Among other automatic aids to railroad operation is the infrared "hotbox detector," which, located at trackside, automatically detects the presence of an overheated wheel hearing and alerts the train crew. Broken flange detectors are used in major terminals to indicate the presence of damaged wheels. Dragging equipment detectors set wayside signals to danger if a car's brake rigging or other component is dragging on the track. Slide detectors warn of rocks or earth that have dropped onto the track from an earth cutting; high-water detectors warn of flood conditions on the track; high-wide detectors alert the train crew of a freight load that may have shifted or of a load that is too high or wide to clear bridges or tunnels.

The automated marshalling yard

A major area for automation techniques in railroading is the large classification or marshalling yard. In such yards, freight cars from many different origins are sorted out and placed in new trains going to the appropriate destinations.

Most large classification yards have a “hump” over which cars are pushed. They then roll down from the hump by gravity and each is routed into a classification or "bowl" track corresponding to its destination.

By 1971, operations in the newer classification yards had reached a high degree of automation. The heart of such a yard is a digital computer, into which is fed information concerning all cars in the yard or en route to it. As the cars are pushed up the hump, electronic scanners confirm their identity by means of a light-reflective label, place the data (car owner, number, and type) in a computer, and then set switches to direct each car into the proper bowl track. Electronic speed-control equipment measures such factors as the weight, speed, and rolling friction of each car and operates electric or electropneumatic "retarders" to control the speed of each car as it rolls down from the hump. Every phase of the yard's operations is monitored by a computerized management control and information system.

Modern classification yards usually also use radio, telephone, teleprinter, pneumatic tube, and closed-circuit television. Repair shops adjacent to the yards are designed for quick, mechanized repair of cars found to be defective as they move over the hump.

Because such electronically equipped yards can sort cars with great efficiency, they eliminate the need to do such work at other, smaller yards. Thus, one large electronic yard may permit the closing or curtailing of a dozen or more other yards. Most modern electronic yards have quickly paid for themselves out of operating savings—and this takes no account of the benefits of improved service to shippers.

REGULATION, ECONOMICS, AND LABOUR RELATIONS

Regulation and public control. Although most of the early railroads were built and operated as private, profit-making businesses, railroads soon came under relatively intense public scrutiny and regulation. This was probably inevitable because of the far-reaching influence railroads quickly developed over the life and the commercial activities of the communities and countries they served. The history of regulation followed the same path with minor variations in all countries; beginning with regulation of railroad construction—that is, deciding whether to permit a new line to be built and approving its location—the government took an increasing interest in details of operation, especially in connection with safety. Railway acts were passed in country after country prescribing signal modes, brakes, track standards, employee training, and other aspects of railroad operation. At the same time, governments took an increasing interest in the financial side of railroads, regulating rates and fares and exercising licensing power over mergers and other financial operations. Degree of public regulation varied, but by the early 1970s in nearly every country in the world, with the notable exception of the United States, regulation had evolved into public ownership and operation. This resulted from the railroads' increasing financial difficulties in the course of the 20th century.

Post-war financial problems

Competition from other modes increased sharply after World War 11 for many of the world's railroads. Because of governmental and labour union restrictions, as well as the large investment required in railroad fixed plant (*i.e.*, track, bridges, buildings, stations), it was difficult for the railroads lo adjust their operations to changing conditions. Unlike other kinds of businesses, a main-line railroad simply cannot cease operating when it gets into financial difficulties; its services are too essential to the economy of the area it serves. (Many secondary and branch-line railroads have, however, been pulled up, especially in Britain and the United States.) Thus, the solution has been to nationalize the railroad—to have the government provide the service. Operating deficits are then met out of tax revenues.

By 1971 only two large countries, the United States and Canada, had major railroads that were privately run. In Canada one large system, Canadian Pacific (CP Rail), remained a private enterprise, while the other line, Canadian National Railways, was a government-owned corporation. France nationalized its remaining privately owned railroads in 1938; Britain nationalized its four major companies (which had been formed out of 123 separate railroads after World War I) in 1948.

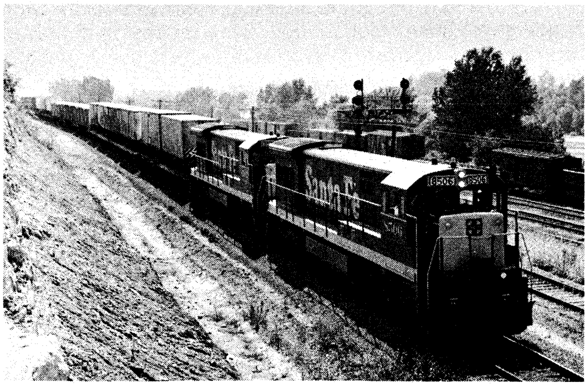
One result of growing financial difficulties in the United States was a wave of mergers during the 1950s and 1960s. Pushed through after protracted regulatory and legal delays were a number of important consolidations. Some of them were the merger of the Erie and the Delaware, Lackawanna and Western railroads to form Erie Lackawanna; Pennsylvania, New York Central, New York, New Haven and Hartford Railroad Company into the Penn Central; merger into the Norfolk and Western Railway of the former New York, Chicago and St. Louis and the Wabash railroads; merger of Atlantic Coast Line and Seaboard Air Line railroads to form Seaboard Coast Line Railroad; merger of Chicago, Burlington and Quincy Railroad, Great Northern Railway, Northern Pacific Railway, and Spokane, Portland and Seattle Railway to form Burlington Northern.

In 1970 the largest railroad in the United States, Penn Central, entered bankruptcy proceedings, and it appeared doubtful that it could be successfully reorganized as private enterprise. Other railroads in that country were also in serious financial difficulties and some form of nationalization appeared increasingly probable.

Innovations by nationalized railroads

While nationalization preserves services felt to be essential, it does not obviate the need for railroads to change, improve, and compete. Some of the most imaginative marketing innovations (for example, Freightliner, Trans-Europ Express, Japan's New Tōkaidō services) have come out of nationally run companies. In France the French National Railways have pioneered in freight-rate innovations. The French National Railways were reorganized to operate much like a privately run business, if possible at a profit. Other nationalized railroads, such as those in Sweden, Switzerland, The Netherlands, and Canada, also operate as much as possible under the incentives of a private business.

Competition and marketing. Planned as money-making enterprises, many early railroads were notably successful financially. Indeed, especially in Britain and the United States, railroad stocks were long highly regarded. Even today, a few of the more strategically located and



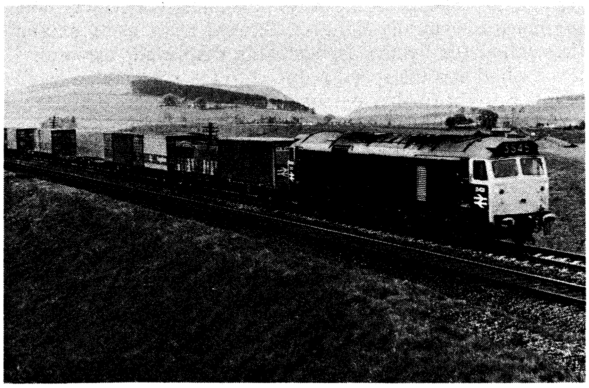


Figure 10: (Left) Santa Fe Railway's new Super C, known as the world's fastest freight train, which goes from Chicago to Los Angeles at top speeds of 79 miles per hour. (Right) British Railways' Freightliner container train, which operates at high speeds throughout the United Kingdom.

well-managed American lines are notably good earners. In recent years, however, the picture has been much different.

The development of the internal-combustion engine and its application to highway vehicles and the invention of the airplane had far-reaching effects on railroad transportation. In the interval between the two world wars, buses, automobiles, and highway trucks were already cutting deeply into traffic that once had been exclusively the railroads'. World War II hastened the technological development of these new competitors as well as of air and pipeline transportation.

By the late 1950s, the inroads of competitors had reached serious proportions, from the railroad viewpoint, in the United States, Britain, and Canada; by 1970 the same situation was developing in western Europe and Japan. The loss of traffic extended to both passengers and freight and was especially pronounced on branch lines. By 1970, railroads in the United States had virtually abandoned the business of carrying intercity passengers, although they still moved much local commuter traffic in several large urban areas. (A quasi-government company, the National Railroad Passenger Corporation [Amtrak], was formed in 1970 to take over and if possible improve the operation of about 200 intercity passenger runs thought to be essential to the national economy.) Railroads in the United States were also suffering from the diversion of profitable freight traffic to trucks and pipelines. Because of the nation's overall economic growth, however, the railroads continued to set records each year in freight volume.

In Britain, western Europe, and Japan, competitors were especially effective in diverting freight traffic from the railroads, although passenger traffic was also affected as the ownership of automobiles grew. Accustomed to competing, if at all, only with each other, the railroads found it hard to adjust their thinking and their operations to meet the challenge of competitors who could offer the public faster, more flexible, and in some cases cheaper service, and who in most cases were burdened much less by government regulation. Many railroads, however, began to fight back against their competitors with considerable success. In the passenger field, typical railroad responses to competition include much faster and more comfortable services, such as the TEE (Trans-Europ Express) services on the European continent, the Inter-City expresses in Britain, and the Metroliners in the United States.

In freight, considerable success has resulted from the "marketing approach," wherein railroads closely tailor their rates, services, and equipment to the particular needs of specific shippers. Typical are the "unit" or "block" trains operated for shippers of bulk commodities, such as coal, oil, ore, and grain. These trains are composed of large, modem cars designed for the commodity to be carried. They operate as a unit on fast schedules between one origin and one destination, bypassing all intermediate yards and terminals en route. With faster operation and larger cars, these trains are so productive that they permit the railroads to offer greatly reduced rates.

Another way in which railroads have responded to new competition is to offer shippers many special types of freight cars designed to load particular commodities quickly and at minimum cost, such as the trilevel autorack car, the 10,000-cubic foot (280-cubic metre) boxcar, and 100-ton (91,000-kilogram) covered hopper cars and gondolas.

The piggyback concept and containerization

Another significant competitive development was piggyback and containerized services (Figure 10). The piggyback idea, which actually dates from the 19th century, combines the flexibility of truck pickup and delivery with the economy of rail movement between cities. Along with piggyback development has come increasing interest among railroads (as well as other modes of transport) in container systems, by which merchandise could be loaded into large standard containers or boxes that could move via highway on a truck chassis, via rail on special container cars, in ships especially equipped to handle them, or even by air. A single shipment might use two or more modes of transport in the course of its trip. In western Europe special TEEM (Trans-Europ Express Merchandise) trains operate between major points, carrying only containers. In Britain, fast container shuttle trains now operate between about two dozen main cities and ports. This Freightliner system (Figure 10) has been highly successful and is said to be competitive with over-the-road trucking, even over relatively short distances. Canadian and Japanese railroads also have extensive container operations, mainly for import-export traffic.

Labour relations. Railroads were among the first industries to feel the effects of trade union activity. Railroad unions in the United States are organized along craft lines; in the early 1970s there were 19 railroad labour organizations. In most countries, however, a single large union embraces all railroad workers. Labour relations are governed by a variety of laws, which, in the democratic countries, guarantee the right of collective bargaining, usually with provision for mediation. Though railroad labour history includes many chapters of violence and bitterness in the past, its more recent era has been relatively peaceful. However, there has been a discernible tendency toward an increase in work stoppages in the 1960s and 1970s.

THE FUTURE OF RAILROADS

The railroad industry can look back over a proud history. Railroads were a vital element in the Industrial Revolution. They helped make Britain an industrial power, played similar roles in countries such as France and Germany, and went on to do much the same in Russia and Japan. Railroads almost literally built the United States and Canada; and they remained the economic backbone of most of the major world powers.

But as the last third of the 20th century began, the railroads in a number of countries, most notably Britain and the United States, were in serious trouble. The railroads' share of the total transportation business was dropping steadily. The railroads in most countries had long since come under state control, and the remaining privately owned lines were finding it difficult to operate at a profit. Some observers believed the end of railroading was in sight. Technology was evolving so rapidly that it was impossible to say, as of the early 1970s, that this could not happen, but it seemed unlikely. It was becoming clear, however, that the railroad of the future would have a different role to play than in the past.

Predictions of the end of railroading

For more than a century the railroad was the dominant form of land transportation in much of the world. It was, and remains, the one land carrier that can carry almost anything, anywhere the tracks go, and do it at a true cost lower than other types of land-air transportation.

Today, however, other modes of transportation have been developed to the point where they can do certain transportation jobs more effectively than the railroads. Pipelines can carry liquids and some solids over long distances economically. Airplanes, with their great speed, can carry some types of light, valuable freight at a saving; and trucks offer speed and flexibility, especially for the shorter hauls. The private automobile, operating over modern highways, and the airplane have taken over much passenger traffic formerly handled on rails. The motorbus is an effective competitor for the short- to medium-distance passenger business. The modern barge, operating on improved inland waterways systems, can move many commodities over specific routes at very low cost.

Undeniably, these competitors of the railroad can do a better job on some types of transportation tasks. The development of these newer modes, therefore, has changed the role of the railroad from that of the general-purpose carrier to that of a more specialized carrier, just as the other modes are specialized.

The future role of the railroad as a specialized carrier will vary in different nations. In general, however, the railroad is particularly strong in these areas:

1. It is especially effective in moving large volumes of bulk commodities, such as coal, ores, chemicals, and grain, over relatively long distances. It can also move large volumes of finished merchandise economically at relatively high speeds over long distances.

2. The railroad can efficiently handle containers in large volumes between major centres, and in some countries, trucks on "piggyback" trains. An efficient railroad container or piggyback shuttle system can be viable even over relatively short distances.

3. The railroad is the best mode for moving large numbers of commuters between big metropolitan centres and the outlying suburban areas.

4. Very high speed intercity passenger services can be successful when operated with modern equipment at distances of up to about 300 miles (500 kilometres).

In short, the railroad under modern conditions is at its best as a high-volume, medium- and long-distance carrier of both passengers and freight. There are, of course, many exceptions to this general rule.

The potential of the modern railroad

In looking at the future place of railroads, three other factors should be noted:

1. A railroad disturbs the natural environment far less than a highway or an air-transport system. It also produces less pollutants per unit of transportation performed than either highway or air transportation. These factors should become more significant as society increasingly concerns itself with the need to preserve the environment and to reduce air, water, and noise pollution.

2. A railroad is far more efficient in its use of fuel than are either highway or air transportation. It is probable that future concern over the best use of these resources will produce more emphasis on rail transportation.

3. While much public money has gone into technological research on the newer forms of transportation and into constructing facilities for them, relatively little has been spent to improve railroad technology. Thus, even the most advanced of today's railroad plants and services, with few exceptions, do not represent anything like the best that is possible from the railroad.

Modern passenger trains. *The New Tōkaidō* Line. In the early 1970s, perhaps the outstanding example of modern railroad technology was the New Tōkaidō Line of the Japanese National Railways (Figure 11). The Tōkaidō (Eastern Sea Route) Line between Tokyo and Osaka serves an area where 40 percent of Japan's population and 70 percent of its industrial output are concentrated. By the early 1960s the original double-track, 3-foot-6-inch- (1.07-metre-) gauge line between those points had reached capacity. The New Tōkaidō Line was opened in 1964 as a completely new, standard-gauge line, entirely separate from the original line, with its own right-of-way and stations, and handling high-speed passenger trains only.

By courtesy of ti-e Museum of Railwav Trafflc, Tokyo

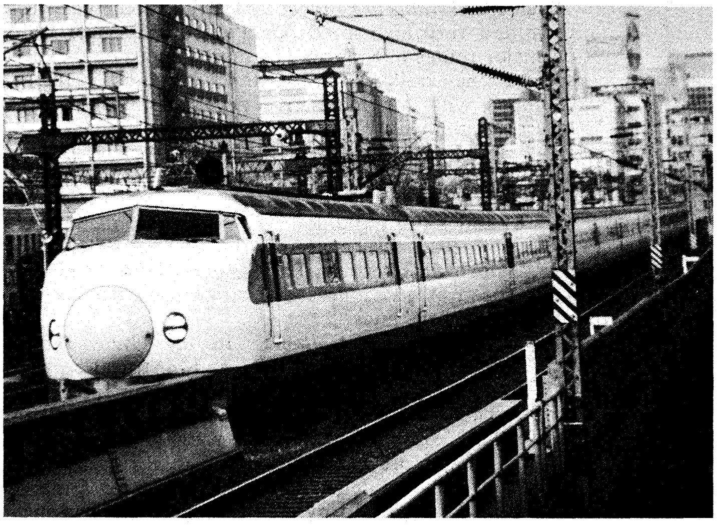

Figure 11: The New Tōkaidō Line train, developed by the Jaoanese National Railwavs. It achieves speeds of uo to 132 miies per hour on its 320-mile run between Osaka and Tokyo. Comprised of six two-car units, the train operates on electric power supplied by overhead wires.

Electrified with a trolley wire voltage of 25,000 volts, 60 hertz, the new line has no grade crossings, and its curves and grades permit operation at 150 miles (240 kilometres) per hour. The track was laid entirely on concrete ties, except at turnouts (switches). Twelve-car electric trains provide the service. The express trains make the 320-mile (510-kilometre) Tokyo–Osaka run in three hours and six minutes, at an average speed of 103 miles (166 kilometres) per hour, stopping at Nagoya-Mura and Kydto. "Limited express" trains make ten intermediate stops and cover the full distance in four hours and ten minutes. The trains reach a maximum speed in normal oyerations of 130 miles (210 kilometres) yer hour.

The New Tōkaidō Line proved outstandingly successful and highly profitable. By the early 1970s it was averaging 233,000 passengers daily, carried in 202 trains (101 each way). Its success prompted the Japanese National Railways to begin constructing a westward extension, the New Sanyo Line, from Osaka toward Hagata, about 350 miles (560 kilometres). This line was expected to open to Okayama, 100 miles (160 kilometres), in 1972; it will handle 16-car trains operating at 155 miles (250 kilometres) per hour. In addition, planning was going ahead for a nationwide network of similar high-speed, standard-gauge trunk lines. Three additional lines—from Tokyo to Morioka, Niigata, and Narita, respectively—were under construction.

Successors to the New Tōkaidō

London–Manchester–Liverpool. Between 1960 and 1966, British Railways carried out a major project to electrify and upgrade its heavy-traffic main lines between London (Euston Station) and Birmingham, Manchester, and Liverpool. This involved electrifying 443 route miles (713 kilometres) or 1,467 track miles (2,360 kiiometres) of line, using a trolley voltage of 25,000, 50 hertz, alternating current. Although this is a modernized existing line, not a completely new railroad as in the case of the New Tōkaidō, it has proved very successful. Passenger carryings on the line doubled in four years after the electrified operation made possible faster, more frequent service. On this line, trains operate regularly at 100 miles (160 kilometres) per hour. Electrification of this line is now being extended all the way to Glasgow.

High-speed trains in France. Electrification has also permitted very high-speed operation of passenger trains on major routes in France. The most famous of the high-speed French trains is the "Mistral," which has now been equipped with the most modern Trans-Europ Express type of equipment. This train makes a daily run between Paris and Nice, 676 miles (1,088 kilometres), at an average speed of 75 miles (120 kilometres) per hour. Another French Trans-Europ Express train, "Le Lyonnais," averages 85 miles (135 kilometres) per hour on its 320-mile (510-kilometre) run between Paris and Lyon. The "Capitole," which runs between Paris and Toulouse, is allowed a top speed of 125 miles (200 kilometres) per hour on some parts of the lines.

The United States Metroliners. In the United States, the strong emphasis on highways and air-travel facilities had, by the 1960s, caused most railroads in the United States to cut their passenger operations drastically. In the Northeast Megalopolis extending roughly from Boston through New York and Washington to Richmond, Virginia, however, the dense population presented a market that could be exploited by a fast, modern rail passenger service. In 1968 the Penn Central railroad, in conjunction with the United States Department of Transportation, began operating an experimental high-speed service on its existing electrified (11,000 volt, 25 hertz) main line between New York and Washington. Comfortable and modern electric multiple-unit train sets provide these services, which in 1971 were taken over by Amtrak (The National Railroad Passenger Corporation). Twelve Metroliner trains daily were operated in each direction as of 1972, with a running time of three hours for the 225-mile (360-kilometre) trip, including five intermediate stops. Average speed is 75 miles (120 kilometres) per hour, but trains are capable of running up to 160 miles (260 kilometres) per hour. The existing line, however, although it has been improved, has a number of highway grade crossings and restrictive curves; top running speed is currently held to 100 miles (160 kilometres) per hour.

Success of the Metroliner

Although the accommodations on the Metroliner trains are as advanced as any, the Metroliners cannot compare in frequency and speed with the high-speed passenger services of other countries described above. Nevertheless, they have reversed a long decline in patronage on the New York–Washington line; the trains consistently operate with large loads of passengers.

Modern freight trains. *Shuttle freight operations.* Perhaps the ideal freight railroad of the future would be one that is essentially a shuttle or "conveyor belt," carrying one commodity continuously between two points. Such a railroad would produce the maximum amount of transportation at the lowest cost. A few such railroads exist; they are mainly mineral railroads carrying coal or ore from mines to points of use.

One such line is an intraplant railroad, double-track, slow-speed, that carries taconite ore from mines 46 miles (74 kilometres) to a boat-loading dock. This relatively short line operates around the clock and carries some 30,000,000 tons of taconite annually; so efficient is the operation that it produces transportation at the rate of about 220,000 gross ton-miles per train-hour (a statistic derived by multiplying the weight of cars and contents by the number of miles hauled, and dividing this figure by the time required) even though half of the train-miles are run empty. This figure is about three times the average of the large general-purpose common carrier railroads in the United States and double the production of the most efficient of the general-purpose railroads.

A one-commodity, shuttle railroad is relatively rare; but similar gains in efficiency can be made on the common carrier railroads by operating unit trains. These are rarely as efficient as the example just cited; but they can be quite effective, especially when operated at fairly high speeds over long distances.

Advantages of the shuttle train

The shuttle-train principle is powerful because it obviates the delay and expense of moving trains through freight yards, since the trains operate directly from shipper to receiver; moreover, it greatly improves the utilization of costly locomotives and cars. Unit trains and similar applications of this principle are being tried by railroads all over the world.

Freightliner and Super C. The container shuttle train holds great promise for similar efficiencies in the hauling of general merchandise. In 1965 the first Freightliner container (Figure 10) shuttle trains began running on British Railways. By 1970 some 28 terminals and container ports were being served; the trains were operating over 80 different routes. More than 500,000 containers were being hauled annually.

The Freightliner system provides an integrated road-rail service direct from shipper to receiver, for both domestic and export–import business. Shippers may use their own containers if they conform to international standards. Space on the fast overnight trains is reserved in advance; the trains operate through to destination without intermediate reclassification in yards. Terminal handling cranes are designed for quick transfer of the containers from rail cars to truck chassis and vice versa. Freightliner service has proved competitive with over-the-road trucking even on many of the shorter runs prevailing in Britain.

Another glimpse of the railroad future is the Santa Fe (United States) railroad's Super C, a freight train carrying only containers or highway trailers. Super C runs 2,200 miles (3,500 kilometres) between Chicago and Los Angeles in less than 40 hours, at an average speed greater than that of the road's fast passenger trains. At this speed, the railroad is more than competitive with express trucks operating over highways.

The examples cited above are representative of some of the better achievements of present-day railroad technology. If they become typical instead of exceptional and if research can further improve existing technology, the railroad of steel rails and flanged wheels will remain viable for many years to come. Passenger train speeds of 125 to 150 miles (200 to 240 kilometres) per hour and freight train speeds up to 100 miles (160 kilometres) per hour can become entirely routine.

Exotic systems. In the 1960s and early 1970s, considerable interest developed in the possibility of building tracked passenger vehicles that could go much faster than conventional trains. Experiments conducted by the Japanese National Railways and others had indicated that the practical upper limit of speed for flanged-wheel railroad vehicles might be in the range of 150 to 200 miles (240 to 320 kilometres) per hour.

A tracked air-cushion vehicle

Several new types of guided vehicle systems have been proposed for possible ultra-high-speed operation. One of the more promising is the tracked air-cushion vehicle, as exemplified by the French Aerotrain (Figure 12). Air-cushion vehicles use a "cushion" of low-pressure air to "float" the vehicle away from the group or the guideway; they have no wheels and, when running, no contact with the guideway.

The Aerotrain has been under development for some years. It is a single vehicle that runs on an elevated beam-

By courtesy of Rohr Corporation

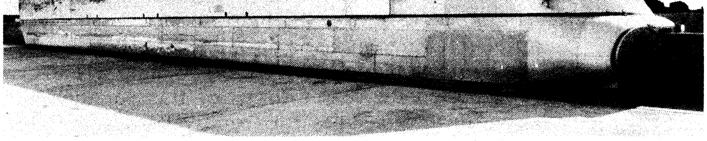

Figure 12: Demonstration model of the French Aerotrain in operation on an 11-mile guideway near Orléans, France. Running at a maximum speed of 170 miles per hour, the train rides on a cushion of air less than one inch above its inverted T-shaped concrete monorail.

way that has a vertical centre guide beam. A prototype 80-passenger vehicle designed for intercity operations used fans to obtain the air for lift and lateral guidance; a propeller driven by two high-powered gas turbines provides propulsion. It has been under test on an elevated guideway near Orléans, France, where it has achieved speeds of up to 180 miles (290 kilometres) per hour. The test section may eventually become part of a projected '70-mile (110-kilometre) Paris–Orléans route.

A tracked air-cushion vehicle project is also under way in Britain. The vehicle, which will be tested at speeds up to 150 miles (240 kilometres) per hour, will be propelled by a linear induction motor. The linear induction motor could also be applied to conventional flanged-wheel vehicles; the United States Federal Railroad Administration is experimenting with this application.

Another proposed type of guided high-speed system is the magnetic-levitation, vacuum-tube system. Vehicles would run at very high speeds in underground tubes from which the air would be exhausted. They would be held away from the tube walls by magnetic force. So far, only small-scale experimental work has been done on this concept.

At their state of development in the early 1970s, none of these proposed systems seemed likely soon to displace the conventional railroad as an all-around high-volume, low-cost mover of both people and goods. They did, however, show promise as high-speed city-to-airport links and perhaps for certain high-speed intercity runs. Much depended on whether the costs of building and operating these still experimental systems could he made comparable to those of the proven flanged wheel, steel-rail system.

Rājasthān

Rājasthān, a state of the Indian Union, is situated in the northwest of India. It is bounded on the west and northwest by Pakistan, on the north and northeast by the states of Punjab, Haryana, and Uttar Pradesh, on the east and southeast by Uttar Pradesh and Madhya Pradesh, and on the southwest by Gujarāt. The Tropic of Cancer passes through its southern tip in the Bānswāra district. The state has an area of 132,149 square miles (342.267 square kilometres) and its population at the 1971 census war 25,724,000. The capital city is Jaipur.

"The abode of the rajas"

Riijasthiin, meaning "the abode of the rajas," was formerly called Rājputana, "the country of the Rājputs" (sons of rajas). Before 1947, when India achieved independence from British rule, it comprised 18 princely states, two chiefships, the small British-administered province of Ajmer-Merwara, and a few pockets of territory outside the main boundaries. After 1947 the princely states and chiefships were integrated with India in stages, and the state took the name of Rājasthān. It assumed its present form on November 1, 1956, when the act for the reorganization of the Indian states came into force (for an associated physical feature, see THAR DESERT).

History. Archaeological exploration has shown that early man lived along the banks of the Banās and its tributaries some 100,000 years ago. Harappan and post-Harappan culture (3rd–2nd millennium BC) is traceable at Kalibangan, Ahār, and Gilund. Pottery fragments at Kalibangan are carbon-dated to 2700 BC. The discovery near Bairāt of two rock inscriptions of the emperor Ásoka (*c.* 250 BC) seems to show that his rule extended westward to this part of the state. Later rulers of the whole or parts of the state were the Bactrian Greeks (2nd century BC), the Scythians (Sakas; 2nd to 4th centuries AD), the Gupta dynasty (4th to 6th centuries), the White Huns (6th century), and Harṣavardhana, a Rājput ruler (early 7th century). Between the 7th and 11th centuries several Riijput dynasties arose, including that of the Gurjara-Pratihiiras, who kept the Arab invaders of Sind at bay.

Rājput strength reached its zenith at the beginning of the 16th century under Rānā Sangriim Singh (Sāngā) of Mewār, but he was defeated in a fierce battle by the Mughal invader Bābur, and the brief splendour of a united Rājputana waned rapidly.

When the Mughal emperor, Akbar, came to power in midcentury, the chief of the Kachwāhās at Amber entered the imperial service; Jodhpur and Chitor were subdued. It is noteworthy that the emperors Jahāngīr and Shāh Jahān were both born of Riijput mothers. After the death (1707) of the emperor Aurangzeb, the Riijput state of Bharatpur was developed by a Jat conqueror, but by 1803 most of the rest of Riijputana was under the domain of the Marāthā people of the central Arabian coast. Later in the 19th century the British subdued the Marāthās and with the gradual penetration of British paramountcy the boundaries of the Riijput states were precisely defined. The government of India was represented in Riijputana by a political officer, styled agent to the governor general, who was also chief commissioner of the small British province of Ajmer-Menvara. Under him were residents and political agents who were accredited to the various states.

The birth of nationalism

During this period the idea of Indian nationalism was born. Maharishi Dayanand wrote at Udaipur his *Satydrath Prakāsh*, intended to restore Hinduism to its pristine purity, which created a ferment in Riijputana. Important movements of thought also occurred among the Jain *sādhus* ("holy men") and scholars. Ajmer was the centre of political activity, and nationalist leaders included Arjun Lal Sethi, Manik Lal Varma, Gopal Singh, and Jai Narain Vyas. The people of Rājputana joined the people of the rest of India in nationalist aspirations and were no longer morally dominated by the princes. When the new constitution of India came into force in 1950 Rājasthān became an integral part of India. The Rājput princes surrendered their powers to the central government.

The landscape. The Arāvalli Hills form a line across the state running roughly from Mount Abu, which is 5,650 feet (1,722 metres) high, in the southwest to Khetri in the northeast. About three-fifths of the state lie northwest of this line, leaving two-fifths in the southeast. These are the two natural divisions of Rājasthān. The northwest tract is sandy and unproductive with little water but improves gradually from desert land in the far west and northwest to comparatively fertile and habitable land toward the east. The area includes the Thar (Great Indian) Desert.

The southeastern area is higher (330 to 1,150 feet [100 to 350 metres] above sea level), more fertile, and very diversified in character. In the south lies the hilly tract of Mewār. A large area of the districts of Kota and Biindi forms a tableland; to the northeast of this there is a rugged region following the line of the Chambal River. Farther north the country levels out; the flat plains of Bharatpur district form part of the alluvial basin of the Yamuna River.

The rivers of Rājasthān

The Arāvallis form the most important watershed, the drainage to the east of the range flowing northeast. The Chambal is the only large and perennial river. Its principal tributary, the Banās, rises in the Arāvallis near Kumbhalgarh and collects all the drainage of the Mewiir Plateau. Farther north, the Bāngangā, after rising in Jaipur, flows east to join the Yamuna. In the northwestern sector the Lūni is the only significant river. This rises in the Pushkar Valley of Ajmer and flows 200 miles west-southwest into the Rann of Kutch.

The soils. The soils in the vast sandy northwestern plain of the districts of Jaisalmer, Barmer, Jālor, Sirohi, Jodhpur, Bikaner, Gangānagar, Jhiinjhunu, Sikar, Pāli, and Nāgaur improve in fertility toward the east and northeast. These soils are predominantly saline or alkaline. Water is scarce but is found at a depth of 100 to 200 feet. The soil and sand are calcareous (chalky). Nitrates in the soil increase its fertility.

The soils in the Ajmer district in central Rājasthān are sandy; clay content varies between three percent and nine percent. The salt content is low. In Jaipur and Alwar districts in the east soils vary from sandy loam to loamy sand. In the Kota, Biindi, and Jhālawār tract, they are in general black and deep and are well drained. In Udaipur, Chitorgarh, Diingarpur, Biinswiira, and Bhīlwāra the eastern area has mixed red and black and the western area red and yellow soils.

Climate. There is a wide range of climate varying from extremely arid to humid, the humid zone comprising the Sirohi, Bānswāra, and Jhālawār districts in the south. Except in the hills, the heat in summer is great everywhere, with a mean maximum of 108" F (42° C). Hot winds and dust storms occur, especially in the desert tract. Winter temperatures vary from 68° F to 76° F (20" C to 24.5" C). The western desert has little rain (annual average ten centimetres [four inches]), but in the southwest rainfall is copious. The southwest benefits from both the Arabian Sea and Bay of Bengaı summer monsoon winds, which bring 90 percent of the rainfall.

Vegetation. The main floral feature is scrub jungle. Toward the west, plants characteristic of the arid zone occur, such as tamarisk and false tamarisk. Trees are scarce, found only sparingly in the Ariivallis and in eastern Rājasthān.

Wild life. Tigers are found in the Ariivallis and in several districts. Leopards, sloth bears, sambur (dark brown Indian deer), and chital (a kind of deer) occur in the hills and forests, where *nīlgais* (blue bulls) are also to be found in parts; black buck and ravine deer are numerous in the plains. Snipe, quail, partridge, and wild duck occur everywhere except in the desert. The Bikaner region is well known for several species of sand grouse.

Tribal peoples

Population. Aboriginal tribes in Alwar, Jaipur, Bharatpur, and Dholpur areas include the Mīnās; the Meos; the Banjārās, who are travelling tradesmen and artisans; and the Gadia Lohārs, another itinerant tribe, who make and repair agricultural and household implements. The Bhils, one of the oldest tribes in India, inhabit the former princely states of Diingarpur and Bānswāra and parts of Partāpgarh, Mewār, and Sirohi. Typical Bhils are small, dark, and broad-nosed. They are famous for their skill in archery. The Grasias and Kathodis live in the Mewiir Hills. The Grasias are tall, with good physique; unflinching loyalty to tribe, friends, or employers is a feature of their character. The Kathodis are nomads, Sahariyas are found in the Kota district, and the Rebaris of Mārwār are cattle breeders.

The Rājputs form, though representing only a small percentage of the population, the most important section of the population in Rājastān. They are proud of their warlike reputation and of their ancestry. The Brahmin class is subdivided into many *gotras,* while the Mahājan (the trading class) is subdivided into a bewildering number of groups. Some of these groups are Jains, some Hindus. In the north and west the Jāṭs and Gujars are among the largest agricultural communities.

The four main dialects

Linguistic patterns. The principal language of the state is Rajasthani, comprising a group of Indo-Aryan dialects derived from Dingal, a tongue in which bards once sang of the glories of their masters. The four main dialects are Marwari (in western Rājasthān), Jaipuri or Dhundari (in the east and southeast), Malwi (in the southeast), and, in Alwar, Mewati that shades off into Braj Bhasa in Bharatpur district. The use of Rajasthani is declining with the spread of modem education, its place being taken by Hindi.

Religious affiliations. Hinduism is the religion of much of the population and takes the form of the worship of Brahmā, Siva, Sakti, Viṣṇu, and other gods and goddesses. There are also followers of the Arya Samaj, a reforming sect of modern Hinduism, and of other forms of that religion. Jainism (*q.v.*) is also important; it has not been the religion of the rulers of Rājasthān but has its followers among the trading class and the wealthy section of society. Mahāvīrji, Ranakpur, Dhulev, and Karera are the chief centres of Jain pilgrimage. Another important religious sect is formed by the *Dādūpanthīs*, the followers of Dādū (d. 1603) who preached the equality of all men, strict vegetarianism, total abstinence from intoxicating liquor, and life-long celibacy.

Islām expanded in Rājasthān with the conquest of Ajmer by Muslim invaders in the late 12th century. Khwājah Mu'in-ud-Din Chishti, the Muslim missionary, had his headquarters at Ajmer; and Muslim traders, craftsmen, and soldiers settled there. There are also a few Christians and Sikhs in the state.

Rural and urban settlements. Rājasthān is one of the least densely populated states in India. There are 195 persons per square mile. Of the 32,000 villages and 145 towns and cities, the greater number lie east of the Arāvallis. The urban population has been growing faster than the rural, but even so there are only seven towns with more than 100,000 inhabitants: Jaipur, Ajmer, Jodhpur, Udaipur, Kota, Bikaner, and Alwar. There are no industrial complexes.

Rural houses are huts with mud walls and roofs thatched with straw. They have a single door, but no windows or ventilators. The houses of well-to-do farmers and artisans in larger villages have more than one room. They are roofed with tiles and have a veranda and large courtyard, whose main door will admit a loaded bull cart. The earthen floors are coated with mud and dung.

Administration **and** social conditions. Rājasthān state is headed by a governor, appointed by the president of the Indian Union, whom he represents, for a five-year term; he exercises administrative, legislative, financial, and judicial powers. The powers of the state government are controlled by the Legislative Assembly, which is unicameral and consists of 184 elected members; 52 seats are reserved for representatives of the scheduled castes and tribes. The state is divided into 26 districts: Ajmer, Alwar, Biinswiira, Barmer, Bharatpur, Bhīlwāra, Bīkaner, Biindi, Chitorgarh, Churu, Dūngarpur, Gangānagar, Jaipur, Jaisalmer, Jālor, Jhālawār, Jhiinjhunu, Jodhpur, Kota, Nāgaur, Pāli, Sawai Mādhopur, Sikar, Sirohi, Tonk, and Udaipur.

In each district the collector, who is also the district magistrate, is the principal representative of the administration. He functions in close cooperation with the superintendent of police to maintain law and order in the district; he is the principal revenue officer; he coordinates the activities of the other departments in the district; and acts as a link between the state government and people.

Rule by *pañcāyat*

RBjasthBn was the first state to try the experiment of *pañcāyat rāj* (rule by *pañcāyat*, or village committee); the system has elicited a response among the villages. In 1968–69 there were about 33,000 educational establishments in Rājasthān, including the three universities of Jaipur, Udaipur, and Jodhpur and the Birla Institute of Science and Technology at Pilani. There were in all about 3,000,000 students and 89,000 teachers. There are 400 state hospitals and dispensaries. There are also many Ayurvedic and Unani (a medicinal system using prescribed herbs and shrubs) institutions. The state incurs heavy expenditure on education, on maternity and child welfare, on rural and urban water supplies, and on the welfare of the backward classes.

The economy. By the end of the third five-year plan (1966) Rs. 3,650,000,000 (Rs. 7.58 = $1 U.S.; Rs. 18.19 = £1 sterling) has been spent on development schemes. The techno-economic survey of 1962 envisaged per capita income nearly doubling in the period from 1960–61 to the early 1970s.

Agriculture. Rājasthān is a predominantly agricultural and pastoral state. Against all probability, food production was increased by about 54 percent during the 12 years 1955–56 to 1967–68 and instead of being a food deficit state as hitherto, Rājasthān began to export food grains and vegetables. Despite a low and erratic rainfall, nearly all types of crops are grown; in the desert area, *bājrā* (millet); in Kota *jowār* (sorghum); in Udaipur mainly maize. Wheat and barley are fairly well distributed, except in the desert area, as are pulses (the edible seeds of leguminous plants, such as peas, beans, and lentils) and oil seeds. Improved varieties of rice have been introduced, and this crop was expected to be expanded in the areas of the Chambal and Rājasthān Canal projects. Cotton is an important cash crop in the south and north. The use of improved agricultural implements is increasing.

Animal products

Although more than half its area is arid or semi-arid, RBjasthBn has a large livestock population in comparison with the rest of India and is the largest wool-producing state. It has a monopoly in camels and in draught animals of various breeds.

Irrigation. Having much arid land, RBjasthBn needs extensive irrigation works. By the early 1970s about 11 percent of the cultivated area was irrigated, more than half by wells and about one-third by canals. RBjasthBn already received 2,870,000 acre-feet of water from the Punjab rivers and was to receive more. It was also claiming a share from the Gurgaon (Haryana) and Agra canals (Uttar Pradesh) and from the Narmada River to the south. These resources, properly utilized, would bring one-third of the cultivated land under irrigation. There are thousands of tanks (village ponds or lakes), but they suffer from drought and silt. In about 1969 the Rājasthān Underground Water Board found a large water supply near Jaisalmer. Rājasthān shares the Bhākra Nangal project with the Punjab and the Chambal Valley project with Madhya Pradesh; both are used to supply water for irrigation as well as for drinking purposes. The Rājasthān Canal project is the largest in the state.

Industries. When the state was formed in 1949 there were only about 900 registered industrial units, but after the establishment of the Directorate of the Economic and Industrial Survey and the Directorate of the Small Industries Service Institute the number of factories rose to more than 2,000 (1969). The main industries are based on textiles, oil, wool, minerals, and chemicals, while the handicrafts formerly patronized by the princely courts have been earning much foreign exchange. Various industrial concerns received substantial loans and subsidies from the government and from the Rājasthān Finance Corporation, a semi-governmental agency.

Kota, which by the early 1970s was becoming the industrial capital of the state, has a nylon factory and a precision-instruments factory, as well as plants for the manufacture of calcium carbide, caustic soda, and rayon tire cord. There is a zinc smelter plant near Udaipur.

Consumption of electricity rose from 274,350,000 kilowatt-hours in 1963–64 to 417,608,000 kilowatt-hours in 1967–68. Electricity supplies are obtained from neighbouring states as well as from the Chambal Valley project. The atomic-energy plant at Rāwatbhāta was due to be commissioned in the early 1970s.

Exploration for oil

Exploration for oil was taking place in the Jaisalmer district in the early 1970s. New mineral deposits recently discovered include copper, zinc, limestone, gypsum, lignite, and marble.

Transportation and communications. The total length of roads of all categories in 1968–69 was 19,500 miles (31,380 kilometres) of which 3,750 miles (6,030 kilometres) were fair-weather roads. Strategic roads were being built in the western sector. There were 81,000 motor vehicles in the state in 1969.

There are 3,868 miles of railway track in the state, of which 3,615 miles are meter gauge. Air services connect Jaipur, Jodhpur, Kota, and Udaipur with Bombay, Delhi, and Agra. Telephone and telegraph facilities are provided at all subdivisional and *tahsil* (district administration) headquarters and at about 100 other centres with a population of 5,000 or more.

Cultural life. Hardly a month passes in Rājasthān without a religious festival. The most remarkable and typical is the festival called Gangor, when clay images of Mahādevī and Pārvatī (representing the benevolent aspects of the Hindu mother goddess) are worshipped by women of all castes for 15 days and are then taken out to be immersed in water. Their procession is joined by priests and officers and is led to the water by trumpeters and drummers. Hindus and Muslims join in each others' festivals; general enthusiasm and gaiety prevail on these occasions.

Another important festival is held at Pushkar near Ajmer, taking the form of a mixed religious festival and livestock fair. It is visited by farmers from all over the state, bringing their camels and cattle, and by pilgrims seeking salvation. The average number of visitors ranges between 100,000 and 300,000.

The typical folk dance of Rājasthān is the *ghoomar*, which is performed on festive occasions only by women. The *geer* dance (performed by men and women), the *panihari* (a graceful dance for women), and the *kacchi ghori* (in which male dancers ride dummy horses) are also popular. The most famous song is the *Kurja*, which tells the story of a woman who wishes to send a message to her absent husband by the *kurja* (a bird), who is promised a priceless reward for his service. RBjasthBn has made its contribution to Indian art, and there is a rich literary tradition, especially of bardic poetry. Chand Bardai's poem, *Prithvi Raj Rasak*, the earliest manuscript of which dates back to the 16th century, is particularly notable. A popular source of entertainment is the *khyāl*, a dance drama composed in verse with gay, historical, or romantic themes.

Rājasthān abounds in objects of antiquarian interest: early Buddhist rock inscriptions, Jain temples, forts, splendid princely palaces, and Muslim mosques and tombs.

Raleigh, Sir Walter

Sir Walter Raleigh (Ralegh), an English soldier, seaman, courtier, writer, explorer, and favourite of Queen Elizabeth I, was also an early English colonizer in America.

A younger son of Sir Walter Raleigh (died 1581) of

Fardell in Devon, by his third wife, Katherine Gilbert (*née* Champernowne), Raleigh was born in 1554 at Hayes Barton near Budleigh Salterton, Devon. In 1569 Raleigh fought on the Huguenot (French Protestant) side in the Wars of Religion in France and later is known to have been at Oriel College, Oxford (1572), and at the Middle Temple (law college, 1575). In 1580 he fought against the Irish rebels in Munster, and his outspoken criticism of the way English policy was being handled in Ireland brought him to the attention of Queen Elizabeth. By 1582 he was the reigning favourite and began to acquire lucrative monopolies, properties, and influential positions. His Irish service was rewarded by vast estates in Munster, where his name is associated with Youghal, Cork, and Lismore. In 1583 the Queen secured him a lease of part of Durham House in the Strand, London, where he had a monopoly of wine licenses (1583) and of the export of broadcloth (1585), and he became warden of the stannaries (the Cornish tin mines), lieutenant of Cornwall, vice admiral of Devon and Cornwall, and frequently sat as a member of Parliament. In 1585 Raleigh was knighted and in 1587 became captain of the queen's guard. His last appointment under the crown was as governor of Jersey (one of the Channel Islands) in 1600.

Effectof his marriage on the Queen

In 1592 Raleigh acquired the manor of Sherborne in Dorset. He wanted to settle and found a family. His marriage to Elizabeth, daughter of Sir Nicholas Throckmorton, possibly as early as 1588, had been kept a secret from the jealous queen. In 1592 the birth of a son betrayed him, and he and his wife were both imprisoned in the Tower of London. Raleigh bought his release with profits from a privateering voyage in which he had invested, but he never regained his ascendancy at court. The child did not survive; a second son, Walter, was born in 1593, and a third son, Carew, in 1604 or 1605.

As a favourite, Raleigh was not popular. His pride and extravagant spending were notorious, and he was attacked for unorthodox thought. A Jesuit pamphlet in 1592 accused him of keeping a "School of Atheism," but he was not an atheist in the modern sense. He was a bold talker, interested in skeptical philosophy, and a serious student of mathematics as an aid to navigation. He also studied chemistry and compounded medical formulae. Some scholars have linked "School of Atheism" with a vaguely similar phrase, the "School of Night," which occurs in *Love's Labour's Lost,* and have read Shakespeare's play as a satire on Raleigh.

Raleigh's breach with the Queen widened his personal sphere of action. Between 1584 and 1589 he had tried to establish a colony near Roanoke Island (in present North Carolina), which he named Virginia; but he never set foot there himself. In 1595, he led an expedition to what is now Guyana, in South America, sailing up the Orinoco River in the heart of Spain's colonial empire. He described the expedition in his book *The Discoverie of Guiana* (1596). Spanish documents and stories told by Indians had convinced him of the existence of Eldorado, a fabulous city of gold in the interior of South America. He did locate some gold mines, but no one supported his project for colonizing the area. In 1596 he went with Robert Devereux, earl of Essex, on an unsuccessful expedition against the Spanish city of Cádiz, and he was Essex' rear admiral on the Islands voyage, in 1597, an expedition to the Azores in the West Indies.

Raleigh's aggressive policies toward Spain did not recommend him to the pacific King James I (reigned 1603–25), Elizabeth's successor. His enemies worked to bring about his ruin, and in 1603 he and others were accused of plotting to dethrone the King. Raleigh was convicted on the written evidence of Henry Brooke, Lord Cobham, and, after a last-minute reprieve from the death sentence, was consigned to the Tower. He fought to save Sherborne, which he had conveyed in trust for his son, but a clerical error invalidated the deed. In 1616 he was released but not pardoned. He still hoped to exploit the wealth of Guyana, arguing that the country had been ceded to England by its native chiefs in 1595. With the King's permission, he financed and led a second expedition there, promising to open a gold mine without offending Spain. A severe fever prevented his leading his men upriver. His lieutenant, Lawrence Kemys, burned a Spanish settlement but found no gold. Raleigh's son Walter died in the action. King James invoked the suspended sentence of 1603, and on October 29, 1618, after writing a spirited defense of his acts, Raleigh was executed.

Writings

Popular feeling had been on Raleigh's side ever since 1603. After 1618 his occasional writings were collected and published, often with little discrimination. The authenticity of some minor works attributed to him is still unsure. Some 560 lines of verse in his hand are preserved. They address the queen as Cynthia and complain of her unkindness, probably with reference to his imprisonment of 1592. His best known prose works in addition to *The Discoverie of Guiana,* are *A Report of the Truth of the fight about the Iles of Açores this last Sommer* (1591; generally known as *The Last Fight of the Revenge)* and *The History of the World* (1614). The last work, undertaken in the Tower, proceeds from the Creation to the 2nd century BC. In the work history is shown as a record of God's providence, a doctrine that pleased contemporaries and counteracted the charge of atheism. King James was meant to note the many warnings that the injusticeof kingsis always punished.

Raleigh survives as an interesting and enigmatic personality rather than as a force in history. He can be presented either as a hero or as a scoundrel. His vaulting imagination, which could envisage both North and South America as English territory, was supported by considerable practical ability and a persuasive pen, but some discrepancy between the vision and the deed made him less effective than his gifts had promised.

Rāmānuja

Early life and development

Rāmānuja, also Rāmānujācārya (Tamil, Iḷeya Perumāḷ), a south Indian brahmin, theologian, and philosopher, was the single most influential thinker of devotional Hinduism. Information on his life consists only of the accounts given in the legendary biographies about him, in which a pious imagination has embroidered historical details. Rāmānuja was born according to tradition about 1017 in Śrīperumbūdūr near Kāñcī (Kānchipuram) in southern India, in what is now Tamil Nadu (formerly Madras) state. He showed early signs of theological acumen and was sent to Kāñcī for schooling, under the teacher Yādavaprakāśa, who was a follower of the monistic system of Vedanta of Sankara, the famous 8th-century philosopher. Rāmānuja's profoundly religious nature was soon at odds with a doctrine that offered no room for a personal god. After falling out with his teacher he had a vision of the god Viṣṇu and his consort Śrī, or Lakṣmī, and instituted a daily worship ritual at the place where he beheld them. He became a temple priest at the Varadarāja temple at Kāñcī, where he began to expound the doctrine that the goal of those who aspire to final release from transmigration is not the impersonal Brahman but rather Brahman as identified with the personal god Viṣṇu. In Kāñcī, as well as Srirangam, where he was to become head priest at the Raṅganātha temple, he developed the teaching that the worship of a personal God and the soul's union with him is an essential part of the doctrines of the *Upaniṣads* (ancient speculative texts that are part of Hindu sacred scriptures) on which the system of Vedanta is built; therefore, the teachings of the Vaiṣṇavas and Bhāgavatas (worshippers and ardent devotees of Viṣṇu) are not heterodox. In this he continued the teachings of Yāmuna (Yāmunācārya; 10th century), his predecessor at Śrīraṅgam, to whom he was related on his mother's side. He set forth his doctrine in three major works, the *Veddrtha-samgraha, Śrī-bhāṣya,* and *Bhagavadgitd-bhāṣya.*

Rāmānuja, bronze sculpture, 12th century. From a Vishnu temple in Tanjore district, India

Like many Hindu thinkers, he made an extended pilgrimage, circumambulating India from Rāmeśvaram (Adams Bridge), along the west coast to Badrīnāth, the source of the holy river Ganges, and returning along the east coast. Tradition has it that later he suffered from the zeal of King Kulottunga of the Cōla dynasty, who adhered to the god Śiva, and withdrew to Mysore, in the west. There he converted numbers of Jains (adherents of a dualistic, ascetic sect), as well as King Bittideva of the Hoyśala dynasty; this led to the founding in 1099 of the town Milukote (Melcote, Mysore state) and the dedication of a temple to Śelva Piḷḷai (Sanskrit, Saṃpatkumāra, the name of a form of Viṣṇu). He returned after 20 years to Śrīraṅgam, where he organized the temple worship, and, reputedly, he founded 74 centres to disseminate his doctrine. After a life of 120 years, according to the tradition, he passed away in 1137.

Rāmānuja's chief contribution to philosophy was his emphasis that discursive thought is necessary in man's search for the ultimate verities, that the phenomenal world is real and provides real knowledge, and that the exigencies of daily life are not detrimental or even contrary to the life of the spirit. In this emphasis he is the antithesis of Sankara, of whom he was sharply critical and whose interpretation of the scriptures he disputed throughout his life. Like other adherents of the Vedānta system, Rāmānuja accepted that any Vedanta system must base itself on the three "points of departure," viz., the *Upaniṣads*, the *Brahma-sūtras* (brief exposition of the major tenets of the *Upaniṣads*), and the *Bhagavadgitd,* the colloquy of the god Kṛṣṇa and his friend Arjuna. He wrote no commentary on any single *Upaniṣad* but explained in detail the method of understanding the *Upaniṣads* in his first major work, the *Vedārtha-saṃgraha* ("Summary of the Meaning of the Veda"). Much of this was incorporated in his commentary on the *Brahma-sūtras*, the *Śrībhāṣya*, which presents his fully developed views. His commentary on the *Bhagavadgītā*, the *Bhagavadgītā-bhāṣya*, dates from a later age.

Influence on Hinduism

Although Rāmānuja's contribution to Vedānta thought was highly significant, his influence on the course of Hinduism as a religion has been even greater. By allowing the urge for devotional worship *(bhakti)* into his doctrine of salvation, he aligned the popular religion with the pursuits of philosophy and gave *bhakti* an intellectual basis. Ever since, *bhakti* has remained the major force in the religions of Hinduism. His emphasis on the necessity of religious worship as a means of salvation continued in a more systematic context the devotional effusions of the Āḷvārs, the 7th–8th century poet-mystics of southern India, whose verse became incorporated into temple worship. This *bhakti* devotionalism, guided by Rāmānuja, made its way into northern India, where its influence on religious thought and practice has been profound.

Rāmānuja's world view accepts the ontological reality of three distinct orders: matter, soul, and God. Like Sankara and earlier Vedanta, he admits that there is nonduality *(advaita),* an ultimate identity of the three orders, but this nonduality for him is asserted of God, who is modified (*viśiṣṭa*) by the orders of matter and soul; hence his doctrine is known as Viśiṣṭādvaita ("modified nonduality") as opposed to the unqualified nonduality of Śaṅkara. Central to his organic conception of the universe is the analogy of body and soul: just as the body modifies the soul, has no separate existence from it, and yet is different from it, just so the orders of matter and soul constitute God's "body," modifying it, yet having no separate existence from it. The goal of the human soul, therefore, is to serve God just as the body serves the soul. Anything different from God is but a *śeṣa* of him, a spilling from the plenitude of his being. All the phenomenal world is a manifestation of the glory of God (*vibhūti*), and to detract from its reality is to detract from his glory. Rāmānuja transformed the practice of ritual action into the practice of divine worship and the way of meditation into a continuous loving pondering of God's qualities; both in turn are subservient to *bhakti,* the fully realized devotion that finds God. Thus, release is not merely a shedding of the bonds of transmigration but a positive quest for the contemplation of God, who is pictured as enthroned in his heaven, called Vaikuṇṭha, with his consorts and attendants.

Rāmānuja's doctrine, which was passed on and augmented by later generations, still identifies a caste of Brahmins in southern India, the Śrīvaiṣṇavas. They became divided into two subcastes, the northern, or Vadakalai, and the southern, or Teṉkalai. At issue between the two schools is the question of God's grace. According to the Vadakalai, who in this seem to follow Rāmānuja's intention more closely, God's grace is certainly active in man's quest for him but does not supplant the necessity of man's acting toward God. The Teṉkalai, on the other hand, hold that God's grace is paramount and that the only gesture needed from man is his total submission to God ***(prapatti)***.

The site of Rāmānuja's birthplace in Śrīperumbūdtūr is now commemorated by a temple and an active Viśiṣṭādvaita school. The doctrines he promulgated still inspire a lively intellectual tradition, and the religious practices he emphasized are still carried on in the two most important Vaiṣṇava centres in southern India, the Raṅganātha temple in Śrīraṅgam, and the Veṅkateśvara temple in Tirupati, both in Tamil Nadu.

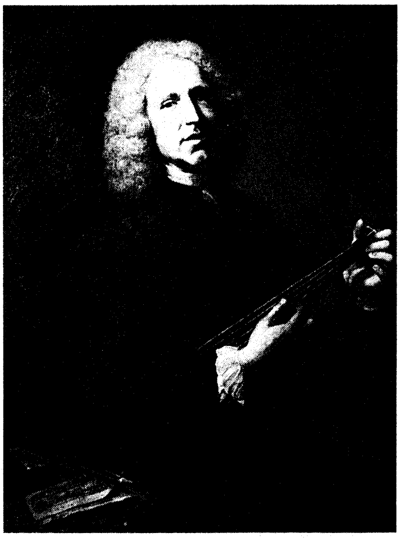
BIBLIOGRAPHY. There are several traditional accounts of Rāmānuja's life. The oldest, on which the others largely rest, is that by ANANTACARYA, entitled the *Prapannāmṛta*, which by some is dated to shortly after Rāmānuja's lifetime. Based on the *Prapannāmṛta* in large parts are the accounts by S.N. DAS GUPTA in his ***History of** Indian Philosophy*, vol. *3 **(1940);***and P.N. SRINIVASACHARI in ***Philosophy*** of *Viśiṣṭādvaita*, 2nd ed. ***(1946).***

(J.A.B.v.B.)

Rameau, Jean-Philippe

The 18th-century French composer Jean-Philippe Rameau is best known today for his harpsichord music, but in his lifetime he was famous as a musical theorist and, above all, as a composer of opera. He is often ranked with the great trio of late-Baroque composers—Johann Sebastian Bach, George Frideric Handel, and Domenico Scarlatti—who were his contemporaries. Rameau is also often paired with François Couperin, who died in 1733, the year that Rameau produced the first of his impressive series of 30 operas and opéra ballets—a medium never attempted by any of the Couperin family. Rameau is recognized as the greatest musical dramatist France has produced.

Snark *International*



Rameau, portrait by Jacques-Andre-Joseph Aved (1702–66). In the Musée des Beaux-Arts, Dijon, France.

Rameau was baptized at Dijon on September 25, 1683. His father, Jean, played the organ for 42 years in various churches in Dijon and hoped one day to see his son on a lawyer's, rather than an organist's, bench. These hopes were dashed by the boy's deplorable performance in school. At the age of 17 he is said to have fallen in love with a young widow who laughed at the errors of grammar and spelling in his letters to her. He tried to refine his language, but, to judge by the prolixity of his later theoretical writings, his efforts resulted in no permanent improvement. At the age of 18, after deciding to pursue a musical career, he travelled to Italy but seems to have gotten no farther than Milan. The following year, he received the first of a series of appointments as organist in various cities of central France: Avignon, Clermont, Dijon, Lyon. There was a brief interlude in the capital, but apparently Paris did not take an immediate fancy to the provincial organist, in spite of his having published there a fine suite of harpsichord pieces in A minor, ***Premier Livre de pièces de clavecin*** (1706). These works show the beneficial influence of Louis Marchand, a famous organist-harpsichordist of the day whose playing Rameau greatly admired.

Organist in the provinces

Back in Clermont by 1715, he rashly signed a contract to be cathedral organist for 29 years. He then settled down to investigate, in an exhaustive and highly original manner, the foundations of musical harmony. He attacked traditional theory on the ground that "The Ancients," who to Rameau included such relatively recent writers as the 16th-century Italian Gioseffo Zarlino, ". . . based the rules of harmony on melody, instead of beginning with harmony, which comes first." Intuitively basing his studies on the natural overtone series, he arrived at a system of harmony that is the basis of most 20th-century harmony textbooks. Finally published in Paris in 1722, his impressive ***Traitk de l'harmonie*** brought him fame at last and a yearning to return to the capital.

Authorities in Clermont were loath to let him go, and the story of his release reveals, as do his own writings and other evidence, something of his thorny personality, his persistence, and his single-mindedness. At an evening service he showed his displeasure with the church authorities by pulling out all the most unpleasing stops and by adding the most rending discords so that "connoisseurs confessed only Rameau could play so unpleasingly." But, after his release from the contract, he played with "so much delicacy, brilliance, force and harmony, that he aroused in the souls of the congregation all the sentiments he wished, thereby sharpening the regret with which all felt the loss they were about to sustain."

Upon his return to Paris, where he was to remain for the rest of his life, Rameau began a new and active life. A second volume of harpsichord pieces, ***Pièces de clavecin avec une méthode pour la mècanique des doigts*** (1724), met with considerably more success than the first, and he became a fashionable teacher of the instrument. A commission to write incidental music for the Fair theatres planted the seeds of his development as a dramatic composer, and the display of two Louisiana Indians at one of these theatres in 1725 inspired the composition of one of his best and most celebrated pieces, ***Les Sauvages,*** later used in his optra ballet ***Les Indes galantes*** (first performed, 1735). The following year, at the age of 42, he married a 19-year-old singer, who was to appear in several of his operas and who was to bear him four children.

His most influential contact at this time was Le Riche de la Pouplinibre, one of the wealthiest men in France and one of the greatest musical patrons of all time. Rameau was put in charge of La Pouplinikre's excellent private orchestra, a post he held for 22 years. He also taught the financier's brilliant and musical wife. The composer's family eventually moved into La Pouplinikre's town mansion and spent summers at their château in Passy. This idyllic relationship between patron and composer gradually came to an end after La Pouplinikre separated from his wife, and Rameau was replaced by the younger, avant-garde composer Karl Stamitz. In the meantime, however, admittance to La Pouplinibre's circle had brought Rameau into contact with various literary lights. Abbé Pellegrin, whose biblical opera ***Jephtk*** had been successfully set to music by Rameau's rival Michel Pinolet de Montéclair in 1732, was to become Rameau's librettist for his first and in many ways finest opera, ***Hippolyte et Aricie.*** It was first performed in the spring of 1733, at La Pouplinibre's house, then, in the autumn, at the Opéra, and the following year it was performed at court. André Campra, perhaps the most celebrated French composer living at that time, remarked to the Prince de Conti: "My Lord, there is enough music in this

Rameau's first opera

opera to make ten of them; this man will eclipse us all."

To some ears there was, indeed, too much music. Those who had grown up with the operas of Jean-Baptiste Lully were baffled by the complexity of Rameau's orchestration, the intensity of his accompanied recitatives (speech-like sections), and the rich and often dissonant diversity of his harmonies. Rameau himself, however, professed his admiration for his predecessor in the preface to *Les Indes galantes*, in which he praised the "beautiful declamation and handsome turns of phrase in the recitative of the great Lully," and stated that he had sought to imitate it, though not as a "servile copyist." Indeed, almost everything in Rameau's operas has, at least technically, a precedent in Lully. Yet the content of his works, the rich dramatic contrasts, the brilliant orchestral sections, and, above all. the permeating sensuous melancholy and languorous pastoral sighings, put him in a different world: in short, the Rococo world of Louis XV.

Collaboration with Voltaire

Among those at the first performance of *Hippolyte* was the great Voltaire, who quipped that Rameau "is a man who has the misfortune to know more music than Lully." But he soon came around to Rameau's side and wrote for him a fine libretto, *Samson*, which was banned ostensibly for religious reasons but really because of a cabal against Voltaire: the music was lost. Their later collaboration on two frothy court entertainments is preserved, however: *La Princesse de Navarre* and *Le Temple de la Gloire* (both 1745). The former was condensed and revised as *Les Fêtes de Ramire* (1745) by Jean-Jacques Rousseau.

Rousseau, Jean Le Rond d'Alembert, and other writers associated with Denis Diderot's *Encyclopédie* began as ardent Rameau enthusiasts, but, by the mid-1750s, as they warmed more and more to Italian music, they gradually turned against him. Rameau appreciated the new Italian music as much as anyone, but the works he consciously composed in this style, such as the overtures to *Les Fêtes de Polymnie* (1745) and to his final work *Abaris ou les Boréades* (1764), are not very individual. He died on September 12, 1764, in Paris.

The zenith of his career may be said to have encompassed the brief span from 1748, when he tossed off the masterpiece *Pygmalion* in eight days and had six other operas on the boards, through 1754, when he wrote La *Naissance d'Osiris* for the birth of the future Louis XVI. Thereafter, his fame diminished, as the prevailing musical style became what is now generally called "Classical." The public preferred catchy tunes with simple harmonies to Rameau's profound emotion and rich, late-Baroque harmony.

MAJOR WORKS

DRAMATIC WORKS: 35 including *Hippolyte et Aricie* (first performed 1733), *Les Indes galantes* (1735), *Castor et Pollux* (1737), *Dardanus* (1739), *Platée* (1745), and *Zoroastre* (1749).

CHAMBER MUSIC: *Pièces de clavecin en concerts* (published 1741).

HARPSICHORD: 3 volumes of pieces under varying titles. Most have either dance titles such as "Allemande" and "Gigue," or illustrative ones such as "Les Tendres Plaintes" and "La Poule."

BIBLIOGRAPHY. JEAN-PHILIPPE RAMEAU, *Traité de l'harmonie* (1722; Eng. trans., *Treatise on Harmony*, with an Introduction and Notes by PHILIP GOSSETT, 1971), a careful translation of Rameau's first great theoretical work; CUTHBERT M. GIRDLESTONE, *Jean-Philippe Rameau: sa vie, son oeuvre* (1962; Eng. trans., *Jean-Philippe Rameau: His Life and Work*, rev. ed., 1969), by far the finest study of the man and his music yet to have appeared; and "Rameau's Self-Borrowings," *Music and Letters*, 39:52–56 (1958), a brief account of a fascinating topic; KATHLEEN DALE, "The Keyboard Music of Rameau," *Monthly Musical Record*, pp. 127–131 (1946), a somewhat out-of-date but elegant introduction to the *Pièces de clavecin;* JOAN FERRIS, "The Evolution of Rameau's Harmonic Theories," *Journal of Music Theory*, 3:231–256 (1959), a highly technical but succinct summary of all Rameau's theoretical writings; ERWIN R. JACOBI, "Rameau and Padre Martini," *Musical Quarterly*, 50:452–475 (1964), a discussion of how Rameau's theories were received in Italy, includes facsimile of autograph letters; SISTER MICHAELA MARIA KEANE, *The Theoretical Writings of Jean-Philippe Rameau* (1961), a thorough discussion of all the theoretical works, including translations of many excerpts and a brief biographical sketch; PIERRE LASSERRE, *L'Esprit de la musique française* (1917; Eng. trans., *The Spirit of French Music*, 1921), an old-fashioned but sympathetic defense of Rameau from his enemies over the ages and an account of his music, especially *Castor;* PAUL-MARIE MASSON, *L'Opera de Rameau* (1930), the most detailed study (in French) of Rameau's music; and "Rameau and Wagner," *Musical Quarterly*, 25:466–478 (1939), what Wagner chose to admire in Gluck is shown to have been foreshadowed by Rameau; WILFRID MELLERS, "Rameau and the Opera," *The Score*, no. 4, pp. 26–51 (1951), an excellent brief introduction to the music of Rameau with special emphasis on his use of harmony in the operas; F. BRUGGEN, S. and W. KUIJKEN, and G. LEONHARDT, *Rameau: Pièces de clavecin en concerts* (Telefunken SAWT 9578–B, 1971), the only recording to combine the use of completely authentic instruments with admirable virtuosity and style.

Ramses II the Great

Until the discovery of the tomb of King Tutankhamen in 1922, Ramses II was the only ancient Egyptian king whose name, apart from those of the builders of the Pyramids of Giza, was familiar to the nonarchaeological public, and, to this day, its bearer remains a prominent figure in the long history of ancient Egypt.

By courtesy of the trustees of the British Museum

Ramses II, upper portion of a granite figure from Thebes, 1250 BC. In the British Museum.

King Ramses II was the third king of the 19th dynasty of Egypt; his reign from 1304 to 1237 BC, was the second longest reign in Egyptian history. His family, of nonroyal origin, came to power after the reign of the religious reformer, Akhenaton (Amenhotep IV, 1379–62 BC), and set about restoring Egyptian power in Asia, which had declined under Akhenaton and his successor, Tutankhamen. Ramses' father, Seti I, subdued a number of rebellious princes in Palestine and southern Syria and waged war on the Hittites of Anatolia in order to recover those provinces in the north that during the recent troubles had passed from Egyptian to Hittite control. Sethos achieved some success against the Hittites at first, but his gains were only temporary, for at the end of his reign the enemy were firmly established at Kadesh, on the Orontes River, a strong fortress defended by the river, which became the key to their southern frontier. Early in his reign Seti made the crown prince Ramses, the future Ramses II, coregent with him, giving him a kingly household and harem, and the young prince accompanied his father on his campaigns, so that when he came to sole rule he had already had experience of kingship and of war. It would appear, however, that Ramses was not the eldest son, for in a relief at Karnak of his father's Libyan war, the figure of a prince whose name is not preserved was inserted into the scene after it had been completed, but the figure was later erased and that of Ramses substituted for it. What lay behind these events is not known, but it is noteworthy that Ramses was

Coregency

crowned coregent at an unusually early age, as if to ensure that he would in fact succeed to the throne. He ranked as a captain of the army while still only ten years old; at that age his rank must surely have been honorific, though he may well have been receiving military training.

Because his family's home was in the Nile Delta and in order to have a convenient base for campaigns in Asia, Ramses built for himself a full-scale residence city called Per-Ramesse ("House of Ramses"; Biblical Raamses), which was famous for its beautiful layout, with gardens, orchards, and pleasant waters. Each of its four quarters had its own presiding deity: Amon in the west, Seth in the south, the royal cobra goddess, Buto, in the north, and, significantly, the Syrian goddess Astarte in the east. A vogue for Asian deities had grown up in Egypt, and Ramses himself had distinct leanings in that direction. The first public act of Ramses after his accession to sole rule was to visit Thebes, the southern capital, for the great religious festival of Taurt (Opet), when the god Amon of Karnak made a state visit in his ceremonial barge to the temple of Luxor. When returning to his home in the north, the King broke his journey at Abydos to worship Osiris and to arrange for the resumption of work on the great temple founded there by his father, which had been interrupted by the old king's death. He also took the opportunity to appoint as the new high priest of Amon at Thebes a man named Nebwenenef, high priest of Anhur at nearby Thinis. It seems that, apart from his extensive building activities and his famous residence city, Ramses' reputation as a great king in the eyes of his subjects rested largely on his fame as a soldier.

The Battle of Kadesh

Military exploits. In the fourth year of his reign, he led an army north to recover the lost provinces his father had been unable to conquer permanently. The first expedition was to subdue rebellious local dynasts in southern Syria, to ensure a secure springboard for further advances. He halted at the Nahr al-Kalb near Beirut, where he set up an inscription to record the events of the campaign; today nothing remains of it except his name and the date; all the rest has weathered away. The next year the main expedition set out. Its objective was the Hittite stronghold at Kadesh. Following the coastal load through Palestine and Lebanon, the army halted on reaching the south of the land of Amor, perhaps in the neighbourhood of Tripolis. Here Ramses detached a special task force, the duty of which seems to have been to secure the seaport of Simyra and thence to march up the valley of the Eleutherus River (Nahr el-Kebir) to rejoin the main army at Kadesh. The main force then resumed its march to the River Orontes, the army being organized in four divisions of chariotry and infantry, each consisting of perhaps 5,000 men. Crossing the river from east to west at the ford of Shabtuna, about eight miles from Kadesh, the army passed through a wood to emerge on the plain in front of the city. Two captured Hittite spies gave Ramses the false information that the main Hittite army was at Aleppo, some distance to the north, so that it appeared to the King as if he had only the garrison of Kadesh to deal with. It was not until the army had begun to arrive at the camping site before Kadesh that Ramses learned that the main Hittite army was in fact concealed behind the city. Ramses at once sent off messengers to hasten the remainder of his forces, but before any further action could be taken, the Hittites struck with a force of 2,500 chariots, with three men to a chariot as against the Egyptian two. The leading divisions, taken entirely by surprise, broke and fled in disorder, leaving Ramses and his small corps of household chariotry entirely surrounded by the enemy and fighting desperately. Fortunately for the King, at the crisis of the battle, the Simyra task force appeared on the scene to make its junction with the main army and thus saved the situation. The result of the battle was a tactical victory for the Egyptians, in that they remained masters of the stricken field, but a strategic defeat in that they did not and could not take Kadesh. Neither army was in a fit state to continue action the next day, so an armistice was agreed and the Egyptians returned home. This battle is one of the very few from Pharaonic times of which there are real details, and that is because of the King's pride in his stand against great odds; pictures and accounts of the campaign, both an official record and a long poem on the subject, were carved on temple walls in Egypt and Nubia, and the poem is also extant on papyrus.

The failure to capture Kadesh had devastating effects on Egyptian prestige abroad, and many of the petty states of South Syria and Palestine under Egyptian suzerainty rebelled, so that Ramses had to start again from the beginning. In the sixth or seventh year of his reign, he stormed Ashkelon; the following year he took a number of towns in Galilee and Amor, and the next year he was again on the Nahr al-Kalb. It may have been in the tenth year that he broke through the Hittite defenses and conquered Katna and Tunip—where, in a surprise attack by the Hittites, he went into battle without his armour—and held them long enough for a statue of himself as overlord to be erected in Tunip. In a further advance he invaded Kode, perhaps the region between Alexandretta and Carchemish. Nevertheless, like his father before him, he found that he could not permanently hold territory so far from base against continual Hittite pressure, and, after 16 years of intermittent hostilities, a treaty of peace was concluded in 1283 BC, as between equal great powers, and its provisions were reciprocal. The wars once over, the two nations established friendly ties. Letters on diplomatic matters were regularly exchanged; in 1270 Ramses contracted a marriage with the eldest daughter of the Hittite king, and it is possible that at a later date he married a second Hittite princess. Apart from the struggle against the Hittites, there were punitive expeditions against Edom, Moab, and Negeb and a more serious war against the Libyans, who were constantly trying to invade and settle in the Delta; it is probable that Ramses took a personal part in the Libyan war but not in the minor expeditions. The latter part of the reign seems to have been free from wars.

The temples of Abu Simbel

Prosperity during his reign. One measure of Egypt's prosperity is the amount of temple building the kings could afford and carry out, and on that basis the reign of Ramses II is the most notable in history, even making allowance for its great length. It was that, combined with his prowess in war as depicted in the temples, that led the Egyptologists of the 19th century to dub him "the Great," and that, in effect, is how his subjects and posterity viewed him; to them he was the king par *excellence.* All the nine kings of the 20th dynasty called themselves by his name; even in the period of decline that followed, it was an honour to be able to claim descent from him, and his subjects called him by the affectionate abbreviation Sese. In Egypt he completed the great hypostyle hall at Karnak (Thebes) and the temple built by Seti I at Abydos, both of which were left incomplete at the latter's death. Ramses also completed his father's funerary temple on the west bank of the Nile at Luxor (Thebes) and built one for himself, which is now known as the Ramesseum. At Abydos he built a temple of his own not far from that of his father; there were also the four major temples in his residence city, not to mention lesser shrines. In Nubia (Nilotic Sudan) he constructed no fewer than six temples, of which the two carved out of a cliffsideat Abu Simbel, with their four colossal statues of the king, are the most magnificent and the best known. The larger of the two was begun under Seti I but was largely executed by Ramses, while the other was entirely due to Ramses. In the Wadi Tumilat, one of the eastern entries into Egypt, he built the town of Per-Atum (Biblical Pithom), which the Bible calls a store city (Ex. 1:11), but which probably was a fortified frontier town and customs station. In fact, there can have been few sites of any importance that originally did not exhibit at least the name of Ramses, for apart from his own work, he did not hesitate to inscribe it on the monuments of his predecessors. Apart from the construction of Per-Ramesse and Pithom, his most notable secular work, so far as is known, was the sinking of a well in the eastern desert on the route to the Nubian gold mines. Of Ramses' personal life virtually nothing is known. His first and perhaps favourite queen was Nefretari; the fact that, at Abu Simbel, the smaller temple was dedicated to her and to the goddess of love points to real affection between them. She seems to have died comparatively early in the reign, and her fine tomb in the Valley of the Tombs of the Queens at Thebes is well known. Other queens whose names are preserved were Isinofre, who bore the king four sons, among whom was Ramses' eventual successor, Merneptah; Merytamun and Matnefrure, the Hittite princess. In addition to the official queen or queens, the King, as was customary, possessed a large harem, and he took pride in his great family of well over 100 children. The best portrait of Ramses II is a fine statue of him as a young man, now in the Turin museum; his mummy, preserved in a mausoleum at Cairo, is that of a very old man with a long narrow face, prominent nose, and massive jaw.

The reign of Ramses II marks the last peak of Egypt's imperial power. After his death Egypt was forced on the defensive but managed to maintain its suzerainty over Palestine and the adjacent territories until the later part of the 20th dynasty, when, under the weak kings who followed Ramses III, internal decay ended its power beyond its borders. Ramses II must have been a good soldier, despite the fiasco of Kadesh, or else he would not have been able to penetrate so far into the Hittite Empire as he did in the following years; he appears to have been a competent administrator, since the country was prosperous, and he was certainly a popular king. Some of his fame, however, must surely be put down to his flair for publicity: his name and the record of his feats on the field of battle were found everywhere in Egypt and Nubia. It is easy to see why, in the eyes both of his subjects and of later generations, he was looked on as a model of what a king should be.

Rangoon

Rangoon, the capital of the Union of Burma, is located 25 miles from the sea on the left bank of the Rangoon (or Hlaing) River, the eastern mouth of the Irrawaddy. With its population of about 1,900,000, with an international airfield and modern port, and with air, rail, road, and river connections with all of Burma, it is the largest as well as the most important city commercially and industrially in the country. Its area is nearly 200 square miles (500 square kilometres).

The focal point of the city is the ancient Shwc Dagon pagoda, the centre of Burmese religious life, which attracts pilgrims from all parts of the country. The pagoda is a solid brick stupa in the form of a cone raised above a relic chamber and is completely covered with gold. It has been rebuilt and its height increased many times; it was raised, by the Burmese king Tharrawaddy in 1841, to its present height of 326 feet, crowning a hill that rose 168 feet above the level of the city.

History. The Shwe Dagon pagoda has been a place of pilgrimage for many centuries. The settlement that apparently had existed there for a long time became known as Dagon in the medieval period, and its status was raised to that of a town by the Mon kings in the early 15th century. King Alaungpaya (founder of the last dynasty of Burmese kings) conquered Lower Burma in 1755 and developed the town as a port to replace the port of Syriam. He renamed it Yangon ("the end of strife"; transliterated as Rangoon). Surrounded by a stockade and with creeks on three sides and the river on the south, its area was only about one-eighth of a square mile. It had, however, three wharves and a thriving shipbuilding industry, using local teak, and it was made the administrative capital of Lower Burma.

Yangon, "the end of strife"

Rangoon was taken by the British at the outbreak of the First Anglo-Burmese War in 1824 but was restored in 1826. The city was again taken in the Second Anglo-Burmese War of 1852 and became the administrative centre of British Lower Burma. After the annexation of the whole country, it became the capital city and grew in importance. The city has remained central to Burmese life since independence in 1948.

The contemporary city. *City site and environment.* The site of the city is a low ridge, with surrounding delta alluvium. The original settlements were located on the ridge; the new satellite towns were built on delta land, where the elevation is only about ten to 15 feet. Alaungpaya's Rangoon was also built on alluvium, and, when Lieutenant A. Fraser planned British Rangoon in 1853, it was necessary to drain the creeks around the old settlement and fill up the depressions.

The climate is warm and humid. Average temperatures are about 80–85° F (27–29" C), and mean monthly temperatures vary by only about 10" F (6° C). Minimum temperatures in January are, however, about 60–65" F (about 16–18" C), and maximum daytime temperatures in April are about 95–100° F (about 35–38" C). Rains begin in May and last till the middle of October. The total rainfall is more than 100 inches a year. The original vegetation, that of tropical semi-evergreen forest, has been completely removed over the centuries. The fertile alluvial lands were transformed into paddy fields, some of which now underlie the new satellite towns set up after 1958.

City plan and growth. Fraser's plans called for a city with a rectangular pattern of streets covering an area of 500 acres to accommodate a population of 36,000. With the great increase of population, settlements were built up in a U shape around the planned city, now known as Cantonment, toward the west along the river and to the east to Pazundaung Creek. To the north, a spacious residential area developed, while farther north, there were gardens until, as population increased, the gardens made way for more settlements. Today the built-up area extends to Insein and Mingaladon, nine miles and 12 miles north, respectively. In the meantime, in order to accommodate a larger population, important institutions within the city limits were moved out. A much bigger Cantonment area was developed at Mingaladon, the university was moved five miles to the north, and a new racecourse was set up at Kyaikkasau five miles to the northeast.

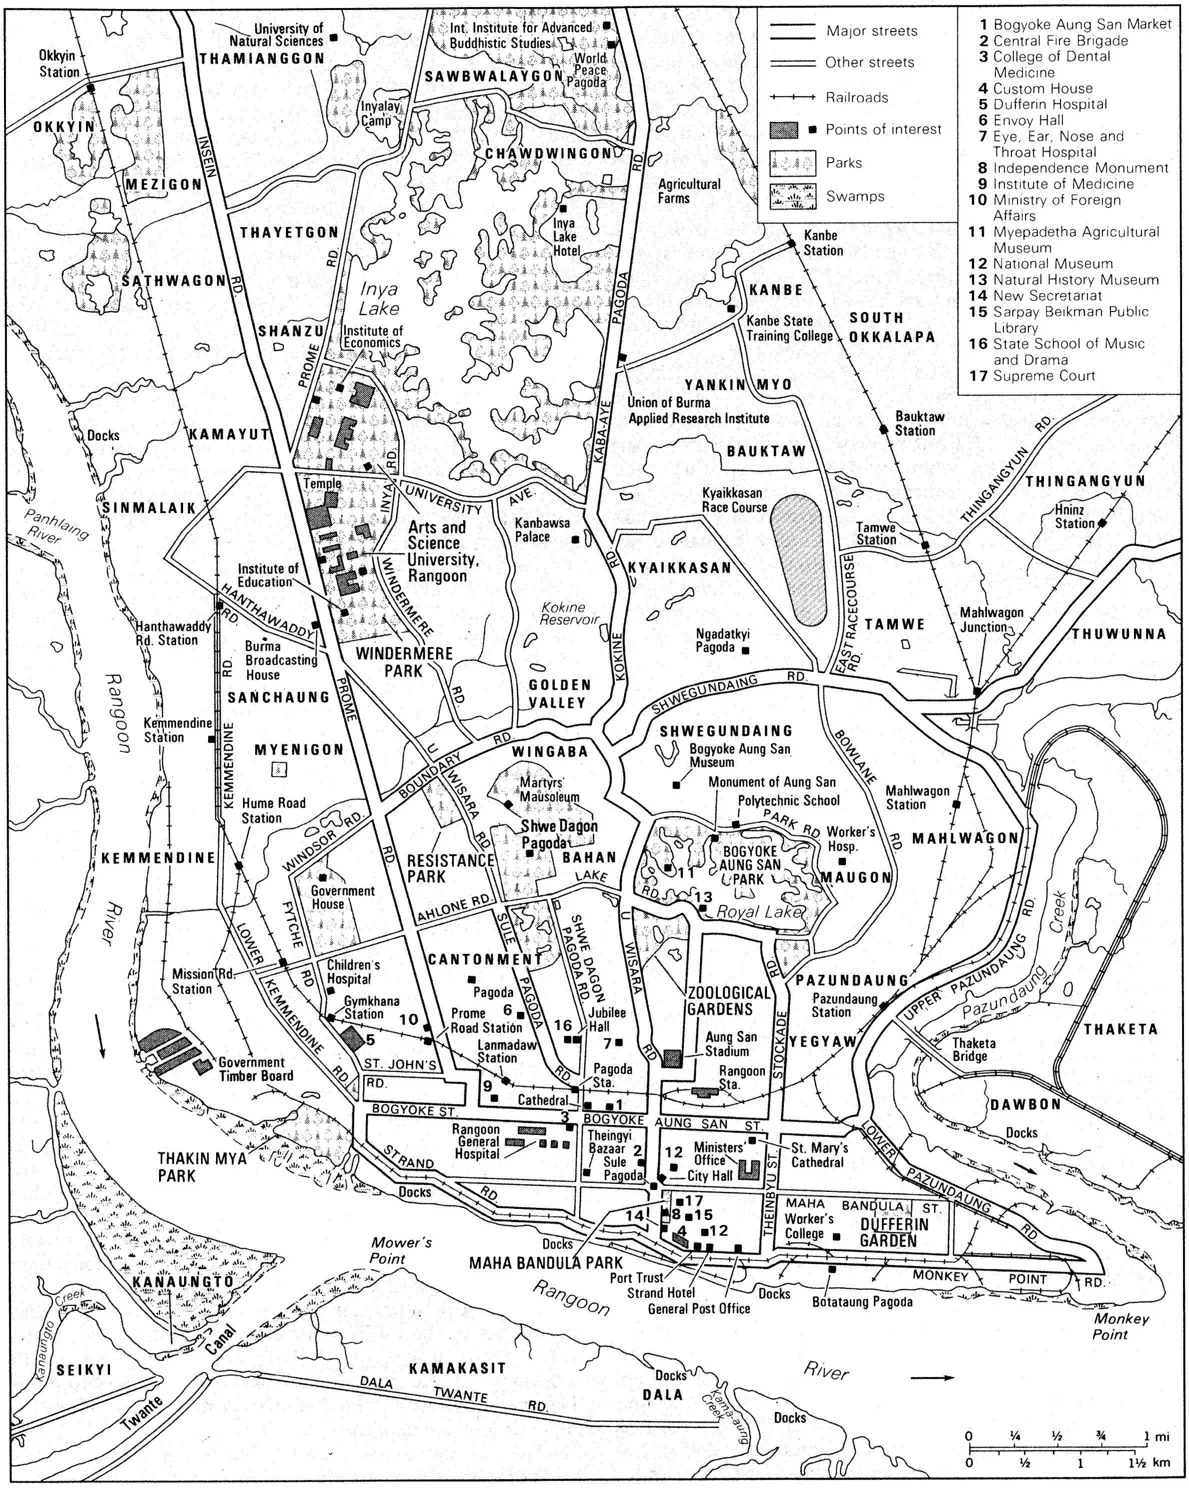
The city plan

The city still maintains the rectangular plan of streets and blocks in the built-up areas of its suburbs and in the new satellite towns of Thaketa and North and South Okkalapa on the east, set up in 1958–59 to accommodate the squatters within the city. A new town, Thuwunna, is also being developed on the east.

Lack of bridging limits the city to the area enclosed by the Rangoon River and Pazundaung Creek; hence, expansion is continuing northward, resulting in lengthening of communication lines and in the necessity of locating cemeteries and factories within the confines of the city.

The city is well served by bus lines, and a railway, using diesel engines, connects all the important suburbs with the centre of the city. In addition there are many local trains.

Demography. In 1971 the population of the city was estimated at 1,900,000. The growth of population has been phenomenal: in 1881 it was 134,176; by 1901 it had risen to 234,881; in 1931 it was 400,415; in 1941, 500,800; and in 1953, 737,079. The present population of nearly 1,900,000 is for the whole of the division covering nearly 200 square miles. In the centre of the city, the density of population is over 100,000 per square mile while in the outskirts it falls to as low as 1,500 per square mile, at Mingaladon.



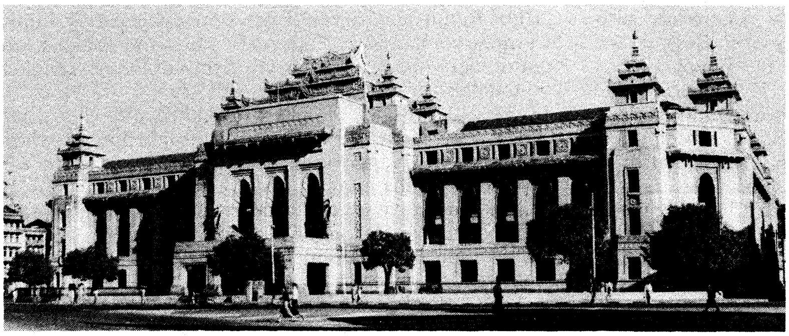
The city of Rangoon and vicinity.

Over the years the ethnic composition of the city also has changed. When first instituted in 1755, the population was made up mainly of Mons with some Burmese and a sprinkling of foreigners. Under the British, the foreign population grew rapidly. In 1901 the Burmese constituted 33% of the population, and Indians 48%. By 1931 the Burmese formed 32%, and the Indians 53%. There was a great exodus of Indians and Europeans during World War II. By 1952 the structure had changed to 60% Burmese, 20.5% Indians, 8% Chinese, 5% Anglo-Burmans, and the rest foreigners, including Europeans, Armenians, Jews, and others. Today 90% of the population is Burmese, and the Chinese outnumber the Indians; a contributing factor is that many Indians and Chinese have adopted Burmese citizenship.

Housing and arclzitecture. The most notable building in Rangoon is the great golden stupa in the Shwe Dagon pagoda. The place of worship is the surrounding tiled terrace with a perimeter of 1,420 feet. In 1952, to celebrate the 2,500th year of the passing of the Buddha, the World Peace Pagoda was built a few miles to the north; around it has been built a complex of buildings, among which a great artificial cave with assembly hall and the International Institute for Advanced Buddhistic Studies are notable. Other religious edifices of note are the Sule pagoda, located in the centre of the city, and Botataung pagoda, demolished by bombing during World War II and completely rebuilt in 1953, near the river to the east.

The Shwe Dagon pagoda

The city centre is made up of brick buildings, mostly three to four stories high, while in the suburbs traditional



City Hall on Sule Pagoda Road, Rangoon.
Richard Allen Thompson

wooden structures are common. Old colonial structures of red brick include the Office of Ministers (formerly the Old Secretariat), the Law Courts, the Rangoon General Hospital, the customhouse, and Government House. New and modern architectural styles are seen in the new secretariat building, the department stores on Shwe Dagon Pagoda Road, the new Polytechnic School, the Burma Broadcasting Service Station, the Institute of Medicine, and the Rangoon Institute of Technology. In housing, too, new styles have appeared.

Economic life. Under the British the most important industries were those using local produce. Hence Rangoon has the biggest rice mills and saw mills in the country, strung out along the riverside. Since independence there has been a great increase in industrialization, including textile mills and soap, rubber, aluminum, and food-processing factories. State-owned industries include pharmaceuticals, soap, and textiles and an iron- and steel-rolling plant. An industrial belt stretches from Kamayut to Insein and beyond to the north and on the east to Thingangyun and beyond.

In the commercial section of the city, located in the central area, are the banks, offices of central trade, and various trade corporations, as well as shops, brokerage houses, and bazaars. In addition there are many local bazaars in various suburbs and, with the program of decentralization, retail shops. Many of the retail shops, formerly state-owned, have been changing over to operation by consumer cooperatives. Private stores, service activities, and workshops are also present in every quarter of the city.

The port of Rangoon

Rangoon commands routes by river, road, and railway to the rest of the country. The Union of Burma Airways connects internally more than 30 airfields in Burma and operates external connections with Bangkok, Hong Kong, Dacca, Calcutta, and Kāthmāndu. The international airport at Mingaladon, built in 1952, accommodates several international airlines. Before World War II, the port of Rangoon handled 84 percent of the country's overseas commerce. During the war it was repeatedly bombed and badly damaged by both the Japanese and the Allies. After independence, with the help of foreign aid, the port was completely rehabilitated. The port now handles all imports that reach the country and 85 percent of all exports, but the overall volume has remained far below prewar totals.

