorsed his position, took place in his absence. He had already been sent to plead the cause before a more powerful if not a higher tribunal. An embassy, with the Earl of Wiltshire at its head, was dispatched to Rome in 1530, and Cranmer was an important member of it. He was received by the Pope with marked courtesy and was appointed grand penitentiary of England, but his argument, if he ever had the opportunity of stating it, did not lead to any practical decision of the divorce question.

In 1532 he was sent to Germany, officially as ambassador to the Emperor Charles V, but with instructions to establish contact with the Lutheran princes. At Nürnberg he made the acquaintance of Andreas Osiander, whose theological position midway between Luther and the old orthodoxy appealed to Cranmer's cautious temperament, while Osiander's niece Margaret appealed even more strongly to the instincts of one who had for too long remained in uncongenial celibacy. Despite his priest's orders he married her in 1532; at the same time, his theological views underwent a further decided change in the direction of reformed opinion.

**Archbishop of Canterbury.** The year 1532 proved to be a critical one altogether, for in August William Warham, the aged archbishop of Canterbury, died. At first the usual practice of extending the vacancy for the benefit of the King's finances was followed, but by the end of the year it was apparent that the see would have to be filled because the divorce question was coming to a head. Thomas Cromwell's arrival in power as chief adviser in ecclesiastical matters had heralded a more energetic policy, and by January 1533 the act against appeals to Rome was being drafted and Anne Boleyn was pregnant. Since Stephen Gardiner, the obvious candidate for the archbishopric, was out of favour, the King chose Cranmer; by March 1533 he was consecrated and instituted at Canterbury, with the assistance of confirmatory papal bulls and after a declaration that he took the obligatory oath to the Pope without feeling bound by it. He proceeded to do what was expected of him. In May he convened his court at Dunstable, declared the King's marriage to Catherine of Aragon void from the beginning and pronounced the second marriage to Anne Boleyn valid.

In 1536, convinced by the dubious evidence of Anne's alleged adulteries, he in turn invalidated that marriage; in 1540 he assisted in the freeing of Henry VIII from his fourth wife, Anne of Cleves; and in 1542 he was forced to be prominent in the proceedings that resulted in

Catherine Howard's execution for treasonable unchastity. There is no question that in these matrimonial politics he did as he was told, though it is entirely improbable that his private opinions on the issues in question in any way contradicted his public doings.

More significant are his activities as archbishop in the reconstructed church. Cranmer had not sought high promotion. His marriage just before his elevation to the archbishopric is fair proof that he expected no such career in the priesthood, in which a necessarily unacknowledged wife would be nothing but an embarrassment. Not until 1548 was he able publicly to recognize her. A story of his carrying her about with him in a chest with air holes is, however, part of the scurrilous legend that grew up around him. Once put in power, however, he could not avoid the consequences; a convinced reformer with leanings toward a succession of continental theological changes, he found himself assisting at the shaping of the Church of England under a master who on the whole had no taste for change. In cooperation with Cromwell he promoted the publication of an English Bible, made compulsory in the parishes by Cromwell's Injunctions of 1538. Even before Henry VIII died (1547), Cranmer had drifted far in the direction of Protestantism; in 1545 he had composed a litany for the reformed Church of England, one of his masterpieces, still in use; and by 1538 had abandoned the traditional Roman Catholic belief in transubstantiation—that Christ is rendered substantially present by the Eucharist (although the properties of bread and wine remain the same)—but retained his belief in the real presence of Christ in the Eucharist. As early as 1536 he was recognized by the northern religious rebels as the leading innovator. His position was in consequence far from comfortable after the Act of Six Articles (1539), which attacked those advocating marriage of the clergy and those denying transubstantiation, and Cromwell's fall in 1540. During Henry's last years, Cranmer's enemies laid at least three elaborate plots to destroy him by convicting him of heresy, but on each occasion they were foiled by Henry's curious attachment to him. In Cranmer, this king, who as a rule kept himself entirely free from personal feelings for his servants and advisers, found a man whom he both trusted and liked. Unlike the rest of them, the Archbishop was neither greedy nor devious; he sought nothing for himself, alone was willing to plead for those who fell into disfavour (a service he performed with equal courage and futility for Sir Thomas More, Anne Boleyn, Thomas Cromwell, and others), and miraculously retained Henry's goodwill throughout. The King regarded him with that mixture of awe and amusement that the worldly and selfish bestow on those who appear simple in affairs; he liked him, listened to him, protected him, but allowed him no political influence whatsoever. It was not surprising that he turned to Cranmer when death came.

**Achievements under Edward VI.** With the accession of Edward VI (Henry's only child by his third wife, Jane Seymour) in 1547, Cranmer's time really arrived. From the first, the young king's guardian, Edward Seymour, duke of Somerset, demonstrated his intention to transform the Church of England into a Protestant church. When he fell in 1549 the expected Catholic reaction did not take place because John Dudley (later the duke of Northumberland), who had ousted Seymour, decided to introduce an even more extreme brand of reformed religion. In the doctrinal labours demanded by these changes, Cranmer took the chief and directing part. In 1547 he was responsible for the publication of a *Book of Homilies* designed to meet the notorious grievance that the unreformed clergy did not preach enough. The first Prayer Book, moderately Protestant, appeared in 1549, to be followed in 1552 by the second, which was more outspokenly Protestant. Cranmer was personally responsible for much of the work, but he had the assistance of a number of foreign theologians for whom Edward VI's England acted as a magnet. The most influential of these was probably Martin Bucer from Strassburg, whose position on the Eucharist is reflected especially in the communion service of the second Prayer Book. It was not so

The 42  
Articles

much Bucer, however, who persuaded Cranmer away from the vague Lutheranism, which seems to have been his position in 1547, as either the Pole Jan Łaski the Younger or the Englishman Nicholas Ridley, both men possessed of a more determined and unquestioning temper than was the Archbishop. The ferment of those years also produced Cranmer's 42 Articles (1553), a set of doctrinal formulas defining the dogmatic position of the Church of England on current religious controversies. All clergy, schoolmasters, and degree candidates in the universities were compelled to subscribe to the articles, which were later reduced to 39 and officially accepted by the Anglican church. At this time, Cranmer also attempted to revise the canon law of the English Church, a proposal never enacted but published in 1571 as the *Reformatio Legum Ecclesiasticarum*. Though still deprived of any serious influence in affairs of state, Cranmer dominated and guided the religious revolution of the reign by his learning, authority, and unwavering diligence. He settled in turn the doctrine, ritual, and law of his church in a manner that was to remain fundamental to later developments; above all, the Church of England owed to him the beauty of its liturgy, which shows him to have been not only a theologian but something of a poet.

Degradation and martyrdom. Edward VI's approaching death (July 1553) at long last involved Cranmer fatally in politics. After prolonged resistance he was forced by the dying King to subscribe the document by which Northumberland hoped to upset custom, statute law, and the will of Henry VIII in order to transfer the succession from the princess Mary (Henry's daughter by Catherine of Aragon) to his daughter-in-law, the great-niece of Henry, Lady Jane Grey. Although proclaimed queen, she was deposed and beheaded nine days later, and Mary I acceded to the throne. The failure of the plot brought charges of treason against Cranmer, and he was condemned by Mary's government in November 1553. It had in any case become obvious before this that his future held no more bright promises. Mary's accession temporarily destroyed the English Reformation; Cranmer's embittered enemy Stephen Gardiner was at once released from imprisonment and promoted to the chancellorship, and in November 1554 Cardinal Reginald Pole arrived to occupy Canterbury and direct the extirpation of heresy. Cranmer's trial for treason was but a pretext; the Queen and her advisers did not intend him to die for the technical offense of having supported Northumberland's insane conspiracy but meant to destroy him for his long-standing offense in promoting Protestantism. They had to wait until they could get Parliament to repeal the acts of Henry VIII and Edward VI and to reintroduce the laws that enabled the secular arm to burn heretics. With Ridley and Hugh Latimer, a Protestant who had formerly been bishop of Worcester, Cranmer in March 1554 was removed to Oxford where the Counter-Reformation felt safer than in Cranmer's own university. Late in that year the heresy laws were revived, and in September 1555, after enfeebling imprisonment, Cranmer was subjected to a long trial in which he stoutly defended himself against the charge of having unjustifiably departed from his own earlier position on the sacraments and the papacy. The foregone conclusion was arrived at after a variety of technical processes; on February 14, 1556, in a ceremony full of carefully designed humiliation, he was degraded from his episcopal and sacerdotal offices and handed over to the state.

But Mary's government had not done with him yet. The burning of the arch-heretic would be an even more useful deed if he could be made to renounce his errors in public, and so a number of ways were tried to break him down. The previous October he had been forced to witness the martyrdom of Ridley and Latimer; now he was temporarily removed from prison into more pleasant surroundings while government agents tried to stir up his doubts. In fact, Cranmer signed five so-called recantations of which the first four did no more than record his consistent belief that what monarch and Parliament had decreed must be obeyed by all Englishmen. His convictions

on this point logically forced him to accept the Marian Counter-Reformation as valid, and this acceptance, in turn, in his weak and uncertain state, not unaffected by the delay of death and the faint hope of mercy, finally induced him to make an abject recantation (the sixth) of his whole religious development. The government had every reason to hope that the publication of Cranmer's defection would wreck Protestantism in England. No mercy was to be extended to the old man. The vengeful Gardiner had died, but Queen Mary and Cardinal Pole were quite determined that the sentence must be carried out. Thus on March 21, 1556, Cranmer was taken out to be burned, being first required to make his recantation public. The proximity of death, however, restored both his faith and his dignity. With nothing to lose and only peace of soul to gain, he shocked his enemies by disavowing his recantation and emphatically reasserting that the Pope's power was usurped and transubstantiation untrue. At one blow Cranmer undid all that government propaganda had achieved and restored heart to the surviving reformers. Then he went to his death. As he had promised, he steadfastly held his right hand—which "had offended" by signing the false recantations—into the flame until it was consumed, and soon afterward the fire killed him. His brave and dignified end made an enormous impression.

Assessment. Cranmer was a very human man who in consequence has attracted a good deal of obloquy from those who have not had to share his tribulations and temptations. Essentially he was and remained a scholar who lacked the strength that singlemindedness and fanaticism instill into the less reflective. He has sometimes been thought of as infirm in moral purpose, but this is to misjudge him. His doubts at the last were cleverly induced by mental torture, and his gradual development away from traditional orthodoxy into more and more definitely Protestant views during the Reformation represents fairly the spiritual career of a man who obeyed reason rather than instinct. Cranmer was always learning and was never ashamed to admit it; his was essentially a humble temper. He had not sought high office and did not particularly enjoy it, though he valued his place for the chance it gave him to promote the changes that he came to regard as essential to the establishment of God's truth. He refused to bear malice or to punish those who traduced him. When Cromwell once told him, in some exasperation, that the "popish knaves" would have his eyes and cut his throat before he would do something about it, Cranmer turned the prophecy with a shrug. In a persecuting age he stood out for his clemency, though in 1550 he did take part in the trial and burning of Joan Bocher. It should be remembered, however, that she was condemned for open blasphemy in denying the Trinity, the one offense that all the church had regarded as unforgivable ever since the struggle with Arianism. For his order and the authority of the church Cranmer had a high respect, which, for instance, appears in his revision of the canon law.

It was part of his religious beliefs that he owed obedience to the king; though he did not worship the state, he served it without hesitation and as a matter of principle. This position did not, as is sometimes alleged, make him servile; alone of Henry VIII's councillors, Cranmer time and again spoke up for the unpopular victim of the moment, and his tart criticism of the King's theology and grammar in the debates over the King's Book of 1543 speaks well for his courage. He stood up to Northumberland when everyone else quailed before that half-demented demon.