Administration. The whole city area is administered by the Municipal Corporation of Rangoon, established in 1874. The development of the city, however, was left to the Rangoon Development Trust, set up in 1920, and is now under the National Housing Board. Since Rangoon division was instituted in 1964, much of the administration has been carried out by local security and administrative committees. The city is now divided into 13 regions and 28 smaller subregions, constituted as townships in 1971. Being the capital, Rangoon has government offices as well as diplomatic missions.

Public utilities. Rangoon draws its water supply from Hlawga Lake and the Gyobyu reservoir, but artesian wells have been drilled to supplement the supply, and the planned construction of a new reservoir at Hpugyi, 35 miles to the north, scheduled for completion in about 1980. The city has had a sewerage system since 1892, but extensive additions are needed for the new towns. Since 1960, Rangoon has drawn its electricity supply from the Balu Chaung hydroelectric project in Kayah State.

Health andsafety. Before World War II, Rangoon had only the Rangoon General Hospital, the Dufferin Hospital for women, and smaller hospitals in the various quarters. Four large new general hospitals have been built, as well as the Workers' Hospital, Children's Hospital, and the Eye, Ear, Nose, and Throat Hospital. The city also has health service stations in all quarters of the city. Medical treatment is free in Burma. Rangoon also has more than a dozen day nurseries in which children of working families are cared for; more are planned.

In addition to the Central Fire Brigade, there are fire stations in the various suburbs, those at Kemmendine and Insein being the largest. Rangoon is troubled by fires fairly often, though on a small scale. Rangoon Division Police Services control 46 police stations.

Institutions of higher education

Education. There are almost 100 high schools, two technical high schools, and several hundred secondary and primary schools, all government supported. The University of Rangoon, established in 1920, was reconstituted in 1964 into separate institutes of arts and science, economics, education, technology, medicine (two institutes), veterinary and animal husbandry, dentistry, and paramedical sciences, and a Workers College. The Inter- [illegible]al Institute for Advanced Buddhistic Studies was established in the 195[illegible] Alt[illegible]th[illegible] R[illegible] [illegible] between 40,000 and 50,000 students, half of whom are in the Arts and Science University. The various institutes and the university maintain hostels for the students. In the early 1970s, a new University of Natural Sciences was being constructed at Thamaing. Rangoon also has a Teachers Training Institute (for secondary and elementary level) and a Technical Institute at Insein.

Museums and libraries

Cultural life. The government of Burma maintains schools of dancing, music, drama, and art in Rangoon and a cultural troupe, which, besides entertaining the public, also preserves ancient dancing and music. An open-air theatre on the old racecourse near Lanmadaw and the former Jubilee Hall serve as theatres. There are about 20 cinema halls. Rangoon has five museums, the National Museum (opened in 1952), Bogyoke Aung San Museum, the Museum of Military Research, the Museum of Buddhistic Studies at the International Institute for Advanced Buddhistic Studies, and the Museum of Natural History. Libraries include the National Library (with more than 100,000 books and volumes of palm leaf and parabaiks), the Central Universities Library, and the libraries of the Burma Translation Society (Sarpay Beikman Public Library) and the Information Department.

Rangoon has many presses publishing books, magazines, and journals, the largest being the government's central press, Sarpay Beikman Press, Myawaddy Press, Buddhist Society Press, and the University Press. Seven daily newspapers are published, five in the vernacular and two in English. There is no television, but the state-owned radio broadcasting station operates from its modern building opened in 1960.

Some 16 parks are maintained in the city, the largest of which are the Maha Bandula Park (the old Fytch Square

Garden) and the Park of Revolution. There are also spacious zoological and botanical gardens. Besides the old racecourse near Lanmadaw, where the Envoy Hall is often open for exhibitions, the old Kyaikkasan race course also serves for exhibitions and as a gathering place on important national days. (Horse racing has been abolished since 1962.) There is a fine 18-hole golf course at Mingaladon, and another one near Insein. There are 19 stadiums for sports and athletic meets, the best known is the Aung San Sports Stadium, which can accommodate 50,000 spectators and has an indoor stadium and lighting facilities for sports at night.

Ranjit Singh

Ranjit Singh, Sikh maharaja of the Punjab (Paiijrib), was the first Indian in 1,000 years to turn the tide of invasion back into the homelands of the traditional conquerors of India, the Pathans and the Afghans, and hence came to be known as the Lion of the Punjab. His domains extended from the Khyber Pass in the northwest to the Sutlej River in the east, and from Kashmir down to the deserts of Sindh. Although unlettered, he was a shrewd judge of men and events, free from religious bigotry, and mild in his treatment of adversaries. An ugly little man, blind in one eye and with a face pitted with pockmarks, he liked to surround himself with handsome men and women; a *bon viveur*, he had a passion for hunting, horses, and strong liquor.

Early life and military conquests

Ranjit Singh was born on November 13, 1780, the only child of Maha Singh, on whose death in 1792 he became chief of the Śukerchakīās, a Sikh group. His inheritance included Gujrānwāla town and the surrounding villages, now in Pakistan. At 15 he married the daughter of a chieftain of the Kanhayas, and for many years his affairs were directed by his scheming and ambitious mother-in-law, the widow Sada Kaur. A second marriage to a girl of the Nakkais made Ranjit Singh pre-eminent among the clans of the Sikh confederacy. In July 1799 he seized Lahore, the capital of the Punjab. The Afghan king, Shrih Zamān, confirmed Ranjit Singh as governor of the city; on April 12, 1801, however, Ranjit Singh proclaimed himself maharaja of the Punjab. He had coins struck in the name of the Sikh Gurūs, the revered line of Sikh leaders, and proceeded to administer the state in the name of the Sikh Commonwealth. A year later he captured Amritsar, the most important commercial entrepôt in northern India and sacred city of the Sikhs. Thereafter he proceeded to mop up smaller Sikh and Pathan principalities scattered over the Punjab. His forays eastward were checked by the English. By a treaty signed in 1806, he agreed to expel a Marāthā force that had sought refuge in the Punjab. His ambition to bring together all the Sikh territories extending up to the vicinity of Delhi was thwarted by the English, and he was compelled to sign another treaty with them on April 25, 1809, relinquishing claims to territories east of the Sutlej River.

Ranjit Singh turned his ambition in other directions. In December 1809 he went to the aid of Raja Sansar Chand of Kangra in the Punjab Hills and, after defeating an advancing Gurkha force, acquired Kangra for himself. In 1813 he joined a Barakzrii Afghan expedition into Kashmir. While the Barakzāis betrayed him by keeping Kashmir for themselves, he more than settled scores with them by rescuing Shiih Shojāʿ, brother of Shāh Zamān, who had fled the Barakzāis, and by occupying the fort of Attock on the Indus. Shrih Shojāʿ was brought to Lahore and pressured into parting with the famous *Koh-i-noor* diamond.

In the summer of 1818 Ranjit Singh's troops captured the city of Multān and six months later entered the Pathan citadel, Peshāwar. In July 1819 he finally expelled the Afghans from the Vale of Kashmir.

All of Ranjit Singh's conquests were achieved by Punjabi armies composed of Sikhs, Muslims. and Hindus. His commanders were also drawn from different religious communities, as were his cabinet ministers.

Modernization of the Punjabi army

In 1820 Ranjit Singh began to modernize his army. Almost 50 foreign officers, a good proportion of whom had served in Napoleon Bonaparte's armies, were employed to train the infantry and artillery. The modernized Punjabi army gave a good account of itself in campaigns in the North-West Frontier (on the Afghanistan border). In 1823 it defeated a combined Afghan and Pathan force at Naushahra. In 1831 it successfully quelled a rising of the Frontier tribesmen roused to a holy war (*jihād*) by the Muslim fanatic Sayyed Aḥmad, and again at Naushahra, in 1837, it defeated a Pathan–Afghan alliance.

In October 1831 the British viceroy, Lord William Bentinck, received Ranjit Singh at Rūpar on the eastern bank of the Sutlej River. The British, who had already begun to navigate the Indus River and were eager to keep Sindh Province for themselves, prevailed upon Ranjit Singh to fall in line with their plan. Ranjit Singh was chagrined by the British design to put a cordon round him. He opened negotiations with the Afghans and sanctioned an expedition led by the Dogra commander Zorawar Singh that extended his northern territories into Ladākh (a region of eastern Kashmir) and brought the Punjabis in confrontation with the Chinese.

In 1838 the British viceroy Lord Auckland met Ranjit Singh at Firozpur and persuaded him to engage in a joint expedition into Afghanistan to place the British nominee, Shrih Shojāʿ, on the throne of Kābul. In pursuance of this agreement, the British Army of the Indus entered Afghanistan from the south, while Ranjit Singh's troops went through the Khyber Pass and took part in the victory parade in Kābul.

Ranjit Singh was taken ill during the victory festivities at Firozpur. He died at Lahore on June 27, 1839, exactly forty years after he had entered the city as a conqueror. At his cremation four maharanis (wives) and seven maidservants immolated themselves on his funeral pyre.

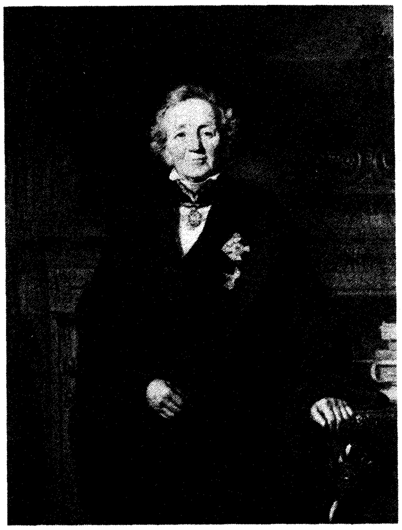
(K.S.)

Ranke, Leopold von

Leopold von Ranke, the leading German historian of the 19th century, has been called the father of modern historiography. Distinguished by his insistence on careful and methodical research, his passion for objectivity, and his belief in the unique importance of historical studies, he transmitted these ideas to several generations of future historians and had profound influence on historiography in the 19th and 20th centuries.

Education

Ranke was born into a devout family of Lutheran pastors and lawyers on December 21, 1795, in Wiehe, Thuringia (now in East Germany). After attending the renowned Protestant boarding school of Schulpforta, he entered the University of Leipzig. He studied theology and the classics, concentrating on philological work and the translation and exposition of texts. This approach he later developed into a highly influential technique of philological and historical textual criticism. His predilection for history arose from his studies of the ancient writers, his indifference to the rationalistic theology still in vogue in Leipzig, and his intense interest in Luther as a historical character. But he decided in favour of history only in Frankfurt an der Oder, where he was a secondary school teacher from 1818 to 1825. Apart from the contemporary patriotic enthusiasm for German history, his decision was



Ranke, oil painting by J. Schrader, 1868. In the National-Galerie, East Berlin.

influenced by Barthold Georg Niebuhr's Roman history (which inaugurated the modern scientific historical method), the historiographers of the Middle Ages, and Sir Walter Scott's historical novels, as well as by the German Romantic poet and philosopher Johann Gottfried von Herder, who regarded history as a chronicle of human progress. Yet Ranke's strongest motive was a religious one: influenced by the philosophy of Friedrich Schelling, he sought to comprehend God's actions in history. Attempting to establish that God's omnipresence revealed itself in the "context of great historical events," Ranke the historian became both priest and teacher.

Early career. The typical features of Ranke's historiographical work were his concern for universality and his research into particular limited periods. In 1824 he produced his maiden work, the *Geschichte der romanischen und germanischen Volker von 1494 bis 1514 (History of the Latin and Teutonic Nations from 1494 to 1514,* 1846), which treats the struggle waged between the French and the Habsburgs for Italy as the phase that ushered in the new era. The appended treatise, *Zur Kritik neuerer Geschichtsschreiber*, in which he showed that the critical analysis of tradition is the historian's basic task, is the more important work. As a result of these publications, he was appointed associate professor in 1825 at the University of Berlin, where he taught as full professor from 1834 to 1871. Many of the students in his famous seminars were to become prominent historians, continuing his method of research and training in other universities. In his next book, Ranke, utilizing the extremely important reports of the Venetian ambassadors, dealt with the rivalry between the Ottoman Empire and Spain in the Mediterranean *(Fiirsten und Völker von Siid-Europa im sechzehnten und siebzehnten Jahrhundert*); from 1834 to 1836, he published *Die romischen Päpste, ihre Kirche und ihr Staat int sechzehnten und siebzehnten Jahrhundert* (changed to *Die romischen Papste in den letzen vier Jahrhunderten* in later editions)—a book that ranks even today as a masterpiece of narrative history. Rising above religious partisanship, Ranke in this work depicts the papacy not just as an ecclesiastical institution but above all as a worldly power.

Excursion into politics

Before this work appeared, Ranke the historian had been drawn briefly into contemporary history and politics. A disillusioning experience, it produced, however, a few short writings in which he expressed his scholarly and political convictions more directly than in his major works. Disregarding his real talents and misjudging the contemporaneous political dissensions, which in 1830 were intensified by the liberal July revolution in France, he undertook to edit a periodical defending Prussian policy and its rejection of liberal and democratic thinking. Only two volumes of the *Historisch-politische Zeitschrift* were published from 1832 to 1836, most of the articles being written by Ranke himself. While he tried to explain the conflicts of the times from a historical—and for him that meant nonpartisan—viewpoint, in essence he sought to prove that the French revolutionary development could not and should not be repeated in Germany. Ranke believed that history evolves in the separate development of individual men, peoples, and states, which together constitute the process of culture. The history of Europe from the late 15th century onward—in which each people, though sharing one cultural tradition, was free to develop its own concept of the state—seemed to him to confirm his thesis. Ranke dismissed abstract, universally valid principles as requirements for the establishment of social and national order; he felt that social and political principles must vary according to the characteristics of different peoples. To him the individual entities of greatest historical importance were states, the "spiritual entities, original creations of the human mind—even 'thoughts of God.' " Their essential task was to evolve independently and, in the process, to create institutions and constitutions adapted to their times.

In this respect Ranke's thinking is related to the philosopher G.W.F. Hegel's theory that what is real is also rational; yet, in Ranke's view, it is not reason that justifies what is real but historical continuity. This continuity is the prerequisite for the development of a culture and also for understanding historical reality. Hence, it is the historian's duty to understand the essence of "historicism": that history determines each event but does not justify it. In practice, however, Ranke endorsed the social and political order of his time—the European system of states, the German Federation with its numerous monarchies, and Prussia before the 1848 Revolution, with its powerful monarchy and bureaucracy, its highly developed educational system, and its rejection of liberal and democratic trends—as resulting from the European cultural process, a process that, according to him, would be demolished by democratic revolution.

The searchfor **objectivity.** But Ranke pleased no one; too devoted to the state for the liberals, he was not sufficiently dogmatic for the conservatives. He therefore returned to his historiographical work in which he thought he could more successfully attain his ideal of objectivity. From 1839 to 1847 the *Deutsche Geschichte im Zeitalter der Reformation (History of the Reformation in Germany,* 1845–47) appeared, the first scholarly treatment of that age. In 1847–48 there followed *Neun Biicher preussischer Geschichte (Memoirs of the House of Brandenburg and History of Prussia, during the Seventeenth and Eighteenth Centuries,* 1849), later expanded to 12 volumes; in 1852–61 the *Franzosische Geschickte, vornehmlich im sechzehnten uizd siebzehnten Jahrhundert,* published in English as *Civil Wars and Monarchy in France, in the Sixteenth and Seventeeth Centuries: A History of France Principally During that Period,* 1852; and, in 1859–69, the *Englische Geschichte, vornehmlich im sechzehnten und siebzehnten Jahrhundert*, published in English as A *History of England Principally in the Seventeenth Century,* 1875—each consisting of several volumes that, although partly rendered obsolete by later research, are still worth reading today for their great narrative skill. In these works, too, Ranke deals with the leading European states at decisive stages of their development within the European system. Ranke typically restricts himself to the Latin and Germanic nations as the protagonists of cultural development, among whom—from the 16th century on—the Protestant states had increasingly assumed leadership; and just as typically, he focusses on political history; *i.e.*, the foreign relations of states and their systems of government and administration. Because economic and social factors were barely reflected in the sources he used, appearing only dimly in the background as "forces" and "tendencies," Ranke found it increasingly difficult to understand the modern age of incipient social change.

His books on the late 18th and early 19th centuries *(Die deutschen Miichte und der Fürstenbund,* 1871–72; *Ursprung und Beginn der Revolutionskriege 1791 und 1792,* 1875; *Hardenberg und die Geschichte des preussischen*

Ranke's theory of history

Staates von 1793 bis 1813, 1877) are subtle accounts of complex political events but address themselves only indirectly to the central problems of a changing age. Like the *Englische Geschichte,* these books exhibit a certain bias against political and social change, especially the appearance of radical movements. In his lectures Ranke often dealt with the history of his time; they did not, apparently, differ in concept or emphasis from his books. History is regarded as a complex process of "historical life," which assumes its most effective "real spiritual" form in the great states and their tensions. The historian, as objectively as possible, must describe "how it really was," keeping the whole picture in mind while extracting the essence. Ranke was thus not an analyst but a "visual" historiographer. Aware of the limitations imposed by time and place on every historian, he attempted to achieve maximum objectivity principally by identifying himself not with a "party" but with the state. Yet his work demonstrates that his intellectual credo influenced his political views.

Ranke reached the peak of his fame as the most important living historian in the second half of the century. In 1865 he was ennobled and in 1882 made a privy counsellor. When Frederick William IV became mentally ill in 1857, Ranke finally withdrew from political life and, after his wife's death (1871), from social life also. Rejecting liberal democratic nationalism and distrusting Chancellor Otto von Bismarck's policy because he believed that it jeopardized the continuity of German history and embraced cooperation with popular movements, Ranke nevertheless welcomed the foundation of the empire in 1871.

In the meantime, failing eyesight had turned him into a lonely scholar who depended on the help of assistants. Yet, despite this handicap, at the age of 82 he began what he claimed to be his greatest work, a "world history" (nine volumes, 1881–88) leading up to the 15th century. Ranke thus fulfilled the task he had set himself as a young man: to tell the "story of universal history." Not a work of critical research or of historical and philosophical speculation but a wide-ranging account of the evolution of culture from the Greeks to the Latin-Germanic nations, it is actually a history of Europe in which the non-European world appears at best only marginally. He wrote it in the conviction that the peaceful evolution of culture was definitively protected against the danger of revolution and that the conflict between popular sovereignty and the monarchy had been settled once and for all in favour of the latter. He died in Berlin on May 23, 1886.

Assessment. Ranke's concept and writing of history predominated in German historiography up to World War I and even after; it also influenced a great many distinguished foreign historians who studied in Germany. Unfortunately, many of Ranke's disciples simply continued, canonized, and debased Ranke's concepts, retaining all of their limitations without the universality of view that gave them meaning. Ranke's own achievements, however, remain unquestioned. He contributed greatly to the progress of historiography: it became more self-assured in its method and proved itself capable of transforming the widely felt need for a historical understanding of the world ("historicism") into an interpretation of the past based on scientific research.

MAJOR WORKS

Geschichte der romanischen und germanischen Volker von 1494 bis 1514, with an appendix *Zur Kritik neuerer Geschichtsschreiber* (1824; *History of the Latin and Teutonic Nations,* 1846); *Fiirsten und Volker von Siid-Europa im sechzehnten und siebzehnten Jahrhundert:* vol. 1, *Die Osmanen und die spanische Monarchie* (1827; *The Ottoman and the Spanish Empires in the Sixteenth and Seventeenth Centuries,* 1843); *Die serbische Revolution* (1829; *A History of Serbia . . . ,* 1847); *Die grossen Miichfe* (1834); *Die römischen Piipste, ihre Kirche und ihr Staat, im sechzehnten und siebzehnten Jahrhundert,* 3 vol. (1834–36; subsequently expanded to *Die römischen Piipste in den letzten vier Jahrhunderten,* 1878; 10th ed., 1900; rev. ed., 1953; *The Ecclesiastical and Political History of the Popes of Rome . . . ,* 3 vol., 1840; and *The History of the Popes during the Last Four Centuries,* 3 vol., 1908); *Das politische Gespräch* (1836); *Deutsche Geschichte im Zeitalter der Reformation,* 6 vol. (1839–47; modern ed., 1925–26; *History of the Reformation in Germany,* 3 vol., 184547); *Neun Biicher preussischer Geschichte,* 3 vol. (184748; *Memoirs of the House of Brandenburg . . .,* 3 vol., 1849), subsequently expanded to *Zwolf Biicher . . .* (1874–79; modern ed., 1931); *Franzosische Geschichte, vornehrnlich in sechzehnten und siebzehnten Jahrhundert,* 5 vol. (1852–61; 4th ed., 6 vol., 1876–77; modern ed., 2 vol., 1954; *Civil Wars and Monarchy in France in the Sixteenth and Seventeenth Centuries,* 2 vol., 1852); *Englische Geschichte, vornehrnlich in sechzehnten und siebzehnten Jahrhundert,* 7 vol. (1859–69; 4th ed., 9 vol., 1877–79; modern ed., 1955; *A History of England, Principally in the Seventeenth Century,* 6 vol., 1875); *Geschichte Wallensteins* (1869); *Der Ursprung des Siebenjährigen Krieges* (1871); *Die deutschen Miichte und der Fiirstenbund,* 2 vol. (1871–72); *Ursprung und Beginn der Revolutionskriege, 1791 und 1792* (1875; 2nd ed., 1879); *Weltgeschichte,* 9 vol. (1881–88, incomplete). The collected edition of Ranke's works comprises 54 vol. (1867–90). There are important collections of his illuminating letters (1949 and 1950).

BIBLIOGRAPHY. HEINRICH VON SRBIK, *Geist und Geschichte vom deutschen Humanismus bis zur Gegenwart,* vol. 1 (1950); and GEORGE P. GOOCH, *History and Historians in the Nineteenth Century,* 2nd ed. (1952), treat in detail the position of Ranke in the development of historical thought and the modern science of history. The philosophical foundations of his view of history are set forth by FRIEDRICH MEINECKE, *Die Entstehung des Historismus* (1946); and CARL HINRICHS, *Ranke und die Geschichtstheologie der Goethezeit* (1954). Of the older investigations in this direction, GERHARD MASUR, *Rankes Begriff der Weltgeschichte* (1926); and ERNST SIMON, *Ranke und Hegel* (1928), are still important. RUDOLF VIERHAUS, *Ranke und die soziale Welt* (1957), deals with the role of social factors in Rankes historiography. Recent critical analyses are THEODORE H. VON LAUE, *Leopold Ranke: The Formative Years* (1950); and HELMUT BERDING, *Leopold von Ranke* (1971), in German.

(Ru.V.)

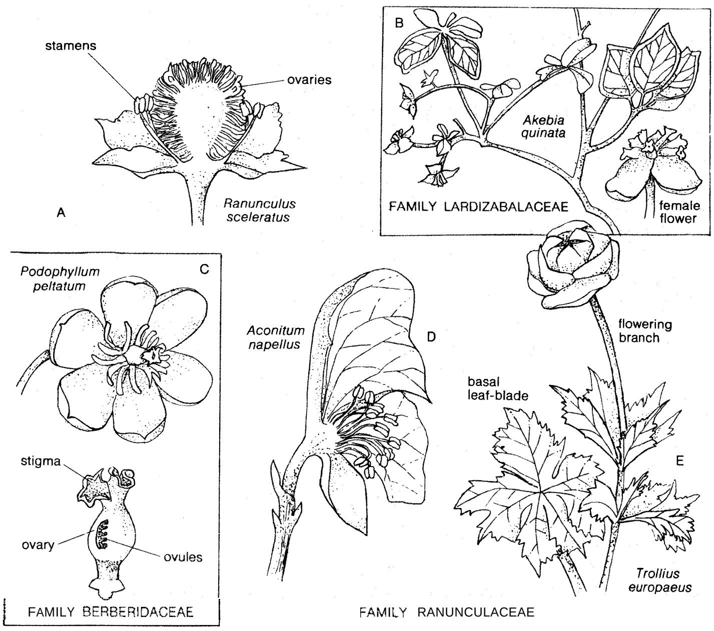
Ranunculales

The Ranunculales order is a large group of plants comprising 10 families, about 140 genera, and approximately 3,000 species. It is a rather diverse grouping, including mainly herbaceous plants and climbers, though some are woody shrubs. They are of considerable interest because they are abundant in most temperate areas, often forming a characteristic element of the floras. They also include many species of great ornamental value, which are grown in gardens in many parts of the world. Several species belonging to the order are common and noxious weeds, particularly in Europe and North America; indeed, many species contain compounds (mainly alkaloids) that are poisonous to man or to livestock. Some of these compounds are also important in folk medicine. In evolutionary terms the group is of especial importance, as it is considered by many botanists to be an early offshoot from the Magnoliales (*q.v.*)—the order generally considered to be the most primitive among the flowering plants.

GENERALFEATURES

Both vegetatively and florally the Ranunculales order is highly variable. There are, nevertheless, a number of features held in common by most members of the group. Among these are the herbaceous or softly wooded habit, and the usually alternately arranged leaves that lack the small leaflike appendages, called stipules, at the bases of their leaf stalks. In the flowers, the segments of the perianth, (sepals and petals) are usually spirally arranged, and the stamens are usually numerous and they, too, are often spirally arranged. There are usually several free carpels (female flower structures) that are spirally arranged or sometimes whorled, but they are rarely united or reduced in number to one in this order. Alkaloid chemical substances are generally present.

Distribution and abundance. The Ranunculales order is a cosmopolitan group and is found everywhere; its species are, however, more common in temperate and subtropical regions than in the tropics. Only one of the ten families of the order (Menispermaceae) is mainly tropical. Members of the order occupy a wide range of habitats, including freshwater, and the species are often very abundant. The barberry genus, *Berberis,* for exam-



Some vegetative and floral diversity in the buttercup order.

From *(Ranunculus sceleratus, Aconitum napellus)* Baillon, Eichler, Firbas, Rassner, Troll, Warming and *(Podophyllum peltatum)* Eichler, A. Gray, Hegi, Maout et Decaisne, Schumann, Warburg, Warming, Wettstein in A. Engler, *Syllabus der Pflanzenfamilien II* (1964), Gebruder Borntraeger, Berlin; (others) G.H. Lawrence, *Taxonomy of Vascular Plants* (1969), The Macmillan Company.

ple, is widespread in temperate South America and also in the Himalayas; the buttercup genus, Ranunculus, is common in Europe and North America, and the monkshood genus, *Aconitum*, is abundant in the Himalayas and Eastern Asia.

Importance. The importance of the group is related to its botanical and economic interest. When considered as an early offshoot from the most primitive flowering-plant stock, the group is of considerable evolutionary interest. Related to this is the fact that the group appears to show a series of structural features that can be construed as showing the origin of flower petals from sterile stamens. Many of the intermediate stages are present in existing species, and almost the whole series is shown by the largest family (Ranunculaceae), with various segments of the series being shown by the other families.

Interpretation of the possible origin of flower petals

The simplest stage in this series is shown by genera such as Anemone and *Pulsatilla,* in which the perianth consists of a single series (*i.e.*, sepals, or, as they are sometimes called, tepals) ; these are usually coloured and serve to attract insects. The stamens (male reproductive structures) are numerous, and all are fertile. Many species of *Clematis* are similar, but others have the outer stamens sterile and somewhat broader than the fertile inner ones. In the genus *Trollius* the outer stamens are more or less flattened and are sterile, the anther-bearing portion being represented by a nectar-secreting pit on the inner surface, near the base. These organs are coloured and very petal-like, though the main insect-attracting function is still carried out by the larger and brightly coloured sepals. In the genus Ranunculus the process is carried further, the sepals being small and usually greenish, whereas the nectar-secreting organs are larger and coloured and take on the main insect-attracting function. Like those of *Trollius*, these organs each bear a nectar-secreting pit on the inner surface, near the base, often covered by a fold or flap of tissue. These organs, which are clearly homologous with sterilized stamens, occur in a close spiral between the sepals and the fertile stamens. They are generally few in number (usually five), alternate in position with the sepals, and are conventionally referred to as petals by most taxonomists, although the Berlin school prefers to call them "honey leaves" (Honigbliitter).

In columbines of the genus Aquilegia the petals are more or less tubular structures, with an expanded and flattened forward portion and backwardly projecting spurs, at the base of which nectar is secreted. The petals are only slightly larger than the sepals, and both series are coloured and serve to attract insects. In *Helleborus, Nigella*, and related genera, the petals are again tubular but much smaller than the usually coloured sepals. They are often of very elaborate construction and serve only to secrete nectar. In those genera with highly zygomorphic (irregular or bilaterally symmetrical) flowers (*Aconitum*, *Consolida*, Delphinium), the petals are much-modified nectar-secreting structures, often enclosed in and hidden by the large coloured sepals.

Thus, there is a series of elaboration of nectar-producing structures and petal-like structures. It must be emphasized, however, that this series cannot be directly interpreted as showing an evolutionary lineage. What it does show, however, is various stages of a process of stamen sterilization and nectary and petal formation that may have taken place in the earliest angiosperms (flowering plants) or pro-angiosperms.

NATURAL HISTORY AND EVOLUTION

Life cycle. The life cycle of the Ranunculales order presents no great differences from that of other flowering plants. The group includes short-lived ephemeral annuais (*e.g.*, many species of the buttercup genus, Ranunculus), perennial herbs of longer or shorter duration, suffrutescent perennials (*i.e.*, those with a woody base that lives from year to year but with branches that die back each year), and woody shrubs and climbers that may persist for long periods. Reproduction is mainly by seed, though various forms of vegetative reproduction do occur (*e.g.*, rhizomes and stolons occur in many species, and bulbils are found in some forms of Ranunculus *ficar*ia). Formation of embryos without fertilization occurs, but it is apparently rare in the group.

Growth forms

Ecology. A very wide range of habitats is occupied by the Ranunculales order, including freshwater (both still and flowing), waste ground, field margins, grassland, pasture, forest, moorland, bogs and marshes, mountain pastures, and mountain slopes. The Menispermaceae family consists of mostly climbers and lianas in tropical forests, whereas the rest of the families in the order tend to avoid tropical areas or to grow only on high mountains (where there is a more temperate climate) within the tropic zone. In general, it may be said that most species of the Ranunculales order are either adapted to average moist habitats or to very wet ones, including even aquatic situations; true dry-habitat species are rare, and desert is essentially the only major plant habitat in which the Ranunculales order is not strongly represented.

The aquatic species of the genus Ranunculus, (Ranun*culus*, subgenus *Batrachium*) are an extremely variable group, difficult to classify, and some of them show the interesting phenomenon of heterophylly—the ability to produce leaves of different shapes depending, in this case, on the depth of the water in which they grow.

In Ranunculus *aquatilis* the plants may bear leaves of three different shapes, depending on the water levels; the submerged leaves are repeatedly divided on a pattern of thirds into threadlike segments; the leaves borne at the surface of the water are simple and palmately lobed, with more or less oblong, toothed segments; and the aerial leaves are divided two or three times by thirds into wedge-shaped segments. Thus, the precise type of leaves that are produced depends on the water levels: at times when the water is high, plants will mainly have leaves of the submerged type; when the water is low, most of the leaves will be of the aerial type. This variation causes difficulty in the classification of the aquatic buttercups.

Pollination. The Ranunculales order shows a very wide variation in methods of pollination, a variation that is reflected in the wide range of floral types found within the group. The mainly temperate families Ranunculaceae and Berberidaceae are the best known in this respect; the range of pollination types in the Ranunculaceae includes almost all of the types in the rest of the order.

In the Ranunculaceae family, as in the Ranunculales order as a whole, insect pollination is the general rule. It seems possible, however, that at least one or two species of *Thalictrum* may be wind pollinated, if not as a general and regular occurrence, then at least sometimes. Self-pollination may be the rule in many of the short-lived annual species in the family.

Insect-pollinated flowers

The insect-pollinated types may be divided into two broad classes — pollenflowers and nectar flowers, depending on what the visiting insect obtains from its visits to the flowers. In the first category are such genera as Anemone, *Pulsatilla*, and Clematis, in which no nectar is produced but from which the insects collect pollen. In the second category are such genera as Aquilegia (columbines), *Ranunculus* (buttercups), Helleborus, and Delphinium (larkspurs), which have well-developed nectaries.

In most cases insects are attracted to the flowers by the coloured perianths. The coloured parts may be sepals, as in Anemone and Clematis; petals (honey leaves), as in Ranunculus; a combination of the two, as in Aquilegia; or the very complex arrangements of sepals and petals containing nectaries in the strongly zygomorphic flowers of Aconitum (monkshood), Delphinium, and Consolida. In some species of *Thalictrum* (meadow rue)—e.g., T. kiusianum — the filaments of the stamens are swollen and coloured, and appear to act as insect attractors.

In all these types the flowers may be obligate outcrossers because either the female ovaries mature before the male anthers of the same flower (protogyny) or because of the reverse situation, in which the anthers mature first (protandry), though these characteristics are usually only weakly developed. Both the male stamens and the female carpels are spirally arranged, and they mature from the margin toward the centre of the flower, so that both sets of organs may contain mature members at the same time. The stamens and stigmas (pollen-receiving surfaces of the female flower structure) are usually situated in such positions that a visiting insect has to touch them in order to obtain pollen or nectar, thus effecting pollination.

In the Berberidaceae family (at least in the two shrubby genera Berberis and *Mahonia*) a different mechanism is employed, involving sensitive stamens. Nectar is secreted in pits on the inner petals, and insects are attracted by the brightly coloured sepals and petals, which, in sunny conditions, are widely spreading. Each of the six inner petals has two nectary pits near the base. The stamens are opposite these petals, and, in sunny conditions, lie along them, the base of the filament thus lying above the line of junction of the two nectary pits. An insect visiting the flower to obtain nectar will necessarily touch the base of the filament. This area is sensitive to touch, and the stimulus causes the filament to spring rapidly into an erect position, thus depositing pollen on the body of the insect. The pollen may then be transferred to another flower by the insect, thus effecting cross-pollination.

Relatively little is known of the pollination mechanisms in the other families of the order, but certain structural modifications suggest that highly adapted mechanisms may be in operation. In the genus *Cissampelos* and other related members of the Menispermaceae family, for instance, the anthers of the six stamens are united into a ring. Cross-pollination is made more certain in this family by the occurrence of separate male and female flowers.

Seed dispersal. Seeds are dispersed in various ways in the Ranunculales order, depending on the nature of the fruit. In those genera with fleshy fruits (*e.g.*, the genus Actaea, and many members of the family Berberidaceae) the seeds are mainly animal-dispersed, whereas in the majority of the order, in which dry fruits prevail, seeds are dispersed by more passive mechanisms. The seeds of many species of Ranunculus have a hard beak, formed by the persistent style, and often, also, a spiny or warty surface; these are dispersed by adhering to the fur of animals. The seeds of genera with single-seeded fruits show adaptation to wind dispersal — those of the genus Thalictrum often being winged and flattened, and those of *Pulsatilla* and Clematis bearing a long, plumose appendage. Genera with many-seeded podlike fruits usually have a spilling mechanism, by which the seeds are gradually shaken out of the open pods when these are agitated by the wind. In Helleborus foetidus and perhaps some other species of Helleborus, the pods, when ripe, are pendent, hanging near the ground surface. All the seeds from each pod are attached to a persistent, fleshy part of the placenta, which becomes detached upon ripening, causing the seeds to fall out, though still attached to the ribbon of placenta; this fleshy tissue is attractive to ants; the ants drag about the strips of seeds, ensuring dispersal.

Evolution and palaeontology. Very few fossil Ranunculales are known, and only a few forms from the Tertiary (about 50,000,000 years ago) have been certainly identified as belonging to the group. These reveal little of the evolution of the order but do indicate that the Menispermaceae family was formerly much more widespread than today, various leaf impressions having been found in Europe, North America, and Greenland.

Possible ancestors of the buttercup order

Most phylogenists believe that the Ranunculales order is an early offshoot from a broadly conceived Magnoliales stock. Some authorities stress the close relationship between the Illiciales order and the Lardizabalaceae, Sargentodoxaceae, and Menispermaceae group of families of the Ranunculales order, and they also point out the close structural relationships between the Berberidaceae, Nandinaceae, Podophyllaceae, Ranunculaceae, and Menispermaceae families, suggesting a common origin for all of them from a possible ancestor of form similar to the order Illiciales. Other workers, however, believe that the Ranunculaceae family within the Ranunculales order could be ancestral to all the other families of the order and that all of the features in which the other families of the order differfrom the Ranunculaceae family appear to represent evolutionary derivations from that family. It is to be doubted, however, whether many phylogenists would accept this latter view, because the Ranunculaceae family itself includes a wide range of types, some generally considered to be primitive, others showing characteristics usually considered to be advanced. In the present state of knowledge, the evolutionary pathways and relationships within the order remain obscure.

CLASSIFICATION

Distinguishing taxonomic **features.** The Ranunculales order is distinguished from its allies by a combination of features, among which the most important is perhaps the widespread occurrence of nectar-producing petals. It differs from the Magnoliales and Illiciales orders by the herbaceous or softly woody habit, the absence of aromatic compounds, the usual absence of stipules, and various floral characters. It differs from the Nymphaeales and Nelumbonales orders by its predominantly terrestrial habit, leaf type, and various floral characters; and from the more advanced Papaverales order by the absence of a latex-conducting vessel system, the free carpels, and other floral characters. It differs from the Paeoniales order, which was included in the Ranunculales order in many older taxonomic systems, by the presence of nectar-producing petals, and by the sequence of stamen maturation.

Annotated classification.

ORDER RANUNCULALES

Herbs, woody climbers, or shrubs. Shoots dimorphic (of 2 kinds) in Berberis, the leaves on the long shoots being replaced by spines. Leaves usually alternate, rarely opposite; exstipulate (without stipules)except in a few genera; variously shaped and divided; deciduous or evergreen; spiny-margined in some genera. Flowers solitary or in inflorescencesof varying degrees of complexity, usually with bracts, usually containing both sexes with flower parts arising at the base of the ovary (hypogynous). Perianth of 1, 2, or 3 (rarely more) series, usually spirally arranged. When the perianth is more than 1-seriate it is usually differentiatedinto an outer series of sepals and 1 or more inner series of petals (honey leaves). The series of the perianth may be in patterns of 3, 4, 5, or larger indefinite numbers. Pcrianth usually regular (radially symmetrical or actinomorphic) but is irregular (zygomorphic) in some genera of the family Ranunculaceae. Nectar absent, or secreted by nectaries of various shapes, often petaloid, or rarely by the ovary (*e.g.*, in the genus *Caltha*). Stamens usually numerous, spirally arranged, and maturing from the margin inward. They are fewer than or equal in number to the petals and opposite them in many Berberidaceae. Stamens are usually free (anthers united in some Menispermaceae). Anthers open by lengthwise slits or by flaplike valves in some. Pollen granular, variable in appearance. Ovary of several to many usually free (united in some Ranunculaceae) carpels, rarely reduced to a solitary carpel.

Ovules several with marginal or sub-basal placentation, or reduced to one. Fruit a berry or a group of follicles or achenes. Seeds usually with endosperm. Alkaloids usually present.

Family Lardizabalaceae

The plants of this family are climbers or rarely shrubs (*Decaisnea*), with alternate, palmate or pinnate leaves, trimerous flowers having 3 or 6 sepals, 6 petals (usually small, rarely absent), 6 stamens, and 3 (rarely more) carpels. The flowers are often functionally unisexual, with stamens represented by sterile stamen structures in the female flowers. The fruit is a group of berries or fleshy follicles, and the seeds have copious, fleshy endosperm. Species of Akebia and Decaisnea are grown as ornamentals; the blue, fleshy follicles of Decaisnea *fargesii* are very noticeable in autumn and never fail to attract attention. Eight genera and about 30 species with a disjunct distribution, most of the genera occurring in the Himalayas and eastern Asia; 1 (*Lardizabala*) is found in Chile.

Family Sargentodoxaceae

A family consisting of a single genus and species occurring in China and Southeast Asia. The only known species is a climber with alternate, trifoliolate leaves and with all floral parts spirally arranged. Sepals 6, petals 6, very small, stamens 6, opposite the petals, carpels numerous. The fruits are berry-like, and each one is stalked, the whole group being borne on the elongated receptacle, which is markedly thickened. The one species, Sargentodoxa cuneata, is sometimes cultivated as a cool-greenhouse climber in temperate areas.

Family Menispermaceae

A large family of woody climbers (rarely erect shrubs), many showing anomalous forms of secondary thickening. Leaves alternate, entire or lobed; flowers unisexual, usually small, sometimes strongly zygomorphic. Sepals 3 to 12 usually, but occasionally as few as 1 or much more numerous than 12; petals various, usually small, often absent; stamens 2 to indefinitely large numbers; when few, they are opposite the petals (if petals are present), anthers often united; carpels usually 3 to 6 but as few as 1, or very numerous. Seeds characteristically half-moon or horseshoe shaped. A few species of Stephania, Cocculus, and Cissampelos are grown as foliage ornamentals. Found more or less throughout the tropics with, however, some genera extending into temperate areas (*e.g.*, Japan, United States, Canada). About 65 genera and 430 species.

Family Ranunculaceae

The largest family in the order, consisting of herbs usually, (Xanthorrhiza, however, is a shrub with soft yellow wood), or rarely climbers (Clematis). Leaves usually alternate (opposite in Clematis), without stipules (with stipules in Thalictrum; Actaea and some others, however), simple to much divided, often with sheathing bases. Flowers actinomorphic or zygomorphic. Sepals 2 to 5 usually, but often numerous and often petaloid; petals zero to 5 usually, but often numerous, nectariferous, sometimes reduced to nectar-producing tubes or sacs. Stamens usually very numerous. Carpels numerous, but occasionally as few as 1, several- to 1-seeded. Fruit a group of achenes, follicles, or a berry. Widely distributed in temperate and subtropical regions of both hemispheres, mainly on mountains in the tropics. About 50 genera with some 2,000 species.

Family Glaucidiaceae

A family of 1 genus and 1 or 2 species from western China and Japan, often included in the Ranunculaceae family. The species are perennial herbs growing from rhizomes with few, palmately lobed, alternate leaves. Sepals 4, petaloid, usually blue; petals absent; stamens numerous; carpels 2. Fruit a group of follicles. Superficially the plants resemble the blue Himalayan poppies (Meconopsis in the family Papaveraceae, order Papaverales), and may indicate a relationship between the two orders. *Glaucidium palmatum* is frequently cultivated as a garden ornamental.

Family Hydrastidaceae

A family of 1 genus with 2 species, from North America. They are rhizomatous herbs with few, simple, cordate leaves. The flowers are small, with 3 sepals, and without petals. The fruit is a raspberry-like group of berries. Hydrastis canadensis, which was once important in folk medicine, has been exterminated by collectors in some parts of the U.S. The genus is usually included in the Ranunculaceae family.

Family Circaeastraceae

Another monotypic family, the one species occurring in the northwest Himalayas. It is an annual herb with spiny-toothed, rather barberry-like leaves, and very reduced flowers with 2 sepals, 2 (sometimes one) stamens, and 1 carpel. Its position is controversial, many authors including it in the Ranunculaceae family.

Family Podophyllaceae

A small family, whose circumscription varies greatly from one authority to another; many treat the group as part of the Berberidaceae family. The family includes 2 genera, each with few species, from eastern Asia and Atlantic North America. The plants are herbaceous with lobed leaves; the flowers have usually 6 sepals, 6 petals, and a single-chambered ovary, with ovules borne in 2 or more series on the adaxial suture. *Podophyllum* is sometimes grown as an ornamental; the fruits of P. peltatum (mayapple) are edible.

Family Nandinaceae

A monotypic family with its one species found in China and Japan. It is a small shrub with alternate, 2 to 3 pinnate leaves and small white flowers in large panicles. Sepals numerous, spirally arranged, petals 6, stamens 6, opposite the petals, carpel 1 with 1 pendent ovule. The one species, Nandina domestics, is frequently grown as an ornamental shrub, mainly for its attractive foliage, which is reddish when young, and which colours well in autumn.

Family Berberidaceae

A large family of 12 genera and about 650 species, most of these (about 500) belonging to the genus Berberis. The circumscription of the family varies greatly with authority, depending on how each individual author treats the Podophyllaceae family. As presented here, the family includes both herbaceous and shrubby genera from most temperate parts of the world. Leaves simple or variously compound, alternate (leaves on the long shoots in the genus Berberis represented by spines), spiny-margined in the shrubby genera. Flowers are variable. Sepals few to numerous, often in 1 to 3, trimerous whorls; petals present or absent, when present nectar-producing, spurred in some genera. Stamens 4–6, opposite to the inner petals, sensitive to the touch in shrubby genera, anthers often opening by flaplike valves. Ovary of 1 carpel; ovules numerous, placentation lateral or basal. Fruit usually fleshy.

Species of Berberis, Epimedium, *Jeffersonia, Mahonia, Leontice*, Ranzania and Vancouveria are cultivated as garden ornamentals.

Disagreements on relationships in the order

Critical appraisal. The contents of this order are not generally agreed upon among taxonomists, and various alternative classifications have been proposed. Specifically, there is no general agreement as to precisely what groups should be included in the Ranunculales order and how the groups should be related to each other; and there is little agreement as to which groups of genera should be recognized at family level.

The following points of agreement should be noted, however. The core of the order consists of the families Lardizabalaceae, Sargentodoxaceae, Menispermaceae, Ranunculaceae, Glaucidiaceae, Hydrastidaceae, Circaeastraceae, Podophyllaceae, Nandinaceae, and Berberidaceae; that is, those families comprising the order as presented here. The other groups in the order in other classifications—viz., the families Paeoniaceae, Ceratophyllaceae, Cabombaceae, Nymphaeaceae, Corynoçarpaceae, Coriariaceae and Sabiaceae—are more often placed in other orders, although the exact relationships of many of them are still controversial.

Within the order, as presented here, however, there is great variability, and it may be doubted whether or not it should be maintained as a whole. The division of it into two orders, Ranales and Berberidales, has been proposed, but this has not been widely accepted, and it may be an improvement to recognize its division into even three groups.

Regarding the placement of the Ranunculales among other orders, the close relationship of Magnoliales, Illiciales, and Ranunculales is generally agreed upon among phylogenists, as is a close relationship of the Ranunculales order with the Nymphaeales and Nelumbonales orders. A relationship with the primitive members of the flowering plant class Monocotyledoneae is postulated by some authors, whereas others suggest that the similarities between Ranunculales and Nymphaeales orders of the dicots and the Alismales order of the monocots are the result of convergent evolution. A fairly close relationship between members of the Ranunculales order (particularly among the Berberidaceae, Glaucidiaceae, and Podophyllaceae families) and the Papaverales order is widely accepted; this is based mainly on structural features, strengthened, however, by the occurrence of the same, or closely related, alkaloids in both groups. A close relationship between the Ranunculales and the Paeoniales orders is not now generally accepted.

Raphael

Working in the spirited atmosphere of the early 16th century, in the culture that came to be called the High Renaissance, Raphael was the most celebrated of those who brought Italian art to its highest level. He seemed to incarnate the spirit of Humanism—with its reverence for classical art and thought, its individualistic and inquiring spirit—and to give it incomparable expression.

At the end of the 15th century the states of Italy were in a politically critical condition, and Italian territory was about to become the battleground of opposing foreign armies. Early forewarnings of the turmoil of the Reformation were also disturbing its religious consciousness. Indeed, Raphael's work has been considered as the symptom of a moral and historical situation, the ultimate refinement of a world that had reached its climax and would before long find itself unable to survive: Raphael is thus the painter and architect of a moment of crisis whose works speak of his absolute assurance of artistic means and of the universality of his conceptual expression.

Early years at Urbino. Raphael was born at Urbino in the Marche, or marches, on April 6, 1483, the son of Giovanni Santi and Magia di Battista Ciarla. His mother died a few years later, in 1491. His father was, according to the 16th-century artist and biographer Giorgio Vasari, a painter "of no great merit." He was, however, a man of culture who was in constant contact with the advanced artistic ideas current at the court of Urbino. He gave his son his first instruction in painting, and before his death in 1494, when Raphael was 11, he had introduced the boy to Humanistic philosophy at the court, where the cultural achievements of the past and new ideas looking forward to the 16th century could be learned.

Early influences

Urbino had become a centre of culture during the rule of Duke Federico da Montefeltro, who died seven months before Raphael was born. Duke Federico, the embodiment of the Renaissance ideal of the cultured prince, had greatly encouraged all the arts and had attracted the visits of men of outstanding talent to the court he kept in the beautiful ducal palace he had had reconstructed; such men included two Urbinates, the architect Donato Bramante, who was to befriend Raphael in Rome later, and the writer Baldassare Castiglione, whose *Il Cortegiano (The Courtier)* celebrated the reign of Guidobaldo and was universally acclaimed as the model for perfect conduct. Neither Bramante nor Castiglione were members of Federico's court; nor were Piero della Francesca or Leon Battista Alberti, two of the dominant spirits in the growth of the visual arts in Urbino during this period. The style of Piero, a painter with a strong mathematical bent, was diametrically opposed to that of Raphael, as it created spatial compositions of extreme austerity that emphasized perspective and the use of human forms as geometrical elements. Alberti was one of the major theorists in the development of perspective in painting and was a strong advocate of the idealization of nature and of architectural proportions based on musical harmonics. The foundation of Raphael's style was the system of artistic principles established by these artists and others such as Justus of Ghent, Ucello, Francesco di Giorgio, and the influence of Flemish painting. Later, in Florence with Leonardo da Vinci, he would synthesize from it a new system of painting as organic and ordered as that of the 15th-century artists, though less crystalline; the principles of order and proportionality he learned at Urbino would be developed by him in a personal and original manner. Although in Perugia and in Florence Raphael would be influenced by other major artists, Urbino constituted the basis for all his subsequent learning. Furthermore, the cultural vitality of the city probably accounted for the exceptional precociousness of the young artist, who, even at the beginning of the 16th century, when he was scarcely 17 years old, already displayed an extraordinary talent.

Apprenticeship at Perugia with Perugino. Vasari's statement that Giovanni Santi accompanied his son to Perugia and apprenticed him there to the great Umbrian painter Pietro Perugino cannot be accepted, for Raphael was hardly 11 at the time of his father's death. Nevertheless, the date of Raphael's arrival in Perugia cannot be long postponed, and several scholars place it definitely in 1495. What is certain, as attested by a notary's deed, is that he was no longer in Urbino on May 13, 1500. Furthermore, another document of December 10, 1500, declares that the young painter, by then called a "master," was commissioned to paint, together with a pupil of his father, an altarpiece to be completed by September 13, 1502. It is clear from this that Raphael's apprenticeship to Perugino was already under way and that he had given immediate proof of his mastery, so much so that between 1501 and 1503 he received a rather important commission—to paint the "Coronation of the Virgin" for the Cappella Oddi in S. Francesco, Perugia, where it remained until 1797, when it was stolen by Napoleonic troops. It was returned to the Vatican in 1815. Perugino was executing the frescoes in the Collegio del Cambio at Perugia between 1498 and 1500, enabling Raphael, as a member of his workshop, to acquire extensive professional knowledge. The art of Perugino, Raphael's first effective teacher, was in harmony with the Humanistic philosophy of the court of Urbino, especially in its iconography.

First major work

In addition to this practical instruction, Perugino's calmly exquisite style also influenced Raphael. The "Giving of the Keys to St. Peter," painted in 1481–82 by Perugino for the Sistine Chapel of the Vatican Palace in Rome, inspired Raphael's first major work, "The Marriage of the Virgin" (1504). Perugino's influence is seen in the emphasis on perspectives, in the graded relationships between the figures and the architecture, and in the lyrical sweetness of the figures. Nevertheless, even in this early painting, it is clear that Raphael's sensibility was different from his teacher's. The disposition of the figures is less rigidly related to the architecture, and the disposition of each figure in relation to the others is more informal and animated. The sweetness of the figures surpasses even that characteristic of Perugino, and the gentle relation between them does not exist in any comparable degree in Perugino's paintings. Three small paintings done by Raphael shortly after "The Marriage of the Virgin"—"Vision of a Knight," "Three Graces," and "St. Michael"—are masterful examples of narrative painting, showing, as well as youthful freshness, a maturing ability to control the elements of his own style. Although he had learned much from Perugino, Raphael by late 1504 needed other models to work from; it is clear that his desire for knowledge was driving him to look beyond Perugia.

Move to Florence. Vasari vaguely recounts that Raphael followed the Perugian painter Bernardino Pinturicchio to Siena and then went on to Florence, drawn there by accounts of the work that Leonardo and Michelangelo were undertaking in that city (their respective designs of the battles of Anghiari and Cascina for paintings in the Palazza della Signoria). By the autumn of 1504 Raphael had certainly arrived in Florence. It is not known if this was his first visit to Florence, but, as his works attest, it was about 1504 that he first came into substantial contact with this artistic civilization, which reinforced all the ideas he had already acquired and also opened to him new and broader horizons. He took in all that he saw, not passively but, as usual, to reaffirm his understanding of the

canons of Renaissance culture. With his incredible capacity to synthesize, Raphael learned from the works of a range of artists—from the old masters of the 15th century to his two great elder contemporaries, Leonardo da Vinci and Michelangelo. Giorgio Vasari records that he studied not only the works of Leonardo, Michelangelo, and Fra Bartolomeo della Porta, a Florentine proponent of the generalized idealism of the High Renaissance, but also "the old things of Masaccio," a pioneer of the naturalism that marked the departure of the early Renaissance from the Gothic. Some of his designs show that he also looked back to the sculptors Donatello and Verrocchio and the engraver Antonio Pollaiuolo, all of whom were avid students of ways of rendering movement in the human form. Thus, by constantly re-examining and re-evaluating the works of his contemporaries and predecessors, he was able to determine which of the artistic principles of the last 100 years were truly classic and which should be disregarded.

Still, his principal teachers in Florence were Leonardo and Michelangelo. Many of the works that Raphael executed in the years between 1505 and 1507, most notably the Madonnas, such as "The Madonna of the Goldfinch," the "Madonna del Prato," the "Esterházy Madonna," and "La Belle Jardinière," are marked by the influence of Leonardo, who since 1480 had been making great innovations in painting. These paintings were influenced by Leonardo's compositions, figure placement, and gestures, all of which are marked by an intimacy and simplicity of setting uncommon in 15th-century art. Raphael also owed much to Leonardo's lighting techniques; he made moderate use of Leonardo's chiaroscuro (*i.e.*, strong contrast between light and dark, seemingly resulting from a natural or fixed light source), and he was especially influenced by his sfumato (*i.e.*, use of extemely fine, soft shading instead of line to delineate forms and features). Raphael also became a master at this technique. Raphael went beyond Leonardo in creating new figure types whose round, gentle faces reveal uncomplicated and typically human sentiments but raised to a sublime perfection and serenity. At the same time, the extraordinary capacity to synthesize that characterizes Raphael enabled him to resolve a variety of treatment—from Masaccio to Michelangelo—of perspectives of movement, dramatic foreshortenings, and the plastic potentialities of the human figure.

Leonardo's influence on Raphael

Between 1504 and 1508 Raphael did not reside continuously in Florence but moved about, even returning to Urbino and, naturally, to Perugia. And it was a Perugian noblewoman who commissioned him, in 1507, to paint the "Deposition" that is now in the Borghese Gallery in Rome, in which the obvious influences of Michelangelo and also of Leonardo are transformed and worked up into an original synthesis.

In general, Raphael differed from Leonardo and Michelangelo, both painters of dark intensity and excitement, in that he wished to develop a totally fresh and completely calm, extrovert communication; through it he wished to achieve a more popular and universal form of expression. Meanwhile, although scarcely 25 years old, he was already in full command of his artistic means and was absolutely certain of his aesthetic principles. He was now ready to impose his style on Rome---on a society as astute and as critically apprised as any in Italy.

Last years in Rome. Raphael was called to Rome toward the end of 1508 by Pope Julius II at the suggestion of Bramante, who wanted to bring his fellow townsmen into the papal court. At this time Raphael was little known in Rome, but the young man soon made a deep impression on the volatile Julius and the papal court, and his authority as a master grew day by day. Identifying himself with Rome and the spirit of its aristocracy, he became so popular that he was called "the prince of painters." The Humanist Celio Calcagnini later said of him in a Latin epigram:

> It took many ancient heroes and a long age to build Rome, and many enemies and centuries to destroy it. Now Raphael has sought and discovered Rome in Rome: it takes a great man to seek, but discovery comes of God Himself.

The epigram is testimony to the success of the style by which the artist gained the respect of the whole city. The Roman aristocracy considered him one of its own; Cardinal Bibbiena in 1514 wished to give his niece in marriage to him; according to Vasari, Pope Leo X, the successor of Julius II and the cultured son of the Medici Lorenzo the Magnificent, had had the intention of making him a cardinal.

Raphael spent the last 12 years of his short life in Rome.

They were years of feverish activity and successive masterpieces. No test frightened him; he faced every task with modesty and deep studiousness, but he aimed at new heights each time and triumphed. Begun at the end of 1508 and completed in less than three years, the decoration of the Stanza della Segnatura in the Vatican Palace was perhaps his greatest work, reflecting the ideology and culture of Julius' pontificate and glorifying the Roman Church in history. The Stanza della Segnatura is one of the rooms in the Vatican papal apartments in which Julius II, who commissioned the decoration, was to live and work. Julius II was a highly cultured man who surrounded himself with the most illustrious personalities of the Renaissance. He entrusted Bramante with the construction of a new basilica of St. Peter to replace the original 4th-century church; he called upon Michelangelo to execute his tomb and compelled him against his will to decorate the ceiling of the Sistine Chapel; and, sensing the genius of Raphael, he committed into his hands the interpretation of the philosophical scheme of the frescoes in the Stanza della Segnatura, the theme of which he had discussed with the Humanists of his court. This theme was the historical justification of the power of the Roman Church through Neoplatonic philosophy. The two most important of these frescoes are called the "Disputa" and the "School of Athens." The "Disputa," showing a celestial vision of God and his prophets and apostles above a gathering of representatives, past and present, of the Roman Church, equates through its iconography the triumph of the church and the triumph of truth. The "School of Athens" shows Plato and Aristotle surrounded by philosophers, past and present, in a modern architectural setting; it illustrates the historical continuity of Platonic thought. In these works, the order conveyed by strong perspective and gradated figure placement and grace in gesture and expression are conjoined with an erudite iconography to make powerful philosophical statements. In executing this cycle, Raphael accepted and interpreted the spirit of Julius' ideology and the will to triumph that animated it and made it his own will and the foundation of the ordered, rational perfection of his artistic language.

Frescoes in the Stanza della Segnatura

The decoration of the apartments continued after the death of Julius in 1513 and into the succeeding pontificate of Leo X until 1517. In spite of this great undertaking, the last sections of which were left almost completely to his pupils, Raphael undertook at the same time a variety of other ambitious tasks—sacred and secular decorations in other buildings, portraits, altarpieces (in which his gentle saints and madonnas introduce a new typology), cartoons for tapestries, designs for dishes, and the painting of stage scenery. While he was at work in the Stanza della Segnatura, he also did his first architectural work, designing the church of S. Eligio degli Orefici. In 1513 the banker Agostino Chigi, whose Villa Farnesina Raphael had already decorated, commissioned him to do his funerary chapel in the church of Sta. Maria del Popolo. There Raphael showed himself to be a complete artist: he designed the chapel and a sculpture that was to adorn it and executed the cartoons for the mosaics in the cupola, creating a complex harmony of the different arts. In 1514 Leo X chose him to work on the basilica of St. Peter's alongside Bramante; and when Bramante died later that year, Raphael assumed the direction of the work, transforming the plans of the church from a Greek, or radial, to a Latin, or longitudinal, design. He also succeeded Brarnante in the decoration of the Vatican loggias, or galleries, in which he engaged himself and his whole workshop. The sweet simplicity of this lyrical decoration seemed to counterbalance the terrifying grandeur of the Sistine Chapel of Michelangelo.

Architectural work

As a result of the philosophical depth of many of Raphael's Roman works, his reputation as a Humanist and Neoplatonist spread through Rome. He counted among his friends there several men of letters—among them, Castiglione, Cardinal Bembo, the satirist Pietro Aretino, and Bibbiena—as well as many artists. In 1519 he designed the sets for the comedy I Suppositi, by Italy's epic poet Ludovico Ariosto. Raphael was a competent scholar, particularly interested in classical antiquity. In August 1515 Pope Leo put him in charge of the supervision of the preservation of marbles with valuable Latin inscriptions; two years later he was appointed commissioner of antiquities for the city, and he drew up an archaeological map of Rome. In this connection, the existence of a letter addressed to the Pope, the content of which, though indited by Castiglione, is said to be Raphael's (though a few scholars would like to attribute it to Bramante), is extremely significant in its preoccupation with the examination, measurement, and classification of ancient monuments according to their artistic and constructional qualities. His admiration of antiquity did not impede his projecting artistic schemes for future execution. At the end of his career, he was creating designs that looked beyond the High Renaissance to a new mode of expression. His plans for the Villa Madama in Rome, the construction of which was begun after 1516, exemplified a new architectural conception of enormous importance to the subsequent development of Italian architecture. Similarly prophetic in his painting, he revealed in his last work, the "Transfiguration" (commissioned in 1517), a new sensibility that is like the prevision of a new world, turbulent and agitated; in its composition it tends toward an expression that is already Baroque.

Raphael died on his 37th birthday, April 6, 1520. A mythical halo had surrounded him during the last years of his life, and the whole papal court mourned him. His funeral mass was celebrated at the Vatican, his "Transfiguration" was placed at the head of the bier, and his body was buried in the Pantheon in Rome.

MAJOR WORKS

PAINTINGS: "Altarpiece: the Crucified Christ with the Virgin Mary, Saints and Angels" ("Mond Crucifixion," c. 1501; National Gallery, London); "An Allegory" ("Vision of a Knight," c. 1501; National Gallery, London); "Three Graces" (c. 1501; Musée Condé, Chantilly, France); "St. Michael" (*c.* 1501;' Louvre); "Coronation of the Virgin" (*c.* 1501–03; Vatican Museum, Rome); "The Marriage of the Virgin" (1504; Brera, Milan); "Portrait of Agnolo Doni" (c. 1505; Pitti Palace, Florence); "Portrait of Maddalena Doni" (*c.* 1505; Pitti Palace); "The Madonna of the Goldfinch" (*c.* 1505; Uffizi, Florence); "The Madonna and Child with St. John" ("Madonna del Prato," c. 1505; Kunsthistorisches Museum, Vienna); "Esterházy Madonna" (c. 1505–07; Museum of Fine Arts, Budapest); "The Ansidei Madonna" (c. 1506; National Gallery, London); "The Deposition of Christ" (1507; Borghese Gallery, Rome); "La Belle Jardinière" (1507; Louvre); "The Niccolini-Cowper Madonna" (1508; National Gallery of Art, Washington, D.C.); "Stanza della Segnatura" (1508–11; Vatican, Rome); "Stanza d'Eliodoro" (1512–14; Vatican, Rome); "Triumph of Galatea" (1511–13; Villa Farnesina, Rome); "Sistine Madonna" (1513?; Gemäldegalerie, Dresden); "Stanza dell'Incendio" (1514–17; Vatican, Rome); Tapestry cartoons for Leo X (c. 1516; Victoria and Albert Museum, London); "Portrait of Balthasar Castiglione" (1516; Louvre); "Transfiguration" (1517–c. 1520; Vatican Museum, Rome); "The Holy Family of Francis I" (1518; Louvre); "St. Michael Vanquishing Satan" (1518; Louvre).

ARCHITECTURE: Chigi Chapel (c. 1513–14; Sta. Maria del Popolo, Rome); S. Eligio degli Orefici (c. 1516; Rome); Palazzo Pandolfini (c. 1516; Florence).

Rare-Earth Elements and Their Compounds

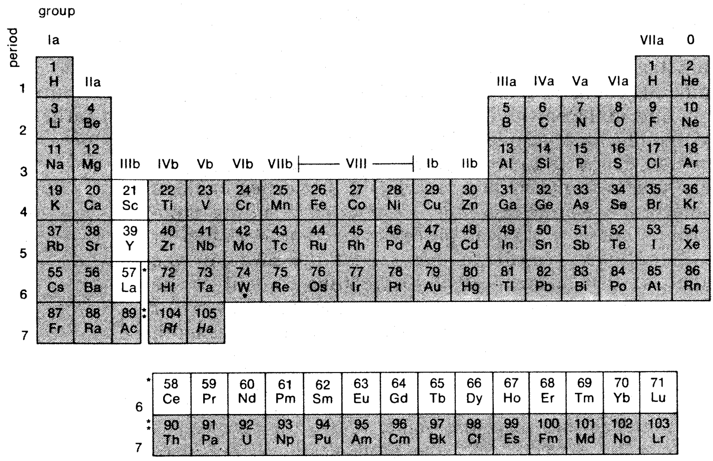
The rare-earth elements form a series of 17 chemically similar metals, all but one of which occur in nature. Often they are called simply rare earths, but this is a misnomer because the term earth properly is applied to the oxide of a metal rather than to the element itself. The rare-earth elements are not even particularly rare, though for a long time they were thought to be.

The 17 rare-earth elements (with their chemical symbols) are: scandium (Sc), yttrium (Y), lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), promethium (Pm), samarium (Sm), europium (Eu), gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), and lutetium (Lu).

Until the mid-20th century, there was not much use for pure rare-earth elements or compounds except cerium and lanthanum; mixtures of the rare earths, however, had found metallurgical and other uses. By the 1970s two of these elements, yttrium and europium, were being used in the red phosphors for colour-television tubes.

Positionin the periodic table

In the periodic table of the elements (see Figure). the rare-earth elements comprise three members of Group IIIb and all 14 members of one of two series of elements generally written apart from the main table. This long series is known collectively as the lanthanide series because it directly follows lanthanum in a different form of the table. The periodic table is based on the electronic structure of the atoms of the various elements, and this structure also determines the chemical behaviour of the elements themselves. As shown below (see *Electronic structure),* the rare-earth elements all have certain common features in the structure of their atoms, the fundamental reason for their chemical similarity.



period	Ia	IIa	IIIb	IVb	Vb	VIb	VIIb	VIII	VIII	VIII	Ib	IIb	IIIa	IVa	Va	VIa	VIIa	0

The positions of the rare-earth elements in the periodic table

The aqueous chemistry of all the rare earths is very similar and changes only slightly in progressing along the lanthanide series. Because of this similarity, it is difficult to separate individual rare earths. In the few cases in which the rare-earth ion can be oxidized or reduced to another valency, however, chemical separations can be carried out readily. Also, artificial mixtures of elements far apart in the series can be separated easily.

All of these elements form trivalent compounds, and in the crystal lattices (the regular arrangement of atoms in the solid forms) of such compounds, one rare-earth ion readily replaces another. The rare-earth metals when heated react strongly with nonmetallic elements to form very stable compounds. They are never found as the free metals in the earth's crust. Pure minerals of individual rare earths do not exist in nature; all their minerals contain mixtures of the rare-earth elements.

Promethium is never found in the earth's crust since it has no stable isotopes and is produced only by nuclear reactions; it can, however, be obtained in quantity from the fission products formed in nuclear reactors.

The chemical properties of scandium differ sufficiently from those of other rare-earth elements for it to have become segregated from them by the action of geological processes. Scandium seldom is associated with the rare earths in minerals.

History. The early Greeks believed that all matter was made up of four elements: air, earth, fire, and water. Earths were defined as materials that could not be changed further by the sources of heat then available. Until late in the 18th century, this Greek conception remained strong in chemistry, and oxides of metals such as calcium, aluminum, and magnesium were known as earths and were thought to be elements.

Discovery of the first rare earth

In 1794, Johann Gadolin, a Finnish chemist, while investigating a rare Swedish mineral, discovered a new earth in impure form, which he believed to be a new element and to which he gave the name ytterbia, from Ytterby, the village where the ore was found. The name, however, was soon shortened to yttria. In 1803, from the same mineral, later named gadolinite in Gadolin's honour, another new earth was reported in the literature independently by several chemists. The new earth became known as ceria, from the asteroid Ceres, which had only just been discovered (1801). Since yttria and ceria had been discovered in a rare mineral, and they closely resembled other known earths, they were referred to as the rare earths. Not until 1808 did the English chemist Sir Humphry Davy demonstrate that the earths as a class were not elements themselves but were compounds of oxygen and metallic elements. Later, a number of chemists verified the existence of ceria and yttria in gadolinite and found that these oxides were also present in a wide variety of other rare minerals. The elements of which yttria and ceria were the oxides were then given the names yttrium and cerium, respectively.

In the period from 1839 to 1843, Carl Gustaf Mosander, a Swedish chemist (and student of Berzelius), found that yttria and ceria were not even the oxides of single elements but were, in fact, mixtures. He reported that if the oxides were dissolved in strong acid and the resulting solution subjected to a long series of fractional precipitations as various salts (oxalates, hydroxides, and nitrates), two new elemental substances could be split off from the main component of each oxide. The two new oxides found in ceria he called lanthana and didymia, and the elements contained in them were named lanthanum and didymium. The new elements found (as their oxides) in yttria he called erbium and terbium, and the oxides were referred to as erbia and terbia. Mosander also was the first to obtain the rare-earth metals themselves from their oxides, although only in impure form. Mosander's researches puzzled the scientists of his time. He seemed to be finding a new group of elements of an entirely different type from any known previously. All formed the same classes of compounds with almost the same properties, and the elements could be distinguished from one another—at that time—only by slight differences in the solubilities and molecular weights of the various compounds.

In the next few years the literature on the rare earths became confused. There was, for example, considerable controversy for a number of years over the existence of didymium. The situation was considerably clarified in 1859 when an instrument called the spectroscope was introduced into the study of the rare earths. This instrument indicated the aatterns of light emission or absorption characteristic of the elements, and, with it, didymium was shown to have a characteristic absorption spectrum. From then on determination of spectra of various types became one of the most important tools in following the progress of the fractionation of rare earths. Somehow during this period the names used for the various fractions differed from laboratory to laboratory. Around 1860, by general agreement, it was decided to interchange the names of Mosander's earths, erbia and terbia.

Scandium and the periodic table

In 1869, when the Russian chemist Dmitry Ivanovich Mendeleyev first proposed the periodic table, he found it necessary to leave a blank at the position now occupied by scandium. He predicted in 1871, however, that a new element would be found to fit that blank in the table, and he also predicted certain properties of the element. The discovery of scandium a few years later (1879) and the agreement of its properties with those predicted by Mendeleyev helped to bring about general scientific acceptance of Mendeleyev's periodic table. Interestingly enough, one of the greatest weaknesses in the table was that it provided no logical place for the lanthanides, a difficulty that was not resolved for some years.

From 1843 to 1939 chemical fractionation of the mixed rare-earth salts obtained from many minerals was intensively investigated in both Europe and North America. Mosander's didymia was resolved into several oxides—samaria (samarium; 1879), praseodymia (praseodymium; 1885), neodymia (neodymium; 1885), and europia (europium; 1901). His terbia and erbia were resolved into holmia (holmium; 1878), thulia (thulium; 1879), dysprosia (dysprosium; 1886), ytterbia (ytterbium; 1876), and lutetia (lutetium; 1907).

During this period many of these elements were discovered independently by more than one investigator, but the credit for the discovery was usually given to the man who first separated sufficient quantities of the oxide to determine some of its properties and who published his results first.

As the scientists carried out their fractionations, they frequently observed changes in colour, apparent molecular weight, and spectra of the substances. Such changes were mainly responsible for the more than 70 claims for the discovery of new rare-earth elements during this period. Many of the observed changes were brought about by the concentration of different impurities, particularly the transition elements, in various fractions of the series. It is now known that such trace impurities in the rare-earth oxides can give rise to such colour changes and that such oxides can be made to fluoresce strongly and exhibit unique spectra.

Contributions of Welsbach

Shortly after Auer von Welsbach isolated praseodymia and neodymia in 1885 he invented an illuminating device that bears his name (Welsbach gas mantle), and a little later he produced a practical lighter flint. Both devices depended upon rare-earth elements. Although minerals rich in rare earths had up to that time been thought to be very rare, the demand for rare earths that developed as a result of Auer von Welsbach's inventions resulted in a worldwide search for rare-earth minerals, and it was found that one of them, monazite, existed in extensive deposits. Monazite, a phosphate of several rare-earth elements, was ideal for Auer von Welsbach's purposes, because it contained a high percentage of the element thorium, which was also used for the mantles. These were prepared by impregnating a cloth fabric with a solution of about 90 percent thorium nitrate, 10 percent cerium trinitrate, and minor amounts of other salts. When heated by a gas flame, these salts were converted to their oxides, which, when heated by the flame, gave off an intense white light. Cerium and iron form an alloy that emits sparks when struck. The discovery of this alloy by Auer von Welsbach started the flint industry. In 1913 about 3,300 tons of monazite were refined to produce the thorium and cerium used in gas mantles and the mixed rare-earth metals for flints and related products.

Atomic numbers of the rare-earth elements

The British physicist H.G.J. Moseley, while studying the X-ray emission spectra of the elements in 1913–14, found a direct relationship between the X-ray frequencies and the atomic numbers of the elements. This relationship made it possible to assign unambiguous atomic numbers to the elements and to verify their locations in the periodic table. In this way, Moseley was able to show clearly that there could be only 14 lanthanides, starting with cerium and ending at lutetium, and, at that time, all of the rare-earth elements had been discovered except for element 61. Because no stable isotopes (forms of the element with differing mass) of this substance exist in nature, it was not isolated until 1945, when one of its radioactive isotopes was separated from atomic fission products produced in a nuclear reactor. The element was named promethium after the Greek Titan who stole fire from the gods and gave it to mankind.

As in most fields of science, the present state of knowledge concerning the rare earths is the result of hundreds of scientists publishing thousands of papers and of the individual scientist making his advances based on the work that had been previously published. There were, of course, a number of men whose outstanding contributions changed the direction of the researches, but space does not permit referring to them by name.

Occurrence and abundance. The rare-earth elements are not rare in nature. They are found in low concentrations widely distributed throughout the earth's crust and in high concentrations in a considerable number of minerals. In addition, they are also found in many meteorites, on the moon, and in the sun. The spectra of many types of stars indicate that the rare-earth elements are much more abundant in these systems than they are in our solar system. Even promethium-147, which has a half-life (time required for one-half the material to undergo radioactive decay) of only a few years, has been observed in certain stars.

Cerium is reported to be more abundant in the earth's crust than tin, and yttrium and neodymium more abundant than lead. Even the relatively scarce lutetium is said to be more abundant than mercury or iodine.

Widespread distribution on earth

The rare-earth elements are found as mixtures in almost all massive rock formations, in concentrations of from ten to a few hundred parts per million (ppm) by weight. The fact that these elements have not been separated into minerals containing individual members of the family at any time in the earth's history--even after eons of repeated melting and resolidifying, mountain formation and erosion, exposure to hot vapour, and immersion in seawater—attests to the great similarity in properties of these elements. Nevertheless, rock formations resulting from some of these geological processes become enriched or depleted in rare earths at one end of the series or the other, so that an analysis of the relative content of the rare-earth elements is never exactly the same, even for similar rocks taken from different locations. In general, it has been found that the more basic (or alkaline) rocks contain smaller amounts of rare earths than do the more acid rocks, and it is believed that as these molten basic rocks intrude into the more acidic rocks, the rare earths are partially extracted into the more acidic rocks. Also, as this extraction takes place, the rare-earth elements of lower molecular weight (lanthanum, cerium, praseodymium, and neodymium) are taken up to a greater extent than the heavier elements.

New analytical methods involving activation' analysis (production of artificial radioactivity) and mass spectroscopy (separation of atoms on the basis of mass) have made it possible to make accurate measurements of the relative abundances of these elements, even when they are present in extremely small amounts. Such measurements are of great interest to geophysicists because they supply valuable information about the development of geological formations. The cooling of molten rocks and superheated water solutions that have percolated through rock under great pressure frequently produces minerals containing up to 50 percent rare earths. (For uniformity, these percentages are calculated as if the entire rare-earth content of the mineral were present in the form of oxides.) From the presence and composition of such minerals, geochemists can learn a great deal about the conditions, such as temperature and pressure, to which the rock mass was subjected. Similarly, the relative abundance of rare earths in the rocks on the moon is of great interest because of what it is expected to reveal about how the moon was formed and whether all or part of the moon was molten at any time.

The average content of rare-earth elements found in certain meteorites (chondrites) and in three types of common rocks is listed in Table 1. Included also is an estimate of the relative abundance of the elements in terms of the overall rank of all known elements and of their concentration in the earth's crust. It is now generally accepted that the relative values of the rare-earth elements in chondritic (granular) meteorites represent their overall relative abundance in the cosmos. The elements

Table 1: Abundance of the Naturally Occurring Rare-Earth Elements (parts per million)

with even atomic numbers are much more abundant than the odd-numbered elements. Such information, together with the relative abundance of their isotopes, is of critical importance to astrophysicists because it bears on theories of the origin of the universe and the genesis of the chemical elements. (See CHEMICAL ELEMENTS, ORIGIN OF.)

This article is divided into the following sections:

I. Comparative chemistry of rare-earth elements

ELECTRONIC STRUCTURE

The existence of the rare-earth elements—a family of elements more alike in their properties than any other group of elements—was one of the puzzles the solution of which led to present-day understanding of atomic structure. It is now well-known that atoms are made up of positively charged protons, neutral particles called neutrons, and negatively charged electrons. The protons and neutrons are located in a minute nucleus at the centre of an atom, and the number of protons in the nucleus is equal to the atomic number of the element. In its neutral state, an atom has as many electrons surrounding the nucleus as there are protons in it. These electrons occupy a series of concentric shells: each successive shell contains a certain number of electrons and is designated by a quantum number, n, which can be any number from 1 to 7 for stable atoms. Electrons in shells with smaller n's usually are closer to the nucleus and are bound much more tightly to it than those in shells with larger n's. For this reason, the shells with low *n*'s fill first as one progresses from elements at the beginning of the periodic table to those with higher atomic number. When a new outer shell starts to fill with electrons, a new horizontal row, or period, of the periodic table begins and, because the outermost electrons in the lanthanide elements have an $n = 6$, these elements would appear in the sixth row of the periodic table if they were not generally moved to a special location (see PERIODIC I AW).

Electron shells and subshells in atoms

Within each shell, electrons occur in certain subshells, which are known (for reasons that are no longer important) as the *s*, p, *d*, and *f* subshells. Each subshell has its own quantum number *l*, which represents the angular momentum possessed by the electrons of that subshell. As extra protons and electrons are added to the atoms one at a time (in proceeding through the periodic table), the electrons fill the various shells and subshells in order of their stability. Because of the shapes of the subshells, it happens that *s* and *p* subshells of higher n are more stable than d and *f* subshells of lower n. Therefore, as electrons are added to atomic structure, they often enter shells of higher *n* before the lower shells are completely filled.

As the fifth period of the periodic table ends (with the element xenon), the 4*s*, 4*p*, and 4*d* subshells are filled, as are the 5*s* and 5*p* subshells. Then, with the beginning of the sixth period, two 6*s* electrons are added for the first two elements of the period, and a third electron goes into a 5*d* orbital as the element lanthanum is reached. Following lanthanum, however, as the next electron is added, it goes into the 4*f* subshell, which up to this point has remained vacant. This shell is capable of holding 14 electrons, and the addition of the next 13 electrons corresponds to the filling of this inner shell. The elements in which this occurs are the 14 lanthanide elements—from cerium through lutetium. These elements are much alike because the differences in their electronic structures chiefly involve the inner 4f electrons, whereas it is the outer *s* and *p* (and sometimes *d*) electrons that are involved in chemical bonding with other atoms and thereby determine the chemical behaviour of the elements. Although lanthanum atoms contain no 4*f* electrons, they resemble the atoms of the lanthanide elements closely, and it is not surprising that lanthanum should behave much as the lanthanides do (the name lanthanide, in fact, merely means lanthanum-like). Scandium and yttrium are elements in the same vertical file in the periodic table as lanthanum, and their atoms, too, have somewhat the same electronic structure but fewer filled shells, the outermost electrons in scandium being two 4*s* electrons and one 3d. In the case of yttrium, however, the outermost electrons are 5*s* and 4*d* electrons, respectively.

Location of lanthanide elements in the periodic table

Because of their general similarity in atomic structure, scandium, yttrium, lanthanum, and the 14 lanthanides are very similar chemically. This similarity is the reason they are found together in nature and also the reason they are so frequently classed together as the rare-earth elements. Interestingly enough, the element directly below lanthanum in the periodic table is the radioactive element actinium, which has properties that much resemble those of lanthanum. Actinium is followed by a series of elements known as the actinides, which correspond to the filling of the 5*f* shell, just as the lanthanides correspond to the filling of the 4*f* subshell. There is much resemblance between the two groups: for further coverage of the actinides, see the articles ACTINIDE ELEMENTS AND THEIR COMPOUNDS and TRANSURANIUM ELEMENTS.

Table 2 lists the lowest energy electronic configurations of the rare-earth elements in gaseous and in condensed

states, *i.e.*, as the free metal or in a crystalline or solution form as a compound. In a compound the $5d6s^2$ electrons (the superscript indicating the number of electrons in the subshell) are the valence, or bonding, electrons. These electrons are involved in the chemical bond and are usually paired with the electrons of the anion (the negative ion included with the rare-earth ion in the compound), with the result that they are no longer closely associated with the rare-earth atom. In the case of the metal, these electrons are free to wander throughout the crystal, being able to carry an electrical current and known, therefore, as conducting electrons. In the case of lanthanides in the gaseous state, the valence electrons are localized at the individual atoms, but in many cases the 5d electron can switch to the 4f subshell, giving rise to a state of different energy and different electronic configuration.

Lanthanide contraction

As the charge on the nucleus increases across the lanthanide series, it pulls the various subshells, especially the 5s and 5*p* subshells, closer to the nucleus. As a result, the radii of the lanthanide ions decrease as the atomic number increases. This effect is known as the lanthanide contraction.

PROPERTIES OF THE RARE-EARTH ELEMENTS AS A GROUP

Chemical **properties.** ***Rare-earth*** *componds.* The chlorides, bromides, iodides, nitrates, acetates, chlorates, and perchlorates of rare-earth elements are extremely soluble in water. The sulfates, $M_2(SO_4)_3 \cdot 8H_2O$, are sparingly soluble and have the property of being more soluble at 0° *C* (32" F) than at room temperature. The hydroxides, fluorides, carbonates, phosphates, and oxalates are insoluble in neutral or alkaline solutions.

Rare-earth ions form hundreds of different complexes with organic molecules. The compounds of these complexes can be soluble, sparingly soluble, or insoluble in aqueous solutions, but most of them are soluble in various organic solvents. More than 75 such families of lanthanide complexes have been studied.

The anhydrous salts (those free of water) are extremely stable, and, although they dissolve readily in water, they are rarely precipitated from solution; they must, therefore, be prepared by other methods, of which there are many. An anhydrous rare-earth chloride, MCl_3, for example, can be prepared by passing dry hydrogen chloride gas with slow heating over the hexahydrate ($MCl_3 \cdot 6H_2O$) or by adding chlorine gas (Cl_2) directly to the metal. Many anhydrous rare-earth compounds are dissolved by certain mixtures of molten salts; many of the rare-earth ions can exist in such solvents in more than one oxidation state (the number of electrons gained or lost by the atom). Compounds such as neodymium(II) chloride (in which the roman numeral indicates the oxidation state), $NdCl_2$, can be formed from neodymium metal and molten neodymium(III) chloride, $NdCl_3$.

Binary compounds with nonmetals

Rare-earth metals combine directly with nonmetallic elements to form very stable borides, carbides, nitrides, oxides, chlorides, bromides, phosphides, and sulfides. Most of these compounds can also be prepared by other methods, and many of them exist in several forms.

The common oxide is the trivalent form or sesquioxide (M_2O_3), and, in proceeding across the lanthanide series, the oxide of this formula is found in three different crystalline forms. These oxides all have high melting points, well above 2,000" C (3,600" F). They also form mixed crystals with other oxides such as alumina (Al_2O_3) and iron(III) oxide (Fe_2O_3). When the sesquioxides of cerium, praseodymium, and terbium are heated in air, they are converted to other oxides, with formulas CeO_2, Pr_6O_{11}, and Tb_4O_7, respectively. When heated in oxygen under pressure, the latter two are also converted to the dioxides PrO_2 and TbO_2. When the sesquioxide of any rare-earth element is heated with a small amount of the corresponding metal, it forms a black nonstoichiometric oxide formulated M_2O_{3-x} (x represents a small fraction) having a crystal structure like that of the sesquioxide but with vacancies at certain points in the crystal lattice. Rare-earth nitrides, MN, also have high melting points; nitrogen-deficient nitrides, MN, $_x$, often crystallize, so preparation of the pure compounds of ideal composition is difficult.

Monocarbides and dicarbides, MC and MC_2, exist for all of the rare-earth elements. A number of nonstoichiometric carbides exist for most of the rare earths. These compounds possess the same crystal structure over an appreciable composition range. In general, all the carbides melt in the range of 2,000" C or higher. Two types of borides, with formulas MB_4 and MB_6, are known for all the lanthanides. The hexaborides have properties that make them useful in electronic applications. Other borides also have been prepared for several of the rare-earth elements.

Solutions. Many rare-earth salts are soluble; the solutions are strong electrolytes (carriers of electric current), and when they are dilute, the salts are ionized completely into positively charged trivalent hydrated rare-earth ions and negatively charged anions. As the solutions become more concentrated, the rare-earth ions frequently form complexes (or associations) with the anion; these take the form either of a so-called outer complex, in which the rare-earth ion is surrounded by a layer of water molecules, with the anion outside these, or of an inner complex, in which the anion has moved next to the rare-earth ion, thereby displacing one or more water molecules.

Studies of rare-earth solutions are useful for understanding the behaviour of concentrated electrolytes, the theory of which is not so well understood as that of dilute electrolytes. The high charge on rare-earth ions enhances the effects of charged particles in solution, and the properties of the solutions change slightly and in a predictable manner for adjacent lanthanides. On the other hand, if the values of certain properties of the solutions are plotted against the atomic numbers of the lanthanides, simple curves are rarely obtained, because the size of the coordination sphere (the sphere encompassing the atoms or ions adjacent to the rare-earth ion) is changed by the lanthanide contraction in traversing the series. The coordination number can vary from 6 to 12, depending upon the size of the lanthanide ion, the nature of the anion or other complexed group (including water), and the solvent.

Formation of hydrates

The lanthanide salts that crystallize from saturated solution are usually hydrated (that is, contain molecules of water), and, in general, as one proceeds across the series, the number of water molecules in the crystal changes. Lanthanum, cerium, and praseodymium chloride, for example, crystallize at room temperature with seven molecules of water for each ion of the rare-earth metal, so that the formula of the hydrate is $MCl_3 \cdot 7H_2O$, in which M represents the ion of the rare-earth metal and Cl stands for a chloride ion. Other chlorides of the series crystallize as hexahydrates, $MCl_3 \cdot 6H_2O$. At different temperatures, pressures, and acidities, other hydrates can form; *e.g.*, praseodymium chloride hexahydrate ($PrCl_3$. $6H_2O$) forms above 60° C (140" F). If other metallic ions are present, substances of variable composition may result, in which either metallic ion can occupy a cation (positive ion) site in the crystal, or they can form orderly stoichiometric double salts; *e.g.*, a mixed nitrate of neodymium and magnesium [$2Nd(NO_3)_3 \cdot 3Mg(NO_3)_2 \cdot 24H_2O$].

With increasing alkalinity (basicity), rare-earth ions in solution hydrolyze (or react with water) as in the following equation:

$$M^{3+} + nH_2O \rightleftharpoons M(OH)_n^{(3-n)+} + nH^+.$$

From these solutions basic salts, such as basic nitrates or oxychlorides, can precipitate.

Physical **properties.** The pure rare-earth metals are bright and silvery. A bar of europium will tarnish almost immediately when exposed to air and will be entirely converted to the powdered oxide in a few days. Lanthanum, cerium, praseodymium, and neodymium also corrode readily in air; bars of these metals become encrusted with a thick layer of oxide in several weeks. Metallic yttrium, gadolinium, and lutetium, on the other hand, remain bright and shiny for years.

The properties of the rare-earth metals are frequently quite sensitive to the presence of impurities; for example, the light lanthanide metals will corrode much more rapidly if small amounts of calcium or magnesium or rare-earth oxides are present in the metal. The melting points and transition temperatures between different crystal forms (allotropic forms) can be changed drastically, frequently by several hundred degrees, when the metals are alloyed with other elements.

Small amounts of nonmetallic impurities also affect many of the properties of the rare-earth elements. Several thousand parts per million by weight of oxygen and even smaller amounts of nitrogen in the metals make them brittle. The effect of nonmetallic impurities on physical properties is determined by atomic percentages (that is, by the relative numbers of atoms present) and not by weight percentages; thus, in lutetium 300 parts per million by weight of hydrogen is about 5 percent on an atomic basis, whereas 1,000 parts per million of oxygen in lutetium by weight represents only 1 percent oxygen on the atomic scale.

In determining properties of the rare-earth metals it is obviously essential to work with well-characterized samples. The amount of each individual impurity present should be accurately known, as well as the previous history of the sample with regard to temperature and work. If the reported values of physical properties are to have much meaning, this information concerning the samples used must be given. Unfortunately, because of a lack of appreciation of the importance of impurities or a lack of proper equipment to adequately characterize the sample, there is a wide variation in the numbers reported in the literature for certain properties. In Table 2 are the values of the properties that—in the author's opinion—are the best values known. Some properties, such as elastic constants, resistivity, and effective magnetic moments, are very sensitive to temperature and show marked anomalies at and in the neighbourhood of crystal or magnetic transformations. Also, some properties depend on the angle at which they are measured with respect to the principal crystal axes in the metal.

In fact, the rare-earth metals do not resemble one another as closely as was generally believed in the early part of the 20th century. Physical properties differ as much across the lanthanide series as they do for most other series in the periodic table. The melting point of lutetium, for example, is almost twice that of lanthanum, and the vapour pressures of ytterbium and europium at 1,000° C (1,832°F) are millions of times greater than those of lanthanum and cerium. Lanthanum is a superconductor of electricity at 6" K (—267" C, —449" F), and gadolinium is a stronger ferromagnet at 0° than iron. The properties of adjacent pairs of lanthanide elements do, however, differ in a predictable and usually regular manner. This behaviour makes these metals uniquely valuable in studying theories of the metallic state, the formation of alloys, and the existence of intermetallic compounds. Each of the rare-earth metals readily combines with almost any other metallic element, and the resulting alloys exhibit a wide variety of properties: they can be hard or soft, brittle or ductile, and they can have high or low melting points. Some are extremely pyrophoric (ignite spontaneously), whereas others cause a coating to be formed on the surface of metals such as magnesium that protects the alloys from corrosion at elevated temperatures.

Rare-earth metals absorb hydrogen to form stable alloy-like hydrides in which percentages of the divalent compounds MH_2 range from zero to 100. These hydrides, brittle and metallic in appearance, have a bluish tinge. After absorption of hydrogen to yield the composition MH_2, further absorption occurs, finally yielding trivalent hydrides MH_3. During the change from MH_2 to MH_3, the properties become more saltlike. The amount of hydrogen per unit volume in yttrium hydride is considerably greater than that in water or liquid hydrogen, and this hydride does not develop a partial pressure of hydrogen gas equal to one atmosphere until the alloy has been heated to a white heat. Cerium metal, once the oxide surface film has been broken, absorbs hydrogen at room temperature and decomposes water vapour at higher temperatures, absorbing the hydrogen and reacting with the oxygen to form a layer of sesquioxide on the surface. The oxides, nitrides, and carbides of the rare-earth elements are soluble in the molten metals: as are the elements oxygen, nitrogen, and carbon. The exact form in which the dissolved substances are present is not known, but it is generally believed that the nonmetallic elements are present as interstitial atoms (atoms inserted in spaces left in the crystal structure). These dissolved nonmetallic elements remain in solid solution over a considerable composition range at temperatures near the melting point. As the metal is slowly cooled, however, the solubility decreases, and the dissolved elements precipitate as a second phase, probably as the sesquioxides, nonstoichiometric nitrides, and carbides. The diffusion rate (rate of movement) for nonmetallic elements in the metal is low below 800" C (1,472" F) and becomes progressively lower as the temperature is lowered. The properties of the metals containing these impurities, therefore, are dependent upon the heat treatment to which they have been subjected.

Heat treatment and crystal structure

Anisotropy. Rare-earth metals often exhibit anisotropy—differences in properties depending on which direction in the crystal they are measured—and the heat treatment of the sample is important in producing polycrystalline metal. It is possible by certain heat treatments to produce large grains oriented preferentially in a given direction. When properties that depend on crystal direction are measured on such polycrystalline samples, the results have little meaning unless the amount of preferred orientation is known.

Spectra of gaseous lanthanides

Energy states of lanthanides. The spark and arc spectra (patterns of emitted light) of the gaseous lanthanides are extremely complicated. There are literally tens of thousands of frequencies of light emitted by each of the lanthanides, and it requires very powerful instruments (spectrographs) to resolve them. This complexity arises from the fact that the lanthanides have an incomplete inner subshell, and the angular moments (spins and orbital motions) of the electrons in this subshell can combine in many ways to give many different energy states. In the most complicated case, that of gadolinium, there are 3,432 different states. Any of these states can combine with the many states arising from the three valence electrons, and this condition results in an incredible number of excited energy levels. The emitted frequencies represent transitions between any of these states. The situation is further complicated by the fact that the ionization potentials of these elements are extremely low, with the result that in the arc- and spark-light sources there are a great many ionized atoms, and their complicated spectra fall on top of those of the neutral atoms. Many thousands of these lines remain to be identified. A start has been made on this task, however, and a few levels—including the basic ones—have been identified. A thorough understanding of the energy levels of the rare-earth atoms will be of great value in arriving at a complete theory by which all the properties of an atom can be calculated from basic principles. Furthermore, the complete identification of the spectral lines of the rare-earth elements will be of great assistance to astronomers in identifying the many lines observed in stellar spectra that are believed to indicate the presence of rare-earth elements.

The first ionization potentials (the energy required to remove an electron from the neutral atom) of these elements are also difficult to determine accurately because of the complexity of the rare-earth spectra.

Rare-earth ions in solids and liquids. The sharp bands in spectra of solid rare-earth elements and compounds are much better understood. These bands arise from transitions between different energy states of the 4f subshell, and the position of the bands seems to be little affected by the atoms surrounding the lanthanide atoms. For this reason, scientists have been able to use these bands for more than a century to determine whether particular rare-earth ions are present in solids or liquids. The fine line structure of the bands, which can be resolved at low temperatures, is sensitive to the environment, and this effect makes such spectra a valuable tool for studying the forces that exist in solids and liquids.

Magnetic properties

The 4f electrons also are responsible for the strong magnetism exhibited by the metals and compounds of the lanthanides. In the incomplete 4f subshell the magnetic effects of the different electrons do not cancel out each other as they do in a completed subshell, and this factor gives rise to the interesting magnetic behaviour of these elements. At higher temperatures, all the lanthanides except lutetium are paramagnetic (weakly magnetic), and this paramagnetism frequently shows a strong anisotropy. As the temperature is lowered, many of the metals exhibit a point below which they become antiferromagnetic (*i.e.*, magnetic moments of the ions are aligned but some are opposed to others), and, as the temperatures are lowered still further, many of them go through a series of spin rearrangements, which may or may not be in conformity with the regular crystal lattice. Finally, at still lower temperatures, a number of these elements become ferromagnetic (*i.e.*, strongly magnetic, like iron). Some of the metals have saturation moments (magnetism observed when all the magnetic moments of the ions are aligned) greater than iron, cobalt, or nickel. They also show a strong anisotropy in their magnetic behaviour depending on the crystal direction. Study of the magnetism of rare-earth elements has had great influence on present-day theories of magnetism.

Electrical conductivity. The rare-earth metals, with the exceptions of cerium, ytterbium, and europium, have three electrons available for carrying electrical current. The space occupied by these electrons apparently represents more than 85 percent of the volume associated with the atom of each metal. Cerium is reported to have an average of 3.1 conducting electrons, presumably as the result of the existence of some of its atoms in a state in which four electrons are free to move through the metal. Pure cerium under high pressure or at low temperature assumes a high-density form in which the four-electron state assumes more importance. Europium and ytterbium are much less dense than the other lanthanides, and they have only two conducting electrons; the third valence electron has moved to an inside subshell (4*f*). In europium this electron half fills this subshell, and in ytterbium it completes it, the two configurations $4f^7$ and $4f^{14}$ being particularly stable. The electrical and chemical properties of these two metals therefore resemble those of magnesium, calcium, strontium, and barium (metals with two conducting electrons) more closely than those of the other lanthanides.

Nuclear properties. As a group the rare-earth elements are rich in total numbers of isotopes. averaging about 20 each. The elements with odd atomic numbers have only one, or at most two, stable isotopes, but those with even atomic numbers have from four to seven stable isotopes. Some of the unstable isotopes are feebly radioactive, having extremely long half-lives. The unstable radioactive isotopes can be produced in many ways; *e.g.*, by fission, neutron bombardment, radioactive decay of neighbouring elements, and bombardment of neighbouring elements with charged particles. The lanthanide isotopes are of particular interest to nuclear scientists because they offer a rich field for testing theories about the nucleus, especially because many of these nuclei are nonspherical, a property that has a decided influence on nuclear stability. When either the protons or neutrons complete a nuclear shell (that is, arrive at certain fixed values), the nucleus is exceptionally stable—the number of protons or neutrons required to complete a shell being called a magic number. One particular magic number—82 for neutrons—occurs in the lanthanide series.

II. Production and processing of rare-earth metals

SOURCES AND EXTRACTION

Though numerous minerals rich in rare earths are found in the earth's crust, many are extremely rare, and many more are found only in small pockets in more massive rocks. Although such minerals are of considerable research interest they are not used commercially. Monazite, a mixed phosphate of calcium, thorium, cerium, and various lanthanides, occurs in extensive deposits and is one of the main sources used commercially to obtain the light rare-earth elements. Monazite contains about 50 percent by weight rare-earth elements, in the approximate proportions 50 percent cerium, 20 percent lanthanum, 20 percent neodymium, 5 percent praseodymium, and lesser amounts of samarium, gadolinium, and yttrium. It also contains small amounts of the heavy rare-earth elements. The actual amounts of each element in the mineral vary considerably, depending on the point of origin of the monazite, because the various metallic elements can substitute for one another in the crystal lattice. The mineral probably formed as small crystals in rocks as they cooled, but as the mountains eroded away and were washed into the sea, the monazite, being denser than most other materials, settled first, while the lighter materials were carried farther out to sea. Apparently as a result of this action, sandbars containing monazite are found along the coasts of Brazil and southwest India. Concentrated deposits are also found on certain uplands, which are thought to have been the beaches of ancient seas or oceans and which were later uplifted. Such deposits in massive amounts are found in Australia, the U.S.S.R., and South Africa, and in the United States in South Carolina, Florida, and Idaho, and in many other locations. The mineral is dredged or scooped up, pulverized if necessary, and concentrated by flotation methods. Sometimes a magnetic-belt separator is used to pull the more magnetic monazite to one side in order to separate it from the nonmagnetic materials. The monazite is then shipped to rare-earth chemical plants. The mineral xenotime, a phosphate of yttrium and various lanthanides, is frequently found associated with monazite and may comprise from 1 to 10 percent of the mixed minerals. It is similar to monazite except that the metallic atoms are about 50 to 60 percent yttrium, and it contains more heavy lanthanides than light ones. Xenotime is one of the main sources of the heavy rare earths, and it can be separated from monazite by the magnetic-belt process because it is more magnetic than monazite.

Monazite

Another important source of light rare earths and europium is the mineral bastnaesite, a fluorocarbonate of lanthanum and cerium, with smaller amounts of neodymium and praseodymium. It is found in extensive deposits in eastern California. It contains almost no heavy rare earths, but there is enough europium (about 0.1 percent) to supply much of the world demand for this element. The mineral is also found in the U.S.S.R. and in parts of Africa. The rock is broken up by blasting and then is crushed and ground to a fine powder. The bastnaesite is separated from the other materials by the usual flotation methods and is then treated chemically so that it can be separated into europium, lanthanum, and cerium fractions by liquid–liquid extraction methods (see below *Liquid–liquid* extraction).

The niobium titanate minerals, such as fergusonite, euxenite, samarskite, and blomstrandine, are rich in the heavy rare-earth elements but are not used much commercially. The same is true of such silicates as gadolinite and allanite. Other commercial sources of rare-earth oxides are certain uranium- and apatite-mining operations in which the rare earths are obtained as a by-product even though the rare-earth content of the ores is low.

Very little scandium is found in rare-earth minerals. Most of the scandium produced commercially is a by-product from uranium processing—the scandium, which may be present in amounts up to five parts per million, being recovered from the uranium solution. There is, however, a rare mineral thortveitite—found in Norway—that contains up to 34 percent scandia, Sc_2O_3.

METHODS OF SEPARATION AND PURIFICATION

Generally, the rare-earth elements exist in dilute solution as trivalent ions. Quite early, however, it was found that a number of the elements could also exist in tetravalent or divalent form—including cerium(IV), samarium(II), europium(II), and ytterbium(II). If an element could be oxidized (to the tetravalent state) or reduced (to the divalent), then it could be removed readily from the other rare earths. Between the years 1930 and 1935, for example, about two kilograms (4.5 pounds) of extremely pure europium compounds were prepared by a separation process making use of the divalent form of europium. Although europium is one of the less abundant rare-earth elements, it was one of the first of the heavier rare earths to become generally available.

Purification of europium

Fractionation. Because the ions of the rare-earth elements are surrounded by tightly bound water molecules in aqueous solution, compounds of the rare earths formed from aqueous solutions have properties much alike and this similarity is particularly true for adjacent elements. The problem is still further complicated by the fact that one rare-earth ion can be substituted readily for another in crystal lattices, with the result that most precipitates consist of crystals of almost the same rare-earth mixture as the solution. Because of this behaviour, chemists of the 19th and early 20th centuries found it necessary to resort to laborious fractionation processes to isolate individual rare-earth elements. At the time, many different processes were used, such as fractional crystallization, fractional precipitation, fractional decomposition. and fractional extraction. All of these consisted of separating the mixed rare earths into two approximately equal fractions, one of which would be enriched in the lighter elements and the other in the heavier elements. Both fractions would then be put back into solution and the process repeated on each of them. Usually the adjacent inner fractions would be iecombined before proceeding to the next stage. Gradually, the lighter rare earths were collected in the beakers toward one end of the system, with the heavier elements concentrated at the other end.

As the quantity of material in the end beakers became small, it was usually customary to combine equivalent fractions from other similar runs. At this point the first series would be split into several independent groups, and a new fractionation process more suited to the elements in each fraction started. Needless to say, the quantity of a relatively pure rare-earth compound obtained from the end beakers was distinctly limited.

Fractional separation methods, particularly for adjacent heavy rare earths, are extremely slow and tedious. One investigator, for example, reported that he had recrystal lized the bromate salt of a thulium fraction 15,000 times

Fractional separation methods

and could see little difference between the first and last fractions. It is now known that even the purest fractions he obtained contained some ytterbium and erbium. If the elements are far apart in the lanthanide series, however, the task is simplified. It takes only a few partial precipitations, for example, to obtain a lanthanum–cerium–praseodymium fraction completely free of erbium, thulium, ytterbium, and lutetium. The most basic (nonacidic) of the rare-earth elements, lanthanum, is very well situated in the series in this respect because it occurs at one end, and a few fractionations suffice to separate a lanthanum–cerium fraction from the other rare earths. Since cerium in its tetravalent form has distinctly different chemical properties from a typical lanthanide in the trivalent state, it can be separated from lanthanum easily by ordinary chemical operations. Consequently, pure lanthanum and cerium compounds have been commercially available for many years, and even today several companies find the fractionation process the most economical method for producing compounds of these elements in ton quantities.

Ion exchange. Ion exchange is a method of separation based on differential absorption and elution (washing off) of substances from certain solid supporting materials, often powdered or finely divided materials held in glass tubes. The technique was first used in the rare-earth field during World War II to separate fission products obtained from nuclear reactors. In December 1943 a research group at the Oak Ridge (Tennessee) national laboratory announced that they had separated the mixed rare-earth elements from certain fission products by ion exchange on an organic resin into three fractions. The first fraction was shown to have radioactivity associated with yttrium, and the final peak to have cerium activity. The middle peak was thought to be a combination of the neodymium and element-61 activities. The group at Oak Ridge continued to develop the elution technique for separating fission products both with and without carriers (nonradioactive materials added to carry with them the radioactive isotopes). By the end of the war, they had succeeded in developing the processes so that they could separate the individual rare-earth elements of the cerium group (cerium through element 61) and yttrium. The carriers usually consisted of a few milligrams of each of the corresponding natural rare earths. In the meantime, a group at Iowa State University applied the ion-exchange process to the separation of gram quantities of adjacent rare earths and succeeded in separating the difficult pair praseodymium and neodymium in fairly high purities in gram quantities.

Ion exchange of fission products

The ion-exclzange elution method. Rare-earth-element separation by the ion-exchange elution process is carried out as follows: At the start of the process, the resin is saturated with monovalent cations, such as ammonium ion, NH_4^+, or hydrogen ion, H^+. Next, a solution of mixed rare-earth ions accompanied by strong acid anions is poured onto the top of the column. When the rare-earth ion encounters the cation-containing resin, it replaces three monovalent cations, and these—along with the strong acid anions—will flow through the column in solution and out the bottom. A band of resin saturated with rare-earth ions forms at the top of the ion exchanger and grows in length as more rare-earth solution is added. There is, however, little separation of individual rare-earth ions as this band forms. An eluant solution containing an anion that complexes with the rare-earth ion is then prepared, for example, an ammonium citrate solution of controlled acidity. This solution is then started flowing through the column to elute the rare-earth band down the column and out the bottom. When the main ions present in ammonium citrate in acid solution, $HCit^{2-}$ or H_2Cit^-, encounter rare-earth ions on the resin, complex ions form; these enter the solution phase, and three monovalent ions deposit on the resin in their place. When the rare-earth complexes reach the ammonium or acid resin, in front of the rare-earth band, the rare-earth ions are again deposited, and the band progresses down the column. The formation constants of the individual rare-earth complexes increase slightly with increasing atomic number. Because the various rare-earth ions on the resin are in equilibrium with the rare-earth complexes in solution as they pass over the band, there is a slight enrichment of heavy rare earths at the front of the band. As the band progresses down the column, this enrichment continues. At the same time, the band grows in length, since ammonium and hydrogen ions are also in equilibrium with the resin and their ions will deposit along with the rare-earth ions. After the band has travelled many band lengths, each rare earth exhibits a bell-shaped elution curve (concentration of rare-earth ions versus volume of eluant leaving the column) and these individual rare-earth bands travel down the column at different rates. The bands overlap badly at first, but after travelling many band lengths, they pull completely apart. The area under each curve is, of course, constant, because the amount of each rare earth on the column does not change, but the concentration of the rare earth in the resin gets less and less relative to the ammonium and hydrogen ions on the resin.

Limitations of the elution technique

With this type of separation, the original mixed rare-earth band must be quite narrow because the band has to travel many band lengths on a given column. The ions in the eluant are constantly overrunning the bands, with the result that large quantities of solution are needed; and the solution coming out the bottom of the column containing the successive pure rare earths is extremely dilute in rare earths. Such a process is obviously ideal for separating radioactive tracers, which one can count by means of radioactivity, and this process is frequently used in analytical chemistry, where only small amounts of the rare earths are separated. When it is necessary to obtain large amounts of rare earths in high purity, this process is not effective. It has the disadvantage of requiring far more chemicals than the displacement method developed later and described below. Furthermore, this process is not particularly adaptable to being scaled up to produce large quantities of ultrapure rare earths, nor is it well suited for recycling the water and chemicals. It does not give the purity of the individual rare earth that displacement methods can achieve. Finally, the elution process is slow compared with the displacement method.

The ion-exchange displacement method. The band displacement method of separating individual rare-earth elements was first published in 1952. This process is capable of being scaled up to handle any quantity of rare earths. The mixture can be resolved so that 98 or 99 percent of each individual rare earth can be recovered with less than 0.1 percent of other rare-earth impurities; and, if the rare earths are taken from the middle third of the bands, the sum total of other rare earths can be kept as low as 0.0001 percent. The same resins and type of equipment are used in this process as in the elution technique. Two strong chemical constraints, however, are imposed at the top and bottom edges of the rare-earth band. The eluant contains a strong complexing ion—such as a chelating agent, an organic molecule that wraps itself around the rare-earth ion, replacing all or most of the adjacent water molecules. The first constraint requires that the formation constants of the rare-earth complexes formed should be large enough so that, when the chelating agent encounters the top edge of the rare-earth band, it complexes in a short distance all of the rare-earth ions, moving them into solution and replacing them with the cation of the eluant. (The formation constant, however, should not be so large as to remove all the rare-earth ions from the solution phase.) The second chemical constraint occurs at the bottom edge of the rare-earth band: the original resin bed, called the retaining bed, down which the rare-earth band is moving, must have cations on its exchange sites that form a much tighter soluble complex with the chelating ion than do the rare-earth ions. Under this constraint the rare-earth complex promptly breaks up at the point where it encounters the retaining bed, and the rare-earth ions completely deposit in the bed, simultaneously removing an equivalent amount of the retaining-bed cations. With these constraints, the rare-earth band, after spreading out slightly to reach equilibrium, remains of constant length, with sharp top and bottom edges, no matter how far down the

The functions of chemical constraints

column it travels. The elution curve is flat-topped (rare-earth concentration remains constant over almost the entire band when plotted against volume of elute leaving the bottom of the column), and the percentage of rare-earth ions in the rare-earth band on the active sites of the resin is close to 100 percent. Here again, there must be a slight difference in the formation constants of the rare-earth chelates, so that the rare-earth ions are constantly interchanging as the eluant flows by the rare-earth band. As the band moves, the individual rare earths separate into individual flat-topped bands, which ride head to tail and never pull apart. By the time the band has travelled a tenth of its length, most of the heavy rare earths are already to be found in the front segments of the total rare-earth band, and, by the time it has travelled one length, all the individual rare earths are in separate bands, which overlap only slightly to give a narrow region consisting of a binary mixture of adjacent elements. These mixed regions, of course, must be recycled. By having a series of columns, however, the original rare earth band can be made very long, and, since the overlap regions are independent of band length, the bulk of each successive rare earth comes out the bottom of the column in high purity.

A number of companies have adopted the displacement process and, using it, have made available highly pure salts of the rare-earth elements of atomic number 59 and above (all the elements from praseodymium through lutetium) in any quantity at reasonable prices. This process has the distinct advantage of allowing the water and the eluting chemicals to be recycled and used over again. One long absorbed band can follow another down a series of columns if a short retaining-bed section is continually regenerated between the absorbed bands.

The first chelating agent used was ammonium citrate at such a low acidity that the citrate ion, Cit^{3-}, predominates in the solution. At this acidity the complex chelate ion, MCit_2^{3-}, forms. This process works well, but in 1954 it was improved by using a buffered ammonium solution of ethylenediaminetetraacetic acid (EDTA) with a cupric-ion retaining bed. A number of other chelating agents and types of retaining beds have also been investigated. Many of these work well, but none is markedly superior to EDTA. Some of these other systems, however, are used for certain regions of the rare-earth series because, for these regions, the processing is accomplished more quickly and cheaply.

Organic
and
aqueous
phases

Liquid–liquid extraction. Liquid–liquid extraction methods also find important applications in the rare-earth industry. The basic principles involved are similar to those operating in the ion-exchange processes. An organic solvent, such as tributyl phosphate, flows countercurrent to an aqueous stream containing the mixed rare-earth salts. Rare-earth complexes are formed with formation constants that vary somewhat across the series. The rare-earth ions can complex with their own anions to form neutral molecules that are soluble in the organic phase, or they can complex with molecules of the organic solvent and thereby join the organic stream. If desired, an organic chelating agent can be added to form complexes with the rare-earth ions. These complexes should be soluble in the organic liquid. As the aqueous phase flows past the immiscible organic stream, an equilibrium is set up between the rare-earth ions in the aqueous solution and the complex ions in the organic solvent. As the two streams flow past each other, the heavy rare-earth elements concentrate in one stream and the lighter ones in the other.

The equilibrium constant for the exchange of one rare-earth ion for another is usually small, with the result that the ions have to exchange with the complex many times before a clear-cut separation between two rare-earth ions is achieved. This process necessitates that the two liquids be in contact with each other through many stages. If the equilibrium constant is equal to 1, no separation will take place, and for adjacent rare earths it is difficult to find complexes—except in special cases—that differ much from that value.

The liquid–liquid extraction process suffers from the disadvantage that for a given system only one cut is made in the rare-earth series, and if 15 pure rare earths were desired 14 cuts would have to be made. It also suffers from the disadvantage that the distance the rare-earth ions must travel in order to complete one exchange is many times that required in the ion-exchange columns. It has the advantages, however, that more concentrated solutions can be used and that the process is more economical for handling large quantities of materials. So far, it has found application mainly in special cases. It is used in some industries to concentrate the total rare earths where their abundance in the original materials is low. It is also used for separating certain elements, such as lanthanum, cerium, europium, and yttrium, with which favourable equilibrium constants are found. This is the case for cerium and europium, because they can be extracted in their tetravalent and divalent forms, respectively. Yttrium is not a lanthanide, and its position in the rare-earth series can be changed by using different organic solvents or complexing agents. First, a complex is used that separates the yttrium and heavy lanthanides from the light lanthanides, and then a different system is used whereby the yttrium is shifted with respect to the lanthanide series, so that it can be separated from the heavy lanthanides.

The liquid–liquid extraction system has not been successful in separating the adjacent heavy rare earths in the quantities desired. If ultrahigh-purity rare earths are required, it is common practice--even in those cases where liquid–liquid extraction methods have been used—to place the somewhat impure rare earth on an ion-exchange column and to use the displacement method for further purification.

PREPARATION OF PURE METALS

Early metal-reduction methods. It is relatively easy to reduce anhydrous halides of the rare earths to metals. What is difficult, however, is to reduce them to high-purity metals in ingot form. The rare-earth metals have a great affinity for the nonmetallic elements—hydrogen, boron, carbon, nitrogen, oxygen, silicon, sulfur, phosphorus, chlorine, and bromine—and form very stable compounds with them. If a small amount of rare-earth metal ıs added to most other metals containing these elements present as impurities, it reacts with the impurities and removes them by gathering them together in nodules or transferring them to the slag phase. There has been a steady market for misch metal, a mixed rare-earth alloy, since Auer von Welsbach's time. A small addition of this alloy greatly improves the mechanical properties of many impure metals or alloys.

Also, hot rare-earth turnings (chips or curls from machining) can be used to produce extremely pure helium, neon, and argon by removing hydrogen, oxygen, nitrogen, carbon dioxide, and hydrocarbon vapours. As is often the case with the rare earths, however, other—and cheaper—materials perform this function equally well, and for this reason the rare-earth elements are seldom used for this purpose.

Finally, molten rare-earth metals dissolve almost all other metals and react with most compounds. They come close to being the hypothetical universal solvent of the ancients. The molten metal attacks any crucible in which it is melted, and the final product generally is a rare-earth-rich alloy of the crucible elements.

First
reduction
to a
metal

*The **metallothermic process.*** Mosander, in 1826, was the first to reduce a rare earth to a metal. He used a metallothermic reaction (heating with active metals) to reduce anhydrous chlorides made from his ceria with metallic sodium or potassium. His yields were low, 26 percent, and the metal existed as small nuggets in a solid slag, from which they could be separated only with difficulty. The metal was very impure; it contained considerable amounts of sodium or potassium and iron and other crucible materials. It also contained considerable amounts of hydrogen, oxygen, nitrogen, and carbon, as well as-a mixture of the ceria group of rare earths.

During the next hundred years, as the individual rare earths were discovered and separated, a number of scientists reduced many of the lighter rare earths to the metal-lit form using the metallothermic process—but sometimes varying it by substituting calcium, magnesium, and aluminum as the reductants and anhydrous fluoride salts as the reactants. Because of the scarcity of pure rare earths, however, as well as the difficulty in finding suitable crucible materials and the poor equipment for keeping out atmospheric gases, the metals were still so impure that no extensive studies could be made of their properties.

In 1935, samples of the purest rare-earth chlorides available were reduced to metals at relatively low temperatures in glass capsules with potassium vapour. This process gave free metals in the form of fine powder imbedded in potassium chloride; no attempt was made to separate the metal from the potassium chloride, because only such properties as crystal structure, density, and magnetic susceptibility were under investigation. Potassium chloride acted as an internal standard in the X-ray investigations, and magnetic susceptibilities could be corrected for the potassium chloride present. Although these metals were not really pure by modern standards—they contained appreciable amounts of potassium and rare-earth impurities—they yielded values for the lattice constants and densities of most of the rare-earth metals that lie within 1 percent of the best modern values.

Development of electrolytic techniques

Electrolytic processes. In 1875, the first successful preparation of rare-earth metals by an electrolytic process was reported. About five grams each of cerium, lanthanum, and didymium (neodymium and praseodymium) in compact form were prepared by electrolyzing the fused chlorides covered with layers of ammonium chloride. The electrolytic technique was later improved, and, in the period 1902–05, misch metal, cerium, lanthanum, praseodymium, neodymium, and samarium were prepared. In 1906, Auer von Welsbach started the commercial production of lighter flints, for which the misch metal was electrolytically reduced. In the years 1923–26, several improvements in the cell designs were made, and somewhat purer samples of lanthanum, cerium, and neodymium were prepared, along with some yttrium, although most of the latter metal deposited as powder.

The electrolytic process suffers from much the same difficulties as the metallothermic methods. It is difficult to find electrodes and cell materials that will stand up to molten rare earths and at the same time not introduce impurities into the ingot. It is also difficult to design cells that exclude all the atmospheric elements. The method works best for the low-melting rare earths, with which the cells can be kept sufficiently hot so that a molten pool of the metal forms in the bottom of the cell. With the higher melting rare earths, only powdered metal is formed, and it is difficult to separate it from the electrolyte in a pure form. By the early 1970s there had not been much success in finding electrolytes that can be heated above 1,000" C.

In 1931, a cell especially designed for producing much purer metals and also capable of reducing the halides of the heavier rare earths was employed to produce a quantity of cerium that contained only a small percentage of impurities and, somewhat later, the same apparatus was used to produce a number of other rare-earth metals, including europium, gadolinium, and yttrium.

By 1939 most of the rare-earth metals had been made in fair purity, and a number of their properties, such as magnetic behaviour, melting point, density, crystal structure, and chemical reactivity had been studied. All of these metals contained small amounts of metallic impurities and unknown amounts of nonmetallic impurities. Most of these impurities were not reported because analytical methods to determine them had not been developed at that time. Almost no work had been done on the properties of the rare-earth alloys except for those of cerium and lanthanum.

Importance of impurities

Modern techniques for producing ultrapure rare-earth metals. As purer rare-earth metals are produced, it is increasingly clear that many of their properties are extremely sensitive to small amounts of impurities. This phenomenon is particularly true with regard to magnetic and to nonmetallic impurities. For many industrial uses extreme purity is not required—nor even desired—since less pure metals can be produced much more cheaply. On the other hand, the presence of impurities can be critical in metal produced for research purposes, especially when experimental properties are being compared with predicted values, or in metal to be incorporated into solid-state devices. The processes described below are those used in making research-grade metal. If less pure metal is satisfactory, many of the steps described can be omitted, and the process can be terminated at the point where the desired purity is attained.

One especially favoured reduction process utilizes metallic calcium (Ca) and the rare-earth fluoride (MF_3). The reaction is as in the following equation:

$$3Ca + 2MF_3 \rightleftharpoons 2M + 3CaF_2.$$

Other metallothermic processes, however, can also be used, such as lithium (Li) metal and the rare-earth chloride (MCl_3):

$$3Li + MCl_3 \rightleftharpoons M + 3LiCl.$$

Variations of these methods, using lithium, sodium, potassium, or calcium as the reducing agent and any halide of the rare earth for the reactant, also are possible. For these alternative processes to succeed, however, the metal must be separable from the slag cleanly without introducing impurities, and all sources of contamination must have been eliminated.

The problem of obtaining sufficient quantities of highly pure individual rare-earth oxides has been solved by the development of the displacement-band method of separating rare earths on ion-exchange columns described above. If the oxides are obtained from the middle third of the pure rare-earth band, the total of other rare-earth impurities in the metals obtained from them does not exceed 10 parts per million. Fractions taken closer to the band edges contain somewhat larger proportions of such impurities. If the same equipment is used to prepare the different raw materials and to make the metals of a number of different rare earths, great care must be taken to prevent cross contamination of the rare earths.

Tungsten and tantalum crucibles

Limiting contamination. Contamination from the crucible cannot be eliminated entirely. Tungsten and tantalum make the best crucibles: they are little attacked by molten rare-earth metals at temperatures below 1,000" *C*, and the crucible material introduced into the rare-earth metals at higher temperatures, if harmful, can be removed by special techniques. Both tungsten and tantalum are available commercially in the form of both crucibles and thin sheets: to prepare them for use, these materials are thoroughly cleaned and baked in a high vacuum to remove impurities that may be adsorbed on their surfaces.

Introduction of impurities from the atmosphere can be largely eliminated by carrying out all operations in an environment of purified helium and by the use of modern high-vacuum ion pumps instead of oil pumps.

Finally, if ultrapure metals are to be obtained, the raw materials from which they are made must also be ultrapure or their impurities will end up in the rare-earth ingot. Commercial calcium is doubly distilled at low pressure in an atmosphere of pure argon or helium to remove iron and various nonmetals that it contains, and thereafter is rigorously protected from carbon dioxide and water vapour. Anhydrous rare-earth halides form oxyhalides upon contact with water vapour; therefore, the preparation of an anhydrous fluoride is carried out in two steps. The first is the passage of dry hydrogen fluoride over the powdered oxide, immediately sweeping away any water formed; and the second is the passage of the pure, dry hydrogen fluoride over the molten fluorides. If this is done, the oxygen content of the fluoride can be kept below ten parts per million.

Groups for standardized operation

Standardizing reduction methods. There are enough differences in the properties of the 17 rare-earth metals that the same reduction process does not work equally well for all of them. If metal containing less than 0.01 weight percent of impurities is desired, each element has to be treated somewhat differently. Many of the operations are the same for all reductions, and if the metals are divided into five groups, standardized operations can be applied for all metals in a group. The groups are as follows: Group I consists of those metals that have low melting points and high boiling points—lanthanum, cerium, praseodymium, and neodymium. Group II consists of those metals having high melting points and high boiling points—gadolinium, terbium, scandium, yttrium, and lutetium. Group III consists of those metals having high melting points, low boiling points, and, in addition. an appreciable vapour pressure at the melting point—dysprosium, holmium, erbium, and scandium. Group IV consists of those metals that have low boiling points—samarium, europium, ytterbium, and thulium. Group V, consisting only of promethium, would be included in Group II, except that serious difficulties result from the intense radioactivity of the metal. All operations with it must be carried out by remote controls, and this is usually done at special installations.

The calcium-reduction process works well for the metals of Groups I, II, III, and V, but not at all well for Group IV. Most of the trifluorides (SmF_3, EuF_3, YbF_3) of this group are reduced only to divalent fluorides, even when a large excess of calcium is used; the resulting material resembles, but is not, the metal. Thulium trifluoride is reduced to the metal, but the high vapour pressure of molten metallic thulium causes difficulty.

The standard procedure for producing the metal by calcium reduction is to load a tantalum container with enough rare-earth fluoride to yield a metal billet weighing about 300 grams (11 ounces). About 10 percent excess calcium is added to drive the reaction to completion. The crucible is then placed in a furnace with a helium atmosphere and heated above the melting point of the rare-earth metal or of the slag—whichever is greater—and held at that temperature until the reaction is complete and the metallic and slag layers have separated because of differences in their densities. After cooling to room temperature, the crucible is taken out of the furnace in the dry box, cut in two at the metal–slag interface, and all slag is knocked off the metal. Usually a bright metal surface can be obtained. The metal ingot, however, contains small amounts of calcium and rare-earth fluoride as impurities. Group I and Group II metals are then put in another tantalum crucible and replaced in the furnace for the boiling-off process. This time a high vacuum is used, and the metal is heated to about 1,400" to 1,500" C (2,552" to 2,732" F) and held there for some time, so that any volatile impurities, particularly calcium and rare-earth fluoride, evaporate. At these temperatures considerable amounts (1 to 3 percent) of tantalum dissolve in the molten metal. The furnace temperature is then slowly lowered until it is just above the melting point of the pure metal, at which temperature it is held for a few minutes to allow most of the tantalum to precipitate onto the walls or sink to the bottom of the crucible. (For Group I metals, the solubility of tantalum is about 50 parts per million or less at the melting point.) The ingot is then removed from the cooled furnace in the dry box, and the tantalum crucible and precipitates are machined off. The resulting ingot usually contains less than 0.01 percent total impurities.

Special problems with groups II and III

Removal of dissolved tantalum. The Group II metals, because of their higher melting points, still contain some tantalum as an impurity when they solidify; usually this tantalum appears as a second phase, showing up as black dots in the metallographic pictures of the metal. It is possible, however, to purify these metals further by distillation from a tantalum still. The still consists of a short tantalum crucible located in a high-vacuum furnace. Affixed to this crucible is an inverted crucible, which is out of the heating zone of the furnace, its upper part being 400" to 500" C (720" to 900" F) cooler because of radiation losses. The rare-earth metal can then be slowly sublimed (changed from a solid into a gas without passing through the liquid state) and resolidified in the inverted crucible. Because volatile impurities usually have different boiling points and heats of sublimation, it is possible (by choosing the right temperature) to sublime the metal in such a manner that the impurities can be separated from the metal. The nonvolatile tantalum remains behind in the still. Finally, the condenser, with its rather porous crystalline mass of rare-earth metal, is removed from the furnace, and the tantalum (or tungsten) is machined off in the dry box. The porous mass is then arc-melted into a billet on a water-cooled copper hearth under an inert atmosphere.

The Group III elements cannot be held at their melting points for long: because of their volatility a considerable quantity of the metal is lost. The boiling process therefore is omitted, but sublimation or volatilization works well, and—by the right choice of temperature in the still—both the volatile and inert impurities can be eliminated.

For the Group IV metals, only a distillation process is used. The pure oxide of the rare earth is dissolved in acid and reprecipitated using ultrapure chemicals to remove traces of calcium and magnesium often introduced from the water and chemicals used in the ion-exchange process. The precipitate is again converted to the oxide and placed in the still. Pure metallic lanthanum, cerium, or misch metal, which has been subjected to the boiling-off process to remove volatile impurities, is added in excess.

The reaction of europium oxide with lanthanum metal ($Eu_2O_3 + 2La \rightarrow La_2O_3 + 2Eu\uparrow$) takes place when the mixture is heated. Because the vapour pressure of europium is millions of times greater than that of lanthanum or of the oxide of either element, the metal distills away from the oxides, and the reaction goes practically to completion. If ultrahigh-purity metal is desired, a second distillation is performed.

Problems with thulium

Thulium poses special problems. Its melting point is so high that the molten metal acquires a considerable amount of impurity from the crucible. On the other hand, it has such a high vapour pressure at the melting point that it is practically impossible to melt it without losing much of the metal. Thulium is never melted, therefore, but is sublimed to the condenser, on which it forms solid crystals but not compact metal. If a solid bar is desired, the porous metal can be pressed into a tantalum tube and reduced to about half its diameter. The tantalum covering can then be machined off and a bar of compact metal obtained.

INDUSTRIAL USES

The properties of the 17 rare-earth elements in the form of their metals, alloys, or compounds—or some combination thereof—are so varied as to make them valuable for many industrial uses. Many other somewhat less costly materials, however, often will perform just as well; and when this is the case, the rare-earth elements are seldom used for these purposes. Only when their properties are unique is the extra cost justified industrially. Nevertheless, in 1969, the world shipments of light rare-earth oxides to be used in industry were reported to be 30,000,000 pounds (U.S.S.R. figures were not included but were substantial). About 20,000,000 pounds of oxides were obtained from bastnaesite, and the remaining 10,000,000 pounds were derived from monazite. About two-thirds of this production was consumed in the United States.

Use as catalysts

In 1969, about 12,000,000 pounds of rare earths were used in the United States to produce catalysts for the cracking of crude petroleum. The natural mixture of rare earths obtained from the minerals accounted for about 20 percent of that total, and the remaining 80 percent was made up of special mixtures of lanthanum, praseodymium, neodymium, and samarium. Rare-earth catalysts have been repeatedly recommended for use in numerous organic reactions, including the hydrogenation of ketones to form secondary alcohols, the hydrogenation of olefins to form alkanes, the dehydrogenation of alcohols and butanes, and the formation of polyesters. The extent to which these catalysts are used in industry seldom is made public, but there is no doubt that the rare earths show marked catalytic properties.

Another substantial use of rare-earth oxides is in the glass industry. Cerium oxide has been found to be a more rapid polishing agent for glass than rouge, and several million pounds a year are consumed in the polishing of lenses for cameras, binoculars, and eyeglasses, as well as in polishing mirrors and television faceplates. Glasses containing lanthanum oxide have very high refractive indexes and low dispersions. Such glasses are used in complex lenses for cameras, binoculars, and military instruments — for the purpose of correcting spherical and chromatic aberrations. Rare-earth oxides often are added to glass melts in order to produce special glasses. Neodymium is added to some glasses to counteract the yellowish tint caused by iron impurities. Very pure neodymium oxide, when added in sufficient quantities (1–5 percent), gives a beautiful purple glass. Praseodymium and neodymium are added to glass to make welders' and glassblowers' goggles, that absorb the bright-yellow light from the sodium flame. The same combination is sometimes added to the glass used in television faceplates to decrease the glare from outside light sources. A beautiful yellow ceramic stain results from the addition of about 3 percent praseodymium oxide to zirconium oxide. Cerium oxide increases the opacity of white porcelain enamels.

Use in metallurgy

The metallurgical industry is another heavy user of rare earths. Small amounts of misch metal and cerium have long been added to other metals or alloys to remove their nonmetallic impurities. Misch metal added to cast iron makes a more malleable nodular iron. Added to some steels, it makes them less brittle. The addition of misch metal to certain alloys has been reported to increase the tensile strength and improve the hot workability and the high-temperature oxidation resistance. The rare earths are particularly effective in iron–chromium and iron–chromium–nickel alloys to improve a number of their properties, especially their resistance to corrosion and oxidation. Yttrium metal is said to work even better than misch metal in removing impurities from certain materials. The flints of cigarette lighters are an alloy of misch metal and iron.

The addition of misch metal or pure rare-earth elements to magnesium increases its high-temperature strength and its creep resistance — that is, resistance to slow deformation under prolonged use. This alloy also makes better castings if small amounts of zirconium or other metals are added, and such alloys are used in jet-engine and precision castings. The addition of small amounts of rare-earth elements to aluminum has also been reported to give better castings.

Use in television screens

By far the heaviest user of ultrapure separated rare earths is the television industry. It has been found that if a small amount of europium oxide (Eu_2O_3) is added to yttrium oxide (Y_2O_3), it gives a brilliant-red phosphor. Colour television screens utilize red, green, and blue phosphors. In the past, a zinc–cadmium sulfide was used as the red phosphor, but it was not completely satisfactory because its fluorescent band was too wide, and it could not be made to fluoresce as intensely as the other phosphors. The Y_2O_3–Eu_2O_3 phosphor corrected these disadvantages and made possible much brighter and more natural coloured pictures. This use has been growing in many countries. Many of the early rare-earth screens used europium–yttrium orthovanadate phosphor, but the industry is shifting heavily toward the oxide phosphor. Some television companies have substituted gadolinium oxide for the yttrium oxide, and the television industry consumed in excess of 10,000 pounds of ultrapure gadolinium oxide in 1969. In the same year, Japan imported over 200 tons of xenotime in order to prepare rare earths for its television industry. The rare-earth phosphors are also finding use in mercury-arc lights, which are used for sporting events and special street lighting. Instead of the unhealthy-looking blue light of the mercury arc, the phosphors give an intense white radiation similar to daylight. Considerable amounts of mixed rare-earth fluorides are used to make cored carbon rods, which are used as arcs in searchlights and in some of the lights used by the motion-picture industry.

Yttrium-iron garnets are synthetic high-melting silicates that can be fabricated into special shapes for use as microwave filters in the communications industry. Yttrium-aluminum garnets also are being produced at an increasing rate for use both in electronics and as gemstones. Both of these synthetic minerals have much use in the jewelry business. These garnets have a high refractive index and a hardness approaching that of diamond. In a solid crystal form they are amazingly transparent, and they are being cut into imitation diamonds.

Another rapidly developing industrial application of rare earths is in the manufacture of strong permanent magnets. Alloys of cobalt with rare earths, such as cobalt–samarium, produce permanent magnets that are far superior to most of the varieties now on the market. Another recent development is the use of a barium phosphate-europium phosphor in a sensitive X-ray film that forms satisfactory images with only half the exposure.

Nuclear applications

Europium, gadolinium, and dysprosium have large capture cross sections for thermal neutrons — that is, they absorb large numbers of neutrons per unit of area exposed. These elements, therefore, are incorporated into control rods used to regulate the operation of nuclear reactors or to shut them down should they get out of control. In addition, rare-earth elements are used as burnable neutron absorbers to keep the reactivity of the reactor more nearly constant. As uranium undergoes fission, it produces some fission products that absorb neutrons and tend to slow down the nuclear reaction. If the right amounts of rare-earth elements are present, they bum out at about the same rate that other absorbers are formed.

Yttrium dihydride is used as a moderator in reactors to slow down neutrons. Certain rare earths are also used in shielding materials because of their high nuclear cross sections. Scandium metal is used as a neutron filter that allows neutrons only of a certain energy (two kiloelectron volts) to pass through.

Complexes of europium, praseodymium, or ytterbium with derivatives of camphor are useful reagents for analysis of optically-active organic compounds, which often are obtained as mixtures containing unknown proportions of two components that differ only in that their molecular structures are mirror images of each other (see ISOMERISM). Determination of these proportions can be very difficult, but the rare-earth complexes provide asymmetric environments in which each component absorbs electromagnetic radiation of a particular frequency in the presence of a strong magnetic field (a phenomenon covered in the article MAGNETIC RESONANCE). Composition of the mixtures then can be determined by measuring the intensities of the separate absorptions.

The rare earths have low toxicities and can be handled safely with ordinary care. Solutions injected into the peritoneum will cause hyperglycemia (excess of sugar in the blood), decreased blood pressure, spleen degeneration, and fatty liver. If solutions are injected into muscle about 75 percent of the rare-earth element remains at the site, the remainder going to the liver and skeleton. When taken orally, only a small percentage of a rare-earth element is absorbed into the body. Organically complexed ions are somewhat more toxic than solids or inorganic solutions. As is true for most chemicals, dust and vapours should not be inhaled, nor should they be ingested. Solutions splashed into the eyes should be washed out, and splinters of metal should be removed.

When handling rare-earth ores or minerals, dust should be avoided because many minerals contain other toxic elements, such as beryllium, thorium, and uranium. Finely divided rare-earth metals can ignite spontaneously, somewhat as magnesium does.

Rashi

Rashi's stature

Rashi (acronym for Rabbi Shlomo Yitzhaqi), medieval French commentator on the Bible and Talmud, the authoritative rabbinical compendium of law, lore, and commentary, holds a unique position in Jewish religious scholarship. In an exegesis-oriented literature, in which commentaries and supercommentaries constitute the most extensive as well as creative literary genre, Rashi is "the commentator" par excellence. The study of his classic commentaries by both schoolchildren and adults, the simple and the sophisticated, still serves among Jews as the most substantive introduction to biblical and post-biblical Judaism.

Shlomo (Solomon) Yitzhaqi (son of Isaac) was born at Troyes, France, in 1040. He studied in the schools of Worms and Mayence, the old Rhenish centres of Jewish learning, where he absorbed the methods, teachings, and traditions associated with Rabbi Gershom ben Judah (c. 960–1028/1040), called the "Light of the Exile" because of his pre-eminence as the first great scholar of north European Judaism. As Rashi transferred his scholarly legacy to the valley of the Seine (*c.*1065), his task was to consolidate and expand, preserve and innovate.

Personal and environmental factors combined to insure that Rashi would not be an ivory-tower scholar but very much involved in the relatively fast-moving social, economic, political, and theological developments of the 11th century. Troyes was a major commercial centre of the province of Champagne. Rashi, the de facto but unofficial head of the small Jewish community (about 100–200 people) in Troyes, was himself a winegrower. The major developments of the period are recorded or reflected in his commentaries, in the codes, liturgical works, and miscellaneous collections edited by his disciples, as well as in the hundreds of his responsa (Hebrew *teshuvot*)—official, authoritative answers to a wide range of questions addressed to him by various people on different occasions. Those texts reflect the intensified Jewish–Christian relations in business and commerce and the concomitant re-evaluation of the Jewish attitude toward Christianity; the church–state struggle known as the investiture controversy; emerging patterns of Jewish self-government (defined in special charters) in relation to both the existing feudal system and incipient urban civilization; the beginning of the Crusades, preached for the first time by Pope Urban II at Clermont (1096); the increased precariousness of the dispersed Jewish settlements; religious persecution and forced baptisms; and the hopes of messianism and the realities of martyrdom. Rashi also composed some penitential hymns (selihot), which revolve around twin themes: the harsh reality of exile and the comforting belief in redemption.

Rashi's method of Biblical interpretation

His Bible commentary illustrates vividly the coexistence and, to some extent, the successful reconciliation of the two basic methods of interpretation: the literal and the nonliteral. Rashi seeks the literal meaning, deftly using rules of grammar and syntax and carefully analyzing both text and context, but does not hesitate to mount Midrashic explanations, utilizing allegory, parable, and symbolism, upon the underlying literal interpretation. As a result, some of his successors are critical of his searching literalism and deviation from traditional Midrashic exegesis, while others find his excessive fondness for nonliteral homilies uncongenial. Yet it is precisely the versatility and mixture, the blend of creative eclecticism and originality, that account for the genius, the animation, and the unrivalled popularity of his commentary, which, symbolically, was the first book printed in Hebrew (1475). The commentary had a significant influence on Christian Bible study from the 12th-century Victorines to the Franciscan scholar Nicholas of Lyra (*c.*1270–1349), who, in turn, was a major source of Luther's Bible work, through the translators responsible for the King James Version of the Bible. Its influence continues in contemporary exegesis and revised translations. Rashi's custom to use a vernacular gloss to clarify the exact meaning of an obscure or technical term—there are over 3,000 of them in his works--also makes his commentary an important source for the study of Old French.

Rashi's commentary on the Talmud, based on the collective achievements of the previous generations of Franco-German scholars, reflects its genesis in the oral classroom instruction that Rashi gave in Troyes for several decades. The commentary, sometimes referred to as kuntros (literally, "notebook"), resembles a living tutor; it explains the text in its entirety, guides the student in methodological and substantive matters, resolves linguistic difficulties, and indicates the normative conclusions of the discussion. Unlike Maimonides' commentary on the Mishna (the authoritative compendium of Jewish Oral Law), which may be read independently of the underlying text whose relevant portions have been quoted or paraphrased in the commentary, Rashi's commentary is interwoven with the underlying text. Indeed, text and commentary form a unified mosaic. Rashi's work was literally epochal, and the agreement of subsequent scholars that the basic needs of text commentary had been fulfilled stimulated the rise of a new school of writers known as *tosafists*, who composed tosafot (glosses), refining, criticizing, expanding, or qualifying Rashi's interpretations and conclusions. The leaders of this great intellectual movement, which spread across all the cities of France and Germany, were Rashi's grandchildren—Samuel ben Meir (Rashbam), Jacob ben Meir Tam (Rabbenu Tam), and Isaac ben Meir (Ri ha-Zaken). Skillfully and honestly combining stricture and supplement, they were able to perpetuate and augment the achievement of the great Rashi, who died at Troyes on July 13, 1105.

BIBLIOGRAPHY. The best biography is the Hebrew study by A.M. LIFSCHITZ, *Rashi* (1966). The standard English biography remains M. LIBER, *Rashi* (1906). More specialized works include: I. AGUS, "Rashi and His School," in *The World History of the Jewish People,* vol. 2, pp. 210–248 (1966), the most recent survey of 11th-century Jewish history in the Franco-German sphere, with a good summary of intellectual and literary developments; HERMAN HAILPERIN, *Rashi and the Christian Scholars* (1963), a meritorious study, written for the non-specialist, of Rashi's influence on Nicholas of Lyra and Christian Bible study; and the *Rashi Anniversary Volume* (1941), a collection of scholarly essays on various aspects of Rashi's life and works.

(I.T.)

Rationalism

Rationalism is the philosophical view that regards reason as the chief source and test of knowledge. Holding that reality itself has an inherently logical structure, the Rationalist asserts that a class of truths exists that the intellect can grasp directly. There are, according to the Rationalists, certain rational principles—especially in logic and mathematics, and even in ethics and metaphysics—that are so fundamental that to deny them is to fall into contradiction. The Rationalist's confidence in reason and proof tends, therefore, to detract from other ways of knowing. Rationalism has long been the rival of Empiricism, the doctrine that all knowledge comes from, and must be tested by, sense experience. As against this doctrine, Rationalism holds reason to be a faculty that can lay hold of truths beyond the reach of sense perception, both in certainty and generality. In stressing the existence of a "natural light," Rationalism has also been the rival of systems claiming esoteric knowledge, whether from mystical experience, revelation, or intuition, and has been opposed to various irrationalisms that tend to stress the biological, the emotional or volitional, the unconscious, or the existential at the expense of the rational.

TYPES AND EXPRESSIONS OF RATIONALISM

Rationalism has somewhat different meanings in different fields, depending upon the kind of theory to which it is opposed.

Nativism in psychology and linguistics

In the psychology of perception, for example, Rationalism is in a sense opposed to the genetic psychology of the Swiss scholar Jean Piaget, who, exploring the development of thought and behaviour in the infant, argued that the categories of the mind develop only through the infant's experience in concourse with the world. Similarly, Rationalism is opposed to Transactionalism, a point of view in psychology according to which man's perceptual skills are achievements, accomplished through actions performed in response to an active environment. On this view, the experimental claim is made that perception is conditioned by probability judgments formed on the basis of earlier actions performed in similar situations. As a corrective to these sweeping claims, the Rationalist defends a nativism, which holds that certain perceptual and conceptual capacities are innate—as suggested in the case of depth perception by experiments with "the visual cliff," which, though platformed over with firm glass, the infant perceives as hazardous—though these native capacities may, at times, lie dormant until the appropriate conditions for their emergence arise.

In the comparative study of languages, a similar nativism was developed in the 1950s by the innovating syntactician, Noam Chomsky, who, acknowledging a debt to Descartes, exylicitly accepted the rationalistic doctrine of "innate ideas." Though the 4,000 languages spoken in the world differ greatly in sounds and symbols, they sufficiently resemble each other in syntax to suggest that there is "a schema of universal grammar" determined by "deep structures" or "innate presettings" in the human mind itself. These presettings, which have their basis in the brain, set the pattern for all experience, fix the rules for the formation of meaningful sentences, and explain why languages are readily translatable into one another. It should be added that what Rationalists have held about innate ideas is not that some ideas are full-fledged at birth but only that the grasp of certain connections and self-evident principles, when it comes, is due to inborn powers of .insight rather than to learning by experience.

Metaphysical and epistemological Rationalism

Common to all forms of speculative Rationalism is the belief that the world is a rationally ordered whole, the parts of which are linked by logical necessity and the structure of which is therefore intelligible. Thus in metaphysics it is opposed to the view that reality is a disjointed aggregate of incoherent bits and is thus opaque to reason. In particular, it is opposed to the logical atomisms of such thinkers as David Hume and Ludwig Wittgenstein, who held that facts are so disconnected that any fact might well have been different from what it is without entailing a change in any other fact. Rationalists have differed, however, with regard to the closeness and completeness with which the facts are bound together. At the lowest level, they have all believed that the law of contradiction "A and not-A cannot coexist" holds for the real world, which means that every truth is consistent with every other; at the highest level, they have held that all facts go beyond consistency to a positive coherence; *i.e.*, they are so bound up with each other that none could be different without all being different.

In the field where its claims are clearest—in epistemology, or theory of knowledge—Rationalism holds that some, at least, of man's knowledge is gained through a priori (prior to experience), or rational, insight as distinct from sense experience, which too often provides a confused and merely tentative approach. In the debate between Empiricism and Rationalism, Empiricists hold the simpler and more sweeping position, the Humean claim that all knowledge of fact stems from perception. Rationalists, on the contrary, urge that some, though not all, knowledge arises through direct apprehension by the intellect. What the intellectual faculty apprehends is objects that transcend sense experience—universals and their relations. A universal is an abstraction, a characteristic that may reappear in various instances: the number three, for example, or the triangularity that all triangles have in common. Though these cannot be seen, heard, or felt, Rationalists point out that man can plainly think about them and about their relations. This kind of knowledge, which includes the whole of logic and mathematics as well as fragmentary insights in many other fields, is, in the Rationalist view, the most important and certain knowledge that the mind can achieve. Such a priori knowledge is both necessary (*i.e.*, it cannot be conceived as otherwise) and universal, in the sense that it admits of no exceptions. In critical philosophy, epistemological Rationalism finds expression in the claim that the mind imposes its own inherent categories or forms upon incipient experience (see below *Kant and Hegel*).

Ethical and religious Rationalism

In ethics Rationalism holds the position that reason, rather than feeling, custom, or authority, is the ultimate court of appeal in judging good and bad, right and wrong. Among major thinkers, the most notable representative of rational ethics is Immanuel Kant, who held that the way to judge an act is to check its self-consistency as apprehended by the intellect: to note, first, what it is essentially, or in principle—-a lie, for example, or a theft—and then to ask if one can consistently will that the principle be made universal. Is theft, then, right? The answer must be "No," because, if theft were generally approved, no one's property would be his own as opposed to anyone else's and theft would then become meaningless; the notion, if universalized, would thus destroy itself, as reason, by itself, is sufficient to show.

In religion Rationalism commonly means that all of man's knowledge comes through the use of his natural faculties, without the aid of supernatural revelation. "Reason" is here used in a broader sense, referring to man's cognitive powers generally, as opposed to supernatural grace or faith—though it is also in sharp contrast to so-called existential approaches to truth. Reason, for the Rationalist, thus stands opposed to many of the religions of the world, including Christianity, which have held that the divine has revealed itself through inspired persons or writings and which have required, at times, that its claims be accepted as infallible, even when they do not accord with natural knowledge. Religious Rationalists hold, on the other hand, that if the clear insights of man's reason must be set aside in favour of alleged revelation, then human thought is everywhere rendered suspect—even in the reasonings of the theologians themselves. There cannot be two ultimately different ways of warranting truth, they assert; hence Rationalism urges that reason, with its standard of consistency, must be the final court of appeal. Religious Rationalism can reflect either a traditional piety, when endeavouring to display the alleged sweet reasonableness of religion, or an anti-authoritarian temper, when aiming to supplant religion with the "goddess of reason."

HISTORY OF RATIONALISM

Pre-Socratics

Epistemological Rationalism in ancient philosophies. The first Western philosopher to stress rationalist insight was Pythagoras, a shadowy figure of the 6th century BC. Noticing that, for a right triangle, a square built on its hypotenuse equals the sum of those on its sides and that the pitches of notes sounded on' a lute bear a mathematical relation to the lengths of the strings, Pythagoras held that these harmonies reflected the ultimate nature of reality. He summed up the implied metaphysical Rationalism in the words "All is number." It is probable that he had caught the Rationalist's vision, later seen by Galileo, of a world governed throughout by mathematically formulable laws.

The difficulty in this view, however, is that, working with universals and their relations, which, like the multiplication table, are timeless and changeless, it assumes a static world and ignores the particular, changing things of daily life. The difficulty was met boldly by the Rationalist Parmenides, who insisted that the world really is a static whole and that the realm of change and motion is an illusion, or even a self-contradiction. His disciple Zeno of Elea further argued that anything thought to be moving is confronted with a row of points infinite in number, all of which it must traverse; hence it can never reach its goal, nor indeed move at all. Of course, perception tells us that we do move; but Zeno, compelled to choose between perception and reason, clung to reason.

The exalting of rational insight above perception was

Plato and Aristotle

also prominent in Plato (*c.* 427–347 BC). In the *Meno,* Socrates dramatized the innateness of knowledge by calling upon an illiterate slave boy and, drawing a square in the sand, proceeding to elicit from him, step by step, the proof of a theorem in geometry of which the boy could never have heard (to double the size of a square, draw a square on the diagonal). Such knowledge, Rationalists insist, is certain, universal, and completely unlearned.

Plato so greatly admired the rigorous reasoning of geometry that he is alleged to have inscribed over the door of his Academy "Let no one unacquainted with geometry enter here." His famous "ideas" are accessible only to reason, not to sense. But how are they related to sensible things? His answers differed. Sometimes he viewed the ideas as distilling those common properties of a class in virtue of which one identifies anything as a member of it. Thus what makes anything a triangle is its having three straight sides; this is its essence. At othei times, Plato held that the idea is an ideal, a nonsensible goal to which the sensible thing approximates; the geometer's perfect triangle "never was on sea or land," though all actual triangles more or less embody it. He conceived the ideas as more real than the sensible things that are their shadows and saw that the philosopher must penetrate to these invisible essences and see with the eye of his mind how they are linked together. For Plato they formed an orderly system that was at once eternal, intelligible, and good.

Plato's successor Aristotle (384–322 BC) conceived of the work of reason in much the same way, though he did not view the ideas as independent. His chief contribution to Rationalism lay in his syllogistic logic, regarded as the chief instrument of rational explanation. Man explains particular facts by bringing them under general principles. Why does one think Socrates will die? Because he is a man, and man as such is mortal. Why should one accept the general principle itself that all men are mortal? In human experience such principles have so far held without exception. But the mind cannot finally rest in this sort of explanation. Man never wholly understands a fact or event until he can bring it under a principle that is self-evident and necessary; and he then has the clearest explanation possible. On this central thesis of Rationalism, the three great Greeks were in accord.

Nothing comparable in importance to their thought appeared in Rationalistic philosophy in the next 1800 years, though the work of Thomas Aquinas in the 13th century was an impressive attempt to blend Greek Rationalism and Christian revelation into a single harmonious system.

Rationalism in non-Western thought

Thoroughgoing Rationalism is to be found only in the philosophical tradition that has come down from Greece; the mysticism of India and the practicality of China have offered a less congenial soil for it. The nearest parallels to it in Eastern thought are found in the work of the Indian philosopher Sankara, who flourished about AD 800, and in that of the Chinese sage Chu-Hsi (1130–1200). Both were commentators on the ancient scriptures of their lands; and in ordering the scattered insights of these sources into intelligible systems, they did for their respective peoples something like what Aquinas did for the West in his harmonizing of Greek with Christian thought. Śaṅkara held, as Sir Sarvepalli Radhakrishnan has expressed it, that "the Absolute is the unattainable goal towards which the finite intellect strives." Perception is confined to what is transient and fragmentary; reason rises to truth that is timeless and universal; but even reason falls short of full understanding, which is achieved, if at all, only through mystical vision. Chu Hsi, who has influenced Chinese thought for the past six centuries, was a disciple of Confucius, though he had a stronger speculative interest than his master. He held that in all human minds a single reason was at work, which he called "the Way." All things were in some degree manifestations of it, and hence the understanding of the world lay in more complete identification with it.

Continental Rationalists

Epistemological Rationalism in modern philosophies. The first modern Rationalist was René Descartes (1596–1650), who was an original mathematician, whose ambition was to introduce into philosophy the rigour and clearness that delighted him in mathematics. He set out to doubt everything in the hope of arriving in the end at something indubitable. This he reached in his famous ***cogito ergo sum***, "1 think, therefore I am"; for to doubt one's own doubting would be absurd. Here then was a fact of absolute certainty, rendered such by the clearness and distinctness with which it presented itself to his reason. His task was to build on this as a foundation, to deduce from it a series of other propositions, each following with the same self-evidence. He hoped thus to produce a philosophical system on which men could agree as completely as they do on the geometry of Euclid. The main cause of error, he held, lay in the impulsive desire to believe before the mind is clear. The clearness and distinctness upon which he insisted was not that of perception but of conception, the clearness with which the intellect grasps an abstract idea, such as the number three, or its being greater than two.

His method was adopted in essentials by both Benedict Spinoza (1632–77) and G.W. Leibniz (1646–1716), who agreed that the framework of things could be known by a priori thinking. They differed from him, however, in their starting points. What was most undeniable to Spinoza was not the existence of his self but that of the universe, called by him Substance. From the idea of Substance, and with the aid of a few definitions and axioms, he derived his entire system, which he set forth in his *Ethics* in a formal fashion patterned after Euclid's geometry. Still, for both Spinoza and Leibniz much in nature remained stubbornly opaque. Leibniz distinguished necessary truths, those of which the opposite is impossible (as in mathematics), from contingent truths, the opposite of which is possible, such as "snow is white." But was this an ultimate distinction? At times Leibniz said boldly that if only man knew enough, he would see that every true proposition was necessarily true—that there are no contingent truths, that snow must be white.

Kant and Hegel

How, then, does reason operate and how is it possible to have knowledge that goes beyond experience? A new answer was given by Immanuel Kant (1724–1804) in his ***Critique of Pure Reason,*** which, as he said, involved a Copernican revolution in philosophy. The reason man can be certain that his logic and mathematics will remain valid for all experience is simply that their framework lies within his own mind; they are forms of arrangement imposed from within upon the raw materials of sensation. Man will always find things arranged in certain patterns because it is he who has unwittingly so arranged them. Kant held, however, that these certainties were bought at a heavy price. Just because a priori insights are the reflection of man's own mind, he cannot trust them as a reflection of the world outside himself. Whether the rational order in which man arranges his sensation—the order, for example, of time, space, and causality—represents an order holding among things-in-themselves (German ***Dinge-an-sich)*** he cannot hope to know. Kant's Rationalism was thus the counterpart of a profound Skepticism.

G.W.F. Hegel (1770–1831), the most thoroughgoing of Rationalist thinkers. attempted to break out of this Skepticism. He argued that to think of an unknowable is already to bring it within the sphere of what is known and that it is meaningless to talk of a region in which logic is invalid. Further, to raise the question "Why?" is to presume that there is an intelligible answer to it; indeed the faith of the philosopher must be that the real is the rational and the rational real, for this faith is implicit in the philosophic enterprise itself, As an attempt to understand and explain the world, philosophy is a process of placing something in a context that reveals it as necessary. But this necessity is not, as earlier Rationalists had supposed, an all-or-nothing affair issuing in a self-evident finality. Understanding is a matter of degree. What alone would wholly satisfy thought is a system that is at once all-inclusive and so ordered that its parts entail each other. Hegel believed that the universe constitutes such a whole and, as an idealist, held that it is a single, absolute mind. To the degree that the philosopher embodies and realizes this mind, his own mind will achieve both truth and reality. Indeed, the advance of civilization reflects the enlarging presence and control of such a system in the human spirit. Broadly similar Rationalistic systems were developed in England by F.H. Bradley (1846–1924) and Bernard Bosanquet (1848–1923) and in America by Josiah Royce (1855–1916).

Legalistic versus utilitarian ethics

Ethical Rationalism. The views of Kant were presented above as typical of this position (see above, *Types and expressions of Rationalism).* But few moralists have held to ethical Rationalism in this simple and sweeping form. Many have held, however, that the main rules of conduct are truths as self-evident as those of logic or mathematics. Lists of such rules were drawn up by Ralph Cudworth and Henry More among the Cambridge Platonists of the 17th century, who were noted for holding that moral principles were intrinsic to reality; and in the 18th century Samuel Clarke and Richard Price, defenders of "natural law" ethics, and the "common sense" moralist Thomas Reid also presented such lists. A 20th-century revision of this Rationalism has been offered by the Rational Intuitionists H.A. Prichard and Sir David Ross of Oxford under the name of deontology (Greek *deon*, "duty"), which respects duty more than consequences. Ross provides a list of propositions regarding fidelity to promises, reparation for injuries, and other duties, of which he says: "In our confidence that these propositions are true there is involved the same trust in our reason that is involved in our trust in mathematics." What is taken as self-evident, however, is not specific rules of conduct, but *prima facie* duties—the claims that some types of action have on men because of their nature. If a man is considering whether to repay a debt or to give the money to charity, each act has a self-evident claim on him; and their comparative strengths must be settled by a rational intuition.

The most influential variety of 20th-century ethical Rationalism has probably been the Ideal Utilitarianism of the British moralists Hastings Rashdall (1858–1924) and G.E. Moore (1873–1958). Both were teleologists (Greek *telos*, "end") inasmuch as they held that what makes an act objectively right is its results (or end) in intrinsic goods or evils. To determine what is right, reason is required in two senses: firstly, the inference to the consequences is an act of inductive reasoning; secondly, the judgment that one consequence is intrinsically better than another is a priori and self-evident. Moore thought that there is a single rule for all conduct—one should so act as to produce the greatest good—and that this is also a principle self-evident to reason.

Religious Rationalism. Stirrings of religious Rationalism were already felt in the Middle Ages regarding the Christian revelation. Thus the skeptical mind of Abelard (1079–1142) raised doubts by showing in his *Sic et Non* ("Yes and No") many contradictions among beliefs handed down as revealed truths by the church fathers. The greatest of the Medieval thinkers, Thomas Aquinas (1225–1274), was a Rationalist in the sense of believing that the larger part of revealed truth was intelligible to and demonstrable by reason, though he thought that a number of dogmas opaque to reason must be accepted on authority alone.

Expansion of religious Rationalism. Religious Rationalism did not come into its own, however, until the 16th and 17th centuries, when it took two chief forms: the scientific and the philosophic.

Galileo and Descartes

Galileo (1564–1642) was a pioneer in astronomy and the founder of modern dynamics. He conceived of nature as governed throughout by laws statable with mathematical precision; the book of nature, he said, is "written in mathematical form." This notion not only ruled out the occasional appeal to miracle; it also collided with dogmas regarding the permanent structure of the world—in particular with that which viewed the earth as the motionless centre of the universe. When Galileo's demonstration that the earth moves around the sun was confirmed by the work of Newton and others, a battle was won that marked a turning point in the history of Rationalism, since it provided a decisive victory in a crucial case of conflict between reason and apparently revealed truth.

The Rationalism of Descartes, as already shown, was the outcome of philosophic doubt rather than of scientific inquiry. The self-evidence of the *cogito,* seen by his "natural light," he made the ideal for all other knowledge. The uneasiness that the church soon felt in the face of such a test was not unfounded, for Descartes was in effect exalting the natural light into the supreme court even in the field of religion. He argued that man's guarantee against the possibility that even this natural light might deceive him lay in the goodness of the Creator. But then to prove this Creator, he had to assume the prior validity of the natural light itself. Logically, therefore, the last word lay with rational insight, not with any outside divine warrant. Descartes was inadvertently beginning a Copernican revolution in theology. Before his time, the truths regarded as most certain were those accepted from revelation; afterwards these truths were subject to the judgment of human reason, thus breaking the hold of authority on the European mind.

Deism

Four waves of religious Rationalism. The Rationalist attitude quickly spread, its advance forming several waves of general interest and influence. The first wave occurred in England in the form of Deism. Deists accepted the existence of God, but spurned supernatural revelation. The earliest member of this school, Lord Herbert of Cherbury (1583–1648), held that a just God would not reveal himself to a part of his creation only and that the true religion is thus a universal one, which achieves its knowledge of God through common reason. The Deistic philosopher John Toland (1670–1722), in his *Christianity Not Mysterious,* sought to show that "there is nothing in the Gospels contrary to reason, nor above it"; any doctrine that is really above reason would be meaningless to man. Attacking revelation, the freethinking polemicist Anthony Collins (1676–1729) maintained that the prophecies of the Old Testament failed of fulfillment; and the religious controversialist Thomas Woolston (1670–1733) urged that the New Testament miracles, as recorded, are incredible. Matthew Tindall (1657–1733), most learned of the English Deists, argued that the essential part of Christianity is its ethics, which, being clearly apparent to natural reason, leaves revelation superfluous. Thus the Deists, professing for the most part to be religious men themselves, did much to reconcile their public to the free play of ideas in religion.

Voltaire and Diderot

The second wave of religious Rationalism, less moderate in tone and consequences, was French. This wave, reflecting an engagement with the problem of natural evil, involved a decay in the natural theology of Deism such that it merged eventually with the stream that led to materialistic Atheism. Its moving spirit was Voltaire (1694–1778), who had been impressed by some of the Deists during a stay in England. Like them, he thought that a rational man would believe in God but not in supernatural inspiration. Hardly a profound philosopher, he was a brilliant journalist, clever and humorous in argument, devastating in satire, and warm in human sympathies. In his *Candide* and in many other writings, he poured irreverent ridicule on the Christian scheme of salvation as incoherent and on the church hierarchy as cruel and oppressive. In these attitudes he had the support of Diderot (1713–84), editor of the most widely-read encyclopaedia that had appeared in Europe. The Rationalism of these men and their followers, directed against both the religious and the political traditions of their time, did much to prepare the ground for the explosive French Revolution.

Hegelianism

The next wave of religious Rationalism occurred in Germany under the influence of Hegel, who held that a religious creed is a halfway house on the road to a mature philosophy, the product of a reason that is still under the sway of feeling and imagination. This idea was taken up and applied with learning and acuteness to the origins of Christianity by David Friedrich Strauss (1808–74), who published in 1835, at the age of 27, a remarkable and influential three-volume work, *Das Leben Jesu* (Eng. trans., *The Life of Jesus, Critically Examined*, 1846). Relying largely on internal inconsistencies in the Synoptic Gospels, Strauss undertook to prove these books to be unacceptable as revelation and unsatisfactory as history. He then sought to show how an imaginative people innocent of either history or science, convinced that a Messiah would appear, and deeply moved by a unique moral genius, inevitably wove myths about his birth and death, his miracles, and his divine communings.

Strauss's thought as it affected religion was continued by the philosophical historian Ernest Renan (1823–92) and as it affected philosophy by the humanist Ludwig Feuerbach (1804–72) of the Hegelian left. Renan's *Vie de Jésus* (1863; Eng. tranr., *Life* of *Jesus)* did for France what Strauss's book had done for Germany, though the two differed greatly in character. Whereas Strauss's work had been an intellectual exercise in destructive criticism, Renan's was an attempt to reconstruct the mind of Jesus as a wholly human person—a feat of imagination, performed with a disarming admiration and even reverence for its subject and with a felicity of style that gave it a large and lasting audience. Feuerbach's *Wesen des Christentums* (1841; Eng. trans, by George Eliot, *Essence of Christianity*, 1853) applied the myth theory even to belief in the existence of God, holding that "man makes God in his own image."

Evolution

The fourth wave occurred in Victorian England, following the publication in 1859 of Darwin's *Origin of Species*. This book was taken as a challenge to the authority of Scripture because there was a clear inconsistency between the Genesis account of creation and the biological account of man's slow emergence from lower forms of life. The battle raged with bitterness for several decades, but died away as the theory of evolution gained more general acceptance.

STATUS OF RATIONALISM

Religious. With increasing freedom of thought and wider acceptance of scientific views, Rationalism in religion has lost its novelty and much of its controversial excitement. To the contemporary mind, it is too obvious to warrant debate that reason and revelation cannot both qualify as sources of ultimate truth for, were they to conflict. truth itself would become self-contradictory. Hence theologians have sought accommodation through new interpretative principles that discern different grades of authenticity within the Scriptures and through new views of religious truth, existential rather than cognitive, that turn from propositional dogmas to the explication of lived human existence. Criticism of supernaturalism, however, is still carried on by such societies as the Rationalist Press Association, in Great Britain, and the Humanist Association, in the United States.

Ethical. Rationalism in ethics has suffered its share of criticism. Regarding its lists of rules—on the keeping of promises, the return of loaned goods, etc.—it has been argued, for example, that if they were specific enough to be useful (as in the rule against lying or stealing), they would tend to have exceptions—which no rule laid down by reason ought to have. On the other hand, if without exceptions, they would often prove to be tautologies: the rule of justice, for example, that we should give everyone his due would then mean only that we should give him what is justly his. After enduring a period of eclipse, however, during which noncognitive theories of ethics (emotive and existential) and relativism had preempted the field, rationalistic views, which agree in holding that moral standards do not depend upon the varying attitudes of persons or peoples, were receiving renewed attention in the mid-20th century. Prominent among these developments has been the "good-reasons" approach taken by the broadly-gauged scholar Stephen Toulmin, by Kurt Baier, and others, which examines the contexts of various moral situations and explores the kinds of justification appropriate for each.

Metaphysical. Typical of the ways of reasoning employed by Rationalists are two approaches taken to the metaphysical doctrine that all things are connected by internal relations: one a logical, the other a causal argument. An internal relation is one that could not be removed without affecting the terms themselves between which the relation holds. The argument runs: Everything is related to everything else at least by the relation "*A is different from* B." But difference is itself an internal relation, since the terms could not remain the same if it were removed. Hence everything is so connected with everything else that it could not be what it is unless they were what they are. The appeal to internal relations played an important part in the philosophies of Hegel, F.H. Bradley, and A.N. Whitehead (1861–1947).

The other line of argument is causal. Every event, it is maintained, is connected with every other, either directly or indirectly. Sir James Jeans argued that if the law of gravitation is valid, a man cannot crook his little finger without affecting the fixed stars. Here the causal relation is direct. It can also be shown that seemingly unrelated events are joined indirectly through their common connection with some remote historical event, by a chain of events leading back, for example, to Columbus' discovery of America. But if this had been different, all of its consequences would presumably have been different; thus an indirect and internal relation proves to have been present.

Many Rationalists have held with Spinoza that the causal relation is really a logical one—that a causal law, if precisely stated, would reveal a connection in which the character of the cause logically necessitates that of its effect; and if this is true, they maintain, the facts and events of the world must thus compose a single rational and intelligible order.

Rationalism and quantum physics

In the 20th century, such Rationalism met with a new and unexpected difficulty presented by quantum physics. According to the indeterminacy principle, formulated in 1927 by the German physicist Werner Heisenberg, it is impossible to discover with precision both the position and the velocity of a moving electron at the same time. This implies that definite causal laws for the behaviour of these particles can never be attained, but only statistical laws governing the behaviour of immense aggregates of them. Causality, and with it the possibility of rational understanding, seemed to be suspended in the subatomic world. Some Interpreters of the new physics, however, notably Max Planck, Albert Einstein, and Bertrand Russell, sustained the hopes of the Rationalists by insisting that what was excluded by the indeterminacy principle was not the fact of causality in this realm, but only the precise knowledge of it.

Indeed, some leaders of 20th-century science took the new developments in physics as on the whole supporting Rationalism. Protons and electrons, they contended, though beyond the reach of the senses, can still be known; and their behaviour, at least in groups, is increasingly found to conform to mathematical law. In 1932, Sir James Jeans, an astrophysicist and popularizer of science, said with a curious echo of Galileo, "the universe appears to have been designed by a pure mathematician."

Challenges to epistemological Rationalism. At first glance the claim of Empiricism that knowledge must come from sense experience seems obvious: how else could one hope to make contact with the world around him? Consequently, Rationalism has been sharply challenged—in the 19th century by the Empiricism of John Stuart Mill (1806–73) and in the 20th by that of the Logical Positivists. Mill argued that all a priori certainties are illusory: why does man believe, for example, that two straight lines cannot enclose a space? Is it because he sees it as logically necessary? No; it is because he has experienced so long and so unbroken a row of instances of it—a new one whenever he sees the corner of a table or the bordering rays of a light beam—that he has formed the habit of thinking in this way and is now unable to break it. A priori propositions, Mill claimed, are merely empirical statements of very high generality.

This theory has now been abandoned by most Empiricists themselves. Its implication that such statements as “2+2 = 4" are only probably true and may have exceptions has proved quite unconvincing. The Rationalist's rejoinder is that one cannot, no matter how hard he tries, conceive 2+2 as making 5; for its equalling 4 is necessary. But a priori knowledge is also universal. Neither of these two characteristics can be accounted for by sense experience. That a crow is black can be perceived, but not that it must be black or that crows will always be black; no run of perceptions, however long, could assure us of such truths. On the other hand, a priori truths can be seen with certainty—that if a figure, for instance, is a plane triangle within a Euclidean space, its angles must and always will equal two right angles.

Perhaps the most formidable challenge to Rationalism has come in the 20th century from such Logical Positivists as the Oxford Empiricist A.J. Ayer *(1910–*) and Rudolf Carnap (1891–1970), who had been a central figure in the Vienna Circle, where this movement first arose. Unlike Mill, they accepted a priori knowledge as certain; but they laid down a new challenge—the denial of its philosophic importance. A priori propositions, they said, are *(1)* linguistic, *(2)* conventional, and (3) analytic: *(1)* They are statements primarily of how one proposes to use words; if he says that "a straight line is the shortest line between two points," this merely reports his definition of "straight" and declares his purpose to use it only of the shortest. *(2)* Being a definition, such a statement expresses a convention to which there are alternatives; it may be defined in terms of the paths of light rays if one chooses. (3) The statement is analytic in that it merely repeats in its predicate a part or the whole of the subject term and hence tells nothing new; it is not a statement about nature but about meanings only. And since Rationalistic systems depend throughout upon statements of this kind, their importance is illusory.

To this clear challenge some leading Rationalists have replied as follows: (1) Positivists have confused real with verbal definition. A verbal definition does indeed state what a word means; but a real definition states what an object is, and the thought of a straight line is the thought of an object, not of words. (2) The Positivists have confused conventions in thought with conventions in language. One is free to vary the language in which a proposition is expressed, but not the proposition itself. Start with the concept of a straight line, and there is no alternative to accepting it as the shortest. (3) Some a priori statements are admittedly analytic, but many are not. In "whatever is coloured is extended," colour and extension are two different concepts of which the first entails the second, but is not identical with it in whole or part. Contemporary Rationalists therefore hold that the a priori has emerged victorious from the Empiricists' efforts to discredit such knowledge and the Positivists' attempts to trivialize it.

BURY, *A History of Freedom of Thought (1913).* SIGMUND *FREUD, Die Zukunft einer Illusion (1927;* Eng. trans., *The Future of an Illusion,* 1928), offers a psychoanalytic study of religious belief.

(B.Bl.)

Ravel, Maurice

One of the most original composers of his time in France. Maurice-Joseph Ravel was an exquisite craftsman, striving always for perfection of form and style, which he judged more valuable and important than an expression of personal feelings. For him, music was a kind of ritual, having its own laws, to be conducted behind high walls, sealed off from the outside world, and impenetrable to unauthorized intruders. When his Russian contemporary Igor Stravinsky compared Ravel to "the most perfect of Swiss watchmakers," he was in fact extolling those qualities of intricacy and precision to which he himself attached so much importance.

Ravel.

Ravel was born at Ciboure, near Saint-Jean-de-Luz, France, on March 7, 1875, of a Swiss father and a Basque mother. His family background was an artistic and cultivated one, and the young Maurice received every encouragement from his father when his talent for music became apparent at an early age. In *1889,* at 14, he entered the Paris Conservatoire, where he remained until *1905.* During this period he composed some of his best known works, including the *Pavune pour une infante défunte* (*Pavane for a Dead Princess),* the *Sonatine* for piano, and the *String Quartet.* All these works, especially the two latter, show the astonishing early perfection of style and craftsmanship that are the hallmarks of Ravel's entire oeuvre. He is one of the rare composers whose early works seem scarcely less mature than those of his maturity. Indeed, his failure at the Conservatoire, after three attempts, to win the coveted Prix de Rome for composition (the works he submitted were judged too "advanced" by ultraconservative members of the jury) caused something of a scandal. Indignant protests were published, and liberal-minded musicians and writers, including the musicologist and novelist Romain Rolland, supported Ravel. As a result, the director of the Conservatoire, Théodore Dubois, was forced to resign, and his place was taken by the composer Gabriel Fauré, with whom Ravel had studied composition.

Maturity of early works

Ravel was in no sense a revolutionary musician. He was for the most part content to work within the established formal and harmonic conventions of his day, still firmly rooted in tonality—*i.e.,* the organization of music around focal tones. Yet, so very personal and individual was his adaptation and manipulation of the traditional musical idiom that it would be true to say he forged for himself a language of his own that bears the stamp of his personality as unmistakably as any work of Bach or Chopin. While his melodies are almost always modal (*i.e.,* based not on the conventional Western diatonic scale but on the old Greek Phrygian and Dorian modes), his harmonies derive their often somewhat acid flavour from his fondness for "added" notes and unresolved appoggiaturas, or notes extraneous to the chord that are allowed to remain harmonically unresolved. He enriched the literature of the piano by a series of masterworks, ranging from the early *Jeux d'eau (Fountains,* completed 1901) and the *Miroirs* of 1905 to the formidable *Gaspard de la nuit* (*Gaspard of the Night,* 1908), *Le Tombcau de Couperin (Couperin: In Memoriam,* 1917), and the two memorable concerti. Both concerti date from 1931, and one was written for the left hand alone. Of his purely orchestral works, the *Rapsodie espagnole* (1907) and *Bolero* (1928) are the best known and reveal his consummate mastery of the art of instrumentation. But perhaps the highlights of his career were his collaboration with the Russian impresario Sergey Diaghilev, for whose Ballets Russes he composed the masterpiece *Daphnis et Chloe* (first performed 1912), and with the French writer Colette, who was the librettist of his best known opera, *L'Enfant et les sortilèges (The Child anti the Enchantments).* The latter work gave Ravel an opportunity of doing ingenious and amusing things with the animals and inanimate objects that come to life in this tale of bewitchment and magic in which a naughty child is involved. His only other operatic venture had been his brilliantly satirical *L'Heure espagnole* (first performed 1911). As a songwriter Ravel achieved great distinction with his imaginative *Histoires naturelles, Trois Poémes de Stéphane Mallarmé,* and *Chansons madécasses (Madagascan Songs).*

Collaborations with Diaghilev and Colette

Ravel's life was in the main uneventful. He never married, and, though he enjoyed the society of a few chosen friends, he lived the life of a semirecluse at his country retreat at Montfort-L'Amaury, in the forest of Rambouillet, near Paris. He served in World War I for a short time as a truck driver at the front, but the strain was too great for his fragile constitution, and he was discharged from the army in 1917.

In 1928 Ravel embarked on a four months' tour of Canada and the United States and in the same year visited England to receive an honorary degree of doctor of music from Oxford. That year also saw the creation of *Bolero* in its original form as a ballet, with Ida Rubinstein in the principal role.

The last five years of Ravel's life were clouded by aphasia, which not only prevented him from writing another note of music but also deprived him of the power of speech and made it impossible for him even to sign his name. Perhaps the real tragedy of his condition was that his musical imagination remained as active as ever. An operation to relieve the obstruction of a blood vessel that supplies the brain was unsuccessful, and the end came on December 28, 1937. Ravel was buried in the cemetery of Levallois, a Paris suburb in which he had lived, in the presence of Stravinsky and other distinguished musicians and composers.

MAJOR WORKS

Stage works

BALLET: *Daphnis et Chloé* (first performed 1912; also two suites for orchestra); *La Valse* (1920); *Bolero* (1928; also arranged for piano and piano four hands).

OPERA: *L'Heure espagnole* (1911); *L'Enfant et les sortilèges* (1925).

Orchestral works

ORCHESTRA ALONE: *Shdhe'razade,* overture (1898); *Pavane pour une infante défunte* (completed 1899); *Rapsodie espagnole* (1907).

SOLO INSTRUMENT AND ORCHESTRA: *Tzigane,* for violin and piano or orchestra (1924); *Piano Concerlo in G Major* (1931); *Piano Concerto in D Major for Left Hand* (1931).

Chamber music

String Quartet (1903); *Introduction et allegro,* for solo harp, string quartet, flute, and clarinet (1905); *Trio for Violin, Cello and Piano* (1914); *Sonata for Violin and Cello* (1922); *Sonata for Violin and Piano* (1927).

PIANO MUSIC: *Jeux d'eau,* for piano solo (1901); *Miroirs* (1905, basis for a later ballet); *Sonatine* (1905); Ma *Mère l'Oye,* piano, four hands (1908, later orchestrated and made into a ballet); *Gaspard de la nuit* (1908); *Le Tombeau de Couperin* (1917, later orchestrated); *Valses, nobles et sentimentales* (1911, later orchestrated and made into a ballet).

Vocal music

SONG CYCLES: *Shéhérazade,* for voice and piano or orchestra (1903); *Histoires naturelles,* for voice and piano (1906); *Trois Poèmes de Stéphane Mallarmé,* for voice, piano, string quartet, two flutes, and two clarinets (1913); *Chansons rnade'casses,* for voice, piano, cello, and flute (1926); *Don Quichotte à Dulcinée,* for voice and piano (1932).

Transcriptions of works by other composers

Mettuet pompeux (1918), from *Dix Pièces pittoresques* (1880) by Emmanuel Chabrier; *Pictures from an Exhibition* (1922), a piano suite with the same title by Modest Mussorgsky.

BIBLIOGRAPHY. An invaluable source of information is the *Catalogue de l'oeuvre de Maurice Ravel,* prepared by the FONDATION MAURICE RAVEL (1954), containing full details of every published and unpublished work and comprehensive bibliography. See also the biographical sketch (in French), dictated by Ravel to Roland-Manuel, and published in *La Revue Musicale* (December 1938), a special issue devoted to Ravel; and H.H. STUCKENSCHMIDT, *Maurice Ravel* (1966; Eng. trans., 1968). A fairiy full bibliography may be found in the full-length study of ROLLO HUGH MYERS, *Ravel: Life and Works* (1960).

(R.My.)

Ravenna

Ravenna is an industrial and agricultural city in northern Italy, on the Po River, about five miles from the Adriatic Sea. It arose on one or more islands near the mouth of the Po, just to the east of a wide band of marshy lowland. The city's location was the cause of its greatness and of the important role it played for 350 years as capital of the Western Roman Empire and later of Ostrogothic and Byzantine Italy. It was a safe base and refuge, immune to attack by land, with access to the sea, and it controlled passage to Rimini, one day's march to the south. During the course of centuries, silt from the river gradually filled in the lagoons to the west and between Ravenna and the sea.

History. The earliest inhabitants of Ravenna were probably Italic peoples who moved southward from Aquileia in about 1400 BC. According to tradition, it was occupied by the Etruscans and later by the Gauls, but information about the city before the time of Caesar is scanty.

Early settlement and growth

The Roman era (to 476 AD). Roman interest in the area centred on maintaining communications with Aquileia, Altino, and Spina. In 132 BC a major highway, the Via Popilia, was built through Ravenna connecting Rimini with these towns. In 89 BC Ravenna was given a special relation to Rome when it was designated a *civitas foederata* (allied community), and in the time of Augustus it became a self-governing Roman community. It was from Ravenna that Julius Caesar, on January 12, 49 BC, launched upon the decisive course that led eventually to his control of Rome.

During the war between Mark Antony and Octavian (later the emperor Augustus), Ravenna was occupied by Antony's supporters, who were thus able to communicate with him by sea. The city's special location caused Augustus to select it as home base of the fleet charged with guarding the eastern Mediterranean; for this use the port of Classis, which was able to accommodate 250 warships, was built about three miles from the city; a canal, the Fossa Augusta, connected it with the Po. All the commercial traffic coming from the East that was destined for northern Italy and the rest of southern Europe passed through this canal.

The growth of population and wealth made Ravenna one of the most important cities of Italy. The emperor Claudius built the first encircling defensive wall, and Trajan built an aqueduct. At the end of the 2nd century, Ravenna became the capital of Flaminia; at the end of the 3rd, of Emilia; and finally, of Flaminia and Picenum Annonarium. In the 5th century AD, as the Roman Empire decayed, Ravenna entered the most important period of its history.

Capital of the Western Roman Empire

In 402 the Western emperor Honorius, seeking a refuge from the invading Goths, took up residence in the city. From then until 476 it remained the imperial capital of the West and as such was embellished with magnificent monuments. With the fall of the Western Empire, it became the capital of Italy under the Ostrogothic kings Odoacer (reigned 476–493) and Theodoric (reigned 493–526). At the same time it became an episcopal see and acquired great prestige under Bishop Peter Chrysologus (died 450).

Under Byzantine rule (540–751). Ravenna played an important role in the Byzantine war to recapture Italy from the Goths; in 540 it was occupied by the Byzantine general Belisarius; when the war ended and the prefecture of Italy was established, Ravenna became capital.

The Byzantine emperor Justinian I (reigned 527–65) had Maximian of Pola named bishop of Ravenna (with the title of ***archiepiscopus),*** and the circumstances of the moment made him in effect the primate of Italy. Maximian dedicated some of the city's major basilicas. The fact that theirs was the church of the Italian capital led the archbishops of Ravenna, in the 7th century, to claim a pre-eminent status; for a time they even obtained autonomy from Rome.

The Byzantine struggle with the Lombards for control of Italy, beginning in 568, went on for practically two centuries; resistance was concentrated at Ravenna, which became the empire's citadel in Italy.

The exarchate of Ravenna. The exarchate (military governorship) of Ravenna was created before 584, and the exarch had the powers of *regnum et principatum Italiae* (kingship and prime authority in Italy); thus Ravenna in the 6th and 7th centuries was the centre of all administrative activity as well as the principal maritime trade centre of Italy. As such, it was a rich, cultivated, and populous city.

Rise of the archbishops of Ravenna

The slackening of control by Byzantium, which was involved in internal and external struggles in the 7th century, allowed the Lombards to gain strength, until the exarch finally had to confine his activity to Ravenna and its vicinity. Many public functions passed to the archbishops and to the popes, who provided for public works and even for the recruiting of armies. Loyalty to the Byzantine government declined when it showed itself incapable of resisting the Lombards. There were recurrent uprisings and, finally, open revolt, and an independent army of the exarchate was created.

Conquest by the Lombards (8th century). In 716 the Lombards under King Liutprand took Classis, and in 727 there was an insurrection against decrees of the Byzantine emperor Leo III banning the use of icons; the exarch was killed, and Liutprand held the city for three years. After the city had been liberated and retaken, Pope Zacharias, in 743, went in person and persuaded Liutprand to give up the city. But in 751 the Lombard king Aistulf captured it, thus ending Byzatine dominion in northern and central Italy. Pope Stephen II called on the aid of Pepin, king of the Franks, who expelled the Lombards in 754.