These occasional disputes only underline the fact that with him submission to royal authority was ordinarily a fundamental, indeed a doctrinal, tenet. Though he may have been more consistent in this than most, he only stressed more heavily what nearly everybody held at the time. His other guiding star was his study of theology, in which he early discarded the arid aftermath of late medieval Scholasticism and turned instead to Scripture and the early Fathers. His belief in the divine right of

Recanta-  
tion and  
disavowalTrial for  
heresy

kings to rule the church as well as the state and his biblical theology made him the characteristic Anglican of his day: the intellectual and in part the spiritual founder-father of the reformed church in England.

**BIBLIOGRAPHY.** The most complete biography is JASPER G. RIDLEY, *Thomas Cranmer* (1962), solid but not subtle and insufficiently sympathetic; A.F. POLLARD, *Thomas Cranmer and the English Reformation, 1489–1556* (1904), is still worth reading. On Cranmer's theology, see C.W. DUGMORE, *The Mass and the English Reformers* (1958); and P.N. BROOKS, *Thomas Cranmer's Doctrine of the Eucharist* (1965); on his place in the history of the English Church, see A.G. DICKENS, *The English Reformation*, rev. ed. (1967).

## Creation, Myths and Doctrines of

Doctrines of creation are philosophical and theological elaborations of the primal myth of creation within a religious community. The term myth here refers to the imaginative expression in narrative form of what is experienced or apprehended as basic reality. The term creation refers to the beginning of things, whether by the will and act of a transcendent being, by emanation from some ultimate source, or in any other way.

### NATURE AND SIGNIFICANCE

The myth of creation is the symbolic narrative of the beginning of the world as understood by a particular community. The later doctrines of creation are interpretations of this myth in light of the subsequent history and needs of the community. Thus, for example, all theology and speculation concerning creation in the Christian community are based on the myth of creation in the biblical book of Genesis and of the new creation in Jesus Christ. Doctrines of creation are based on the myth of creation, which expresses and embodies all of the fertile possibilities for thinking about this subject within a particular religious community.

Myths are narratives that express the basic valuations of a religious community. Myths of creation refer to the process through which the world is centred and given a definite form within the whole of reality. They also serve as a basis for the orientation of man in the world. This centring and orientation specify man's place in the universe and the regard he must have for other humans, nature, and the entire nonhuman world; they set the stylistic tone that tends to determine all other gestures, actions, and structures in the culture. The cosmogonic (origin of the world) myth is the myth *par excellence*. In this sense, the myth is akin to philosophy, but, unlike philosophy, it is constituted by a system of symbols; and because it is the basis for any subsequent cultural thought, it contains rational and nonrational forms. There is an order and structure to the myth, but this order and structure is not to be confused with rational, philosophical order and structure. The myth possesses its own distinctive kind of order.

Myths of creation have another distinctive character in that they provide both the model for nonmythic expression in the culture and the model for other cultural myths. In this sense, one must distinguish between cosmogonic myths and myths of the origin of cultural techniques and artifacts. Insofar as the cosmogonic myth tells the story of the creation of the world, other myths that narrate the story of a specific technique or the discovery of a particular area of cultural life take their models from the stylistic structure of the cosmogonic myth. These latter myths may be etiological (*i.e.*, explaining origins); but the cosmogonic myth is never simply etiological, for it deals with the ultimate origin of all things.

The cosmogonic myth thus has a pervasive structure; its expression in the form of philosophical and theological thought is only one dimension of its function as a model for cultural life. Though the cosmogonic myth does not necessarily lead to ritual expression, ritual is often the dramatic presentation of the myth. Such dramatization is performed to emphasize the permanence and efficacy of the central themes of the myth, which integrates and undergirds the structure of meaning and value in the culture. The ritual dramatization of the myth is the begin-

ning of liturgy, for the religious community in its central liturgy attempts to re-create the time of the beginning.

From this ritual dramatization the notion of time is established within the religious community. To be sure, in most communities there is the notion of a sacred and a profane time. The prestige of the cosmogonic myth establishes sacred or real time. It is this time that is most efficacious for the life of the community. Dramatization of sacred time enables the community to participate in a time that has a different quality than ordinary time, which tends to be neutral. All significant temporal events are spoken of in the language of the cosmogonic myth, for only by referring them to this primordial model will they have significance.

In like manner, artistic expression in archaic or "primitive" societies, often related to ritual presentation, is modelled on the structure of the cosmogonic myth. The masks, dances, and gestures are, in one way or another, aspects of the structure of the cosmogonic myth. This meaning may also extend to the tools man uses in the making of artistic designs and to the precise technique he employs in his craft.

Mention has been made above of the fact that the cosmogonic myth situates man in a place, in space. This centring is at once symbolic and empirical: symbolic because through symbols it defines the spatiality of man in ontological terms (of being) and empirical because it orients him in a definite landscape. Indeed, the names given to the flora and fauna and to the topography are a part of the orientation of man in a space. The subsequent development of language within a human community is an extension of the language of the cosmogonic myth.

The initial ordering of the world through the cosmogonic myth serves as the primordial structure of culture and the articulation of the embryonic forms and styles of cultural life out of which various and differing forms of culture emerge. The recollection and celebration of the myth enable the religious community to think of and participate in the fundamentally real time, space, and mode of orientation that enables them to define their cultural life in a specific manner.

The primordial structure of culture

### TYPES OF COSMOGONIC MYTHS

The world as a structure of meaning and value has not appeared in the same manner to all human cultures. There are, therefore, almost as many cosmogonic myths as there are human cultures. Until quite recently, classification of these myths on an evolutionary scale, from the most archaic cultures to contemporary Western cultures (*i.e.*, from the assumedly simplest to the most complex) was the most dominant mode of ordering these myths. Recent 20th-century scholars, however, tend to look at the various types of myths in terms of the structures that they reveal rather than on an evolutionary scale extending from the so-called simple to the complex, for, in a sense, there are no simple myths regarding the beginning of the world. The beginning of the world is simultaneously the beginning of the human condition, and it is impossible to speak of this beginning as if it were simple.

**Creation by a supreme being.** The 19th-century scholars who took an evolutionary survey of human culture and religion (*e.g.*, Sir James George Frazer and Edward Burnett Tylor) held that the notion of the creation of the world by a supreme being occurred only in the highest stage of cultural development.

Andrew Lang, a Scottish folklorist, challenged this conception of the development of religious ideas, for he found in the writings of anthropologists, ethnologists, and travellers evidence of a belief in a supreme being or high god among cultures that had been classified as the most primitive. This position was taken up and elaborated by an Austrian priest-anthropologist, Wilhelm Matthäus Schmidt, who reversed the evolutionary theory, holding that there was a primordial notion of a supreme being, a kind of original intellectual and religious conception of a single creator god, that degenerated in subsequent cultural stages. Though Schmidt's theories of cultural historical stages and diffusion and an original primordial revelation have for the most part been discredited and

Primordial supreme beings or creator gods

The basis for man's placement and orientation in the world

The ritual expression of creation: sacred time

abandoned, the existence of a belief in a supreme being among primitive peoples (a notion discovered by Andrew Lang) has been proven and attested to over and over again by investigators of numerous cultures. This belief has been found among the cultures of Africa, the Ainu of the northern Japanese islands, Amerindians, south central Australians, the Fuegians of South America, and in almost all parts of the globe.

Though the precise nature and characteristics of the supreme creator deity may differ from culture to culture, a specific and pervasive structure of this type of deity can be discerned. The following characteristics tend to be common: (1) he is all wise and all powerful. The world comes into being because of his wisdom, and he is able to actualize the world because of his power. (2) The deity exists alone prior to the creation of the world. There is no being or thing prior to his existence. No explanation can therefore be given of his existence, before which one confronts the ultimate mystery. (3) The mode of creation is conscious, deliberate, and orderly. This again is an aspect of the creator's wisdom and power. The creation comes about because the deity seems to have a definite plan in mind and does not create on a trial-and-error basis. In Genesis, for example, particular parts of the world are created seriatim; in an Egyptian myth, Kheper, the creator deity, says, "I planned in my heart," and in a Maori myth the creator deity proceeds from inactivity to increasing stages of activity. (4) The creation of the world is simultaneously an expression of the freedom and purpose of the deity. His mode of creation defines the pattern and purpose of all aspects of the creation, though the deity is not bound by his creation. His relationship to the created order after the creation is again an aspect of his freedom. (5) In several creation myths of this type, the creator deity removes himself from the world after it has been created. After the creation the deity goes away and only appears again when a catastrophe threatens the created order. (6) The supreme creator deity is often a sky god, and the deity in this form is an instance of the religious valuation of the symbolism of the sky.

Rupture of  
primordial  
harmony  
and  
perfection

In creation myths of the above type, the creation itself or the intent of the creator deity is to create a perfect world, paradise. Before the end of the creative act or sometime soon after the end of creation, the created order or the intent of the creator deity is thwarted by some fault of one of the creatures. There is thus a rupture in the creation myth. In some myths this rupture is the cause of the departure of the deity from creation.

An African myth from the Dogon peoples of West Africa illustrates this point. In this myth the creator deity first creates an egg. Within the egg are two pairs of twins, each pair consisting of one male and one female. These twins are supposed to mature within the egg, becoming at maturation androgynous (both male and female) beings, the perfect creatures to inhabit the earth. One of the twins breaks from the egg before maturation because he wishes to dominate the creation. In so doing he carries a part of the egg with him, and from this he creates an imperfect world. The creator deity, seeing what he has done, sacrifices the other twin to establish a balance in the world. The creation is sustained by this sacrifice, and it is now ambiguous, instead of the perfect world intended by the god.

This myth not only shows how a rupture takes place within the myth itself but also points out the fact that the characteristics of the supreme creator deity noted above seldom exist apart from other mythological contexts. The widespread symbols of dualism (the divine twins), the cosmic egg, and sacrifice are basic themes in the structure of this African creation myth. In myths of this kind, however, prominence must always be given to the might of a powerful creator sky deity under whose aegis the created order comes into being.

**Creation through emergence.** In contrast to the creation by a supreme sky deity, there is another type of creation myth in which the creation seems to emerge through its own inner power from under the earth. In this genre of myth, the created order emerges gradually in continuous stages. It is similar to a birth or meta-

morphosis of the world from its embryonic state to maturity. The symbolism of the earth or a part of the earth as a repository of all potential form is prominent in this type of myth. In some myths of this type (e.g., the Navajo myth of emergence), the movement from a lower stage to a higher one is initiated by some fault of the people who live under the earth, but these faults are only the parallels of an automatic upper movement in the earth itself.

Just as the supreme-creator-deity myth forms a homology to the sky, the emergence myth forms a homology to the earth and to the child-bearing woman. In many cases the emergence of the created order is analogous to the growth of a child in the womb and its emission at birth. This symbolism is made clear in a Zuni myth that states,

Anon is the nethermost world, the seed of men and creatures took form and increased; even as in eggs in warm places speedily appear . . . Everywhere were unfinished creatures, crawling like reptiles one over another, one spitting on another or doing other indecencies . . . until many among them escaped, growing wiser and more manlike.

The underworlds prior to the created order appear chaotic; the beings inhabiting these places seem without form or stability, or they commit immoral acts. The seeming chaos is moving toward a definite form of order, however, an order latent in the very forms themselves rather than from an imposition of order from the outside.

From another perspective the emergence myth is homologous to the seed. When the homologue of the seed is referred to, the meaning of fertility and death are at once introduced. The seed must die before it can be reborn and actualize its potentiality. This symbolism is dramatically presented in a wide range of funerary rites: one is buried in the earth in hope of a renewal from the earth, or the earth is the repository of the ancestors from whom the new generation emerges. In every case, emergence myths demonstrate the latent potency immanent in the earth as a repository of all life-forms.

**Creation by world parents.** Closely related to the above type of myth is the myth that states that the world is created as the progeny of a primordial mother and father. The mother and father are symbols of earth and sky, respectively. In myths of this kind, the world parents generally appear at a late stage of the creation process; chaos in some way exists before the coming into being of the world parents. In the Babylonian myth *Enuma elish*, it is stated,

When on high the heaven had not been named  
Firm ground below had not been called by name,  
Naught but primordial Apsu, their begetter,  
(And) Mummu-Tiamat, she who bore them all,  
Their waters comingling as a single body;

The Maori make the same point when they state that the world parents emerge out of *po*. *Po* for the Maori means the basic matter and the method by which creation comes about. There is thus some form of reality before the appearance of the world parents.