Domination by the archbishops. Though Ravenna's great historical importance had ended, it continued for some centuries in the role of capital of the former exarchate, now under the dominion of the archbishops. They were strengthened by their alliance with the local aristocracy, by quarrels between emperors and popes and the consequent enfeeblement of the latter, and by the political confusion of the times.

Concessions made by the Ottonian dynasty—which ruled the Holy Roman Empire from 962 to 1024—transformed Ravenna's archbishops into great imperial feudatories, completely independent of papal dominion. Ravenna also became the preferred seat of the later Saxon and Franconian emperors when they came to Italy. The archbishops were among the highest imperial dignitaries, and sided with the empire in its 11th-century struggle with the papacy. In 1080, Henry IV (emperor from 1084) had Archbishop Guiberto of Ravenna elected antipope under the name Clement III.

Decline of Ravenna

Under papal rule (1278–1859). Then began Ravenna's slow decline. The communes, which began to develop in Italy in the 10th or 11th century, dealt the final blow to the temporal power of the archbishops, whose domain finally was reduced to the city of Ravenna itself. After 1278, the city was under papal rule though power was held by the Polentani family. By the late Middle Ages, the city had lost its importance as a port, its trade having gone to the Venetians. In 1441 Venice established direct rule over Ravenna. But in 1509, as a result of the war of the League of Cambrai (against Venice), the city once again became part of the Papal States. In 1512 it suffered fire and devastation following the Battle of Ravenna, in which the city was seized by the French. It was soon recaptured.

Ravenna was doomed to decadence by the silting up of the port and by floods to which the rivers were subject. In the 18th century a new port, Corsini, was built, as was the Canale Candiano, which connected the port with the city. Ravenna's resources were thenceforth agricultural, providing wealth for the principal families, whose prosperity is attested by the handsome palaces of the 17th and 18th centuries.

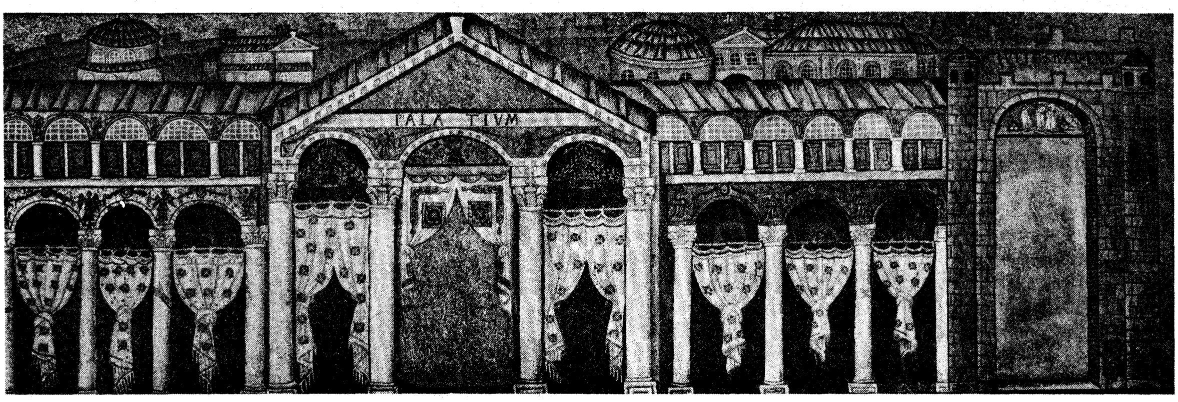
Napoleon occupied Ravenna in 1797. It was returned to the pope in 1815 and, with the exception of brief revolutionary episodes in 1831 and 1848–49, remained under this rule until 1859. In that year the city rebelled and proclaimed its union with the kingdom of Sardinia, which became the kingdom of Italy in 1861.

The modem city

Growth in the 20th century. Ravenna today, though still an agriculture centre, is also a growing industrial and port city. The administrative centre of the province of Ravenna, the city is surrounded by intensely cultivated and productive fields. Its population, 27,500 in 1931, rose in consequence of industrialization to about 60,000 in the 1960s; the size of the built-up area was tripled. In the early 1970s the population was about 133,000. Significant industrialization began about 1950. Principal enterprises include petroleum and natural-gas refining, the production of fertilizers and synthetic rubber, and the processing of oilseeds. Other industries and commercial activities have grown with these; by the 1970s the activity of the port had more than quadrupled. (During 1958–68, tonnage increased from 2,138,000 to 9,879,000.)

Links with the past. ***Modern excavations.*** Since about 1950 there has been extensive research in Ravenna (including the use of aerial photography), on the remains of pre-Roman and Roman times. North of the city the course of the Fossa Augusta was determined; to the southeast a settlement, perhaps the original one, was discovered. In the Classis area the floors and foundations of buildings and some seawalls, probably of the port, were found, but it is not yet possible to determine the plan of the whole.

Monuments. Many of Ravenna's monuments have been destroyed. Those that remain include the church of St. John Evangelist (S. Giovanni Evangelista), built in the 5th century by Galla Placidia, sister of the emperor Honorius, and sometimes mistakenly called her tomb. Older by a few years is the shrine of San Lorenzo, located at the right-hand extremity of the portico of Sta. Croce, attached to the imperial palace and entirely covered with splendid mosaics. Neon (bishop from 451 to 460) is credited with the mosaic decoration of the Catholic baptistery. Also erected in his time was the church of S. Pier Maggiore, now S. Francesco, which retains its original architecture. Another structure with complete mosaic decoration is the oratory of S. Andrea in Arcivescovado, built by Pietro II (archbishop from 494 to 520). The church of Sta. Agata was probably begun in the 5th century and completed some time later. Of Arian monuments there remain the cathedral (now Spirito Santo), almost entirely rebuilt in the 16th century, the adjoining baptistery with mosaic decoration, and S. Apollinare Nuovo, also with mosaic decoration, erected by Theodoric beside the royal palace. Its series of pictures showing the martyrs and the virgins was substituted by Archbishop Agnellus (6th century) for earlier mosaics. The mausoleum of Theodoric culminates in a marvelous cupola made of a single piece of stone from Istria, weighing almost 30 metric tons. The church of S. Vitale, the masterpiece of Byzantine art in



The palace of Theodoric and the rooftops of Ravenna, detail from a 6th-century mosaic in the nave of the church of S. Apollinare Nuovo, Ravenna.
Alinari

Ravenna, was begun by Bishop Ecclesius under the Ostrogothic queen Amalasuntha (died 535), and consecrated in 547; its presbytery is decorated with mosaics including two famous pictures representing Justinian and his wife Theodora. The basilica of S. Apollinare in Classe, begun in 535 and consecrated in 549, has a large mosaic in the vault of the presbytery. From the era of Venetian dominion there remain various palaces and a fortress, the Rocca Brancaleona.

BIBLIOGRAPHY. EDWARD HUTTON, *Ravenna: A Study* (1913), gives the history of the city up to the Renaissance with much information on the Byzantine churches. More recent is G. BOVINI, *The Ancient Monuments* of *Ravenna* (1955) and *Ravenna Mosaics* (1957), illustrated accounts; and A. TORRE, *Ravenna: Sforia di 3000 anni* (1967), a brief synthesis of the fundamental events of the city from its origin to the present day. AGNELLO (AGNELLUS), *Liber Pontificalis Ecclesiae Ravennatis,* ed. by O. HOLDER-EGGER (1878), a 9th-century writer, deals with church events up to 846, mixing history and fable.

Ray, John

John Ray was one of the leading naturalists during the age of scientific revolution in the 17th century. Primarily a botanist but learned throughout the entire range of natural history, he contributed significantly to the progress in taxonomy whereby the apparent chaos of organic nature was reduced to an ordered and intelligible classification. His natural theology, based on his work in natural history, influenced popular religious thought throughout the 18th century.

Ray was born on November 29, 1627, the son of the village blacksmith in Black Notley, a hamlet in Essex, England. He attended the grammar school in nearby Braintree. Ray was fortunate in growing up at a time and place in which a fund had been left in trust to support needy scholars at Cambridge. In 1644 he matriculated at one of the colleges there, Catherines Hall, and moved to Trinity College in 1646. Fortune again was with Ray. He had come to Cambridge at the right time for one with his talents, for he found a circle of friends with whom he pursued anatomical and chemical studies. He also progressed well in the prescribed curriculum, taking his bachelor's degree in 1648 and being elected to a fellowship at Trinity the following year; during the next 13 years he lived quietly in his collegiate cloister.

Ray's string of fortunate circumstances ended with the Restoration. Although never an excited partisan, he was thoroughly Puritan in spirit and refused to take the oath prescribed by the Act of Uniformity. In 1662 he lost his fellowship. Prosperous friends, mostly students he had tutored at Trinity, supported him during the subsequent 43 years while he pursued his career as a naturalist.

That career had already begun with the publication of his first work in 1660, a catalog of plants growing around Cambridge; he had worked on the catalog for nine years, during which he trained himself, without benefit of preceptor, in natural history. After he had exhausted the Cambridge area as a subject for his studies, Ray began to explore the rest of Britain. An expedition in 1662 to Wales and Cornwall with Francis Willughby, when Ray's dismissal from Trinity was imminent, was a turning point in his life. Willughby, of a prosperous Warwickshire family, had been fired by Ray's enthusiasm for natural history while a student at Trinity. They now agreed to undertake a study of the complete natural history of living things with Ray responsible for the plant kingdom and Willughby the animal. Implicit was Willughby's material support of Ray.

Travels for collecting specimens

The first fruit of the agreement, a tour of the Continent lasting from 1663 to 1666, greatly extended Ray's firsthand knowledge of flora and fauna. Back in England, the two friends set to work on their appointed task, with Ray established more or less permanently in Willughby's home, Middleton. In 1670 Ray produced a *Catalogus Plantarum Angliae* ("Catalog of English Plants"). Then in 1672 Willughby suddenly died. Ray took up the completion of their project as a sacred duty owed to him; he was aided by an annuity of £60 left to him by Willughby and by his position as tutor to the Willughby children. In 1676 Ray published F. *Willughbeii . . . Ornithologia* (Eng. trans. *The Ornithology* of *F. Willughby. . . ,* 1678) under Willughby's name even though he had contributed at least as much as Willughby. Ray was already at work on F. *Willughbeii . . . de Historia Piscium* (1685; "History of Fish") when Willughby's mother, his remaining support in the household, died. Willughby's widow, who had never liked Ray or his work, immediately forced him from the house. After he completed the "History of Fish," also with Willughby's name, she refused to aid in its publication. Eventually the Royal Society, of which Ray was a fellow, financed the publication.

Meanwhile, Ray returned to his native village of Black Notley. In 1673 he had married a young governess in the Willughby household, Margaret Oakley, and after 11 childless years, they produced four daughters. The girls collected caterpillars and butterflies, which they brought to their father to identify and classify. Among the younger generation of scientists, Ray formed a new circle of friends. From the cottage in which he lived, perhaps not in poverty but certainly not in plenty, Ray, now more than 60 years old, far removed from an adequate library, and tormented by sores on his legs and recurrent diarrhea, poured out an incredible volume of scientific work.

Important publications

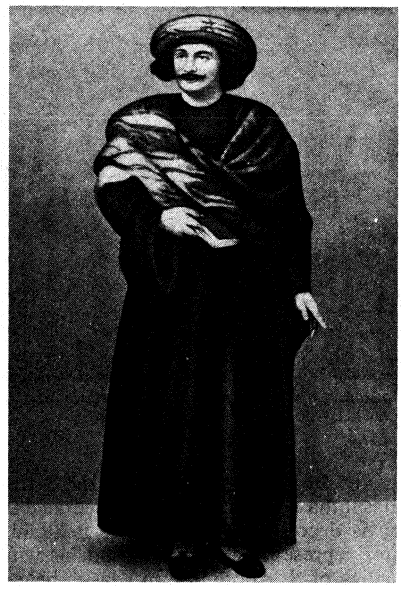
Ray had never interrupted his research in botany. In 1682 he had published a *Methodus Plantarum Nova* (revised in 1703 as the *Methodus Plantarum Emendata . . .*), his contribution to classification, which insisted on the taxonomic importance of the distinction between monocotyledons and dicotyledons, plants whose seeds germinate with one leaf and those with two, respectively. Ray's enduring legacy to botany was the establishment of species as the ultimate unit of taxonomy. On the basis of the *Methodus,* he constructed his master work, the *Historia Plantarum,* three huge volumes that appeared between 1686 and 1704. After the first two volumes, he was urged to compose a complete system of nature. To this end he compiled brief synopses of British and European plants, a *Synopsis Methodica Aviunt et Piscium* (published posthumously, 1713; "Synopsis of Birds and Fish"), and a *Synopsis rnethodica Animalium Quadrupedum et Serpentini Generis* (1693; "Synopsis of Quadrupeds"). Much of his final decade was spent on a pioneering investigation of insects, published posthumously as *Historia Insectorum.* In all this work, Ray contributed to the ordering of taxonomy. Instead of a single feature, he attempted to base his systems of classification on all the structural characteristics, Including internal anatomy. By insisting on the importance of lungs and cardiac structure, he effectively established the class of mammals, and he divided insects according to the presence or absence of metamorphoses. Although a truly natural system of taxonomy could not be realized before the age of Darwin, Ray's system approached that goal more than the frankly artificial systems of his contemporaries. He was one of the great predecessors who made possible Linnaeus' contributions in the following century. Nor was this the sum of his work. Ray had always asserted that "Divinity is my profession," and in the 1690s he also published three volumes on religion. *The Wisdom of God Manifested in the Works of the Creation* (1691), an essay in natural religion that called on the full range of his biological learning, was his most popular and influential book. It argued that the correlation of form and function in organic nature demonstrates the necessity of an omniscient creator. This argument from design, common to all the leading scientists of the 17th century, implied a static view of nature that impeded the development of evolutionary ideas even throughout the 19th century. Still working on his *Historia Insectorum*, John Ray died at Black Notley on January 17, 1705, at the age of 77.

Jahrhundert bis 1860* (1864; Eng. trans., *History of Botany, 1530–1860,* 1890); and for the intellectual background to his thought, see R.S. WESTFALL, *Science and Religion in Seventeenth-Century England* (1958); and JOHN GREENE, *The Death of Adam* (1959).

(R.S.W.)

Ray, Rammohan

Rammohan Ray, who is sometimes called the father of modern India, founded a movement for a renaissance of Hindu culture in 19th-century Bengal. He challenged traditional culture by organizing religious dissenters and championing educational, social, and political reforms.



Rarnmohan Ray.

By Courtesy of the Nehru Memorial Museum and Library. New Delhi

He was born on May 22, 1772, in the village of Rādhānagar, Hooghly district, in British-ruled Bengal. His family, which was prosperous and of the Brahmin caste, was in the service of a prominent landholder. His father, Ramkanta Ray, claimed descent from Narottama Thakur, a follower of the 16th-century Bengali Vaiṣṇava (cult of Viṣṇu) reformer, Caitanya. His maternal forebears were the Bhattacharyas of Chatra, chief priests of the Śākta sect (mother-goddess cult), with whom Vaiṣṇavas, historically, had few dealings.

Little is known of his early life and education, but his home life was marked by active religious conflict. He seems to have developed unorthodox ideas at an early age; after the death of his father, his mother unsuccessfully attempted to disinherit him on grounds of apostasy.

Alienated from his family, Rammohan supported himself by moneylending, managing his small estates, and speculating in British East India Company bonds. In 1805 he was employed by John Digby, a lower company official. Through Digby he was introduced to Western culture and literature. For the next ten years Rammohan drifted in and out of British East India Company service as Digby's assistant.

Revival of Vedanta doctrines

Rammohan continued his religious studies throughout this period. In 1803 he had composed a tract denouncing religious divisions and superstition and advocating "natural religion" in which reason guides to ". . . the Absolute Originator who is the first principle of all religions." By 1815 his spiritual roots were more clearly discernible, when he composed a brief summary of the *Vedānta-sūtras* (an ancient Sanskrit religious treatise), in Bengali and Hindi, entitled *Vedāntagrantha.* In the same year he published vernacular and English translations of his abridgment of an unknown compendium of Vedanta doctrines, the *Vedāntasāra.* There followed Bengali and Hindi translations of the *Kena* and *Īśa Upaniṣads* (1816), the *Kaṭha* and *Māṇḍūkya Upaniṣads* (1817), and the *Mundaka Upaniṣad* (1819). The central theme of these texts, for Ray, was the worship of the Supreme God, beyond human knowledge, who supports the universe. These publications established Rammohan, in the eyes of contemporaries, both as a modern exponent of the Vedānta school of Hindu philosophy and as a scriptural nonconformist. He rejected the label of reformer. By translating the sacred Sanskrit *Upaniṣads* into modern Bengali, Rammohan violated a long-standing tradition. In appreciation of these translations, however, the French Société Asiatique, in 1824, elected him to an honorary membership.

In 1815 Rammohan founded the short-lived Atmiya Sabha (Friendly Society) to unite his growing following.

These activities attracted the attention of Baptist missionaries, with whom he began work on a new Bengali translation of the New Testament. This lasted long enough for a dispute to arise over the divinity of Christ. For Rammohan the issue was the same as with his Hindu critics: the unity of the godhead. Yet he published, in 1820, the ethical teachings of Christ, excerpted from the four Gospels, under the title *Precepts* of *Jesus, the Guide to Peace and Happiness.* A vigorous debate with missionaries followed, centring upon the authority of the Bible and the doctrine of the Trinity. Ray closely argued the Unitarian anti-trinitarian position, publicly challenging Christian spiritual supremacy.

Shift to social and political action

In 1823, when the British imposed censorship upon the Calcutta press, Rammohan, as founder and editor of two weekly newspapers, organized a protest, arguing in the spirit of the American and French revolutions, in favour of freedom of speech and religion as natural rights. This protest marked a turning point in Ray's life, away from preoccupation with religious polemic toward social and political action. In 1822 he founded the Anglo-Hindu School and foui years later the Vedanta College. When the Rengal government had proposed a more traditional Sanskrit college, in 1823, Rammohan protested that classical Indian literature would not prepare the youth of Bengal for the demands of modern life. He proposed, instead, a modern, Western curriculum of study. Rammohan, furthermore, led a protest against the outmoded British legal and revenue administration, advocating the separation of the legal and revenue functions, and the adoption of the *pañcāyat* system, the Indian jury-trial system.

Rammohan Ray's opposition to *sati* (ritual death of widows upon the funeral pyres of their husbands) placed him in the centre of the biggest public controversy of his generation. In 1818 he had issued his first pamphlet denouncing the rite from sacred literature. He followed in 1820 with another, arguing from Hindu law. Two years later he published *Brief Remarks Regarding Modern Encroachments on the Ancient Rights of Females According to the Hindu Law of Inheritance.* His newspaper *Sambad Kaurnudi* joined in the already growing public outcry against *sati.* Rammohan's actual influence on the passage of the 1829 act prohibiting *sati* is not clear, though there were many who afterward remarked upon his role in the debate. It has been widely accepted that he had the effect of emboldening the government to act decisively, though he himself favoured caution in governmental interference in public religious life.

In August 1828 he formed the Brahmo Samaj (Society of Brahmā). The deed of the first Sarnaj building declared its purpose to be

> . . . a place of public meeting of all sorts and descriptions of people, without distinction, as shall behave and conduct themselves in an orderly, sober, religious and devout manner: for the worship and adoration of the Eternal, Unsearchable and Immutable Being, who is the Author and Preserver of the Universe. . . .

The Brahmo Samaj was to play an important part, later in the century, as a Hindu movement of reform.

Mission to Europe

The following year, Ray journeyed to England, as the unofficial representative of the titular King of Delhi, to petition the East India Company for an increase in the royal pension. The King granted him the title "Raja," though it was unrecognized by the British. Ray's personal objectives for the visit were to lobby for reforms in Indian government and to support the abolition of *sati.* He was received with adulation, especially by English Unitarians and by King William IV. During the summer of 1833 he travelled to Paris, where he was received by King Louis-Philippe. But his health had declined in Europe, and, on September 27, 1833, he died in the care of Unitarian friends at Bristol, England.

Rammohan Ray's importance in modern Indian history rests upon the facts that he revived interest in the ethical principles of the Vedānta school as a counterpoise to the Western assault on Indian culture and contributed to the popularization of the Bengali language, while at the same time he was the first Indian to apply to the Indian environment the fundamental social and political ideas from the American and French revolutions.

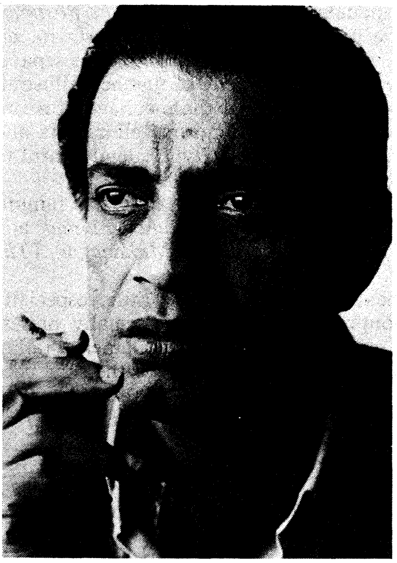
BIBLIOGRAPHY. SOPHIA DOBSON COLLET, *The Life and Letters of Raja Rammohun Roy,* ed. by D.K. BISWAS and P.C. GANGULI, 3rd ed. (1962), is the best known, most comprehensive study of the life of Rammohan Ray, although it contains some inaccuracies. KALIDAS NAG and DEBAJYOTI BURMAN (eds.), *The English Works of Raja Rammohun Roy* (1945), is the most up-to-date edition of Ray's English writings. RAMAPRASADA CHANDA and JATINDRA MAJUMDAR (eds.), *Selections from Official Letters and Documents Relating to the Life of Raja Rammohun Roy* (1938); and JATINDRA MAJUMDAR (ed.), *Raja Rammohun Roy and Progressive Movements in India* (1941), shed light on details of Ray's life from letters, legal documents, and contemporary newspapers. As a critical estimate of Ray's life and writings, SUSHIL KUMAR DE, *Bengali Literature in the Nineteenth Century, 1757–1857,* 2nd ed. rev., pt. 2, ch. 3 (1962), is abbreviated but free of the eulogistic tone that characterizes much of the literature on Ray.

(B.C.R.)

Ray, Satyajit

Of all the film directors of India—which is one of the leading nations of the world in motion-picture production—the most famous is the Bengali Satyajit Ray, who developed entirely apart from the industry as an independent. His first film, *Pather Panchali* (1955), won the attention of audiences throughout the world to his subtle and sensitive work, and his subsequent efforts have confirmed the initial evaluation of him as one of the most important contemporary directors. His inspiration has much in common with the thought and lyricism of the Bengali poet Rabindranath Tagore.

Camera Press—Publix



Satyajit Ray.

Tagore's influence on Ray

Ray was born May 2, 1922, at Calcutta, into a family of artists—his grandfather was a well-known painter, and his father, who died in 1923, was the author of works that are now Bengali classics. The future director completed his secondary schooling at Presidency College in Calcutta. He was then destined for scientific research, but through the influence of Tagore, a family friend, he turned to artistic studies. He took courses given by the poet at Visva-Bharati in Santiniketan.

After Tagore's death in 1941, Satyajit Ray returned to Calcutta. Hoping to make a career in illustrating, he joined a publicity firm and soon became artistic director. In 1945, while illustrating the works of the Bengali writer Bibhuti Bhnsan Bandyopadhyay, the idea of becoming a film maker occurred to him. His interest was heightened by his contact with the great French director Jean Renoir, who made his film *The River* (1951) in India. But Ray's plans to adapt Bandyopadhyay's work to the screen met with many obstacles. Producers hesitated to entrust so much responsibility to a beginner, especially as Ray wanted to employ nonprofessionals and to show the life and customs of the Bengali peasants without anecdotes of the sort that were common in Indian films. Seven years later, in 1952, thanks to the help of friends, he succeeded in raising the capital to start the film. Except for the camera operator, Subrata Mitra, none of the people who plunged into this adventure had ever worked in films. At the end of three months their small capital was exhausted. But after long talks, the West Bengal government agreed to provide the needed finances for the first film of the anticipated trilogy.

The film, *Pather Panchali,* was completed in 1955 and was a great success. Acclaiming its significance, the Asian public was enthusiastic, and the next year it won a prize at the highly prestigious film festival at Cannes, France. This success assured the completion of the other two films of the trilogy: *Aparajito,* which earned the "Golden Lion" award of the 1957 Venice Film Festival, and *Apu Sansar,* made in 1959. In these films, Ray, in the style of an Oriental Dickens, relates the story of a Bengali child, Apu, from youth to maturity. The slow rhythm of the narrative creates a timeless poetic climate, halfway between dream and reality.

Between *Aparajito* and *Apu Sansar,* Ray produced two films of an entirely different sort: *Paras Pathar,* a satirical film adapted from a novel by Parasuram, and *Jalsaghar* (1958; *The Music Room),* an amusing comedy of manners.

As soon as the Apu trilogy was completed he undertook a long documentary illustrating the life and work of Tagore, which was released in 1960. To celebrate the centennial of the poet's birth, in 1961, he brought to the screen three of Tagore's novels grouped under the title of *Teen Kanya* ("Three Girls"). Its Western version (called *Two Daughters)* includes only two stories: *The Postmaster,* which tells the adventures of a village postman, his love affair with a young orphan, and their final separation; and *The Conclusion,* a comedy of manners illustrating the disastrous consequences of the marriage of a student to an eccentric girl. The humorous characters and the portrayal of small details of daily life lend charm to these minor sketches.

Devi (The Goddess), his best film after the famous trilogy, was followed in 1962 by *Kanchenjunga* and *Abhijan (The Country).* He made *Mahanagar (The Big City)* in 1963.

Ray's style

Ray usually rehearses his actors very little, especially when they are nonprofessionals, and he usually prefers the first film of a scene, because of its spontaneity, rather than a "retake." In response to criticisms of the slow pace of his work, he has defended its rhythm as a reflection of the style of the life he is trying to interpret. He has cited as the greatest influences on his work the documentaries *Nanook of the North* (1920–21) and *Louisiana Story* (1948) by the American Robert Flaherty, and *Earth* (1930), set on a collective farm, by the Soviet director Alexander Dovzhenko.

MAJOR WORKS

Pather Panchali (1955; On the Road); Aparajito (1956; The Unvanquished); Jalsaghar (1958; The Music Room); Paras Pathar (1958; The Philosopher's Stone); Apu Sansar (1959; The World of Apu); Devi (1960; The Goddess); Rabindranath Tagore (1960); Teen Kanya (1961; Two Daughters); Kanchenjunga (1962); Abhijan (1962; The Country); Mahanagar (1963; The Big City); Charulata (1963); Kapurush-o-Mahapurush (1965; The Coward and the Saint); Nayak (1966; The Hero); Goopy Gyne, Bagha Byne (1969; The Adventures of Goopy and Bagha); Days and Nights in the Forest (1970).

BIBLIOGRAPHY. MARIE SETON, *Portrait of a Director: Satyajit Ray* (1971), is a detailed biographical and critical study, profusely illustrated and including an appendix of Ray's own writings.

(Je.M.)

Rayleigh, John William Strutt, Lord

Lord Rayleigh, last of the great British classical physicists, made notable contributions to every branch of physical science known in his day. His profound insight and enormous capacity for detailed work enabled him to solve many problems previously considered intractable as well as to suggest new lines of research that materially furthered 20th-century science and technology. His sound judgment and diplomatic manner made him an unusually valuable coordinator in British academic and governmental scientific circles.

Rayleigh, engraving by R. Cottot (20th century).

Rayleigh was born John William Strutt at Terling Place, Witham, in the county of Essex, England, on November 12, 1842. Poor health throughout his childhood and youth frequently interrupted his education, and it was necessary for him to be withdrawn from both Eton and Harrow. In 1857 he began four years of private study under a tutor. In 1861 Strutt entered Trinity College, Cambridge, from which he was graduated with a B.A. as Senior Wrangler (highest honour) in the Mathematical Tripos in 1865, a distinction that foreshadowed his future success. He early developed an absorbing interest in both the experimental and mathematical sides of physical science, and in 1868 he purchased an outfit of scientific apparatus for independent research. In his first paper, published in 1869, he gave a lucid exposition of some aspects of the electromagnetic theory of James Clerk Maxwell, the physicist, in terms of analogies that the average man would understand.

The Theory of Sound

An attack of rheumatic fever shortly after his marriage in 1871 threatened his life for a time. A recuperative trip to Egypt was suggested, and Strutt took his bride, Evelyn Balfour, the sister of Arthur James Balfour, the well-known politician and statesman, on a houseboat journey up the Nile for an extended winter holiday. On this excursion he began work on his great book, *The Theory of Sound,* in which he examined questions of vibrations and the resonance of elastic solids and gases. The first volume appeared in 1877, followed by a second in 1878, concentrating on acoustical propagation in material media. After some revision during his lifetime and successive reprintings after his death, the work has remained the foremost monument of acoustical literature.

Shortly after returning to England he succeeded to the title of Baron Rayleigh in 1873, on the death of his father. Rayleigh then took up residence at Terling Place, where he built a laboratory adjacent to the manor house. His early papers deal with such subjects as electromagnetism, colour, acoustics, and diffraction gratings. Perhaps his most significant early work was his theory explaining the blue colour of the sky as the result of scattering of sunlight by small particles in the atmosphere. The Rayleigh scattering law, which evolved from this theory, has since become,classic in the study of all kinds of wave propagation.

Rayleigh's one excursion into academic life came in the period 1879–84, when he agreed to serve as the second Cavendish professor of experimental physics at Cambridge University, in succession to James Clerk Maxwell, the distinguished Scottish physicist. Rayleigh took his university duties very seriously both with respect to the instruction of students and to the carrying out of a vigorous research program on the precision determination of electiical standards. A classical series of papers, published by the Royal Society, resulted from this ambitious work. After a tenure of five years he returned to his laboratory at Terling Place, where he carried out practically all of his scientific investigations.

A few months after resigning from Cambridge, Rayleigh became secretary of the Royal Society, an administrative post that, during the next 11 years, allowed considerable freedom for research.

Discovery of argon

Rayleigh's greatest single contribution to science is generally considered to have been his discovery and isolation of argon, one of the rare gases of the atmosphere. Precision measurements of the density of gases conducted by him in the 1880s led to the interesting discovery that the density of nitrogen obtained from the atmosphere is greater by a small though definite amount than is the density of nitiogen obtained from one of its chemical compounds, such as ammonia. Excited by this anomaly and stimulated by some earlier observations of the ingenious but eccentric 18th-century scientist Henry Cavendish on the oxidation of atmospheric nitrogen, Rayleigh decided to explore the possibility that the discrepancy he had discovered resulted from the presence in the atmosphere of a hitherto undetected constituent. After a long and arduous experimental program, he finally succeeded in 1895 in isolating the gas, which was appropriately named argon, from the Greek word meaning "inactive." Rayleigh shared the priority of the discovery with the chemist William Ramsay, who also isolated the new gas, though he began his work after Rayleigh's publication of the original density discrepancy. In 1904 Rayleigh was awarded the Nobel Prize for Physics for his role in the discovery of argon; Ramsay received the award in chemistry for his work on argon and other inert elements. The next year Rayleigh was elected president of the Royal Society.

A decided catholicity of taste characterized Rayleigh's choices in research. It was not his habit to devote his exclusive attention to one problem over a long interval but to divert it frequently to a wide variety of topics, such as optics, acoustics, electricity, or fluid mechanics. He preferred to work on several research projects at once, but he was by no means erratic; his work was consistently of high quality throughout his career, both in the brilliance and thoroughness of experimental execution and in the lucidity and precision of his writings. He not only expanded and consolidated existing knowledge in important branches of the physical sciences, but he also opened up important new research frontiers, especially in acoustics and fluid dynamics.

In his later years, when he was the foremost leader in British physics, Rayleigh gave freely of his time and helpful counsel by serving in influential advisory capacities in education and government. In 1908 he accepted the post of chancellor of Cambridge University, retaining this position until his death. He was also associated with the National Physical Laboratory and government committees on aviation and the treasury.

Retaining his mental powers until the end, he worked on scientific papers until five days before his death, on June 30, 1919, at Terling Place.

BIBLIOGRAPHY. ROBERT JOHN STRUTT (4th Baron Rayleigh), ***Life of John William Strutt, Third Baron Rayleigh*** (1924), augmented ed. (1968); R. BRUCE LINDSAY, ***Lord Rayleigh: The Man and His Work*** (1970), contains a complete bibliography of Rayleigh's writings and includes excerpts from his 450 scientific articles.

(R.B.L.)

Realism

Understood in its broadest philosophical sense, Realism connotes any viewpoint that accords to the objects of man's knowledge an existence that is independent of whether he is perceiving or thinking about them. Though it may seem strange to the unphilosophical layman that the independent existence of objects "out there" should be questioned, the philosopher, faced with the many profound challenges that Idealists have posed against the independence of objects, knows that the problem is far from trivial.

The Idealist challenge

Clearly, Idealists have argued, musical tones such as middle C do not have existence as tones in the air; they appear, instead, to be qualities that the mind itself generates when the zppropriate hair cells in the organ of Corti are stimulated. Nor does the colour purple have existence as a quality in the world outside of the mind; there can be, in fact, no such thing as a beam of pure (monochromatic) purple light inasmuch as purple is a unique kind of colour that is perceived when vibrations at the opposite extremes of the visual spectrum (red and violet) are mixed together in the same beam. At least in this one case, the colour seems created by the mind. But if this is so of purple, the Idealists ask, is it not true, also, of all colours? Similarly, under certain circumstances heat is felt as cold and rotation as oscillation. It is not surprising, therefore, that philosphers have asked what, if any, residual properties an object might have in and of itself after due allowance has been made for those qualities that the mind and perspective of the observer have imposed upon it; nor is it surprising that they have asked what, if anything, it would mean to insist on the objective existence of an object of which all of the qualities were mental. Realists, on the other hand have held that, in spite of the foregoing considerations as proposed by the Idealists, there still remains a sense in which objects can have an existence that is independent of minds.

Realism exists, however, in several strikingly different versions: its objects may be, for example, either individual things (such as "the Moon"), or merely particular qualities of things (such as "roundness," "yellowness"), or species and genera of things (such as "moons," "planetary bodies"). In one way or another, however, whether from the viewpoint of the things themselves or from that of the human activities related to them, Realism tends to stress some definite function of the independent existence of objects.

NATURE AND SCOPE OF REALISM

Realism and the problem of knowledge. One of the major problems confronting Realism involves the distinction between private, public, and so-called ontological objects. A private object is a sheer datum (such as a perceived patch of yellow) taken purely as an uninterpreted item in the knower's own inner experience; a public object is one that the mind has projected into an objective conceptual frame of space and time shared in common with other minds, an object that the mind has constituted as a percept (such as the perceived Moon)—though it is still acknowledged to be in part mental (*e.g.*, its yellowness; or its visual size, which is larger when it is near the horizon); and an ontological object is the Kantian "thing-in-itself" (the Moon as it really is), which may as well consist of monads, of God's thoughts, of will, or of action, as of force and matter. Though Realists and Idealists both acknowledge that the knower transcends the private object, they make different assumptions about the relationship between the public and the ontological object: on the one hand, the Realist holds that the physical sphericity, yellowness, and hardness perceived (or perceivable) in the public object are in some degree actual properties of the ontological thing-in-itself; the Idealist, on the other hand, holds that the public object is merely a phenomenon, from which little can be inferred about the underlying *onta* (realities), least of all of their basic qualities, which are probably quite different from the roundness and hardness of the perceived object. The Idealist may, in fact, surmise that the nature of the *onta* is conveyed more faithfully in the fundamental mental tone of the public object—in the colours, feelings, and durations (which are of the nature of mind)—than in its specific material properties. (A third contender, the metaphysical solipsist, would hold that the ontological object does not exist at all.)

Private, public, and ontological objects

Similarly, if a particular thing regarded in its particularity (such as the Moon) is distinguished from a universal—

i.e., an entity comprising the essence of the thing (moonness)—that which it shares with all the other things of the same species or genus (as with the moons of Jupiter)—then a form of Realism can be defined as asserting the independent reality of universals, which it may even exalt above that of particulars.

Contrast with other views

Accordingly, Realism may be variously opposed to the tenets of other philosophical positions. As opposed to Nominalism, which denies that essences (or the specific and generic natures of things) have any reality at all (except as names), and conceptualism, which grants such universals reality only as concepts within the mind, Realism allows to the specific or generic nature of the thing a distinct existence in reality outside the mind. Against Idealism (see above), it asserts that the existence of sense objects (such as the perceived Moon) and that of their qualities is external to thought. In opposition to phenomenalism and sensationalism, which regard objects as comprising mere private volleys or families of disconnected sense fragments, Realism grounds objects in real unified and enduring substances. Unlike conventionalism, a philosophy of science that regards scientific laws and theories as freely chosen constructs devised by the scientist in order to describe reality, Realism holds that laws and theories have determined and real counterparts in things.

The term Realism first aaaeared earlv in the 19th century, though the adjective Realist dates from the late 16th century. These terms have been applied, however—often retroactively—to various systems that have arisen throughout history.

In its broadest scope, the term Realism has application in a number of distinct areas. In literature, art, and aesthetics (see ART, PHILOSOPHY OF; AESTHETICS), in law (see LAW [WESTERN], PHILOSOPHY OF), and in philosophy, it emphasizes real existence or relation to it. The present article is concerned solely with Realism in the philosophical area.

Philosophical senses of Realism. Even within philosophy Realism has a wide range of applications. Though a definitely modern term, Realism is freely used today for tenets of the Greek and medieval epochs, as well as for the modern period.

Basic kinds of Realism. Among philosophical Realisms, two fundamentally different kinds can be distinguished: the Realism of natures and the Realism of things. In the Realism of natures, that which is viewed as having an existence external to the mind is an entity that, in some sense, is set apart in the world of things—an entity that is variously understood as the Form or Idea in which a thing participates, such as "manness" or "bedness" (Platonic Realism), as the essence or *to ti ēn einai*, "the 'what it is' of a thing" (Aristotelian Realism), or as its nature, either absolute, specific, or generic (medieval Realism or the Realism of universals), or, finally, as laws or theoretical models abstracted from scientific observations (see SCIENCE, PHILOSOPHY OF: III. *Deeper issues and broader involvements of science: Status of scientific propositions and concepts or entities).* In the Realism of things, on the other hand, that which is viewed as having an existence external to the mind is the total, concrete, and individual object of experience, which the Realist regards as retaining its chief properties even when left unseen. This Realism, too, can be variously conceived: the externality of the world, for example, can be regarded as simply and obviously given (commonsense Realism); the object itself, though external, can be viewed as the sole entity standing before the mind and grasped by it (neo-Realism); or the object can be conceived as, in some sense, duplicated, so that the mind directly encounters only a counterpart of the external object and not the object itself (critical Realism), a counterpart which was sometimes regarded as a representation of it (representational Realism).

Realism of natures

Distinctions among the Realisms. As previously noted, the term Realism has been applied retroactively to the transcendence of the Platonic Forms or Ideas, to the extent that for Plato the natures of things have, in the ideas of them, an existence more real than that of sensible, individual things (see METAPHYSICS). Yet from its emphasis on ideal as opposed to concrete existence, this Platonic doctrine would be classed as an Idealism instead of a Realism. In the parallel issue in Aristotelianism, the stand that the universals, or specific and generic natures, exist only in the mind but are nonetheless grounded in the real forms of things has been called a moderate Realism. Aristotle himself, however, vigorously denied that the universals have any substantiality *(Metaphysics,* Z: 13–14; 1038^b8–1039^b19), which clearly suggests that, for him, the universals have no existence independently of cognition; this tends, in this first context, to invalidate the designation Realism for the Aristotelian doctrine.

Correspondingly, Realism is used to describe medieval views that allowed species and genera some kind of distinct existence outside the mind. There it meant that not only individual men and individual animals and so on exist outside cognition but also that the specific nature of man and the generic nature of animal and the like have an existence of their own in the outside world. For Realism, objects "fall into" such categories as humanness, mountainness, etc., *naturally.* For its opponents, however, this is not always the case: thus, in terms of a modern illustration, graniteness—that which all the granite rocks share in common—does not exist except as an artificial category set up by the mind (conceptualism) because it merges by imperceptible gradations into diorite or felsite as its mineral composition and texture gradually change.

Yet in actual fact the various medieval doctrines do not fit neatly under these divisions. In the philosophies of several medieval Scholastics, for instance, both the particular thing and the universal are distinguished in one way or another from a third entity, the specific or generic nature *taken absolutely* in itself. This so-called absolute nature is given a "being of its own" by the influential Persian Avicenna, an early-11th-century philosopher and physician; and—in the 13th century—by Henry of Ghent, an eclectic Christian Scholastic, and by the voluntarist Duns Scotus, the greatest medieval British Scholastic, who gave the absolute nature a reality that was distinct in form from the individual thing, but unitively contained in it. Thomas Aquinas gave it no being at all. Though these views reflect radically different metaphysical settings, they all variously bar the natures from real existence when separated in any way from the individual.

In its conventional applications to Greek and medieval thought, accordingly, Realism turns out to be an elusive and even confusing notion. It seems to be an inept way of emphasizing difficulties that are significantly present in the philosophies of these epochs, which require understanding and solution. But the granting of extramental existence to the generic and specific natures has raised more difficulties than it has solved.

Realism of things

All of these ancient and medieval doctrines—whether Realistic, conceptualistic, or nominalistic—accept the external existence of individual sensible things. From this viewpoint, they would all be Realisms in the second main sense of the term, that of the Realism of ordinary things, which is the sense in which Realism is predominantly employed in the modern era. Here it means the epistemological (or theory-of-knowledge) view that things taken as individual wholes exist outside cognition.

HISTORY OF WESTERN REALISM

In these and other related ways, modern writers have seen the philosophic attitude called Realism continually surfacing in the stream of Western thought, suggesting that it is a perennial feature (see PHILOSOPHY, HISTORY OF WESTERN).

Ancient Realism. In pre-Socratic thought, even in Parmenides (late 6th century), known for reducing reality to the One, the relevant reality of the objects of cognition was everywhere assumed. In Plato (5th and 4th centuries BC), the separate and more excellent existence of the natures, or Forms, was strongly asserted at times, though quite often the immanence of the form in individuals was just as surely implied without any satisfactory reconciliation of the contradiction. With Philo of Alexandria, a

Scholastics, Cartesians, and Platonists

Hellenistic Jewish philosopher in the 1st century AD, the existence of the Platonic Forms was located within the mind of God, a view also found in the early 5th century in Augustine of Hippo (*De diversis quaestionibus*, "On Diverse Questions"). In the medieval Augustinian tradition, for instance in Anselm of Canterbury, the influence of this interpretation persisted. In the early 6th century, on the other hand. Boethius, perhaps the intellectual founder of the Middle Ages, in transmitting Aristotelian logic to the West, presented the universal notions with a strong cast of Platonic Realism, while acknowledging that the Aristotelian view was different. Among medieval thinkers in the early 12th century, such as William of Champeaux, the Parisian logician and theologian, the Platonizing tradition of Boethius was dominant, though it was brought under fire by such men as Roscelin, founder of nominalism, who saw universals as mere words. With the stormy controversialist Peter Abelard, foremost dialectician of his time, the Boethian Realism was attacked. But more than mere words were required to justify universality; in his view, universals were concepts signifying real things and had their ultimate basis in the divine ideas, as in the Augustinian tradition.

Moderate Realism

Medieval Realism. The approach of the early medieval thinkers to the problem of universals was made from the side of logic. But it soon involved theological issues, which, when added to the much deeper study of its metaphysical backgrounds made by Boethius, led the scholars to place the relevant questions in a different setting. The natures or common essences of things came to be scrutinized from a threefold viewpoint: as existent in sensible things, as existent in the mind, and as absolutely existent in themselves. This subjected the problem to metaphysical investigation. In that setting, Aquinas allowed neither being nor unity to be attributed to the nature taken absolutely. Duns Scotus, however, accorded it a lesser unity than that of the individual and gave it a kind of being proportionate to this real specific unity, but which required unitive containment of the nature by the individual. In these different ways the nature, so taken, provided the ground for the universal that existed only in the mind. Views incorporating this feature have been called moderate Realisms, though the designation is open to the same objection as it is in its application to Aristotle (see above, *Distinctions among tlze Realisnzs).* In later Scholastic tradition the currents became badly confused, and unending controversy raged on the various kinds of universals and the respective status of each type.

Modern Realism. In the familiar formula *cogito ergo sum* ("I think; therefore, I am") proffered by the first notable modern philosopher, René Descartes, methodical thinking was rooted in thought itself, thus raising the problem of how any material world outside of thought could be reached philosophically. In Descartes and a half century later in the British Empiricist John Locke, an external origin for sensations was accepted, though without any thoroughly philosophical justification. Rather, the denial of an external world was regarded as too absurd to be countenanced. In this perspective Locke's philosophy displayed a commonsense Realism. According to one of Locke's contemporaries, the Cartesian Nicolas Malebranche (known for his claim that God's will is the true cause of motion), religious faith guaranteed the external world. The Cambridge Platonists, a sober group of 17th-century moral and religious Rationalists, in a similar atmosphere of faith and with a Cartesian understanding of sensation, acquiesced in the external existence of sensible things while, against a Neoplatonic background, they accorded a respectively greater reality to the objects of intellectual cognition. For Berkeley, an early 18th-century Empiricist and Idealist, the scriptural guarantee was lacking because matter was nowhere mentioned in the revealed descriptions of the sensible universe; accordingly, in his view, no sensible world outside cognition was left. But in David Hume, who marked the climax of the Empiricist movement, even the cognitive subject, or soul. vanished.

Views based on common sense

Facing the impossibility of a genuine philosophical justification for arguing to an external world from the starting point of mind or idea, Claude Buffier, an early-18th-century French Jesuit, and shortly later, the Scottish Realists, leaned explicitly on common sense as the motive for accepting the world's external existence. Most prominent in this school was Thomas Reid, an opponent of paradox and skepticism. And John Witherspoon, who was called from Scotland to the presidency of Princeton University, held that "the impression itself implies and supposes something external that communicates it, and cannot be separated from that supposition." Consequently, the attempt of Berkeleian immaterialism "to unsettle the principles of common sense by metaphysical seasoning" could, in his view, never produce conviction.

20th-century Realism. Around the turn of the 20th century, a strong revolt against Kantian subjectivism and the dominant Idealisms appeared in such thinkers as William James, a psychologist and Pragmatist; Bertrand Russell, perhaps the most inflnential logician and philosopher of his time; and G.E. Moore?a meticulous pioneering Analyst. Thus it was that very early in the century philosophers came to use Realism, as opposed to Idealism, for their own ways of thinking. In 1904, James signalled the resurrection of natural Realism. In 1910, W.P. Montague of Columbia University and Ralph Barton Perry of Harvard University and several others signed an article entitled "The Program and First Platform of Six Realists," and followed it with a cooperative volume *The New Realism* (1912). New Realism, or neo-Realism, in defending the independence of known things, explained that in cognition "the content of knowledge, that which lies in or before the mind when knowledge takes place, is numerically identical with the thing known." To other Realists this epistemological monism, as Perry called his theory of knowledge, failed to extricate itself from the egocentric predicament (*i.e.*, from the incapacity of the mind to transcend its private experience) that they all professed to see in the logic of Idealism. Nor could it give a satisfactory explanation of the mind's proneness to error, or even of cognition itself as being significantly different from the things known. Another type of Realism was advanced against neo-Realism in a similarly cooperative volume entitled *Essays in Critical Realism* (1920), by the naturalist George Santayana and several others. To the monism of the neo-Realists such writers opposed an epistemological dualism, in which the object in cognition and the object in reality are numerically two at the time of perception. They divided, however, into a majority group and a minority group on the status of the immediately given object. For the majority group this datum was not an existent but merely an essence; for the others it was an existent—a mental or psychic existent for some and a physical (brain) existent for others. Here agreement failed, and the cooperative effort of the critical Realists soon fell apart.

These and the ensuing discussions left a recognized distinction between representative and direct Realism: for representative Realism the immediate confrontation of cognition occurred over against a mental representation of the external object; for direct Realism the confrontation was immediately with the thing existent outside of cognition. The critical Realists themselves, in claiming that the datum was not an object as such but only the means of perceiving it, disavowed any representationalism; but in others, who proposed that the sense-datum was the image directly apprehended and was markedly different from the physical object, representative Realism was definitely present. Representationalism may also be seen in the Realism of the Belgian Neoscholastic Desire Mercier, who founded the school of Louvain, and in the physiological Idealisms of contemporary neurophysiologists. In essence, representationalism was the inferential procedure employed by Descartes and Locke for reaching the external world. Direct Realism, on the other hand—as defended by recent writers—acknowledged no intermediate object between cognition and the external thing perceived.

Naive and tacit Realisms

Within the ambit of contemporary discussions, naive Realism was the label for any unquestioning belief that things in reality correspond exactly to human cognition of them. Expressly meant as a prephilosophical attitude, naive Realism can hardly be included under philosophical procedures. Yet its appropriateness to the man in the street has also been widely challenged; for the ordinary man is keenly interested in distinguishing critically between reality and figments of cognition and is continually doing so in ordinary life. He does not proceed, however, as did the aforementioned Realisms: he does not first regard the object in terms of its status in cognition and then explore its relation to reality. But to come under the notion as introduced by the Realists, naive Realism must be explained in terms of the cognitional relation—*e.g.*, as one of the "three typical theories of the knowledge relation." It is, accordingly, a philosophical category, though historians and controversialists shun the listing of recognized philosophers under such a title.

Metaphysical Realisms

Further, philosophies that neither bore the name of Realism nor defined reality in terms of its relation to cognition are frequently called Realisms today. Aristotelianism, for example, explained the reality of things through their substantiality, Thomism through their existence in themselves, Scotism through the metaphysical priority of a nature possessed in common, and contemporary linguistic philosophy, as in John Austin, an important mid-20th-century Oxford Analyst, through a completely ostensive view of language; yet all have been seen as Realisms. The process philosophies of the Pragmatist John Dewey and of Alfred North Whitehead, an influential cosmologist and metaphysician, and—still more controversially—the philosophy of Charles Sanders Peirce, an individualistic American logician and Pragmatist, may also be taken as Realisms, even though they did not stress the basic relation to cognition; for these thinkers agreed that things as a fact do have, or may have, existence outside cognition, even though this existence was not reached from cognition nor defined through its relation to cognition. With them the cognitional relation was only an inessential afterthought. Serious interest in explaining as Realism the traditional tenets of pre-Cartesian philosophies may be seen in the writings of many contemporaries. Yet for Aristotle and Aquinas, what was meant by the reality of sensible things is already established metaphysically, through their substantiality or ontal (real) existence, before they are compared with cognition; hence to bring in the further notion of Realism for this purpose seems meaningless. The notion is therefore extraneous to the philosophical procedures of thinkers who locate the starting point of their philosophy in some actuality of the real thing itself; for relation to cognition does not play an operative role in their basic procedures. Only by means of entirely extrinsic bonds can they be grouped with the genuine Realisms.

MAJOR ISSUES AND EVALUATION OF REALISM

From the foregoing survey, the major issues upon which Realism focusses attention stand out clearly. For both speculative and practical reasons, men wish to distinguish sharply between what they call reality and what they recognize or suspect to be merely products of their own cognition. Accordingly, the ancient Platonic concentration on specific and generic natures and, in Aristotle, the essential role played by the universal in reasoning led to a close scrutiny of the way in which these natures exist. Undoubtedly, they exist in human thought. For the Realistically inclined thinker, however, their crucial role tends to demand counterparts if human thinking is to bear on what really exists. Still more drastic are the post-cartesian philosophies in which the existence of external things themselves does not enter human cognition in direct confrontation. Finally, the mathematical and scientific constructs, which have been so fruitful in man's struggle for mastery over nature, seem to require for the Realistically minded thinker some counterpart in the things themselves in order to provide an adequate philosophical explanation of their success.

Problems and current status

When the issues are faced in the foregoing manner, some lines of a procedure common to the various explicit Realisms emerge. Universals, sensations and perceptions, scientific formulas and laws are all found to be existent in cognition. From that sure starting point, attempts are made to show that objects either corresponding to them or identical with them exist outside the mind. That pattern seems to be the general procedure followed in any way of thinking that has spontaneously given rise to the notion of an epistemological Realism and that can, with historical and philosophical significance, be labelled such. As is likewise apparent from the foregoing survey, this way of thinking follows a dubious procedure: Realism is not primarily a doctrine of the existence of things but rather a doctrine of cognition. In Realism, cognition is regarded as the object most present to itself; *i.e.*, a man knows his own thought processes more intimately than anything else. But the genuine Realist seems unwittingly to take the material thing as his model in conceiving cognition. No external object can be more present to a material thing than that material thing itself. If cognition is conceived after this analogy, it will be what is most present to itself and will have to be the starting point from which the Realist reasons. This starting point seems to offer no exit. The objects reached from it can be only internal products or occurrences in the mind, for it offers nothing more basic from which to reason than the cognition itself. Any philosophically genuine Realism seems, in consequence, prone to failure in its basic objective.

Accordingly, Realism, in the senses responsible for the epistemological use of the term, has long since ceased to inspire vigorous debate. In a Platonic tradition that continues in modern thought, however, Realism in respect to the natures of things is by no means dead. In regard to the Cartesian problem of the world's external existence, representative Realism seems to have shared the fate of the sense-datum and to be quite inoperative outside of the wake of neurophysiological writings. But attempts at direct Realism are still made. In the scientific field the opposition to conventionalism and to retaining a merely instrumental status for laws or theories has remained a lively issue (see SCIENCE, PHILOSOPHY OF: III. *Deeper issues and broader involvements of science: Status of scientific propositions and concepts or entities).* Moreover, modern means, such as the electron microscope (which shows molecules in real existence) and the hope of being able to see atoms foretoken a greater correspondence of scientific constructs with the structure of reality than had previously been demonstrated. But this verification process consists in a comparison of reality with thought rather than in any attempt to reach reality from cognition alone.

BIBLIOGRAPHY. There is no single monograph that covers comprehensively the whole topic of Realism. The following works will be helpful for the study of its particular phases.

Medieval Realism: M.H. CARRÉ, *Realists and Nominalists* (1946, reissued 1967).

Neo-realism and critical Realism: E.B. HOLT *et al., The New Realism* (1912, reprinted 1970); DURANT DRAKE *et al., Essays in Critical Realism* (1920, reprinted 1968); RENÉ KREMER, *La Théorie de la connaissance chez les néo-réalistes anglais* (1928); T.E. HILL, "Realistic Theories," *Contemporary Theories of Knowledge,* pp. 77–205 (1961, reissued 1980), good general coverage of the American and English fields.

Neoscholastic Realisms: LÉON NOËL, *Le Rkalisme immkdiat* (1938); and works by ÉTIENNE GILSON: *Le Rkalisme méthodique* (1936), presents the author's own views; ch. 5, "Vade Mecum of a Young Realist," trans. by W.J. QUINN, in R. HOUDE and J. MULLALLY (eds.), *Philosophy of Knowledge* (1960); and *Réalisme Thomiste et critique de la connaissance* (1939), a critique of the leading Neoscholastic views.

Linguistic approach: MARTIN LEAN, *Sense-Perception and Matter* (1953, reprinted 1973); J.L. AUSTIN, *Sense and Sensibilia* (1962).

Universals in contemporary thought: I.M. BOCHENSKI, ALONZO CHURCH, and NELSON GOODMAN, *The Problem of Universals* (1956); FARHANG ZABEEH, *Universals* (1966); PANAYOT BUTCHVAROV, *Resemblance and Identity: An Examination of the Problem of Universals* (1966, reissued 1982); NICHOLAS WOLTERSTORFF, *On Universals: An Essay in Ontology* (1970).

Scientific Realism: BERTRAND RUSSELL, *Our Knowledge of the External World,* rev. ed. (1926, various printings); W.H. WERKMEISTER, *The Basis and Structure of Knowledge* (1948, reissued 1968), bibliography, pp. 420–438; MORITZ SCHLICK, "Are Natural Laws Conventions?" in H. FEIGL and MAY BRODBECK (eds.), *Readings in the Philosophy of Science,* pp.

181–188 (1953); ROMANO HARRÉ, *Theories and Things* (1961); GROVER MAXWELL, "The Ontological Status of Theoretical Entities," in *Minnesota Studies in the Philosophy of Science*, 3:3–27 (1962); J.J.C. SMART, *Philosophy and Scientific Realism* (1963).

Other 20th-century Realisms: G.D. HICKS, *Critical Realism* (1938); JAMES FEIBLEMAN, *The Revival of Realism* (1946, reissued 1972); WILFRID SELLARS, *Science, Perception and Reality* (1963); R.M. CHISHOLM (ed.), *Realism and the Background of Phenomenology* (1961), convenient bibliography, pp. 290–304; J.D. WILD (ed.), *The Return to Reason: Essays in Realistic Philosophy* (1953); E.B. MCGILVARY, *Toward a Perspective Realism* (1956); D.M. ARMSTRONG, *A Materialist Theory of the Mind* (1968); INGEBORG WIRTH, *Realismus und Apriorismus in Nicolai Hartmanns Erkenntnistheorie* (1965); GUSTAV BERGMANN, *Realism: A Critique of Brentano and Meinong* (1967).

(J.O./L.H.St.)

Recife

The capital of the state of Pernambuco, in the northeastern region of Brazil, Recife stands on one of the easternmost points of the Atlantic coast of South America, where two river mouths form a lagoon around a central island.

Recife is Brazil's sixth largest city, with a population in 1980 of almost 1,205,000. It combines historic reminders of Brazil's colonial past with the bold lines and skyscrapers of 20th-century town planning. The city has been called the Venice of Brazil because it is crossed by the Capibaribe and Beberibe rivers, its quarters linked by numerous bridges. It is also a centre of learning and of the arts. The city is the major metropolis of Northeast Brazil. Greater Recife includes not only the old city of Olinda, five miles (eight kilometres) to the north, but also a ring of industrial towns.

The name is derived from the Portuguese *recife*, or *arrecife* ("reef"), an allusion to the offshore chain of rocks that shelters the city's harbour and the neighbouring beaches from the full force of the sea. The reef, however, is breached by the discharge of the Rio Capibaribe into the Atlantic. The name Pernambuco, often applied to the port by itself, is taken from the Tupi Indian expression *para-nambuco* ("broken sea").

The Dutch occupation

History. In the second quarter of the 16th century Recife was merely an anchorage that handled the exports and imports of Olinda's wealthy Portuguese colonists. It was raided by French pirates in 1561 and by the English in 1595. In 1630 it was captured by the Dutch, who held it for 24 years. It prospered under the governorship of Count John Maurice of Nassau and is still sometimes called the Cidade Mauricia in his honour. The Dutch occupation was, however, constantly resisted by the Portuguese settlers, whose campaigns in the nearby hills mark the beginning of Brazilian nationalism.

Recife's libertarian spirit was shown on many occasions. In 1710 the inhabitants revolted against the magnates of Olinda in what is now called the War of the Mascates (*i.e.*, "peddlers") because the small tradesmen of Recife tried to organize a municipality of their own. During the revolt of 1817 a republic was formed that lasted for 90 days. In 1824 there was an attempt to establish the Confederation of the Equator as a republic independent of the Brazilian Empire. This spirit may also be seen in the socialistic revolution of the Praieiros of 1848 and in the series of civil movements for reform, best exemplified by the campaign that culminated in the decree of 1888, abolishing slavery. In 1823 Recife became the official capital of the province of Pernambuco.

Landscape. Recife stands at an altitude of 26 feet (eight metres) above sea level. The climate is humid and hot: annual rainfall varies between 60 and 80 inches (1,500 and 2,000 millimetres), and the temperature ranges from a maximum of about 90° F (32° C) to a minimum of 63° F (17° C). The trade winds, however, play a mitigating role during the hottest season, from October to March.

The *bairros*

The Rio Capibaribe winds about Recife from the west and is joined by the Beberibe River flowing from the northwest. It is to these two rivers, whose branches separate the various *bairros*, or quarters, of the city, that Recife owes its peculiar charm.

Recife, on the Rio Capibaribe.
Carl **Frank**

The *bairro* of Recife proper is that of the port. It can be considered either as an island or as the tip of a peninsula because the sand-built isthmus that links it with Olinda is very narrow. One of the oldest *bairros*, it contains some splendid houses of the colonial period, and banks and consulates line its broader avenues. The port itself has been modernized both for coastal and for oceangoing traffic. Its waterfront, backed by customs warehouses, is almost two miles long and can accommodate ships of 25-feet draft everywhere and ships of 31 feet at some berths. Nearby are the great storage tanks of the petroleum companies that supply the northeastern region of Brazil.

The *bairro* of Santo Antônio stands on an island, formerly named Antônio Vaz, in the lagoon, inland from Recife proper and from the isthmus. The commercial centre of the city, it contains the best cinemas, restaurants, and hotels, in addition to the law courts, the state treasury, the palace of government, the public library, the Santa Isabel Theatre, and the offices of Latin America's oldest newspaper still in circulation, the *Diário de Pernambuco.* Though such magnificent avenues as Guararapes, Dantas Barreto, and Nossa Senhora do Carmo have replaced many of the narrower streets of the colonial era, many churches of historical interest remain: Santo Antônio, São Francisco, Nossa Senhora do Carmo, Espirito Santo, São Pedro dos Clérigos, and others. The beautiful Nassau Bridge memorializes Count John Maurice, whose own palace was on this island.

Adjacent to Santo Antônio is the *bairro* of São José, where narrow streets and colonial houses still predominate, despite the pressures of urban development. The basilicas of the Penha and of São José de Ribamar are noteworthy among the churches.

The Boa Vista quarter

The *bairro* of Boa Vista, on the mainland west of the central island, is partly residential and partly commercial. It is also the centre of Recife's student life, though some schools of the universities have been moved to the Cidade Universitaria in the city's outskirts. The splendid premises of the Faculty of Law are located in Boa Vista.

The outer ring of industrial towns that are regarded as belonging to Greater Recife includes Paulista, Jaboatão, São Lourenço da Mata, and Cabo.

Railroads, highways, airlines, and shipping connect Recife with other parts of Brazil. Guararapes Airport serves both international and domestic flights. The city maintains a bus and trolley service, and there also are many private bus companies.

Population. In the 1980 census metropolitan Recife had almost 2,400,000 inhabitants. The majority are of European origin, but Africans and American Indians are also represented. There is a considerable population of mixed racial background. Most of the people are Roman Catholics, but other Christian persuasions and other religions are also found.

Economic life. Recife has shared in the prosperity of northeastern Brazil that resulted from development promoted by Sudene (Superintendência para o Desenvolvimento do Nordeste), a federal organization; signs of poverty continue, nevertheless, to be widespread. Industries of many types have been promoted in the peripheral areas of Greater Recife, and the city itself has expanded rapidly; as in other developing cities, however, there are beggars in the streets. New apartment buildings have continued to rise in the centre of the city and in the suburbs; many homeless people are, however, obliged to sleep outdoors. Branches of the major banks of Rio de Janeiro, São Paulo, and Minas Gerais do considerable business in Recife, and there also are U.S., French, and Italian concerns. The U.S. Agency for International Development (AID) has offices in the Recife financial district.

Administration, services, and institutions. Although the government of Pernambuco, with its seat in Recife, is invested with legislative, executive, and judiciary powers affecting the entire state, the city of Recife is governed by a mayor (*prefeito*) and the Chamber of Councillors (*vereadores*). Security is normally maintained by the civil police, but the state military police and some of Brazil's armed forces are also based in Recife.

Reservoirs outside the city supply Recife with water. Electricity is provided by CHESF (Companhia Hidrélétrica de São Fernando), which supplies hydroelectric power to the metropolitan area.

There are more than 50 hospitals and sanatoriums in Recife, together with organized emergency services.

Universities

Recife provides primary education, at public expense, to some 260,000 children each year, while public and private schools give secondary education to some 60,000. Institutions of higher learning include the Federal University of Pernambuco, the Federal Agricultural University of Pernambuco, the Catholic University of Pernambuco, and the numerous research institutes attached to them. The independent Joaquim Nabuco Institute of social researches, which is distinguished for its anthropological studies, is also located there.

The Pernambuco State Public Library in Recife has more than 80,000 books, and the Federal University's Faculty of Law has a library of 113,000 volumes. The Portuguese Reading Room houses about 40,000 books. Besides the State Museum, there are museums of sugarcane and of popular art. Recife has six daily newspapers, four television stations, and seven radio stations.

The cultural milieu. Recife has a symphony orchestra, a conservatory of music, and several theatrical companies, including the nationally famous Pernambuco Amateur Theatre and the Popular Theatre of the Northeast. Reflecting the area's distinctive cultural composition are the folklore festivals: the Xangô is typically African, while Carnival time is vibrant with the compulsive music of the *passo*, an emotionally and physically exacting dance. Other popular entertainments include the fandango dance, the *bumba-meu-boi* (a pageant with dancing), the *pastoris* (open-air plays), and the *lapinhas* (Nativity scenes).

Beaches

The city is well endowed with open spaces—squares, parks, and gardens. At Dois Irmãos, seven miles from the city centre, there is a nature reserve in a beautifully wooded landscape well appointed for visitors. The region of hills outside the city is included in the National Historic Park of the Guarapes. The beaches, extending for about seven miles in all, offer a special attraction: bright sunlight with Atlantic breezes to temper the heat, placid emerald-green water, and ever-present palm trees providing coconut milk to slake thirst. The beaches nearest to central Recife include Pina, Piedade, and fashionable Boa Viagem, with its lights and playgrounds and an adjacent residential area that is practically a self-contained community. Candeias, Olinda, Rio Doce, and Pau Amarelo, farther away, are served by good roads.

Numerous clubs cater to social life and sports. Some are renowned for their festivities during Carnival time.

(J.L.de L.)

BIBLIOGRAPHY. Reference works providing information on the city and metropolitan area include: JOSUE DE CASTRO, *A Cicade de Recife* (1954); ROBERT M. LEVINE, *Pernambuco in the Brazilian Federation, 1889–1937* (1978); GOVERNO DE ESTADO, FUNDAÇÃO DE DESENVOLVIMENTO DA REGIÃO METROPOLITANA DO RECIFE, *Região Metropolitana do Recife, Plano de Desenvolvimenro Inregrado* (1976); MINISTERIO DA SAUDE, CENTRO REGIONAL DE ESTATISTICA DE SAUDE DO NORDESTE, *Indicadores de saude sobre os municipios das Capitais do Nordesre do Brazil 1977*, contains health statistics for the capitals of northeastern Brazilian states including Recife.

(Ed.)

Red Sea

The Red Sea is a narrow strip of water extending southeastward from Suez for about 1,300 miles (2,100 kilometres) to the Straits of Bāb el-Mandeb, which connects with the Gulf of Aden and thence with the Indian Ocean. The sea separates the coasts of Egypt, The Sudan, and Ethiopia to the west from those of Saudi Arabia and Yemen (San'a') to the east. Its maximum width is 190 miles; its greatest depth 9,580 feet (2,920 metres); and its area approximately 169,000 square miles (438,000 square kilometres). The Red Sea contains some of the world's hottest and saltiest seawater. When the Suez Canal is open, it is one of the most heavily travelled waterways in the world, carrying maritime traffic between Europe and Asia. Its name derived from the colour changes observed in its waters. Normally the Red Sea is an intense blue green; occasionally, however, it is populated by extensive blooms of the algae *Trichodesmium erythraeum*, which, upon dying off, turn the sea a reddish-brown colour. (For associated physical features, see ARABIAN DESERT; ARABIAN SEA; ADEN, GULF OF; and SINAI DESERT; see also SUEZ CANAL.)

Physiography and submarine morphology. The Red Sea lies in a fault depression that separates two great blocks of the Earth's crust—Arabia and North Africa. The land on either side, inland from the coastal plains, reaches heights of more than 6,560 feet above sea level, with the highest land in the south.

At its northern end the Red Sea splits into two parts, the Gulf of Suez to the northwest and the Gulf of Aqaba to

Red Sea area. Inset shows the relative motions of the three plates that make up the Red Sea area.

The Gulfs of Suez and Aqaba

the northeast. The Gulf of Suez is shallow—approximately 180 to 210 feet deep—and it is bordered by a broad coastal plain. The Gulf of Aqaba, on the other hand, is bordered by a narrow plain, and it reaches a depth of 5,500 feet. From approximately 28° N, where the Gulfs of Suez and Aqaba divide, south to a latitude near 25° N, the Red Sea's coasts parallel each other at a distance of about 110 miles apart. Here the sea floor consists of a main trough, with a maximum depth of some 4,100 feet, running parallel to the shorelines.

South of this point, and continuing southeast to latitude 16" N, the main trough becomes sinuous, following the irregularities of the shoreline. About halfway down this section, roughly between 20" and 21° N, the topography of the trough becomes more rugged, and several sharp clefts appear in the sea floor. Because of an extensive growth of coral banks, south of 16° N only a shallow narrow channel remains. The sill separating the Red Sea and the Gulf of Aden at Bāb el-Mandeb is raised by this growth; therefore, the depth of the water is only about 380 feet, and the main channel becomes very narrow.

The clefts within the deeper part of the trough are unusual sea floor areas in which hot brine concentrates are found. These patches apparently form distinct and separated deeps within the trough having a north-south trend, whereas the general trend of the trough is from northwest to southeast. At the bottom of these areas are unique sediments, containing deposits of heavy metal oxides from 30 to 60 feet thick.

Most of the islands of the Red Sea are merely exposed reefs. There is, however, a group of active volcanoes just south of the Dahlak Archipelago (16° N), as well as a recently extinct volcano on Jebel Tier.

Relationship to the Great Rift System

Geology. The Red Sea occupies part of a large rift valley in the continental crust of Africa and Arabia. This break in the crust is part of a complex rift system that includes the East African Rift valley, which extends southward through Ethiopia, Kenya, and Tanzania for almost 2,200 miles, and northward for over 280 miles from the Gulf of Aqaba to form the great Wadi Aqaba–Dead Sea–Jordan Rift, also extending eastward for 600 miles from the southern end of the Red Sea to form the Gulf of Aden.

The Red Sea Valley cuts through the Arabian-Nubian Massif, a central mass of Precambrian igneous and metamorphic rocks (*i.e.*, formed deep in the earth under heat and pressure from 570,000,000 to 4,600,000,000 years ago), whose outcrops form the rugged mountains of the adjoining region. The massif is surrounded by Paleozoic marine sediments (from 225,000,000 to 570,000,000 years old). These sediments were affected by the folding and faulting that began in the Late Paleozoic Era; the laying down of deposits, however, continued to take place during this time and apparently continued into the Mesozoic Era (from 65,000,000 to 225,000,000 years ago). The Mesozoic sediments appear to surround and overlap those of the Paleozoic and are in turn surrounded by Early Tertiary sediments (from about 54,000,000 to 65,000,000 years old). In many places large remnants of Mesozoic sediments are found overlying the Precambrian rocks, suggesting that at one time a fairly continuous cover of deposits existed above the older massif.

The Red Sea is considered a relatively new sea whose development probably resembles the Atlantic Ocean in its early stages. The Red Sea's trough apparently formed in at least two complex phases of land motion. The movement of Africa away from Arabia began during the lower Eocene Epoch (50,000,000 years ago). The Gulf of Suez opened up during the lower Oligocene Epoch (about 35,000,000 years ago), and the northern part of the Red Sea in early Miocene time (25,000,000 years ago). The second phase began about 3,000,000 to 4,000,000 years ago, creating the trough in the Gulf of Aqaba and also in the southern half of the Red Sea Valley. This motion, estimated as amounting to 0.59 to 0.62 inches a year, is still proceeding, as indicated by the extensive volcanism of the past 10,000 years, by earthquake activity, and by the flow of hot brines in the trough.

Economic resources. Three major types of mineral resources are found in the Red Sea region: petroleum deposits, evaporite deposits (sediments laid down as a result of evaporation, such as salt, gypsum, and dolomite), and the newly discovered heavy metal deposits in the bottom oozes of the Atlantis II and Discovery deeps, which lie between 21°15′ and 21°30′ N. The oil and gas deposits are being exploited to varying degrees by the nations adjoining the sea. In the mid-1970s the evaporites were utilized only very slightly, primarily on a local basis. Of the heavy metal deposits, none of which had been touched, those contained in the sediments of the Atlantis II Deep alone were estimated as having a $25,000,000,000 value. The sediment of the Discovery Deep also has a significant metalliferous content but at a lower concentration than that in the Atlantis II Deep. These deposits are in the form of fairly fluid oozes, with an average of about 85 percent brine. The average analysis of the Atlantis II Deep deposit reveals an iron content of 29%; zinc 3.4%; copper 1.3%; lead 0.1%; silver 54 parts per million; and gold 0.5 parts per million. The total brine-free sediment estimated to be present in the upper 30 feet of the Atlantis II Deep is about 50,000,000 tons. These deposits appear to extend to a depth of 60 feet below the sediment surface, but the quality of the deposits below 30 feet is unknown.

Mineral deposits

The recovery of sediment located beneath 5,700 to 6,400 feet of water poses problems. But since most of these metalliferous deposits are fluid oozes, it is anticipated that it may be possible to pump them to the surface much the same way as oil. There are also numerous proposals for drying and beneficiating (treating for smelting) these deposits after recovery. It would indeed seem that exploitation is now feasible, provided international agreements can resolve legal difficulties.

Climate. The Red Sea region has very little precipitation in any form, although prehistoric artifacts seem to indicate that there were greater amounts of rainfall in times gone by. In general, the year-round climate makes an active life difficult, for the average temperature varies between 77" and 82" F (25" and 28° C), and there is a very high degree of relative humidity in summer. In the northern part of the Red Sea area, extending down to 19° N, the prevailing winds are north to northwest. Best known are the occasional westerly, or "Egyptian," winds, which blow with some violence during the winter months and are generally accompanied by fog and blowing sand. From latitudes 14° to 16° N the winds are variable, but during the months of June through August strong northwest winds move down from the north, sometimes extending as far south as the Straits of Bāb el-Mandeb; by September, however, this wind pattern retreats to a position north of 16° N. South of 14" N the prevailing winds are south to southeast.

Hydrography. No water enters the Red Sea from rivers, and rainfall is scant; but the evaporation loss, in excess of 80 inches a year, is made up by an inflow through the eastern channel of the Straits of Bāb el-Mandeb from the Gulf of Aden. This inflow is driven toward the north by prevailing winds and generates a circulation pattern in which these low salinity waters (the average salinity is about 36 parts of salt per thousand) move northward. Water from the Gulf of Suez has a salinity of about 40 parts per thousand due to evaporation, and consequently a high density. This dense water moves toward the south and sinks below the less dense inflowing waters from the Red Sea. Below a transition zone, which extends from depths of about 300 to 1,300 feet, the water conditions are stabilized at about 72° F (22° C), with a salinity of almost 41 parts per thousand. This south-flowing bottom water, displaced from the north, spills over the sill at Bāb el-Mandeb, mostly through the eastern channel. It is estimated that there is a complete renewal of water in the Red Sea every 20 years.

Salinity and temperature

In the 1960s it was discovered that below this southward flowing water, in the deepest portions of the trough, there is another transition layer, only 80 feet thick, below which, at some 6,400 feet, lie a number of pools of hot brine. The brine in the Atlantis II Deep has an average temperature of almost 140" F (60" C), a salinity of 256 parts per thousand, and contains no oxygen. There are similar pools of water in the Discovery Deep, and in the Chain Deep (at about 21°18′ N). Heating from below renders these pools unstable so that their contents mix with the overlying waters; they thus become part of the general circulation system of the sea.

Early use as a route to India

History. The Red Sea is one of the first large bodies of water mentioned in recorded history. It was important in early Egyptian maritime commerce (2000 BC) and was used as a water route to India by about 1000 BC. It is believed that it was reasonably well charted by 1500 BC, because at that time Queen Hatshepsut of Egypt sailed its length. Later the Phoenicians explored its shores during their circumnavigatory exploration of Africa in about 600 BC. A deep canal between the Mediterranean and the Red Sea was first suggested about 800 BC by Caliph Hārūn ar-Rashīd of Baghdad. Shallow canals were dug between the Nile and the Red Sea before the time of Christ, but were later abandoned. It was not until 1869 that Ferdinand Marie de Lesseps completed the Suez Canal (*q.v.*) connecting the Red and Mediterranean seas.

Navigation. Navigation in the Red Sea is difficult. The unindented shorelines of the northern half provide few natural harbours; in the southern half the growth of coral reefs has restricted the navigable channel and blocked some harbour facilities. At Bāb el-Mandeb the channel is kept open by blasting and dredging. Atmospheric distortion (heat shimmer), sandstorms, and highly irregular water currents add to the navigational hazards.

Prospects for the future. It seemed clear in the 1970s that the Red Sea would be subjected to extensive study for some time to come because of its unusual geology and its enormous untapped economic potential. Further, thorough understanding of the region would throw light on the study of worldwide continental drift and on the origin of the modern sea floor. Economically, further investigation of its mineral concentrations, in a mineral-hungry world, appeared to be imperative.

Reed, Walter

Walter Reed, a United States Army pathologist and bacteriologist, proved that yellow fever, for several centuries one of the great scourges of the Western Hemisphere, is transmitted by the bite of a mosquito.

Early career

Reed was born at Belroi in Gloucester County, Virginia, on September 13, 1851. He was the youngest of five children of Lemuel Sutton Reed, a Methodist minister, and his first wife, Pharaba White. In 1866 the family moved to Charlottesville, where Walter intended to study classics at the University of Virginia. After a period at the university he transferred to the medical faculty, completed his medical course in nine months, and in the summer of 1869, at the age of 18 graduated as a doctor of medicine. To obtain further clinical experience he matriculated as a medical student at Bellevue Medical College, New York, and a year later took a second medical degree there. He held several hospital posts as an intern and was a district physician in New York. He decided against general practice, however, and for security chose a military career. In February 1875 he passed the examination for the Army Medical Corps and was commissioned a first lieutenant.

Reed.
The Bettmann Archive

After marrying Emilie Lawrence in April 1876, Reed was transferred to Fort Lowell, Arizona, where his wife soon joined him. During the next 18 years—changing stations almost every year—Reed was on garrison duty, often at frontier stations. His letters provide vivid pictures of the rigours of frontier life. In 1889 he was appointed attending surgeon and examiner of recruits at Baltimore. He had permission to work at the Johns Hopkins Hospital, where he took courses in pathology and bacteriology. In 1893 Reed was assigned to the posts of curator of the Army Medical Museum in Washington and of professor of bacteriology and clinical microscopy at the newly established Army Medical School. During the Spanish–American War of 1898 he was appointed chairman of a committee to investigate the spread of typhoid fever in military camps. Its report, not published until 1904, revealed new facts regarding this disease. On the completion of the committee's work in 1899, he returned to his duties in Washington. Almost immediately he became involved in the problem of yellow fever. The result was a brilliant investigation in epidemiology.

The problem of yellow fever

During most of the 19th century it had been widely held that yellow fever was spread by fomites—*i.e.*, articles such as bedding and clothing that had been used by a yellow-fever patient. As late as 1898, a U.S. official report ascribed the spread to this cause. Meanwhile, other methods of transmission had been suggested. In 1881 the Cuban physician and epidemiologist Carlos Juan Finlay began to formulate a theory of insect transmission. In succeeding years he maintained and developed the theory but did not succeed in proving it. In 1896 an Italian bacteriologist, Giuseppe Sanarelli, claimed that he had isolated from yellow-fever patients an organism he called ***Bacillus icteroides.*** The U.S. Army now appointed Reed and army physician James Carroll to investigate Sanarelli's bacillus. It also sent Aristides Agramonte, an assistant surgeon in the U.S. Army, to investigate the yellow-fever cases in Cuba. Agramonte isolated Sanarelli's bacillus not only from one-third of the yellow-fever patients but also from persons suffering from other diseases. Reed and Carroll published their first report in April 1899 and in February 1900 submitted a complete report for publication. It showed that Sanarelli's bacillus belonged to the group of the hog-cholera bacillus and was in yellow fever a secondary invader.

Before this report had actually been published, an outbreak of yellow fever occurred in the American garrison at Havana, and a commission was appointed to investigate it. The members of the commission were Reed, who was to act as chairman, Carroll, Agramonte, and a bacteriologist, Jesse W. Lazear. In the summer of 1900, when the commission investigated an outbreak of what had been diagnosed as malaria in barracks 200 miles (300 kilometres) from Havana, Reed found that the outbreak was actually yellow fever. Of the nine prisoners in the prison cell of the post, one contracted yellow fever and died, but none of the other eight was affected. Reed thought it possible that this patient, and only he, might have been bitten by some insect. Reed therefore decided that the main work of the commission would be to prove or disprove the agency of an insect intermediate host.

Proof of the mode of transmission

On July 27, 1900, an infected mosquito was allowed to feed on Carroll, and he developed a severe attack of yellow fever. Shortly afterward Lazear was accidentally bitten, developed yellow fever, and died. In November 1900, a small hutted camp—Camp Lazear—was established, and controlled experiments were performed. Reed proved that an attack of yellow fever was caused by the bite of an infected mosquito, ***Stegomyia fasciata*** (later renamed ***Aedes aegypti),*** and that the same result could be obtained by injecting into a volunteer blood drawn from a patient suffering from yellow fever. Reed found no evidence that yellow fever could be conveyed by fomites, and he showed that a house became infected only by the presence of infected mosquitoes. In February 1901 official action in Cuba was begun by U.S. military engineers under Maj. W.C. Gorgas on the basis of Reed's findings, and within 90 days Havana was freed from yellow fever.

On his return to Washington in February 1901, Reed continued his teaching duties. He died following an operation for appendicitis on November 22, 1902. The army general hospital located in Washington D.C. was named in his honour.

Reformation

The Reformation was a religious movement beginning in the 16th century that attempted to purify the Christian Church morally and doctrinally on the basis of biblical norms, and which had far reaching effects in political, economic, and social spheres.

The article is divided into the following sections:

I. Interpretations of the Reformation

The Reformation shattered Christendom and saved the papacy. Such was the judgment of Jacob Burckhardt, the historian of the Renaissance. The outward framework of a society under a single church was gone, but the papacy, fast sinking into a secularized Italian city-state under the frivolous popes of the Renaissance, became again a religious institution under the austere popes of the Counter-Reformation.

The great upheaval of the Reformation has been variously assessed and explained. Since it began in Germany, German nationalists have regarded it as an upsurge from the profound depths of the German soul, but profound depths can be found in the souls of all peoples. After all, the Apostle Paul was a Jew. Others have suggested in broader terms that Protestantism was the form of Christianity suited to the temper of the northern peoples, Catholicism to that of the southern. Plausibility is leant to the thesis because, in the final stabilization, northern Europe was largely Protestant and southern largely Catholic. But the lines were not sharply drawn. In the Germanic lands the Rhine area, Bavaria, and ultimately Austria were Catholic; and Calvinism, the most militant and widely distributed variety of Protestantism, was Latin in origin. Moreover, the demarcation would have been less sharp save for the migration of minorities. In the Low countries 60,000 moved from the Catholic south to the Protestant north, leaving one-third of the houses in Ghent vacant. And, of course, the great example is the Huguenot dispersion from France to Germany, England, Ireland, the American colonies, and South Africa. The religious revolution cannot be explained in terms of race.

Ethnographic, social, and psychological interpretations

The social historians investigate the coincidence of the religious confessions with class structures. There were some. In France, the Huguenot movement had its strength among the nobility. The few Protestants in Spain and Italy were intellectuals. Later, during the Puritan revolution, Anglicanism had its following in the landed aristocracy and the peasantry, Puritanism among the merchants. But in Germany all classes were enlisted. The Marxists look for economic causes and see the basic reason for the upheaval in the restiveness of the disinherited, notably the peasants, who became Anabaptists. But the Anabaptists were not Anabaptists because they were disinherited, they were disinherited because they were Anabaptists. The earlier Marxist historians regarded the religious terminology of the social prophets as a device to enlist the masses. The more recent admit that the leaders believed their own slogans and were led by their illusions to become the unwitting agents of the social revolution. The psychiatrists have scarcely ventured to analyze the entire movement. They fasten rather on individual leaders, notably Martin Luther. But psychoanalysis of the dead is a precarious enterprise, and to explain Luther in terms of parental friction is to miss his sense of cosmic alienation, the terror of the holy. Some interpreters find the locus of Luther's religion in the stomach or the anus because of the misreading of an abbreviation in a manuscript to make it mean that Luther had his evangelical experience while attending to the needs of nature, as if, were it true, elimination would preclude illumination. And should any of these interpretations of Luther be correct there is still the question of how his message should have enlisted millions, most of whom did not have his physical or mental constitution.

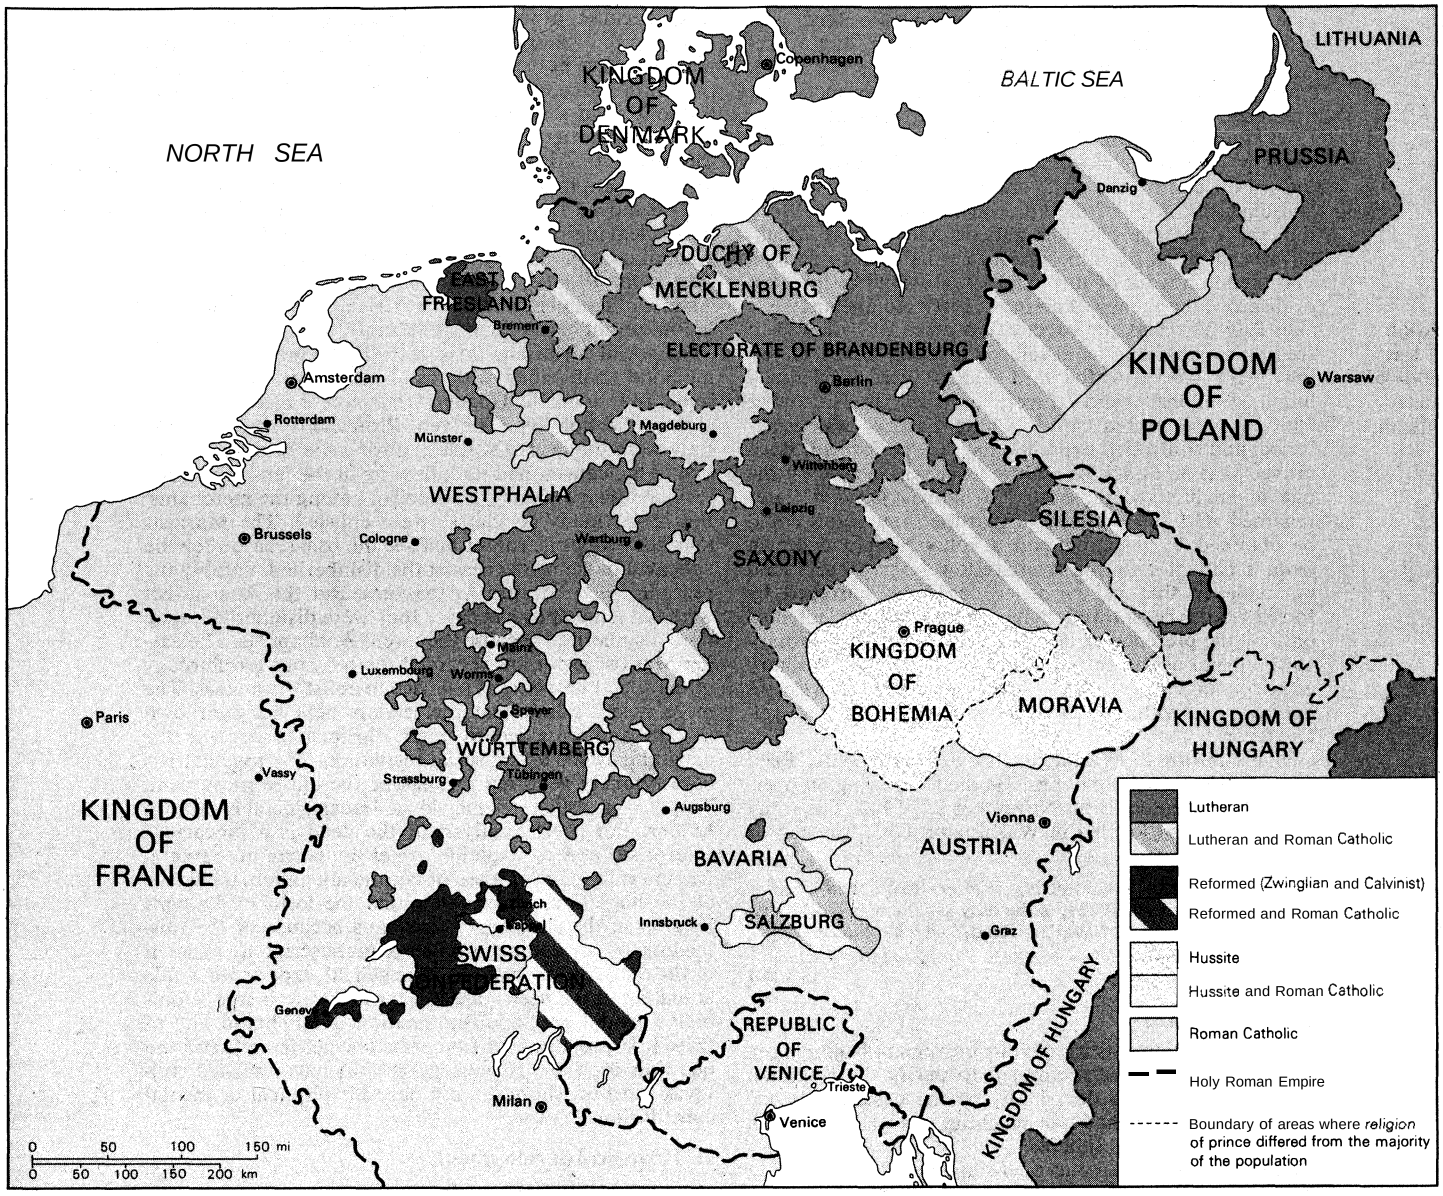
II. Historical development

THE LATE MEDIEVAL CHURCH

Recovery of the lost golden age

To understand the re-formation of the Christian Church one must begin with the de-formation. The Reformation was an attempt to recover a lost golden age of primitive purity as set forth in the Bible. Why and how did the fall occur? Partly because in life as in nature molten lava cools into pumice stone and new eruptions alone can revive the primal heat. But perhaps an even more fundamental reason in Christianity lay in the failures of success. The first success was in expansion. In order to gain converts the church had to accommodate herself to their modes of thought, language, and behaviour, and when they became converts they brought with them much of their former paganism. This was true to a degree in the Roman world, where Christianity was spread chiefly through the conversion of individuals, but much more in the Germanic lands, where whole tribes embraced the faith at the behest of rulers. The ancient gods then survived either as demons or by having their functions transferred to Christian saints. Fertility rites attached themselves to Christian feasts, for example eggs and rabbits to Easter. The Germanic custom of commuting a penalty for crime to a money payment affected the theory of indulgences. The Christian apostles, saints, and even archangels were militarized as Santiago, St. George, and St. Michael who led the hosts in battle.