Even though the world parents are depicted and described as in sexual embrace, no activity is taking place. They appear as quiescent and inert. The chthonic (underworld) structure of the earth as latent potentiality tends to dominate the union. The parents are often unaware that they have offspring, and thus a kind of indifference regarding the union is expressed. The union of male and female in sexual embrace is another symbol of completeness and totality. As in the African myth from the Dogon referred to above, sexual union is a sign of androgyny (being both male and female) and androgyny, in turn, a sign of perfection. The indifference of the world parents is thus not simply a sign of ignorance but equally of the silence of perfection. The world parents in the Babylonian and Maori myths do not wish to be disturbed by their offspring. As over against the parents, the offspring are signs of actuality, fragmentation, specificity; they define concrete realities.

The separation of the world parents is again a rupture within the myth. This separation is caused by offspring who wish either to have more space or to have light, for they are situated between the bodies of the parents. In

From the  
embryonic  
or inchoate  
to the  
mature and  
definite

From  
inertness  
to activity

some myths the separation is caused by a woman who lifts her pestle so high in grinding grain that it strikes the sky, causing the sky to recede into the background, thus providing room for the activities of mankind. In both cases an antagonistic motive must be attributed to the agents of separation. In the Babylonian and Maori versions of this myth, actual warfare takes place as a result of the separation.

Over against the primordial union of the world parents, there is the desire for knowledge and a different orientation in space. After the separation, lesser deities related to solar symbolism take precedence in the creation. The sun and light must be seen in these myths as representing the desire for a humanizing and cultural knowledge as over against the passive and inert forms of the union of the parent deities. From the point of separation, the mythic narrative of the world-parent myths states how different forms of cultural knowledge are brought to man by the offspring, the agents of separation. The separation of the world parents is the sign of a new cosmic order, an order dedicated to the techniques, crafts, and knowledge of culture.

**Creation from the cosmic egg.** In the Dogon myth referred to above, the creation deity begins the act of creation by placing two embryonic sets of twins in an egg. In each set of twins is a male and female; during the maturation process they are together thus forming androgynous beings. In a Tahitian myth, the creator deity himself lives alone in a shell. After breaking out of the shell, he creates his counterpart, and together they undertake the work of creation.

A Japanese creation narrative likens the primordial chaos to an egg containing the germs of creation. In the Hindu tradition the creation of the world is symbolized in the *Chandōgya Upaniṣad* by the breaking of an egg, and the universe is referred to as an egg in other sources. The Buddhists speak of the transcending of ordinary existence, the realization of a new mode of being, as breaking the shell of the egg. Similar references to creation through the symbol of the egg are found in the Orphic texts of the Greeks and in Chinese myths.

The egg is a symbol of the totality from which all creation comes. It is like a womb containing the seeds of creation. Within the egg are the possibilities of a perfect creation (*i.e.*, the creation of androgynous beings). The egg, in addition to being the beginning of life, is equally a symbol of procreation, rebirth, and new life. In a version of the Dogon, one of the twins returns to the egg in order to resuscitate the other.

**Creation by earth divers.** Two elements are important in myths of this type. There is, first, the theme of the cosmogonic water representing the undifferentiated waters that are present before the earth has been created. Secondly, there is an animal who plunges into the water to secure a portion of earth. The importance of the animal is that the creature agent is a prehuman species. This version of the myth is probably the oldest version of this genre. This basic structure of the earth-diver myth has been modified in central Europe in myths that relate the story of the primordial waters, God, and the devil. In these versions of the earth-diver myth, the devil appears as God's companion in the creation of the world. The devil becomes the diver sent by God to bring earth from the bottom of the waters. In most versions of this myth, God does not appear to be omniscient or omnipotent, often depending on the knowledge of the devil for certain details regarding the creative act—details that he learns through tricks he plays upon the devil.

In still different versions of this myth, the relationship between God and the devil moves from companionship to antagonism; they become adversaries, though they remain as co-creators of the world. The fact that the devil has had a part in the creation of the world is one way of explaining the origin and persistence of evil in the world.

Mircea Eliade, a noted historian of religions, has pointed to another theme in certain Romanian versions of this myth. After God has instructed the devil to dive to the bottom of the waters and bring up the earth, the devil obeys, diving several times before he is able to bring up

and hold on to a small portion of earth. After the creation of the world from this small portion of earth, God sinks into a profound sleep. This sleep is a sign of mental exhaustion, for only the devil and a bee know the solution to certain details of the creation, and God must, with the help of the bee, trick the devil into giving him this vital information. God's sleep, according to Eliade, is a sign of his passivity and disinterest in the world after it has been created, and it harks back to certain archaic myths in which the supreme deity retires from the world after its creation, becoming disinterested and passive in relationship to his work.

#### DOCTRINES OF CREATION

Some of the major types of creation myths have been presented above. It is from myths of this sort and their dominant themes that theological and philosophical speculation have been developed in the various religious communities.

**Basic mythical themes. Primordiality.** In several myths it is stated that the primordial stuff of creation was some form of undifferentiated matter (*e.g.*, water, chaos, a monster, or an egg). It is from this undifferentiated matter that the world evolves or is made. In the case of the egg and monster symbols, there seems to be a notion of a definite original form, but the egg is undifferentiated; for its form is vague and embryonic, and the monster figure ---containing all of the forms of chaos in a terrible way---expresses the theme that chaos is not only passive' (as is water) but resists creation. Although creation results as a modification of the primordial matter, however, it is this matter that determines and sets the limits to the extension of the world in space and time. Thus, in communities in which myths of this type find their expression, there are periods of mythical-ritual renewal at certain cyclical periods in which the world returns to its original chaos to rise again out of this initial state.

When it is stated that the supreme being created the world and that there was no primordial matter prior to his being, then the determination of the world is in the mind and will of the deity. This leads to distinctive conclusions regarding the destiny of the world and man. The end (and meaning) of the world is thus not determined by the primordial matter but by the deity who created the world. It is he alone who determines the preservation, maintenance, and end of the world.

**Dualisms and antagonisms.** In emergence myths there seems to be an easy movement from one stage of creation to the next, but, as has been shown in the Navajo myth, at each subterranean level there is some type of antagonism among the developing embryonic creatures. This is one of the reasons for the separation of the creatures and the movement to another level. Though the emergence myths portray the mildest form of this antagonism, it is still present in myths of this sort.

In the world-parent myths there is antagonism between the offspring and the parents. This is a conflict between generations, expressing the desire of the children to determine their own place and orientation in existence against the passivity of the parents.

A dualism and antagonism is found again in the cosmic-egg myths, especially in the myths in which the egg contains twins. One twin wishes to take credit for the creation of the world alone, interrupting the harmonious growth within the egg before maturation. The faulty creation by this evil twin accounts for the ambiguous nature of the world and the origin of evil.

This observation applies equally to the dualistic structure in some versions of the earth-diver myths. The devil moves in the various versions of this myth from companion to antagonist of God, possessing power to challenge the deity.

**Creation and sacrifice.** In many cosmogonic myths, the narrative relates the story of the sacrifice and dismemberment of a primordial being. The world is then established from the body of this being. In the myth *Enuma elisk*, the god Marduk, after defeating Tiamat, the primeval mother, divides the body into two parts, one part forming the heavens, the other, the earth. In a West

God's post-creation sleep

The creator deity as sole determiner of creation's nature and destiny

The cosmogonic water and the diver animal or diver devil

Sacrifice of primordial beings

African myth, one of the twins from the cosmic egg must be sacrificed to bring about a habitable world. In the Norse *Prose Edda*, the cosmos is formed from the body of the dismembered great Ymir, and, in the Indian *Rgveda*, the cosmos is a result of the sacrifice of man.

In these motifs of sacrifice, something similar to the qualification of the undifferentiated matter of creation is suggested, for, just as the primal stuff of creation must be differentiated before the world appears, the sacrifice of primordial beings is a destruction of the primal totality for the sake of a specific creation.

When the victim of the sacrifice is a primal monster, the emphasis is on the stabilization of the creation through the death of the monster. The monster symbolizes the strangeness and awesomeness occurring when a new land or space is occupied. The "monster" of the place is the undifferentiated character of the space and must be immobilized before the new space can be established.

In a myth from Ceram (Molucca Islands), a beautiful girl, Hainuwele, has grown up out of a coconut plant. After providing the community with their necessities and luxuries, she is killed and her body cut into several pieces, which are then thrown over the island. From each part of her body a coconut tree grows. It is only after the death of Hainuwele that mankind becomes sexual; that is, the murder of Hainuwele enables mankind to have some determination in the process of bringing new life into the world.

**Theological and philosophical doctrines.** Myths and poetic renderings in legends, sagas, and poetry express the basic cultural insights into some of the elements involved in the human consciousness about creation. Theological, philosophical, and scientific theory are types of rationalizations of these basic insights in terms of the particular culture and historical periods of the cultures in question.

The attempt to integrate the meanings of primordially, dualisms and antagonisms, sacrifices, and ruptures and to meet demands of some kind of logical order and, at the same time, keep alive the meaning of these structures as religious realities, objects of worship, and a charter for the moral life, has led to the development of doctrines.

In "primitive" and archaic societies, the correct ritual enactment of mythical symbols ensures the order of the world. These rituals usually take place at propitious moments (e.g., at the birth of a child, marriage, the founding of a new habitation, the erection of a house or temple, the beginning of a new year). In each case, the seemingly practical activities imitate the mythic structure of the first beginning.

Theological and philosophical speculations and controversies centre within and between religious communities over the issues of the primordial nature of reality, dualisms, the process of creation, the nature of time and space. A doctrine of creation must contain or suggest the manner in which all cultural meanings, empirical and abstract, constitute an integral totality. Speculations based on the initial insights of a mythical theme explicate some principle in the myth as a basis for generalization and logical form on which all elements and themes may be ordered.

**Transcendence and otherness.** Doctrinal positions may be modelled around any or all of the themes of the cosmogonic myth. If the emphasis falls upon creation by a high god through his thought, word, or other mode, the problem of the otherness and difference between creator and creature becomes a source of theological discussion and philosophical speculations. In Judaism, Christianity, and *Islām*, the classical locus of this issue is found. All of these religions have theological traditions that raise this problem. Related to this issue is the transcendence and arbitrary action of the creator deity. Because he is prior to the world and its creatures, the question arises whether there are modes of creaturely knowledge or apprehension capable of knowing him; of whether he is subjected to the same categories of being as his creatures; of whether his time and space are the time and space of his creation.

To some extent, the a priori nature of this type of deity creates an apparent dualism between the creator and the

world and creatures. This dualism is mediated in various forms in the traditions. In Judaism it is mediated through nature and the covenant Yahweh has with his people; in Christianity through the mediatorship of his son, Jesus Christ; and in *Islām* through the sacred word of the Qur'ān by the prophet Muhammad. Even within these traditions, however, the transcendent nature of the deity and his mediatorship through some other being or principle does not settle the doctrinal issue, for different cultural-historical periods of these traditions offer a variety of theological speculation concerning the nature and meaning of the deity, the world, and the mediator. The traditions offer a structure through which such speculation is ordered and clarified.

**Creation through emanations.** The theme of emergence is related to theological and philosophical notions of emanations from a single principle and the idea of the transmutation of being. Ideas of this kind are found in "primitive" religion (Dogon, Polynesian), in Taoism, and in the Pre-Socratic philosophers Thales and Anaximander.

In one version of the Dogon myth, creation proceeds from a small seed. Within the seed spontaneous movements begin. These movements, which burst from the shell of the seed and make contributions in space, create all forms of beings and the universe. Similarly, in the Polynesian myth Ta-aroa develops the world out of himself and the shell in which he lived.

A pervasive theme in Chinese thought is that of a universe in a perpetual flux. This flux follows a fixed and predictable pattern either of eternal oscillation between two apparently opposed poles or of a cyclical movement in a close orbit. The oscillation pattern is expressed by the Yin-Yang doctrine of Taoism. In the five element doctrine, a cyclical movement is correlated with the five elements, earth, wood, metal, fire, and water; these in turn form an equivalence with the third month of summer and with spring, autumn, summer, and winter, respectively. These parallelisms then form equivalences with the five directions, and they in turn with the five primary colors. Ancient Chinese thinkers never discuss an initial conscious act of creation. The cyclical movement itself produced the empirical and abstract form of the cosmos. The oscillation between the Yin and the Yang forms a correlation in all phenomena extending to the realms of time, space, number, and ethics.

Thales thought that the fundamental principle of cosmos was water. The earth floated on water; water was the natural cause of all things. Anaximander taught that there was an eternal undestructible something out of which everything arises and everything returns. In other words, the fundamental substratum of the world could not be an element of the world. The importance of Anaximander was in his use of the term *archē* ("beginning" or "rule") to refer to a principle unlike any other principle or element in the world to explain the cause of all other things in the universe.

**Dualisms.** Dualistic conceptions of creation come to the fore in the theme of earth-diver myths, in which there is an antagonism between the co-creators of the universe. This conception is present again in myths of divine twins and in Zoroastrianism where the Ormazd and Ahriman represent the creative and destructive principles in creation. In some sense this is not an ontological dualism for the first creative act of Ormazd was the limitation of time and thus the limitation of the power of Ahriman to carry out his destruction. Doctrines of this kind are related to the origin of evil in the world.

#### SKEPTICISM REGARDING CREATION

Alongside the various myths and doctrines regarding creation, there are equally skeptic positions concerning the unknowability of creation. This critique is present in several religious and philosophical traditions. It may be correlated with the mythical meaning of *deus otiosus*, the deity who retires from the world after his creation, or with the mythic theme from some earth-diver myths that emphasize the physical and intellectual fatigue of the deity after creation. In the first case, the removal of the

The notion of the universe in a perpetual flux

The problem of difference between creator and creature

deity from creation leaves no access to his plan or will; in the other case, because of the fatigue of the deity who has exhausted all of his knowledge in creation, there is thus nothing for man to learn from him.

In the Indian tradition the *R̥gveda*, an ancient sacred text, expresses skepticism in this manner:

He, the first origin of this creation, whether he formed it all or did not form it,

Whose eye controls this world in highest heaven, he verily knows it, or perhaps he knows not.

The Buddha declared certain cosmological and metaphysical questions unanswerable. His refusal to answer questions of this kind gave rise to the "silence of the Buddha" as a philosophical style in Buddhism. They included such questions as: whether the world is eternal or not or both; whether the world is finite (in space) or infinite or both or neither.

In the Chinese tradition Kuo Hsiang (died AD 312) questioned the origin of the basic oscillation of the Taoist movement. For Hsiang there is no such thing as Non-Being for Being is the only reality. Being could not have evolved from Non-Being nor can it revert to Non-Being. As Kuo Hsiang put it,

I venture to ask whether the Creator is or is not? If He is not, how can He create things? If He is, then (being one of these things), He is incapable of creating the mass of bodily forms. . . . The creating of things has no Lord; everything creates itself. Everything produces itself and does not depend on anything else. This is the normal way of the universe.

Skepticism of this same kind is expressed by Parmenides, a Pre-Socratic, and in the modern tradition of Western philosophy from Immanuel Kant's *Kritik der reinen Vernunft* (1st ed. 1781; Eng. trans., *Critique of Pure Reason*, 1929) to Ludwig Wittgenstein's *Tractatus Logico-Philosophicus* (1922). Skepticism of this kind about the nature of the cosmic order and especially about the ultimate origin of the universe places limitations on the possibility of the rational consciousness to authentically ask these questions. In some instances theologians have agreed and held to a notion of revelation as a response to these unanswerable questions. In other cases, the questions themselves have been labelled nonsensical.

Charles Hartshorne and William Reese, 20th-century U.S. philosophers, have attempted to clarify and criticize all possible rational reflections concerning the relationship of deity to the universe. They state two opposed positions. The first is that of classical theism in which there is the admission of plurality, potentiality, becoming, as a secondary form of existence outside of God. The other position, that of classical pantheism, says that though God includes all within himself, he cannot be complex or mutable, for such categories only express human ignorance and illusion. They attempt to overcome this dilemma by combining these contrary poles into a dipolar conception of the meaning of deity. Because classical theism is primarily a Western approach to the problem and classical pantheism an Eastern approach, the dipolar conception of the relationship of deity to the created order is at the same time a synthesis of Western and Eastern thought. In addition to this, these philosophers set forth a method of analyzing all conceptions of deity and world according to basic religious and rational categories. As metaphysicians they go far in refuting the skepticism regarding rational knowledge of the relationship between the deity and the universe.

#### BIBLIOGRAPHY

*Cosmogonic myths*: CHARLES H. LONG, *Alpha: The Myths of Creation* (1963), gives examples of various types of cosmogonic myths from different cultures. *La Naissance du Monde* (1959), gives myths from several cultures with a commentary by MIRCEA ELIADE. For ancient Near Eastern myths, see *Ancient Near Eastern Texts Relating to the Old Testament*, ed. by JAMES B. PRITCHARD, 3rd ed., with suppl. (1969). JOHANNES PEDERSEN, *Israel*, 4 vol. (Eng. trans. 1926–40), is a cultural-religious study that shows the relationship between the creation myth, the land, and kinship system (see especially the chapter on "World of Life and Death"). For the nature and structure of myths and symbols, see ERNST CASSIRER, *Philosophie der symbolischen Formen*, 4 vol. (1953–56; Eng. trans., *The Philosophy of Symbolic Forms*, 3 vol.,

1953–55); MIRCEA ELIADE, *Le Mythe de l'éternel retour* (1949; Eng. trans., *The Myth of the Eternal Return*, 1954), *Traité d'histoire des religions* (1948; Eng. trans., *Patterns in Comparative Religion*, 1958), and *Myth and Reality* (1963).

*The development and structure of Greek myths*: JOHN BURNET, *Early Greek Philosophy*, 4th ed. (1930, reprinted 1963), is a well-written interpretation of the pre-Socratic myths of creation. ARNOLD EHRLICH, *The Beginning* (1968), shows the common structure of the cosmologies of the Gospel of John and pre-Socratic thinkers. BENJAMIN FARRINGTON, *Science and Politics in the Ancient World*, 2nd ed. (1946), attempts to place the development of scientific thought in ancient Greece within the context of the social history of the period. W.K.C. GUTHRIE, *In the Beginning* (1957), is limited to a study of Greek notions of the origins of man and the state. JEAN-PIERRE VERNANT, *Mythe et pensée chez les grecs*, 2nd ed. (1966), explores the interrelationships of time, space, memory, and technique in Greek myths.

*Christian doctrine*: For a theological history of the Christian doctrine of creation in its variety and continuity, see JAROSLAV PELIKAN, *Development of Christian Doctrine* (1969), *The Christian Tradition* (1971), and *Historical Theology: Continuity and Change in Christian Doctrine* (1971). JOHN MACQUARRIE, *Principles of Christian Theology* (1966), presents a structural and systematic analysis of the elements of Christian theology, showing how the doctrine of creation fits into theological systems.

*Islām*: DE LACY O'LEARY, *Arabic Thought and Its Place in History*, rev. ed. (1939, reprinted 1963), deals with the internal and external sources of Arabic philosophy and cosmology. SEYYED HOSSEIN NASR, *An Introduction to Islamic Cosmological Doctrines* (1964), explicates a tradition in Arabic thought that expresses creation in symbolic and cosmological images.

*Zoroastrianism*: Several Zoroastrian myths and doctrines of creation are found in R.C. ZAEHNER, *The Dawn and Twilight of Zoroastrianism* (1961).

*Chinese*: ARTHUR F. WRIGHT (ed.), *Studies in Chinese Thought* (1953), brings together ten essays on various aspects of Chinese thought. Most valuable is DERK BOEDE, "Harmony and Conflict in Chinese Philosophy," pp. 19–80. For a history of Chinese philosophical speculation as it relates to cosmogony and cosmology, see FUNG YU-LAN, *A History of Chinese Philosophy*, 2nd ed., 2 vol. (Eng. trans. 1952–53).

*Indian*: Philosophical speculations about creation in the various schools of Indian philosophy can be found in SURENDRANATH DAS GUPTA, *A History of Indian Philosophy*, 5 vol. (1922–55); and HEINRICH ZIMMER, *Philosophies of India* (1951), especially the chapter on philosophies of time. ALAIN DANIELOU, *Le Polythéisme hindou* (1960; Eng. trans., *Hindu Polytheism*, 1964), is a description and interpretation of the gods of Hinduism in relationship to their philosophical meaning. T.R.V. MURTI, *The Central Philosophy of Buddhism* (1955), is an explication of the Mādhyamika system of Buddhist philosophy that denies creation.

*Comparative works*: HAJIME NAKAMURA, *Ways of Thinking of Eastern Peoples* (1964), is a comparative work showing the similarities and contrast between Indian, Chinese, Tibetan, and Japanese modes of thought especially as it concerns creation. C.F. VON WEIZSACKER, *The Relevance of Science: Creation and Cosmogony* (1964), deals with the evolution of thought about creation from myth to scientific theory. The same ground is covered in MILTON MUNITZ, *Space, Time, and Creation* (1957). CHARLES HARTSHORNE and WILLIAM REESE (eds.), *Philosophers Speak of God* (1953), is a text in comparative philosophy that explores the rational bases for several conceptions of God and creation in Eastern and Western thought.

(C.H.Lo.)

## Creed and Confession

Creeds and confessions of faith are authoritative formulations of the beliefs of religious communities (or, by transference, of individuals). The two terms are sometimes used interchangeably, but when distinguished, a "creed" refers to a brief affirmation of faith employed in public worship or initiation rites, while a "confession" is generally a longer, more detailed, and systematic doctrinal declaration. Both creeds and confessions were historically called symbols, and the teachings they contain are termed articles of faith or, sometimes, dogmas.

The role of belief within religion is interpreted differently in the various empirical disciplines and by the proponents of particular theological or philosophical positions. Traditionally, it has been considered the primary

Role of  
belief

The work  
of Hart-  
shorne  
and Reese

factor in religion, but some modern scholars often regard beliefs as rationales for ritual, secondary expressions of religious experience or ideological sanctions for social and cultural patterns. The present article follows a current anthropological and sociological tendency to define religion as a symbolic system in which ideas and their concomitant attitudinal aspects and actions provide to an individual or group a model of itself and its world. From this perspective, every religion involves distinctive views or beliefs regarding the nature of ultimate reality.

Origins and functions of creeds. These beliefs, however, need not be explicitly articulated, but, may be wholly embedded and transmitted in rituals, myths, and social structures and practices. This is especially true in primitive religions. Even when differentiated from other factors, beliefs are frequently not stated in creedal form but are diffusely expressed in sacred writings, legal codes, liturgical formulas, and theological and philosophical reflection. This was true in the ancient cultural religions of Egypt, Mesopotamia, Greece, and Rome, and in traditional Hinduism, Confucianism, and Taoism. When, however, a religion is transmitted from one culture to another (as from Semitic to Hellenistic; *i.e.*, Palestine to Rome) or claims some degree of universal or exclusive truth, formal creeds often develop as aids in maintaining continuity and identity. They serve this purpose because the relative abstractness, comprehensiveness, and concentration of the verbal expressions of beliefs enable them to serve better than most other forms of religious symbolism as stable identifying marks in pluralistic, changing, proselytizing, and missionary situations.