Another success was in philanthropy. The church so devotedly served the poor that she was inundated with donations. Wealth accumulated and men decayed. Discipline also produced wealth. The great struggle of serious



Religious situation in Europe in 1546.

monks in the Middle Ages was to stay poor. Their industry and thrift continually defeated their resolve. A monk formulated the rule that piety begets industry, industry creates wealth, wealth destroys piety, and piety in its collapse dissipates wealth.

A further success was in the realm of government. With the fall of the empire under the barbarian impact, the church took over many governmental functions and became thereby enmeshed in political complications. The great Gregorian reform movement of the 11th and 12th centuries achieved notable success, engendering disastrous failures. The churchmen who initiated the reform were resolved not to withdraw from the world, not to collaborate with the world but to dominate the world through the church after she herself had been reformed. The clergy should be as austere as monks. They must put away their wives. But the enforcement of clerical celibacy resulted in widespread clerical concubinage. The church took the lead in seeking to allay the wars of Christian princes, who should stop devouring each other and go against the common foe, the infidel. The great peace campaign thus ended in the Crusades, and the Crusades in the end attracted the dregs of Europe. The church undertook to direct all Christian rulers on the ground that those who administer the saving sacraments ministering to man's eternal salvation have an authority superior to that of rulers dealing with man's temporal welfare. The papacy in the 13th century succeeded to an amazing degree in regulating the behaviour of rulers, but only at the expense of pitting one power against another and of becoming so enmeshed in political manipulations as to approach the verge of secularization. The international role of the papacy called for immense financial levies on local churches, which the faithful resented, particularly when the money was squandered on wars and luxurious living.

In the realm of theology the great new synthesis of Christianity with congenial elements in Judaism, Islām, and Aristotle, and the surmounting of the dichotomy between reason and faith by a scale of ascents at the hands of Thomas Aquinas produced in the late Middle Ages a recession from universals to particulars and such a rift between reason and faith as to call for two systems of logic. These many failures led those who were actuated by the very ideals of the Gregorian reformers to initiate sects composed of those committed to the practice of the ideal, even in defiance of the church as an organized structure. For 300 years prior to the Reformation the sects swarmed in southern France and northern Italy. Bohemia had the Hussite movement and England that of John Wycliffe and his followers, the Lollards. The programs of these groups centred on the ethical, though some introduced theological ideas of great moment. One was the idea of predestination coupled with a test for identifying if not the elect, then at least the nonelect. The test was moral, with

the conclusion that scandalous popes were "the damned limbs of Lucifer," and the very Antichrist, a figure comparable to Satan. Some predicted and even set dates for the speedy return of Christ to overthrow so depraved a church and to set up the reign of the Spirit.

THE CONTINENTAL REFORMATION: GERMANY, SWITZERLAND, AND FRANCE

Luther, Luther said that what differentiated him from previous reformers was that they attacked the life, he the doctrine of the church. Whereas they denounced the sins of churchmen, he was disillusioned by the whole scholastic scheme of redemption. The assumption was that man could erase his sins one by one through confession and absolution in the sacrament of penance. Luther discovered that he could not remember or even recognize all of his sins, and the attempt to dispose of them one by one was like trying to cure smallpox by picking off the scabs. The whole man is sick. The church held that man is not too sick to make up for bad deeds by some good deeds. God gives to all a measure of grace. If a man lays hold of it and does the best he can, God will reward him with a further gift of grace with which he can perform deeds of genuine merit which will give him credit before God. He may even die with more than enough credits for his salvation. These extra credits constitute a treasury of the merits of the saints, from which the pope can make transfers to those whose accounts are in arrears. The transfer is called an indulgence and for this the grateful recipient makes a contribution to the church. This arrangement proved to be a popular way of raising money particularly because, unlike tithes, it was voluntary and could provoke no resentment. By this means crusades, cathedrals, hospitals, and even bridges were financed. At first the indulgence, according to the Germanic law of commutation of a physical punishment to a fine, applied only to penalties imposed by the church on earth. Then it was extended to penalties imposed by God in purgatory. In Luther's day immediate release from purgatory was being offered, and the remission not only of penalties but even of sins was assured. Thus the indulgence encroached upon the sacrament of penance.

The indulgence system and its effects

Luther was desperately in earnest about his standing before God and Christ. The woodcuts of Christ the Judge on a rainbow consigning the damned to hell filled him with terror. He believed the monastic life to be the way par *excellence* to acquire those extra merits which would more than balance his account. He became a monk and subjected himself to rigorous asceticism, but could never reach the assurance that a sinful pygmy like himself could ever stand before the inexorable justice and majesty of God. Continual recourse to the confessional simply convinced him of the fundamental sickness of the whole man. Then he began to question the goodness of God who would make a man so weak and then damn him for what he could not help. The advice of the confessor to love God brought the retort, "I hate him." Relief came through the study of the psalms. Luther found the 22nd Psalm particularly revealing, because it contains the words quoted by Christ upon the cross, "My God, my God, why hast thou forsaken me?" Evidently then, Christ, being without sin, so identified himself with sinful humanity as to feel himself estranged from God. Christ the Judge seated upon the rainbow had become Christ the Derelict upon the cross, and here the wrath and the mercy of God could find their point of meeting so that God was able to forgive those utterly devoid of merit. He could justify the unjust, and this required of man only that he accept the gift of God in faith. This was the doctrine of justification by faith which became the watchword of the Reformation.

Ninety-five Theses as the catalyst of the Reformation

What this insight meant for the doctrine of indulgences is at once apparent. The great offense was not the financial aspect, even though it stank, but rather the very notion that man could engage in bookkeeping with God. Luther by now had become a professor at the University of Wittenberg and also a pastor. His parishioners were obtaining the indulgences issued by Albert, the new archbishop of Mainz, half of the proceeds to be retained by him as reimbursement for his installation fee as archbishop, the other half to go to the pope for the building of the Basilica of St. Peter's at Rome. For this indulgence Albert made unprecedented claims. If the indulgence were on behalf of the donor himself, he would receive preferential treatment in case of future sin, if for someone else already in purgatory he need not be contrite for his own sin. Remission was promised not only of penalties but also of s$~, and the vendor of the indulgences offered immediate release from purgatory. Against these instructions Luther launched his Ninety-five Theses on All Saints Day of the year 1517. In the theses he presented three main points. The first concerned financial abuses; *e.g.*, if the pope realized the poverty of the German people he would rather that St. Peter's lay in ashes than that it should be built out of the blood and hide of his sheep. The second focussed attention on doctrinal abuses; *e.g.*, the pope has no jurisdiction over purgatory and if he does he should empty the

place free of charge. The third attacked religious abuses; *e.g.*, the treasury of the merits of the saints was denied by implication in the assertion that the treasury of the church is the gospel. This was the crucial point.

When the papacy pronounced Luther's position heretical he countered by denying the infallibility of popes and for good measure of councils also. Scripture was declared to be the only basis of authority. Luther found support in many quarters. Already a widespread liberal Catholic evangelical reform sought to correct the moral abuses such as clerical concubinage, financial extortion, pluralism (*i.e.*, the holding of several benefices by one man), and ridiculed the popular superstitions associated with the cult of the saints and their relics, religious pilgrimages, and the like. This movement had representatives in all lands. One thinks of John Colet in England, Jacques Lefèvre in France, Francisco Jiménez de Cisneros in Spain, Juan de Valdés in Naples, and, above all, Erasmus of Rotterdam. Erasmus found nothing amiss in Luther's theses except that he had been too tart as to purgatory, and when the cry of heresy was raised against Luther, he wrote to the Elector Frederick III the Wise, Luther's prince, telling him that as a Christian ruler he was obligated to see to it that his subject should have a fair hearing. Under the impact of the Neoplatonic revival, Erasmus popularized a view destined to find radical implementation by the left wing of the Reformation, namely the view that the body is an impediment to the spirit and that in consequence the sensory aids to religion by way of art, music, and the sacraments should be inwardly surmounted. Others were to say they should be ruthlessly abolished.

Another party that rallied to Luther was that of the German nationalists led by Ulrich von Hutten, who aspired to convert the Holy Roman Empire into a German national state. This program would entail the suppression of the whole system of prince-bishops and could never be achieved without a war with the papacy. Luther was hailed because of his attack on the papacy, though he would not condone the program of violence.

Reaction of Pope Leo X

Yet despite the support from these parties, Luther would have been speedily crushed had Pope Leo X taken seriously the religious side of his office. The secularization of the papacy saved Luther, and he destroyed the secularization of the papacy. At the moment when Luther appeared to be foredoomed, an election for the office of Holy Roman emperor was pending. It was elective and any European prince was eligible, Henry VIII of England, Francis I of France, Charles I of Spain. The Pope wished none of them because the position gave control over Germany, and the augmentation of power to one of the three would destroy the balance. His preference was for a minor prince and none better fitted the role than Luther's protector, Frederick the Wise of Saxony, the senior member of the electoral college. In consequence the Pope dallied in the case of Luther and even after Charles was elected was willing to play Frederick against him. Not until June 1520, nearly three years after the Ninety-Five Theses, was Luther summoned to submit within 60 days. The time was reckoned from the date of the actual delivery of the bull to the person named. So great was the obstruction to Rome on the part even of German bishops that the bull was not handed to Luther until October 10.

Address to the Christian Nobility of the German Nation

He employed the summer of 1520 to bring out some of the great manifestos of the Reformation. The ***Address to the Christian Nobility of the German Nation*** called upon the ruling class in Germany, including the emperor, in whom Luther had not yet lost confidence, to reform the church in externals by returning to apostolic poverty and simplicity. This appeal to the civil power to reform the church was a return to the earlier practice of the Middle Ages when emperors more than once had deposed and replaced unworthy popes. Luther affirmed that the papacy of his day was only 400 years old, meaning that the Gregorian reform had given the church the lead in matters political, encroaching thereby on the sphere of the magistrate on the ground that the lowliest priest does more for mankind than the loftiest king. Luther countered with the doctrine of the priesthood of all believers, including Christian magistrates. Any layman is spiritually a priest, though not vocationally a parson. The Christian ruler, then, being himself a priest, may reform the church in externals, as the church may excommunicate him in spirituals. The liberal Catholic reformers could sympathize with this program except for the identification of the papacy with Antichrist. This savoured of the medieval sects.

The sacraments as defined in ***The Babylonian Captivity***

Another tract dealt with the sacraments. The title was ***The Babylonian Captivity,*** meaning that the sacraments themselves had been taken captive by the church. Luther reduced the number of the sacraments from seven to practically two. The seven are Baptism, the Eucharist or mass, penance, confirmation, ordination, marriage, and extreme unction. Luther defined a sacrament as rite instituted by Christ himself. By this token only Baptism and the Eucharist were strictly sacraments and penance only as confession. Extreme unction, that is anointing with oil those on the verge of death, was dropped entirely. Confirmation went out for a time but was later restored. Ordination continued as a rite of the church. Penance included contrition, confession, and satisfaction. Luther felt that none can be sure of genuine contrition, none can make satisfaction. Confession is wholesome but should be voluntary and may be made to any fellow Christian. Marriage is not a Christian sacrament, because it was not instituted by Christ but by God in the garden of Eden, and valid not only for Christians but also for Turks and Jews. Baptism is to be administered but once only and to babies on the ground of their dormant faith.

This leaves the mass, and at this point Luther gave the greatest offense.The wine, said he, should be given to the laity as well as the bread, as in the Hussite practice. No masses should be said for the dead by the priest alone without communicants, because the Eucharist involves fellowship not only with Christ but also with believers. The most drastic change was that Luther denied the doctrine of transubstantiation, according to which, at the pronouncement of the words of institution, the elements of bread and wine, though retaining their accidents of colour, shape, and taste, nevertheless lose their substance, which is replaced by the substance of the body of Christ as God. This Luther denied, saying that no change is wrought by the words of Christ.

Nevertheless, the body of Christ is physically present upon the altar because Christ said, "This is my body."

The doctrine of Real Presence

Therefore, in some inexplicable manner, his body must be "with, in, and under" the elements. But if no change is wrought, how does his body come to be on the altar? Because his body is everywhere. But if everywhere, why especially here? Because in view of human limitations God has decreed two modes of self disclosure, the preaching of the Word and the administration of the sacrament. Here the eyes of the believer are opened. This view undercuts sacerdotalism, since the words of the priest do not bring the body of Christ to the altar. The undercutting of sacerdotalism destroys the hierarchical structure of society, culminating in the papacy.

Diet of Worms as the watershed of Luther's career

But now, what was to be done with Luther? On December 10, instead of submitting, he defiantly burned the papal bull together with a copy of the canon law. The normal course would then have been to excommunicate him outright, but Frederick the Wise insisted that he be given a fair hearing. The natural body to pass judgment would have been a council of the church, but the popes themselves were the greatest obstructionists with respect to the calling of a council because they feared the revival of conciliarism, which in the previous century bade fair to convert the church into a constitutional monarchy. There would have been no Council of Trent save for Luther. Only after another 20 years, when the spread of his teaching left no other expedients, was a council convened. Consequently, his hearing had to be before a secular tribunal, the Diet of the empire meeting at Worms in the winter and spring of 1521. Since this was a secular tribunal the attempt was made to prove that he was not simply a heretic but also a rebel whose views were more subversive of the civil than of the ecclesiastical order, because he was undermining the very principle of authority. Luther was brought before the Diet and given an opportunity to repudiate his books. Had he disclaimed the one on the sacraments the other points might have been negotiated. He acknowledged them all. Would he then disclaim some of their teaching? Who was he to reject the teaching of the ages? Let him give an answer without horns, to which he replied: "I will answer without horns and without teeth. Unless I am convicted by Scripture and plain reason—I do not accept the authority of popes and councils, for they have contradicted each other—my conscience is captive to the Word of God, I cannot and I will not recant anything, for to go against conscience is neither right nor safe. God help me. Amen." The emperor then placed Luther under the imperial ban. The bull of excommunication by the church was formally released only later. Frederick the Wise at this point intervened and wafted Luther away to a place of hiding.

He was concealed for a year at the castle of the Wartburg. During this enforced withdrawal he made perhaps his greatest contribution in that he translated the whole of the New Testament from the Greek text of Erasmus into an idiomatic, pungent, powerful German. In many respects his German helped to create the idiomatic. Nothing did so much to win popular adherence to his teaching as the dissemination of this translation. Earlier translations were by comparison wooden. Now the common man, on reading or merely hearing the simple, vigorous words of Jesus and of Paul would say of Luther's teaching, "By God, he's right."

But some were not so convinced. Many of the liberal Catholic reformers, like Erasmus, recoiled from Luther's paradoxes, from his confidence that his interpretation of Scripture was correct, from his acceptance of the doctrine of predestination which makes of God a tyrant when he elects some and damns others, regardless of their behaviour. The German national movement collapsed. Then in Luther's own circle variant forms of Protestantism arose, which in the aggregate are variously described as the left wing of the Reformation or as the radical Reformation. The terminology does not matter so much as the recognition that no neat classification is possible. The alignments vary in accord with the criterion. If the mainstream of the Reformation is that which made alliances with the state, then Huldrych Zwingli belongs with Luther, John Calvin, and Thomas Cranmer; but if the point is the spiritualizing of the Lord's Supper, then Zwingli belongs with the radicals. If the rejection of infant Baptism is the test, Zwingli moves back to the mainstream and the Anabaptists stand alone. If the denial of the doctrine of the Trinity is determinative, the Socinians are the only radicals. And there were also some individual and rationalist Reformers who formed no communities and dissolved the very structure of the church.

Radical Reformers related to Luther's reform. Two figures emerging in Luther's circle are significant by way of anticipation. One was Karlstadt, who drew the radical inference from the dualism of flesh and spirit that art and music should be abolished as external aids to religion, and the Presence of Christ's body on the altar should be interpreted in a spiritual sense. His program issued in iconoclastic riots. He extended Luther's doctrine of the priesthood of all believers to mean that all laymen are pastors. If one person is assigned the tasks of a parson he should dress like others and, like others, should work with his hands. The clergy not only might but must marry. The sabbath should be strictly observed. This program anticipates the Puritan movement. It entails a blending of spiritualism and legalism. The sensory aids to religion are to be discarded by those advanced in the spiritual life and then snatched away by laws from those still weak.

Karlstadt's and Thomas Miintzer's social and ecclesiastical reforms

A much more disquieting figure was Thomas Muntzer, a man of learning and a creative firebrand, who may be regarded not as the progenitor but as the first formulator of the concept of the Protestant Holy Commonwealth. He believed that the elect, those predestined by God for salvation, could be sufficiently identified to compose a definite group. Luther denied the possibility of distinguishing the elect from the nonelect. Muntzer's test was the new birth in the spirit. The test was not for him an absolute mark, and he recognized that among the wheat there might be some weeds, yet it was an adequate test for the formation of a community bound together by a covenant. The mission of this group was to set up the Kingdom of God on earth, the Holy Commonwealth, by wiping out the ungodly. In the attempt they would have to endure suffering, and here Miintzer drew from German mysticism the theme of walking in Christ's steps toward the cross. But the trial would end in triumph, for the Lord Jesus would speedily come to vindicate his saints and erect his Kingdom. There are obviously incompatibles here, the way of suffering and the infliction of suffering, the feverish activity of man to achieve that which will be established by God. But logical incompatibles fuse at high emotional temperatures. Miintzer appealed to the Saxon princes to implement his program, but they banished him. He found a hearing among the revolting peasants and led them at the Battle of Frankenhausen, where they were butchered and he captured and beheaded. Luther execrated his memory because he seized the sword in defense of the gospel. The Marxists have exalted him as the prophet of social revolution. He was the only one of the Reformers who had a deep feeling for the sufferings of the socially oppressed. In grasping the sword he did not essentially differ from Zwingli, Gaspard de Coligny, or Oliver Cromwell.

Zwingli. Zwingli, the great figure in Swiss Protestantism, was in fact if anything more military than Miintzer because he fell as a combatant with sword and helmet on the field of battle. He became a Reformer independently of Luther, with whom he was entirely in accord as to justification by faith and predestination. At certain points Zwingli drew from Erasmus and Karlstadt, notably with respect to the disparagement of the sensory aids to religion. Zwingli, though an accomplished musician, considered that the function of music is to put the babies to sleep rather than to worship God. The organ was dismantled and the images removed from the cathedral at Zurich. The Lord's Supper was understood by Zwingli in his most extreme period simply as a memorial of Christ's death and, on the part of the recipient, as a public declaration of faith with more significance for the members of the congregation who saw him take his stand than for his own spiritual life. Zwingli could the more readily retain the Baptism of infants because it was simply a recognition that the child belongs to the people of God as the child in the Old Testament belonged by circumcision to Israel. The analogy with Judaism applied at many points, for Zwingli regarded the Christian congregation as the new Israel of God, an elect people, reasonably identifiable, not as with Miintzer by the new birth but by adherence to the faith. This company could be called theocratic in the sense that it was under the rule of God, whom church and state should alike serve in close collaboration. The identification of the whole populace of Zurich with this elect people was the more tenable because those not in accord with the ideal were disposed to leave. As ancient Israel had defended herself by force of arms against the Canaanites and Philistines, so Zwingli approved of even an aggressive war to forestall interference from the Catholic cantons. In the second war of Kappel he fell in 1531.

Zwingli's theocratic ideals

Radical Reformers related to Zwingli's reform. In his circle arose the group who formed the mainstay of the radical Reformation. They shared with Zwingli, and with all the reformers to a degree, the desire to restore the church to the primitive pattern, but they were more drastic in their restitution. Manifestly the early church had not been allied with the state. Luther, Zwingli, and other Reformers saw no sense in forcing the church back into the period when the state was hostile and the Christians were persecuted. After the state became Christian there could very well be a close alliance, as indeed there had been in ancient Israel. The radicals restricted their biblicism to the New Testament and espoused three tenets therefrom that have come to be axiomatic in the United States: the separation of church and state, the voluntary church, and religious liberty. They were called Anabaptists on the ground that, having rejected infant Baptism, they rebaptized adults previously baptized. But they called themselves simply Baptists, denying that they repeated Baptism since the dipping of babies was no Baptism at all. Baptism does not itself regenerate but is only the outward sign of an inner experience, the rebirth in the spirit, of which only an adult is capable. The Anabaptists, so-called, also believed in the possibility of a Christian society whose members were marked both by the conversion experience and also by a highly disciplined deportment. In obedience to the New Testament they repudiated swearing oaths and recourse to violence, whether in war or at the hands of the magistrate. To be sure the rulers bear the sword from God, as the Apostle Paul said, but God instituted the sword because of sin, and its use should be left to sinners. The saints should withdraw from the wicked world.

Influence of Anabaptist tenets

This whole program obviously had political and social aspects and was a threat to that society or any other, for no society, save that of a small sect, has ever renounced the use of the sword. The Anabaptists were marked for extermination by Catholics and Protestants alike. One of their first leaders, Felix Manz, was drowned in Ziirich in 1527. The Diet of Speyer in 1529, at which the Lutherans protested, subjected the Anabaptists to the penalty of death with the concurrence of the Lutherans. Persecution in the first decade eliminated the leaders, most of them educated and moderate men. Less temperate spirits came to the fore, sustaining their courage by setting dates for the speedy coming of the Lord. One band, composed mainly of Anabaptists, took over the town of Munster in Westphalia in 1534 and, contrary to the tenets of their fellows, seized the sword and, in accord with Old Testament practice, restored polygamy. The town was captured by Catholics and Lutherans conjoined and the leaders were executed. Persecution everywhere intensified. In Holland Menno Simons, the founder of the Mennonites, repudiated violence, polygamy, and the setting of dates for the coming of the Lord and returned to the teaching of the early founders. The Mennonites have survived partly by reason of accommodation to military service in Holland, partly by migration first to eastern Europe and then to the Americas. Another group, named Hutterites from Jakob Hutter, was allowed to form communal colonies in Moravia on the estates of tolerant feudal nobles who were willing to drop the demand for military service in return for excellent craftsmanship in field and shop. Because of subsequent persecution these groups also migrated to the New World. The Swiss branch, which survives in the United States, is called the Amish. The entire pattern of ideas has reappeared in various combinations in subsequent history, not only among the Church of the Brethren and the Quakers but among all of the free churches disclaiming a state connection.

Role of Menno Simons

Calvin. Another form of Protestantism was Calvinism, named for John Calvin, a Frenchman educated in humanist and legal studies, who in consequence of a conversion to the Protestant reform had to flee France. In Basel, at the age of 27, he brought out the first edition of his ***Institutes of the Christian Religion,*** which in successive expansions became for centuries the manual of Protestant theology. Calvin was in basic agreement with Luther as to justification by faith and the sole authority of Scripture. On the sacrament of the Lord's Supper he took a mediating position between the radical Swiss and the Lutheran view. Whereas the body of Christ is not everywhere present, his spirit is universal and there is a genuine communion with the risen Lord. Calvin took a middle view likewise with respect to music and art. He favoured congregational singing of the psalms, and this became a characteristic mark of the Huguenots in France and the Presbyterians in Scotland and the New World. As to art he rejected the images of saints and the crucifix (that is, the body of Christ upon the cross), but allowed a plain cross. These modifications do not refute the generalization that Calvinism was alien to art and music in the service of religion, but not in the secular sphere.

As over against Luther there is a shift of emphasis in Calvin whose ***Institutes*** do not begin with justification by faith but with the knowledge of God. Luther found refuge from the terror of God's dispensations in the mercy of Christ. Calvin could the more calmly contemplate the frightfulness of God's judgments because they would not descend upon the elect. Luther, as noted, saw no way of knowing who were the elect. He could not be sure of himself and throughout his life had a continual struggle for faith and assurance. Calvin had certain approximate and attainable tests. He did not require the experience of the new birth which is so inward and intangible, though to be sure later Calvinism moved away from him on this point and agonized over the marks of election. For Calvin there were three tests: the profession of faith, as with Zwingli; a rigorously disciplined Christian deportment, as with the Anabaptists; and a love of the sacraments, which meant the Lord's Supper since infant Baptism was not to be repeated. If a person could meet these three tests let him assume his election and stop worrying.

If one could achieve such assurance, what anenormous release of energy to be directed to the glory of God and the erection on earth of some semblance of a holy commonwealth! The term became common in New England. Calvin's own statement was that "the Church reformed is the kingdom of God." Calvin saw more of a possibility of its realization through the efforts of the elect because he muted the expectation of the imminent return of the Lord. The service of the Kingdom did not require a particular vocation. Any worthy occupation is a divine calling demanding unremitting zeal. Luther had emphasized the secular callings as over against the monastic, which in the Middle Ages alone had been called a vocation. With Calvin the point was not so much that one should accept one's lot and rejoice in the assigned task, however menial, as that the work would contribute to the larger realization of the Christian society.

Geneva as the centre of Calvinistic reform

Calvin had a concrete opportunity for the realization of his ideal, albeit at first only on a small scale. The city of Geneva had recently thrown off the authority of the bishop and of the duke of Savoy and had not yet joined the Protestant Swiss Confederation, though aided in the fight for liberation by the Protestant city of Bern. Through the Bernese, Protestant preachers began to evangelize Geneva. The city was threatened by civil war. The bellicose preacher Guillaume Farel, unable himself to contain the violence he had helped to unleash, laid hold of Calvin merely passing through the city and impressed him into the unwelcome task of leadership. This was to be his vocation. After turbulent years, a banishment and a recall, he was able for the last two decades of his life—he died in 1564—to direct the city which John Knox considered "the most godly since the days of the apostles." There was actually scarcely a feature of Thomas More's *Utopia* that Geneva did not seek to realize.

The program, despite all the turbulence, was the more attainable because of a selective process with respect to the population. At the outset all the Catholics who would not submit to the new regime had to leave. Among those who remained, excommunication from the church, if not removed within six months, meant banishment from the city. Control over excommunication, after a long struggle, came to be entirely in the hands of the church. The state, having long suffered from the abuse of excommunication for political purposes, was loath to concede to the church exclusive control. Abortive attempts to achieve independence had been made by the Protestant churches at Basel and Strassburg. Calvin succeeded, with the result that one who was not in the graces of the church could not for long be a member of the community. A further factor ensuring a select constituency was the influx of 6,000 refugees fleeing from persecution in France, Italy, Spain, and, for a time, from England into a city of 13,000. Thus in Geneva, church, state, and community came to be one. The ministers and the magistrates with differentiated functions were alike the servants of God in the erection of this new Israel; and the comparison with ancient Israel was the more striking and the inner cohesion the more intensified because Geneva also was begirt by foes, the duke of Savoy and the duke of Alba, like the old Canaanites and Philistines.

Max Weber's thesis on capitalism and Calvin

Much discussion has been precipitated by the thesis of Max Weber that Calvinism fostered the spirit of capitalism. This is the reverse of the Marxist contention that economics determine religion. In this instance religion fashioned the course of economics. Weber had in mind not the structure of capitalism with bookkeeping and credit matured through papal finance during the Renaissance, but rather the building up of morale for economic endeavour by the removal of restrictions and the supplying of incentive. The restriction was the removal of the ban on usury (though as a matter of fact Catholic theologians had circumvented it by synonyms); the incentive was to work furiously for the glory of God in gainful employ as a vocation. Wealth ensued. What could be done with it? There should be no expenditure on pleasure, for Calvinism was as austere as monasticism. There remained only philanthropy or return to the business with the accumulation of capital.

There can be no question that capitalism developed mainly in the north, but Calvinist theology need not have been the reason. Minorities of any sort may develop economic power as, for example, the Armenians and the Jews. Spain declined, perhaps through overreaching in the colonial adventure, to be supplanted by England and Holland. And men will work simply to improve the standard of living. Witness in North America the Irish, the Italians, and the Poles, all Catholics. But there is no question that Calvinism engendered an enormous dynamism not only in economics but in many areas, least of all in the artistic, mostly in the political, first in France and the Low Countries, then in England, Scotland, and the New World.

Calvinism in France. The situation in France with respect to the Reformation was not altogether dissimilar to that in Germany because, although the decentralization of government was not so great, nevertheless some of the French provinces enjoyed a considerable autonomy, particularly in the south, and it was in the Midi and French Navarre that the Protestant movement had its initial strength. Then, too, noble houses were continually conspiring to manipulate or eviscerate the monarchy. The religious issues came to be intertwined with the political ambitions. The ruling houses, first the Valois from Francis I through Henry III and then the Bourbon, beginning with Henry IV, sought to secure the stability of the land and the throne by quelling religious strife either by the extermination or toleration of minorities.

The ground was better prepared for the reform of the church in France than in Germany because of the efforts of the liberal Catholics such as the scholar Lefèvre and the bishop of Meaux, Guillaume Briçonnet. King Francis I and his sister Margaret of Angoulême not infrequently intervened to save humanist reformers from the menaces of the obscurantists, and Margaret's daughter, Jeanne d'Albret, the queen of Navarre, a feudatory of France, provided an asylum for the persecuted in her domain, though she did not herself espouse the Huguenot cause until 1560. When Lutheran teaching first began to infiltrate France, Francis I, who would not abet positive heresy, fluctuated in his policy of repression depending on whether he desired a political alliance with the pope, the Turk, or the German Lutherans. The year 1534 precipitated a crisis when placards were posted in Paris savagely attacking the mass. Severe repression followed. Bishop Briçonnet made his submission. Farel fled to Geneva, Lefèvre to Strassburg, Calvin to Basel. Under Henry II, the son of Francis, repression was intensified, particularly when in 1559 France and Spain made peace and thus each was free to devote attention to the suppression of heresy at home. The persecution of the Huguenots, as the Protestants came to be called in France, would have been intense save for the death of the king in a tournament.

The Huguenots and the French religious wars

At this point the rivalry of the noble houses injected itself more overtly into the religious struggle. The crown, with its alternating policy of eradication or recognition, was flanked by two extreme houses for whom the religious issue was of intense concern. The house of Guise was so Catholic as to be willing to call in Spanish aid, and the family of Admiral Coligny so Huguenot as to be willing to court help from England and even from Germany. Under Francis II the Guises were in the ascendant, because the queen, later queen of Scots, was of that house. Some of the Huguenots, foreseeing the suppression in store, hatched the Conspiracy of Amboise, an attempted assassination of the leaders of the Guise party and transferral of power to the house of Bourbon.

This was plainly rebellion and acutely raised a problem with which the Protestants had long been wrestling. The Lutherans had had to face it earlier when the Diet of Augsburg in 1530 gave them a year in which to submit on pain of war. The Lutheran princes then had formed the Schmalkaldic League to resist arms with arms. Luther was loath to condone any use of the sword in defense of the Gospel and absolutely forbade any recourse to violence on the part of a private citizen against the magistrates. This was his reason for disapproval of the Peasants' War. But now the jurists pointed out to Luther that the emperor was an elected ruler and that if he transgressed against the true religion he might be brought to book by the electors, who also were magistrates. Thus arose the doctrine of the right of resistance of the lower magistrate against the higher. The concept lost its pertinence in Germany after the Peace of Augsburg in 1555, which granted toleration to the Lutherans in the territories where they were predominant. Minorities in Lutheran and Catholic lands were granted the right of migration without loss of goods.

But the Calvinists were not included in the peace, and the problem of armed resistance again became acute in France. Calvin would not condone the Conspiracy of Amboise because it was not led by a lower magistrate. The term was now applied to the princes of the blood in line for succession to the throne. This meant the house of Bourbon. The Conspiracy of Amboise failed. Francis II died, and was succeeded by his brother the young Charles IX. The queen mother, Catherine de Médicis, took the lead and sought to avert religious war by granting the Huguenots limited toleration in restricted areas in the edict of 1562. When François, duc de Guise, discovered the Huguenots worshipping outside the prescribed limits, as he claimed, he opened fire. The Massacre of Vassy set off the wars. The Huguenots now were led by a prince of the blood, Louis I, 1st prince de Condé, of the house of Bourbon. Calvin approved. There followed three inconclusive wars. Condé was killed in the first and François, duc de Guise, was assassinated. His son, now Henri, duc de Guise, believed in the complicity of Coligny, the new leader of the Huguenots. At the end of ten years of indecisive conflict, Catherine made another effort at a settlement to be cemented by the marriage of Henry of Navarre, a Bourbon, the son of Jeanne d'Albret and the hope of the Huguenots, and her own daughter Margaret (Marguerite de Valois), a Catholic. The leaders of all parties came to Paris for the wedding. The Duke of Guise made an attempt on the life of Coligny, which failed. Then the Guise, with the connivance of Catherine and her son Charles, who panicked, tried to wipe out all of the leaders of the Huguenot party in the Massacre of St. Bartholomew's Day in August 1572. Other massacres followed in the provinces.

The St. Bartholomew's Day Massacre and the subsequent Edict of Nantes

Charles IX was succeeded by his brother, Henry III, two years later (1574). Such was the revulsion against the massacre that the King could rule only by forming an alliance with the Huguenot Henry of Navarre. A fanatical Catholic was thereby so outraged that he assassinated the King. Both sides had abandoned the fiction of the inferior magistrate and had gone in unabashedly for popular revolution. Henry of Navarre then became Henry IV, but he was unable to take Paris and rule France so long as he was a Protestant. In order to pacify the land he made his submission to Rome and promulgated an edict of toleration for the Huguenots, the Edict of Nantes in 1598. It gave them liberty of worship again in limited areas but full rights of participation in public life. The edict remained in force until the revocation in 1685.

THE REFORMATION IN ENGLAND AND SCOTLAND

Henry VIII. In the meantime the Reformation had taken hold in England. The beginning there was political rather than religious, a quarrel between the king and the pope of the sort that had occurred in the Middle Ages without resulting in a permanent schism, and might not have in this instance save for the total European situation. The dispute had its root in the assumption that the king was a national stallion expected to provide an heir to the throne. England did not have the Salic law, which in France forbade female succession, but England had just emerged from the Wars of the Roses and the fear was not unwarranted that the struggle might be resumed if there were not a male succession. Catherine of Aragon, the queen of Henry VIII, had borne him numerous children of whom only one survived, the princess Mary, and more were not to be expected. The ordinary procedure in such a case was to discover some flaw in the marriage which would allow an annulment or, in the terminology of that day, a divorce. In this instance the flaw was not difficult to find, because Catherine had been married to Henry's brother Arthur, and the law of England, following the prohibition in the book of Leviticus, forbade the marriage of a man with his deceased brother's widow. At the time of the marriage the pope had given a dispensation to cover this infraction of the rule. The question now was whether the pope had the authority to dispense from the divine law. Catherine said there had been no need for a dispensation because her marriage to Arthur had not been consummated and there had been no impediment to her marriage to Henry. The knot would have been cut by some casuistry had Catherine not been the aunt of the Emperor Charles V, who was not prepared to see her cast aside in favour of another wife, and who controlled the pope. Clement VII, wishing neither to provoke the emperor nor to alienate the king, dallied so long that Henry took the matter into his own hands, repudiated papal authority, and in 1534 set up the Anglican Church with the king as the supreme head. The spiritual head was the archbishop of Canterbury, now Thomas Cranmer, who married the king to Anne Boleyn. She bore the princess Elizabeth. By still another wife Henry did have a son who succeeded as Edward VI.

England's problem of succession

Although the basic concern of Henry was political, the alterations in the structure of the church gave scope for a reformation religious in character. Part of the impulse came from the survivals of Lollardy, part from the Lutheran movement on the continent, and even more from the Christian humanism represented by Erasmus. The major changes under Henry were the suppression of the monasteries, the introduction of the Bible in the vernacular in the parish churches, and permission to the clergy to marry, though this was later revoked. The resistance to Henry's program was not formidable and the executions resulting were not numerous. Henry was impartial in burning some Lutherans who would not submit to his later reactionary legislation and toward some Catholics who would not accept the royal supremacy over the church, notably John Fisher and Thomas More.

Under Edward VI, the boy-king, the English Reformation took on a more distinctly Protestant character. Cranmer prepared a liturgy in English, The *Book of Common Prayer,* in two editions. The first used the formula in the Lord's Supper: "The body of our Lord Jesus Christ which was given for thee preserve thy body and soul unto everlasting life." This was susceptible of a Lutheran and even a Catholic interpretation. The second edition substituted: "Take and eat this in remembrance that Christ died for thee and feed on him in thy heart by faith with thanksgiving." This was susceptible of a Calvinist and even a Zwinglian interpretation as a memorial and an act of spiritual communion.

The Book of Common Prayer

After Edward a woman did succeed to the throne, the princess Mary who, married to Phillip II of Spain, reintroduced Catholicism. The leaders of the Anglican Church went to the stake, some 288 in number. Among them was Archbishop Cranmer. Mary was succeeded in 1558 by her half sister Elizabeth, who espoused a moderate Protestantism constructed on the idea of comprehension; that is, the inclusion of all the inhabitants of the land in one national church. To this end the doctrinal requirements were not rigidly pressed and the formulas for the Lord's Supper in the two prayer books of Edward VI were simply combined, thus inviting divergent interpretations. The number of executions was as great under Elizabeth as under Mary, but the reign of Mary was five years and that of Elizabeth 45, and the cause was chiefly political since the pope had the indiscretion to excommunicate Elizabeth and absolve her subjects from allegiance, so that obedience to the pope meant treason to the queen.

John Knox. In Scotland the Reformation is associated with the name of John Knox, who declared that one celebration of the mass is worse than a cup of poison. He faced the very real threat that Mary, Queen of Scots (formerly queen of France) would do for Scotland what Mary Tudor had done for England. Therefore Knox defied her to her face in matter of religion and, though a commoner, addressed her as if he were all Scotland. He very nearly was, because in the period prior to 1560 many an obscure evangelist had converted the lowlands largely to the religion of John Calvin. The church had been given a Presbyterian structure, culminating in a General Assembly, which had actually as great and perhaps a greater in-

John Knox's opposition to Mary, Queen of Scots fluence than the Parliament. Because of her follies, and very probably her crimes (complicity in the murder of her husband), Mary had to seek asylum in England. There she became the focus of plots on the life of Elizabeth until Parliament decreed her execution. Presbyterianism came to be established in Scotland, and this very fact alone made possible the union of Scotland with England. Union of Protestant England with a Catholic Scotland would have been unthinkable.

Knox is frequently reproached for his intolerance in regarding one celebration of the mass as worse than a cup of poison, but one must remember that the year 1560 marked the peak of polarization between the confessions. Similar intolerance had been mounting at Rome. Paul III, after an abortive attempt at reform, had introduced the Roman Inquisition in 1542. His successor, Paul IV, placed everything that Erasmus had ever written on the Index. The Council of Trent began its sittings in 1545, introducing rigidity in dogma and austerity in morals. The Protestant views of justification by faith alone, the Lord's Supper, and the propriety of clerical marriage were sharply rejected. All deviation within the Catholic fold was rigidly suppressed. When Carranza, the archbishop of Toledo, returned to Spain in 1559, after assisting Mary in the restoration of Catholicism in England, he arrived in time for the last great ***auto-da-fe'*** of the Lutherans. Himself under suspicion for ideas no more heretical than those of Erasmus, he was incarcerated for 17 years in the prison of the Inquisition. The liberal Cardinal Giovanni Morone was imprisoned during the pontificate by Paul IV, and under Pius V Pietro Carnesecchi, an Erasmian and onetime secretary of Clement VII, was burned in Rome. John Knox and Pope Pius V represent the acme of divergence between the confessions.

Council of Trent

Developments in the English Reformation. The real parallel in England to the continental Reformation followed only in the 17th century, for not until then did the populace come to be passionately concerned over the religious issues and broke into a welter of sects, many of them reviving various tenets of the Anabaptists. The English Baptists rejected infant Baptism; the Quakers rejected war and the oath; the Fifth Monarchy Men incited armed revolution, like the Anabaptists at Miinster; the Congregationalists and the Baptists demanded the "gathered" church consisting only of convinced believers. All of them, including the Presbyterians, objected to the episcopal structure of the Anglican Church. The Unitarians grew out of the Presbyterians, at first more as a revolt against the Calvinist doctrine of the depravity of man and the severity of God than over the doctrine of the Trinity, which was questioned only later. The Quakers went beyond all in rejecting a professional clergy and the outward sacraments. All of them rejected the authority of government if it contravened their principles, but the Presbyterians and the Congregationalists were willing to set up theocratic commonwealths if the government were favourable. The Quakers did so also in Pennsylvania, though without constraint of Dissenters. Such diversity raised acutely the problem of religious pluralism and contributed to the outbreak of the civil war in which the demand for independence in religion coincided with the curtailment of the monarchy in economics and politics. A further concomitant resulted from the union of Scotland and England under James I. As already remarked, the union would have been impossible if one of the parties had been Catholic, the other Protestant, but even varieties of Protestantism could fight before agreeing to tolerate diversity. In the sequel the political union did not require an ecclesiastical union.

The theory of revolution ran the same course in England as on the Continent. The king was at first said to be controlled by evil counsellors, then that he might be resisted by the inferior magistrate, in this case Parliament, finally that Parliament was a supreme court of judicature with authority to take the life of the king. After the execution of Charles I, successor to James I, Cromwell set up the establishment of a national religion rather than of a single confession. His establishment rested on three pillars, Congregational, Presbyterian, and Baptist. He excluded the Catholics and Unitarians on doctrinal grounds and the Quakers for refusal to swear. His scheme anticipated the pattern of the United States where, despite the separation of church and state, the government covets the sanction of three religious bodies, Jews, Catholics, and Protestants. The Puritan revolution was not as bitter as the wars of religion on the Continent because all of the contestants were Protestant and because the death penalty for heresy had been dropped early in the 17th century. The Restoration under Charles II began with a promise of toleration, which broke down because the sects were not willing to be tolerated if the Catholics were included. The definitive edict came only with the "Glorious Revolution" of William and Mary in 1688. The ideal of the comprehension of all Englishmen in one church was abandoned in favour of the establishment of the Church of England and the toleration of Dissenters, but Catholic emancipation did not come until 1829.

THE EXPANSION OF THE REFORMATION: SCANDINAVIA; THE BALTIC STATES; EASTERN, CENTRAL, AND SOUTHERN EUROPE

By the middle of the 16th century Lutheranism was dominant in northern Europe. Wiirttemberg, after the restoration of Duke Ulrich, adopted the reform in 1534. The outstanding Reformer was Johannes Brenz and the great centre Tiibingen. Brandenburg, with Berlin as its capital, embraced the reform in 1539. In that same year ducal Saxony, until then vehemently Catholic, changed sides. Elisabeth of Braunschweig, also in that year, became a convert, but only after long turbulence did her faith prevail in the land. Very significant for the north as a whole was the stand taken by Albert of Prussia, married to a Danish wife and a member of the Polish Diet. He secularized the Teutonic Knights and in 1525 acknowledged himself a Lutheran. In the Scandinavian lands Denmark toyed with Lutheranism as early as the 1520s, but not until 1539 was the Danish Church established on a national basis with the king as the head and the clergy as leaders in matters of faith. Norway followed Denmark. The Diet of Västerås officially declared what had for some time been true, namely, that Sweden was an evangelical state. The outstanding Swedish Reformers were the brothers Olaus and Laurentius Petri. Finland, under Swedish rule, followed suit. The Reformer there was Mikael Agricola, called "the father of written Finnish." The Baltic states of Livonia and Estonia were officially Lutheran in 1554. Subsequently ravished by the Russians, portions of these lands united with Sweden, Denmark, and Poland. Lutheranism survived. Toward the east, Austria under the Habsburgs could enjoy no state support for the evangelical movement, which nevertheless gained adherents. In Moravia, as noted, the Hutterites established their colonies under tolerant magnates.

Eastern Europe offered a seedbed for even more radical varieties of Protestantism, because kings were weak, nobles strong, and cities few, and because religious pluralism had long existed: in a given political area one section might be Roman Catholic, another Orthodox of one variety or another, and in Bohemia the Hussites had gained toleration. Poland acquired a large German Lutheran population when the Danzig area came under Polish control, and a considerable contingent of the Bohemian Brethren migrated to Poland when the Habsburg ruler attempted their extermination. Several of the Polish noblemen adopted their pacifism and would wear only wooden swords. To Poland also flocked the Italian anti-Trinitarians, having been granted an asylum, perhaps merely because they were Italian, by the Italian queen of Poland, Bona Sforza. Named Socinians from their leader Faustus Socinus, they flourished until dissipated by the Counter-Reformation. Much more extensive was the Calvinist influx not only into Poland but into the whole of eastern Europe. This variety of Protestantism appealed to those of non-German stock because it was not German and no longer markedly French, as well as because of its revolutionary temper and republican sentiments. The Compact of Warsaw in 1573 called the ***Pax Dissidentium*** ("The Peace of Those Who Differ") granted toleration to Catholics, Lutherans, Calvinists, and Bohemian Brethren, but not to the Socinians.

In Hungary, the Turkish victory at the Battle of Mohács in 1526 brought about a division of the land into three sections, the northwest ruled by the Habsburg Ferdinand, the eastern province of Transylvania under Zfipolya, and the area of Buda under the Turk. Even before this date Lutheranism had made inroads not only in the German but also in the Magyar sections. Subsequently Calvinism made even greater gains. The anti-Trinitarians found a permanent locus in Transylvania. The weakness of the government and the diversity of religion in this whole area made for a large degree of toleration.

The Inquisition

The Reformation notoriously gained no lasting hold in Spain and Italy. In Spain the main reason grew out of the conflicts of the previous century when the Christians were striving to achieve political, cultural, and religious unification by converting or expelling the unbelievers, the Jews and the Moors. The Inquisition was introduced in 1482 to root out all remnants of Jewish practices among the Marranos, the Jewish converts to Christianity. The non-Christian Jews were expelled in 1492. Then Granada fell and the same process was applied to the Moriscos, the Moorish converts, and the unconverted Moors, after a century, also were expelled. The process had thus far been successful so that early in the 16th century the pressures were relaxed and Spain enjoyed a decade of Erasmian liberalism in the 1520s, but with the infiltration of Lutheranism the machinery of repression again was brought into force.

Italy had no political unity. There were five great city-states, Florence, Milan, Venice, Naples, and Rome. Roman spiritual overlordship alone gave a semblance of unity, and Rome was never servilely followed. In the late Middle Ages sectarian and heretical movements had proliferated in Italy. One by one they had been crushed, and the Italians may well have felt that such rebellions were futile. Another factor was that the friars preached moral rather than doctrinal reform, as Luther had done. A further consideration was that the new monastic orders, the Capuchins, Theatines, and Jesuits, gained papal favour and became a mighty force in counteracting Protestant infiltration, which nevertheless did take place. Venice was a centre, with its branch house of the banking family of Fugger who brought in Lutheranism. Lucca was a centre At Naples the Spanish mystic Valdés, though not a Protestant, expounded a piety of the type of the liberal Catholic reform, and some of his followers were attracted to the movements coming from beyond the Alps. Calvinism gained a hold. But the Roman Inquisition, as above noted, was established in 1542, and those with Protestant leanings either made cloisters of their own hearts in silence, or went to the stake, or crossed the mountains into permanent exile. The most radical theological views of the Reformation were those propounded by the Spanish and Italian anti-Trinitarians.

III. Religious liberty

POLITICAL

Legal recognition of non-Roman Catholics

The question of religious liberty as a political problem has already received frequent notice. Toleration was achieved at first only by groups strong enough to imperil the peace if denied liberty of faith. The first to gain official recognition of the right were the Zwinglians of Ziirich, who after the second war of Kappel in 1531 were not to be molested but were not to expand. The Lutherans gained recognition by the Peace of Augsburg in 1555, the Huguenots by the Edict of Nantes in 1598, the English sects in 1688. In Holland legal restraints on Catholics and Anabaptists were not removed until late in the 17th century, but earlier practice was lax and a commercial city like Amsterdam did not allow dogmatic rigour to hamper trade. On the Continent, the Peace of Westphalia in 1648 was constructed on the same territorial principle as the Peace of Augsburg but included the Calvinists and revised the lines to correspond to what had come to be a fairly stabilized distribution of the confessions.

INDIVIDUAL

Servetus and religious dissent

Individual religious liberty came much more slowly. The political and economic arguments in favour of liberty were chiefly valid only for groups, but the pleas based on the nature of faith cut athwart all persecution. The great toleration controversy in Protestantism was precipitated by the burning at Geneva of Michael Servetus for anti-Trinitarianism and the rejection of infant Baptism. The following year (1554) Sebastian Castellio issued pseudonymously a tract ***Concerning Heretics*** in which he employed the rationalist argument that the doctrines for the rejection of which men were being put to death must be uncertain for the very reason that they were controverted. This left open the possibility of constraint with respect to those doctrines which in that day were assumed to be certain, such as the existence of God and immortality. A further point was that even if these controverted doctrines were true, they need not be believed in order to be saved. A distinction was thus drawn between the fundamentals and the nonessentials. Castellio, following Erasmus, was much more concerned to enumerate the nonessentials than to formulate the essentials. Another proponent of religious liberty, the Italian Jacobus Acontius, said that those doctrines are alone necessary to be believed which are stated in Scripture to be such. He could find only justification by faith and belief on the Lord Jesus. Excommunication should be the only penalty. His two points were taken to exclude the Catholics on justification and the anti-Trinitarians on the Lord Jesus. One recalls that these were the two excluded by Cromwell. Other arguments cut deeper, being rooted in the spiritual rather than the rational. Religious faith is inward and cannot be created by coercion. All that force can do is to provoke revolution in a group or to induce hypocrisy in an individual. Servetus was executed because he told the truth, that is, what he believed to be the truth. Had he lied and denied his conviction he could have been saved. There also were ethical considerations. God is better pleased by deeds than by creeds. In the case of groups, the argument ran that the toleration of error is better than the devastation of the land. Such was the line taken by the party in France called the ***Politiques.***

DOMESTIC

Notice has already been taken of the effects of the Reformation in economics and politics, but in no area were they so great as in the domestic sphere. Since marriage was no longer a sacrament it became a civil contract and special matrimonial tribunals were created. The degrees of consanguinity impeding marriage were repealed. The church in the Middle Ages had at one time excluded marriages to the seventh degree. This was reduced to the fourth in canon law. The Reformers left only incest. Spiritual impediments to marriage were removed. Hitherto, godparents could not marry their children to godchildren, that is to say, without a dispensation. Differences in religion led to a relaxation of the rule that divorce was to be allowed only for adultery. Luther held to this but the Calvinists ruled that if one partner refused to follow the other into exile for religion the bond was dissolved.

Revolution in the concept of marriage

The deepest revolution may well have been with respect to the concept of marriage, because monasticism died out and the home came to be the area ***par excellence*** for the practice of the gentler virtues. The church had solved the discrepancy between man's usual behaviour in society and the precepts of the gospel about nonresistance, love of enemies, sharing of goods, and the like by a vocational division, relegating these injunctions primarily to the monasteries. When these were gone the home may not have become actually more loving but it was exalted as the area for self-effacement, mutual forbearance, and the sharing of goods. An emphasis was placed also, notably in Calvinism, not so much on marriage as a remedy for sin or a device for progeny, but rather as a partnership in the vineyard of the Lord, in the rearing of children in the faith and the advancement of God's Kingdom.

Reformed and Presbyterian Churches

Sharing a common origin in the 16th-century Reformation in Switzerland, Reformed and Presbyterian churches are one of the major representative groups of classical Protestantism. Reformed is the more inclusive term identifying those Reformation churches that are regarded Calvinistic in doctrine, rather than Lutheran, the other major Protestant doctrinal system that arose in the 16th century (in Germany). The term presbyterian designates a collegiate type of church government by pastors and lay leaders who are called elders, or presbyters, from the New Testament term *presbyteroi.* Presbyters rule through a series of representative bodies from the local congregation to area and national organizations, commonly termed sessions, presbyteries, synods, and assemblies. Not all Reformed churches are presbyterian in their form of government, but the churches that use the name Presbyterian are a part of the Reformed tradition.

Meaning of Presbyterian and Reformed

In 1970 over 35,221,000 people identified themselves as being affiliated with Reformed and Presbyterian churches; of these, 15,960,000 were in Europe; 8,441,000 in the United States and Canada; 4,402,000 in Africa; 4,203,000 in Asia; 1,589,000 in Australasia; and 626,000 in Latin America and the West Indies. These figures include neither China nor Reformed groups that are not members of the World Alliance of Reformed Churches, which has about 130 member denominations.

A slogan for the Lutheran Reformation was "by faith alone." Reformed Christians added to that principle "to God alone the glory." Reformed Christians thus emphasized that God's word alone and no mere human opinion should be the norm for faith. Apprehension that something less than God would take the place of God determined Reformed attitudes toward church government and worship, the furnishing and design of church buildings, and secular authority.

HISTORY

The Reformation (1517–1660). The Swiss Reformation leaders were Renaissance Humanists who were inspired by Desiderius Erasmus, a Dutch Humanist, to regard the Greek New Testament as the basis for Christian faith and action. They shared his concern to reform the life of the church and make the Bible available to all.

Zwingli in Ziirich. Erasmian ideas were put into practice in Ziirich in 1519 by Huldrych Zwingli. Later, after Zwingli recovered from the plague with a sense of God's providence in his life, he confided to a friend that the church that had come into life by means of blood could only be resurrected through the spilling of blood. This sentiment went beyond the views of Erasmus, but it also appeared in the views of later Reformers.

A difference of spirit with the Lutherans became apparent in 1525, when Zwingli published a letter of Cornelius Hoen, a Dutch Humanist, regarding the Lord's Supper, interpreting the "is" in the statement "This is my body" to mean "signifies." John Oecolampadius, the Protestant leader of Basel, joined Zwingli in a pamphlet controversy with Luther over the nature of the sacrament. The controversy between Luther and Zwingli led to the Colloquy of Marburg of 1529, in which Philip the Magnanimous, landgrave of Hesse, sought to bring about a consensus between Saxon and Swiss theologians. They reached agreement on 14 out of 15 key points, but, on the issue as to whether the body and blood of Christ are physically present in the bread and wine, they disagreed. The divergence of the Reformed and Lutheran Protestant traditions stems from this issue. When Zwingli was killed in a war between Roman Catholic and Reformed forces at the Battle of Kappel in 1531 and Oecolampadius died shortly thereafter, Luther considered his own position to be vindicated.

Bucer in Strassburg (Strasbourg) and Calvin in Strassburg and Geneva. In the 1530s Martin Bucer, the Reformation leader in Strassburg, saw a need for lay elders chosen from the congregation to assist the pastor in church discipline. Oecolampadius had earlier identified such officials with the presbyters of the New Testament congregations. On the basis of this identification, the presbyterian form of church government was initiated on a congregational level. In debates with Anabaptists, radical Protestant Reformers who stressed a rigid congregational discipline, Bucer conceded that, unless discipline could be maintained, there was no real community.

The civic leaders of Strassburg resisted Bucer's disciplinary measures in 1534. Later, a similar reaction took place in Geneva against John Calvin, who had become the Reformation leader in that city. Forced to leave Geneva in 1538, Calvin became pastor to the French-speaking congregation in Strassburg. There Calvin expanded his famous *Institutes of the Christian Religion,* the first edition of which had been published in Basel in 1536. He also experimented with new forms of worship and discipline. When he returned to Geneva at the invitation of the civil and religious leaders in 1541, Calvin brought with him a developed idea of doctrine, worship, and discipline, which he sought to realize in Geneva. Though his model for the Christian Church and commonwealth was opposed, by 1555 the Reformation in Geneva had been formulated according to Calvinistic principles. Geneva became a centre for Protestant refugees and developed an international training school for pastors. John Knox of Scotland was representative of many who saw in Geneva "the most perfect school of Christ that ever was in earth since the days of Apostles."

Calvin's doctrinal and discipline accomplishments

Calvin sought to bring about a consensus between Lutherans and Zwinglians on the matter of the Lord's Supper. He found value in both of their positions, though he favoured Luther, who, on occasion, spoke favourably about Calvin. When Calvin's friend Philipp Melanchthon lost influence among Lutherans, however, hope of uniting the two traditions diminished. Calvin and Heinrich Bullinger, Zwingli's successor in Ziirich, reached an understanding in the Ziirich Consensus (Latin Consensus Tigurinus) of 1549. The Second Helvetic Confession of 1566, written by Bullinger, became the most widely held Reformed confession of faith, just as Calvin's final edition of the *Institutes* in 1559 became the basic theological text for Reformed Christians throughout the world.

The Reformation in France. In 1555 Calvin turned his attention beyond Geneva. He sent Geneva-trained ministers into the Piedmont, as well as into France, to contact the remnants of the Waldenses, a medieval reform group active mainly in Italy. He also sent pastors trained in Geneva into France, where many new congregations were formed. By 1562 the Huguenots, as French Protestants came to be known, claimed 2,150 congregations with a membership estimated at 3,000,000. After discussions between Catholic and Reformed representatives at the Colloquy of Poissy in 1561, the Huguenots expected toleration from the queen regent Catherine de Médicis. The massacre of a Protestant congregation by the Duc de Guise, however, led the Huguenots to take up arms. The ensuing religious wars reached a climax with the St. Bartholomew's Day Massacre of August 23–24, 1572, when thousands of Huguenots were killed. As a result of the massacre, Philip du Plessis Mornay, a French Protestant diplomat and writer, developed a theory of resistance. He held that, when a monarch persecutes the true religion, he has become a rebel against God, and his people are absolved from loyalty to him.

The Edict of Nantes

A third party, known as the Politiques, included representatives from both Catholics and Huguenots. They believed religious uniformity to be desirable, but, if this was not practical, the welfare of the state should be put above religious interests and the religious minority tolerated. This policy took effect on the accession of King Henry IV, who on April 13, 1598, proclaimed the Edict of Nantes. This edict permitted the profession of Protestantism in many towns and castles south of the Loire River.

Peace ended when Huguenots rose to protest the restoration of Roman Catholicism in the territory of Béarn. Resistance ended in 1628 with the fall of La Rochelle. The Huguenots were no longer a military power.

The Huguenots made a lasting contribution to the development of Presbyterianism. The presbyterian form of church government was organized for the first time on a national basis in France. The national synod of the Reformed Church in France in 1559 planned consistories on the congregational level, colloquies on the regional level, and provincial synods, thus setting the pattern for national Presbyterian organizations in other countries.

The Reformation in the Rhineland. The Reformed cause was advanced in Heidelberg when Frederick III, elector of the Palatinate, took as advisers Geneva-trained Caspar Olevianus (1536–87) and Zachary Ursinus (1534–83). Heidelberg became a flourishing centre of Reformed theology, and there the Heidelberg Catechism of 1562, one of the great international Reformed confessional documents, was produced.

In 1568 the Erastian controversy broke out in Heidelberg, showing that differences over discipline still existed within Reformed churches. A young English student, George Withers, in defending his doctoral theses at Heidelberg, maintained

> that in every church . . . there ought to be a government or discipline observed, whereby the ministry, in conjunction with elders . . . should have the right and authority to excommunicate any vicious liver, even princes themselves.

Thomas Erastus, a Swiss physician living in Heidelberg, insisted that law and order should be maintained by the state and not the church. From his arguments the term Erastianism was coined.

The religious and political struggle in the Netherlands. In 1559, when William I of Orange decided to resist Spanish power, a number of Reformed congregations appeared in the Netherlands. These congregations soon became associated with the cause of Dutch nationalism, especially during the struggle for independence from Spain between 1566 and 1578. Because of this association, the Reformed Church became established once freedom for the Netherlands had been obtained. The early national synods of the Reformed Church of the Netherlands, resembling those of France, adopted the Belgic Confession and the Heidelberg Catechism.

The Arminian controversy

Controversy engulfed the Reformed Church of the Netherlands, however, as a result of the writings of Jacobus Arminius (died 1609), a professor of theology at the University of Leiden who objected to the doctrine of predestination taught by William Perkins, an English theologian. Arminius held that God's offer of grace to man was universal rather than relegated to the elect few and that man was free to accept or reject God's offer. After Arminius' death, men of his party presented a ***Remonstrance*** to the State in 1610, requesting a synod to settle the controversy. The debate that followed polarized elements on all levels of Dutch society until a-synod met at Dort from November 13, 1618, to May 28, 1619. Representatives came from the churches of England, Scotland, and eight of the Reformed churches of Germany and Switzerland. The decision went against the Remonstrants, but, even though forced out of their positions in the official church, the Remonstrants continued as an independent church. The Synod of Dort became the touchstone of Reformed orthodoxy in the 18th century. In Holland the primary spokesman for that orthodoxy was Gisbertus Voetius (died 1676), who did his best to stand firm against every new idea that appeared in the 17th century. He was an important link between English Puritanism and, later, continental Pietism (see also PURITANISM; PIETISM).

In spite of controversy, the 17th century was a period of the flowering of the Dutch republic in culture and in international trade. This commercial expansion makes plausible the Weber–Tawney thesis (formulated by Max Weber, a German sociologist, and Richard Tawney, an English economist) that Calvinism has given rise to the spirit of capitalism.

Reformed influence on the English Reformation. England received its major influx of Reformed influence during the reign of Edward VI (1547–53). Martin Bucer became professor at Cambridge; Zurich-trained John Hooper was named bishop; Dutch and French refugees established the Church of the Strangers along Reformed lines in London; and constant counsel was sought and received by the English from Heinrich Bullinger, Philipp Melanchthon, and John Calvin.

The rise of the Puritan controversy

With the death of Edward and the restoration of Catholicism under Mary I, exiles from England took refuge in Zurich, Basel, Strassburg, and Geneva. In 1558—after Queen Elizabeth I assumed the throne—the exiles returned, with intentions of reforming the Church of England beyond the desires of the Queen. Yet, when the Puritan controversy over the extent of the reform of the Church of England broke out in earnest in the 1570s, men of Reformed persuasion did not necessarily take the Puritan side, which intended to rid England of all vestiges of "popery." The son of John Knox at Cambridge and the grandson of Huldrych Zwingli at Oxford, for example, opposed the Puritans. Bishops siding with Elizabeth considered themselves Reformed theologians, quoting Calvin's works that favoured retaining bishops in the church. Heinrich Bullinger of Ziirich supported the English bishops, many of whom were his personal friends.

The Puritans, during the last years of Elizabeth's reign, were subdued, but they never lost hope of further reformation. They wanted to modify the power of bishops in favour of presbyterian government and the enforcement of discipline in local congregations. Their opportunity came with the outbreak of civil war in 1642 and the calling of the Westminster Assembly of divines (Puritan clergymen) in 1643.

Shocked by the radical developments in the Civil War, Presbyterians and Erastians worked toward the restoration of Charles II as king of England in 1660. They hoped for a restored episcopate that would be broad enough to comprehend the "tender consciences" of Presbyterians and Independents. This did not occur, however, and the latter continued to exist only as Nonconformist sects.

The Reformation in Scotland. Scotland's Reformation dates from the return of John Knox from Geneva in May 1559. The following year the Scottish Parliament adopted the Scots Confession, which was drafted in part by Knox, but it did not ratify the ***Book of Discipline,*** which applied Genevan ideals to a national system. The lay lords accepted those parts of the ***Book of Discipline*** designed to improve the behaviour of the populace but not those limiting their own power. Knox reshaped the medieval episcopal dioceses into ten districts, each with a superintending pastor, but he did not envision a developed Presbyterianism.

Scottish Presbyterianism was promoted by Andrew Melville (died 1622), a theologian and educational reformer who had taught in Geneva. The episcopal system had been restored in Scotland by 1572. In opposing episcopacy backed by the civil powers, Melville fought for church authority parallel to but not subject to the state. Between 1576 and 1584 he made progress with his proposals, but King James VI (James 1 of England) exiled him in 1607. When James became king of England as well as of Scotland, he sought conformity between the churches of the two countries. Episcopacy was re-established in Scotland but with the apparatus of presbytery.

Even under an episcopal form of church government, the Reformed Church of Scotland followed the liturgical ideas of John Knox. Charles I continued the policy of James in using the episcopacy to further royal power. His misunderstanding of the importance of the Reformed liturgy to the Scottish church precipitated the overthrow of episcopacy in Scotland. A prayer book, which many considered a "popish book," was introduced in Edinburgh on June 23, 1637, resulting in an uprising that Charles I was unable to subdue. He then had to concede a presbyterian government for Scotland.

When English Puritans sought Scottish aid in 1643 during the Civil War, the price of the Scots was the adoption of the Solemn League and Covenant, committing English leadership to a church government such as that which existed in Scotland. The beheading of Charles I by the English Independents, who had purged Presbyterians from the government, shocked the Scots, but they could do little against the forces of Cromwell, the leader of the Commonwealth. With the restoration of the kingdom in 1660, Scotland became episcopal once again. Those who remained loyal to the Solemn League and Covenant faced what was called "the killing times," during which the Covenanters were virtually wiped out.

Reformed Churches in Hungary, Bohemia, and Poland. Reformed Protestantism gained headway in Hungary in the 1550s. In 1566 and 1567 the Geneva Catechism and the Second Helvetic Confession were adopted by Hungarian synods, and in 1576 the government of the Reformed Church of Hungary emerged, with superintending bishops chosen by the church councils of pastors and elders. István (Stephen) Bocskay, prince of Transylvania, secured recognition of the rights of the Reformed Church in both Habsburg and Turkish territories in 1606.

Development of Czech Reformed churches

In Bohemia two dissenting church bodies (the Utraquists and Unity of Brethren) remained from the days of Jan Hus, the 15th-century Reformer burned at the stake at the Council of Constance in 1415. In aligning themselves with the views of the 16th-century Reformation, the Utraquists favoured Lutheranism, and the Unity of Brethren preferred the Reformed position. As early as 1540 the Czech Brethren had been in contact with Bucer and Calvin in Strassburg. In 1575 the Brethren and the Utraquists adopted a Bohemian Confession, and the Habsburg emperor Maximilian II guaranteed religious liberty to those who held this confession. Because Calvinist leaders in 1617 feared a revocation of the guarantee, they decided upon resistance. When they threw three agents of Archduke Ferdinand out of a window in Prague on May 23, 1618, they precipitated the Thirty Years' War. This war was absolutely devastating to Czech Protestantism, which was able to survive only in exile or underground.

Poland made a contribution to the Reformed churches of western Europe through the nobleman and Humanist Jan Łaski the Younger (died 1560), who was with Erasmus in Basel in 1523. Refusing a bishopric in Poland, he became superintendent of the church in Emden in 1542 and developed the Frisian Church on Reformed principles. In England, from 1549 to 1553, he was superintendent of the Church of the Strangers in London and in 1556 became a superintendent of the Polish Reformed Church, supervising the translation of the Bible into Polish.

Three Protestant groups attempted to unite in Poland. The Reformed and the Czech Brethren held a joint synod in 1555, and in 1570 the Lutherans joined these in the adoption of the Consensus of Sandomir. As a result of the Counter-Reformation, however, the Reformed Church in Poland was reduced to a small sect in the early 17th century.

The Reformed Confessions of the 16th and early 17th century. Because Reformed churchmen believed that new situations required new responses, a large number of manifestos of the Reformed faith were written. A harmony of confessions, prepared in 1581, indicated that there was agreement both among Reformed churches and with the Lutheran Confession of Augsburg. Some of these confessions were theses for debate, such as Zwingli's *Sixty-seven Articles* of 1523. Others, such as the Zürich Consensus of 1549, sought unity between groups on controversial doctrines. Still others, such as the Heidelberg Catechism of 1563, were intended for the nurture of people through teaching and preaching. The very names of the Geneva, Helvetic, French, Belgic, and Scots confessions indicate a relationship of Reformed confessions to the rising sense of nationhood in the 16th century. Many of these national confessions took on international significance.

Perhaps the most elaborate statement was the Westminster Confession of faith of 1648, produced by the Assembly of divines meeting under the authority of the English Parliament. It became a standard of the English-speaking Presbyterian churches and, on a modified basis, of Congregational churches.

After the Reformation in Europe (1660 to the present). ***France.*** On October 18, 1685, the Edict of Nantes was revoked, and 250,000 Huguenots emigrated from France. After the suppression of the Camisard (French Protestant peasant) revolt in 1715, Protestantism in France seemed at an end. For the survivors, toleration finally came in 1787 and with the Revolution equality under the law. Napoleon placed Reformed congregations under state control, with pastors on state salary.

Revocation of the Edict of Nantes

A national synod did not meet again until 1848. At that time the free Evangelical Synod was organized, separating from the state-recognized church over the issue of state support. In 1905 state support of the old synod was withdrawn, and the two synods were united in 1938. The Reformed Church in Alsace–Lorraine has a different history and remains separate from the Reformed Church of France. Recently, French Reformed Christians have played a notable role in the development of the World Council of Churches, in liturgical and theological renewal, in relating the church to technology and urbanization, and in Catholic–Protestant and Communist–Christian dialogue. Outside of French-speaking Switzerland, they remain the largest Protestant group in the Latin countries of Europe, each of which has a small Reformed Church.

Reformed churches in Germany. The Peace of Westphalia in 1648, ending the Thirty Years' War, established the legality of Reformed churches in German states, according to the pleasure of the ruling prince. The Reformed Christians in the Palatinate faced a systematic attempt at their destruction at the beginning of the 18th century, and many fled to the Netherlands and to America. The Hohenzollern elector of Brandenburg converted to Calvinism in 1609; thereafter, Reformed congregations developed in Brandenburg, and Reformed territories came under the control of its electors. Refugees from France and the Palatinate were invited to settle in Brandenburg.

The Hohenzollerns worked toward union between Reformed and Lutheran churches, and King Frederick William III of Prussia in 1817 proposed completion of this union. The Reformed theologian Friedrich Schleiermacher led ministers in support of the Prussian Union. The Evangelical Reformed Church of Northwest Germany, a result of the Prussian Union, is the largest Reformed Church in Germany today and is a constituent part of the Evangelical Church in Germany.

In 1884 a Reformed League was organized in Germany to preserve the Reformed heritage. Its synod, held at

Barmen in 1934, helped to form the Confessing Church in Germany. The Barmen Declaration, inspired by the theology of Karl Barth, a 20th-century Reformed theologian, became the manifesto for Reformed, Lutheran, Union, and Free churches in opposition to Nazi corruption of the gospel. Though after World War II the Confessing Church ceased to exist, the Reformed League from which it originated is still active.

The Synod of Barmen

Reformed churches in England, Scotland, Holland, and Switzerland. The Glorious Revolution of 1688–89, which expelled the Roman Catholic sovereign James II, left English Presbyterians and Independents with limited toleration outside the state (Episcopal) church. The Toleration Act of 1689 granted protection to all Protestants who accepted the doctrine of the Trinity. In Scotland, however, the state church became Presbyterian. Because of subsequent state interference in the appointment of pastors, several secessionist churches arose in Britain. The Evangelical awakening, a religious revival of the 18th century, brought about a renewed sense of purpose among Christians both within and without the state churches. Membership of churches increased, and new denominations came into being. The free-church spirit changed the Reformed emphasis from concentration upon parish discipline to the support of voluntary societies dedicated to the uplift of the community: to preserve the sabbath, to suppress vice, to abolish slavery, and to work for moral reform.

Evangelicalism in The Netherlands, Switzerland, and Scotland had popular support but could not move ecclesiastical bureaucracies. The resulting conflicts within the churches caused all three countries to experience separatist movements that eventually formed their own ecclesiastical organizations. In The Netherlands, conservative separatist elements formed the Christian Reformed Church in 1869. Migrants to the United States from various Dutch separatist groups united to form the Christian Reformed Church in 1890. A Free Church—based on evangelical principles—was constituted in 1843 in Scotland. Within 15 years it had 1,000 ministers and 800 churches. In Switzerland, in 1845, a Free Church Synod was organized when the state forbade pastors to hold revival meetings.

Reunions of separated churches have occurred in the 20th century, but there has also been a marked decline of influence of these churches among the masses. A theological revival, led by the Swiss theologians Karl Barth and Emil Brunner, enlivened Reformed churches between 1920 and 1960.

Churches elsewhere in Europe. The Reformed Church of Hungary remains the largest Reformed group in eastern Europe. It survived an attempt at extermination under the Habsburgs; toleration came in 1781, and in 1884 equality under the law. Divisions of land after the world wars resulted in large Hungarian-speaking Reformed churches in Czechoslovakia, Yugoslavia, Romania, and the Soviet Union.

In Czechoslovakia some toleration for Protestants came in 1781, and an Evangelical Church of the Czech Brethren was reconstituted on the basis of both Lutheran and Reformed confessions.

The surviving Reformed community in Poland has nine congregations. There are five congregations in Lithuania and one in Latvia.

Reformed and Presbyterian churches in the United States. *In the colonial period.* Reformed influences in what became the 13 original United States were quite noticeable. Persons of Reformed background and Reformed institutions were prominent in directing the course of the colonies in matters of religion, politics, and other areas. Alexander Whitaker, who established churches in Virginia, was the son of a famous English Reformed theologian. On Manhattan Island a Dutch Reformed Church was organized in 1628. Elder William Brewster, of the Plymouth Colony of 1620, used the writings of the English Presbyterian Thomas Cartwright as his guide in church government, and the Massachusetts Bay Colony of 1628 was an attempt at a new model Reformed Church and commonwealth. During the 17th century Waldensian refugees came to Staten Island, and Huguenots settled in New York and New England. These were followed by a Scots-Irish migration that ranged throughout the colonies and by German Reformed refugees from the Palatinate.

Influence of Reformed churches

Varieties of Reformed and Presbyterian churches whose lives were based on the experiences of these various colonists contributed to developing a diversity of religion in the American colonies.

The 18th-century Great Awakening—led by such Calvinist preachers as Jonathan Edwards, Theodore Frelinghuysen, George Whitefield, and Gilbert Tennent—encouraged an evangelical Christianity that was often at odds with traditional church attitudes, and the revival-seasoned leaders learned to fight for the free expression of religious differences. For differing reasons, evangelistic churchmen were able to join with Deists (Rationalists) in supporting religious liberty as a part of the constitutional foundations of the United States.

The 19th century: the Calvinist mold of U.S. life. The new nation's largest denominations were Congregationalist, Presbyterian, Baptist, Episcopalian, and Dutch and German Reformed. Each of these groups had a measure of Reformed tradition and often worked in the same cause. Presbyterians and Congregationalists cooperated in the settlement of the frontier, but Baptists and Methodists adapted better to the frontier and thus became the largest U.S. Protestant denominations. New denominations, such as the Cumberland Presbyterians and the Disciples of Christ, developed among the Western settlements.

A Calvinist viewpoint and pattern of life, favouring constructive activity rather than idle enjoyment, helped shape U.S. habits and ethics. Art, music, literature, and recreation were approved only if edifying. Sunday was viewed as a quiet day with freedom from business cares, minimal attention to farm chores, Sunday school and church attendance, and quiet conversation among friends. Reformed concern for a disciplined community, as interpreted by the Puritans, became a major influence on United States local, state, and national concerns. By its attendance to a proper discipline, the nation might receive the blessing of God and thereby enjoy peace and prosperity.

Presbyterian revivalist Charles G. Finney (1792–1875) saw the fruits of Christian revival in movements for women's rights, abolition of slavery, and temperance. The saving of souls for Christ and the building of a better world were two aspects of the same vision of the Kingdom of God in the United States.

In the 20th century: the breakdown of Calvinist dominion in U.S. Protestantism and U.S. life. After the U.S. Civil War (1861–65) there appeared new kinds of divisions in U.S. religion that made the older denominational distinctions obsolete. Conflict broke out between those who adapted Darwinism (evolutionism) to theology and those who viewed evolution as a threat to biblical authority, between the champions of biblical criticism and those who opposed it. These eventuated in a fundamentalist–modernist controversy that reached its peak in the 1920s.

Conflicts and divisions

In the latter part of the 20th century, the issues producing tensions apparently are focussed on the disagreements between Christians who would relate the churches to the restructuring of society and those who would work for the salvation of individuals. Reformed Christianity traditionally has held the individual and social emphases together, but its ability to continue to stress and to affirm both has been challenged. Another factor affecting Reformed and Presbyterian churches in the United States is the rise in numbers and importance of Roman Catholics, Lutherans, black religious groups, and non-Christian religions. The rising importance of these other religious groups has caused Calvinists to take a more humble place in the U.S. religious procession.

Reformed and Presbyterian world mission. *Asia.* In 1622 a seminary was instituted in Leiden (the Netherlands) to prepare missionaries for the Dutch Asian colonies (now Indonesia). Building upon work begun by

Catholic missionaries, they established a church in Indonesia that now numbers one-third of all Asians belonging to Reformed and Presbyterian churches.

The great century of world mission

The 19th century was the great century for the world mission of Reformed and Presbyterian churches. An ecumenical mission was designed by the U.S. Board of Commissioners for Foreign Missions, which was originally formed by Congregationalists, Presbyterians, and Dutch Reformed. It was decided, after a survey of the Middle East, that the primary task of missions in Muslim lands was to contact the minority Orthodox and independent Eastern churches that did not accept the decrees of the Council of Chalcedon of 451 (*e.g.*, Armenian, Nestorian, and Coptic), in order to strengthen them through fellowship.

The Presbyterian churches of Korea are second in numbers to Indonesia among Asian churches. The work there of missionaries became identified with the cause of Korean nationalism.

In other Asian countries there were missionary heroes, such as Robert Morrison in China and Alexander Duff in India. Churches in those countries, as well as in Japan, the Philippines, and Thailand, formed united churches with other Protestants. The Asian Reformed churches since World War I1 have shared the difficulties of being identified with Western institutions. Anti-colonialism, combined with Communism, had a devastating effect upon the churches of China.

In Africa. Reformed churches in Africa date from Dutch settlement in South Africa in 1652, soon followed by Huguenot and German Reformed refugees. With British occupation of South Africa in 1806, Scots brought Presbyterianism. In the 20th century, half of Presbyterian and Reformed church membership in Africa is in the Republic of South Africa. The Dutch Reformed churches have been closely identified with Boer (Dutch settler) nationalism and with its recent policy of apartheid (separating blacks and persons of mixed blood from whites). Churchmen opposed to this policy have been suppressed by the state.

Other Presbyterian and Reformed churches in Africa date from the early 19th century and are based on the work of such organizations as the London Missionary Society, which sponsored the missionary-explorer David Livingstone. The largest church outside South Africa is in the Malagasy Republic, followed by those in Ghana, Malawi, Cameroon, and Congo.

In other areas. Large Presbyterian churches of Australia, New Zealand, and Canada resulted from British colonization. In Canada the majority of Presbyterians united with Methodists and Congregationalists in 1925. There are many Presbyterians in former British colonies of the West Indies, and Presbyterian churches of Brazil include over half of the Latin American Reformed Christians.

Reformed Christians in the ecumenical movement. Since the time of Martin Bucer and John Calvin, the Reformed movement has had leaders who were untiring in their efforts toward church unity. In the 17th century the Scot John Dury and the Bohemian John Amos Comenius were notable for their ecumenical efforts. Dury's ability to work with both Archbishop William Laud (Anglican) and Oliver Cromwell (Puritan) demonstrated his love of unity.

Efforts toward church unity

The pietism of the 18th century helped to divide churches, but it also tended to encourage people to put aside their differences in pursuit of common goals. Missionary societies received support and sent out missionaries from diverse groups.

The union of individual denominations has proceeded gradually. A Consultation on Church Union in the United States began discussions in 1961 in response to a sermon by Eugene Carson Blake, a Presbyterian leader who became a leader of the World Council of Churches. In 1970 a plan for union known as The Church of Christ Uniting was sent to the member denominations for study, but was rejected in 1973. Included in this consultation are Reformed, Presbyterian, Congregational, Methodist, Episcopal, and Disciples churches.

In 1948, at Amsterdam, most Presbyterian and Reformed churches became members of the World Council of Churches. There are also many national and local councils of churches in which Reformed and Presbyterian churches participate. Since the second Vatican Council (1962–65), called by Pope John XXIII, there has been increased dialogue with Roman Catholics.

THE TEACHING OF THE REFORMED CHURCHES

Doctrines shared with most historic Christian communions. The Reformed churches consider themselves to be the Catholic Church, reformed. Calvin in his *Institutes* speaks of the holy Catholic Church as mother of all the godly. Bullinger in the Second Helvetic Confession makes it clear that Reformed churches condemn what is contrary to ecumenical creeds. The interpretations of the early Church Fathers and the decrees and canons of councils are not to be despised, "but we modestly dissent from them when they are found to set down things differing from, or altogether contrary to, the Scriptures." Universal articles of Christian faith, such as the doctrines of the Trinity, the humanity and divinity of Christ, and the sin of man and the saving work of Christ, are affirmed in Reformed faith.

The Catholic Church reformed

Doctrines shared with other Protestant communions, especially Lutherans. Reformed churches share with Lutheran and other Protestant communions the concept of justification by grace through faith. The essence of faith is trust in God's forgiving love coming as a gift through Jesus Christ. For Reformed Christians, as for Luther, the true treasure of the church is the good news of the grace of God. Scripture is the authoritative witness to the good news, but, as the Westminster Confession states, "authority thereof is from the inward work of the Holy Spirit, bearing witness by and with the word in our hearts." Calvin states: "There is no doubt that faith is a light of the Holy Spirit through which our understandings are enlightened and our hearts are confirmed in a sure persuasion." This is in accord with the Confession of Augsburg of the Lutheran churches.

The church and the sacraments. When Calvin tried to mediate between Luther and Zwingli on the Eucharist, he believed that Zwingli had been more concerned to show how Christ was not present than how he was. Calvin thought that Christians are raised by the Spirit into the presence of the risen Christ in the Lord's Supper.

Both Calvin and Bucer were concerned to keep the profane from unworthily receiving Communion. This influenced the development of church discipline. Some Lutherans developed disciplinary bodies within the church, but Luther himself was opposed to such coercion. The use of elders to oversee discipline within the parish became a prominent feature of Reformed church life. Calvin called such discipline the very sinews of the church.

In the struggle to maintain and extend that discipline after the death of Calvin, his successor, Theodore Beza, asserted that the presbyterian form of government was ordained by Christ. This led to men speaking of the divine right of presbyteries.

Scripture and tradition. Before the Reformation, Humanists rejected arguments that appealed to the authority of church tradition. They raised up the authority of Scripture within the church. Following them, Reformed churchmen insisted that nothing in terms of authority was on a level with Scripture; by Scripture all tradition is to be judged. They were free to quote copiously from early Church Fathers and medieval theologians but only when consistent with Scripture.

Church and state. The position worked out in Basel and Strassburg and put into practice in Geneva was that church and state should render reciprocal service yet remain separate and distinct. The church invisible consisted only of God's elect, and the membership of a particular visible church approximated the actual population of the corresponding state. Beyond their borders such national churches kept communion with each other in spite of differences of custom.

Separation of church and state

Obedience was required of Christians, even to kings viewed as less than good, unless the ruler commanded disobedience to God. On such occasions, man must obey God rather than man, but, even then, the private individual should not actively resist the ruler. The lesser magistrates were responsible to bring such rulers into line. The early resistance of Huguenots in France, John Knox in Scotland, and Puritans in England was justified on this basis.

English Puritans asserted that the government of the state should be patterned after the government of the church. This was one of the doctrinal sources of modern constitutional government, and another source was the Reformed belief that no man should be trusted with unlimited power.

There has been a constant Reformed belief that the kingdoms of this world can be brought closer to the will of God so that there might be a better justice for humankind, and this view involves churchmen in politics.

The sovereignty of God and double predestination. There has been little argument in Reformed theology about the positive side of the doctrine of predestination concerning the election of those whom God wills to save. Difference of opinion arose over whether God himself determines who is to be reprobated. Bullinger did not believe that it was God's will that "one of these little ones should perish." He therefore maintained that Christians should always hope for the best for all. John Calvin affirmed "double" predestination, meaning that both reprobation and election are within the active will of God. His reason found this appalling but scriptural. To call God, thereby, unjust was to judge the very standard of justice.

In his *Institutes* Calvin discussed predestination in the context of the love and grace of Jesus Christ. Later theologians expounded predestination more abstractly as an aspect of God's sovereignty. Arminianism rose in protest to this. The defenders of double predestination thought that Arminianism would cut the nerve of the Protestant doctrine of justification by grace alone and lead men back to popery (Roman Catholicism). Hence, at Dort, double predestination was affirmed as orthodoxy.

Man and society. The sociologist Max Weber and the economist R.H. Tawney attributed the economic vigour of Reformed countries to the Calvinist doctrine of double predestination. Calvinists were thought to be uneasy about their election and looking for outward signs of it. This uneasiness led to a this-worldly asceticism that gradually produced persons such as Benjamin Franklin, for whom pursuit of profit was a way of life. This thesis concerning Calvinism and capitalism has been criticized in detail. Capitalism can also be seen as a late medieval phenomenon that was able to develop in Reformed territory, while the Counter-Reformation stifled it in Catholic lands.

This-worldly asceticism

Real advance took place in Reformed countries not only in the economic area but also in science and technology, democratic institutions, and public education. Present scholarship is looking more to the actual social, political, and economic ideas of the Reformers. The zeal for a disciplined community may have had more to do with the social impact of Reformed Christianity than the doctrine of predestination.

WORSHIP AND ORGANIZATION

Liturgy. Reformed liturgies modified earlier forms of worship by using the vernacular, removing anything that implied the doctrine of sacrifice in the mass (as in Roman Catholicism), providing for congregational confession, and emphasizing the preaching of the word. Following Erasmus' recommendation, the singing of psalms became a characteristic feature of Reformed worship. To this day, there are some Reformed churchmen who are opposed to singing anything else.

Stress on preaching reached its peak among English Puritans. Some clergymen preached two hours on an Old Testament text on Sunday morning, two hours on a New Testament text in the afternoon, and devoted the evening to discussion of the day's sermons with the congregation.

Calvin held that the Eucharist should be celebrated weekly, though others believed that it was too sacred for frequent use. Care was taken to prepare participants for instruction and confession, and they were served around a table.

In the 20th century fresh attention has been given to the relevance of worship to the actual social, psychological, and material needs of human beings, as well as to the need for communicating the word to human hearts and minds. At the Iona Community in Scotland, where worship is directed to those who would work in economically deprived human situations, and at the Taizé Community in France, new forms of worship are being developed. In recent years there has been more emphasis upon celebration in response to the good news of God in Reformed worship and a greater appreciation of the various arts in worship than was true in the past.

Religious education. The requirements of Reformed life have demanded an educated clergy and an informed laity. Besides academic training for pastors, the practice has been for them to meet together frequently, at which meeting a pastor would interpret Scripture and the others join in critical discussion. Queen Elizabeth suppressed the custom in England, because she believed that four sermons a year were quite enough and that gatherings of pastors might be subversive.

The education of the laity was accomplished through preaching the word and teaching the catechism, such as Calvin's ***Little Catechism,*** which was designed for instructing the very young. Others, such as the Larger Westminster Catechism, were to be used to instruct pastors and teachers.

More recently, catechetical instruction has given way to inductive forms of education with emphasis on the age level at which instruction is taking place. There is also a greater concern to relate the Christian faith to the total community in which individuals are involved so that what is learned has direct meaning and relevance to daily life.

Present organization of Reformed and Presbyterian churches. In Presbyterian churches each local congregation is ruled internally by a session moderated by the pastor and composed of laymen (elders) elected from the congregation. A presbytery formed of ministers and elders representing each congregation rules over the local congregations on a district level. In other Reformed churches the district association has less power and the local congregation more than in Presbyterian churches. In a few Reformed churches there is a presiding bishop who moderates the presbytery.

Beyond the district association are regional synods or conferences and national assemblies. These bodies are usually composed of an equal number of clergy and laity. Since 1877, there has been a World Alliance of Reformed Churches, which was joined in 1970 at Nairobi, Kenya, by the International Congregational Council to form the World Alliance of Reformed Churches (Presbyterian and Congregational).

Although a few Reformed organizations are still state establishments, their ties with the state are increasingly tenuous. In practice, there is now little difference between established and free Reformed churches.

Social ethics. Reformation leaders were much involved in the total life of their communities. Calvin's relation to the education, health and welfare services, industry, finance, and politics of Geneva is well documented; and R.H. Tawney, impressed by this, has called Calvin a "Christian socialist." The English Puritans believed that, if they could discipline the nation, God's blessing would come upon the land, instead of war, famine, and pestilence.

Concern to reshape society in the direction of a more just situation for mankind has been normative among Presbyterian and Reformed churches. Sometimes, the actualizing of this concern in the past has resulted in petty rules and harsh administration, but it has also had humane dimensions. Such concern is still a living force among Reformed churchmen, even though they do not intend it in the same way as Calvin or the Puritans.

Types of Reformed piety. In Zwingli, Calvin, William I of Orange, and Cromwell, a classic type of Reformed piety is manifest. Each man viewed himself as God's instrument in redeeming human affairs, even at great cost to himself. In obedience to God, these men disciplined their lives, and they expected others to do the same. Living under God's mercy, they were not afraid of the powers of this world, were men of prayer and action, and were remarkably pragmatic in their choices.

In a less heroic mold was the Reformed churchman who personally did not expect to change history but who encouraged the development of godliness in those about him, beginning with himself. The increasing emphasis in the late 16th century upon the personal experience of saving faith caused the Reformed tradition to become a nursery for pietism in the late 17th and 18th century.

Along with a more confessional orthodoxy and a more rationalistic liberalism, such pietism remains to the present day. A new style of worldly Christianity now seems to be emerging, with Christ, the man for others, as its model.

Current Reformed doctrines and practices. For those who interpret Reformed Christianity as a strict adherence to old confessional standards, there is only a small group of "true Calvinists" left. More influential than these have been Karl Barth, Emil Brunner, John and D.M. Baillie, Hendrik Kraemer, and Reinhold and H. Richard Niebuhr (all 20th-century theologians in the Reformed tradition). They have shown that Reformed doctrine can be stated in a fresh way so that it is alive and active in the 20th century.

CONCLUSION

World civilization gradually has become secularized in the past five centuries: constitutionalism in politics has replaced the divine right of kings; the economic process has been rationalized, and no one advocates a theocratic regulation of commerce and banking; and new scientific models of the universe have supplanted earlier mythological models. Reformed Christianity has not only lived through this secularization, but it bears partial responsibility for it.

The problem of the churches is to relate relevantly to secular men in a secular world. There are still human beings who need a new sense of confidence and hope, and there are institutions that need to be modified. Reformed churchmen continue to work at both tasks: communicating the good news of the Christian faith to those who seek meaning in their lives and attempting to reshape society so that individuals can live more tolerably.

Refrigeration Equipment

Refrigeration implies the development and use of temperatures lower than those existing in ambient space, from the cooling of a beverage with ice to the maintenance of large chilled or frozen storage space, or even the production of the extremely low temperatures of the cryogenic region.

Artificial refrigeration has been known only since the early 19th century and has been in widespread use in homes and industry only since the early 20th. Without refrigeration, most perishable foods would have to be consumed where they are produced, and the transportation of foodstuffs over long distances in chilled or frozen form would be impossible. The manufacture, operation, and maintenance of refrigeration equipment is a major world industry.

Distribution as an indicator of technological development

The distribution of refrigeration equipment throughout the world reflects the varying levels of technological development. In the industrially advanced countries, refrigeration is accepted as an indispensable part of contemporary life. In the less developed countries, refrigeration facilities are often available for the affluent but almost completely lacking for most of the population. Even in these countries, however, limited central refrigeration must be provided for many perishable products that cannot be consumed as soon as they are produced.

Foodstuffs deteriorate less rapidly as the storage temperature is lowered; and, at temperatures below 40° F (4° C), many food products can be kept for days or even weeks without serious loss in quality and appearance. If perishable products must be kept for long periods, it may be possible to freeze them with little loss in character and maintain their quality for periods of six months or longer. The most important causes of food deterioration are the destructive action of bacteria, yeast, and molds, the growth of which is inhibited by low temperature. Refrigeration has made it possible for such meat-producing nations as Australia and Argentina to export much of their output to Britain and western Europe, usually in frozen form.

Refrigeration for comfort cooling has been developed extensively in the United States and is gaining wider acceptance in other portions of the world (see HEATING, VENTILATING, AND AIR CONDITIONING).

HISTORY

Before the advent of mechanical refrigeration, man had to depend on nature for means of cooling. The Greeks and Romans, among other ancient people, transported snow and ice from the high mountain levels to the cities. They also made use of the snow cellar—a cavity dug in the ground, its sides stabilized with boards or logs behind which heavy layers of straw provided insulation. Snow was packed into the cavity, and the top of the snow was covered with straw. So insulated, the snow, usually packed down to solid ice, kept for long periods of time and could be used for refrigeration, at least by those wealthy enough to afford the cost of transportation and of storage.

During the 19th–early 20th centuries, in Europe and the United States, ice was sawed in large blocks from northern lakes in the winter and stored for use during the summer in icehouses constructed either above or below ground. Such ice could be successfully shipped, insulated by sawdust, to the southern United States and the tropics.

Evaporative cooling

In India and Egypt, evaporative cooling combined with night radiation to outer space was long used to manufacture ice. Under clear skies and in a dry climate, if water is placed in shallow earthenware trays on a straw bed, the rapid evaporation from the water surface and from the wet sides of the trays, combined with nocturnal radiation, can result in ice forming in the trays, even though the night air temperature does not fall below the freezing temperature of water. Under certain conditions, only a film of ice is formed; but under other conditions, it is possible to freeze the water into solid blocks.

Prior to the advent of mechanical refrigeration, natural ice or tray ice as described above represented the only means available for the creation of refrigeration. Ice is useful for refrigeration because it has the unique characteristic of always melting and freezing at a fixed temperature, 32" F (0° C); furthermore, when it melts it absorbs an unvarying amount of heat energy per unit of weight. Thus, an area surrounded by or containing melting ice will be refrigerated, or held at a lower temperature. Man learned at an early date that temperatures much lower than that of normal ice melting could be created by mixing salt with the ice. Ordinary salt (sodium chloride), when mixed with ice, can drop the temperature (and the freezing point) of the mixture to −6° F (−21° C); calcium chloride can lower the temperature to −67" F (−55° C). Some liquid organic compounds, such as ethyl alcohol, methyl alcohol, and certain glycols, also lower the freezing point of water.

The first man-made refrigeration, produced by the evaporation of ethyl ether into a partial vacuum, is credited to William Cullen at the University of Glasgow in 1748. Although his procedure involved vapour refrigeration, development of a successful refrigeration machine of this type was not achieved until Jacob Perkins, in 1834, obtained a British patent on a volatile-liquid closed-cycle system using a compressor. Perkins made at least one successful ice machine but did not actively promote his invention.

In 1844 a U.S. physician, John Gorrie, in Apalachicola, Florida, developed a machine to provide ice and air cooling for his hospital. His machine, which operated successfully, was similar to one proposed (but never constructed) by the inventor Oliver Evans in Philadelphia in 1805. Gorrie's machine consisted of a compressor that compressed air, which was then cooled by circulating water. As the air re-expanded in an engine cylinder, it dropped to a sufficiently low temperature to create useful refrigeration for the production of ice or other cooling. The expanded air was then drawn back to the compressor cylinder for compression and recirculation.

The first ice machine

In 1856 another American, Alexander C. Twinning of Cleveland, produced what is believed to have been the first commercial ice by means of a vapour-compression machine. His first patent was taken out in 1850. James Harrison, who emigrated from Scotland to Australia in 1837, became interested in refrigeration. After surveying the machines of Gorrie and Twinning, he developed the first vapour-compression machines for use in the brewing industry and for freezing meat for shipment. Harrison's machines, which were produced for several decades, used ethyl ether as the refrigerant.

A second type of refrigeration machine was developed in France in the 1850s by Ferdinand Carré. In Carré's system the refrigerant, normally a vapour, as in the vapour-compression machines, is absorbed in a suitable liquid. This solution is heated, driving off the refrigerant as a vapour, which is then condensed. Evaporation of the liquid, in a manner very similar to that in the vapour-compression system, produces the desired cooling. This refrigerant vapour is again absorbed in the liquid, thus completing the cycle.

Carré's first machines employed water as a refrigerant with sulfuric acid as an absorbent, but in 1859 he introduced ammonia as a refrigerant with ammonia–water as an absorbent. This successful combination was used widely throughout the world. Some of Carré's machines passed through the Federal blockade during the American Civil War and supplied the Confederacy with much-needed ice when the supply of natural ice from the northern United States was cut off.

The basic principles on which refrigeration machines operate were thus developed by 19th-century inventors. Subsequent inventions involved only modifications and improvements in the machines and processes.

Improvements in vapour-compression refrigeration using ammonia hinged largely on the development of successful compressors in the last half of the 19th century. Efficient ammonia compressors gradually edged out the air-cycle machine, and vapour-compression refrigeration came to predominate. As a vapour-compression refrigerant, however, ammonia had a number of disadvantages, the most important being that it was toxic and extremely objectionable when breakage or other sources of leakage occurred. This meant that it was undesirable for use on shipboard and in places where air cooling for comfort was required. The search for refrigerants that were nontoxic, had no odour, and could perform effectively in conventional equipment led to the use of carbon dioxide; a major objection, however, was the fact that the pressures required for its use were extremely high. In addition, carbon dioxide, although not toxic itself, is lethal in high concentrations, because it excludes oxygen and interferes with the regulatory breathing system of man. In the 1920s a group of synthetic refrigerants known as halogenated hydrocarbons was developed. It was found that by starting with a hydrocarbon such as methane (CH,), it was possible to substitute two chlorine and two fluorine atoms for the four hydrogen atoms and produce a new chemical (CCl_2F_2) with highly desirable properties as a refrigerant. This new chemical was called dichlorodifluoromethane and was named refrigerant-12. It was essentially nontoxic, had no odour, and could exist in the air in concentrations as high as 18 percent, by volume, without lethal effects. It was also found to have refrigerant properties resembling ammonia and to perform well in compressors. The early halogenated-hydrocarbon refrigerants were licensed by one company and carried the name of Frwn, with an appropriate numerical designation.

Once the basic patents expired, these refrigerants were made freely throughout the world by many chemical-manufacturing companies. These substitution-type halogenated-hydrocarbon refrigerants can be based on molecular structures other than methane, and a broad range of special-purpose refrigerants is now available. The two additional ones that are most important at the present time are monochlorodifluoromethane, $CClHF_2$, also known as refrigerant-22, and trichloromonofluoromethane, CCl_3F, known as refrigerant-11. Refrigerant-22 operates at higher pressure than refrigerant-12 and is suitable for the production of lower temperatures because of its high-pressure characteristics. Refrigerant-11 is extremely desirable for use with centrifugal compressors in which it operates in a low-pressure range, often in the vacuum region. Refrigerant-22 and refrigerant-1 1 are slightly more toxic to humans than refrigerant-12 but are used extensively.

Refrigerant number

The numbers used with refrigerants represent an internationally accepted designation system, originally adopted by the American Society of Heating, Refrigerating, and Air-Conditioning Engineers.

TYPES OF REFRIGERATION SYSTEMS

Modern mechanical refrigeration. For continuous mechanical refrigeration, the same refrigerant must be repeatedly used for an indefinite period. Three patterns for doing this are now in common use: the vapour-compression system, the gas-expansion cycle, and the absorption system. Of these, the vapour-compression system is by far the most effective and is used more extensively than any other arrangement. It consists basically of three elements: an evaporator, a compressor, and a condenser. The vapour-compression-system cycle is very similar to the air-compression-system cycle described later.

Referring to Figure 1, in the evaporator the refrigerant boils (evaporates) at a temperature sufficiently low to absorb heat from a space or from a medium that is being cooled. The boiling temperature is controlled by the pressure maintained in the evaporator, since the higher the pressure, the higher the boiling point. The compressor removes the vapour as it is formed, at a rate sufficiently rapid to maintain the desired pressure. This vapour is then compressed and delivered to the condenser. The condenser dissipates heat to circulating water or air. The condensed liquid refrigerant, now ready for use in the evaporator, is then sharply reduced in pressure by passing through an expansion valve: Here, the refrigerant's pressure and temperature drop until they reach the evaporator pressure and temperature, thus allowing the cycle to be repeated.

During expansion some of the liquid flashes into vapour so that a mixture of liquid and flash vapour enters the evaporator. In a refrigeration system the low pressure in the evaporator is set by the refrigeration temperature which is to be maintained. The high pressure maintained in the condenser is determined ultimately by the available cooling medium; *i.e.*, the temperature of circulating water or the atmospheric air temperature. The process is one in which the refrigerant absorbs heat at a low temperature and then, under the action of mechanical work, the refrigerant is compressed and raised to a sufficiently high temperature to permit rejection of this heat. Mechanical work or energy supplied to the compressor as power is always required to raise the temperature of the system.

Compressors. The compressor, the key element of the system, can be powered by electric motor, steam or internal-combustion engine, or steam or gas turbine. Most compressors are of the reciprocating (piston) type and range from the fractional-horsepower size, such as those found in domestic refrigerators or in small air-conditioning units, to the large multicylinder units that serve large industrial systems. In these large multicylinder units, capacity can be controlled with automatic devices that prevent the valves in certain cylinders from closing. For example, in a six-cylinder unit, if the valves are held open on two of the cylinders to keep them inoperative, the capacity of the machine is reduced by one-third when operating at normal speed.

Centrifugal compressors are used for large refrigeration units. These employ centrifugal impellers that rotate at high speed. Centrifugal compressors depend for their compression largely on the dynamic action of the gases themselves as they flow in the diffusion passages of the compressor (see also PUMP). These compressors can be large centrifugal compressors made with a single impeller, or with two to four or more impellers in series, to compress the gas through the range required. Centrifugal compressors are built for capacities ranging from approximately 600,000 BTU per hour to over 12,000,000 BTU per hour (50 to 1,000 tons). These are used extensively for large air-conditioning installations, and also find usage in the industrial field when gases are compressed for liquefaction or for transportation, such as in the natural-gas industry, and when air is compressed to produce liquid oxygen or nitrogen.

Evaporators. The evaporator is the part of a refrigeration system in which the cooling is actually produced; the liquid refrigerant and vapour from the expansion valve are introduced to it. As it vaporizes, the liquid absorbs heat at low temperature and cools its surroundings or the medium in contact with it. Evaporators may be direct expansion—that is, acting directly to cool a space or product---or they may operate as indirect-expansion units to cool a secondary medium, such as water or a brine, which, in turn, is pumped to a more distant point of utilization. A domestic refrigerator, for example, is a direct-expansion unit in that its evaporator directly cools the air in the food compartment and also directly contacts the water trays used for making ice. Evaporators vary greatly in design, with those used for cooling air often made as continuous pipe coils, with fins mounted outside the pipes to give greater surface contact to the air being chilled. For cooling liquid, such as a brine or water, the shell and tube arrangement is common. In this, the brine passes through tubes surrounded by the boiling (evaporating) refrigerant, which is contained in a larger cylindrical shell. The brine tubes, in turn, are welded or rolled into tube sheets at the shell's end to prevent leakage of the refrigerant from the shell or into the brine circuit.

The expansion valve that feeds the evaporator must control the flow so that sufficient refrigerant flows into the evaporator for the cooling load but not in such excess that unevaporated liquid passes over to the compressor, with the possibility of causing damage to it.

Condensers. The condenser of a vapour system must dissipate heat from the hot vapour it receives from the compressor and condense this vapour to liquid for reuse by the evaporator. Condensers either dissipate heat to the ambient atmosphere through externally finned surfaces or by a shell and tube arrangement in which the vapour delivers heat to circulating water that passes through tubes contacting the refrigerant vapour. The temperature of the vapour is kept above that of the circulating water or air by compression to insure that heat is transferred to the coolant; thus, when the vapour is allowed to expand, its temperature drops well below that of the coolant.

Double-pipe condensers are also used. In such units the refrigerant vapour and condensate pass in one direction through the annular space between the two tubes, while the water, flowing in the opposite direction through the central tube, performs the cooling function.

Air-cycle refrigeration. This type of refrigeration came into extensive use before the nontoxic halogenated-hydrocarbon refrigerants were developed. In this system the refrigerating medium, instead of operating at two essentially fixed temperatures, operates over a range of temperature. In the conventional arrangement the same air is continuously circulated. This makes possible a plant of smaller physical size, because the air is compressed at all stages of the cycle, and, with dry gas charged into the system, moisture does not create a problem.

Adapted from B. Jennings, *Air Conditioning and Refrigeration*

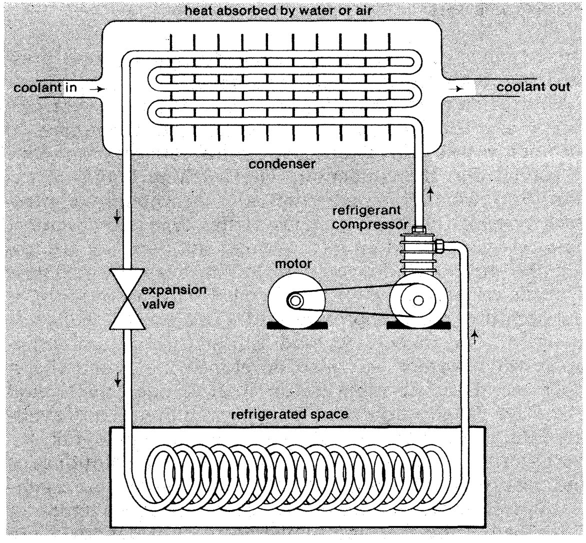

Figure 1: Elements of a vapour-compression refrigeration system.

Operation of the closed-air-cycle system somewhat resembles that of the mechanical system just described. Air from the chilled space enters the compressor, where it is compressed; this process also raises the temperature. The hot compressed air then enters the water-cooled heat exchanger, which corresponds to the condenser of a vapour system. Here the air is cooled to **a** temperature only a few degrees warmer than the inlet-water temperature. The cooled compressed air then enters the expander engine, where, in expanding, both the temperature and the pressure are lowered.

Systems used in aircraft

Air-cycle refrigeration systems of the nonclosed type are used in many modern commercial aircraft for air-conditioning the cabin. Here, a small part of the air, partially compressed by the main power compressors of the aircraft, can be cooled by circulation of high-altitude ambient air over the compressed-air coils. The compressed air, when expanded in an expander turbine, drops enough ın temperature to be used to chill the cabin air. Such a system for aircraft is effective and lightweight because it makes use of air already compressed by the power compressors. Representative values for an aircraft system show that the expander turbine can readily lower the temperature of the compressed air supplied to it by 100" F or more, so that with 100" F (38" C) air entering the turbine, 0° F (–18° C) air becomes available. This cold air is mixed with sufficient reduced-pressure warm air from the compressor system to temper it, and the

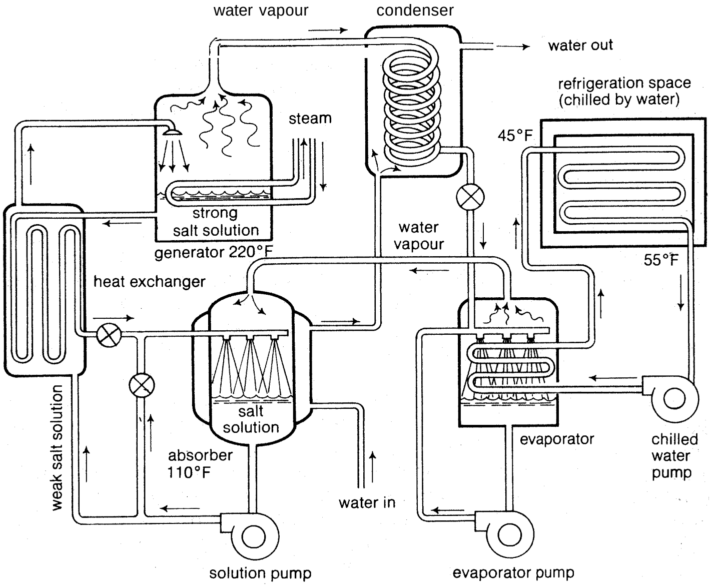

Figure 2: Absorption system using aqueous solution of lithium bromide with water as the refrigerant.

mixed air is delivered to the cabin for cooling and pressurizing to a satisfactory value for the flight altitude.

Absorptionrefrigeration. In this method the refrigerant is absorbed in a chemical solution, then pumped to another vessel. There, on heating, the refrigerant vapour is forced into the condenser. The resulting liquid on expansion lowers its temperature as in the vapour-compression system. Industrial systems of this type use ammonia as a refrigerant and ammonia–water solutions for absorbing the ammonia delivered from the evaporator. These systems can operate over an extended range of evaporator temperatures from approximately —40" to 40° F (—40" to 4° C) or higher. A modification of the ammonia-absorption system was also developed for use in heat-operated domestic refrigerators and, at one time, found extensive usage where heat energy was more readily available than electricity. Another type of unit employing water as a refrigerant, with lithium bromide salt solutions for the absorption medium, has found wide use in air conditioning. Even though these units cannot produce temperatures below the freezing temperature of water, they are very effective for the 38" to 58° F (3° to 14° C) range required for air-conditioning use.

An ammonia–water system is effective in its operation because water will absorb large quantities of ammonia vapour, the amount absorbed increasing with the external pressure and decreasing with rising temperature. The absorber operates at about evaporator pressure and is supplied with a cooled solution of water–ammonia having a low concentration of ammonia. This weak solution absorbs ammonia gas until the liquid becomes almost saturated with ammonia. The heat created during the absorption process is then removed by cooling water. The ammonia-laden solution is pumped through a heat exchanger into the generator. The generator employs steam or another heat source to boil off ammonia until the solution is reduced to a saturated condition (low in ammonia) at generator pressure and temperature. The ammonia vapour from the generator moves over to the condenser, where it is condensed; and then, as liquid, it passes through the expansion valve into the evaporator. The hot, weak solution from the generator passes through the heat exchanger, where it cools in warming the strong liquid and is again throttled into the absorber to absorb ammonia vapour from the evaporator.

Absorption units in air conditioning

Absorption systems for air conditioning use water as the refrigerant and a water–salt solution as the absorbent, with lithium bromide salt having the widest acceptance. In a vacuum system, the vapour pressure of an aqueous solution of concentrated lithium bromide is so low that, when an evaporator supplied with water is connected to a vessel in which such a salt solution is being circulated, the water evaporates to produce cooling. For example, the vapour pressure of a 61 percent (by weight) lithium bromide solution has a vapour pressure of 0.27 inch (6.86 millimetres) of mercury (Hg) at 110" F (43" C). This vapour pressure is sufficiently low to cause water to evaporate (boil) at 43° F (6" C).

The diagrammatic layout of such a system is shown in Figure 2. The absorber is supplied with a slightly cooled solution, high in salt concentration (about 65 percent), that will absorb the water produced in the evaporator as the cooling takes place, ultimately producing a chilled product at approximately 45° F (7° C). The salt solution in the absorber, when it absorbs the water vapour, changes it to liquid and in so doing releases the latent heat of condensation along with some heat of mixing. Such cooling must be provided for the absorber to keep it below the 110" F mentioned above for effective operation. The salt solution from the absorber, now greatly diluted by the water added, is pumped through a heat exchanger on its way to the generator. In this vessel the temperature of the solution is increased to about 220" F (104" C), and the surplus water is driven out of solution by heat from the steam supply. The water vapour that is given off passes to a condenser in which it is condensed back to water, and from the condenser the water can then be throttled into the evaporator. A circulation pump is required at the evaporator to distribute the liquid water over the coils to promote better evaporation. Similarly, recirculation is also used in the absorber to improve the absorption process. In the generator, with the temperature of the solution at 220" F, the vapour pressure is approximately three inches (75 millimetres) of mercury absolute.

Thus, the system described operates at a generator–condenser pressure of three inches of mercury and an evaporator–absorber pressure of 0.27 inch of mercury.

The Peltier effect

Thermoelectric refrigeration. Thermoelectric refrigeration came into prominence only during the 1960s, when the unusual characteristics of semiconductor materials showed a sufficiently satisfactory performance to justify commercial usage. The useful effect for refrigeration is the so-called Peltier effect, observed in France in 1834 by Jean Peltier, who noticed that, if an electric current was passed through junctions of two dissimilar metals, one junction cooled. If the current was reversed, the junction heated; or, to complete the picture, if two such junctions were included in a circuit, one junction always cooled, while the other junction heated. The use of properly doped semiconductor materials, such as bismuth telluride (Bi_2Te_3), for the junction materials gave this method of refrigeration commercial significance (see also THERMOELECTRIC DEVICES).

Many such junctions can be placed in series and attached to a plate in such a manner that heat is absorbed on the cold side, producing useful refrigeration, while heat is dissipated on the other side. Modules can be designed in functional forms and shapes to meet the needs of the particular application. The performance of such a system is far from ideal, however, because the junctions must be made short to decrêase electrical resistance and to decrease the cost of materials. Such shortening increases the transfer of heat through the assembly and thereby offsets some of the useful cooling. In any specific application, a compromise must be made to achieve optimum characteristics. Although the Peltier effect is the important phenomenon in cooling, the closely related Seebeck effect is more easily measured and is used to indicate the thermoelectric performance of semiconductor materials.

APPLICATIONS

Household refrigerators and freezers. Household refrigerators normally employ a vapour-compression system, with the motor and compressor mounted in a hermetically sealed container. In such a unit, refrigerant leakage from the system is minimized; most domestic units go through their complete life without the need of additional refrigerant charge or change of lubricant. The evaporator serves to cool the storage space for food supplies and usually is set to maintain this space at a range of 33° to 45° F (1° to 7" C). The evaporators of most units are also equipped to freeze water into ice cubes. Many domestic units also provide, in the evaporator section, a low-temperature storage compartment for holding foods in frozen condition, with the temperature controlled between −10" and 20° F (−23" and −7° C).

Domestic home freezers are usually designed to maintain a temperature range of −10" to 10° F (−23" to −12" C), a range in which foodstuffs remain in a frozen state and can be kept for extended periods. The home freezer usually employs a vapour-compression system, with a compressor delivering the refrigerant to an air-cooled condenser. The liquid refrigerant from the condenser passes through an expansion valve to the evaporator, which carries out the useful cooling for the freezer. One problem with domestic refrigerators and freezers is that ice (frost) collects on the coils and must be removed periodically. This requires the application of sufficient heat to the coils to melt the ice, which can be done automatically at timed periods, usually by bypassing hot condenser gas to the evaporator coils or by the rapid addition of heat from electrical resistors. Usually, the time required for melting (defrosting) is so short that the product does not warm up to the point of damage.

Defrosting

Cold-storage warehouses. Cold-storage warehouses usually have rooms that store frozen food and others in which the food is only chilled. The storage life of nonfrozen products is improved by keeping the temperature as close to 32" F (0° C) as possible without actually freezing. Some vegetable products can tolerate temperatures slightly below 32° F and not suffer damage; but others, such as lettuce, are extremely sensitive to freezing and must always be kept slightly above 32° F. Bananas must not be chilled below 55° F (13" C), or the ripening process stops. Cold-storage warehouses usually have a central refrigeration plant of the vapour-compression type in which the evaporator cools a salt or glycol brine; the brine is pumped to the various storage rooms, where it flows through coils to hold the room at a required temperature. Frozen-food rooms operate frequently in the range of −20" to 0° F (−29" to −18° C). It is more desirable, however, to maintain a temperature with a minimum of variation.

Refrigerated transport. Refrigerated products are moved over long distances by specially insulated trucks and railroad cars. Many of these involve the operation of a complete refrigeration system driven by a gasoline or diesel engine. Others employ liquid nitrogen or Dry Ice (frozen carbon dioxide) to provide the cooling.

Ice making. During the early part of the 20th century, the commercial manufacture of ice was a major industry. The ice was usually made in cans holding about 300 pounds of water, from which the ice was removed in blocks for cutting and distribution. Some commercial ice is still made in blocks, but most frequently it is broken up into small pieces—for example, for distribution over green produce and other food products prior to shipment. Large amounts of ice for this purpose are also made in small cube for·m or in cylindrical tubes that are broken into useful sizes. Ice is also made in chip, flake, or slush form by freezing it onto a surface and scraping it off.

Air conditioning and other uses. Air-conditioning systems use refrigeration equipment to produce the required cooling. Refrigeration for public buildings can be produced in large central plants from which the cooling is distributed either as chilled air or as chilled water, pumped to the points of utilization. Residence air conditioning may also make use of a central refrigeration plant and distribute the cooling to various areas of a house, either by air or chilled water. In addition to central systems, extensive use is made of unit air-conditioners, which, when placed in a window, dissipate the heat load from the compressor to the outside and, using a separate fan, distribute chilled air from the evaporator to the inside space. Unitized-space conditioners are also used, placed completely within the air-conditioned space. These house the whole refrigeration system but always require a means of heat dissipation, such as a circulating water supply or an air circuit to the outside (see also HEATING, VENTILATING, AND AIR CONDITIONING).

Refrigeration is also used for many other purposes, such as chilling drinking water by means of a unit mounted in a drinking fountain. In medical practice, refrigeration is required to store biological and other temperature-sensitive materials and is also employed for direct chilling of patients in cases in which, under certain circumstances, by lowering the deep-tissue temperature of the body, the life-process rates can be slowed down to permit carrying out certain types of surgical operations or to reduce the speed with which a disease might spread throughout the body.

Freeze-drying

Lyophilization (freeze-drying) is used to preserve certain delicate chemicals, biologicals, or tissues. In this process the material is rapidly frozen, and under high-vacuum conditions the water is removed by subliming it to the vapour phase while the material is still frozen. During lyophilization the cell structures of many materials are maintained essentially intact, and the character of the basic product is preserved; while in others the form changes to that of a powder, but the character is unaltered. The process is necessary for certain extremely delicate materials, but the process is also being applied to foodstuffs for commercial use. Meat, for example, can be lyophilized into a material with spongelike appearance that, when reconstituted by the addition of water, has much the same character, taste, and form as the original material.

Refugees

A refugee, according to the 1951 statute of the Office of the United Nations High Commissioner on Refugees (UNHCR), is any person who, "owing to well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence, is unable or, owing to such fear, is unwilling to return to it." The definition offered in 1951 by the Intergovernmental Committee for European Migration (ICEM) included an additional broad category: any person who "has been the victim of a war or a disaster which has seriously disadvantaged his condition of living."

This article will apply the more circumscribed and concise definition offered in Elfan Rees' ***We Strangers*** and ***Afraid*** (1959) : that a refugee is "anyone who has been uprooted from his home, has crossed a frontier—artificial or traditional—and looks for protection and sustenance to a government or authority other than his former one." The operative terms of this definition are first, "uprooted," indicating a forced departure from the home country, as distinguished from a migratory movement that is essentially the result of differential population or economic pressure, and, second, having "crossed a frontier," denoting the difference between a refugee and a person displaced (mostly temporarily) within his own country (an internal refugee). The misery of internal or national refugees is real and urgent, but they belong to a category of their own whose origin, plight, problems, and prospects are different from those of international refugees.

THE NATURE OF THE REFUGEE PROBLEM

Historic forces. Man's story is in large measure the story of his wanderings. Throughout recorded history, invasions, wars, and conquests were followed by large-scale movements of populations. The so-called Great Peoples' Migration in the wake of the fall of Rome involved multitudes of human beings driven away from their home countries by invading hordes. By AD 900 the chain of "great migrations" had come to an end, and Europe's various tribes had settled in their respective areas. The continent entered a "sedentary" era. But within the new ethnoterritorial framework, the forcible removal and flight of religious groups has, since medieval times and especially since the Reformation, constituted a constant and important element in social and economic history of the European continent. Expulsions of Jews from western Europe, Catholics from Protestant countries, and Protestants from Catholic states are examples.

At a time when state frontiers were less clearly defined and jealously guarded than they are now, the movement from one country to another did not require passports and visas; the right to asylum, which for a refugee is a corollary to the right to life, was commonly recognized and honoured. As a result, although there were numerous waves of refugees in earlier centuries, there was no refugee problem. Avenues of escape were narrowed only with the emergence of fixed and closed state frontiers characteristic of the late 19th and of the 20th century and with the complete control of the globe by sovereign nation-states. The era of open frontiers was over.

The era of intolerance

The lines of sovereignty have become drawn ever sharper. The value apparently placed on national and racial homogeneity has inspired intricate networks of immigration restrictions in areas in which freedom of movement had been unimpeded for centuries. This "new order" has created a huge category of uprooted people facing immense, often insuperable difficulty in finding a temporary asylum, let alone a new home, outside of their regular habitat. Ethnic, religious, and political minorities have been persistently—and increasingly—singled out as objects of intolerance, discrimination, and persecution on the part of the government or public of the countries they have lived in, often irrespective of how ancient and deep were their roots in these countries and how willing they were to assimilate completely into the cultural and social fabric. A classical case in point were the 600,000 Jews in Germany who were deprived of citizenship and property, deported, or forced to flee Hitler's Third Reich.

By the 1920s and 1930s the long-standing tradition of political asylum had broken down completely, partly because of growing insensitivity to human suffering and partly because of unprecedented numbers of refugees. Existing mechanisms of immigration and naturalization, which had been adjusted to a smaller, "normal" influx of people, ground to an actual standstill.

The worldwide nature of the refugee problem. In modern times each great upheaval casts up its own living jetsam—the fugitives, the expellees, the homeless ones, more than 40,000,000 of them since World War II. The "Age of the Uprooted" and the "Century of the Homeless Man" have become common labels to describe the first half of the 20th century. The concurrent assumption that the problems of the world's uprooted and homeless multitudes are so great as to be altogether insoluble does not, however, appear to be justified. It is a fact that by 1966 the number of uprooted persons the world over had been reduced to 11,000,000. But between the years 1967 and 1970 there was a new upsurge; by the end of 1970, a total of 18,173,011 refugees were counted by the United States Committee for Refugees; they were spread over more than 80 countries of Africa, Asia, Europe, Latin America, and North America. Their numbers declined by some 2,470,000 during 1971, however, and despite the enormous numbers displaced by the India-Pakistan war, the total was reduced to about 15,700,000. These millions became refugees in stages, group by group. Each refugee entity, while it bears some similarity to other groups, is unique. The reasons for displacement differ in each case, as do the circumstances of asylum and the opportunity for resettlement and integration.

TYPES OF REFUGEES

Refugees from advancing armies. The military, political, and ethnic convulsions of the 20th century have sent millions of uprooted and dispossessed swarming over the earth. World War I (1914–18), the Chinese-Japanese War (1937–45), World War II (1939–45), and their aftermaths triggered movements of populations far exceeding in scope the sufferings caused by mass displacements in previous centuries. Some of them were of a temporary and transient nature, such as flight from advancing or occupying enemy armies: Belgians fleeing from the German invaders; refugees from German-occupied provinces of France, Italy, and Romania; Turks from Greek-conquered eastern Thrace and Smyrna; and so forth. When peace was restored, most of these wartime refugees, as a matter of course, returned to their former homes.

Greek and Turkish refugees of 1923

Refugees expelled or evacuated by political authorities. The collapse of the Greek invasion troops in Turkish Asia Minor in September 1922 caused 1,000,000 of the area's indigenous Greek population to flee to Greece. A Greco-Turkish convention concluded in 1923 at Lausanne legalized the newly created situation, providing at the same time for the compulsory transfer to Greece of the surviving 189,000 Greeks in Asia Minor and for a compulsory transfer of the 355,000-strong Turkish minority in Greek Macedonia and Ípiros (Epirus) to Turkey. This exchange of minorities—a border case between a mass flight of desperate refugees and organized, government-supervised transfer—served as a pattern for other similar arrangements.

World War II refugees

During World War II and after, many peoples in eastern and central Europe were thus exchanged: Bulgarians, Romanians, Czechs, Slovaks, Ukrainians, Russians, White Russians, Germans, Poles, Hungarians, and so on. In February 1946, for instance, Hungary and Czechoslovakia agreed on a voluntary exchange of their respective ethnic minorities involving the transfer of 31,000 Magyars to Hungary and of 33,000 Slwaks to Czechoslovakia. The inhabitants of the Karelian Isthmus in Finland had the sad distinction of experiencing the refugee plight three times. When, in March 1940, defeated Finland was forced to cede Karelia to the Soviet Union, 415,000 Karelians left for Finland proper; in June 1941, Finnish troops recaptured the region, and some 305,000 started the return trek; Soviet Russia reconquered and incorporated Karelia in 1944, and the returnees for the third time became refugees, moving to their hard-tested homeland.

Political refugees. Politically motivated refugee movements, frequent in modern times, have been occurring intermittently since the earliest development of state entities powerful enough to oppress nonconformist minorities. The Russian Revolution of October 1917 and the postrevolutionary civil war (1917–21) caused the exodus of 1,500,000 opponents of the regime. Scattered throughout France (400,000), Germany (300,000), Poland (400,000), the Baltic States (100,000), parts of the Far East (100,000), and the Balkan countries, they refused to return to their Communist-ruled home country.

More than a million Armenians were deported or fled from Turkish Asia Minor to Russia, the Middle East, the Balkan States, and North and South America between 1915 and 1923; a million and a half are estimated to have been massacred by the Turks or to have perished as a result of forcible deportation.

Four to five hundred thousand Spanish Loyalists poured into France to escape the newly established regime of General Franco in the wake of the 1936–39 civil war. At first, able-bodied men of military age were sent back; later, they were admitted and interned in refugee camps. Those who had fled primarily from military action were repatriated to Spain after the end of hostilities. Many migrated to North Africa, Mexico, the Dominican Republic, and Latin and South American countries.

Following the abortive Hungarian Revolution of October 1956 and the subsequent Soviet occupation, some 203,000 Hungarians, mostly members of the liberal professions and skilled technicians, fled the country. In an unusual display of international concern and assistance, 172,000 of them were speedily and successfully resettled by the end of 1958 (18,000 eventually chose to return to Hungary). Between 1945 and 1961, when the Communist regime erected the Berlin Wall, a total of 3,700,000 political refugees from East Germany found asylum in West Germany. From 1961 until June 30, 1969, only 128,000 crossed the border illegally. Now, scarcely 20 people a month escape to West Berlin.

After 1960, some 750,000 Cubans—nine percent of Cuba's population—left their country and the regime of Fidel Castro; some 608,000 now live in the United States. Of the 450,000 registered as immigrants to the U.S., 380,000 had been, by the end of 1971, resettled in communities in all 50 states of the Union and Puerto Rico, 280,000 as resident aliens and nearly 100,000 had acquired U.S. citizenship. Some 48,000 Cubans found refuge in other countries, mostly Spain, where they are trying to obtain visas to the U.S.

When the People's Republic of China was established in 1949, some 2,000,000 Chinese, remnants of Chiang Kai-shek's army and civilians, escaped to the island of Taiwan, 121 miles off the mainland. Other sizable groups of refugees, totalling 340,000, went to such places as Burma, Vietnam, Japan, Laos, India, and Macau. The overwhelming majority, however, found sanctuary in the British Crown Colony of Hong Kong, just across the borders of mainland China. Together with early Chinese refugees who had left southern China before the advance of the Japanese armies, their number amounts to 2,065,000. The take-over of Tibet by People's Republic of China in 1959 resulted in the flight to India, Bhutan, Sikkim, Nepal, and Macau of 76,000 Tibetan refugees.

Ethnoreligious refugees. For many centuries, the refugee phenomenon was a corollary of religious and racial intolerance. Entire ethnoreligious entities were uprooted, exiled, or deported by secular or religious authorities in an effort to enforce conformity. In 1492 Spain expelled 150,000 Jews, who found asylum mainly in Turkey, Holland, and North Africa; 400,000 Huguenots had to leave France after the revocation of the Edict of Nantes in 1685 and found refuge in England, Germany, Holland, and South Africa. In the 1930s, as a result of the Third Reich's anti-Jewish policies, 400,000 Jewish refugees in all fled (1) from Germany proper (283,000), (2) from Austria (95,000), and (3) from the Sudetenland (23,600).

Israeli Jews

More than 50,000 Jewish refugees from Yemen were transported to Israel by "Operation Magic Carpet" in 1949–50, which had constituted almost the entire Jewish community of Yemen; all 7,700 Jews of the British colony of Aden fled, mostly to Israel, in 1947–60; 123,000 Jewish refugees were airlifted from Iraq to Israel in 1950–51; of the 29,770 Jewish nationals of Syria (as of 1943), more than 80 percent left the country as refugees to Israel, the United States, and Latin America. It was announced in mid-1969 that 97 percent of the Jewish population of Yemen, Aden, Iraq, and Syria had found asylum in Israel.

Refugees from territorial realignment. Several major refugee movements were caused by the partition of existing territorial entities. Defeated in World War II, Germany was compelled to disgorge all the territories she had gained since 1938; in addition, 117,000 square kilometres (about 44,300 square miles) of prewar German territory, with a prewar population of nearly 10,500,000, were detached and placed under Polish and Soviet administration. The Potsdam Conference in 1945 authorized the compulsory "transfer to Germany of German population or elements thereof" from Poland; authorization for the compulsory transfer of their respective German minorities was also given to Czechoslovakia and Hungary. Without applying for Allied approval, the Romanian government deported 165,000 ethnic Germans, and the government of Yugoslavia expelled 150,000. A total of some 12,000,000 refugees and expellees were dumped on the truncated territory of Germany, split into the Federal Republic of Germany (West Germany) and the German Democratic Republic (East Germany).

Hindus and Muslims

The partition of the Indian subcontinent in 1947 resulted in the two-way flight of 18,000,000 Hindus from Pakistan and Muslims from India—the greatest population transfer in history. With a dual religious and communal background, it is still continuing: between 1962 and 1971, 1,032,000 Hindus were reported to have been evicted from Pakistan, while 260,000 Muslims had reportedly fled or were evicted from India and Kashmir. Eight to ten million persons were temporarily made refugees by the creation of Bangladesh in 1971.

Palestine's partition in 1948 triggered an almost wholesale exodus of Palestinian Arabs in the wake of the military-political confrontation between the newly established state of Israel and the five neighbouring Arab states. The number of Arabs who had actually left the territory of Israel at that stage was variously estimated as between 419,000 (by Jewish sources) and one to two million (by Arab spokesmen at the United Nations).

Another major determinant of recurring refugee waves resulting from territorial realignments was the liquidation of European colonial possessions in Africa and Asia. The stream of British subjects from all parts of these continents—of French refugees from Morocco, Algeria, Tunisia, and Indochina; of Italians from Libya; of the Dutch from Indonesia—was a by-product of the progressive disintegration of the vast British, French, Italian, and Dutch colonial empires. The emerging independent regimes were intent on the speediest possible elimination of what they consider personified "vestiges of colonial domination." In one way or another, life became, or was made, unbearable for the European "colonials," even though many were second- or third-generation settlers, with deep roots in the local economy. In the North African countries, this trend engulfed not only nationals of the former colonialists but all resident minority groups of European origin. Tens of thousands of Greek and French refugees from Egypt, of Greek refugees from Sudan, of Italian refugees from Tunisia indicate that in the Arab-Muslim states along the Mediterranean coast and in parts of black Africa no room is left for communities that are neither Arab nor Muslim. A similar phenomenon has recently become noticeable in regard to the millions of people of Indian ancestry in several countries of Asia and Africa whose forebears had lived there for generations but who are now being compelled to "return" to India, leaving behind their family businesses and possessions.

Africa entered the orbit of refugee movements in the 1960s, becoming by 1963 a major centre of refugeeism, deserving particular attention because of the novelty and diversity of its refugee problems. In the past, black Africa's peoples moved freely within their often ill-defined tribal areas in search of game, more fertile soil, or forage for their herds. Existing national boundaries were no handicap for such intermittent or seasonal movements. But with the emergence, in the late 1950s and early 1960s, of several sovereign African states, these boundaries—arbitrarily traced lines on the map, often cutting across traditional tribal grounds — became barriers to population movements. They were jealously watched and often aggressively defended. To most Africans the notion of a modern nation-state with often artificial boundary lines is, however, still alien and incomprehensible. It is extremely hard for them to adjust to the new realities imposed by modern political developments. Many African refugees, cast adrift by this underlying incongruity, were abruptly thrust from an almost prehistoric way of life into new patterns of society totally unfamiliar to them. The situation in most African countries, the "to and fro" of warfare and revolution, is so volatile and precarious that additional refugee waves have to be considered a continuing probability. The power struggle in some new states, generated by an interplay of internal and external forces and tribal animosities has to be seen against the background of hunger, hope, remnants of colonialism, and great power tensions. Refugees in Africa increased from 860,000 at the end of 1968 to 1,858,000 by 1971.

Black Africans

The states represented in the 38-member Organization of African Unity (OAU) have shown a remarkable degree of goodwill and understanding for the rights and interests of their respective refugees. The Conference of Heads of State and Government of OAU, meeting in Addis Ababa in September 1969, approved a Convention Governing the Specific Aspects of the Problem of Refugees in Africa. One of the convention's key provisions established the principle that "no person shall be subject by a Member State to measures such as rejection at the frontier, return or expulsion which would compel him to return or to remain in a territory where his life, physical integrity or liberty would be threatened." It was the first time that such a principle had been enunciated in a binding international legal instrument. A second valuable innovation was the stress on the necessity of handling refugee problems in a peaceful and humanitarian spirit. The convention specifically enjoined a refugee from engaging in any subversive activity against any member state of the OAU while obliging the countries of asylum to prohibit refugees from attacking any member state through subversive activities, "especially through arms, press and radio." It also provided that "for reasons of security, countries of asylum shall settle refugees at a reasonable distance from the frontier of their country of origin."

THE CONDITIONS OF REFUGEE MOVEMENT AND SETTLEMENT

Refugees on the move. Only in a few exceptional cases have displaced refugee groups been able to reach their respective destinations speedily and with a minimum of hardship. In general, most refugees are traditionally on the move for long periods of time and under the most trying circumstances.

In April–May 1945, in the final phase of World War II, for example, more than five million Germans rushed from the provinces of Silesia, East Prussia, East Brandenburg, and the German-occupied West Polish areas to escape the advancing Soviet and Polish armies. They dragged along with them horses, cattle, and cars, packing the roads and fighting their way across the Oder River. In the summer of that year, after the conclusion of military operations, large numbers of these refugees began remigration through the still open frontiers to their abandoned homes. In the winter months of 1945 and in 1946–47, the entire German population of the former German eastern provinces was forcibly expelled in accordance with the Potsdam decision of the Big Three. The aggregate number of casualties during this three-stage, back-and-forth mass movement was variously estimated as between one and two million.

Similar, in 1947, was the plight of the 18,000,000 Hindu and Muslim refugees fleeing to their respective national countries. Mostly on foot, they were on the move for extremely long periods, flooding every highway, road, and cow path linking Pakistan with India. Some of their caravans were giant, unwieldy columns of hundreds of thousands of people, crawling for weeks at the slow pace of the bullock carts and herds of cattle. Casualties — killed outright or dying from starvation and exhaustion — were estimated to be nearly 10 percent of the total.

Displaced persons' camps. In the wake of World War II, hundreds of thousands of refugees and displaced persons, deported by the Germans or fleeing from the advancing Soviet armies, were housed in Allied-supervised camps, mostly in Germany, Austria, and Italy. By March 31, 1946, the UN Special Committee on Refugees and Displaced Persons estimated their number at 1,100,000. That the total figure remained the same in September 1947, in spite of repatriation and an initiated resettlement, was due to the influx of Jewish refugees from the east. The 100,000 Jewish displaced persons who lived in the camps at V-E Day became 250,000 in 1947; departures were offset by a high birth rate.

The situation in the camps grew increasingly strained. Morale declined and patience ran thin among people uncertain about the possibility of their resettlement. Many Jewish camp inmates took recourse to illegal immigration into British-occupied Palestine. Of those intercepted by the Royal Navy, 51,500 were put behind barbed-wire in hastily improvised new special camps on the island of Cyprus. The emergence of the state of Israel in May 1948 opened the channels of migration to Jewish displaced persons. By the spring of 1959, only 21,000 hard-core refugees remained in the European camps.

Vietnamese

But such camps are still very much in evidence in Asia. As late as June 1969, the large majority of refugees in South Vietnam were housed in temporary shelters, which are loosely described as "camps." Their number was estimated by a committee of the U.S. Senate to approach 4,500,000 in mid-1972. Many of them, having been among the 900,000 who left North Vietnam at the time of the partition in 1954, have become refugees for a second time. As a result of Arab-Jewish hostilities in June 1967, some 350,000 Arab refugees were newly displaced and fled to east Jordan, Syria, and the United Arab Republic. Some 130,000 of this total were already refugees from the 1948 conflict and were uprooted for the second time; new tented and hutted camps had to be hastily established to house them.

Refugee resettlement. The bulk of the refugees resettled since the end of World War II were integrated by their respective conational governments. In nearly all cases, the theme was basically "do-it-yourself." The U.S. Marshall Plan aid to Germany and the massive UN financial assistance to South Vietnam and South Korea were applied to the general recovery of these countries devastated by war; nonetheless, such aid has but indirectly facilitated refugee integration. In 1960 Pakistan's President Mohammed Ayub Khan pointedly noted that his country had received 9,000,000 Muslim refugees from India as compared with only "three-quarters of a million refugees from Palestine" in Arab lands; his people had had to face the problem themselves without "substantial support from Muslim brethren over the world." Similarly had India, while accepting some aid from many private organizations the world over, borne the major burden of rehabilitating its millions of refugees. As a rule, there was little or no direct contribution on the part of the international community for the specific purpose of refugee rehabilitation and resettlement.

The sole exception is the Palestinian refugees in Arab countries who have been the wards of the international community for more than two decades. They are commonly considered to be the only refugee group firmly resisting integration. Backed by the governments of the Arab host countries, they insist on return to Israel as the only solution to their problem.

Rehabilitation and integration of refugees

Integration of refugees in the countries of their resettlement, no matter how advanced, is, however, in no way equivalent to the restoration of their previous economic, occupational, and social status. The very idea of "integration" is by definition relative. Economic recovery does not equal genuine rehabilitation, any job does not necessarily mean integration. Among those employed are many whose new status is lower than their predisplacement level and whose income compares unfavourably with what it used to be. Most refugees had to start working in poorly paid jobs in fields not to their liking; many who had worked independently have had to accept salaried positions. This was especially the case of middle class refugees —the fortunate exceptions being members of the free, liberal professions such as medicine, law, and pharmacy.

The character and pace of the integration process largely depend on the general standard of life in the receiving country. In such highly developed countries as The Netherlands, Great Britain, the United States, West Germany, and France, even a successfully integrated refugee group usually needs much time and luck to reach a position approaching that of the natives. In underdeveloped countries, on the other hand, where the majority live in poverty, the lowest common denominator is attained more speedily and easily, the initial discrepancy between refugee and native being almost unnoticeable.

Refugees in a new culture. Refugees resettling in countries with a culture different from their own have always faced problems of adaptation to an unfamiliar way of life and to an alien language and culture.

Many post-World War II refugees in Europe were survivors of concentration camps and slave labour. Their emotional state was a mixture of bewilderment, anxiety, and shock, combined with gratitude for deliverance and an intense desire to shake off the past and make good. Resettlement took two principal forms. One was group resettlement under organized programs conducted by individual governments and by the International Refugee Organization; during the IRO's first year of operation (July 1, 1947 to June 30, 1948) 156,925 persons were brought to 73 countries, mostly to Great Britain, Canada, Belgium, and the United States. The other form was individual resettlement, whereby the IRO, in consultation with voluntary agencies, arranged immigration for individuals and small groups of refugees (a total of 47,652 for the same period). Those arriving as individuals usually felt utterly lost in the new surroundings; they had to begin rebuilding their lives on their own, from scratch. For many, the process of acculturation was painfully slow. In the initial stages most of them understandably tended to settle in the neighbourhoods of earlier immigrants from the same countries of origin and to seek employment in identical or similar professions. Organizations of former fellow countrymen were often instrumental in finding them jobs or dwelling accommodations. This attachment to existing ethnocultural communities mitigated the new arrivals' feeling of loneliness and smoothed the first stages of their economic adjustment, yet it also had a retarding influence on their assimilation.

REFUGEES AND THE WORLD COMMUNITY

International and intergovernmental agencies. Paul Weis, a UN expert on refugee matters, has drawn attention to the fact that though the refugee problem is as old as history, international action for refugees did not start until after the Russian Revolution.

League of Nations

In 1921 Fridtjof Nansen of Norway was appointed by the League of Nations as high commissioner for Russian and Armenian refugees and devised a so-called League of Nations Passport ("Nansen Passport"), a travel document recognized "in principle" by 53 states. It restored their identity to its beneficiaries and made them somewhat less vulnerable to arbitrary action by the authorities of the countries of their sojourn. After Nansen's death in 1930, the protection of refugees was entrusted by the League to the Nansen International Office for Refugees, established as an autonomous body with a mandate to wind up its functions by 1938. In 1933, consequent to Nazi racial persecution, James G. Macdonald was appointed the League's high commissioner for refugees, largely concerned with Jewish and other refugees from Germany. He resigned after two years because of lack of cooperation from the League's member states; his successors were restricted to purely legal protection of the refugees, and their efforts were just as fruitless.

In an attempt to substitute planned migration of refugees for their chaotic dispersion, President Franklin D. Roosevelt of the United States, in July 1938, invited 32 governments to a conference at Évian, France. Only the Dominican Republic, however, offered to admit 100,000 refugees for rural settlement; no other country responded. Nevertheless, an Intergovernmental Committee on Refugees (IGCR) was organized, with a seat in London, to look for new areas of settlement for nonrepatriable refugees; its efforts proved to be unsuccessful.

A conference of 44 nations, convened in Washington, D.C., in November 1943, resulted in the signing of the charter of a new international body, the United Nations Relief and Rehabilitation Administration, whose main task was postwar reconstruction of devastated areas, as well as help for and repatriation of uprooted people, both refugees and displaced persons. By the time of its dissolution in 1947, UNRRA had repatriated nearly 7,000,000 anti-Nazi and anti-Fascist refugees, but there still remained, in 920 refugee camps of Europe, a hard core of 1,600,000 unrepatriables of 52 nationalities; a count made in 1964 revealed that 95 percent of the camps' remaining small populations did not want to be repatriated.

IRO

In 1947, both the IGCR and the League's high commissioner were replaced by a nonpermanent specialized agency of the United Nations, the International Refugee Organization (IRO), whose mandate expired in 1952, while there were still in Europe alone some 15,000,000 unsettled refugees. On the initiative of the United States, 16 nations met in Brussels in December 1951 and set up the Intergovernmental Committee for European Migration (ICEM), which was not to be a UN agency but would be "responsible for the movement of migrants, including refugees, for whom arrangements could be made with the governments of the countries concerned." By 1971 the number of sponsoring nations in ICEM reached 31. Since the beginning of its operations in 1952, ICEM has processed and moved 1,775,000 European refugees to resettlement countries of their choice. Member governments have contributed nearly $400,000,000 for ICEM's activities. Particularly successful was its handling of the sudden refugee influx in the wake of the Hungarian Revolution in 1956: within six months after the first refugee crossed the Austrian border, ICEM had moved over 160,000 Hungarians to all parts of the world.

UNHCR

In 1950, shortly before ICEM was created to take care of the refugees' transportation and resettlement, the Office of the United Nations High Commissioner for Refugees (UNHCR) was established to ensure the legal and political protection of refugees previously under IRO mandate and to promote permanent solutions to their problems. By ensuring that he is not sent back to the country of his origin against his will, the UNHCR is enabling the refugee freely to choose either to return voluntarily to his country of origin, to remain permanently in the country of first asylum, or to resettle in another country depending on the possibilities made available by governments. Sixty-seven of the UN member-states support the UNHCR financially, but the agency budget is still inadequate.

In addition to these bodies dealing with the general problems of refugeeism, several regional agencies have been established. To provide for the needs of Arab refugees from Palestine, the UN General Assembly in December 1949 established the United Nations Relief and Works Agency for Palestine Refugees (UNRWA), which began operations in May 1950. In 1951 the United Nations Korean Reconstruction Agency (UNKRA) was founded, and in March 1952, the U.S. Escapee Program (USEP), with a central office at Geneva, was set up to assure for escapees from behind the Iron Curtain adequate opportunities in the free world.

Nongovernmental voluntary agencies. All international or intergovernmental agencies established on behalf of refugees were conceived as temporary organizations to deal with each refugee problem as it arose; consequently, international agencies have succeeeded each other frequently. The only ***permanent*** relief work has been conducted by the numerous voluntary agencies, national and international, which have become increasingly active in the last several decades. Their permanency enabled them to pursue and attempt to conclude the tasks that the ephemeral intergovernmental bodies were unable to complete. By the end of 1947, the IRO had concluded agreements with 128 voluntary organizations belonging to three major categories. First were denominational organizations that extended support to refugees of their own faith, such as the National Catholic Welfare Conference, the World Council of Churches (for Protestant refugees), the American Jewish Joint Distribution Committee, the Jewish Agency for Palestine, and the Hebrew Immigrant Aid Society (HIAS). Second were the worldwide nondenominational organizations such as the International Red Cross, the International Social Service, the International Rescue Committee, the Organization for Rehabilitation and Training, and the YMCA. Third were a number of private organizations, mostly national groups, working almost exclusively on a local scale. In Korea alone in 1970, there were 77 private organizations from 13 countries spending the equivalent of $13,000,000 a year to sustain programs of wide variety.

In 1962 the International Council of Voluntary Agencies (ICVA) was formed. By 1969 it had a membership of some 100 organizations and a central bureau in Geneva. In November 1969, there convened in Washington, D.C., a National Conference on World Refugee Problems, which attempted (1) to arrive at a common definition of the term refugee and of the criteria for determining needs and services; (2) to design patterns of interagency cooperation in refugee assistance programs; and (3) to elicit citizen participation in overseas assistance programs.

The problems of assimilation. In pre-World War II Europe and during the early postwar years the world over, a refugee's two major predicaments were (1) his practically extralegal status as a "stateless person," living on sufferance in his countries of refuge, and (2) his sojourn in an ethnically and culturally alien milieu. This twin disadvantage is now endured by only a minority, though a sizable one, of the refugee mass; as late as June 1962, a tabulation by the United States Committee for Refugees established that about 200,000 persons were still stateless in Europe, as against nearly a million in 1957; the bulk of the stateless in Asia comprised the 1,270,000 Chinese from mainland China, the 70,000 Tibetans, and the 532,625 Palestinian refugees in Syria, Lebanon, and the Gaza Strip; there were 320,000 stateless Africans in the Congo, Burundi, Tanganyika, and Togo; 175,000 Cubans were at that time stateless in the Western Hemisphere—a total of 2,567,625.

UN Convention relating to the Status of Refugees

The 1951 United Nations "Convention relating to the Status of Refugees," which granted a minimal legal status to refugees falling under the terms of that instrument, by January 1972 had been ratified by 62 states; in a number of other countries, the question of accession was under consideration; the United States was still withholding ratification.

The rights granted to refugees under the convention can be divided into (1) those relating to the refugee's needs as a member of the community of his country of residence and (2) those relating to his specific status as a refugee. The first group of rights involves the exercise of religion, economic pursuits in general, wage earning and independent employment, taxation, public relief, the acquisition of property, education, civil rights (access to courts), and freedom of movement. To the second group belong the personal status of the refugee (legal capacity, family rights, succession and inheritance), the delivery of documents relating to his personal status (which cannot be obtained from his native country), the issuance of identity and travel documents, treatment of refugees who enter or reside unlawfully in a country, the possibility of their expulsion, the question of their naturalization, and the exceptional measures taken in time of war or other emergency against nationals of the country of which the refugee was, or formally may still be, a citizen. Despite all the recent improvements, however, the situation of the residual stateless refugee is still abnormal and unenviable.

The predicament of statelessness was spared the great majority of the 40,000,000 people who became refugees during the period after 1945. The 18,000,000 Hindus and Muslims involved in the postpartition exodus from India and Pakistan suffered greatly; yet they enjoyed from the very beginning, in both countries, the security of full citizenship and the protection and encouragement of the respective conational state in which they found a new life, not on sufferance but as of right. Full citizenship rights were also granted to the 12,500,000 expellees in Germany, the 400,000 Karelians in Finland, the 250,000 Indonesian Dutch repatriates in Holland, the millions of refugees from North Vietnam and North Korea, the more than a million Jewish refugees in Israel, the 1,060,000 refugees from North African Arab-Muslim states in metropolitan France, and 300,000 Italian repatriates from the provinces of Dalmatia and lstria ceded to Yugoslavia. Of the Palestine Arabs on UNRWA's relief rolls, 989,000 were in 1967 full-fledged citizens of Jordan.

Apart from statelessness, the other common feature of the refugees' classic plight was that they usually arrived defenseless and helpless in a strange country with a strange language and other customs, the bewildered guests of embarrassed hosts who had no obligation toward them except that dictated by common humanity. Yet every refugee group enumerated above went to a country with whose people they were linked by common language, religion, and customs. In the words of Elfan Rees, they have all found asylum among their own kind:

> They are strangers but not among a strange people. Community of language, faith, culture, and social organization provides a cushion that both minimizes the shock of exile and increases the chance of assimilation.

Major waves of refugees have rarely been officially welcomed in the countries of refuge, however—the only exception being Israel, for whom the "ingathering of the exiles" is a national policy. The more than a million refugees from mainland China were a nearly unbearable burden for overcrowded, British-governed Hong Kong, and sporadic attempts were made to stem their influx forcibly. But even when the newcomers were ethnic brethren of the resident population (as was the case with the eastern Germans expelled to Germany, the Algerian French returned to metropolitan France, and the Dutch repatriates from Indonesia in The Netherlands), there was noticeable initial friction between the incoming refugees and the local residents. The West German government strongly resented the imposed necessity of accepting and resettling millions of forcibly expelled Germans from Czechoslovakia, Poland, and Hungary; it considered that the decision of the Potsdam Conference made the Big Three, which endorsed this compulsory transfer, morally and politically coresponsible for the refugees' predicament. There was also initial bitterness in both India and Pakistan in the wake of the frantic two-way stream of refugees, although both governments eventually accepted the new states of affairs created by the de facto exchange of population. After the first shock subsided, there was no talk about the return of the Hindus and Muslims to their previous homes. The national efforts were fully concentrated on their resettlement and integration, on abolishing their refugee status. "Do you intend to go about all your lives with the word 'refugee' inscribed on your foreheads?" Prime Minister Jawaharlal Nehru admonished India's new citizens. "This word connotes dependence and helplessness—the sooner you get rid of it the better."

A refugee who has reached his chosen country of resettlement legally has ceased to be a "refugee," both in law and in fact: his status and problems, for all practical purposes, have become identical with those of an immigrant admitted on a regular consular visa. Only refugees who have settled among people of their own culture and ethnic nationality have sometimes been singled out for special preferential treatment. In countries of mass immigration (such as the United States, Canada, and Australia) they have been treated, on the whole, not better and not worse than the average immigrant.

Refuse Disposal Systems

The term refuse refers to solid wastes, and the two are used more or less synonymously to describe those discards of society that are not liquid or gaseous in nature. Solid-waste management is the development and operation of refuse disposal systems designed to handle community refuse in a healthful, economic, and conserving manner. The amount of solid wastes produced can be correlated to the output of goods and services; in the late 1970s the United States, which consumed nearly half of the world's annual production of industrial raw materials, produced more than 600,000,000 tons of solid wastes each year, excluding wastes from agriculture and mining. Inclusion of wastes from agriculture and mining increases the total more than sevenfold (see Table 1).

A comparison of the average output of refuse per family (3–4) per week in eight countries is shown in Table 2.

Table 1: Solid Wastes in the United States (1977)

waste source	amount (lb/capita/year)*
Municipal	
Residential, commercial, and institutional	1,340
Sewage sludge	46
Automobiles and construction demolition	410
Industrial	3,330–3,680
Radioactive	0.4
Mining and milling	21,210
Agricultural	23,030–30,640
Utility (electrical)	710
Total	50.076–58,036

*1 pound = 0.45 kilogram
Source: U.S. Environmental Protection Agency, *Solid Waste Data,* 1981.

These figures indicate the effect of degree of industrialization on family refuse, entirely apart from the waste contributed by industry itself.

The character of refuse varies considerably. The ash content of refuse in the United Kingdom is 20–30 percent, whereas in the United States it ranges from 5 to 20 percent. Paper and paper products constitute by weight about 30–50 percent of the U.S. and Canadian household refuse, and in Europe they reach as much as 40 percent.

Table 2: Generation of Household Refuse per Family per Week

country	weight (pounds)*
Canada	48
Czechoslovakia	46
France	37
Israel	31
Poland	26
Spain	29
United Kingdom	35
United States	53

*1 pound = 0.45 kilogram

There are three environmental depositories for society's discards—the air, the water, and the land. Air and water pollution control has historically been based on control or treatment of effluents discharged into the air or water. There has been little effort in the past to control the production of solid waste. Rather, control programs have centred on methods to salvage that part economically feasible and to reduce the remainder by burning or compaction to minimize transport costs and the environmental space required to harbour it.

Problems of solid-waste management

Refuse collection and disposal is nearly universally regarded as a responsibility of local government and as a major public health and welfare service. Improperly handled refuse serves as a breeding ground and food supply for flies and rats. The former practice of feeding raw garbage to swine has been shown to be a link in the transmission of trichinosis to humans. Outbreaks of the virus disease of swine, vesicular exanthema, which is similar to foot-and-mouth disease, have resulted in the requirement that garbage fed to swine be heat-treated and that the practice of raising hogs on garbage dumps be discontinued. Heat treatment of garbage has been required in the United Kingdom since the early 1900s.

Most communities in Europe and the United States no longer permit leaf burning. Smoke and odours from open burning dumps and particulate matter from stacks of improperly designed or operated incinerators are sources of pollution. Furthermore, rubbish has been found to be a significant factor in causing fires in buildings.

Improper disposal of refuse has resulted in pollution of surface and ground water. Indiscriminate dumping in pits or on river banks is not uncommon. A problem particularly acute in the United States is the littering of highways and roadside areas. Materials jettisoned in the United States have been estimated to comprise a bulk of 20,000,000 cubic yards (15,300,000 cubic metres) annually.

Besides population growth, a number of other factors have contributed to the world's increased solid-waste problem: design of products leading to accelerated obsolescence; higher real income resulting in the increased manufacture and sale of consumer items; and packaging to improve sales appeal, prolong shelf life, and reduce marketing cost per unit.

The refuse collection and disposal function is ordinarily grouped with other municipal sanitation operations as a major department of local government. Traditionally, collection and disposal service has been oriented to a single-city institutional arrangement. In most metropolitan areas political fragmentation is a serious problem. Regional groupings have been suggested as an avenue of improvement, particularly for the disposal function.

MODERN COLLECTION AND DISPOSAL METHODS

Most cities require household garbage be well wrapped and stored in durable, easily cleaned containers with tight-fitting covers. Ashes are stored in metal containers. Plastic or paper bags as container liners have come increasingly into use, particularly in commercial food preparation areas and institutions. Many new multiple-dwelling units are equipped with refuse compaction systems. A pneumatic pipeline refuse transport system, first installed in a high-rise development in Stockholm in the late 1960s, has come to be used widely in Europe.

Dustless systems

Collection and disposal in urban areas. In some urban commercial areas bulk containers are mechanically lifted into large compactor-equipped trucks for transport to the disposal site. In Europe, because of the ash content of household refuse, service provided by some municipal authorities features dustless systems, wherein heavy metal containers are mechanically dumped into the collection vehicle through a tight-fitting portal designed to accommodate standard bins. A decrease in the ash content, however, has resulted in greater use of smaller, lighter containers, including plastic bags.

Household refuse collection in both the United Kingdom and the United States is generally characterized as a combined collection of household food wastes and rubbish from containers placed at the house line, alley, or curb. Loading is done by hand, but research has been undertaken to reduce labour requirements through increased mechanization. Household refuse collection vehicle design incorporates a rear-, front-, or side-loading closed metal body equipped with a mechanically or hydraulically operated compaction plate to increase the load capability. This has become more important as travel distances to disposal sites have increased, and in many large cities transfer of refuse from neighbourhood collection vehicles to long-haul vehicles, which can carry 60 or more cubic yards of compacted refuse to disposal facilities, is not uncommon. In most of the world household refuse-collection systems are operated by local government authorities. By contrast, in the United States private contractors and private systems provide almost half of the household and the majority of the commercial and industrial service. Frequency of collection varies from daily to less than once per week. Reported collection costs vary widely, depending on such factors as haul distance, type of service, climate, and wage levels.

Incineration. Combustible wastes may be reduced to inert residue by high-temperature burning. An incinerator is composed of a furnace into which the refuse is charged and ignited, a secondary combustion chamber in which burning at a high temperature is continued to complete the combustion process, and flues wherein the gases of combustion are cleansed as they are conveyed to a chimney and thence to the atmosphere. Incinerator plants also include facilities for unloading and storing refuse for short periods, to permit uniform charging of the furnaces, and a building to house the incinerator appurtenances.

The growth of large cities has been primarily responsible for the development of refuse incinerators because it was not practical from nuisance, public health, and aesthetic viewpoints to permit refuse dumps in their midst. The burning of refuse provided an efficient means of inoffensively reducing the bulk of the refuse (about 95 percent by volume) to a readily transportable and often usable ash. Municipal refuse contains a great variety of combustible items; some require special treatment before processing through a conventional incinerator, and air pollution agencies have come to regulate the use of such incinerators. Bulky refuse may be preprocessed by size reduction through such equipment as shredders, hammermills, and impact mills. Many special incinerators have been designed for bulky refuse. Hazardous and obnoxious wastes, such as highly volatile dusts and flammable liquids, are also usually disposed of in specially designed plants.

Size reduction

On-site incineration of combustible refuse is an economical method for many industries, apartment dwellings, and large commercial establishments, as well as in certain instances for householders. The basic furnace design for such units is similar to that required for their larger municipal counterparts. Apartment house incinerators, which are often flue-fed with a chute directly to the furnace, have been found to be a significant source of air pollution; their design and operation is stringently regulated.

Waste heat utilization

Heat from incinerator furnaces may be used to generate steam for use in industrial processes, for space heating and power generation, or in sewage disposal plants and other public facilities. The economics of the use of waste heat for steam generation depend primarily on the steam requirements of users within a reasonable distance of the plant and the market rates. A number of European cities such as Paris, Munich, and Frankfurt am Main operate steam-generation plants in conjunction with municipally-operated power plants. Montreal has a steam-generating plant that began operations in 1970. In such arrangements the price of coal is a crucial factor.

Disposal into sewerage system. Garbage ground into minute particles can be discharged into the community sewerage system. Little difficulty is encountered in a properly designed sewer system as a result of this, and household water consumption increases only 1 to 2 percent with the installation of a grinder. Increases in solids-handling capacities are needed at the sewage treatment plants in cities where large numbers of grinders are in service, however, and for this reason some communities with overloaded treatment plants have forbidden their use. They have, however, found increasing application in commercial and institutional food-handling establishments.

Ocean disposal. The practice by coastal cities of barging garbage and rubbish to sea has come under critical pressure as the lighter material finds its way back to the beaches. New York City, a major offender, was prohibited from this practice in 1933 by the U.S. Supreme Court. Nevertheless, by the late 1960s an estimated 50,000,000 tons of solid wastes, including dredging spoils, ship refuse, waste oil, industrial chemicals and sludges, and sewage sludge were annually disposed of at sea by the United States. Of that total 30,000,000 tons were dredging spoil. Some resort communities along the Atlantic coast pump sewage into the ocean. Similar practices on a lesser scale are worldwide; guidelines for regulation of ocean disposal have become a matter for United Nations action.

The sanitary landfill method

Disposal on land. Indiscriminate dumping of refuse on land is an age-old practice; in the late 1960s more than 90 percent of land disposal sites in the United States were classified as "dumps." The unsightliness and unavoidable presence of flies, rats, smoke, and odours at dump grounds led to the development of the sanitary landfill method (see illustration). A sanitary landfill is defined by the American Society of Civil Engineers as a method of disposing of refuse on land without creating nuisances or hazards to public health or safety, engineered to confine the refuse to the smallest practicable area and volume and to cover it with a layer of earth on at least a daily basis. It requires the same careful preliminary and operational planning and design that any engineering construction job must have to be successful. Site selection includes zoning arrangements, accessibility, haul distance from collection routes, availability of cover material, a study of geological formations to assess water pollution hazards, and the ultimate land use plan for the completed site.

Trench method of sanitary landfill used to dispose of refuse in a flat land area.

The most commonly used equipment on sanitary landfills is the bulldozer or rubber-tired tractor. It performs the spreading, compacting, covering, and trenching operations; and in many instances it hauls the cover material. Other equipment includes scrapers, graders, compactors, draglines, and water sprinklers for dust control. Sanitary landfills serving up to 50,000 people, or handling up to 115 tons of solid wastes per day, may operate with one piece of equipment. Suitable land in urban areas has become increasingly scarce. Space requirements almost doubled between 1950 and 1970 (0.7 to 1.25 acre-feet [863 to 1542 cubic metres] per thousand persons). Intensive work has been under way to investigate the feasibility of long-distance haul of refuse by rail to remote disposal sites, such as abandoned strip mines. Reported sanitary landfilling costs range from $1.25 to $5.00 per ton of refuse disposed of depending on the size of the operation, land and site preparation costs, operational requirements, and the ultimate land use construction requirements.

Completed sanitary landfill sites are most commonly used for recreational areas, such as parks, playgrounds, and golf courses. An arboretum has been constructed on a Los Angeles County landfill site. Heavy construction on completed sanitary landfill sites, however, has generally been avoided.

Shredding automobiles into scrap

Abandoned automobiles. The problem of the derelict automobile has developed into a serious one in the United States and other countries. Large shredders that process automobile hulks into scrap were developed in the late 1960s, but despite the processing of more than 8,000,000 U.S. vehicles annually, it has been estimated that the number of unprocessed abandoned vehicles increased from about 6,500,000 in 1965 to as many as 20,000,000 by the late 1970s. The state of Maryland was a pioneer in government action to encourage the salvaging of automobiles when, in 1969, it passed legislation that provided a bountry for automobile hulks brought to regional processing centres.

Collection and disposal in rural areas. The collection and disposal of refuse in rural areas presents a special problem because sparse population and small communities result in high unit costs for transportation and disposal. In industrialized countries rural per capita generation of refuse is nearly as great as that in urban areas; the failure to provide services often results in indiscriminate dumping and littering.

RECLAMATION AND RECYCLING

The removal of salvageable items such as metals and paper from solid wastes–for direct reuse or as raw materials for industrial reuse is termed reclamation and recycling. The amount and kind of refuse salvaged from the solid-waste stream has traditionally followed economic patterns. Before World War II a number of cities operated garbage reduction plants to reclaim grease and produce tankage that was sold to reduce the cost of collection and disposal. Picking belts were operated to remove items such as metals and cardboard for resale. Rising labour costs, difficulty in obtaining labour for the separation process, and lack of markets for grease contributed to the closing of these plants.

Composting

Composting is the biochemical alteration of organic refuse from a noxious conglomerate to an innocuous and usable soil humus. A number of anaerobic and aerobic processes have been tried on varying scales in the United States. None has been successfully employed in U.S. communities on a continuing basis, primarily for economic reasons. Composting has been successfully undertaken in Europe, particularly in France, where more favourable economics prevail, but even in The Netherlands, where reclamation provides much of the arable land, the practice of cornposting refuse has been diminishing as other more economic methods of supplying needed humus to the soil are adopted. While limited markets and related economics have discouraged the salvage of the quality materials contained in household refuse, large quantities of industrial and commercial solid waste are recycled.

A continuing sharp rise in per capita generation of solid wastes has occurred as a result of increased materials production. For example, beverage containers produced for "consumption" by the U.S. populace doubled from 30,000,000 in 1965 to 63,000,000 in 1976. The productive energies of both industry and government have largely been centred on the goal of increasing the recycle of this waste material through better technology and the development of economic incentives to encourage re-use of the materials. Research has included utilization of fibrous wastes as sources of nutrients, laser-mediated lignin solid-waste fermentation, and the design of a water-disposable packaging container. Major governmental attention has been given to finding means of recovering materials and energy from solid waste. In addition, several states have enacted laws to reduce beverage-container refuse by placing a cash deposit on all containers, which is refunded when the containers are returned.

STREET CLEANING

Sweeping. Until recent times city streets were depositories of garbage and all forms of refuse, a situation that contributed to widespread epidemics. The paved streets of the 20th century, together with the development of mobile, powered cleaning equipment, have led to the establishment of street cleaning as one of the major tax-supported efforts of municipal government. Effective street-cleaning programs not only enhance the appearance of the community, but they protect the public health by reducing disease and injury from dirt entering the eyes, ears, nose, and throat; and they promote safety by eliminating causes of skidding, fire hazards, and sources of water pollution in storm runoff. Flushing and hand sweeping have long been supplemented by mechanical sweeping; by the 1970s vacuum techniques had been introduced in many European cities.

Vacuum sweeping

Snow and ice removal. Except in far northern regions, most cities treat snow and ice storms as emergencies, marshalling all forces available until traffic is moving freely, at least along main arteries. Many factors affect the impact of a storm on a community, including the amount and dryness or wetness of the snow, timing, rate, and duration of the storm, wind conditions, and the temperature. The emergency nature of snow and ice control work requires careful planning, organization, and operation; reliable weather forecasting service is essential. The four general categories of snow removal efforts used to combat snow storms in urban areas are: salting and abrasive spreading; plowing; physical removal (or lifting) of snow from business and commercial areas; and special removal operations in such areas as crosswalks and sidewalks, parking areas, fireplugs, and bus stops. Spreading chemicals (most commonly rock salt) or sand, or both, is the customary first line of offense against snow and ice. Salt has no effect, however, when the temperature drops below −6° F (—21" C), the temperature at which a concentrated solution of saltwater will freeze. Many cities start plowing operations before a depth of 1½ inches (3.8 centimetres) of snow has fallen, particularly if a severe storm has been forecast. Plows are mounted on various types of vehicles, including dump trucks, wheeled tractors, refuse collection trucks, and road graders. Where snow must be removed completely, mechanical loading equipment, such as elevating conveyors and front-end loaders, is used. Vehicles equipped with rotary plow blades, called snow blowers, are widely used to load hauling vehicles or to remove large accumulations of snow from highways or airport runways. Disposal of snow that is loaded and hauled away is accomplished by dumping it into large bodies of water or large sewers. Unlimited amounts of snow ordinarily can be dumped into large lakes, rivers, or in the ocean without undesirable side effects. Sometimes snow is dumped on vacant land. Snow melting is expensive but is used in some cities where the quantity of snow, haul costs, and other alternatives make it economically attractive. Montreal undertakes to clear all snow within 72 hours of a snowfall and not only maintains a large snow "tip" (dump) but operates several batteries of snow melters capable of melting 560 tons per hour. The method reportedly costs twice that of dumping and four times that of disposing of it into convenient sewers.

Snow blowers

SPECIAL PROBLEMS

Solid wastes include many types of refuse that constitute special and unique problems. The wastes may be hazardous, for example, radioactive wastes, toxic chemicals, and pathogenic wastes from hospitals or research laboratories, or they may be otherwise unique in nature, such as demolition wastes from urban renewal projects and ash by-products from the energy industry. All of these materials require special handling.

Concern over the control of radioactive wastes is worldwide, but no uniform policy for their handling and disposal has been formulated. Since the late 1970s, the U.S. Department of Energy has maintained control of the containment and disposal of nuclear wastes, a task originally performed by the former Atomic Energy Commission. Although the federal government has begun to delegate some authority to certain state agencies, it has not considered this to be a responsibility of local governments.

Solid wastes originate in all operations of the nuclear energy industry and include such items as contaminated paper, laboratory glassware and equipment, as well as end products, such as chemical slurries and sludges, evaporation solids, and ion-exchange resins. For a number of years radioactive wastes have been temporarily stored in above-ground repositories. Extensive planning and research have been undertaken to develop methods for permanent disposal of such wastes. One method under consideration involves the placement of radioactive wastes in an underground cavity, such as a mine, vault, or drill hole, in a geologically stable rock formation. A pilot project has been planned in which high-level wastes are to be buried deep in a bedded salt formation. Other proposals have included burial in the seabed and burial in the Antarctic ice sheet. Numerous technological problems must be solved before these methods can be implemented.

Demolition and construction refuse consists of lumber, pipes, brick masonry, and other materials from buildings and other structures. Some of this material is salvaged for resale (*e.g.*, old bricks, lead pipe, and copper), but most is hauled away by the contractor for disposal at landfill sites. Explosives and inflammable materials, highly alkaline or acidic sludges, magnesium, manganese, and cyanides are not handled as part of the regular community collection system because of potential injury to workers and special disposal requirements. Other special wastes include large dead animals and quantities of condemned food. Each is subject to special handling procedures before burial or incineration.

Regeneration, Biological

Organisms differ markedly in their ability to replace lost or amputated body parts. Some grow a new structure on the stump of the old one. By such regeneration organisms may dramatically replace substantial portions of themselves when they have been cut in two, or may grow organs or appendages that have been lost. Not all living things regenerate parts in this manner, however. The stump of an amputated structure may simply heal over without replacement. This wound healing is itself a kind of regeneration at the tissue level of organization: a cut surface heals over, a bone fracture knits, and cells replace themselves as the need arises.

SIGNIFICANCE

Regeneration, as one aspect of the general process of growth, is a primary attribute of all living systems. Without it there could be no life, for the very maintenance of an organism depends upon the incessant turnover by which all tissues and organs constantly renew themselves. In some cases rather substantial quantities of tissues are replaced from time to time, as in the successive production of follicles in the ovary or the molting and replacement of hairs and feathers. More commonly, the turnover is expressed at the cellular level. In mammalian skin, the epidermal cells produced in the basal layer may take several weeks to reach the outer surface and be sloughed off. In the lining of the intestines, the life span of an individual epithelial cell may be only a few days.

The motile, hairlike cilia and flagella of single-celled organisms are capable of regenerating themselves within an hour or two after amputation. Even in nerve cells, which cannot divide, there is a continuous flow of cytoplasm from the cell body out into the nerve fibres themselves. New molecules are continuously being generated and degraded with turnover times measured in minutes or hours, in the case of some enzymes, or several weeks, as in the case of muscle proteins. (Evidently, the only molecule exempt from this turnover is deoxyribonucleic acid [DNA], which ultimately governs all life processes.)

There is a close correlation between regeneration and generation. The methods by which organisms reproduce themselves have much in common with regenerative processes. Vegetative reproduction, which occurs commonly in plants and occasionally in lower animals, is a process by which whole new organisms may be produced from fractions of parent organisms; *e.g.*, when a new plant develops from a cut portion of another plant, or when certain worms reproduce by splitting in two, each half then growing what it has lost. More commonly, reproduction is achieved sexually by the union of an egg and sperm. This is a case in which an entire organism develops from a single cell, the fertilized egg, or zygote. This remarkable event, which occurs in all organisms that reproduce sexually, testifies to the universality of regenerative processes. During the course of evolution the regenerative potential has not changed; only the levels of organization at which it is expressed have altered. If regeneration is an adaptive trait, it would be expected to occur more commonly among organisms that have the greatest need of such a capability, either because the hazard of injury is great or the benefit to be gained is great. The actual distribution of regeneration among living things, however, seems at first glance to be a rather fortuitous one. It is difficult indeed to understand why some flatworms are able to regenerate heads and tails from any level of amputation, while other species can regenerate in only one direction or are unable to regenerate at all. Leeches fail to regenerate, while their close relatives, the earthworms, replace lost parts with ease. Certain species of insects regularly grow back missing legs, but many others are totally lacking in this capacity. Virtually all modern bony fishes can regenerate amputated fins, but the cartilaginous fishes (including sharks and rays) are unable to do so. Among the amphibians, salamanders regularly regenerate their legs, which are not very useful for movement in their aquatic environment, while frogs and toads, which are so much more dependent on their legs, are unable to replace them. If natural selection operates on the principle of efficiency, it is difficult to explain these many inconsistencies.

Whether regeneration is adaptive

Some species are so clearly adaptive that they have evolved not only mechanisms for regeneration, but mechanisms for self-amputation, as if to exploit the regenerative capability. The process of losing a body part spontaneously is called autotomy. The division of a protozoan into two cells and the splitting of a worm into two halves may be regarded as cases of autotomy. Some colonial marine animals called hydroids shed their upper portions periodically. Many insects and crustaceans will spontaneously drop a leg or claw if it is pinched or injured. Lizards are famous for their ability to release their tails. Even the shedding of antlers by deer may be classified as an example of autotomy. In all these cases autotomy occurs at a predetermined point of breakage. It appears that wherever nature contrives to lose a part voluntarily, it provides the capacity for replacement.

Sometimes, when part of a given tissue or organ is removed, no attempt is made to regenerate the lost structures. Instead, that which remains behind grows larger. Like regeneration, this phenomenon—known as compensatory hypertrophy—can take place only if some portion of the original structure is left to react to the loss. If three-quarters of the human liver is removed, for example, the remaining fraction enlarges to a mass equivalent to the original organ. The missing lobes of the liver are not themselves replaced, but the residual ones grow as large as necessary in order to restore the original function of the organ. Other mammalian organs exhibit similar reactions. The kidney, pancreas, thyroid, adrenal glands, gonads, and lungs compensate in varying degrees for reductions in mass by enlarging the remaining parts.

It is not invariably necessary for the regenerating tissue to be derived from a remnant of the original tissue. Through a process called metaplasia, one tissue can be converted to another. In the case of lens regeneration in certain amphibians, in response to the loss of the original lens from the eye, a new lens develops from the tissues at the edge of the iris on the upper margin of the pupil. These cells of the iris, which normally contain pigment granules, lose their colour, proliferate rapidly, and collect into a spherical mass which differentiates into a new lens.

MODES OF REGENERATION

Basic patterns. Not all organisms regenerate in the same way. In plants and in coelenterates such as the hydra and jellyfishes, missing parts are replaced by reorganization of preexisting ones. The wound is healed, and the neighbouring tissues reorganize themselves into whatever parts may have been cut off. This process of reorganization, called morphallaxis, is the most efficient way for simple organisms to regenerate. Higher animals, with more complex bodies, regenerate parts differently, usually by the production of a specialized bud, or blastema, at the site of amputation. The blastema, made up of cells that look very much alike despite their often diverse origins, made its first appearance evolutionarily in flatworms and is encountered in the regenerative processes of all higher animals. It provides the tissue that will form the regenerated part.

Atypical regeneration. Sometimes the part that grows back is not the same as that which was lost, and, occasionally, regeneration may be induced without having lost anything at all. It is not uncommon for a regenerated part to be incomplete. Earthworms, for example, usually regenerate only five segments in the anterior direction even if more than that number have been amputated. Many insects regenerate abnormally small legs from which some segments may be missing. Tadpole tails when amputated grow back to about only half their original length. These and other cases testify to the fact that a little regeneration is often good enough—that it is not necessary in every case to reproduce a flawless copy of the original.

Variations from the originals in regenerated parts

Sometimes that which is regenerated is very different from the original. Among the arthropods there are cases in which the stump of an antenna grows a leg, while a cut eyestalk regenerates an antenna. More commonly, the regenerated part may be a reasonable facsimile of the original but will differ in details. A regenerated lizard tail contains an unsegmented cartilaginous tube instead of a series of vertebrae as did the original tail. The spinal cord lacks segmented ganglia, and the scales in the skin differ in character from the original ones. A regenerated tail, therefore, is easily distinguished from one that has never been amputated, yet it is apparently sufficient to serve the purpose. Another interesting case is that of jaw regeneration in salamanders. If the lower jaw is amputated a new one will grow back, but it is often smaller than the original. It contains teeth and a mandible, but lacks a new tongue. Furthermore, the mandible that is produced is a cartilaginous model of the original, and is not known to convert into bone.

Sometimes more of a part grows back than has been removed by amputation. A limb stump, for example, can occasionally give rise to hands with extra digits. Lobsters have been known to regenerate double structures, in which case the new parts are mirror images of each other.

THE REGENERATION PROCESS

Origin of regeneration material. Following amputation, an appendage capable of regeneration develops a blastema from tissues in the stump just behind the level of amputation (see Figure 1). These tissues undergo drastic changes. Their cells, once specialized as muscle, bone, or cartilage, lose the characteristics by which they are normally identified (dedifferentiation); they then begin to migrate toward, and accumulate beneath, the wound epidermis, forming a rounded bud (blastema) that bulges out from the stump. Cells nearest the tip of the bud continue to multiply, while those situated closest to the old tissues of the stump differentiate into muscle or cartilage, depending upon their location. Development continues until the final structures at the tip of the regenerated appendage are differentiated, and all the proliferating cells are used up in the process.

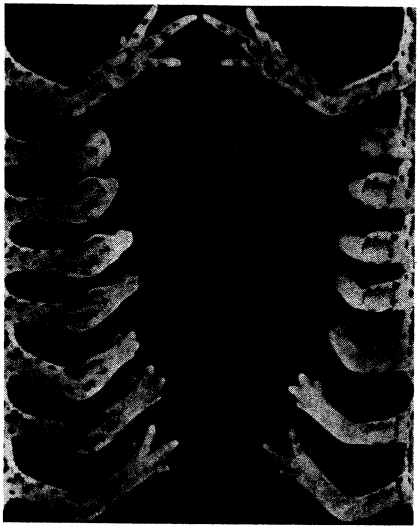

Figure 1: Successive stages in the regeneration of opposite limbs in a newt following amputation through (left) lower and (right) upper arms. At the top are the original limbs. From top to bottom are the successive stages of regeneration at 7, 21, 25, 28, 32, 42, and 70 days after amputation. The (right) more proximal stump elongates faster but differentiates more slowlv than does the (left) more distal stump.

R.J. Goss, Principles of *Regeneration* (1969), Academic Press. New York

The blastema cells seem to differentiate into the same kind of cells they were before, or into closely related types. Cells may perhaps change their roles under certain conditions, but apparently rarely do so. If a limb blastema is transplanted to the back of the same animal, it may continue its development into a limb. Similarly, a tail blastema transplanted elsewhere on the body will become a tail. Thus, the cells of a blastema seem to bear the indelible stamp of the appendage from which they were produced and into which they are destined to develop. If a tail blastema is transplanted to the stump of a limb, however, the structure that regenerates will be a composite of the two appendages.

Polarity and gradient theory. Each living thing exhibits polarity, one example of which is the differentiation of an organism into a head, or forward part, and a tail, or hind part. Regenerating parts are no exception; they exhibit polarity by always growing in a distal direction (away from the main part of the body). Among the lower invertebrates, however, the distinction between proximal (near, or toward the body) and distal is not always clear cut. It is not difficult, for example, to reverse the polarity of "stems" in colonial hydroids. Normally a piece of the stem will grow a head end, or hydranth, at its free, or distal, end; if that is tied off, however, it regenerates a hydranth at the end that was originally proximal. The polarity in this system is apparently determined by an activity gradient in such a way that a hydranth regenerates wherever the metabolic rate is highest. Once a hydranth has begun to develop, it inhibits the production of others proximal to it by the diffusion of an inhibitory substance downward along the stem.

Differences between whole organisms and appendages

When planarian flatworms are cut in half, each piece grows back the end that is missing. Cells in essentially identical regions of the body where the cut was made form blastemas, which, in one case gives rise to a head and in the other becomes a tail. What each blastema regenerates depends entirely on whether it is on a front piece or a hind piece of flatworm: the real difference between the two pieces may be established by metabolic differentials. If a transverse piece of a flatworm is cut very thin—too narrow for an effective metabolic gradient to be set up—it may regenerate two heads, one at either end. If the metabolic activity at the anterior end of a flatworm is artificially reduced by exposure to certain drugs, then the former posterior end of the worm may develop a head.

Appendage regeneration poses a different problem from that of whole organisms. The fin of a fish and the limb of a salamander have proximal and distal ends. By various manipulations, it is possible to make them regenerate in a proximal direction, however. If a square hole is cut in the fin of a fish, regeneration takes place as expected from the inner margin, but may also occur from the distal edge. In the latter case, the regenerating fin is actually a distal structure except that it happens to be growing in a proximal direction.

Amphibian limbs react in a similar manner. It is possible to graft the hand of a newt to the nearby body wall, and once a sufficient blood flow has been established, to sever the arm between the shoulder and elbow. This creates two stumps, a short one consisting of part of the upper arm, and a longer one made up of the rest of the arm protruding in the wrong direction from the side of the animal. Both stumps regenerate the same thing, namely, everything normally lying distal to the level of amputation, regardless of which way the stump was facing. The reversed arm therefore regenerates a mirror image of itself.

Clearly, when a structure regenerates it can only produce parts that normally lie distal to the level of amputation. The participating cells contain information needed to develop everything "downstream," but can never become more proximal structures. Regeneration, like embryonic development, occurs in a definite sequence.

Regulation of regeneration. There are certain prerequisites without which regeneration cannot occur. First and foremost, there must be a wound, although the original appendage need not have been lost in the process. Second, there must be a source of blastema cells derived from remnants of the original structure or an associated one. Finally, regeneration must be stimulated by some external force. The stimuli often involve the nervous system. An adequate nerve supply is required for the regeneration of fish fins, taste barbels, and amphibian limbs. In the case of many tail regenerations, the spinal cord provides the necessary stimulus. Lens regeneration in salamander eyes depends upon the presence of a retina. Arthropod appendages regenerate in the presence of molting hormones. Protozoan regeneration requires the presence of a nucleus. In case after case, regeneration depends on more than a healed wound and a source of blastema cells. It is often triggered by some physiological stimulus originating elsewhere in the body, a stimulus invariably associated with the very function of the structure to be regenerated. The conclusion is inescapable that regeneration is primarily the recovery of deficient functions rather than simply the replacement of lost structures.

The imperative of need is of further importance in suppressing excess regeneration. To be able to regenerate is to run the risk of regenerating too much or too often. If regeneration did not depend upon a physiological stimulus, such as those mediated by nerves or hormones, there would be no reason why simple wounds should not sprout whole new appendages.

Failure of regenerative processes

It is not known why regeneration fails to occur in many cases, as in the legs of frogs or the limbs and tails of mammals. The nerve supply might be inadequate, for when the number of nerves is artificially increased, regeneration is sometimes induced. This cannot be the whole answer, however, because not all appendages depend on nerves for their regeneration; newt jaws, salamander gills, and deer antlers do not require nerves to regenerate.

Possibly the failure to regenerate relates to the ways in which wounds heal. In higher vertebrates there is a tendency to form thick scar tissue in healing wounds, which may act as a barrier between the epidermis and the underlying tissues of the stump. In the absence of direct contact between these two tissues, the stump may not be able to give rise to the blastema cells required for regeneration.

THE RANGE OF REGENERATIVE CAPABILITY

Virtually no group of organisms lacks the ability to regenerate something. This process, however, is developed to a remarkable degree in lower organisms, such as protists and plants, and even in many invertebrate animals such as earthworms and starfishes. Regeneration is much more restricted in higher organisms such as mammals, in which it is probably incompatible with the evolution of other body features of greater survival value to these complex animals.