Creeds in the full sense are therefore found only in so-called universal religions, such as Zoroastrianism, Buddhism, Judaism, Christianity, Islām, and certain modern Hindu movements (*e.g.*, Brahmo Samaj). Even here they are of variable importance, with some groups rejecting all formal creeds. Confessions are less common. They function to define the distinctive beliefs of opposing or uniting groups within a given religion or to formulate doctrines appropriate to new circumstances, and are chiefly a Christian phenomenon during the period from the Reformation to the present.

Religions of the East. Related to creeds in the full sense are certain words and phrases which have partially creedal functions. Terms like *tao* (literally, the "way") in Taoism or *li* (rules of propriety) and *hsiao* (filial piety) in Confucianism summarize fundamental emphases of the religious systems of which they are a part. The endlessly repeated *mantra* (evocative sacred syllables) of magic invocation, *Om mani padme hiim* ('*Ū* the jewel in the lotus'), especially popular in Tibetan Buddhism, is in one sense a profession of belief in the Avalokiteśvara (jewel's) presence in the world (lotus). Various Hindu mantras, most notably the *Gāyatrī* prayer from the *Ṛgveda* (3.62.10) that is learned as part of the initiation rites of Brahmin youth, also serve in part as professions of faith. Indeed, it is primarily through liturgical utterances (*e.g.*, the Lord's Prayer in Christianity), that religious identity is signaled and faith confessed in most religions.

More specifically creedal is the early thrice-repeated tri-ratna of Hīnayāna Buddhism: "I take my refuge in the Buddha. I take my refuge in the *dharma* (doctrine). I take my refuge in the *saṅgha* (monastic community)."

Religions of the West. Even earlier perhaps are such Zoroastrian formulations as "I profess myself a Mazdāh-worshipper, a Zarathustrian, enemy of the demons, servant of the Lord" (*Yasna* 12,1), whereby the believer declared himself a monotheist, a member of a specific community, and a dualist.

*Islām*. The intensely anti-polytheistic faith of Islam is summed up in the *shahādah*: "there is no God but God; Muhammad is the Prophet of God." This is proclaimed in the daily calls to prayer from every mosque, and every Muslim must recite it aloud with full comprehension and assent at least once in his life, and profess it without hesitation until his death. Doctrinal disputes have contributed to the development of additional creedal formula-

tions called '*aqā'id*' (singular, '*aqidah*'), but these do not divide Islām into clearly marked confessional groupings or denominations such as exist in Christianity.

*Judaism*. In Judaism, the central affirmations of belief are parts of worship; *e.g.*, the confessions of the oneness of God in the *Shema* (Deut. 6:4 "Hear, O Israel: The Lord our God is one Lord") and of the resurrection of the dead in the *amidah* (standing prayer). Of the various medieval attempts to formulate creeds, the most enduring has been Maimonides' Thirteen Principles of Faith, but these have never become formally binding. The Reform movement's doctrinal declarations, such as the Pittsburgh Platform (1885), have been without lasting influence. The reason for this paucity of creeds is that Jewish identity has been chiefly defined in terms of the observance of the commandments and of the Oral Law, not the acceptance of doctrines.

Christianity. In Christianity, in contrast, there are over 150 officially recognized creeds and confessions. In part this is because the church was from the beginning doctrinally oriented, making the acceptance of a specific kerygma (proclamation) a condition for membership. The faith of the community was expressed in acclamations such as "Jesus is Lord" (*e.g.*, Rom. 10:9, I Cor. 12:3) and in longer, partly stereotyped summaries of essential beliefs (*e.g.*, I Cor. 15:3 ff.) For the New Testament community, in contrast to some Christian groups in later times, a creedless Christianity was inconceivable.

Fully formed creeds first developed for use in baptismal rites and catechetical instruction. They generally had three sections concerned with God the Father, Jesus Christ, and the Holy Spirit, but were variable in wording and content and only gradually became standardized.

This process culminated in the West in the Apostles' Creed, which is now almost universally recognized by Western churches, and is still used in baptismal rites as well as public worship by Catholics and most Protestants. This creed is wholly derived from New Testament affirmations, but the 5th-century legend that the Twelve Apostles were its authors is without foundation. Not until the 8th century is it quoted in its present wording. Its sources, however, are to be found in earlier baptismal creeds, most probably in the Old Roman Symbol, which appears to go back in its essentials to the 2nd century. As is true of other creeds, it is in part intended to exclude heretical views. For example, against Gnosticism and Marcionism (dualistic heresies), it emphasizes that God, not an evil demiurge, is the creator of the world, and against docetic views that Jesus was a heavenly being with a phantom body, it insists that he was born of the Virgin Mary and actually suffered and died and was buried.

The Nicene Creed exists in two versions and represents a new type of doctrinal statement. It was first formulated at Nicea in 325 by the first of the universal, or ecumenical, councils, after Christianity became the official religion of the Roman Empire, and was designed not as a baptismal confession but as a binding standard of orthodox teachings. Its second version has become the most fully ecumenical of Christian creeds, accepted in East and West alike, including the major Protestant bodies. In Eastern churches, it is regularly employed in both Baptism and eucharistic worship; in the West, only in the Eucharist, and chiefly by Roman Catholics, Anglicans, and Lutherans.

The first version of this formulary is that promulgated at the Council of Nicea in 325, but the second version, the "Niceno-Constantinopolitan Creed," which has everywhere become standard and is generally referred to as the Nicene Creed, was affirmed at the Council of Chalcedon (451) as the Nicene "faith of the 150 fathers" (*i.e.*, the Council of Constantinople of AD 381). In 4th- and 5th-century usage, "the Nicene faith" did not refer to the creed of Nicea as such, but rather to its teaching.

Both versions make the same fundamental affirmations against the Arian heresy that denied the equality of the Father and the Son, asserting that Jesus Christ, the Son of God, is homoousion ("of one substance") with the

Purpose  
of creeds

The Ecumenical  
Creeds:  
Apostles',  
Nicene,  
and Athanasian

Father. They are also both derived from Eastern baptismal formulas, though which ones is in dispute.

The *filioque* clause, affirming that the Spirit proceeds "from the Son" as well as the Father, was inserted into the text in Spain during the 6th century and gradually spread to all Western churches, but was probably not used in Rome itself until 1014. Eastern Christians continue to reject this addition, though now they do not generally regard it as heretical, especially if it is understood in the sense of "through the Son."

The Athanasian Creed, also called the *Quicumque vult* from its initial words, is the last of what in the West are regarded as the three catholic or ecumenical creeds. It has received some slight recognition in the East, but only since the 16th century. While officially accepted in the Roman Catholic, Anglican, and Lutheran communions, its liturgical use has greatly declined in recent centuries. In part this is because it is in form more a theological exposition than a creed, and in part because of the damnatory clauses that exclude from salvation all those who do not accept every detail of its teaching. The main themes are the nature of Christ and the Trinity, and these are developed in opposition not only to Arianism but also apparently to later heresies such as Nestorianism and Eutychianism. While its doctrine can in general be attributed to the 4th-century Church Father Athanasius, he was not its author. It probably originated in southern France about 450–500, although there is no scholarly consensus on this point.

**Origins and functions of confessions.** Official doctrine has chiefly developed during later periods of church history by the formulation of confessions of faith, rather than new creeds. This process did not begin, however, until the 16th-century Reformation. During the Middle Ages, dogmas evolved slowly, almost unconsciously, and then were ratified from time to time by decisions of the church councils, such as the decision on the seven sacraments at the Council of Ferrara-Florence in 1439. The Protestant Reformers, however, were confronted with the need to define and make legitimate their views over against the established system, and thus issued comprehensive manifestos that, much more than the early creeds, were not only catalogues of beliefs but also interpretations and apologies for them. The Roman Catholic and Eastern Orthodox churches responded with their own confessional statements.

**Lutheran confessions.** The Augsburg Confession (1530) was the first of these statements, and still remains the most authoritative standard in Lutheran churches. It (as well as the Apology of the Augsburg Confession of 1531) was written by Philipp Melancthon and approved by Martin Luther, and presents an irenic statement aiming to show that the pope and his allies, not the Reformers, had departed from Scripture and the tradition of the early Fathers. Luther's Small Catechism also enjoys official status in all Lutheran churches and has been determinative for most Lutheran preaching and instruction. The Formula of Concord (1577) further defined the Lutheran position in reference to controversies both within and outside the ranks. These four writings, together with the Large Catechism (1529), the Schmalkald Articles, and the Treatise were assembled into the Book of Concord (1580), which has official status in many Lutheran churches.

**Reformed churches confessions.** In the Reformed tradition stemming from John Calvin (1509–64) and Huldrych Zwingli (1484–1531), each national church produced its own confessional documents. No one of these is authoritative for all, though some (e.g., the Heidelberg Catechism; 1563) are widely esteemed and used. In Switzerland, the First (1536) Helvetic Confession and the Second (1566) Helvetic Confession are the most generally accepted. The French Gallican Confession of 1559 is much admired, and in the Low Countries, the Belgic Confession of 1561 is important. The Netherlands was also the site of the international Synod of Dort (1619) that presented an especially rigid statement of Calvinism against Arminianism (a view that asserted the compati-

bility of God's sovereignty and man's free will). This same emphasis, combined with Puritan covenantal theology, is reflected in the English Westminster Confession of 1646 that in Scotland replaced the Scots Confession in 1560, was adopted with modifications by Congregationalists and many Baptists, and still remains standard for American Presbyterian churches, though with some revisions.

**The Anglican Communion.** The Thirty-Nine Articles (1563) is the only doctrinal formulation other than the early creeds recognized in the Church of England and its offshoots, but its authority is not great. In the Anglican Communion, *The Book of Common Prayer* plays the identity-sustaining role served by confessions in Lutheran and Reformed churches. The Thirty-Nine Articles, abbreviated to 25, are also the chief doctrinal standard in the Methodist churches, but their authority is uncertain.

**Confessions of other Protestant groups.** Confessional documents are of little significance for most of the radical groups (e.g., Anabaptists) coming out of the Reformation. To be sure, the Anabaptist Schleitheim Confession (1527) was historically important, the Dordrecht Confession (1632) still has some standing in Mennonite churches, and various Baptist and Congregationalist statements could also be mentioned. The general tendency in these churches, however, has been to oppose formal creeds and confessions for fear of stifling the workings of the Holy Spirit or imperilling the sole authority of the Bible or, in theologically liberal circles, endangering freedom of thought and conscience.

**Roman Catholic doctrinal statements.** Roman Catholic doctrinal statements are not usually called confessions, but the presentation of the distinctive points of Catholic dogma in the Decrees and Canons of the Council of Trent (1564) is as fully elaborated as are Protestant confessional writings. The dogmatic constitutions of the first Vatican Council (1869–70) and papal definitions of the dogmas of the Immaculate Conception (1854) and of the Assumption (1950) also have some of the character of confessions.

**Eastern Orthodox doctrinal statements.** Eastern Orthodoxy responded to Protestant and Roman Catholic challenges with the confessions of Peter Mogila, Metropolitan of Kiev, in 1643 and of Dositheos, the Patriarch of Jerusalem, in 1672, both adopted by the Synod of Jerusalem (1672), as well as with the Catechism of Philaret, Metropolitan of Moscow, revised and approved by the Holy Synod in 1839. The Orthodox, however, place little emphasis on these documents, for they regard only the Nicene Creed with its Chalcedonian additions as fully authoritative, and in practice also treat their historic liturgies as doctrinally more important than later statements.

**Creeds and confessions today.** Recently new types of confessions have begun to emerge. With the decline of state churches, confessions are no longer legally established norms and can once again regain their original function of witnessing to basic convictions. Especially notable in this respect is the Barmen Declaration, formulated in 1934 by a group of Reformed and Lutheran churchmen in opposition to the Nazi-influenced "German Christians." Because of the advance of the ecumenical movement, recent confessional statements have usually been unitive rather than divisive. The doctrinal basis of the World Council of Churches is limited to the affirmation that it is "a fellowship of churches which accept our Lord Jesus Christ as God and Savior" (1961). Preparation of joint Protestant and Roman Catholic official translations into English of the Apostles and Nicene Creeds commenced in 1969. Another characteristic of contemporary doctrinal statements, such as those of the Roman Catholic second Vatican Council (1962–64) and the Presbyterian (U.S.A.) Confession of 1967, is the attempt to reformulate traditional beliefs in ways appropriate to modern circumstances.

Despite these developments, creeds and confessions are losing influence in both Christian and non-Christian

tion

groups. They are, among other things, often attacked as obstacles to the individual's freedom of thought. This objection applies with special force against a fideistic attitude, such as is illustrated in extreme form by the well-known saying attributed traditionally, though not altogether correctly, to the 2nd-century North African Church Father Tertullian, *credo quia absurdum est*, "I believe because it is absurd." It is less applicable to another ancient and theologically more common approach summed up in the 11th- and 12th-century theologian Anselm's (and, in a somewhat different wording, Augustine's) classic phrase, *credo ut intelligam*, "I believe in order that I may understand." The latter view claims that true faith promotes rather than suppresses inquiry and intellectual liberty.

Yet, whatever the merits of such views, doctrinal convictions are clearly weakening, even in traditionally creedal and confessional bodies. The search for creedless religion is widespread. There is the possibility, however, that this trend may be eventually reversed because the quest for religious community is also strong, and may require the formation or re-affirmation of community-identifying beliefs; *i.e.*, of creeds or confessions.

**BIBLIOGRAPHY.** Still the most comprehensive treatment of creeds in all religions is "Creeds and Articles," in the *Encyclopaedia of Religion and Ethics*, 4:231-248 (1912). For anthropological, sociological, and phenomenological considerations, see the *International Encyclopedia of the Social Sciences*, 13:398-414 (1968); G. VAN DER LEEUW, *Phänomenologie der Religion* (1933; Eng. trans., *Religion in Essence and Manifestation*, 2 vol., with new appendices, (1963); and J. WACH, *Sociology of Religion* (1944). Works devoted specifically to creedal and confessional formulations are rare for most religions, but see S. SCHECHTER, "The Dogmas of Judaism," *Studies in Judaism*, pp. 147-181 (1896); and A.J. WENSINCK, *The Muslim Creed: Its Genesis and Historical Development* (1932). For Christianity, the fullest collection of texts remains P. SCHAFF, *The Creeds of Christendom*, 3 vol., 6th ed. (1919); for Roman Catholicism, H.J.D. DENZINGER and A. SCHONMETZER, *Enchiridion Symbolarum* (1963); and W.M. ABBOTT (ed.), *The Documents of Vatican II* (1966); for Protestantism, T.G. TAPPERT (ed. and trans.), *The Book of Concord* (1959); and A.C. COCHRANE (ed.), *Reformed Confessions of the 16th Century* (1966). On the Ecumenical movement, see L. VISCHER (ed.), *A Documentary History of the Faith and Order Movement 1927-1963* (1963). Brief but representative collections are B.A. GERRISH, *The Faith of Christendom: A Source book of Creeds and Confessions* (1963); and J.H. LEITH (ed.), *Creeds of the Churches* (1963). Secondary works on early creeds include: O. CULLMANN, *Die ersten christlichen Glaubensbekenntnisse* (1943; Eng. trans., *The Earliest Christian Confessions*, 1949); J.N.D. KELLY, *Early Christian Doctrines*, 2nd ed. (1960); A.E. BURN, *The Athanasian Creed*, 3rd impression (1930); D.L. HOLLAND, "The Earliest Text of the Old Roman Symbol," *Church History*, 34: 262-281 (1965), and "The Creeds of Nicea and Constantinople Reexamined," *Church History*, 38:248-261 (1969). On later confessions, the fullest recent treatment with good bibliographies is E. MOLLAND, *Christendom* (1959), but this is usually supplemented by W.A. CURTIS, *A History of Creeds and Confessions of Faith in Christendom and Beyond* (1911); and C.A. BRIGGS, *Theological Symbolics* (1914).

(G.A.L.)

## Cretaceous Period

The Cretaceous Period is the youngest period of the tripartite Mesozoic Era. Its name, proposed by Omalius d'Halloy in 1822, referred to chalk (*creta* in Latin), the characteristic rock formed during the period in many parts of Europe (*e.g.*, the White Cliffs of Dover, England). The Cretaceous Period is an internationally accepted time unit, which is geologically well defined regardless of the presence or absence of chalk; it spans 71,000,000 years, from approximately 136,000,000 to 65,000,000 years ago. The Cretaceous was preceded by the Jurassic Period and succeeded by the Tertiary Period of the Cenozoic Era.

The rocks formed during the Cretaceous Period are called the Cretaceous System. They are distributed in various parts of the world and show considerable variation in their lithological character and the thickness of

the sequences. Because a large-scale marine inundation took place during this period, lower areas of various continents were extensively covered by the fine-grained marine sediments, namely chalk, marl, and clay. On the other hand, orogenies, or mountain-building episodes, accompanied by volcanism and plutonic intrusion, took place in the circum-Pacific region and in the site of the Alpine system. In these geosynclinal areas predominantly clastic sediments, including conglomerates, sandstones, shales, and tuffs accumulated in sinking troughs and basins (geosynclines) and were later folded. In many parts of the circum-Pacific area igneous rocks of Cretaceous age are widely exposed.

The Cretaceous Period was a time of great inundation by shallow seas that created swamp conditions favorable for the accumulation of fossil fuels. Many important oil and gas fields produce from subsurface Cretaceous (and also overlying Tertiary) deposits; among them are those of western Siberia, southwestern Asia, the Persian Gulf, northern Africa, Mexico and other areas in North America, Venezuela, and Argentina. Coal measures are also found in some parts of Cretaceous sequences in Siberia, Australia, New Zealand, Mexico, and western United States.

Certain porous, permeable sandstones in the Cretaceous sequence are important for underground water resources (*e.g.*, the Dakota Sandstone of western United States), and certain others are used as glass material. Bauxite produced from the Cretaceous weathering of limestone is an aluminum source in Europe. Cretaceous limestones are quarried for cement and building stone. Smaller pits of clay, shale, and bentonite are worked for ceramic material. The widespread phosphatic beds in the Upper Cretaceous-Lower Tertiary sequence of northern Africa and southern Soviet Union are of economic importance.

In the circum-Pacific mountain systems and island arcs a variety of metals, such as gold, silver, copper, lead, zinc, molybdenum, tungsten, tin, iron, and manganese, were concentrated as ore deposits of various dimensions associated with the igneous activity of the Late Mesozoic.

This article treats the rocks, life, and environments of Cretaceous time. For information on the preceding and subsequent intervals of geological time, see JURASSIC PERIOD, and TERTIARY PERIOD; for an overview of the Cretaceous Period, see MESOZOIC ERA; and for additional detail of relevance on stratigraphy and paleontology, see STRATIGRAPHIC BOUNDARIES, and FOSSIL RECORD.

### WORLD STRATIGRAPHY AND PALEOGEOGRAPHY

The Cretaceous System, the rock sequences formed during the 71,000,000-year Cretaceous time interval, is stratigraphically divided into the Lower and the Upper Cretaceous subsystems, each of which is subdivided into six stages. The 12 stages are indicated in the left column of Table 1. Their names were taken from localities of rock exposures in France and adjacent areas in Switzerland and The Netherlands. The lower four stages are called the Neocomian Series and the upper four the Senonian, although some authors may exclude the Maastichtian Stage from the latter. Each stage is defined by the rock sequence in the type of exposures and also by a particular fossil content of characteristic species. Ammonites, among other fossils, are important for the definition and the international time correlation of the stages. The indices of the ammonite zones in the type sequences in France and related areas in western Europe are shown in the second column of Table 1. The third column cites the belemnites, bivalves, and other ammonites selected as zonal indices for northern Europe, which was part of the Cretaceous boreal province. The stages, thus defined, are now internationally used as time-stratigraphic units, although the characteristic species may differ in separated regions. Tables 1 and 2 show the correlation of the better studied sequences among selected regions of the world.

Some geologists have employed the Danian as the uppermost stage of the Cretaceous from a type section at the top of the chalk sequence in Denmark. The section con-

[illegible]

tains a nautiloid genus, *Hercoglossa*, but no ammonites or belemnites. Recent investigation of microfossils have led many authors to ascribe the Danian to the Paleocene at the base of the Tertiary System, however. Seas have invaded the continents a number of times in geological history. The Cretaceous inundation was one of the greatest because of the extent and duration of the invasions on various continents. The marine transgression, however, may not be synchronous everywhere. The accompanying paleogeographic map indicates the regional differences in the mode of inundation. Major geotectonic conditions (regional deformation of the Earth's crust) also are shown.

Early  
Cretaceous  
time

In the Neocomian Epoch of Early Cretaceous, the marine invasion was extensive around the Arctic Ocean. The Neocomian marine beds, mainly consisting of black bituminous clays, were deposited on the Russian Platform, West Siberian Plain, part of Far East Siberia, Alaska, and adjacent areas in Canada. They contain *Buchia* and particular assemblages of ammonites of the boreal fauna. The boreal fauna extended as far south as western Germany and eastern England in Europe and to California in North America. Neocomian marine beds are present in the Andean region of South America, some parts of southern Africa, Madagascar, and western India. The Neocomian of the Tethys region (principal east-west trending geosyncline from Europe across southern Asia), as exemplified by well-known sequences in southeast France and adjacent areas, and also in Mexico, consists mainly of marls of offshore sedimentary facies (*q.v.*), and, in lesser amount, of limestone and calcareous sandstone of near-shore environmental character. Each facies is characterized by a particular biota.

In the same epoch, lacustrine and deltaic deposits, called the **Wealden**, were formed in lakes and rivers in southern England and adjacent areas of Europe. These contain dinosaur and other fossils. Nonmarine Neocomian beds of a similar type occur on the Atlantic coast of North America, the coastal area of Africa, various parts of Australia, and shoreward of the Neocomian Seas that invaded Siberia. The predominance of coarse clastics in some parts of these nonmarine Neocomian deposits may reflect the crustal instability at or immediately before the beginning of the Cretaceous Period. Earth movements would produce high and low areas, thereby increasing stream gradients and allowing coarser material to be transported to basins. In addition to topography, factors such as climate, of course, affect the nature of the sediment yield of drainage systems (*q.v.*).

Aptian and  
Albian  
stages

In the succeeding times of the Early Cretaceous, in Aptian and Albian Stages, the sea around the Arctic Ocean retreated. Although there are marine beds of those stages in the southern part of Russia, they are **unrelated** to the boreal provinces and are intimately connected with those of the Mediterranean (Tethys) region. In western Europe, the sea invaded the **Wealden** plain resulting in the deposition of glauconite-bearing green sands of near-shore facies. Above the sands lies black clay, called the Gault, of somewhat offshore but not deepwater facies; it is characterized by a wealth of ammonites. The cycle ended with deposition of the upper sand of regressive facies, the Upper Greensand of England (Table 1). In the Mediterranean region, marls and limestones continued to be deposited in Aptian and Albian times, although local variation in facies occurred from place to place, and Aptian glauconitic sandstone may rest disconformably on older rocks in some areas.

At approximately the same time, the sea transgressed the Gulf Coast of North America, depositing a sequence of sandstones, shales, marls, and limestones that are called the Comanche Series (Table 1). In the western interior a roughly contemporaneous **transgression** from the north occurred. Its maximum extent in the Albian, with *Gastropilites-Neogastropilites* faunas, reached as far south as Montana, whereas the invasion from the south, with *Oxytropidoceras* ammonite fauna, reached Kansas.

In Australia the basins that were filled with Neocomian nonmarine deposits were invaded extensively by an Ap-

lian to Albian shallow sea, depositing marls or calcareous mudstones. Coastal swampy sediments formed marginally. In Late Cretaceous times the sea retreated almost entirely from Australia, except for several narrow areas. Fluviolacustrine sediments accumulated in the basins until the area became dry land.