Protists and plants. ***Algae.*** One of the most outstanding feats of regeneration occurs in the single-celled green alga ***Acetabularia.*** This plant-like protist of shallow tropical water consists of a group of short rootlike appendages; a long thin "stem," up to several centimetres in length; and an umbrella-like cap at the top. The entire organism is one cell, with its single nucleus situated at the base in one of the "roots." If the cap is cut off, a new one regenerates from the healed over stump of the amputated stem. The nucleus is necessary for this kind of regeneration, presumably because it provides the information needed to direct the development of the new cap. Once this information has been produced by the nucleus, however, the nucleus can be removed and regeneration continues unabated.

If the nucleus from one species of ***Acetabularia*** is added to a cell-body of another species, and the cap of the recipient cell is amputated, the new cap that regenerates will be a hybrid because each nucleus exerts its own morphogenetic influences. On the other hand, if the nucleus from one species is substituted for that in another, regeneration reflects the properties of the new nucleus.

Protozoans. Most single-celled, animal-like protists regenerate very well. If part of the cell fluid, or cytoplasm, is removed from ***Amoeba,*** it is readily replaced. A similar process occurs in other protozoans, such as flagellates and ciliates. In each case, however, regeneration occurs only from that fragment of the cell containing the nucleus. Amputated parts that lack a nucleus cannot survive. In some ciliates, such as ***Blepharisma*** or ***Stentor***, the nucleus may be elongated or shaped like a string of beads. If either of these organisms is cut in two so that each fragment retains part of the elongated nucleus, each half proceeds to grow back what it lacks, giving rise to a complete organism in less than six hours. The way in which such a bisected protozoan regenerates is almost identical with the way it reproduces by ordinary division. Even a very tiny fragment of the whole organism can regenerate itself, provided it contains some nuclear material to determine what is supposed to be regenerated.

Green plants. The mechanisms by which vascular plants grow has much in common with regeneration. Their roots and shoots elongate by virtue of the cells in their meristems, the conical growth buds at the tip of each branch. These meristems are capable of indefinite growth, especially in perennial plants. If they are amputated they are not replaced, but other meristems along the stem, normally held in abeyance, begin to sprout into new branches that more than compensate for the loss of the original one. Such a process is called restitution.

Plants are also capable of producing callus tissue wherever they may be injured. This callus is proliferated from cambial cells, which lie beneath the surface of branches and are responsible for their increase in width. When a callus forms, some of its cells may organize into growing points, some of which in turn give rise to roots while others produce stems and leaves.

Invertebrates. ***Coelenterates.*** The vast majority of research on coelenterates has been focussed on hydras and some of the colonial hydroids. If a hydra is cut in half, the head end reconstitutes a new foot, while the basal portion regenerates a new hydranth with mouth and tentacles. This seemingly straightforward process is deceptively simple. From tiny fragments of the organism whole animals can be reconstituted. Even if a hydra is minced and the pieces scrambled, the fragments grow together and reorganize themselves into a complete whole. The indestructibility of the hydra may well be attributed to the fact that even the intact animal is constantly regenerating itself. Just below the mouth is a growth zone from which cells migrate into the tentacles and to the foot where they eventually die. Hence, the hydra is in a ceaseless state of turnover, with the loss of cells at the foot and at the tips of the tentacles being balanced by the production of new ones in the growth zone. If such an animal is X-rayed, the proliferation of new cells is inhibited and the hydra gradually shrinks and eventually dies owing to the inexorable demise of cells and the inability to replace them.

In colonial hydroids, such as ***Tubularia,*** there is a series of branching stems, each of which bears a hydranth on its end. If these hydranths are amputated they grow back within a few days. In fact, the organism normally sheds its hydranths from time to time and regenerates new ones naturally.

Planarian regeneration

Flatworms. Planarian flatworms are well-known for their ability to regenerate heads and tails from cut ends (see Figure ***2).*** In the case of head regeneration, some blastema cells become brain tissues, others develop into the eyes, and still others differentiate as muscle or intestine. In a week or so, the new head functions almost as well as the original.

After (top) T.H. Morgan in E. Korschelt, *Regeneration und Transplantation*, from (bottom: V. Hamburger, *Manual of Experimental Embryology* (© 1960), University of Chicago Press

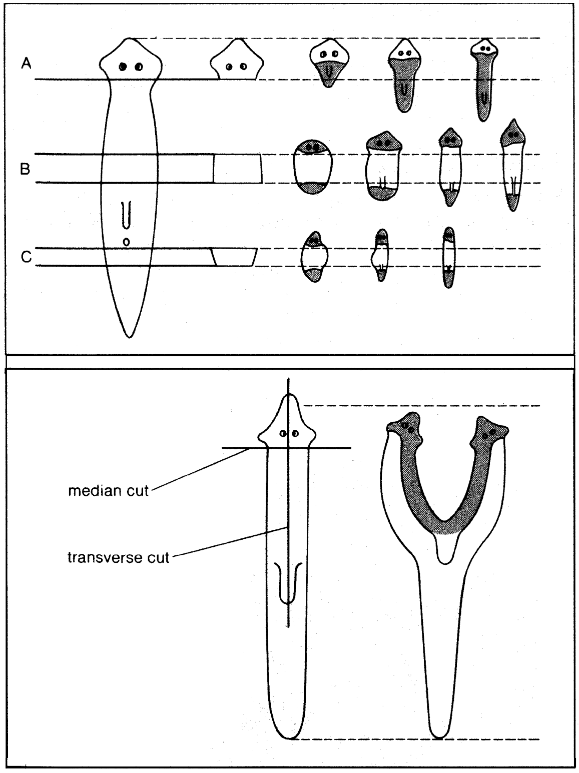

Figure 2: (Top) Regeneration in the planarian flatworm Dugesia. The three rows show regeneration from (A) anterior section, (B) midsection, and (C) posterior section of the animal at the left. (Bottom) Regeneration of a double head in a planarian. Regenerated tissue is shaded.

The blastema that normally gives rise to a single head is, under certain circumstances, even capable of becoming two heads if the stump of a decapitated flatworm is divided in two by a longitudinal cut. Each of the two halves then gives rise to a complete head. Thus, each blastema develops into an entire structure regardless of its size or position in relation to the rest of the animal.

In the case of flatworms there is still considerable disagreement concerning the origins of the blastema. Some investigators contend that it is derived from neoblasts, undifferentiated reserve cells scattered throughout the body. Others claim that there are no such reserve cells and that the blastema develops from formerly specialized cells near the wound that dedifferentiate to give rise to the blastema cells. Whatever their source, the cells of the blastema are capable of becoming many different things depending upon their location.

Regeneration in flatworms occurs in a stepwise fashion. The first tissue to differentiate is the brain, which induces the development of eyes. Once the head has formed, it in turn stimulates the production of the pharynx. The latter then induces the development of reproductive organs farther back. Thus, each part is necessary for the successful development of those to come after it; conversely, each part inhibits the production of more of itself. If decapitated flatworms are exposed to extracts of heads, the regeneration of their own heads is prevented. Such a complex interplay of stimulators and inhibitors is responsible for the successful regeneration of an integrated morphological structure.

Annelids. The segmented worms exhibit variable degrees of regeneration. The leeches, as already noted, are wholly lacking in the ability to replace lost segments, whereas the earthworms and various marine annelids (polychaetes) can often regenerate forward and backward. The expression of such regenerative capacities depends very much on the level of amputation. Anteriorly directed regeneration usually occurs best from cuts made through the front end of the worm, with little or no growth taking place from progressively more posterior bisections. Posteriorly directed regeneration is generally more common and extensive. Some species of worms replace the same number of segments as were lost. Hypomeric regeneration, in which fewer segments are produced than were removed, is more common, however.

Anterior regeneration depends upon the presence of the central nerve cord. If this is cut or deflected from the wound surface, little or no forward regeneration may take place. Posterior regeneration requires the presence of the intestine, removal of which precludes the formation of hind segments. Thus, it would seem that no head will regenerate without a central nervous system, nor a tail without an opening.

Arthropods. Many insects and crustaceans regenerate legs, claws, or antennas with apparent ease. When insect legs regenerate, the new growth is not visible externally because it develops within the next proximal segment in the stump. Not until the following molt is it released from its confinement to unfold as a fully developed leg only slightly smaller than the original. In the case of crabs, regenerating legs bulge outward from the amputation stump. They are curled up within a cuticular sheath, not to be extended until the sheath is molted. Lobsters and crayfish regenerate claws and legs in a straightforward manner as direct outgrowths from the stumps. As in other crustaceans, however, these regenerates lie immobile within an enveloping cuticle and do not become functional until their sheath is shed at the next molt.

Molting

In all arthropods regeneration is associated with molting, and therefore takes place only during larval or young stages. Most insects do not initiate leg regeneration unless there remains ample time prior to the next scheduled molt for the new leg to complete its development. If amputation is performed too late in the intermolt period, the onset of regeneration is delayed until after shedding; the regenerate then does not appear until the second molt. Metamorphosis into the adult stage marks the end of molting in insects, and adults accordingly do not regenerate amputated appendages.

Crustaceans often tend to molt and grow throughout life. They therefore never lose the ability to grow back missing appendages. When a leg is lost, a new outgrowth appears even if the animal is not destined to molt for many months. Following a period of basal growth, during which a diminutive limb is produced, the regenerated part eventually ceases to elongate. Not until a few weeks before the next molt does it resume growth and complete its development, triggered by the hormones that induce molting.

Vertebrates. Fishes. Many different parts of the fish's body will grow back. Plucked scales are promptly replaced by new ones, and amputated gill filaments can regenerate easily. The "whiskers," or taste barbels, of the catfish grow back as perfect replicas of the originals. The most conspicuous regenerating structures in fishes, however, are the fins. When any of these are amputated, new fins grow out from the stumps and soon restore everything that was missing. Even the coloured stripes or spots that adorn some fins are reconstituted by new pigment cells that repopulate the regenerated part. Fin regeneration depends on an adequate nerve supply. If the nerves are cut leading into the fin, regeneration of neither the amputated fin nor excised pieces of the bony fin rays can take place.

Amphibians. Salamanders are remarkable for their ability to regenerate limbs. Larval frogs, or tadpoles, also possess this ability, but usually lose it when they become frogs. It is not known why frog legs do not regenerate, and under appropriate stimuli they can be induced to do so.

Tadpoles and salamanders can replace amputated tails. Tadpole tails have a stiff rod called the notochord for support, whereas salamanders possess a backbone, composed of vertebrae. Both tails contain a spinal cord.When the salamander regenerates its tail, the spinal cord grows back and segmental nerve-cell clusters (ganglia) differentiate. Tadpoles also regenerate their spinal cords, but not the associated ganglia. If the spinal cord is removed or destroyed in the salamander, no tail regeneration occurs; if it is removed from the tadpole tail, however, regeneration can proceed without it.

Reptiles. Lizards also regenerate their tails, especially in those species that have evolved a mechanism for breaking-off the original tail when it is grasped by an enemy. When the lizard tail regenerates, however, it does not replace the segmented vertebrae. Instead, there develops a long tapering cartilaginous tube within which the spinal cord is located and outside of which are segmented muscles. The spinal cord of the lizard tail is necessary for regeneration, but the regenerated tail does not reproduce the ganglia that are normally associated with it. Occasionally, a side tail may be produced if the original tail is broken but not lost.

Birds. Regeneration of amputated appendages in birds is not known to occur; however, they do replace their feathers as a matter of course. While most species shed and regenerate feathers one at a time so as not to be grounded, flightless birds, such as penguins, may molt them all at once. Male puffins cast off their colorful beaks after the mating season, but grow new ones the following year. In like manner, the dorsal keel on the upper beaks of male pelicans is shed and replaced annually.

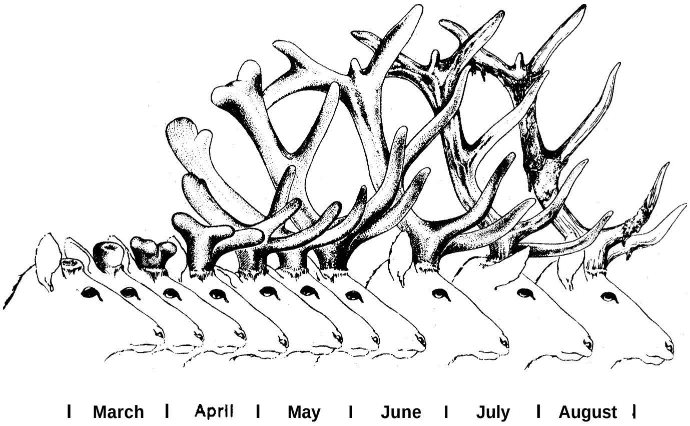

Figure 3: Regeneration of antlers in the elk (see text).

Mammals. Although mammals are incapable of regenerating limbs and tails, there are a few exceptional cases in which lost tissues are in fact regenerated. Not the least of these cases is the annual replacement of antlers in deer. These remarkable structures, which normally grow on the heads of male deer, consist of an inner core of bone enveloped by a layer of skin and nourished by a copious blood supply. During the growing season the antlers elongate by the proliferation of tissues at their growing tips. The rate of growth in some of the larger species may surpass one centimetre per day; the maximum rate of growth recorded for the elk is 2.75 cm per day. When the antlers have reached their full extent, the blood supply is constricted, and the skin, or velvet, peels off, thus revealing the hard, dead, bony antlers produced by the male deer in time for the autumn mating season. The regeneration of elk antlers spans about seven months (see Figure 3). The following spring, the old antlers are shed and new ones grow to replace them.

Still another example of mammalian regeneration occurs in the case of the rabbit's ear. When a hole is punched through the external ear of the rabbit, tissue grows in from around the edges until the original opening is reduced or obliterated altogether. This regeneration is achieved by the production of new skin and cartilage from the margins of the original hole. A similar phenomenon occurs in the case of the bat's wing membrane.

Reinhardt, Max

A man of few words and little inclination or ability to develop or expound a dramatic theory, Max Reinhardt was a pragmatist whose instinctual feelings for the rightness of things transformed theatrical production in the 20th century. Before him, the idea of the director as a creative artist in his own right had been barely embryonic. With his work, the director emerged as the dynamic formative mind behind the production of a dramatic work.

Reinhardt.

Discovery of the theatre. Reinhardt was born on Sept. 9, 1873, in Baden, near Vienna, the oldest of the seven children born to Wilhelm and Rose Goldmann, an orthodox Jewish couple. With his equally introverted only brother, Edmund, young Max played long hours with puppets and from their balcony watched the real puppets in the streets.

Though his parents were remote from theatrical life, they were sympathetic to his fascination with the actors of the Vienna Burgtheater, and at the urging of one of these, they allowed their son to exchange his boredom as a bank clerk for the excitement of drama school. Although he proved to be an inhibited actor, needing a beard and heavy makeup to release his talents, Reinhardt won local fame and friends in Salzburg. In 1894 he succumbed to an invitation from Otto Brahm, who had brought the drama of Henrik Ibsen to Germany, to join

With
Brahmin
Berlin

his Deutsches Theater in Berlin. He had assumed the stage name Reinhardt some time prior to moving to Berlin.

Reinhardt learned much from Brahm but was never wholeheartedly committed to the naturalism of his productions. He tired of "sticking a beard . . . and eating noodles and sauerkraut on stage every night," which latter activity was required by Brahm's notion of realism, in which nothing was to be simulated. This was not to be his direction in theatre. Quick to make friends despite his shyness, he met other young artists in cafes, gossiping, and loving. From their gatherings there emerged a lighthearted revue, ***Schall und Rauch (Sound and Smoke),*** to which Reinhardt contributed sketches. Playing before invited audiences, it was so successful that it was transformed into a serious work and settled into the Kleines Theater, a converted hall, in 1902. He planned a full season and directed his first play, Oscar Wilde's ***Salome.***

Career in full flower. Reinhardt evidenced his ability to make the right contact at the right time when he produced 14,000 marks to placate Brahm, who was furious over his breach of contract. He took over the Neues Theater in 1903, and his career moved ahead rapidly. By the end of 1904, he had directed 42 plays, but his early landmark of genius was the production in 1905 of Shakespeare's ***Midsummer Night's Dream.*** Reinhardt's staging was swift, light, and joyous, capturing for audiences the theatrical brilliance that had been buried for so long beneath productions devoted to a ponderous, reverent delivery of Shakespeare's words.

Direction of the Deutsches Theater

The young director became famous over night. Offered the artistic directorship of the Deutsches Theater, he would settle for nothing less than ownership. He purchased it for 1,000,000 marks, and at age 32 he had reached the pinnacle of his profession. He completely rebuilt the theatre, introducing the latest technological innovations in scenic design, and started a school. Purchasing a tavern next door, he remodelled it into a small theatre for plays that needed intimacy with the audience, summarizing the new concept in his word ***Kammerspiele,*** "chamber plays."

In his success, Reinhardt remained close to his family. He brought his brother, Edmund, who suffered from depressions, to Berlin and acted almost as his psychiatrist, setting him to work in the theatre to regain his confidence. Beginning in 1907, the Deutsches Theater toured throughout Europe and the United States. The production of ***The Miracle,*** which premiered in 1911 in London and played subsequently in New York and European cities, was Reinhardt's most spectacular work and, at the same time, probably the most characteristic. Reinhardt was fascinated by the sensuous quality of Roman Catholic rites and Gregorian chants. ***The Miracle,*** a work involving over 2,000 actors, musicians, dancers, and other personnel and without dramatic dialogue, was a modem-day reunification of drama and ritual. It was pure theatre in the most archetypal sense.

If in ***The Miracle*** he re-created an ancient unity, Reinhardt was equally important in giving new life to many of the great dramas from the theatre's past. His staging of Sophocles' ***Oedipus Rex*** in 1910 initiated the first large-scale revival of classical Greek drama in over 2,000 years. During the 1913–14 season he mounted new productions of 10 of 22 Shakespearean plays he had directed, using few, or no, settings and creating a major Shakespearean revival. In 1911 he brought a modem point of view to opera with his direction of the premiere of Richard Strauss's ***Rosenkavalier,*** with a libretto by Hugo von Hofmannsthal. After many years he succeeded in establishing the Salzburg Festival in 1920, staging Hofmannsthal's ***Jedermann (Everyman)*** in the city's cathedral square. It became an annual event, bringing about, before its termination in 1934, a new interest in the dramas of the Middle Ages from which ***Jedermann*** was adapted.

Return home and exile. Reinhardt had continued his work throughout World War I with no lessened sense of duty toward his art and his audience. In 1920, save for occasional engagements, he gave up direction of the Deutsches Theater. Retiring to a castle he had purchased in Austria, he attempted to find in his native country the regard he had been accorded abroad. His home was a meeting place for international celebrities, but enemies prevented him from feeling at home in his home town. He commuted in a circuit of Berlin, Vienna, and Salzburg. When the Nazis assumed power in Germany in 1933, Reinhardt was luckily abroad. In a letter to the Nazi government that was a typical blend of conceit, irony, rejection of politics, and prophetic perception, he left his theatrical empire to the German people. The era of private management of such institutions as the theatre is past, he wrote, and he foresaw that in the future it would be impossible to manage cultural undertakings without state backing.

Legacy to the German people

After further work in Europe, Reinhardt moved to the United States in 1938. He opened a workshop in Hollywood, where he had made a film of A ***Midsummer Night's Dream*** in 1934–35. His staging of ***Everyman*** in modem dress was followed by an unrealized plan for an all-Negro production of it. The final years of his life were filled with lesser fortunes and poor health, and he died speechless in New York City on Oct. 31, 1943.

Like the plots of the tragedies he so loved, Reinhardt's life was a rise to the heights of success and a fall to a life of uprooted exile. With his first wife, Else Heims, a beautiful and sensual actress, he had two sons. His second wife, Helene Thimig, was also a beautiful actress but, like Reinhardt, a shy person moved by an immense inner force and alive with conflicting appearances. He was an introvert capable of extreme extroversion and Falstaffian laughter. He disliked sentimentality in others yet was himself filled with romantic sentiments, a combination of Viennese sensitivity and German discipline with cosmopolitanism. His work summed up all theatre before him and opened new vistas for the theatre that followed.

Relativity

Relativity is concerned with measurements made by different observers moving relative to one another. In classical physics it was assumed that all observers anywhere in the universe, whether moving or not, obtained identical measurements of space and time intervals. According to relativity theory, this is not so, but their results depend on their relative motions.

There are really two distinct theories of relativity known in physics, one called the special theory of relativity, the other the general theory of relativity. Albert Einstein (*q.v.*) proposed the first in 1905, the second in 1916. Whereas the special theory of relativity is concerned primarily with electric and magnetic phenomena and with their propagation in space and time, the general theory of relativity was developed primarily in order to deal with gravitation. Both theories centre on new approaches to space and time, approaches that differ profoundly from those useful in everyday life; but relativistic notions of space and time are inextricably woven into any contemporary interpretation of physical phenomena ranging from the atom to the universe as a whole.

This article will set forth the principal ideas comprising both special and general relativity. It will also deal with some implications and applications of these theories.

THE SPECIAL THEORY OF RELATIVITY

Historical background. Classical physics owes its definite formulation to the British scientist Sir Isaac Newton (1642–1727). According to Newton, when one physical body influences another body, this influence results in a change of that body's state of motion, its velocity; that is to say, the force exerted by one particle on another results in the latter changing the direction of its motion, the magnitude of its speed, or both. Conversely, in the absence of such external influences, a particle will continue to move in one unchanging direction and at a constant rate of speed. This statement, Newton's first law of motion, is known as the law of inertia.

As motion of a particle can be described only in relation to some agreed frame of reference, Newton's law of inertia may also be stated as the assertion that there exist frames of reference (so-called inertial frames of reference) with respect to which particles not subject to external forces mave at constant speed in an unvarying direction. Ordinarily, all laws of classical mechanics are understood to hold with respect to such inertial frames of reference. Each frame of reference may be thought of as realized by a grid of surveyor's rods permitting the spatial fixation of any event, along with a clock describing the time of its occurrence.

The idea of absolute time

According to Newton, any two inertial frames of reference are related to each other in that the two respective grids of rods move relative to each other only linearly and uniformly (constant direction and speed) and without rotation, whereas the respective clocks differ from each other at most by a constant amount (as do the clocks adjusted to two different time zones on Earth) but go at the same rate. Except for the arbitrary choice of such a constant time difference, the time appropriate to various inertial frames of reference then is the same: If a certain physical process takes, say, one hour as determined in one inertial frame of reference, it will take precisely one hour with respect to any other inertial frame; and if two events are observed to take place simultaneously by an observer attached to one inertial frame, they will appear simultaneous to all other inertial observers. This universality of time and time determinations is usually referred to as the absolute character of time. The idea that a universal time can be used indiscriminately by all, irrespective of their varying states of motion—that is, by a person at rest at his home, by the driver of an automobile, and by the passenger aboard an airplane—is so deeply ingrained in most people that they do not even conceive of alternatives. It was only at the turn of the 20th century that the absolute character of time was called into question, and this as the result of a number of ingenious experiments described below.

As long as the building blocks of the physical universe were thought to be particles and systems of particles that interacted with each other across empty space in accordance with the principles enunciated by Newton, there was no reason to doubt the validity of the space–time notions just sketched. This view of nature was first called into question in the 19th century by the discoveries of a Danish physicist, Hans Christian Ørsted, the English scientist Michael Faraday, and the theoretical work of the Scottish-born physicist James Clerk Maxwell, all concerned with electric and magnetic phenomena. Electrically charged bodies and magnets do not affect each other directly over large distances, but they do affect one another by way of the so-called electromagnetic field, a state of tension spreading throughout space at a rapid but finite rate, which amounts to a speed of propagation of approximately 186,000 miles (300,000 kilometres) per second. As this value is the same as the known speed of light in empty space, Maxwell hypothesized that light itself was a species of electromagnetic disturbance; his guess has been confirmed experimentally, first by the production of lightlike waves by entirely electric and magnetic means in the laboratory by a German physicist, Heinrich Hertz, in the last quarter of the 19th century.

Maxwell's ether hypothesis

Both Maxwell and Hertz were puzzled and profoundly disturbed by the question of what might be the carrier of the electric and magnetic fields in regions free of any known matter. Up to their time, the only fields and waves known to spread at a finite rate had been elastic waves, which appear to the senses as sound and which occur at low frequencies as the shocks of earthquakes. Maxwell called the mysterious carrier of electromagnetic waves the ether, thereby reviving notions going back to antiquity. He attempted to endow his ether with properties that would account for the known properties of electromagnetic waves but was never entirely successful. The ether hypothesis, however, led two U.S. scientists, Albert Abraham Michelson and Edward Williams Morley, to conceive of an experiment (1887) intended to measure the motion of the ether on the surface of the Earth in their laboratory. On the reasonable hypothesis that the Earth is not the pivot of the whole universe, they argued that the motion of the Earth relative to the ether should result in slight variations in the observed speed of light (relative to the Earth and to the instruments of a laboratory) travelling in different directions. The measurement of the speed of light requires but one clock, if, by use of a mirror, a pencil of light is made to travel back and forth so that its speed is measured by clocking the total time elapsed in a round trip at one site; such an arrangement obviates the need for synchronizing two clocks at the ends of a one-way trip. Finally, if one is concerned with variations in the speed of light, rather than with an absolute determination of that speed itself, then it suffices to compare with each other round-trip-travel times along two tracks at right angles to each other, and that is essentially what Michelson and Morley did. To avoid the use of a clock altogether, they compared travel times in terms of the numbers of wavelengths travelled, by making the beams travelling on the two distinct tracks interfere optically with each other. (If the waves meet at a point when both are in the same phase—*e.g.*, both at their peak—the result is visible as the sum of the two in amplitude; if the peak of one coincides with the trough of the other, they cancel each other and no light is visible. Since the wavelengths are known, the relative positions of the peaks give an exact measure of how far one wave has advanced over the other.) This high-precision experiment, repeated many times with ever-improved instrumental techniques, has consistently led to the result that the speed of light relative to the laboratory is the same in all directions, regardless of the time of the day, the time of the year, and the elevation of the laboratory above sea level.

The special theory of relativity resulted from the acceptance of this experimental finding. If an Earth-bound observer could not detect the motion of the Earth through the ether, then, it was felt, probably any observer, regardless of his state of motion, would find the speed of light the same in all directions.

Relativity of space and time. An Irish and a Dutch physicist, George Francis FitzGerald and Hendrik Antoon Lorentz, independently showed that the negative outcome of Michelson's and Morley's experiment could be reconciled with the notion that the Earth is travelling through the ether, if one hypothesizes that any body travelling through the ether is foreshortened in the direction of travel (though its dimensions at right angles to the motion remain undisturbed) by a ratio that increases with increasing speed. If v denotes the speed of the body relative to the ether, and c is the speed of light, that ratio equals the square root of the quantity 1 minus the fraction speed squared over speed of light squared: $(1 - v^2/c^2)^{1/2}$. At ordinary speeds, c is so much greater that the fraction, practically speaking, is zero, and the ratio becomes $\sqrt{1}$, which is 1; *i.e.*, the foreshortening is nil; as v approaches c, however, the fraction becomes significant. The travelling body would be flattened completely if its velocity through the ether should ever reach the speed of light.

Suppose, now, that the variations in the speed of light were to be determined not by interference but by means of an exceedingly accurate clock and assume further that in such a modified experiment (whose actual performance is precluded at present, because even the best atomic clocks available do not possess the requisite accuracy) the motion through the ether were still imperceptible, then, Lorentz showed, one would have to conclude that all clocks moving through the ether are slowed down compared to clocks at rest in the ether, again by the factor $(1 - v^2/c^2)^{1/2}$. Thus, all rods and all clocks would be modified systematically, regardless of materials and construction design, whenever they were moving relative to

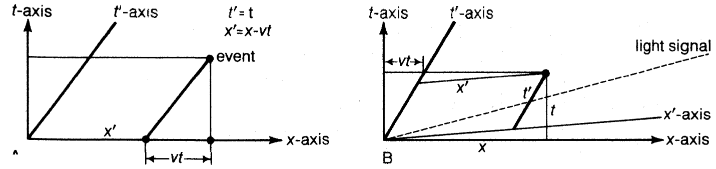
"Apparent" and "true" time and space

the ether. Accordingly, for theoretical analysis, one would have to distinguish between "apparent" and "true" space and time measurements, with the further proviso that "true" dimensions and "true" times could never be determined by any experimental procedure.

Conceptually, this was an unsatisfactory situation, which was resolved by Albert Einstein in *1905.* Einstein realized that the key concept, on which all comparisons between differently moving observers and frames of reference depended, is the notion of universal, or absolute, simultaneity; that is to say, the proposition that two events that appear simultaneous to any one observer will also be judged to take place at the same time by all other observers. This appears to be a straight-forward proposition, provided that knowledge of distant events can be obtained practically instantaneously. Actually, however, there is no known method of signalling faster than by means of light or radio waves or any other electromagnetic radiation, all of which travel at the same rate, c.

Suppose, now, that someone on Earth observes two events, say two supernovae (suddenly erupting very bright stars) appearing in different parts of the sky. Nothing can be said about whether these two supemovae emerged simultaneously or not from merely noting their appearance in the sky; it is necessary to know also their respective distances from the observer, which typically may amount to several hundred or several thousand light-years (one light-year, the distance light moves in one year, equals approximately 5.88×10^{12} miles, or 9.46×10^{12} kilometres). By the time one sees the eruption of a supernova, it has in actuality faded back into invisibility hundreds of years ago. Applying this simple idea to the observations and measurements made by different observers of the same events, Einstein demonstrated that if each observer applied the same method of analysis to his own data, then events that appeared simultaneous to one would appear to have taken place at different times to observers in different states of motion. Thus, it is necessary to speak of relativity of simultaneity.

Once this theoretical deduction is accepted, the findings of FitzGerald and Lorentz lend themselves to a new interpretation. Whenever two observers are associated with two distinct inertial frames of inference in relative motion to each other, their determinations of time intervals and of distances between events will disagree systematically, without one being "right" and the other "wrong." Nor can it be established that one of them is at rest relative to the ether, the other in motion. In fact, if they compare their respective clocks, each will find that his own clock will be faster than the others; if they compare their respective measuring rods (in the direction of mutual motion), each will find the other's rod foreshortened. The speed of light will be found to equal the same value, $c = 186{,}000$ miles per second, relative to every inertial frame of reference and in all directions. The status of Maxwell's ether is thereby cast in doubt, as its state of motion cannot be ascertained by any conceivable experiment. Consequently, the whole notion of an ether as the carrier of electromagnetic phenomena has been eliminated in contemporary physics.



From P. Bergmann, The Riddle *of Gravitation;* Charles Scribner's Sons

Figure 1: The Lorentz transformations.
(A) Nonrelativistic transformation; (B) relativistic transformation (see text).

The Lorentz transformations

The mathematical equations that relate space and time measurements of one observer to those of another observer moving are known as Lorentz transformations. If the relative motion is along the x-axis and if its magnitude is v, these expressions are (see Figure *1):*

$$x' = (1 - v^2/c^2)^{-1/2}\,(x - vt),\ y' = y,\ z' = z,$$
$$t' = (1 - v^2/c^2)^{-1/2}\,(t - vx/c^2).$$

Consequences. ***The limiting character of the speed of light.*** As the relative speed of one inertial frame of reference to another is increased, its rods appear increasingly foreshortened and its clocks more and more slowed down. As this relative speed approaches c, both of these effects increase indefinitely. The relative speed of the two frames cannot exceed c if light and other electromagnetic phenomena are to travel at the speed c in all directions when viewed from either frame of reference. Hence the special theory of relativity forecloses relative speeds of frames of reference greater than c. As an inertial frame of reference can be associated with any material object in uniform nonrotational motion, it follows that no material object can travel at a rate of speed exceeding c.

This conclusion is self-consistent only because under the Lorentz transformations the velocity of a body with respect to one inertial frame of reference is related to its velocity with respect to another frame not by the Newtonian rule that the difference in velocities equals the relative velocity between the two frames but by a more involved formula, which takes into account the changes in scale length, in clock time, and in simultaneity. If all velocities involved are in the same direction, then the velocity (see Figure **2)** in one frame, u, is related to the velocity in the other frame, u', by the expression stating that u' equals the sum of u and v divided by *1* plus the product of u and v divided by the square of c:

$$u' = (u + v)/(1 + uv/c^2).$$

As long as neither u nor v exceeds the speed of light, c, u' also will be less than c.

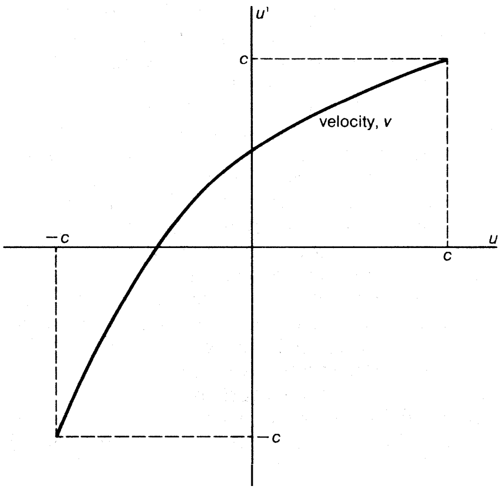


Figure 2: Velocities of the same body in two frames of reference (see text).

Variable mass. The mass of a material body is a measure of its resistance to a change in its state of motion caused by a given force. The larger the mass, the smaller the acceleration. If a material body is already moving at a speed approaching the speed of light, it must offer increasing resistance to any further acceleration so as not to cross the threshold of c. Hence the special theory of relativity leads to the conclusion that the mass of a moving body m is related to the mass that it would have if at rest, m_0, by a formula in which m equals m_0 divided by the square root of one minus the fraction v^2/c^2:

$$m = (1 - v^2/c^2)^{-1/2} m_0.$$

Relativistic mass

This changing value of the mass of the moving body, m, is called the relativistic mass. As v approaches c, the figure within the parentheses approaches zero and, ultimately, $m = m_0/0$, which would be an infinitely large number.

The relativistic mass formula may be interpreted as indicating that the relativistic mass of a body exceeds its rest mass m_0 by an amount that equals its kinetic energy E, divided by c^2: $m - m_0 = E/c^2$. Hence the hypothesis that generally the energy is c^2 times the mass, or $E = mc^2$, and that energy and mass are, in fact, equivalent physical concepts, differing only by the choice of their units. This hypothesis has been verified experimentally, in that all massive particles have been converted into forms of energy (for instance, gamma radiation) and conversely have been created out of pure energy. It was in part the recognition of this relationship that led to research out of which grew the technology of nuclear fission and fusion.

Invariant intervals. Data on pure time intervals obtained with respect to two relatively moving inertial frames of reference will differ and so will data on spatial distances. It is possible, however, to form from time intervals plus distances a single expression that will have the same value with respect to all inertial frames of reference. If the time interval between two distant events be denoted by T and their distance from each other by L, an expression, symbolized by τ, can be derived in which τ squared equals the square of the time interval minus the fraction of distance squared over speed of light squared: $\tau^2 = T^2 - L^2/c^2$. This will have the same value as $\bar{T}^2 - \bar{L}^2/c^2$, with $\bar{T}$ and $\bar{L}$ having been obtained in another inertial frame of reference. If τ^2 is positive, then τ is called the invariant (timelike) interval between the two events. If τ^2 is negative, then the expression λ, derived from the above as $\lambda^2 = L^2 - c^2T^2$, will be called the invariant (spacelike) interval.

The invariant interval between two instants in the history of one physical system equals the ordinary time lapse T measured by means of a clock at rest relative to that physical system, because, in such a comoving frame of reference, L vanishes. That is why such an invariant (timelike) interval is also referred to as the "proper time" elapsed between the two instants. Any clock will read its own proper time.

The "twin paradox." Given an inertial frame of reference and two similar material systems ("twins")—for instance, two atomic clocks of identical design—suppose now that one of these clocks remains permanently at rest in the given frame, whereas the other clock is moved at a high speed first in one direction away from the first clock and subsequently in the opposite direction until the two clocks are again close to each other. According to the Lorentz transformation, the second clock has been slower than the first throughout its journey, and hence it shows a smaller lapse of time than the clock that has remained at rest. By reading the clocks, one can then tell which clock has remained at rest, which one has moved. This difference in behaviour of the two clocks has been called the clock paradox, or the twin paradox if the clocks are replaced by space-travelling human twins.

The clock "paradox"

The "paradox" supposedly consists of a violation of the principle of relativity, according to which no asymmetric distinctions exist between different inertial frames of reference. The fallacy of this argument lies in the fact that no inertial frame of reference is associated with the second clock, as it cannot have moved free of acceleration throughout its journey: at least once its velocity (*i.e.*, the direction of its motion) must have been changed drastically, so as to enable it ever to return to its mate. Hence no violation of the principle of relativity; no paradox is involved. Various experiments on moving particles and atoms have indeed confirmed the predictions of the theory.

Four-diinensional space-time. The German mathematical physicist Hermann Minkowski pointed out that the invariant interval between two events has some of the properties of the distance in Euclidean geometry. Based on Euclidean geometry, the Cartesian coordinate system is designed to identify any point (event) in space by its reference to three mutually perpendicular lines or axes meeting at zero. The distance between two events, in accordance with Pythagoras' theorem, in any Cartesian (rectilinear) coordinate system is obtained by taking the square root of the sum of the squares of coordinate distances, $s^2 = x^2 + y^2 + z^2$, and its value is independent of the choice of coordinate system, though the values of x, y, and z are not. The invariant interval, similarly, is the square root of a sum and difference of squares of intervals of bcth space and time. Accordingly, Minkowski suggested that space and time should be thought of as comprising a single four-dimensional continuum, space–time, often also referred to as the Minkowski universe. Events, localized both as regards space and time, are the natural analogues of points in ordinary three-dimensional geometry; in the history of one particle, its proper time resembles the arc length of a curve in three-space.

In Minkowski's space–time the invariant interval may be either timelike or spacelike. If $L^2 - c^2T^2$ for two events happens to be zero, the invariant interval is neither, but null, or lightlike, as a light signal emanating from the earlier of the two events may just pass the second as the latter occurs. By contrast, in ordinary geometry the distance between two points, s, vanishes only if the two points coincide. To this extent the analogy between space–time and ordinary space is imperfect.

Minkowski's four-dimensional, geometric approach to relativity appears to add to the original physical concepts of relativity mostly a new terminology but not much else. Nevertheless, for the further conceptual development of relativity Minkowski's contribution has been of inestimable value.

THE GENERAL THEORY OF RELATIVITY

Physical origins. The general theory of relativity derives its origin from the need to extend the new space and time concepts of the special theory of relativity from the domain of electric and magnetic phenomena to all of physics and, particularly, to the theory of gravitation. As space and time relations underlie all physical phenomena, it is conceptually intolerable to have to use mutually contradictory notions of space and time in dealing with different kinds of interactions, particularly in view of the fact that the same particles may interact with each other in several different ways–electromagnetically, gravitationally, and by way of so-called nuclear forces.

Newton's theory of gravity

Newton's explanation of gravitational interactions must be considered one of the most successful physical theories of all time. It had accounted for the precise motions of all the constituents of the solar system with uncanny accuracy, permitting, for instance, the prediction of eclipses hundreds of years ahead. But Newton's theory visualizes the gravitational pull that the Sun exerts on the planets and the pull that the planets in turn exert on their moons and on each other as taking place instantaneously over the vast distances of interplanetary space, whereas according to relativistic notions of space and time any and all interactions cannot spread faster than the speed of light. The difference may be unimportant, for practical reasons, as all of the members of the solar system move at relative speeds far less than 1/1,000 of the speed of light; nevertheless, relativistic space–time and Newton's instantaneous action at a distance are fundamentally incompatible. Hence Einstein set out to develop a theory of gravitation that would be consistent with relativity.

Proceeding on the basis of the experience gained from Maxwell's theory of the electric field, Einstein postulated the existence of a gravitational field that propagates at the speed of light, c, and that will mediate an attraction as closely as possible equal to the attraction obtained from Newton's theory. From the outset it was clear that mathematically a field theory of gravitation would be more involved than that of electricity and magnetism. Whereas the sources of the electric field, the electric charges of particles, have values independent of the state of motion of the instruments by which these charges are measured, the source of the gravitational field, the mass of a particle, varies with the speed of the particle relative to the frame of reference in which it is determined and hence will have different values in different frames of reference. This complicating factor introduces into the task of constructing a relativistic theory of the gravitational field a measure of ambiguity, which Einstein resolved eventually by invoking the principle of equivalence.

The principle of equivalence. Everyday experience indicates that in a given field of gravity, such as the field caused by the Earth, the greater the mass of a body the greater the force acting on it. That is to say, the more massive a body the more effectively will it tend to fall toward the Earth; in fact, in order to determine the mass of a body one weighs it—that is to say, one really measures the force by which it is attracted to the Earth, whereas the mass is properly defined as the body's resistance to acceleration. Newton noted that the ratio of the attractive force to a body's mass in a given field is the same for all bodies, irrespective of their chemical constitution and other characteristics, and that they all undergo the same acceleration in free fall; this common rate of acceleration on the surface of the Earth amounts to an increase in speed by approximately 32 feet (about 9.8 metres) per second every second.

Weightlessness

This common rate of gravitationally caused acceleration is illustrated dramatically in space travel during periods of coasting. The vehicle, the astronauts, and all other objects within the space capsule undergo the same acceleration, hence no acceleration relative to each other. The result is apparent weightlessness: no force holds the astronaut to the floor of his cabin or a liquid in an open container. To this extent, the behaviour of objects within the freely coasting space capsule is indistinguishable from the condition that would be encountered if the space capsule were outside all gravitational fields in interstellar space and moved in accordance with the law of inertia. Conversely, if a space capsule were to be accelerated upward by its rocket engines in the absence of gravitation, all objects inside would behave exactly as if the capsule were at rest but in a gravitational field. The principle of equivalence states formally the equivalence, in terms of local experiments, of gravitational forces and reactions to an accelerated noninertial frame of reference (*e.g.*, the capsule while the rockets are being fired) and the equivalence between inertial frames of reference and local freely falling frames of reference. Of course, the principle of equivalence refers strictly to local effects: looking out of his window and performing navigational observations, the astronaut can tell how he is moving relative to the planets and moons of the solar system.

Einstein argued, however, that in the presence of gravitational fields there is no unambiguous way to separate gravitational pull from the effects occasioned by the noninertial character of one's chosen frame of reference; hence one cannot identify an inertial frame of reference with complete precision. Thus the principle of equivalence renders the gravitational field fundamentally different from all other force fields encountered in nature. The new theory of gravitation, the general theory of relativity, adopts this characteristic of the gravitational field as its foundation.

Curved space–time. *The* principles. In terms of Minkowski's space–time, inertial frames of reference are the analogues of rectilinear (straight-line) Cartesian coordinate systems in Euclidean geometry. In a plane these coordinate systems always exist, but they do not exist on the surface of a sphere: any attempt to cover a spherical surface with a grid of squares breaks down when the grid is extended over a significant fraction of the spherical surface. Thus a plane is a flat surface, whereas the surface of a sphere is curved. This distinction, based entirely on internal properties of the surface itself, classifies the surface of a cylinder as flat, as it can be rolled off on a plane and thus is capable of being covered by a grid of squares.

Einstein conjectured that the presence of a gravitational field causes space–time to be curved (whereas in the absence of gravitation it is flat), and that this is the reason that inertial frames cannot be constructed. The curved trajectory of a particle in space and time resulting from the effects of gravitation would then represent not a straight line (which exists only in flat spaces and space–times) but the straightest curve possible in a curved space–time, a geodesic. Geodesics on the surface of a sphere (such as the Earth) are the great circles. (The plane of any great circle goes through the centre of the Earth; all lines of longitude are great circles, but the Equator is the only line of latitude that is a great circle.) They are the least curved lines one can construct on the surface of a sphere, and they are the shortest curves connecting any two points. The geodesics of space–time connect two events (or two instants in the history of one particle) with the greatest lapse of proper time, as was indicated in the earlier discussion of the iwin paradox.

Riemannian space

If the presence of a gravitational field amounts to a curvature of space–time, then the description of the gravitational field in turn hinges on a mathematical elucidation of the curvature of four-dimensional space–time. Before Einstein, the German mathematician Bemhard Riemann (1826–66) had developed methods related directly to the failure of any attempt to construct square grids. Considering any small piece of (two-dimensional) surface and constructing within it a quadrilateral whose sides are geodesics, if the surface were flat, the sum of the angles at the four corners would be 360". If the surface is not flat, the sum of the angles is not 360". The deviation of the actual sum of the angles from 360" will be proportional to the area of the quadrilateral; the amount of deviation per unit of surface will be a measure of the curvature of that surface. If the surface is imbedded in a higher dimensional continuum, then one can consider similarly unavoidable angles between vectors constructed as parallel as possible to each other at the four corners of the quadrilateral, and thus associate several distinct components of curvature with one surface. And, of course, there are several independent possible orientations of two-dimensional surfaces, for instance, six in a four-dimensional continuum, such as space–time. Altogether there are 20 distinct and independent components of curvature defined at each point of space–time; in mathematics these are referred to as the 20 components of Riemann's curvature tensor.

The mathematical expression. Einstein discovered that he could relate ten of these components in a natural way to the sources of the gravitational field, mass (or energy), density, momentum density, and stress, if he were to duplicate approximately Newton's equations of the gravitational field and, at the same time, formulate laws that would take the same form regardless of the choice of frame of reference. The remaining ten components (usually referred to together as Weyl's tensor) may be chosen arbitrarily at any one point but are related to each other by partial differential equations (Bianchi's identities) at neighbouring points. Einstein's field equation,

$$R_{\mu\nu} - \tfrac{1}{2} g_{\mu\nu} R = 8\pi\kappa \mathrm{T}_{\mu\nu}$$

($R_{\mu\nu}$ stands for those ten components of the curvature tensor that are called Ricci's tensor, $g_{\mu\nu}$ is the metric tensor, R is a combination of Ricci's tensor components known as the Ricci scalar, κ is a universal constant proportional to Newton's constant of gravitation, and $\mathrm{T}_{\mu\nu}$ denotes the components of the energy–stress tensor), along with the rule that a freely falling body moves along a geodesic, together form the comprehensive theory of gravitation known as the general theory of relativity.

Confirmation of the theory. The general theory of relativity is constructed so that its results are approximately the same as those of Newton's theories as long as the velocities of all bodies interacting with each other gravitationally are small compared to the speed of light; *i.e.*, as long as the gravitational fields involved are weak. The latter requirement may be stated roughly in terms of the escape velocity. The escape velocity is defined as the minimal speed with which a projectile must be endowed at any given location to enable it to fly off to infinitely removed regions of the universe without the application of further force. On the surface of the Earth the escape velocity is approximately 7.5 kilometres (4.7 miles) per second. A gravitational field is considered strong if the escape velocity approaches the speed of light, weak if it is much smaller. All gravitational fields encountered in the solar system are weak in this sense.

The success of Newton's theory, incidentally, must be considered a confirmation of the general theory of relativity to the extent that that application of the theory remains confined to situations involving small relative speeds and weak fields. Obviously, any superiority of the new theory over the old one may be inferred only if their predictions disagree and if those of the general theory of relativity are confirmed by experiment and observation.

As the principle of equivalence forms the cornerstone of general relativity, experiments testing this principle are of considerable inieresi. High-precision experiments with

Tests of the principle of equivalence

this objective were first performed by a Hungarian physicist, R. von Eotvos, who confirmed the principle to an accuracy of one part in 10^8 and, in the 1960s, by a U.S. physicist, Robert Dicke, who improved Eotvos' accuracy by another factor cf 1,000, achieving an accuracy of one part in 10^{11}. Through this work the principle of equivalence has become one of the most precisely confirmed genera! principles of contemporary physics.

Some other new predictions of general relativity are explained below.

Advance of Mercury's perihelion. All ellipses forming the trajectories of the various planets about the Sun turn slowly within their planes, because of the interactions of the planets with each other, but it was discovered in the 19th century that interplanetary perturbations could not account fully for the turning rate of Mercury's orbit, leaving unexplained about 43" of arc per century. The general theory of relativity predicts this discrepancy as a relativistic effect. R. Dicke has proposed that about one-tenth of Mercury's perihelion advance may be caused by the Sun's oblatencss (slight flattening at the poles), which, if confirmed, would spoil the otherwise perfect agreement between theory and observation. This matter was still unresolved in the early 1970s.

Gravitational red shift. General relativity predicts that spectral lines emanating from sources within a gravitational field will be shifted toward longer wavelengths (toward the red end of the spectrum) by an amount proportional to the gravitational potential at the site of the source. This effect was searched for and found first in astronomical objects, particularly in stars called white dwarfs, on whose surfaces the gravitational potential is relatively large. The best quantitative confirmation of gravitational red shift was obtained in laboratory experiments performed in Great Britain and the U.S. In the 1960s an accuracy of one part in 100 was achieved using the minute difference in gravitational potential between two sites differing in altitude by a few metres.

Optical effects of gravitation. General relativity predicts that the curvature of space–time results in the apparent bending of light rays passing through gravitational fields and in an apparent reduction of their speeds of propagation. The bending was first observed, within a couple of years of Einstein's publication of the new theory, during a total eclipse, when stellar images near the occulted disk of the Sun appeared displaced by fractions of 1″ of arc from their usual locations in the sky. The associated delay in travel time was observed in the late 1960s, when ultraintense radar pulses were reflected off Mercury and Venus just as these planets were passing behind the Sun. These experiments are difficult to perform and difficult to evaluate as to their ultimate accuracy, but it seems conservative to estimate the accuracy of confirmation of the relativistic effect no worse than a few parts in 100.

Gravitational waves. General relativity predicts the occurrence of gravitational waves, whose properties should resemble in some respects those of electromagnetic waves; they should travel at the same speed, c, and they should be capable of being polarized. It appears that a U.S. physicist, Joseph Weber, detected gravitational waves in the late 1960s by means of vibrations excited in large aluminum cylinders, each weighing several tons, that had been insulated with great care from all other contacts that might give rise to similar vibrations (from mechanical and electromagnetic forces). Though the pulses detected by Weber can be observed only marginally in the background of noise caused by self-generated thermal motions of the cylinders, the sources of these pulses must possess almost unimaginable intensities. Weber has coniectured that the sources are collapsing or exploding stars near the core of the Galaxy, which cannot be observed because of intervening dust and gas clouds.

Sources of gravitational waves

Because of the awesome implications of Weber's discovery, along with the admitted difficulty of evaluating the observations themselves, both Weber and other workers in the early 1970s were making great efforts to improve the sensitivity of the instrumentation, in hope of achieving more definitive results.

Future astrophysical tests. The discovery of quasars (quasi-stellar objects; see below ***Relativistic cosmology)*** in the early 1960s and of pulsars (sources of rapidly pulsing, intensive radiation in the range of radio frequencies) in the latter part of the same decade has made it probable that there are astrophysical situations involving "strong" gravitational fizlds, in which general relativity will play a more than marginal role in interpreting observational data. New space techniques, such as the establishment of a laser gauge between the Earth and the Moon, the launching of deep-space probes, and the construction of orbiting space observatories, wili probably give rise to new and sensitive tests of general relativity; in the early 1970s such experiments had not progressed beyond the planning stage, however.

Conceptual implications of general relativity. The general theory of relativity represents a further modification of classical concepts of space and time that goes far beyond those implicit in the special theory. The special theory does away with the absolute character of time and with the absolute distance between two objects that are at rest relative to each other. The geometric concepts appropriate to the special theory are the four-dimensional space–time continuum, in which events that are fixed in space and in time are represented by points, often referred to as world points (to distinguish them from the points of ordinary three-dimensional space), and the histories of particles moving through space in the course of time by curves (world curves); the representations of particles that are not accelerated by forces are straight lines.

Minkowskian space–time

Minkowski's space–time is a rigidly flat continuum, as is the three-dimensional space of Euclid's geometry. Distances between world points are measured by the invariant intervals, whose magnitudes do not depend on the particular coordinate system, or frame of reference, used. The Minkowski universe is homogeneous: that is to say, geometric figures constructed at any site may be transferred to another site without distortion. Finally, among all the possible frames of reference there is a special set, the inertial frames of reference, just as in ordinary space the rectilinear coordinate systems are distinguished by their simplicity among all conceivable coordinate systems. Space–time serves as the immutable backdrop of all physical processes, without being affected by them.

In general relativity, space–time also is a four-dimensional continuum, with invariant intervals being defined at least locally between events taking place close to each other. But only small regions of space–time resemble the continuum envisagec! by Minkowski, just as small bits of a spherical surface appear nearly plane. In the broad sense, according to general relativity, space–time is curved, and this curvature is equivalent ta the presence of a gravitational field. Far from being rigid and homogeneous, the general-relativistic space–time continuum has geometric properties that vary from point to point and that are affected by local physical processes. Space–time ceases to be a stage, or scaffolding, for the dynamics of nature; it becomes an integral part of the dynamic process. General relativity, it has been said, makes physics part of geometry. With at least equal justification it may be claimed that general relativity makes geometry part of physics; thai is to say, of a natural science. Not only are the properties of space and time subject to scientific investigation, to a study by means of experiments, but specific properties, such as the amount of curvature in a particular location at a specified time, are to be measured with the help of physical instruments.

Though the general theory of relativity is universally thought to be the most nearly perfect theory of gravitation now known and its new approach to space and time accepted, most theories of the atom and of elementary particles current in the early 1970s are based on the space–time concepts of the special, not the general theory of relativity. This is in part because currently available mathematical techniques are adapted to treating these problems against the flat background of the original Minkowski space–time. Perhaps more important is the fact that by the early 1970s the fusion of general relativity and of quantum theory (*i.e.*, the theory that energy does not exist as a continuous phenomenon but as "particles" called quanta, the interactions between particles of matter and quanta of energy being explained in terms of quantum mechanics and wave mechanics), which certainly cannot be circumvented in dealing with atomic and subatomic phenomena, had not been completed successfully.

A number of scientists, foremost among them Einstein himself, attempted, during the first half of the 20th century, to increase the flexibility of the geometric structure of space–time further, so as to incorporate into the geometric structure all known physical forces and perhaps the quantum phenomena as well. This program is known as that of unitary field theory. None of the attempts at unitary field theory has been sufficiently successful to find favour with the community of physicists, and these endeavours have received relatively little support until now.

Unitary field theory

Schwarzschild's solution of the field equations. Immediately on publication of Einstein's paper on general relativity, the German astronomer Karl Schwarzschild found a mathematical solution to the new field equations, which corresponds to the gravitational field of a compact massive body. such as a star or planet, and which is now referred to as Schwarzschild's field. If the mass that serves as the source of the field is fairly diffuse, so that the gravitational field on the surface of the astronomical body is fairly weak, Schwarzschild's field will exhibit physical properties very similar to those described by Newton. Gross deviations will be found if the mass is so highly concentrated that the field on the surface is strong. At the time of Schwarzschild's work, 1916, this appeared to be a purely theoretical speculation; but with the discovery of pulsars and their interpretetion as probable neutron stars composed of matter that has the same density as atomic nuclei (so-called nuclear matter), there exists the distinct possibility that strong fields may soon be available to astronomical observation.

The most conspicuous feature of the Schwarzschild field is that if the total mass is thought of as concentrated at the very centre, then at a finite distance from that centre, the Schwarzschild radius, the geometry of space–time changes drastically from that to which we are accustomed. Particles and even light rays cannot penetrate from inside the Schwarzschild radius to the outside and be detected. Conversely, to an outside observer any objects approaching the Schwarzschild radius appear to take an infinite time to penetrate toward the inside. There cannot be any effective communication between the inside and the outside.

The exterior and the interior of the Schwarzschild radius are not cut off from each other entirely, however. Suppose an observer were to attach himself to a particle that is falling freely straight toward the centre and that this observer is equipped with a clock that reads its own proper time. This observer would penetrate the Schwarzschild radius within a finite proper time (see Figure 3); moreover, he would find no abnormalities in his environment as he did so. The reason is that his clock would deviate from one permanently kept outside and at a constant distance from the centre, so grossly that the same event that seen from the outside takes forever occurs within a finite time to the free-falling observer.

From P. Bergmann, *The Riddle of Gravitation*; Charles Scribner's Sons

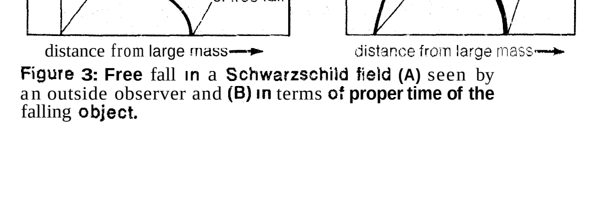

Figure 3: Free fall in a Schwarzschild field (A) seen by an outside observer and (B) in terms of proper time of the falling object.

These peculiarities of the Schwarzschild field may well have practical applications in astronomy. The U.S. physicist J. Kobert Oppenheimer had found that a star whose mass exceeds the mass of the Sun bv an appreciable factor is bound to contract and, eventually, to collapse under the Influence of its own gravitational pull, no matter how resistant its constituent matter. As a good many stars are believed to have such large masses, it is likely that there already exist some collapsed stars, so-called black holes. Though continuing to make its presence known by the gravitational attraction it exerts on other stars, a biack hole would absorb but not emit light, and thus be invisible, hence its name. In the early 1970s a number of astronomers had claimed the discovery of black holes, but these claims have not been confirmed.

APPLICATIONS OF RELATIVISTIC PRINCIPLES

Particle accelerators. Modem particle accelerators speed up particles to energies at which they very nearly achieve the speed of light. At tnese energies and speeds the differences in behaviour predicted by classical physics and by the special theory of relativity are huge; the machine must be designed in accordance with relativistic principles, or it will not operate.

In the early 1970s the most powerful electron synchrotrons were operating at energies of several thousand million electron volts, which means that the relativistic mass of one electron orbiting at maximum energy was roughly 10,900 times its rest mass. Accordingly, the magnetic field required to maintain the electrons in orbit was 10,000 times as powerful as it would have to be if nonrelativistic physics held, at the same speed. On the other hand, at that given energy the speed of the electrons is in fact very nearly equal to the speed of light, the difference amounting to no more than one part in 100,000,000 (10^8). *At* the same energy, but by nonrelativistic mechanics, the speed of the electrons would have been about 100 times the speed of light. This difference has a very practical consequence: in those panicle accelerators designed for highly relativistic energies, the synchrotrons, particles are injected into a circular orbit already near the speed of light, and their velocities change only slightly as their energies are brought up to the highest design value. If the orbit diameter is kept nearly constant. particles at all energies will circulate at the same frequency, and only the magnetic field that keeps them in orbit needs to be increased to keep pace with the increasing mass. The accelerating voltage is applied at the constant frequency required so that the particles will always be accelerated forward.

Operations of the synchrotron

Relativisticparticle physics. The physics of elementary particles (that is to say, subatomic particles) depends on the principles of the special theory of relativity. These principles have their greatest application when particles are created, annihilated, or converted into different particles. In most particle transformations, large amounts of energy are involved; the total (rest) masses of the particles involved in the transformations will change, and this change will be related to the amounts of energy expended or gained by the rule that the change in mass *(Am,)* is balanced by a corresponding change in energy (ΔE), divided through by the square of the speed of light (c^2): $\Delta m_0 = -c^{-2}\Delta E$. This rule has been confirmed universally and, by now, is being taken for granted.

The units, or quanta, of electromagnetic energy, increasing with frequency and called photons, have long been regarded as a species of particle in which are combined the properties of zero rest mass with nonvanishing relativistic mass, because they travel at the speed of light. The relativistic mass equals its total energy E, according to an equation in which $\hbar$ denotes Planck's universal constant h divided by 211 and ω the angular frequency of the radiation: $E = \hbar\omega$, divided again by c^2. The relativistic mass of a photon can be checked experimentally if the photon is absorbed or deflected in its interactions with particles, when the change in its linear momentum (product of velocity and relativistic mass) results in a recoil by the other particles. If a high-frequency photon, a gamma photon, collides with a free electron, the result is called the Compton effect, which involves both an observable recoil on the part of the electron and an altered frequency of the deflected photon. Again, relativity is confirmed by experiment.

It has been conjectured that gravitational waves, also, are composed of zero-rest-mass quanta travelling at the speed of light. These hypothetical particles have been dubbed gravitons. As the quantum theory of the gravitational field has not been definitely established and as the detection of individual gravitons may remain beyond experimental capabilities for years to come, the existence of gravitons could not be considered assured in the early 1970s.

Neutrinos

There is another species of zero-rest-mass particles, produced in radioactive decay involving the ejection of electrons or positrons from atomic nuclei (so-called beta decay). These particles, known as neutrinos, have no electric charge and travel at the speed of light. Four distinct species of neutrinos are now known, each of which is produced in a different kind of beta decay. Neutrinos interact with any type of particle extremely weakly. As a result, they are capable of traversing large amounts of matter with but a slight chance of being deflected or absorbed in the process. Though their existence has been confirmed beyond a doubt, their detection and detailed examination remained a challenging problem in the early 1970s.

Relativistic cosmology. Theories concerning the structure and history of the whole universe have assumed an increasingly empirical aspect in the course of the 20th century. In the 1960s, particularly, a combination of new observation techniques, new discoveries, and applications of the special and general theories of relativity has resulted in considerable progress.

The most important techniques added to those of observations by means of visible light were: radio astronomy; infrared, ultraviolet, X-ray, and gamma-ray astronomy from extraterrestrial platforms; cosmic-ray investigations; neutrino astronomy; and examination of the Moon and other astronomical bodies by unmanned and manned space exploration. Discoveries with cosmological impact included: the expanding universe, quasars, and the "primeval fireball." Each is explained briefly below.

Edwin Powell Hubble, a U.S. astronomer, had discovered that the more distant astronomical objects exhibited a shift of spectral lines toward the red (long wavelength) end of the spectrum, the extent of the shift increasing the greater their distance from Earth. This cosmological red shift has been generally interpreted as evidence of rapid recession of these distant objects in an expanding universe. The present rate of expansion is expressed as the amount of recession per unit distance and is known as the Hubble constant. It amounts to about a mile per second recessional velocity for a distance of 10^5 light-years. Equivalently, if the rate of expansion has been constant, it must have started about 2×10^{10} years ago.

Quasars, also called quasi-stellar objects (QSO's), appear to be structures that combine extreme luminosity (100 times that of a bright galaxy) with great compactness, taking up less space than the distance between the Sun and its nearest neighbour star. Wherever a spectral analysis of a quasar's emitted light has been possible, the spectral lines have been considerably red shifted, increasing their wavelengths from a few percent to several hundred percent. If these red shifts are interpreted as cosmological (and this interpretation has not been accepted by all astronomers), some quasars are more distant from the Galaxy than any other known objects. As such they may provide indications of the large-scale structure of the universe, which could not be obtained from investigations confined to "close" surroundings. The term close is to be understood in relation to distance in which Hubble's red shift becomes large ("cosmological distances"), distances amounting to thousands of millions of light years.

The notion of the primeval fireball

Finally, the term primeval fireball refers to the discovery of an all-pervasive background of radiation whose frequencies lie in the border region between microwave radio frequencies and infrared, corresponding to wavelengths of the order of millimetres and centimetres. In the early 1970s this radiation was interpreted as a remnant of the original intensive radiation that must have been associated with the early history of the universe, when matter was both extremely dense and extremely hot; hence its name. Its spectral composition, which at the time of writing was the object of intensive investigation, might provide some clues to the early history of the universe.

General relativity contributes to a theoretical discussion of cosmology the idea that the universe as a whole need not be flat even on the average and that it probably is not. Even if one were to assume that on a very large (cosmological) scale the universe is homogeneous and isotropic (*i.e.*, having the same properties in all directions), which appears a reasonable working hypothesis in the absence of any evidence to the contrary, there are a number of different possibilities. The universe might be spatially open (as a flat one surely is), or it might be closed, somewhat as the surface of a sphere is closed, without boundaries. Likewise, in the time direction the universe might be either open or closed; it is a little difficult to visualize a time-wise closed universe, which appears to be inconsistent with ordinary notions of cause and effect. But as these notions are distilled out of normal experience, which does not extend too far beyond one human lifetime, they might be inapplicable on the scale of billions of years. In brief, many different cosmological models have been proposed and investigated theoretically, but present observational information does not seem to favour one particular type. The information at hand appears to favour types that involve an expansion from an early stage involving fireball conditions.

MODIFICATIONS OF GENERAL RELATIVITY

The steady-state theory of the universe

Aside from the attempts at unitary field theories, which have been mentioned above, two modifications have been proposed in the past three decades. One is the steady-state cosmological theory developed in England by the astronomers Hermann Bondi, Thomas Gold, and Fred Hoyle. These authors have suggested that the exotic early stage of the universe and its progressive thinning out could be obviated if it were assumed that matter is created continuously at a very low rate, just sufficient to maintain a constant density of matter in the universe, in spite of the observed expansion. On the cosmological scale their model of the universe would persist forever without changing its over-all characteristics. The steady-state theory evoked much interest for some years, but in the early 1970s discovery of the universal background radiation was considered an indication that there was an early dense state of the universe very different from the universe known today. Nevertheless, the discussion cannot be considered definitely closed.

The other modification to be mentioned is the scalar-tensor theory proposed by a German physicist, Pascual Jordan, and, independently, by a U.S. physicist, R. Dicke. This theory proposes to make the universal constants of nature, such as the ratio of electric charge to mass of the electron, variable and dependent on the expansion of the universe. The proponents of this theory have adduced evidence gathered from the history of the Earth and the structure of the Sun, and they have designed experiments that would make it possible to make a clear-cut choice between the scalar-tensor theory and conventional general relativity. By the early 1970s the evidence in hand appeared to favour Einstein's theory, but not decisively.

(P.G.Be.)

Relaxation Phenomena

The term **relaxation** is used by chemists and physicists to describe the interval or time lag between the application of an external stress to a system—that is, to an aggregation of matter—and its response. The relaxation effect may be caused by a redistribution of energy among the nuclear, electronic, vibrational, and rotational energy states of the atoms and molecules that comprise the system, or it may result from a shift in the ratio of the number of product molecules to the number of reactant molecules (those initially taking part) in a chemical reaction. The measurement of relaxation times can provide many insights into atomic and molecular structures and into the rates and mechanisms of chemical reactions.

Historical survey. The word relaxation was originally applied to a molecular process by the English physicist James Clerk Maxwell. In a paper "On the Dynamical Theory of Gases," which he presented in 1866, Maxwell referred to the time required for the elastic force produced when fluids are distorted to diminish or decay to l/e (*e* is the base of the natural logarithm system) times its initial value as the "time of relaxation" of the elastic force. The earliest suggestion of a chemical relaxation effect is contained in a dissertation (Berlin, 1910) based on research directed by the German physical chemist Walther Nernst. Measurements of sound propagation through the gas nitrogen tetroxide, which breaks up, or dissociates, into nitrogen dioxide, led Nernst to suggest that experiments at frequencies at which the dissociation reaction could not keep pace with the temperature and pressure variations that occur within a sound wave, would permit evaluation of the dissociation rate. Ten years later, at a meeting of the Prussian Academy of Sciences, Albert Einstein presented a paper in which he described the various theoretical aspects of this relaxation effect.

Dielectric relaxation

The detection of the chemical relaxation effect predicted by Nernst and Einstein did not become technically feasible until the last half of the 20th century. In the first half of the century physicists and chemists in studying relaxation concentrated on physical relaxation processes. Peter Debye referred to the time required for dipolar molecules (ones whose charges are unevenly distributed) to orient themselves in an alternating electric field as dielectric relaxation. Sound absorption by gases was used to investigate energy transfer from translational, or displacement in space, to rotational (spinning and tumbling) and vibrational (oscillations within the molecule) degrees of freedom, the three independent forms of motion for a molecule. The former requires only a few molecular collisions, but the transfer of energy between translational and vibrational modes may require thousands of collisions. Because the processes are not instantaneous but time dependent, relaxation effects are observed. Their measurement provides information about molecular bonding and structure. Chemical relaxation was rediscovered by the German physical chemist Manfred Eigen in 1954. Since then, technological advances have permitted the development of techniques for the measurement of relaxation times covering the entire range of molecular processes and chemical reactivity.

The great variety of relaxation phenomena and of the techniques developed for their study precludes a comprehensive survey. To facilitate a general discussion, the relaxing system, its initial and final states, the nature of the disturbance, and the system's response are considered separately. Examples are cited that emphasize the important features of relaxation phenomena and illustrate the variety of information that can be obtained from their study. A moderately detailed description of one relaxation technique, the temperature-jump method, is used to summarize the discussion.

Dimers and monomers

Relaxation. *General* considerations. The chemical relaxation of nitrogen tetroxide is easy to visualize, and it illustrates principles common to all relaxation phenomena. Nitrogen tetroxide (formula N_2O_4) actually is a dimer (a molecule consisting of two similar molecules called monomers) that dissociates into two monomers, or molecules of nitrogen dioxide (formula NO.,). The monomer and dimer are easily distinguishable: the former is a brown gas; the latter is a colourless gas. The product and reactants exist in equilibrium, represented by the reversible reaction,

$$N_2O_4 \rightleftarrows 2NO_2.$$

1 molecule 2 molecules

At ambient (room) temperature and atmospheric pressure, approximately 80 percent of the molecules in the mixture are dimers and the remaining molecules are monomers. The distribution of molecules between the two forms remains unchanged as long as the temperature and pressure are held constant. If the external conditions are altered, then the ratio of monomers to dimers will adjust to a new value. The dependence of the equilibrium on pressure is intuitively understandable as follows: to a good approximation the volume that a gas occupies at a given pressure and temperature depends directly on the number of gas molecules. The dissociation of one molecule of nitrogen tetroxide into two moiecules of nitrogen dioxide entails an expansion of the gas, a doubling of molecules, which is opposed by the external pressure. If the external pressure is increased, the system acts to relieve the stress by reducing its volume; *i.e.*, by combining monomers to form dimers and thus reducing the number of molecules. The equilibrium shifts in favour of dimers under increased pressure, and in favour of monomers under reduced pressure. At any steady pressure, the ratio of the two forms eventually becomes constant.

Chemical relaxation results from the inability of systems at equilibria to respond instantaneously to changes in external conditions. The rate of re-establishment of equilibrium, or re-equilibration, is limited by the concentrations of the reactants and their reactivities. At any specified temperature and pressure, there is a definite probability per unit time that a nitrogen tetroxide molecule will dissociate into two nitrogen dioxide molecules and that the latter will recombine to form a dimer. The average lifetime of a nitrogen tetroxide molecule at ambient temperature and atmospheric pressure, for example, is about one-third of a microsecond (one-millionth of a second). The product of the reciprocal of the average lifetime times the concentration of nitrogen tetroxide molecules gives the rate at which they dissociate. At equilibrium there is no net change in the number of nitrogen tetroxide molecules, because their dissociation rate is exactly balanced by the rate at which they are being re-formed through association of nitrogen dioxide molecules. If the external conditions are altered, the reactivities of the monomer and dimer change instantaneously but their concentrations change at a finite rate until the balance between the association and dissociation rates is re-established.

Sound propagating through a gas can be pictured as a

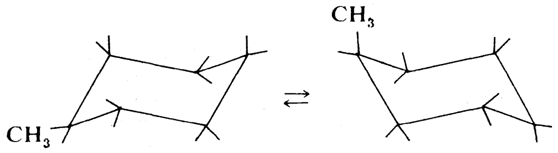
Sound waves in gases

pressure wave whose alternating increase and falling off of pressure, called a sinusoidal variation of pressure, with time at any point in the medium is accompanied by a corresponding fluctuation in the temperature. The effect of the varying temperature and pressure of a sound wave moving through nitrogen tetroxide gas on the dissociation of nitrogen tetroxide depends on the frequency of that sound wave. When the pressure oscillates slowly enough, the dissociation reaction will remain at equilibrium with the oscillation; that is, the extremes in the monomer–dimer ratio will coincide with the extremes of pressure and temperature. If, on the other hand, the pressure fluctuates too rapidly for the reaction to follow, the ratio of monomers to dimers will remain constant at the equilibrium value for the ambient temperature and pressure; but at intermediate frequencies, a relaxation effect may be observed, and a readjustment of the chemical equilibrium will lag behind the pressure variation within the gas.

The relaxing chemical equilibrium results both in the absorption of sound by the gas and in dispersion of, or changes in, the sound velocity. Measurement of either of these effects permits evaluation of the relaxation time. The maximum absorption of sound occurs, for example, when the angular frequency (two pi times cycles per second) of the sound wave equals the reciprocal of the relaxation time. The relaxation time can then in turn be related to the mechanism of the chemical reaction and to the reactivities of the reactants.

The relaxing system. Relaxation may occur between any two allowed energy states of nuclei, atoms, or molecules in the solid, liquid, or gas phase. A distinction has already been made between chemical relaxation, which involves a transformation between two chemically distinguishable molecules such as the dissociation of nitrogen tetroxide, and physical processes such as the transfer of energy between translational and vibrational states of a molecule displayed by sound absorption in a homogeneous gas. Although it is useful to classify relaxation processes as chemical or molecular, the distinction between them depends on the height of the energy barrier separating the chemical species, and it becomes blurred when structural isomerizations are considered. Liquid methylcyclohexane, for example, absorbs sound of ultrahigh frequency. The relaxation effect is attributed to an isomerization (change in structure) between two forms of the molecule called the axial and equatorial chair forms, as shown below:

Isomerizations



equatorial form of methylcyclohexane

axial form of rnethylcyclohexane

In the axial form, the methyl group lies perpendicular to the principal axis of the carbon ring, whereas in the equatorial form the methyl group lies in the plane of the ring. Whether or not the interconversion is considered a chemical or a molecular relaxation process is largely a matter of definition.

Atomic nuclei may exhibit relaxation effects. Some nuclei spin mechanically. Because nuclei are charged, there is a magnetic field associated with a spining nucleus: it behaves like a simple bar magnet with a north and south pole. The nucleus is said to have a magnetic moment that will experience a force when placed in an external magnetic field. A hydrogen nucleus in an external magnetic field, for example, may orient its nuclear magnetic moment either parallel or antiparallel to the external field. The latter is a higher energy orientation, called the upper spin state. The equilibrium distribution of many hydrogen nuclei between the two spin states (parallel and antiparallel) can be perturbed (*i.e.*, changed) by the absorption of electromagnetic radiation of appropriate frequency. The system will then relax to the equilibrium distribution by time-dependent radiationless transitions of the hydrogen nuclei from the upper to the lower spin state. This process of returning to the equilibrium distribution is called spin-lattice relaxation, because the excess energy of the upper spin state is transferred to molecules surrounding the relaxing hydrogen nuclei as increased translational, rotational, or vibrational energy.

As with nuclei, atoms and molecules can be excited to higher energy states by the absorption of electromagnetic radiation. A nonequilibrium distribution of atoms or molecules in excited states is frequently accomplished by a technique, called flash photolysis, in which the system of atoms or molecules is subjected to an intense flash of visible or ultraviolet light. The excited species may undergo many fates, but if they decay to the equilibrium distribution between the ground, or lowest, states and the excited states of the original atoms or molecules, the system is said to have relaxed.

The word relaxation is sometimes used to describe the radiation of energy by individual molecules, atoms, or nuclei, rather than by a large number. A hydrogen nucleus, for example, may decay from the upper to the lower spin state by transferring radiant energy to a nearby hydrogen nucleus in the lower spin state. This exchange of spins is called spin-spin relaxation. It shortens the lifetime of an individual excited nucleus, but it does not restore the equilibrium distribution of parallel and antiparallel spins. Although it is convenient to think of an individual excited nucleus as relaxing, only the response of an excited population of many nuclei can be measured. This usage of the term relaxation obscures the most useful experimental feature of relaxation processes.

The initial and final states. In virtually all relaxation experiments a thermodynamic equilibrium state is disturbed, and the time required for re-equilibration is measured. The practical advantage of starting with a system at equilibrium is most apparent in the study of chemical reactions in solution. Nearly all of the elementary steps in chemical reactions, such as transfers of protons and electrons from one molecule to another, occur in less than a millisecond, and yet as late as the 1960s solution reactions with half-times (time in which the reaction is half completed) shorter than a millisecond could not be studied. This limit was imposed by the hydrodynamic problem of mixing two solutions. Reaction rates had been studied by mixing the reactants and monitoring the rate at which products appeared. The most elaborate mechanical mixing devices that have been built so far require a millisecond to initiate a solution reaction. Manfred Eigen was the first person to clearly perceive that mixihg could be avoided by perturbing an equilibrium and watching it relax. His enormous contribution to the study of fast chemical reactions was recognized by the award of a Nobel Prize in 1967.

Perturbation

Instead of disturbing an equilibrium system, a stationary state may be perturbed. Many enzyme-catalyzed reactions, for example, are experimentally irreversible. Nevertheless, for much of the time course of the reaction, the chemical intermediates are present in a stationary state; that is, their concentrations do not change. The stationary state can be disturbed and the rate of its re-establishment may be used to deduce the lifetimes of the chemical intermediates. Combined rapid mixing and relaxation techniques have been used successfully in a study of catalysis by the enzyme ribonuclease.

The nature of the disturbance. Eigen has divided the methods used to disturb systems into indirect, or competition, methods and direct, or perturbation, methods. In the first method, the relaxing system is continuously disturbed. The competition between the disturbance and the relaxation process results in the establishment of a stationary state, from which information about the relaxation process must be inferred. Ultrasonic absorption is an example of a competition method. The competition between the temperature and pressure variations in the sound wave and the dissociation of nitrogen tetroxide sets up a stationary state in which re-equilibration of the chemical reaction lags behind the pressure fluctuations in the sound wave. The reactivities of the monomer and dimer are derived indirectly from measurements of sound absorption. Flash photolysis is an example of the second method, in which the system is momentarily perturbed. The molecules are electronically excited from the ground, or lowest and normal, energy state to higher energy states by the flash. Their return, or decay, to the ground state can be followed directly by monitoring the reemission of the absorbed light.

A chemical equilibrium can be disturbed by changing the pressure or temperature or by applying an electric field. If a volume change accompanies a chemical reaction, the ratio of products to reactants at equilibrium will depend on the pressure. The point at which equilibrium sets in will depend on temperature, if heat is absorbed or released in the reaction. The ratio will also depend on electric field strength, if the polarizabilities (change in orientation or position of electric charges) of the reactants and products are different. Nuclear and electronic states can be excited by the absorption of electromagnetic radiation, and the latter can also be excited thermally. Perturbation forces, when expressed mathematically in terms of strength and time, are called forcing functions. In principle, a forcing function may assume any form, but in practice, it must be easy to generate experimentally and to analyze mathematically. Examples of forcing functions are the sinusoidal temperature and pressure variations in a sound wave (charting the variations produces a curve called a sine curve—which varies from positive to negative values) and sinusoidally alternating electric fields, which are used in dielectric relaxation measurements. Other convenient forcing functions are step, or incremental, perturbations and rectangular pulses (pulses of which the strength rises nearly instantaneously, remains at the higher value for a period of time, and then rapidly returns to its initial value).

Step perturbations of the temperature and pressure can be produced in shock tubes. A gas at high pressure is separated by a membrane from the gas being studied at low pressure. When the membrane is burst, a plane pressure wave caused by the high-pressure driving gas moves through the low-pressure gas under study. Temperature increases of several thousand degrees may accompany moderate pressure shocks. The shock front travels through the gas with a velocity comparable to the mean molecular velocity, so that the width of the shock front is only a few mean free paths (average distances travelled by the molecules between collisions). As the shock passes, the translational energy of the molecules in the shock front is increased. The system relaxes as the excess energy is distributed by collisions to rotational and vibrational degrees of freedom.

Rectangular temperature perturbations (plotted on a graph these show up as a curve that periodically rises suddenly, stays constant for an interval, then drops suddenly to original value) can be produced in aqueous solutions of reacting systems by using microwaves to heat the solution. Water molecules can absorb energy of rotation at 10^{10} hertz (cycles per second). By concentrating the microwave energy in a small volume, an increase of several degrees in temperature can be obtained in one microsecond using pulses of radar. Since the radar generator can be repeatedly pulsed, coupling it with a continuous flow system improves the experimental accuracy by averaging over the period of the experiment.

Detection

Response of the system. Any of the techniques for disturbing an equilibrium can be combined with a variety of detection systems. Depending on the nature of the relaxation effect, it can be monitored by absorption or emission spectroscopy, by fluorometry, or by polarimetry. Conductance changes can be measured. Crystals are used to detect ultrasonic waves and to measure absorption effects.

While a priori there is no restriction on the magnitude of the displacement from equilibrium, in practice small disturbances are used to permit the application of a linear rare equation (terms denoting changes with time are to the first power). The rate of disappearance, for instance, of a small displacement from equilibrium is approximately proportional to the magnitude of the displacement. This relationship is given by the differential equation

$$-\frac{d}{dt}(\mathrm{AX}) = \frac{\Delta X}{\tau}.$$

Here, the displacement (AX) is the difference between the instantaneous and the equilibrium values of the relaxing property, which might be the kinetic energy of molecules behind a shock front or the concentration of a chemical reactant. The reciprocal of the constant of proportionality has units of time and is called the relaxation time (τ, tau). Since the equilibrium values may be time dependent, the solution of the rate equation depends on the form of the forcing function. Propagation of a sound wave through nitrogen tetroxide gas, for instance, causes a sinusoidal variation of the equilibrium concentrations of monomers and dimers with time. A great advantage of relaxation methods is that the response to small disturbances can be approximated by a first order differential equation.

The relaxation time for a chemical process can be related to the reactivities of the reactants if the reaction mechanism is known. Conversely, it may be possible to deduce the reaction mechanism from the dependence of the relaxation time on reactant concentrations. If several chemical reactions are coupled, or if more than one vibrational state is excited, a spectrum of relaxation times may be observed. The relaxation times for the individual relaxation processes can be determined from the measured relaxation times, which are the normal modes for the coupled system.

Temperature-jump experiment. To summarize and to clarify this discussion, a temperature-jump relaxation experiment will be described. The name temperature jump is reserved for the relaxation technique in which a stepwise temperature perturbation is achieved by passing a large electric current through the solution under study and thus heating it almost instantaneously. Instrumentally, it is one of the simplest relaxation techniques. It is also the most generally useful method for the study of fast chemical reactions in solution.

A typical temperature-jump instrument produces a temperature rise of approximately **8° *C*** within five microseconds. The principles of this instrument are briefly explained as follows. A 0.05-microfarad capacitor is charged to between 30 and 40 kilovolts. The electrical energy stored on the capacitor is proportional to its capacitance and to the voltage squared. It is discharged through the reaction cell at time zero by closing a variable spark gap. The time required for dissipation of roughly 80 percent of the stored energy is given by the product of the capacitance times the cell resistance. The energy is dissipated through collisions between the ions, which conduct the discharge current through the solution and the solvent molecules. The rapid temperature increase causes a shift in the concentrations of reactive molecules in the solution to new equilibrium values. If this shift is accompanied by a colour change, the reaction rate can be monitored spectrophotometrically (*i.e.*, the change in the intensity of light of a selected wavelength with time is measured). The results are recorded on a storage oscilloscope for later display. Provided thar the rise time of the temperature pulse is much shorter, and that the thermal re-equilibration time is much longer, than the response time of the chemical reaction being studied, the temperature jump can be apprcximated as a step perturbation. At times greater than zero, the equilibrium concentrations of the reactants remain constant at the values corresponding to the higher temperature. Consequently, the differential equation for the disappearance of the displacement of reactant X from equilibrium can be integrated to show that this value decays exponentially.

In the introduction to an article on the ***Molecular Basis of*** Visual *Excitation* the Nobel laureate George Wald wrote,

> I have often had cause to feel that my hands are cleverer than my head. That is a crude way of characterizing the dialectics of experimentation. When it is going well, it is Like

a quiet conversation with Nature. One asks a question and gets an answer; then one asks the next question, and gets the next answer. An experiment is a device to make Nature speak intelligibly. After that one has only to listen.

Relaxation phenomena afford a unique method for making nature speak intelligibly about rapid energy transfers and chemical reactions. They have only begun to be exploited, especially to probe the elementary steps in complex biochemical reactions.

(L.D.F.)

Religion, Philosophy of

In addition to treating what is commonly called the philosophy of religion, this article considers a wide spectrum of situations, experiences, and issues recognized as "religious" and endeavours to appraise the characteristic approaches and attitudes not only of the adherents of particular religions but also of those who stand outside any particular religion, whether as sympathizers or caustic critics. Outside the scope of this article, however, are questions relating to the study of religions and its methodology or questions relating to the types of argument by which one interpretation of a religious claim is preferred to another (see also RELIGION, STUDY OF).

This article is divided into the following sections:

I. Nature and characteristics: preliminary approaches and common or typical views

RELIGION AS A FACT IN HUMAN EXPERIENCE, CULTURE, AND HISTORY

Evidences of religious attitudes and loyalties exist in every sector of human life—in human experience in general; in "culture," the complex interweaving of attitudes, concerns, and views; and in history, the record of social and personal behaviour.

Characteristic feelings and emotions of religion

The findings of psychology. Religion incorporates certain characteristic feelings and emotions such as wonder, awe, and reverence. The religious person tends to show a concern for values, moral and aesthetic, and to seek appropriate action to embody these values. He is likely to characterize behaviour not only as good or evil but also as holy or unholy and people as not only virtuous or unvirtuous but also as godly or ungodly.

As a feature of human existence, religious life can be studied, for example, in terms of psychology, sociology, and history. Among the first books in the psychology of religion were two by Jonathan Edwards, an 18th-century American theologian: ***A Faithful Narrative of the Surprising Work of God*** (1737) and ***A Treatise Concerning Religious affections***(1746). About a century later, during a period of religious "revivals," interest developed concerning the age at which conversions most often took place—the period of adolescence. Reflections on such facts, and in this sense the psychology of religion, only came, however, with the works of two American psychologists: Edwin Diller Starbuck's ***Psychology of Religion*** (1889) and the classical treatment by William James's ***Varieties of Religious Experience (1902).*** Generally, the psychology of religion has shown that though religion for some is a crisis experience, for others it is a natural growth.

As psychology became more analytical it became more interested in the abnormal, in neuroses and dreams, in the techniques of hypnosis, and in the kinds of experience induced by drugs. When Freud spoke of religion as an illusion, he maintained that it is a fantasy structure from which a man must be set free if he is to grow to maturity; and in his treatment of the unconscious he moved toward atheism. The study of the unconscious by the Swiss psychiatrist Jung, however, suggested that dominant archetypes (implying innate tendencies to form symbolic images) are supplied by a racial unconscious, thus providing a psychological approach to belief in God.

Classifications of individuals

In classifying individuals into different types, psychology has distinguished between religious people who are: "extrovert" or "introvert" (Jung), "healthy minded" or "sick" (William James), and "objective" or "subjective" worshippers (J.B. Pratt). There is always the danger, however, that psychological distinctions may beg too many philosophical questions.

One of the most widely accepted studies of religious experience in regard to feelings was written by the modern German Protestant theologian Rudolf Otto. In his ***Idea of the Holy,*** Otto analyzed what is distinctively religious in terms of the unique concept of the "numinous"; *i.e.*, something both awesome and appealing, both fearful and attractive.

Psychology, however, is concerned not only with individuals but also with what is known about group behaviour, which can also be of importance in any study of the Christian Church or other religious institutions regarded as communities of religious people. The authority of a religious leader, like that of all leaders, is derived from his symbolic character and the extent to which the leader and his followers share a common ideal.

The findings of sociology. The ideas and images of a religion are much influenced by the social culture in which it emerges. Some of the oldest social institutions and practices, such as those concerning birth and death, marriage and the family, and art and music, have developed in a religious context. Religion has often been a driving force in the reform of social abuses, but also it has been associated with reaction and oppression. More recently, the sociology of religion—influenced by contemporary sociology—has been concerned with making use of sociological criteria and of demographical and statistical studies in planning the church's mission and appraising its significance.

The findings of the history of religions. Conclusions in the history of religions have been largely determined by the particular ideas of man or history with which the study was approached. Some scholars have supposed that at the dawn of human existence there was a belief in a single god and that only later there occurred a development into a belief in many gods as well as animism (a belief in souls or spirits in man and other aspects of nature). Other scholars have supposed an evolutionary development of religion, which only reached monotheism—considered to be the highest form of religious belief—after a long period of purification. The two approaches sponsor, respectively, two contrasting myths about primitive man. According to the one, there was once a golden age of innocence and harmony; according to the other, the life of the earliest man was hasty, brutish, and short.

Granted the ubiquity of religion and its diversity, historians have found no universal essence expressible in terms of common beliefs. What is probably common to all religions is nothing more than the claim that reality is not restricted solely to what is yielded by sense experience itself.

The ambiguity of religion's influence on culture

The role of religion in culture. Religion has had a strong but ambiguous cultural influence. The thought that a man depended for his life and existence on a power not his own has encouraged some persons to be lazy, as it has inspired others to greater effort. A conviction about another world has led some religious people to disvalue human life; it has led others to view human life as having the significance of a state of probation. It has been plausibly argued by some (*e.g.*, the German sociologist Max Weber) that Protestantism provided a seedbed for modem capitalism; Catholicism, according to others, easily accommodates a Socialist point of view.

Because a religious view is generally associated with a conviction about the inadequacy of "things seen and temporal," religion as a cultural influence usually shows itself dissatisfied with things as they are. Often, however, when confronted with novelty, religion has tended to be conservative. Thus, religion has alternately opposed or fostered social and cultural development.

VIEWS WITH TRANSCENDENT REFERENCES

A situation is regarded as religious when through its spatiotemporal features what can be termed depth or another dimension can be disclosed objectively. In this sense, there cannot be such a thing as a religion that is nontranscendent. On the subjective side, there will be a matching self-disclosure, a "coming to one's self" that occurs as a response to a vision of the eternal in and through the temporal.

Relation to an ultimate power, or being, to values, or to ideals. Different religious approaches can be distinguished by the different interpretations they give of what is objectively disclosed, of what in this sense is the transcendent. In primitive religion, for example, the transcendent is always interpreted in terms of an ultimate power or activity expressing itself, whether singly (monism) or with multiplicity (pluralism), through the objects and events of the world.

Animism, totemism, and interpretations of cosmic power

Animism views the world as having life, power, and feeling as do men. A monistic view of the universe is conceptually akin to the view according to which people or objects exert the peculiar influence they do and have the strange significance they possess because of mana—a power or force somewhat similar to the scientific concept of energy—that they embody. Animism becomes more diversified and pluralistic when it becomes spiritism, which locates the cosmic life, power, and feeling in particular objects. Totemism involves a highly complex system of beliefs and practices whereby an animal or plant becomes a totem, or a focal symbol for the life and well-being of a tribe. Just as tribal communities are sustained by a power that the totem symbolizes and expresses, so the patterns of tribal behaviour are maintained by taboos. Persons, things, and behaviour are taboo, or are prohibited to members of a society, when they are judged to be so highly charged uith sacred power that ordinary "profane" persons must keep their distance. (See also the articles PRIMITIVE RELIGION; ANIMISM; TOTEMISM.)

These primitive viewpoints have a certain conceptual kinship with what the more sophisticated religious viewpoints have labelled with such terms as theism, polytheism, pluralism, and Idealism. Theism interprets the one cosmic, life-giving power in personal terms-different versions varying in their views of the adequacy of those personal terms. Polytheism posits a multiplicity of cosmic personal powers on whose activity (whether in cooperation or conflict) the universe depends. Pluralism views cosmic power as mediated and expressed through a multiplicity of ultimates (*e.g.*, finite persons) or otherwise views the universe as best understood in terms of ultimate atomic units, with no claim made for the absolute supremacy of any one of them. In this way, pluralism—even of a personal kind--differs from theism, which holds that God is a Supreme Person.