Generally speaking, however, the marine inundation in the Late Cretaceous was of a grand scale in its global extension and its long duration. In Europe, for instance, almost the entire area, except for the Baltic Shield and several islands, was covered by the sea in which was laid down a stratigraphic sequence from Cenomanian to Maastrichtian (to Danian in some places). The rocks characteristically are chalk, with some interbedded marl, sandstone, and siliceous rock. A wide area of western Siberia was under the sea that transgressed from the north, depositing clays and silts and siliceous sediments. Still more extensive areas in the present-day deserts—Libya, Egypt, Arabia, and Central Asia—were invaded by a shallow-sea extension of the Tethys. Calcareous sediments predominated in these regions; clastics were only marginally distributed, as exemplified by the Nubian Sandstone in northeastern Africa. The littoral zone is often represented by phosphatic beds. The maximum inundation in most of the above regions occurred in Turoonian to Senonian times.

In North America (see map), the Late Cretaceous sea invaded deeply into the interior province, forming a broad seaway joining the Gulf of Mexico and the Canadian Arctic Ocean. In that area shale was the main constituent of the sequence. Chalk and limestones were deposited in the southern part of the area during the time of extensive inundation. From the rising cordillera to the west, clastics were transported to the sedimentary basins, where they formed sandstone wedges in the shaly sedimentary sequence. From those basins the present Rocky Mountains rose. The clastic deposits accumulated as thick units (about 4,500 metres [15,500 feet] maximum) in the subsiding basins in front of the rising cordillera, generally thinning out eastward. In this vast seaway, faunas of the Gulf series in the south and the **Colorado-Montana** groups in the north were dissimilar. The northern groups were closely allied to the Upper Cretaceous fauna in the interior provinces of Canada and in Greenland.

The Atlantic coast of the United States was also under a fluctuating shallow sea in Late Cretaceous times. Toward the end of the Cretaceous Period the sea retreated from North America. Nonmarine beds of the Lance Formation rest on the Montana Group. Remains of the dinosaur *Triceratops* have been found in that younger sequence.

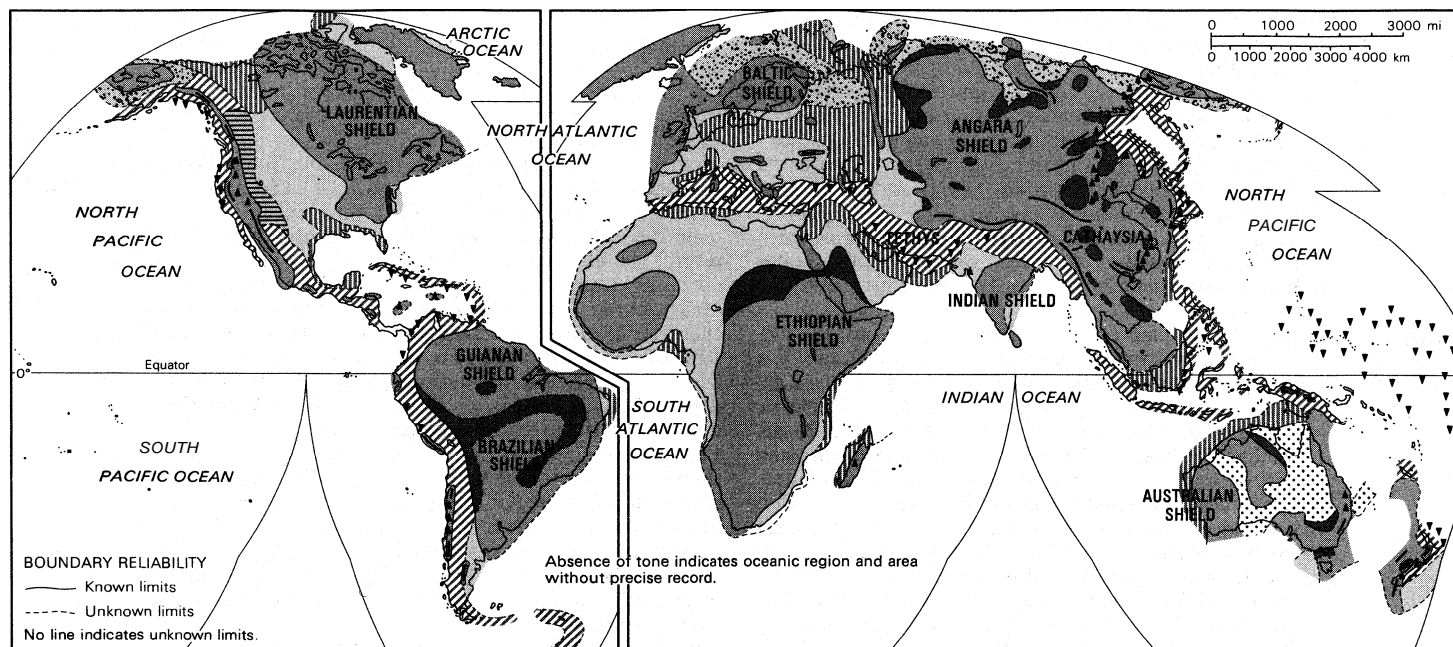

Marine formations from Albian to Maastrichtian in age are exposed in the South Atlantic coastal regions of Brazil and Argentina and of Africa from Nigeria to Angola. In Turoonian time this South Atlantic seaway was connected through Nigeria to an extension from the Tethys in North Africa, as shown by the affinity of the faunas.

In several regions facing the Indian Ocean—the eastern coast of South Africa and Mozambique, coasts of Madagascar, peninsular India, and western and northern Australia—shallow-sea Cretaceous sediments containing common or allied faunas are found. Three times of major transgression are recorded: (1) the older Neocomian, already noted from South Africa, Madagascar, and Kutch (western India); (2) the Albian to Coniacian; and (3) the Santonian to Maastrichtian. These cycles of sedimentation are recognized by examining the prolific fossil faunas and sedimentary sequences of Indo-Pacific affinity (see PALEOGEOGRAPHY; STRATIGRAPHIC BOUNDARIES). Marine Upper Cretaceous rocks are also present on the southern coast of Australia, facing the Antarctic Ocean, and in Antarctica.

A continuous depositional sequence from Cretaceous to Tertiary is observable in a few areas, such as Venezuela, Trinidad, and Egypt, but the precise definition of the Mesozoic-Cenozoic boundary is under debate among the specialists of several geologic disciplines. The retreat of the sea and the rise of the continents at the end of the pe-

## MOUNTAIN-BUILDING AND IGNEOUS ACTIVITY

In the circum-Pacific and Alpine zones, indicated as marine geosynclines and mountain systems (see map), remarkable crustal movements occurred during the Mesozoic and Cenozoic eras (see EARTH, GEOLOGICAL HISTORY OF). The movements began with earlier phases of geosynclinal sinking and sedimentation associated with submarine basaltic volcanism and continued during later phases of orogeny, which included folding, thrusting, regional metamorphism, plutonic intrusion, andesitic to rhyolitic volcanism, and uplift of mountains. The details in the time and mode of activity were dissimilar among provinces. There were a number of such major events of the Cretaceous Period.

In the North American cordillera, the so-called Nevadan orogeny took place in the Sierra Nevada and Klamath mountains in Late Jurassic to Neocomian times; the Santa Lucia, in the Coast Ranges, in Middle to Late Cretaceous times; and the Laramide, in the Rocky Mountains and Sierra Madre Oriental in Late Cretaceous to Early Tertiary times. In the South American Andean system, where marine geosynclinal conditions prevailed in Early Cretaceous times, the mountain building reached its climax in the Mid-Late Cretaceous. In New Zealand the most remarkable orogeny, called the Rangitata, took place in Early Cretaceous times. In Japan the Sakawa orogeny proceeded through a number of phases during the Cretaceous Period. In Far East Siberia the Verkhoyansk and other ranges were formed mainly by Late Jurassic orogeny, referable to the Cimmerian folding, but the crustal mobility continued into Cretaceous times.

In typical examples of these circum-Pacific orogenic systems, the regional metamorphism of high-temperature type and large-scale granitic emplacement occurred on the inner, continental side, whereas geosynclinal sinking, rapid sedimentation, and regional metamorphism predominated on the outer, oceanic side. The voluminous intrusion of granitic rocks, accompanied in some areas by extrusion of volcanic rocks, is one of the most significant

events in geological history. The upheaval of the mountains, subject to intense erosion, kept pace with the subsidence of the trough where a thick pile of clastics was deposited. This is well exemplified by the upheaval of the Sierra Nevada, with intermittent emplacement of granitic bodies and the deposition in the Great Valley of California of thick units of Cretaceous shales and sandstones with many conglomerate tongues.

Another well-studied example is found in southwest Japan, where the inner (northern) belt is characterized by volcanic series, with some nonmarine beds, and also by granitic bodies, which can be grouped into three major cycles from Early Cretaceous through Late Cretaceous to Early Tertiary. The outer (southern) belt comprises the depositional basins of mainly marine Cretaceous to Lower Tertiary sequences of clastics, which can again be grouped into three major cycles. The accumulations are extremely thick in certain belts, in which sedimentation accumulated at the rate of 300 to 500 metres (1,000 to 1,600 feet) per 1,000,000 years (approximately ten times the present average marine rate). Similarly, rapid subsidence, with clastic sedimentation keeping pace with the upheaval of volcanic and granitic mountains, is suggested by the Andean system of South America. These sedimentary groups are often of flysch type (rapidly deposited clastic sediments) and frequently show features of sediments deposited by turbidity currents.

In addition to the mountain systems that were derived from the embedded geosynclines of preceding ages, new geosynclines appeared in Cretaceous times. The new geosynclines, with which submarine basaltic volcanism was associated, went on to subside with more sedimentation and finally became mountain systems or island arcs (*q.v.*) in Cenozoic times. Good examples are: the trough of the Franciscan Group on the Pacific side of California, that of Upper Cretaceous to Lower Tertiary sequence in the Antillean belt encircling the Caribbean Sea, that of the Upper Jurassic to Cretaceous Sorachi and Yezo groups in the meridional belt of Hokkaido and Sakhalin, that of the corresponding groups in Kamchatka, and the so-called Luzon Geosyncline in the eastern Philippines.

The Late Mesozoic crustal movements were not only active in the geosynclines and marginal mountain systems

Circum-Pacific events

Cretaceous geosynclines

that encircle the Pacific Ocean floor but also affected some inland areas extensively. In the continental area of China, Korea, and Far East Siberia, a crustal disturbance called the Yengshan movement occurred intermittently in the period from Jurassic to Cretaceous; it gave rise to inland basins of various dimensions, thrust ranges, faulted blocks, and even volcanoes and granite masses. The old, consolidated, continental mass was thus **tectonically** rejuvenated in Late Jurassic to Cretaceous times. The Maryborough Trough, where thick Cretaceous **clastic** and volcanic rocks were accumulated and then folded, may represent a similarly rejuvenated movement in eastern Australia.

#### Alpine–Himalayan events

Along the Alps–Himalaya orogenic system, **geosynclinal** conditions generally prevailed during Jurassic to Cretaceous time. In the earlier phases of the history of the **geosynclines**, submarine eruptive rocks from basic to **ultra-basic** magma (ophiolites) were predominant in some belts associated with radiolarian cherts (see **SILICEOUS ROCKS**). White pelagic limestones were formed, probably on offshore submarine mounts of moderate depth. Reef limestone accumulated on near-shore, shallower banks. Ammonite-bearing marls may have been deposited at intermediate depths. In the later phases, the major Alps–Himalaya Geosyncline was differentiated into **geanticlinal** ridges and sinking troughs, which migrated as thrusting proceeded. A particular type of sediment called flysch, typically consisting of alternating sandstones and shales with characteristic current marks and displaced fossils, was deposited in the trough. Conglomerates and breccias (*q.v.*) were deposited around the rising ridges, whereas bathyal marls were carried to the distal part of the trough. These and other tectonic and sedimentary features have been studied intensively in the Alps, Carpathians, Pyrenees, and other areas (see **SEDIMENTARY FACIES**).

In the Alpine system of Europe, orogenic phases are known at the middle of the Cretaceous, immediately before the Senonian Gosau Beds, and at the end of the period, although Alpine orogeny did not reach its climax until Early Tertiary times. The history in the Himalayas and other orogenic systems in southern Asia has not been investigated so precisely as has the European Alpine system, but the events in Cretaceous times seem to have been important in the tectonic development of those areas also.

#### Volcanic activity in the Pacific Ocean

In an extensive area of the central and western Pacific Ocean are found groups of volcanic seamounts of basaltic rock with summit depths of 1,300 to 21,000 metres (4,300 to 69,000 feet). Some of them are flat topped, with shelves on their flanks on which rest reef deposits or gravels indicating a shallow-water environment. Some of the deposits contain recognizable Cretaceous fossils. Although the seamounts were formed at various times during the Late Mesozoic and Cenozoic eras, a great number of them were submarine volcanoes building to the sea surface during the Cretaceous. They sank to their present deep levels some time after the age date of their youngest shallow-water fossil. In the northwestern Pacific between that submarine volcanic region and the Japanese islands, chalky sediments containing Cretaceous **microfossils** have been recovered in deep-sea coring operations. The extent of those Cretaceous deposits can be determined by seismic studies. Another such seamount off the southern coast of Hokkaido contains evidence of Cretaceous shallow-water gastropods, indicating that it too must have existed in Cretaceous times, although it may have moved to its present position resting on the westward-spreading sea floor.

#### CRETACEOUS LIFE

#### Invertebrates

Chalk and other offshore fine-grained calcareous sediments consist of the remains of nannoplankton (floating forms). The tiny coccolithophorids and other organisms that often are grouped under the name Protista are so minute that they must be examined by electron microscope. Smaller benthonic foraminiferids (protozoans) are also common in fine-grained sediments, and planktonic

forms, which also contribute to chalk, are widespread and useful for correlating the ages of strata between distant places. Diatoms, radiolarians, ostracods, pollen, and spores also are identified microscopically in some Cretaceous sediments. Detailed study of these microfossils is helpful in the exploration for oil and gas.

On the very shallow banks of tropical to subtropical seas, reef-building organisms such as colonial corals, bryozoa, stromatoporids, and other calcareous algae flourished. Large foraminiferans (Orbitoidaceae); sessile (anchored) bivalves resembling corals, called rudistids; thick-shelled gastropods (nerineids); and certain kinds of echinoids were associated with them. Reefs were distributed mainly in the equatorial Tethys region, including the so-called American Tethys (Caribbean), and they extended to Japan and some central Pacific seamounts at certain times.

Ammonites were predominant among the marine invertebrates of the Cretaceous Period, which also was the final stage in the evolutionary history of this group of cephalopods, which has no Cenozoic survivors. Although the families that lived in the Jurassic persisted up to Early Neocomian times, new families became dominant after the middle of the Neocomian, and other renewed differentiations occurred at a number of times during the Cretaceous. Ammonites of various aberrant forms occur fairly commonly, exemplified by Nipponites and *Madagascariites*. Examples of gigantism are found in certain families, with shells as much as six feet in diameter. Pseudoceratitic sutures (superficially resembling a Triassic simpler type) are present in certain other Middle and Late Cretaceous families.

Belemnites, a group of coleoid cephalopods that left their cigar-shaped internal shells as fossils, occur in Cretaceous rocks but are extremely rare in the Late Cretaceous strata of the Pacific region. Why both ammonites and belemnites became extinct at the end of the Cretaceous Period still lacks explanation. Nautiloid cephalopods slowly and gradually evolved during that period and persist to the present without great change.

Bivalves (clams and relatives) and gastropods (snails) of the Cretaceous Period show a variety of forms, adapting themselves to various environments. Most Trigonians, for instance, lived in shallow, open sea; oysters (including *Ostrea*, *Amphidonta*, *Exogyra*, and *Gryphaea*) in the littoral zone; rudistids and nerineids in Mediterranean reef facies; and some special groups (*e.g.*, *Trigonioides*, *Plicatounio*, *Nipponaia*) in nonmarine basins of eastern Asia. Certain thin-shelled bivalves, such as *Inoceramus*, *Aucellina*, *Maccoyella*, and *Didymotis*, were widely distributed in offshore sediments and are useful as time indicators because of their rapid evolution and wide dispersal. They disappeared at or before the end of the period.

Echinoderms, asteroids, **crinoids**, sponges, brachiopods, bryozoans, simple corals, and decapods (lobsters and crabs) occupied various habitats in the sea. Some of these groups are beautifully preserved and are good material for paleobiologic and evolutionary studies. Estherians (see **BRANCHIOPODA**), tiny bivalved crustaceans, lived in abundance in ponds and lakes and were preserved under certain favourable conditions in continental sediments.

Cretaceous fish faunas generally appear more modern than those of the Jurassic because of the presence of groups that are closely allied to present-day rays, **porbeagle** sharks, herrings, and other bony fishes. *Macropoma*, a coelacanth, has been found fossilized in chalk.

In addition to the ichthyosaurs (fishlike reptiles), the **mosasaurs** (marine lizards), which seem to have eaten fishes and ammonites, were abundant. The pterosaurs, winged reptiles, evidently lived on the seashores or cliffs, soaring to the sea to catch fishes. Their remains are more common in marine sediments. Some pterosaurs in the Cretaceous Period (*e.g.*, *Pteranodon*) were very large with maximum wingspread of eight metres (27 feet). Although the fossils of birds are rare, *Hesperornis* (a flightless diver) and *Zenaidura* (small winged form), whose remains were discovered from the Upper Cretaceous of

#### Vertebrates

Kansas, represent fish-eating seabirds that had long jaws bearing teeth.

Dinosaurs were predominant among the land animals. Characteristic examples include *Tyrannosaurus*, the largest flesh-eating dinosaur; *Iguanodont*, a plant eater that walked on hind feet; *Trachodont*, which had numerous rough teeth; *Triceratops*, with three peculiar horns on the head; and *Struthiomimus*, which probably ate insects or seeds, judging from the elongated bill-like mouth. It is one of the most remarkable events in the history of life that the reptiles (see REPTILIA), which flourished during the Mesozoic Era, declined at the end of the Cretaceous Period, and the dinosaurs became extinct. The mammals (see MAMMALIA), on the other hand, were quite indistinct in Mesozoic times but burgeoned with multiple divergence and development early in the Cenozoic Era.

Plants

The land plants in the Early Cretaceous differed little from those in the Jurassic. The main constituents of the flora were cycadeoids (cyad-like plants), conifers, ginkgos, and ferns. Toward the middle of the period, angiosperms increased their dominance. In the Late Cretaceous the flora became more like those of the Cenozoic Era; they included figs, magnolias, poplars, plane trees, and willows. With the increasing predominance of flowering plants, insects also may have developed in the period; but their fossil record can exist only under special, rare conditions of preservation (see FOSSIL RECORD).

#### CRETACEOUS CLIMATES

On the evidence of fauna and flora distribution, climatic zones are roughly outlined between the tropical to subtropical equatorial Tethys region and the warm or somewhat cooler boreal and austral regions at higher latitudes. Expanded seas of the period should have produced an equitable climate. In the Cretaceous System, evaporites are comparatively few. Coal seams, indicating relatively high humidity, are intercalated in a number of places. Bauxite occurs at the unconformity between limestone sequences of the Cretaceous in some areas of Europe (Hungary, Yugoslavia, southern France, etc.), probably indicating that weathering (q.v.) took place under warm, humid conditions.

Although the quantitative data of paleotemperature are not sufficiently numerous, the available measurements by an oxygen-isotope method on some shells (belemnites and others) indicate warmer seawater even in the boreal region (see CLIMATIC CHANGE; DATING, RELATIVE AND ABSOLUTE). They also suggest some decline of the temperature in the Maastrichtian Stage and possibly also in the Cenomanian. On the basis of the paleomagnetic study of some Cretaceous rocks (see ROCK MAGNETISM), the North Pole is presumed to have been somewhere to the south of the present one. Evidence of glaciers is almost entirely absent in the period, except for the mountain glaciers, which might have existed in the southern part of the then-rising, high Andean orogenic system. So far as the available evidence indicates, the marine Late Cretaceous (Senonian) fauna of the Antarctic Peninsula (Graham Land) was essentially similar to that of nearby Chile and to New Zealand and also had some species in common with the Senonian fauna of India and Japan.

## Crete

The fifth-largest island in the Mediterranean and the largest of the many islands that form part of modern Greece, Crete (Kriti) is officially merely an administrative subdivision, but its extraordinary history has earned the island a status accorded many independent entities with areas much larger than its 3,189 square miles (8,260 square kilometres) and population of about 500,000. The island is relatively long and narrow, stretching for some 152 miles on its east-west axis and varying from 35 to 7½ miles in width.

Lying on Europe's southern fringe, Crete is halfway between Asia Minor and mainland Greece and is twice as far from Libya and Egypt; it also helps enclose the Aegean Sea, a geographical factor that has had considerable influence on its history and culture. Crete's political and economic affairs may be domestically linked with Greece, but the island is an international archaeological and tourist attraction. Crete, moreover, has survived so many challenges to its individuality that there will probably always be people who consider themselves first and foremost Cretans. (For related historical information, see AEGEAN CIVILIZATIONS; see also GREECE; AEGEAN SEA; MEDITERRANEAN SEA.)

**History.** Crete's history is often a part of the eastern Mediterranean's, yet it can boast distinct moments of its own. There is no evidence that man arrived on the island before 6000-5000 BC, and the first inhabitants undoubtedly came from somewhere in Asia Minor or the Levant (possibly from Egypt or Libya). They, their descendants, and subsequent groups of migrants introduced the full range of Neolithic culture—stone tools, cultivated plants, domesticated animals, weaving, pottery, houses, and, by about 3000 BC, copperworking. Whatever the various origins of these peoples, their fusion with the Mediterranean environment produced a Bronze Age culture, which is called the Minoan civilization after the island's legendary ruler Minos. The first centuries (2600-2000 BC, the Early Minoan, or Pre-Palace [Prepalatial] Period) produced nothing more spectacular than fine stone-carved vases and circular vaulted tombs. But, about 2000 BC, "palaces" began to be built on the sites of Knossos, Phaestos, and Mallia, inaugurating the Middle Minoan, or Protopalatial Period. Economic, political, and social organization began to flourish, with increased trade in the eastern Mediterranean, while stone carving, goldwork, jewelry, and pottery demonstrated aesthetic progress.

About 1700 BC, one of Crete's periodic earthquakes destroyed parts of the three major palaces, but there was no break in the continuity of Minoan culture. The palaces were reconstructed and even enlarged, introducing the Middle Minoan III, or New Palace (Neopalatial) Period. These ambitious complexes, with a medley of sculpture, fresco painting, pottery, and metalwork, are still visible today. A rich ceremonial life included snake goddesses and bull-leaping. The Minoans' ships, meanwhile, ranged even farther, possibly as far west as Spain; but whatever power Cretan rulers exercised in those areas was economic. Indeed, since the same Linear B script (as

Minoan  
Bronze  
Age  
civilization

philologists call this early Greek writing) recording the same Greek language was more widespread at Achæan-Mycenaean sites on the Greek mainland than at Minoan sites, it has been conceded that, by about 1500 BC (Late Minoan I), Mycenaean Greeks had assumed an influential, perhaps dominant role in Minoan affairs.

Then, about 1450 BC, Knossos and many other centres suffered another earthquake, possibly related to the catastrophic explosion at Thira, the volcanic island north of Crete. This ushered in the Late Minoan II, or Post-Palace (Postpalatial) Period, completing the Mycenaean Greek ascendancy in Mediterranean commerce. Minoan civilization did not become definitely stagnant, however, until the Iron Age, which commenced about 1200 BC. Eventually the Dorians, another Greek-speaking people, moved in and organized Crete, while some Minoans retreated into the mountains, to become known later as Eteocretans — "true Cretans."