Absolute Idealism maintains that activity is an ultimate category but makes no claim, as does theism, for this activity to be personal. Instead, it takes a biological organism as its dominant model. Theism, like deism, has sometimes posited an ultimate personal power or being beyond, above, and certainly separated from the changing scenes of life, whereas absolute Idealism posits an ultimate power or being that is considered to be the whole, of which the changing scenes of life are but a part (see also THEISM; POLYTHEISM; DEISM; IDEALISM).

Interpretations of salvation

Seeking salvation in a life beyond. Religion is not merely a matter of being aware of a transcendent dimension nor is it merely a claim for a broader and more comprehensive view of the reality. Fundamental to religion is the conviction that through a right relation with a cosmic power or powers, man will find his salvation. Various views of such salvation have been held. Salvation has been regarded as something attainable only after this life. Other views, however, tend to posit a salvation for man through escape lather than fulfillment. Alternatively, salvation may be viewed as something anticipated in the present but fulfilled perfectly after this life. Salvation also has been interpreted in terms of fellowship with God or as a state of bliss needing no God (as by the early 20th-century British philosopher J.M.E. McTaggart), as a state of ultimate peace that arises when man sees his peculiar and rightful place in the whole universe (as by Spinoza), and as a state of bliss in which man cannot properly speak of himself as a self-conscious individual as in the Buddhist state of Nirvāṇa.

VIEWS WITH ANTHROPIC REFERENCES

Inner attitudes and dispositions. A religious view of the universe contends that a new dimension and depth can be disclosed within the person who responds. Though religious faith has its characteristic inner attitudes and dispositions, they must be of a transcendently self-involving kind, and there must be a depth to any attitude or disposition before it can be called religious. Thus, the attitude of awe is related to the feeling of fear. For fear to become awe, however, it must be characterized by a particular depth and self-involvement that come from responding to the presence and activity of God, or of the sacred or holy that call it forth.

The concept of conversion

Religion relates to the whole of a man's personality and because of this totality of human response, people speak of "conversion" in relation to religious attitudes. Generally, a person who becomes religious or ceases to be religious undergoes a profound transformation. Persons who have become converted to religion speak of the world as having taken on a fuller and richer dimension; those for whom the religious vision has disappeared speak of a world as having become flat, dead, and bleak.

Behavioral discipline with prescribed practices. Many religions bind their adherents to specific practices and particular moral codes. Thus, conversion has often shown itself in radical changes of behaviour; *e.g.*, an alcoholic becoming a total abstainer. Such behaviour as murder, lying, breaking promises, stealing, and committing adultery have been condemned by the world religions. So strong is the ethical element in Confucianism that some regard it more as an ethical system than a religion. Yet, ethical (and ceremonial) codes can be transformed imperceptibly into no more than current social conventions and mere customs. Whether such codes have changed or not, their range and detail vary widely. Pork is eaten by Christians but is considered to be unclean by Jews and Muslims. Muslims and Buddhists abstain totally from alcohol; Christians and Jews need not. A Sikh will not shave his beard; but Hindus, Christians, and Muslims are free to do so if they wish. In contrast with Christians, Buddhists will not kill animals, and Muslims may practice polygamy.

Participation in a social institution. Whatever the diversities, religious faith is not only self-involving, but it has a social dimension as well. Hermits apart, religion brings people together as children of one family having a common father. For Christians, the significance of the universal religious community, the church, has been variously interpreted. Some, with a Protestant emphasis, have viewed the church as a voluntary institution created ad hoc for the convenience of its members to enable them to gather together to worship, to sing hymns, and to share common interests and beliefs. The Catholic view is that the church is a social institution that is derived from God and whose structure expresses the givenness of God himself.

To be of religious significance, however, social practices and moral codes, like inner experiences must have depth, a transcendent dimension, or they become superficial and dangerous parodies of religion, all the more dangerous for being in their outward features so similar.

II. The meaning of religion for persons within the particular religions

THE VIEW FROM WITHIN AS PRIVILEGED

The assertion that the view of religion from within is privileged needs careful analysis.

First, religious faith is logically privileged insofar as it is characterized by a self-involvement, commitment to which partial commitments can only point. A temporary loyalty, however intensive, is at best a distant pointer to a conversion. Further, because religious faith is grounded in a disclosure, there is something logically privileged about it in the same sense that some are "privileged" to understand a joke when others do not. Yet, even though religion has a disclosure basis, it is still true that just as there are techniques for jokes so also are there techniques for meditation, whether in Christianity or in other religions. By virtue of such techniques men can have a reasonable expectation of a view of religion from within. In another sense, the view that religion from within is privileged may merely mean that if a man believes something and is committed, he is more involved than a man who does not believe.

One aspect of the logically privileged position of religion might be called its semantic privilege; *i.e.*, the fact that a religious vision cannot adequately be expressed. One fundamental problem for religious language, according to linguistic analysts, is to discover more reliable rather than less reliable ways of talking. One need not presuppose, however, so fundamental a distinction between the sacred and the secular that men become committed to total silence on religious matters. When St. Paul, for example, wrote of being "caught up" (in II Cor.) he "heard things that cannot be told, which man may not utter." If this statement of Paul's were generally true of religion, however, religious people would be so privileged that they would be living in a segregated silence.

Some scholars have argued that the privileged character of religion makes it unsuitable as a proper study for the philosopher, who must in principle be detached, not committed, and have an openness to all truth. The lack of finality in philosophical thought is contrasted with religious commitment and the final claims sometimes made for religious doctrine. Nevertheless, insofar as anyone has a coherent world view, there will be some degree of commitment.

Religion is not, however, altogether beyond argument, and those who are outside a religion can still have some inkling of what is being discussed within a religion and the manner in which it is being discussed, especially when the social, cultural, historical, and psychological embodiments of the religion are described. For this reason Western Christians and Jews, for example, are able to know something about the primitive religion of an African or Indonesian tribe.

Thus, much about religion can be known by those outside it, however, views about the nature of religion and definitions of religion have a systematic inadequacy about them. Like everything of the spirit, religion cannot be described so as to make clear to the detached observer the characteristic quality and depth of religious awareness and commitment.

THE DIMENSION OF RELIGION FOR INSIDERS

The essence or core of religion. For the insider, the essence of religion is given in a moment of vision and disclosure. Friedrich Schleiermacher, a German philosopher of the 18th and 19th centuries, described the basic religious experience in terms of a kiss or an embrace. Attempts to understand such a unity can only be made in terms of the particulars into which the unity subsequently breaks, and such particulars then fall broadly into subjective and objective compartments.

Faith, prayer, and ritual

The subjective and objective aspects of religion. Faith describes a subjective state that accepts what a disclosure discloses and is akin to personal trustfulness, to a conation or striving that, according to Spinoza, all living things display. Prayer is the utterance of words (rite) with or without some dramatic context (ceremonial) designed either to carry one into the presence of what is worshipped or to express appropriate sentiments in the presence of what is worshipped. Most prayers incorporate words that function in both ways. Ritual is especially concerned with events in human life that have disclosure possibilities and in which mystery is at its highest.

Mystery in the context of religion refers to situations, such as birth, reproduction, death, and suffering, in which there are numerous possibilities for new insights and yet further insights. Public worship must constantly renew and realize in the liturgy the possibilities of the past disclosures. If the outward expressions and forms come to dominate, ritual can become an empty shell, and religious practices can become devoid of religious significance.

Effects of religious beliefs and practices. One of the effects of religious beliefs and practices is sacralization, a process in which certain persons, days, or objects become regarded as sacred. If such objects are granted more than the status of symbols, they may become objects of idolatry or superstition.

Belief in salvation, which often accompanies religious commitment, can have various practical results. If salvation is viewed as something that inspires progress and may be accomplished in the realm of time, such doctrines of salvation encourage social reforms and projects that envision an abundant life for humanity. If, on the other hand, salvation is viewed as something that is beyond the realm of time and set entirely apart from this world—something for which at best this world is a probation and at worst a sink of misery and iniquity from which the sooner man is released the better—such doctrines of salvation can be excessively individualistic and may even encourage oppression and tyranny.

Conclusions about nature and history

Religious belief has sometimes led men to detailed conclusions about nature and history. Good harvests have been interpreted as due rewards for appropriate worship or good behaviour, or both; calamities have been viewed as the results of sin, either ceremonial or moral. If God is believed to be in control of history, a nation that does what is right and follows his guidance, as expressed through its prophets and other religious personages, is expected to experience national prosperity and success. In previous periods, when this did not occur, the ensuing calamities were attributed to the backslidings of earlier generations.

Many observers of religion claim that in the modern world few would suppose that God intervenes in this direct and predictable way. According to this view, God's activity in the world, apart from being expressed in its constant creativity and conservation, is effective through man's own intellectual and physical activity. Insofar as man's own creativity is exercised, however, within the framework of the order that the world displays, and in no way violates it, one cannot exclude a similar creativity on the part of God. Admittedly, the fact that man expresses his activity through an intermediate organism (his body) indicates that there is no exact parallel between God and man; nevertheless, because God's activity terminates with the universe, the analogy with God's activity might very well be expressed in the number of ways in which man can effect creative development in his own body.

INTERNAL CRITICISMS OF RELIGION

Internal criticisms of religion have their basis in the imbalance that occurs when one aspect or one understanding of religion is allowed to dominate the rest. Heresies have arisen when one way of understanding has been developed without balancing it with another. In the development of doctrines concerning the nature and person of Christ within Christianity, for example, heresies arose when a particular model (*e.g.*, that of fatherhood and sonship) was believed to be capable of infinite development. The model of the Father–Son relationship was pressed too far, and the Son was subordinated to the Father in a way inconsistent with Christian orthodoxy, thus leading to what became heresy. Sectarianism develops when religious insights are associated exclusively with one particular doctrinal or theological phrase, such as justification by faith, or with one particular theological view regarding religious practices; *e.g.*, baptism. Because religion is at once infinite and mysterious, it is important that religious belief does full justice to a wide variety of approaches.

Another criticism of religion has been that it has tended to be overintellectual; and when this trait has been combined with moral laxity and factional rivalries, it has led to protests about the arrogance of intellectualized religion, often leading to the opposite error of supposing that belief does not matter as long as common sentiments are shared. Religious believers have not always recognized that for the most part their belief explicates metaphors, images, and symbols. Though ways of religious reasoning are appropriately informal and variegated, having their origins in a multitude of images and symbols, it nevertheless is considered a religious duty to produce the most reliable overall discourse based on the various images and models.

Balancing intelligibility and mystery

The fundamental difficulty of all religious understanding, however, is to balance intelligibility and mystery. If the intelligibility is neglected, religious belief can become dishonest and religious men can lose integrity; if mystery is neglected, there may be splendid controversy and exercises in logical appraisal, but the heart of religion will have disappeared.

The basic difficulty of all religions and of historical religions in particular is to effect a constant rebirth of symbols in changing cultures. In the course of time some of the most powerful images and symbols lose their fertility in promoting ideas that inform a religious community. This might be said of the image of sacrifice in the Christian religion. Religious practices and institutions, though they may have social merits, can all become stereotyped routine, as happens when they fail to preserve a sense of reverence and fail to disclose the givenness of the sacred or holy. Because religious belief is so important and influences all aspects of a society, there is a tendency for religious institutions to become authoritarian and oppressive. If a religious institution becomes interwoven with political views it can become tyrannical. Religion's only compulsion, according to some scholars, must be the compelling power of a vision, as the modern English–American philosopher Alfred North Whitehead expressed it: "The power of God is the worship He inspires." The authority of any religion is the authority of a vision, the authority of that which, in being disclosed, inspires men and leads them to fulfillment in their lives. For a Christian, the final authority is the love of God in Christ, and love is not love if its power is anything but inspiration. For other religions there is the compelling inspiration of that to which—Nirvāṇa or the Qur'ān, the Buddha or Muhammad—point.

Internal criticisms of religion usually focus on such themes as narrowness, sectarianism, traditionalism, conventionalism, materialism, and immorality. Some criticism is also reserved for religiosity, which, though granting a dimension of faith, treats faith in an altogether superficial and often unbalanced way. Religiosity represents an excessive preoccupation with religion that is depicted in an incoherent and oversimplified relating of religious faith to intellectual views and social and personal practices.

III. Attitudes toward religion by persons outside particular religions

THE REJECTION OF RELIGION OR RELIGIOUSNESS

Because religious commitment is so all-embracing and tends to influence thought, feelings, and behaviour, it is not surprising that there are many reasons why religious claims have been rejected.

Rejections because of alleged incoherence. Religious claims have been rejected because of their alleged logical or moral incoherence.

Alleged logical incoherence. Logical incoherence may arise internally or externally and in relation to different issues. In regard to internal coherence, critics have maintained that man should be able to expect that God would see to it that there could be no possibility of ignoring his existence or of making mistakes about religious beliefs and behaviour, if religious convictions are so important. They have also claimed that it is altogether too naïve, though inevitable, to think of God as made in the image of man. Some have rejected theistic belief because of the incoherence of the idea of God, which must—they claim—combine so many incompatible predicates; *e.g.*, God is eternal, yet acts in time, or he is loving and yet incapable of suffering or feeling.

External incoherence, in conflict with other views of world

Religious beliefs have been alleged to be externally, as well as internally, incoherent because of their conflict with other views about the universe, especially scientific views. The doctrines of heaven and hell, in particular, which have given great personal and social significance to religious belief, have been rejected by many critics when these doctrines were viewed literally. Yet it has been the supposed actuality of heaven and hell that has given religious persons their hope and their terror respectively. Absolute Idealism, it has sometimes been alleged, is incoherent insofar as it states that time is not "real" and that evil does not really exist. This is not to say, however, that there is no temporal succession or nothing evil, claims that would be obviously incoherent. What is being claimed is that within a particular interpretation of the universe, time and evil are not left as ultimate categories but are in some sense derivative from other categories.

It has been argued that by far the greatest problem of external incoherence that belief in God has to face is that of the evil and suffering that characterize the world. Critics have stated that if God cannot rid the world of evil and suffering, he is not all-powerful; if he could, but he won't, then he isn't all-good; if he is powerful and good but not all-wise, then, even though he is trying his best, there are bound to be disasters. The most serious classical expression of this problem was given by David Hume, in his ***Dialogues Concerning Natural Religion (1779).*** With such considerations in mind, some philosophers, such as John Stuart Mill, have been willing to argue for a limited God—*i.e.*, the great fellow-sufferer who understands and has compassionate sympathy.

Alleged moral incoherence. Though religious conviction shows itself in moral behaviour, it has been argued that religious people have not shown outstanding moral qualities. An 18th-century English philosopher and churchman, Bishop George Berkeley, when presented with this objection, remarked that nothing evil can be attributed as such to the Christian religion and that the only legitimate comparison is that between a person who is a Christian and what the same person would have been otherwise. The distinctiveness of the Christian faith, however, has sometimes been supported by arguing a stark contrast with morality. The 19th-century Danish philosophical theologian Søren Kierkegaard, for example, by a too literal misreading of the biblical story of Abraham and Isaac (Gen. 22), supposed that religious obedience must be in radical opposition to moral duty. However that may be, religious men often may be only too well aware of their moral lapses, their sins, and for this very reason they seek the grace and power of God. The good that they would do they do not do, and the evil that they despise they continually do, as St. Paul noted in his letter to the Romans. In this moral predicament, those with a Christian commitment believe that the grace and power

The problem of sin and grace

of God comes to inspire and release them from the dominion of sin. This does not mean that the Christian never sins, but it does mean that he is assured of ultimate victory over sin. The Christian Church is viewed not as a society of saints but a school for sinners.

The exclusiveness of religious sects is regarded by those outside the sects as hardly to the sectarians' credit. For Christians, sectarian exclusiveness is viewed as a scandal to the gospel that they preach. On the other hand, the criticisms of Puritanism that hold it as inevitably negative and oppressive sometimes fail to see that it may be neither negative nor oppressive if it is grounded in a spiritual and religious vision.

The doctrine of grace (the view that God grants man abilities that man does not merit by his own efforts) has sometimes appeared to make God himself—interpreted as the spirit dwelling in a man—the actual agent of good behaviour. In this way, some interpretations of the doctrines of grace have compromised man's freedom and come close to denying man responsibility for his actions.

Outside Christianity, critics have pointed to the gap between religious profession and moral action, though within Christianity, with its strong emphasis on moral transformation, the gap has been very wide and the criticism most challenging. In Hinduism, for instance, Gandhian reformational and nonviolence ideals have not mixed well with social corruption or with the type of neutralism that allowed China to persecute Tibetan Buddhists. Again, the Buddhist who goes to a temple is not necessarily compassionate as his religion dictates, and the Muslim who attends services in a mosque may be less filled with an inner sense of justice and patience than with thoughts of a holy war. In Sri Lanka (Ceylon) and Vietnam nationalist loyalties have given rise to a violence untypical of Buddhism. In the last resort, however, each religion will appeal to its doctrine of salvation when presented with a gap between its moral ideals and the actual actions and behaviour of its adherents.

Other grounds for the rejection of religion. *Rejection of historical beliefs, practices, and institutions as spurious or irrelevant.* When a religion appeals to historical events, other grounds for its rejection arise. The Old Testament view of history appears to have been exceedingly selective in order to emphasize a particular point about God and his activity. The miracles of Jesus—both those relating to his own person (his birth and Resurrection) and those that he himself performed (especially nature miracles)—conflict with what men experience in the normal course of their natural lives and experience. Prayers requesting favourable weather, plentiful crops, or safety in a journey are characterized by many as spurious and irrelevant. Ideas of God intervening in the universe, according to such critics, satisfy neither science nor religion. From a scientific point of view, "laws" of nature are no longer viewed as divine prescriptions; and the word law becomes, in fact, misleading. Furthermore, in order to allow for miraculous intervention of this kind, God's providential care is viewed as a compromise. He thus becomes the absentee landlord who absented himself from the world, which must take care of itself except for some spectacular visitation. According to this view, the only coherent way to speak of an intervention of God is to interpret it in the context of personal intervention.

Religious institutions have been criticized on the grounds that they conflict with the ideas of the founder and are supported by claims that cannot be historically verified. These claims, according to critics, depend on taking certain historical events on which the religion is founded, and reinterpreting them by theological speculation or a very full imagination, to produce, for example, a doctrine of papal supremacy according to which Christ is believed to have given explicitly to the successors of St. Peter final jurisdiction over the church.

Rejection of religious sentiments or dispositions as valueless. According to some views, anyone who prizes "another world" must despise this world and be uncertain in his attitude toward the world around him. In this way, it is said, religion dries up the sources of its activity and attacks such happiness as this world can provide—though promising happiness hereafter, which has been called "pie in the sky" or "opiate of the people" by critics of religion. A humanist concern to liberalize and relax laws (*e.g.*, on abortion and divorce), to abolish capital punishment, and to encourage birth control has always been opposed, according to humanists, by Christian orthodoxy, which they interpret as having a negative and conservative attitude that has proceeded from a nervous fear of a decline in moral standards. At the same time, humanists would continue, moral standards have hardly been upheld by sectarian strife and persecutions. Further, they point out, too often the church, in its desire to indicate what abides, has confused what is abiding with current social and political institutions and traditions inherited from the past, generally resulting in an illiberal obscurantism and a reactionary outlook.

Humanist criticisms of religion

Some critics of religion have contended that almost all scientific progress has been hindeied by religious beliefs and attitudes. Biology, physics, and geology, they have claimed, only made the rapid progress that they did when they were freed from a context of religious belief by the 17th-century philosopher René Descartes, who devised a metaphysical myth of the separation of mind and body.

Naturalistic or skeptical views of the origin and development of religion. In the matter of the origins and development of religion, many (*e.g.*, the psychologist James Henry Leuba in his *Psychology of Religious Mysticism* [1925]) have argued that there is a close connection between mysticism and hallucination, between hysteria and ecstatic institutionalized inspiration as, for example, in Pentecostal churches. Religious people, according to such views, often have personality weaknesses and are psychologically disturbed. Freud, the founder of psychoanalysis, maintained that inner conflicts--often the result of repression, particularly in relation to sex—become expressed in peculiarities of behaviour and mood, especially in the vivid imagery of dreams that erupt from the unconscious area of one's personality. By comparing the symbolism of dreams and mythology, Freud held that belief in God—in particular, the father image—merely perpetuates in fantasy what the individual must in actual fact overcome as part of his growth to maturity, thus giving religious belief a treatment that not only made belief in God unnecessary but positively unhelpful.

Carl Jung, a former disciple of Freud, gave a different account of the psychology of the unconscious. Each person displays a libido, a fundamental striving that is creative and purposive and of which there is evidence in the symbolic language of dreams. Behind all such symbolic language are archetypes (innate tendencies to form symbolic images), which all humanity shares and which inspire a person to move toward a balanced integration to which the energy of the libido would creatively move, if given proper freedom and encouragement. Thus, Jung posits a racial or impersonal unconscious in which, at the deepest level, all individual human beings share. Jung's archetypes raise the metaphysical question of whether they are symbols of an existent God or gods—a question that psychology leaves open. For many psychologists it is a question of little interest, because for them the archetypes themselves suffice in practice.

Problem of the genetic and reductionist fallacies

In addition to such naturalistic or skeptical views about the origin and development of religion are other claims that religion is merely an infantile reaction to fear, a more or less harmful sublimation of sex, a projection of wishful thinking, or a social device for use in the class struggle. On the other side, however, it is likely to be pointed out that one must be careful not to indulge in the genetic fallacy: no account of the origin and development of anything, of religion in particular, is necessarily a reliable analysis of what that particular phenomenon is now; a single explanation of the origin and development of a phenomenon as complex and variegated as religion is difficult to describe and maintain. It is also necessary to beware of the "really only," or reductionist, fallacy. To say "x is really only *y*" is, in effect, denying the significance of *y* language despite the fact that y-talk as well as x-talk already occurs; *e.g.*, persons are really only "machines," or worship is really only a social occasion. Oversimplification streamlines discourse at the cost of adequacy and truth.

Some have thought of religion as no more than a body of stories designed to encourage a noble attitude toward life and humanity. If, however, one asks why or how these attitudes encourage and why a particular attitude is valued, what begins as a simple account of religion becomes, in the end, as complicated as any. Another criticism of religion, arguing for its redundancy, claims that the progress of man in society can and should be determined by scientific considerations. This contention, however, goes beyond the particular conclusions of the individual sciences; it is to make a philosophy out of science. On the one hand, such a scientific view of man and society would be open to philosophical criticism, not the least if it were suggested that man's subjectivity—that which makes him the unique person he is—has to be analyzed in terms of the objects of science. On the other hand, if science becomes a philosophy, it might be said to have assumed a religious dimension itself.

Ambiguities in attitudes of persons in Christian societies

In the realm of religion in the latter part of the 20th century, in what might still be called the Christian societies of the West, the attitude of very many people lies in an intermediate zone between religious belief and atheism, but the content appears rather to be given to agnosticism. Such persons believe in God but dislike formal worship, pray only on exceptional occasions, and find it difficult to have a sense of sin but admire saintliness. They are critical of the need for a Christian ministry except insofar as a priest or pastor can show sympathy and social concern. They are distrustful of dogma and critical of Christian sectarianism. They may be uncertain of Christ's divinity, but the words and example of Jesus are viewed as a guide to the good life. This outlook has many affinities with the "natural religion" of the 18th century in which the ethical example and teachings of Jesus were emphasized. Though, as in the 18th century, there may be an intent to reject revelation, persons holding such an outlook may rather be rejecting certain stylings of Christian revelation.

Examples of occurrence of such a "natural piety" can also be found in religions other than Christianity, though significantly not in Islām—unless the Baha'i movement be taken as an approximation of this outlook. This attitude, for example, has provided the basic cohesion for the State of Israel in the latter half of the 20th century. Further, the spread of technology has gradually been alienating many Hindus and Buddhists from their traditional beliefs, but the Hindu has continued to treasure his spiritual ideology, which may well give to technological development its needed direction and wider setting. Buddhism in Japan, and perhaps elsewhere in the East, is still valued in the 20th century insofar as it supplies a local religious dimension to a society whose public and industrial life has been increasingly Westernized. Thus, an attitude has arisen that is sympathetic to the broad claims of religion, but has been critical, if not disdainful, of theological dogma and rivalries.

THE ACKNOWLEDGMENT OF I OR RELIGIOUSNESS AS VALID

Traditional **iustifications.** *Religion* as *pointing* to an *ultimate* power, *being,* or value. More generally, persons who are outside the particular religions and who have nevertheless acknowledged religion as significant often seem to base their views on a fundamental feeling of absolute dependence. The grandeur of the universe, the character of the moral struggle, reflections on human nature, and an awareness of moral values inspiring men to reform society have all pointed men to an ultimate power or being—a "power, not ourselves, which makes for righteousness," according to the 19th-century English poet Matthew Arnold.

The fundamental difference in the latter part of the 20th century between the secularist and the religious person most likely has been between someone who takes a narrower and someone who takes a wider view of humanity. That there is an acknowledged need in modern times to give a moral direction to technology seems to many to bring with it the need for a religious view of the universe, even though they may not themselves be adherents of a particular religion.

Religion as producing wholesome spiritual or moral effects. Others point to examples of the wholesome moral and spiritual effects that religion has had. They mention that society has ceased to practice child exposure and there has been a notable development in the status of women in society. Religion, where it is not parodied, misrepresented, or misunderstood, broadens rather than narrows vision. Insofar as human nature is inadequately understood, if no place is granted to the spirit of man, human nature, it is argued, will never find satisfaction except through the self-realization and self-fulfillment that come from responding to the inspiring ideal.

Alternatives to traditional beliefs, practices, and institutions. The quest for authentic existence. In the 20th century various alternatives to traditional religious beliefs, practices, and institutions have become apparent. Chief among these is the quest for authentic existence. This has been encouraged and portrayed by various Existentialists (those who view man in terms of his existing thoughts and actions rather than in terms of his "essence"), who have been concerned in one way or another with emphasizing the significance of certarn situations. In this way, they have given their own versions of salvation —that situation in which a person finds his true significance. For some, such as the German philosopher Martin Heidegger, a sense of authentic existence is given to each person when he realizes his true subjectivity, which his life in the world and his social transactions so often conceal. Authentic existence is often contrasted with cosmic **anxiety**—*i.e.,* anxiety of a deep and far-reaching kind to which the antidote is to find oneself and one's freedom in a total commitment to what is called the ground of Being.

Existentialists of an atheistic persuasion, such as the philosopher and Nobel laureate Jean-Paul Sartre, regard human existence as absurd and other people as hell, because, though one needs other people, they can never be other than "other people^{w}—their subjecthood, their freedom is inaccessible. Love is, thus, doomed to permanent frustration. The need to know others like oneself is matched by its impossibility. According to Sartre, this condition only reflects the absurdity of man's own existence, which is always attempting to overcome a radical estrangement between man as the object of scientific study and man himself (en soi) and the subjectivity man knows in consciousness (pour soi). Suicide is the final absurdity, for in getting rid of en soi, what man is, pour soi disappears at the same time.

Religious Existentialism as a God-given fellowship

This pessimistic estimate of human life and its apparent absurdity, however, has been converted into a religious view by other Existentialists, such as Gabriel Marcel, another French philosopher, who point to a participation —a mysterious self-involvement that persons can have intersubjectively with each other—in a kind of fellowship that is viewed as God-given. According to this view, man needs to open himself to the presence and grace of God for a dynamic transformation in which the mysterious transcends the purely problematic. Common to all Existentialists, however, is the view that the authentic man is not merely satisfied with playing a role, with being a cog in industrial society. He breaks free and realizes himself —for better or worse. One way or another, the quest for authentic existence is to discover the means by which man can recapture and enjoy occasions of self-disclosure. So significant are these occasions that they have been viewed by some theologians to be the paradigm for the kind of situation that the Christian gospels recount.

Secular religion. Another feature of 20th-century development has been society's rediscovery of the significance of the secular. This change has led to an outlook and attitude that has been characterized as "religionless Christianity," a Christianity influenced by its residual social and political ideal, but bereft of its specifically religious practices, doctrines, or institutions. Such practices as traditional intercessory prayer are dismissed as empty approximations to magic; doctrine is condemned as outdated and expressed in terms of past cultures; institutions are criticized as oppressive and conservative.

Behind all this suspicion of structures and doctrinal schemes and practices, however, is a desire to get back to basic principles and origins, to learn again what is distinctive about the religious point of view. According to some proponents, such a goal might be attained by beginning with the secular, with activities in the secular world, not least with compassionate service, by seeing where the need arises for religious conviction and by ascertaining what contribution faith will make to secular endeavour. Though secular religion broadens out into a more sympathetic and a more positive attitude than agnosticism, it is never as explicit or particularized as orthodoxy.

Marxism. Marxism, which provides remarkable evidence of the power of dominant key ideas to inspire and direct man, is undoubtedly one of the greatest challenges to traditional religious belief. Based on the socio-economic philosophical thought of the 19th-century thinker Karl Marx, Marxism can be said to be a quasi-religion on two counts. First, Marxism had connections with the metaphysics of G.F.W. Hegel, an 18th–19th-century German philosopher who interpreted reality in terms of a spiritual Absolute. Furthermore, the thinking of Marx had religious overtones, whether from his own Jewish background or from a Christian atmosphere, not least in Britain where he lived from 1849 to 1883. Second, Marxism can be called a quasi-religion insofar as it calls from its followers a devotion and a commitment that in their empirical character greatly resemble the commitment and devotion that characterize religious people. Marxism has undoubtedly fired the spirit of man and given to revolutions, whether in Russia or China, a powerful direction that has maintained stability and avoided anarchy. Furthermore, like a religion, it has provided themes of fulfillment and hope—a revolution interpreted as the initiation of a Communist world society that would be a final consummation. There are many logical similarities between the doctrine of the Marxist millennium and the Christian doctrine of Christ's Second Coming. Marxism has also stressed the significance of cooperating with the immanent spirit of the times—something comparable to the providence of God—in economic and military struggles that are viewed as the travail by which society would be reborn. The main difference between Marxism and Christianity in the 19th and eariy 20th centuries, according to some scholars, was that for many the Christian vision encouraged men to endure tyranny, while the Marxist view inspired men to rebel. Yet, once it can be established that religion is not the servant of oppression, is not necessarily linked with an illiberal regime, and does not use concepts of "other worldliness" to make men content with tyranny and injustice, then religion may yet have a place in the Communist state. Such a religion would not have to concern itself with the kind of supernaturalism that Marxism now rejects; it would not have to appeal to an invisible world entirely other than the present world. It is not without significance that Marxism has its own form of public ceremonial and its own language of glorification. If it has to be granted that many religions have a ceremonial, a symbolism, and a moral code that has lost the vision they once had, Marxism is a social program, a doctrine, and a ceremonial searching for a vision that haunts it and that may at some time bring it to fruition. In this regard, Chinese Marxism is particularly significant insofar as Marxism in China cannot escape some interweaving with Chinese Buddhism. Chinese Buddhism brings with it a natural framework of absolute Idealism, which may yet supply Marxism with the spiritual dimension that for many critics appears to be Marxism's main inadequacy, something it lost when it shed its Hegelian metaphysics and became the anti-God Materialistic world-view of the U.S.S.R.

Marxism as a quasi-religion

IV. The professional philosophy of religion

HIST OF THE PHILOSOPHY OF RELIGION OR RELIGIOUS PHILOSOPHY

Most philosophies have incorporated religious views in the wide sense of being concerned with a reality beyond appearance, and in this sense they have provided a philosophy of religion.

Developments* in *the West. *Ancient and medieval concepts.* For the Greek philosophers Plato and Aristotle, wonder was the beginning of philosophy. From such wonder, according to Plato, emerged religious knowledge that was also mediated through Ideas, eternal entities or concepts in which the things of time participate. In performing every good act, man realizes his link with eternity and the Idea of the Good. For the moment, however, man, as in a cave, is chained by his earthly existence so that he cannot see the light outside; he can only see shadows on the wall, which are signs and tokens of the eternal light behind him. This was Plato's way of styling the relationship between time and eternity, between appearance and reality, and it is a styling that found a particular welcome in the Christian tradition and not least by Christian Platonists, whether of the 2nd or 17th centuries. Plato's philosophy also led to belief in God, and his *Timaeus* is a philosophical creation story.

Religious ideas of Plato and Aristotle

Aristotle, impressed with organic life in man and animals, took as his fundamental category growth and development. The nature of anything was thought of as a form by which its movement and development as an organism was to be understood. It was as if the form supplied the driving force. In this context, God was thought of as pure form, as final cause, and as prime mover. Aristotle provided for St. Thomas Aquinas, the great medieval philosopher of Western Christendom, the foundation on which he developed Scholasticism, which has been a distinctive feature of Christian philosophy of religion since the 13th century. Other medieval philosophers, such as Erigena, with his pantheism (God in all); Abelard, with his critical questions; Eckehart, with his mysticism; and Duns Scotus and Bonaventure, with a wider view of reason than could be contained in the Scholastic philosophy, all illustrate the variety and independence of Christian thinkers.

Modern concepts. Descartes, the "father of modern philosophy," is significant in terms of his reacting against external authority in matters of belief, seeking a fresh basis for certainty, and finding it in the existence of his own mind. He must think in order to doubt his existence, hence his famous statement, *Cogito ergo sum ("I* think, therefore, I am"). Henceforward, much significance was given to the individual mind, and the resulting myth of the body–mind separation enabled both physics and biology to develop without the risk of ecclesiastical interference. Only in recent years has the inadequacy of the Cartesian body–mind myth come under general criticism not only because of the metaphysical problems it poses but also because it fails to do justice to the unity of personality that recent developments in medicine, such as those pertaining to psychosomatic disorders, presuppose.

The myth of the body–mind separation

Many of Descartes's 17th- and 18th-century successors can be best understood by reference to him. Nicolas Malebranche, a French Cartesian philosopher, and the occasionalist philosophers, were more radical than Descartes; they dispensed with any unity whatever in man himself and linked together man's mind and body by means of the constant correlation effected by God himself, claiming that mental events were merely "occasions" for God effecting material change. For Spinoza, the whole universe had not only Descartes's two attributes of mentality and materiality but an infinite number of attributes, and it could be alternatively named God or Nature. Each existent in the world could be pictured as a particular whirlpool in an infinitely deep sea made up of endless layers of particular fluids of which man knows only two—mentality and materiality. Gottfried Leibniz viewed Descartes's minds as the only ultimate existents, so that even material things were colonies of souls. God was viewed as the supreme monad (the ultimate substance) that establishes coherence and harmony among all other monads. What appears to men as the external world is, so to speak, the result of blurred vision on the part of those groups of monads that are human beings.

After Descartes there appeared the British Empiricists:

John Locke, George Berkeley, Joseph Butler, and David Hume. Locke, though rejecting some of Descartes's characteristic doctrines, nevertheless took over Descartes's view of the human mind and then concerned himself with the philosophical psychology of how the mind comes to have the ideas it possesses. By the time of David Hume (died 1776), the mind was viewed as nothing more than a collection or bundle of ideas thought of as very similar to images, which means, as Hume frankly admitted, that it becomes impossible to do justice to the subjectivity that makes each person distinctively the person he is. The significance of Berkeley (died 1753) in this sequence is that he saw the need for an extended Empiricism that took the notion of personality seriously and that regarded activity as a key concept. Indeed, for Berkeley the fundamental unit for thought was "activity-directed-towards-and-terminating-in ideas," and it was the activity of God directed to those ideas, which make up the external world, that gave to this world its continuous independent existence. His contemporary Butler also argued for a broader Empiricism, which for him centred on the significance of man as a moral agent and on a reasonableness that need not always conform to a mathematical paradigm. In a matter of great consequence, a man's action can be reasonable even though there may be little supporting evidence for his decision and though, indeed, the evidence may be very much against it. It may, thus, often be a moral duty to act in such problematical circumstances. This led to Butler's famous doctrine of probability—"probability is the very guide of life"—a view that influenced the treatment of belief in ***The Grammar of Assent*** (1870), by the English theologian John Henry Newman.

The Kantian and Hegelian idea of unity

Irnmanuel Kant has been called the second founder of modern philosophy. With Kant, late 18th-century philosophy began to take an interest in human knowledge, its varieties, scope, and limits. In Kant's critical philosophy, which emerged in his old age, he showed how scientific knowledge left room for morality. Though he was inclined to interpret all religious assertions in terms of morality, belief in God was justified as the holding of a regulative idea that brings coherence into all of man's thinking. The foundation of this idea is to be found, in fact, in those experiences of unity to which moral ideals, beauty, and the notion of a purposive universe all point. This idea of unity, largely implicit in Kant, was developed by Hegel, who came to regard the universe and its cultural, social, and political progress as but manifestations in time of an unchanging absolute spirit. In this way, Hegelianism provided a spiritual interpretation of the universe, but it regarded particular religions as no more than visual aids toward understanding Hegelian truths. A century later, the British philosopher F.H. Bradley was able to use a Hegelian approach in a much more empirical and far less intellectual context. Whatever form Hegelianism took and though its spiritual insights seemed on first view to make it a friend to religion, it has proved to be a position in opposition to Christianity, whether by its minimizing the historical element or by the way in which it compromises belief in a personal God.

Since the absolute Idealists, there has perhaps been only one philosopher in the mainstream of tradition—Alfred North Whitehead—who, in taking becoming rather than being as the fundamental category, made "process philosophy" possible. This philosophical view maintains a metaphysics that not only provides an interpretative scheme linking God, man, and the world but one that incorporates scientific and historical thinking, though in taking growth and process as fundamental, Whitehead seems, to some, to have an evolutionary God.

There were two main reactions against Hegelianism. The first, initiated by Kierkegaard, viewed Hegelianism as altogether too detached and objective and its ways of reasoning entirely unsuited to the deepest experiences of human life, the tragic situations in which human beings find themselves. From Kierkegaard, the Existentialist movement began. Also, in reaction against Hegel, were the modern Empiricists, such as Bertrand Russell and G.E. Moore from England, whose watchword was clarification in their attempts to create a straightforward, unambiguous language. This movement passed easily into Logical Positivism (a philosophical position that accepts only scientific knowledge as factual and rejects metaphysics), which challenged not only the truth but the meaning of theological assertions. (See also JEWISH PHILOSOPHY; PHILOSOPHY, HISTORY OF WESTERN; CHRISTIAN PHILOSOPHY.)

The concept of Nirvana

Developments in the East. ***Buddhist concepts.*** Among the religious philosophies of the East, the conservative Theravāda (Way of the Elders and another term for Hinayiina) Buddhism regarded all existence as a succession of transitory states: what alone was permanent was Nirvana, a deathless realm the existence of which was revealed to the Buddha himself in the Enlightenment that came to him while he meditated beneath the bo tree (late 6th century BC). About Nirvāṇa, the wise will say little more except to affirm its existence and to express their conviction that the plurality of individual souls that man knows in this world cannot in the same way exist in that deathless realm where there is no rebirth. Such ideas find a natural home in the philosophical standpoint of absolute Idealism, and Nirvāṇa can be regarded as an alternative word for the Absolute. Broadly speaking, Buddhism is agnostic both about a personal creator and personal immortality, though Theraviida Buddhism explicitly rejects belief in a creator. Undoubtedly, the dominant theme of Buddhism is the quest for release from the changes and chances of this world, which will lead to the serenity and peace of Nirvāṇa. A Buddhist saint is someone who has indeed become the Absolute, which thus incorporates and transcends all human imperfections and struggles and all the imperfect ideas, ideals, and deities of popular religion and popular ways of thinking. The difference between the ***arhat*** of Theravāda, and the ***bodhisattva*** of the Mahāyāna is one between two different routes of realizing Nirvāṇa—the one through self-concentration; the other through self-sacrifice for the welfare of others. The difference is one between two "saintly" routes to the one saintliness—being possessed by and dwelling in the Absolute.

Thus, Buddhism, by embracing what is, in effect, a metaphysical concept of the absolute, not only could but did hold together a complex mythology within a unifying philosophical insight and was able, as in Japan and China, to incorporate a complex popular pantheon of the cult of ancestors. Furthermore, it could combine a popular devotion to a personal lord with a mystical contemplation that had encouraged the development of Buddhist monasteries. In sponsoring such a broad synthetic (all-embracing) view, the philosophical significance of Mahāyāna (Greater Vehicle) Buddhism emerged. Such developments began about 100 BC and lasted for several centuries; it was Mahāyāna Buddhism that spread to China and East Asia to influence and modify the religions native to those areas. In Mahāyāna, the humanitarian saviour notion of the ***bodhisattva*** has some echoes in Kenotic Christianity (*i.e.*, emptying oneself to become a suffering servant), and attitudes to the Buddhist scriptures have parallels with those of Christians toward the Bible. Common to both is the view that revelation can express itself in developing forms and that it is a mistake to concentrate on the texts themselves, sacred though they are, rather than on that which transcends them and of which they are symbols and to which they point. In this respect, one may contrast the open and exploratory attitudes of many Buddhists and Christians toward their sacred books with the closed and rigid attitudes of most Muslims.

Confucian, Taoist, and Japanese concepts. Prior to the introduction of Buddhism into China in the 1st century AD, the two main strands of religious thought in that country were represented by Confucianism and Taoism. Confucianism displays a reverential propriety that is expressed and developed in social relationships and fulfilled in Heaven. Taoism claims that the wise man will constantly seek harmony and rapport with Tao (the Way), which, at one and the same time, is the way for men to follow if they would reach blessedness and the principle that underlies and sustains the world. As a concept that is both moral and cosmological, Tao has a logical status similar to that of the Logos (or Word, the active principle of God in creation and revelation) in Christian philosophy. The Taoist thinks little of the ways of the world, including the decorum of the Confucianist; his outlook rather encourages a laissez-faire policy toward the world and even withdrawal from its affairs. 'The immediate mystical experience of Taoism or the inspired behaviour of Confucianism can easily blend with Buddhism, which sets both within a metaphysics of the Absolute.

In Japanese religion are found the same two themes that are found in most religions, though in their extreme forms they are mutually exclusive. On the one hand is mysticism—specifically, nature mysticism, of which the mysticism of the Zen practitioner belonging to an intuitive meditative form of Buddhism is a specific example. In Zen Buddhism, religion is scarcely distinguished from an aesthetic experience in which shrines, gardens, mountains, woods, and streams reveal a mysterious beauty and in which the exercise of the intellect is at a minimum. In contrast to mysticism, there is devotion to a supreme personal lord, at one time symbolized in the emperor as a descendant of Amaterasu, the Sun-Goddess. At other times Shintb ("Way of the gods") devotion focussed on particular shrines and particular deities, just as Zen Buddhism could concentrate on a particular image or on particular events. In both types of devotions, however, it could be argued that such particularity was fulfilled and transcended in the unity revealed to a mature mystical insight. These different philosophical positions have an interesting reflection in the Christian position in which the Christian claims to find evidence of God's presence and activity in particular places and situations (especially in the incarnation of Christ), though at the same time allowing for God to be omnipresent.

Doctrine of an eternal soul and rebirth

Hindu concepts. This mixture of a mystical contemplation, which sees the divine everywhere, and a personal devotion to a particularized divinity recur in Hinduism. The most characteristic feature of Hinduism, however, is the doctrine of an eternal soul and its rebirth. The universe is pictured as the arena in which the immortal soul engages in a succession of incarnations from which man seeks release, a release that true contemplation can give him, especially when approached through Yoga (a mental, physical, and spiritual meditation technique). At the same time, a sensitivity to the numinous (spiritual) has left open the possibility of and certainly encouraged personal devotion. The most famous of Indian scriptures, the ***Bhagavadgitd*** ("Song of God") has for its recurrent theme the majesty, glory, and terror of God and the devotion due to him, though as in Christianity these attributes are compatible with a loving God. In the matter of revelation and incarnation, it is an open question as to how far the Hindu conception of revelation is the same or similar to Christian or Muslim conceptions. The Hindu view of ***avatiira*** ("incarnation"), however, implies many incarnations and in a Christian context would demand many Christs; thus, the concept of ***avatiira,*** a salient feature of Vaiṣṇavism (centring on the veneration of Viṣṇu, the preserver), cannot be easily reconciled with the uniqueness attributed to Jesus.

Depending on the particular questions that determine a particular content of discussion, Hinduism can talk of a plurality of souls, when it would concentrate on the theme of reincarnation, but, especially when influenced by Buddhist (and also pre-Buddhist) ideas, it can also sponsor an absolutism, or a monism; yet, again, it can come very close to a traditional Western theism. On the whole, however, it might be said that Hinduism holds together in a creative tension both theism and monism, though often it appears that in conceptual foundations and philosophical discussion the theistic strand predominates. Even in its classical period (600 BC to 450 BC) Hinduism was characterized by an astonishing variety of doctrines and cultures. Indeed, it well illustrates a characteristic of Indian thought that is becoming more acceptable to Western ways of thinking—the notion that there are many different approaches to the truth, which matches the concept of a multiple theology. It was regarded, however, as a retrograde step when these varieties of culture, ritual, and mythology became hardened into social strata and castes.

Concepts of *ātman* and Brahman

In the medieval period, Sankara (*c.* 788-4320), the leading exponent of Advaita Vedanta, or nondualism, is the most significant Hindu figure in the philosophy of religion. Arguing in a way very reminiscent of absolute Ide-. alism, he claimed that the only existent was an absolute and that all else was an illusion. In this context he equated *ātman* (the individual soul) with Brahman (the universal or absolute soul). Both were viewed as one in a cosmic consciousness. For Sankara, only ignorance or lack of insight into the nature of being prevents a man from realizing his identity with Brahman and thus becoming here and now aware of the freedom that is his. Sankara also allows as permissible, without being accepted as the truth, talk of God as personal and as creator and of men as separate souls related to one another and to him. This, however, is only considered a way of talking—salvation in the Absolute transcends all such imperfect discourse. The same logical problems recur here in the concept of Nirvana in Buddhism. In Hinduism, the ***Upaniṣads,*** Hindu philosophical treatises, and the ***Bhagavadgitd*** use the imperfect language of finite man, who has not yet found release, and in this way they can only point beyond themselves to that which they cannot adequately express. Here again are ideas reminiscent of some of those in Western philosophy of religion in the modern world: the importance of theological reticence, the limitations of theological language, and, in another context, the significance of "existential situations."

Twentieth-century Hinduism has been chiefly characterized by attempts to purify and reform the doctrines of its medieval period, to deepen its spirituality, to reassert its moral dimension, and to inspire social reform. Mahatma Gandhi and Sri Aurobindo, the founder of a spiritual community and a Communist, were significant in such ventures. Aurobindo has been compared with the French Jesuit paleontologist and theologian Teilhard de Chardin insofar as both have a repeated experience of cosmic consciousness and a profound belief in evolution, both of which point to a divinization of man.

The strength and limitations of a total surrender

Islāmic concepts. At the heart of Islam is an experience of awe before the one, all-powerful, mysterious creator Allah. Thus, its dominant theme has been surrender, though it must not be forgotten that it has nurtured mystics to whom the mysterious and awesome God has revealed himself through created things. Allāh controls man's destiny, whether to salvation or damnation, which points to the ultimacy of God, to his majesty and power. The concept of heaven inspired warriors to fight to the death; the concept of hell encouraged loyalty by showing what terrible punishments awaited the disloyal. The Qur'ān (the Islamic sacred scriptures) is regarded as an infallible book—a transcript of a tablet that is eternal in the heavens. Islām shows pre-eminently the strength and limitations of a total surrender based on clear-cut beliefs, themselves arising from a basis in infallible texts, the whole being translated into vigorous political and social practices associated with a rigorous ritual and ceremonial discipline. Its mixture of both rigour in theology and vigour in politics in India and the Middle East from the Middle Ages to the 20th century can perhaps be compared with the same mixture as has been seen in the Protestant and Catholic communities in Ireland since the 17th century. However much the concept and practice of holy warfare is repugnant to many minds today, in the context of Islām it implies a sensitivity to evil and a conviction that evil has to be resisted and overcome in a total dedication. In this way the faith of Islām has shaped human history by obedience to a resolute and powerful God. Islam also illustrates the point that predestination need not bring with it a submissive fatalism. Furthermore, it has to be granted that Islām has allowed, within itself, for some allegorical interpretations of the scriptures–explicitly by the Ṣūfīs (mystics)—and it has also allowed for differences of piety and beliefs and even intellectual exploration on the part of particular disciples. Nevertheless, to other religions Islām has shown itself to be very conservative and with a distrust of compromise and a passionate desire to proselytize.

East and West: common ground. In reviewing the different philosophical understandings of religions in both East and West, two points clearly emerge. First, that however great the variety, there is almost universal agreement that "what there is" is not restricted to the facts and features of the world as they are given to or received by man's senses. Secondly, what has been for the philosophy of religion in the East almost a permanent problem is coming to be a crucial problem for the West, viz., how to preserve both the concept of absolute spirit and the significance of personal individuality or, alternatively, how far one can speak reliably of God as a person. The West is becoming aware of the problematic character of religious discourse. If, in such ways, Western philosophy of religion can benefit from some of the insights of the East, so also can the East—as a growing interest in the Empiricists of the West demonstrates—gain from the West. Not least, scientific developments have created Eastern interest in the English Empiricists, particularly John Locke; Eastern philosophers also have been impressed by the political liberalism of some modern Western Empiricists, such as Bertrand Russell. The Empirical philosophy of religion, as it has been recently developed in the West, may provide basic approaches and techniques for a closer mutual study of religions in East and West. (See also INDIAN PHILOSOPHY; CHINESE PHILOSOPHY; JAPANESE PHILOSOPHY; ISLAMIC THEOLOGY AND PHILOSOPHY.)

BASIC THEMES AND PROBLEMS IN THE PHILOSOPHY OF RELIGION

The kinds of proofs of God's existence

The problem of God, the Absolute, or the supreme value. The existence of God. The so-called proofs of God's existence are of two kinds: independent logical exercises or particular conclusions set within an overall metaphysics. Either way, the discourse of these independent proofs or metaphysical schemes is best viewed as speech designed to evoke a disclosure. A particular argument recommends, as a way of speaking about what the disclosure discloses, a particular brand of discourse offering an interpretation of the world and man and one that develops from a specific key idea grounded in the disclosure. The existence of an Absolute or a supreme value has never been concluded as a result of an isolated logical exercise but has always arisen in the context of a total metaphysics. Thus, a quasi-mathematical structure, for Spinoza; a dialectic method, for Hegel; and evolutionary considerations, for the modern French philosopher Henri Bergson, determined the discourse that these three philosophers used in order to evoke that situation to which God or Nature, the Absolute Spirit, or the life force became for them respectively key concepts of interpretation. Bradley similarly reached a belief in an Absolute Spirit by reflecting on the logical problems of relatedness.

The following are some traditional arguments for the existence of God restyled along the lines suggested above:

The ontological argument of Anselm of Canterbury (*c.* 1033–1109) takes a phrase "that than which nothing greater can be conceived" and uses it as a technique for disclosure, directing one without limit to an ever-increasing perspective, in the hope that at some point the light will dawn, whereupon the phrase "necessary being" will be used to develop talk of the God.

The cosmological argument uses as a technique for disclosure such questions as "Why is this thus?" or "Why is there anything at all?" In receiving replies to these questions in causal terms, the cosmological argument builds up an ever-increasing causal spread until a disclosure occurs, whereupon the phrase "first cause" specifies what is disclosed and advocates certain ways of talking.

The argument from design takes a story with acknowledged disclosure possibilities—*e.g.*, the inter-related parts of a watch—and uses this as a catalyst to evoke a disclosure around some ever-broadening purpose patterns of the universe, in relation to which one can speak of God in terms, for example, of eternal purpose.

What is, in different ways, implied by these arguments is that the word God is unique in its logic, that it works in discourse as no other word exactly works. Thus, one cannot say "God exists" but rather "God necessarily exists." This is sometimes expressed by remarking that the existence of God is not the existence of a physical object or even the existence of a person, though what can be said about persons is less misleading in speaking about God than in speaking about the logic of things. This point is sometimes made, albeit misleadingly by saying that God does not exist, but this is only a picturesque way of saying that he does not exist in the way that a table exists.

Qualifications for personal models

The *nature* of God. These reflections are of wider applicability in relation to the nature and attributes of God. Such attributes are spoken of in terms of personal models, such as wisdom, goodness, power, love, mercy, righteousness, and so on. These models, however, will always need qualification by words such as infinite, perfect, and all. What is quite clear is that grammar itself is no clue to the logic of phrases such as "infinitely wise." Although that phrase is similar in grammar to one such as "exceedingly wise"—a phrase that is entirely descriptive in its logic—it is logically quite different, because "infinitely wise" has both descriptive and what has been called performative force. In other words, it not only describes some matters of fact—some specimens of wisdom—because of the word wise, which works descriptively as a model, but it also generates something—the word infinite acting as an operator, continually directing persons to expand their understanding until a moment of vision emerges. Alternatively, the point that God is not a being has sometimes been made by saying that God is the ground of Being—"the ground of" functioning as a qualifier, operating as the model of beings, or things. The emphasis of such qualifiers is twofold. First, they remind one of the inadequacy of all language used to speak of God—language authorized by particular models that, arising in a moment of vision or disclosure, naturally originate speech about what the disclosure discloses. Secondly, qualifiers constantly point one back through developed discourse to that moment of vision in which the discourse originated and in which alone one knows what the discourse is speaking about. The logic of models and qualifiers is a way of combining the intelligibility and mystery that any philosophy of religion must preserve.

Language about God thus develops as a multiple discourse, having various strands of which each is authorized by a particular model and of which each must, somewhere along the line, be modified by the presence of the others. Thus, theological understanding is a complex interweaving of different strands, and not least is the task of the philosopher of religion to produce the most comprehensive, coherent, consistent, and simple discourse he can. When problems arise that seem to be problems about the nature of God—for example, the conflict between different attributes--these are most profitably translated into problems of language. They then become problems of how to create discourse of the kind that in the end produces the best understanding of a cosmic disclosure with a single individuation, in which all the pertinent discourse originates and about which all the different strands endeavour to speak.

Natural and revealed theology

The knowledge of God. Natural theology is the name given to the kind of discourse about God and the world that originates in natural moments of vision without reference to God's revelation of himself in an incarnation, and in this sense "natural theology" is distinguished from "revealed theology." Among some philosophers—*e.g.*, Locke—the distinction is one between general and special revelation. In natural theology are generally included the "proofs" of the existence of God, discussions about the immortality of the soul, and discussions about God's providential control of the world, which provides for man a state of moral probation.

Some have viewed religious experience as affording direct evidence for the existence of God. In any discussion of religious experience, however, it is important at the outset to distinguish religious experience in general—a sense of awe or reverence, or a sense of the numinous—

from mystical experience. The language of mystics is notoriously confusing to those not accustomed to the mystical idiom, and a leading question is how far mystical experience can establish the kind of objective reference it claims. Words such as immediate, direct, and intuitive refer rather to the way in which the experience occurs as a disclosure rather than justifying one in taking as guaranteed the interpretation that this disclosure appears to bring with it. If one already has an interpretative scheme, then mystical experience may provide an instance of such a scheme, but this has been rightly described as supporting belief in God "on the way back" rather than "on the way out." The concept of revelation is used by Christians to describe the way in which God's activity is uniquely disclosed in Christ, and faith relates to the human attitude and response that matches revelation subjectively. Revelation is sometimes contrasted with discovery, the former being said to relate to a passive subject, the latter to an active subject, but the distinction is largely one of emphasis. Philosophers of religion are now inclined to view revelation in terms of activity that waits to be interpreted rather than as a revelation of propositions. Revelation thus relates to events rather than to doctrine. According to this view, doctrine could never have the ultimacy and finality that necessarily belongs to the givenness of God in his incarnation or incarnations.

Special problems. Freedom. Among the classical problems in the philosophy of religion are those of free will, self-identity, immortality, evil, and suffering. The freedom of the will is a claim for the uniqueness of the subject, known in occasions of activity in which the subject "comes alive" and realizes his subjectivity as that which cannot be reduced to the behaviour patterns and facts—*i.e.*, the objects—of the natural and social sciences. Such freedom is realized in responding to a situation that has equally come alive objectively to inspire a person and call forth such response. Some claim the predictable character of human behaviour rules out man's freedom; others state that the extent to which human behaviour is unpredictable argues for freedom. This controversy, however, does not in any way solve the problem of freedom; it only makes evident what kind of problem the problem of freedom is, viz., how far human nature is capable of being analyzed into behavioral terms without any residue.

Arguments for personal immortality

Self-identity *and* immortality. When there has been a self-disclosure of transcendence, of what cannot be characterized in space and time, one cannot say that any self so disclosed entirely comes to an end. In this sense, there is an argument for personal immortality, though one can only talk sensibly about it by expressing immortality in terms of continuing personal life. In Christianity this becomes speech about the resurrection of the body, and in Hinduism it becomes speech about reincarnation in this world or in the universe at large. All detailed talk about a future life, whether in Christianity or other religions, is only a way of spelling out and pointing back to that experience of man's transcendence here and now, in terms of language that expresses the claim that such a transcendent element is not annihilated by death. To be articulate about immortality, emphasis is placed on features of life that, at first view, have high significance and point here and now to experiences in which man's self-disclosure is most often found—*e.g.*, inspiring music or the intimate and deep fellowship of a particularly significant meal. General claims for immortality in relation to an objective disclosure (whether it be spoken of in terms of God or moral ideals) have to be distinguished from, though they have evident similarities to, the Christian claim for eternal life. Eternal life is, according to the Christian view, a subjective self-disclosure alongside the objective disclosure of God's activity in Jesus Christ, and it is as unique as the uniqueness of God in Christ, a uniqueness that is, however, an inclusive, and not exclusive, uniqueness.

Evil and suffering. The problem of evil arises (1) from the loss of a sense of God's presence in the face of evil or suffering and (2) from an apparent conflict between the language used to describe God (*e.g.*, all powerful, all good, and all wise) and that to describe the world as being characterized by evil and suffering. The solution proffered by the Book of Job in the Old Testament is that of evoking such a sense of awe around the created universe that, discovering in this way a renewed sense of God's presence, one accepts both evil and good and contents himself verbally by acknowiedging a final incomprehensibility.

Other solutions relate good and evil to God and thus seek consistency by relating good and evil to God's primary and secondary will or to God's willing and permitting, respectively. In demanding some overall purpose to complete such a story, however, these solutions point to others that seek to resolve the conflict between good and evil within some reconciling model, which is then used to specify, with suitable qualification, a purpose or attribute of God. Thus, the conflict necessarily involved in the creation of a community of freely responsible persons is used as a model to illuminate a personal conflict exhibited, for example, by war. Also, the conflicts resulting from general rules imposed for the sake of training are used to provide a model to illuminate the disharmony exhibited in, for example, earthquakes or floods. These models are then developed and amplified in order to lead one to a renewed disclosure of God's presence. These solutions—by raising questions about God's character—perhaps point to another solution that attributes to God redeeming love—something that, as directed to evil, can be creative of personal maturity and fulfillment in a way not otherwise attainable. This attribute must then be appropriately qualified so as to lead to a renewed disclosure of God's presence, in this way enabling one both to face evil and to talk of it more coherently in relation to God.

In the matter of absolute Idealism, which is the kind of metaphysics implied in Eastern religions generally, evil and good are transcended in the Absolute Spirit that is beyond good and evil. Logically, this is akin to the solution of the Book of Job.

THE PRESENT SITUATION IN THE PHILOSOPHY OF RELIGION

Interest in religious language

In the latter part of the 20th century in western Europe and the United States there has been an Empirical philosophy of religion the interest of which has been in religious language and the kind of Empirical basis there can he for religious discourse. The definitive question has been concerned with what are the patterns of religious reasoning and what is the character of religious language if such discourse points back to and articulates situations of the particular kind that have been discussed above. The approach originated in what has been called Logical Positivism. According to the verification principle, which gave what the Positivists considered to be the touchstone of meaning, an zssertion had meaning if and only if it was verifiable at least in principle by sense experience. Logical Positivists were not at all daunted when this seemed to exclude the whole of theology and a good deal of ethics from meaningful discourse.

Since the 1950s, however, there has been a reaction against the Positivist's veto, and the works of the Austrian British philosopher Ludwig Wittgenstein are symptomatic of those who broadened Empiricism so that it has become interested in displaying and elucidating the variegation of language, in setting language in actual contexts, and in relating it to specific situations. Significantly, this mellowing of Empiricism has been accompanied by a growing interest in personality and the self. This newer emphasis of Empiricism unites with Existentialism in suggesting that personal situations may very well provide helpful parallels to religious situations. There has been introduced into the philosophy of religion a renewed sense of the significance of mystery and a new emphasis on theological reticence. With this has come a renewed awareness of the significance of metaphor, myth, and symbol, and there has also emerged a significant use of the concept of the model. The use of terms like myth and mythological, it is important to recognize, does not mean that the assertions so called are false. Myth includes stories that try to articulate what is objectively given in a certain religious situation. Myths also relate to historical events—though the myth may be selective in its choice of such events—when speech about these events is used to articulate a claim of a transcendent kind. In other words, myth, metaphor, symbol, and model are all ways of expressing in ordinary language an extraordinary point.

Questions of reference and criteria

The present stress on metaphors and models in religious language, however, inevitably raises two far-reaching questions: the question of reference and the question of criteria. The former concerns the possibility of the assurance that one is talking about anything at all. The latter concerns what the criteria are for better and worse ways of talking. The question of criteria has been answered in terms of the logical character and the empirical pattern of the multimodel discourse to which the different strands arising from the different metaphors or models give rise. That this discourse talks about something must in the end rest on the claim that, in a disclosure situation, a subject is relatively passive—*i.e.*, aware of an activity bearing on his own and thus aware of something other than himself about which he is talking.

In this context the significance of the Existentialist approach is to underline, as does recent Empiricism, the importance of a wider view of human experience than ordinary scientific experience might allow and to point one to highly significant personal situations that cannot be netted in scientific terms. The phenomenological approach, as developed by the Moravian philosopher Edmund Husserl, represents an attempt to be objective and scientific about experience, an endeavour to set out facts uncompromised and unprejudiced by metaphysical frameworks. As an endeavour to reach agreement on what is being talked about and as an attempt to seek the simplest and clearest interpretations, the phenomenological approach has been applauded by many philosophers of religion and theologians. There can be no question, however, about a purely scientific account of a religious situation-—that would be a contradiction in terms, and, though there can be a phenomenological approach to religious situations, there can be no phenomenological explanation of them that claims to be adequate. The main contribution of Phenomenology is that of encouraging scholars to describe situations with as much critical analysis as possible.

Logical Empiricism, it might be said, has absorbed something of the Phenomenologists' concern. It has certainly raised questions about and directed interest toward the way situations are talked about and interpreted, the possibility of there being different interpretations of the same situation, and so on. In this way it has provided the tools for and greatly stimulated contemporary interest in hermeneutics (critical interpretations)—a second order appraisal of interpretations together with an interest in their empirical bases.

The future of the philosophy of religion

As to the future of the philosophy of religion, a merging of the Empirical and Existential strands may well be expected. Metaphysical and religious views of the future most likely will combine conviction with tolerance and commitment with openness. The commitment and the conviction will probably come from moments of vision. Claims to finality, fanaticism, and bigotry will disappear, it is hoped, when it is realized that there are no self-guaranteed translations of what is disclosure-given and tolerance and openness will arise from the acknowledgment that all understanding of these moments of vision is a multiple exploration, an exploration yielding different strands of discourse. Solutions to contemporary problems, social and intellectual, demand a multiple consideration by scholars from many disciplines of all the issues involved in the problem, a consideration set within a framework of faith and morality in which man is interpreted as distinctively human, characteristically a person. Prom such interprofessional, interdisciplinary groups may emerge a new metaphysics and a new theology linked with, but by no means prescriptive of, assertions in other subjects. In this way there may be created a new culture—scientific, moral, religious, and technological at the same time. To be involved in such groups would seem to he the main task of the philosopher of religion, as of the metaphysician, today. If he is successful and if these interdisciplinary groups are creative, the modern period will then take its place among those that have marked crucial turning points in the history of mankind and its culture.

HICK, ***Philosophy of Religion*** **(1963).** Introductory books that range over a somewhat narrower field include J.L. GOODALL, ***An Ztztroducrion to the Philosophy of Religion*** **(1966);** I.T. RAMSEY, ***Religious Language*** **(1957** and **1963);** and THOMAS FAWCETT, ***The Symbolic Language of Religion*** (**1971).** NINIAN SMART, ***Philosophers and Religious Truth, 2nd*** ed. (1969), centres discussion of some salient issues around particular philosophers. NINIAN SMART, ***The Religious Experience of Mankind*** **(1969);** and EDWARD GEOFFREY PARRINDER, ***Comparative Religion*** (1962), provide general introductions to the comparative study of religions. In *World* ***Religions*** (1966), H.D. LEWIS and R.L. SLATER consider issues in the world religions that are highlighted by contemporary approaches in the philosophy of religion and the comparative study of religions respectively. In the psychology of religion, the classic work of WILLIAM jAmes, ***The Varieties of Religious Experience*** **(1902,** reprinted 1952), is probably still the best introduction that might then be followed by a comprehensive survey of the contemporary field, such as L.W. GRENSTED, ***The Psychology of Religion*** **(1952).** Most of these books contain excellent bibliographies for further reading. NINIAN sMART, ***Historical Selections in the Philosophy of Religion*** **(1962);** and I.T. RAMSEY, ***Words About God*** (1971), are useful sourcebooks for some classic discussions of topics in the philosophy of religion; an excellent survey of recent thought is given in JOHN MACQUARRIE, ***Twentieth-Century Religious Thought: The Frontiers of Philosophy and Theology, 1900–1960*** **(1963).** F.R. TENNANT, ***Philosophical Theology, 2*** **vol. (1928–30);** H.H. FARMER, ***The World and God: A Study of Prayer, Providence and Miracle in Christian Experience*** **(1935);** and H.D. LEWIS, ***Our Experience of God*** (1959), represent different general treatments of the subject.

Books dealing with specific problems of religious belief are: PETER R. BAELZ, ***Prayer and Providence*** **(1968);** J. HICK, ***Evil and the God of Love*** **(1966);** A. FARRER, ***Love Almighty and Ills Unlimited*** **(1966);** I.T. RAMSEY, ***The Problem of Evil*** **(1972)**; and W.T. STACE, ***Mysticism and Philosophy*** **(1960).**

Books concerned with the challenge of recent Empiricism to religious beliefs are: R. ROBINSON, ***An Atheist's Values*** **(1964)**; and R.W. HEPBURN, ***Christianity and Paradox*** **(1958);** FREDERICK FERRE surveys the challenge in ***Language, Logic, and God*** **(1961).** D.D. EVANS, ***The Logic of Self-Involvement*** (1963), develops ***J.L.*** Austin's doctrine of performatives in a religious direction. GEDDES MACGREGOR, ***God Beyond Doubt*** **(1966)**; H.P. OWEN, ***The Christian Knowledge of God*** **(1969)**; and JOHN MACQUARRIE, ***God-Talk: An Examination of the Language and Logic of Theology*** (1967), represent different reactions to the empirical challenge, as do the books by **I.T.** Ramsey above. NINIAN SMART, ***Reasons and Faiths*** **(1958);** and H.H. FARMER, ***Revelation and Religion: Studies in the Theological Interpretation of Religious Types*** (1954), are examples of a predominantly philosophical approach to the study of differentreligions.

Books concerned with particular issues in different religions are: R.C. ZAEHNER, ***Evolution in Religion*** (1971), ***Mysticism, Sacred and Profane*** (1961), and ***At Sundry Times: An Essay in the Comparison of Religions*** **(1958);** and EDWARD GEOFFREY PARRINDER, ***Avatar and Incarnation*** **(1970).**

In the psychology of religion, P.E. JOHNSON, ***The Psychology of Religion*** **(1945);** and G.W. ALLPORT, ***The Individual and His Religion*** (1950), give comprehensive treatments of the subject and discuss a wide range of material from different schools of psychology. Recent books of importance in the psychology of religion dealing with specific topics are: VICTOR WHITE, ***God and the Unconscious*** **(1952);** DAVID COX, ***Jung and Sr. Paul*** **(1959);** R. HOSTIE, ***Analytische Psychologie en Godsdienst*** **(1954;** Eng. trans., ***Religion and the Psychology of Jung,*** **1957);** and R.S. LEE, ***Freud and Christianity*** **(1949).** W.G. MACLAGAN, ***The Theological Frontier of Ethics*** (1961), raises difficulties, from the standpoint of moral philosophy, about certain stylings in Christian theology of the doctrines of grace and freedom. Further discussions of topics on the frontier of theology, ethics, and philosophy are to be found in ILLTYD TRBTHOWAN, ***Absolute Value: A Study in Christian Theism*** **(1970);** and KEITH WARD, ***Ethics and Christianity (1970).***

(I.T.R.)

Religion, Social Aspects of

Religion can be viewed from many perspectives: by philosophers, historians, aestheticians, and theologians. The subject of this article is the study of religion from the perspective of social scientists. Social scientists ask how religion is related to the structure and processes of human societies and how it both reflects and affects stratification systems in society, political and economic processes, levels of integration and of conflict, and the course of social change. In viewing the religious patterns themselves—in which the varieties of religious organizations and the types of leaders will be examined—this article will not be simply concerned with description but also with identifying the conditions under which these varieties appear. Varieties of individual religious experience will also be considered.

NATURE AND SIGNIFICANCE

To examine religion from the perspective of the social sciences is to require a rather drastic shift in the way religion is usually viewed. The sharply contrasting beliefs about the road to salvation, for example, are neither evaluated nor simply described. The social scientist is rather concerned with the conditions under which the various beliefs appear, the variations of beliefs among societies, groups, and individuals, and the consequences of the various conceptions for social interaction.

Concerns of social scientists

The social aspects of religion are thus studied in the conviction that major dimensions of religious belief and practice are only partly understood if they are not seen as part of a larger social order. The reverse of this is also true: many of the most critical problems in the social sciences involve a religious factor. A purely rational economic model of man, for example, whether it involves the market as a system or individual economic behaviour, must take account of the "distortions" produced by religious motivations and values. Prediction and explanation of political behaviour are improved if, in addition to knowledge of class, education, occupation, traditional political identity, and the like, there is a knowledge of religious group membership, belief, and behaviour.

Economics and political science, however, have not made extensive use of religion as a factor in their studies. Theory and research dealing with the social aspects of religion have been developed more fully by anthropology, sociology, and psychology. In the first two particularly, most of the major theorists have given a prominent place to the study of religion, and for some of them—despite wide variation in their perspectives—it has been the central concern.

Alongside such disciplinary studies of religion—which, however, are seldom narrowly constrained to one discipline—there has developed a more general science of religion. To some degree, this represents the pressure toward synthesis of the analytic studies. Few of the major problems are specifically social or psychological or even cultural. To understand them, the theorist must take each of these areas and their interactions into account, however much he may think of himself as a specialist. To see the Black Muslim movement in the latter half of 20th-century America, for example, simply as an expression of the needs of certain individuals or as a manifestation of a cultural system or as the product of Negro-white interactions is to receive only a partial picture. There is no universally accepted term for this anthropology psychology sociology of religion, though the terms science of religion or sociology of religion—since sociologists have perhaps been most active in developing a general theory of religion—have been most frequently used.

Theology, critical studies of sacred texts, and philosophy are also—somewhat indirectly—major stimulants to the emerging science of religion. They too are pressed toward a general theory of religious structures and behaviour as one of their concerns. Some of their tendencies toward a science of religion have been caught up, in recent years, in the study of comparative religion and the history of religion, although these disciplines are seldom limited to, or explicitly concerned with, the science of religion. From the Anglo-German philologist Max Miiller's "Comparative Mythology," written more than a century ago, to such recent works as *The Comparative Study of Religions*, by Joachim Wach, a German-American historian of religion, can be seen the interweaving of scientific, moral, and theological interests. This tends to be true also of German *Religionswissenschaft* (science of religion). Despite the multiplicity of interests, many comparative and historical works contribute valuable data and interpretations to the science of religion.

Tendencies toward a science of religion

MODERN THEORIES OF RELIGION

Systematic thought about religious institutions and behaviour goes back many thousand years, but this article will refer only to some of the major modem theories of religion and society.

Evolutionary theories. Reflecting in part the intellectual impact of evolutionary theory, late-19th- and early-20th-century students of the social aspects of religion were strongly interested in the origin of religion. An empirically based theory of religious origins is impossible since only remnants of archaeological evidence are preserved to give hints of what the earliest forms might have been like. Theories of origin, nevertheless, have proved to be valuable starting points for functional and other theories of religion and thus deserve attention. Some authors have emphasized what they saw as the individual elements in religious origins. In the 19th century the British anthropologist Edward B. Tylor, in his book *Primitive Culture,* interpreted religion in its earliest forms as an effort to deal with the many puzzling phenomena that the "savage mind" had insufficient knowledge to explain. Dreams, echoes, visions, and, above all, death were accounted for by the idea of a soul that could leave the body. This animistic (soul) view, which Tylor considered the basis of religion, represented what he called a "fairly consistent and rational primitive philosophy." On it, he claimed, were built all later and more complex forms of religion, first polytheism and then monotheism.

Tylor's theory was sharply criticized for its rather formal evolutionism (according to which religion disappears as scientific explanations improve), for its excessive individualism, and for its rationalism. The evolutionary perspective was developed more fully by the British folklorist Sir James G. Frazer in his great compendium of facts about religious and magical practices, *The Golden Bough.* He viewed human thought as developing from magic, to religion, to science. The oversimplification and ethnocentrism (upholding the superiority of one's race) of such social evolutionism, and scarcely less of its critics, nearly halted the exploration of systematic processes of change for half a century. In the latter half of the 20th century, evolutionism is reappearing, although in a more cautious and empirical, as well as a less ideological, form. New efforts are being made to discover whether social change, when studied comparatively, proceeds in a random, a cyclical, an evolutionary, or some other pattern. The American sociologist Robert Bellah, in investigating whether or not religion evolves along with science in a parallel fashion, has suggested five "ideal typical" stages through which religion tends to move: primitive, archaic, historic, early modem, and modem, the last of which is characterized by the possibility of a continuously self-revising religious system congruent with science. Magic also probably evolves similarly, taking new forms in a literate, mobile, and scientific era, though not disappearing, since the needs that it expresses have not disappeared. Thus, societies faced with sudden and dramatic challenges to a moral order or a physical security that has been taken for granted may seek out the "witches" in their midst—whether through witch trials (as was done in Salem, Massachusetts, in the late 17th century) or through public hearings concerning threatening ideologies (as was done in the United States in the 1950s under the leadership of Senator Joseph McCarthy)—in an effort to help the societies to redefine what is bad and to discover where the boundaries of the social order are.

Magic and religion

Psychological and sociological theories. The rationalistic quality of Tylor's theory, and of 19th-century evolutionism generally, was drastically modified by psychological and sociological theories that followed. Although he referred to Tylor favourably at several points and did not explicitly criticize his theory, Sigmund Freud developed a sharply contrasting theory of the origins of religion. According to Freud, a primeval slaying of a tyrannical father by his sons––primarily because the father had monopolized the females of the horde—led to guilt and then repression. Totemism (a belief system involving animal symbolism), which Freud' regarded in his book *Totem and Taboo* as the earliest form of religion, was an effort to deal with this guilt and repression.

> The totemic system was a kind of agreement with the father in which the latter granted everything that the child's phantasy could expect from him, protection, care and forbearance, in return for which the pledge was given to honor his life, that is to say, not to repeat the act against the totem through which the real father had perished. (From Sigmund Freud, *Totem and Taboo; A.A.* Brill [tr.], 1927.)

More generally, and moving from an origins theory to a functional theory, Freud viewed religion as a culturally furnished system of projection, derived from family experiences, particularly as characterized by the helpless child and the powerful father. Society could not exist, according to Freud, without the repressions of culture—despite their psychic costs—and man's natural frustrations. In this context Freud wrote:

> The gods retain their three-fold task: they must exorcise the terrors of nature, they must reconcile one to the cruelty of fate, particularly as shown in death, and they must make amends for the sufferings and privations that the communal life of culture has imposed on man. (From *The Future of an Illusion.* By permission of Liveright Publishers, New York.)

Sociological theories of the origin of religion view various human interactions, rather than individual needs, as the starting point. The German sociologist Ceorg Simmel developed the thesis that religion is the heightening and abstracting of various human relations found widely in social life from their particular content. Faith, he suggested, was first of all a relationship between individuals, an essential element in group life.

> In faith in a deity the highest development of faith has become incorporate, so to speak; has been relieved of its connection with its social counterpart. (From Georg Simmel, "A Contribution to the Sociology of Religion," *American Journal of Sociology,* November 1905.)

This same idea has been expressed by the American theologian Reinhold Niebuhr. In regard to the question as to why religious faith persists three centuries after the first major triumphs of modern science, his answer was a functional interpretation that contrasts sharply with Freud's theory. He stated that basic trust in human relations is born from the security given to a child by his parents.

> But life is full of ills and hazards, of natural and historical evils, so that this childlike trust will soon be dissipated if maturity cannot devise a method of transmuting the basic trust of childhood, based on obvious security, to a faith which transcends all the incoherences, incongruities, and ills of life. (From Foreword to *The Religious Situation: 1968,* Donald Cutler [ed.]; Beacon Press, 1968.)

Religious faith, Niebuhr affirmed, is such a transmutation.

The role of ritual in religion

The French sociologist Émile Durkheim developed a more thoroughly sociologistic view of the origin of religion. In *The Elementary Forms of the Religious Life,*he focussed attention on the rites, cult organization, and shared sacred beliefs of society, which itself was the object of religious veneration.

> So everything leads us back to this same idea: before all, rites are means by which the social group reaffirms itself periodically.

Although propounded as a theory of religious origins, Durkheim's theory, like most other origin theories, stands or falls on its ability to aid in the understanding of the persistent interconnections of religion and society, not of the historical origin of religion. Freed of its exaggerations, it furnishes a necessary complement to individualistic theories. Like Plato, Durkheim emphasized religion as a source of social integration at a time when social dissolution was feared and experienced.

Karl Marx also developed a social theory of religion in the 19th century, but it stressed the relationship of religion to social conftict rather than to integration. Since command–obey relationships are viewed as the central facts of society, religion, it follows, will reflect them. Religion was thus viewed by Marx as "the opiate of the people" administered by those in high positions to preserve their power. One of the ironies of history is that the partial truth of the Marxian theory of religion is well documented by communisni as a religion. The opposite truth—religion as a stimulant of the people—is also documented by communist movements, as well as by other sectarian protests.

RELIGION VIEWED SOCIOLOGICALLY

Many attempts have been made to describe the essence of religion and to indicate its basic dimensions. Rudolf Otto, a German theologian and philosopher, described the essence of religion as the experience of "the holy," which engenders a dialectic between two contrasting attitudes: awe and dread (*mysterium tremendum*) and wonder and attraction (*mysterium fascinans*). The Belgian-French ethnologist Claude Lévi-Strauss stated that the essence of religion is embodied in its symbol systems (*i.e.,* its myths), which express the basic qualities of social reality. Such formulations have stimulated the work of many scholars but are themselves too general to form the basis of an empirical science of religion. Joachim Wach noted that all religions, despite their differences, are characterized by systems of belief, of worship, and of organization. He referred to these as the theoretical, the practical, and the sociological expressions of religion. Although belief aspects seem most visible to modern man, rites and worship and the groups that sustain them are no less important and perhaps historically prior to elaborated systems of belief.

Religious systems

Another line of thought views religion as basically the effort of man to bring some order (cosmos) into the universal experience of disorder (chaos). Baffling, unpredictable, and uninterpretable chaos impinges upon man in many ways, but especially at points of unmitigated suffering, of persistent violation of principles of justice as expressed in a given society (for everywhere "the ungodly" appear to prosper), and of incomprehensible mystery and meaninglessness. These three manifestations of chaos are particular expressions of more general categories of human experience labelled, in the work of the American sociologist Talcott Parsons, desires, values, and ideas. In terms of his vocabulary of motives, responses to these experiences are cathectic, evaluative, and cognitive, which in religion refer positively to efforts to achieve salvation, justice, and truth, or, negatively, to avoid suffering, injustice, and error.

Many secular activities, however, are also involved in these quests. Religion is differentiated from them because of the ultimacy or final quality of the effort. Knowledge appears to fail man just when he most needs it—to make some sense out of existence. Efforts to produce a just society seem always to fall short. Man reduces some forms of suffering only to discover that his capacity to create new forms is impressive. Thus, man's intellectual, legal-moral, and magical systems seem inadequate unless they can be made to go beyond the crushing impact of the reality of experience. Religion is obliged, as Durkheim said, to "pass science and complete it prematurely" in the effort to keep the experience of chaos within limits that man can sustain. Religion, thus viewed, is the expression of man's attempt to formulate some ultimate solution, which is more abstract, less ephemeral, and, in the last analysis, beyond tragedy.

Religion, viewed here as a generic phenomenon and not as a series of specific religions, will now be considered in terms of the beliefs and practices by means of which a group (1) designates its deepest problems of meaning, suffering, and injustice; (2 j specifies its mosi fundamental ways of trying to reduce those problems; and (3) seeks to deal with the fact that, in spite of all efforts to eliminate them, meaninglessness, suffering, and injustice continue.

TYPES OF RELIGIOUS ORGANIZATIONS

Variations in religious organizations

Even a quick glance at the range of religious organizations reveals that they vary widely in a number of ways. They differ, for example, in the degree to which local groups are bound together into larger structures, recognizing their religious kinship; in the number and level of training of professional leaders; and in the extent to which a hierarchical or bureaucratic structure has been created. On the one hand there are small, independent local groups; on the other, there are international ecclesia (religious organizations) that bind thousands of local units together under a professionally trained, hierarchical leadership. A somewhat different contrast can be drawn between diffused and specialized religious patterns. In some societies (particularly isolated, preliterate societies) one finds an organizationally indistinct religious process, diffused through the social system, that is an integral part of familial, political, economic, and artistic activity. In more heterogeneous and complex societies, specialized religious institutions as well as religious specialists have appeared, with at least the possibilities for lines of action separate from other major institutions.

Viewing these facts, the social scientist asks two clusters of questions: Can the great diversity of religious organizations be classified; would some system of taxonomy (classification) help in viewing the range more clearly? And how does one account for the diversity; does it reflect, and in turn perhaps affect, secular diversity?

Church and sect types in Christianity. Fundamental answers to these questions were given by the German church historian Ernst Troeltsch, primarily with reference to Christian materials. Building on an earlier distinction between priest and prophet, he described two basic types of religious organization, the church and the sect. These are best understood as abstract types, marking the end points of a continuum that ranges from the most thoroughly established, formalized, and complex religious organization to the least established, least bureaucratized. These types express, in Troeltsch's judgment, differences in religious values and emphases; but more particularly, they express different ways of dealing with the secular world and its power.

The church, typologically, recognizes the strength of the secular world but neither abandons the attempt to influence it nor risks quick defeat by challenging the secular powers directly. The economic, political, and military powers that be are seen, in the Roman Catholic phrase, as part of the "relative natural law," as proximate goods, to be accepted, yet criticized. The church is built, therefore, on compromise. It

> . . . utilizes the State and the ruling classes, and weaves these elements into her own life; she then becomes an integral part of the existing social order; from this standpoint, then, the Church both stabilizes and determines the social order; in so doing, however, she becomes dependent upon the upper classes, and upon their development. (From Ernst Troeltsch, ***The Social Teaching of the Christian Churches;*** Olive Wyon ftr.], The Macmillan Co., 1931.)

Group and individual needs

Religion, viewed functionally, is connected with two partially competitive sets of needs. On the group level are the needs for stability, for predictability in the behaviour of others, and for processes that control the potentially destructive responses of individuals to tragedy and severe frustration. On the individual level is the need to handle problems of tension, guilt, anguish, and frustration. These societal and individual aspects are partially competitive, because processes that promote integration may do so only by demanding sacrifices from individuals that increase their anguish; or individuals may pursue salvation from their most grievous difficulties in ways that disrupt social order. The church, as a type, strives to be coextensive with society in its membership and thus to maximize integration. In the effort to achieve this, emphasis is placed on sacrament and creed, not on right behaviour. In the logically extreme case, the church type lends itself to the support of the secular order, even when it is authoritarian.

The sect, on the other hand, is best understood in connection with efforts to satisfy fundamental individual needs. Individuals who feel particularly deprived (and there are many forms of deprivation) may feel alienated from society and from the dominant religious organization closely connected with it. Participation in a sect expresses that alienation. In the extreme case, it is purely a religion of laymen, free from both worldly and ecclesiastical authority. The sect repudiates what it views as the compromises of the church, preferring isolation to compromise; its members cannot believe that a society that has filled them with such anguish or a church so well accommodated to that society is worthy of allegiance.

Troeltsch's description of the contrast between church and sect is a good starting point for the classification of religious organizations. It requires modification, however, in two ways: Since it is based wholly on Christian materials, its value in the analysis of other religious traditions must be examined. And as a dichotomy, even if the two types are understood as the extreme cases of a range, it leaves unexamined the wide variety of organizations within each type.

Structured and unstructured types in other religions. When one moves from a Christian to a universal perspective, the need for a distinction between formally organized, highly structured churches and religion as a pervasive quality of the social system becomes apparent. Joachim Wach distinguished between a religion that is coterminous with a "natural group" and "specifically religious groups." In a tribal or other homogeneous society, one does not belong to a church; he belongs to the society, which has certain religious qualities. In modern urban societies, the two memberships are separable, in fact and in imagination. The Chinese-American sociologist C.K. Yang suggests "diffused religion" and "institutionalized religion" as terms that convey this distinction.

Diffused and institutionalized religion

This distinction has influenced the comparative study of world religions in various ways. Hinduism and Buddhism, for example, have no "church" in the Troeltsch sense. This is not true if what is meant by "church" is an inclusive religious structure, accommodated to the world around it, to which individuals are affiliated by birth rather than choice. It is true, however, to a substantial degree if "church" conveys the connotations of formal organization and hierarchical structure, for these are less characteristic of Hinduism and Buddhism than of Islām and Christianity. Thus, churches should be identified as more or less institutionalized or diffused. Or perhaps the term ecclesia should be used to avoid the somewhat limiting connotations of "church."

Religions vary, however, historically and geographically in the degree of their institutionalization. Although Hinduism, for example, tends to be diffused, not institutionalized, and has no congregation in the Western meaning of the term, Brahminism (in the sense of an organized and partly hierarchical Hindu priesthood) has been characteristic of some periods in Indian history. Within the Buddhist tradition, the *saṅgha* (the organization of monks) represents a complex ecclesiastical structure in Theravāda (Way of the Elders, or southern Buddhist) countries, such as Thailand.

The concept of church, or ecclesia, thus has general analytic value when subtypes are described on the basis of their degree of institutionalization.

The sect type. An adequate formulation of the concept of "sect" requires a similar process of refinement and extension. The members of sects share in common a strong sense of deprivation and alienation. Since they can differ widely, however, in the forms of deprivation and alienation, they have quite different kinds of relationships to the surrounding society. In purely typological terms, sects can be described as shared and heightened expressions of three fundamental religious styles, each indicating a different form of deprivation. An American scholar, J. Milton Yinger, has suggested that these three styles are those of the prophet, the ascetic, and the mystic.

> The prophet sees himself outside the structure of power; he feels alienated from the social structure. He has not given up on the world; he wants power over it. The ascetic sees himself outside the cultural system; he feels alienated from prevailing values. The values he most esteems seem beyond realization within the human communities he knows, so he is ready to withdraw to achieve them. The mystic sees himself outside the usual motivational systems; he feels alienated from himself and lonely; he lacks morale; he feels guilty and baffled. He may join with others, without reference to the world around them, to achieve poise, insight, and control over their spiritual and physical malaise. (From J. Milton Yinger, ***The Scientific*** Study ***of Religion;*** The Macmillan Co., 1970.)

These prophetic, ascetic, and mystical sects are analytic types, not actual organizations. Particular sects may develop values and activities with reference to all three types of deprivation. There may be internal struggles within the group, accounting for frequent schisms, because individuals want different emphases. Nevertheless, description of pure types can facilitate cross-temporal and cross-cultural comparisons.

An appropriate taxonomy (classification system) for religious organizations is helpful in answering the problem of diversity. The social scientist looks for an answer not in the contrasting beliefs and rites---indeed, he sees these as the dependent variables to be explained--but in the structural and cultural differences within a group or between groups. The American theologian H. Richard Niebuhr, in his ***The Social Sources of Denominationalism,*** has stated that if men had similar needs, were placed in equivalent positions in the social structure. and were trained to share the same cultural heritage, their religious outlooks would be quite similar. Religious divisions and schisms occur, in fact, because of various combinations of the following highly interactive influences.

Individual variations. Individuals vary in their feelings of frustration and guilt, in the level of their intellectual development, in their tendencies toward authoritarianism or dogmatism, in their capacities for the several kinds of religious experience, and in many other ways. The beliefs and rites that are resonant and meaningful, therefore, vary among them.

Economic and political variations. There are differences in economic and political interests. Since religion is involved in social conflict as well as integration, it carries the imprint of these interests. The German philosopher Friedrich Nietzsche described religion as an expression of class-determined resentment, an–effort by the powerless to enchain the powerful. This was a great oversimplification, but it focusses attention on the interconnection of religion and stratification systems. The German sociologist Max Weber is closer to the mark in his discussion of the contrast between upper and lower class religious views. On the one hand, there is a theodicy (justification of evil in accordance with a view of a good and righteous God) of good fortune—the beliefs and rites that serve to justify one's relatively favourable position and give assurance that it will not disappear. On the other hand, there is a glorification of suffering—perhaps even the seeking out of suffering to achieve salvation—by the powerless; or the theodicy of rebirth, as in Hinduism and Buddhism; or the religious downgrading of worldly success, Struggles within a religious group often reflect these contrasting locations in the social structure. The prophetic and pharisaic (legalistic reinterpretive) elements in early Judaism, for example, match the economic and cultural conflicts between the seminomadic shepherds and the settled farmers, the lanaless and the landowning, and the artisans and the nobles.

Societal and nutional variations. Even the world religions manifest wide societal and national differences. They carry the imprint of the demographic, historical, and institutional facts of the societies of which they are a part. Thus, one must note not only the contrast between the Theravāda (southern) and Mahāyāna (northern) Buddhist traditions but also the national variation within each. It is not enough to note the distinctions between Buddhism in China, where it interacts in a large and complex society with many other major religious traditions, and Buddhism in Thailand, where its influence is relatively unalloyed. The Theravāda Buddhism of Burma differs from that of Thailand in important ways. Differences in the national expressions of religious traditions persist, often for several generations, even when they have been transplanted into new nations, as shown by continuing variation in religious beliefs and practices among the several Lutheran or Roman Catholic groups in the United States.

National contrasts within a religion

The student of such national and societal differences within a religious tradition must also be a student of variation in the interpretations of the differences. Most scholars would agree that it is only on a fairly abstract level that one can speak of Islām, without noting the contrasts among the African, Arabic, Pakistani, Indonesian, and other varieties; but it is well to note also that the interpretations of the differences vary, as between Islāmic and non-Islāmic scholars, and within each of these groups.

Social mobility and change variations. Social mobility and social change do not affect the members of a society in the same way or at the same speed; and one of the consequences of the differences in experience is variation in religious perspective. In the 20th century every major religious tradition is divided between traditionalists and modernists, literalists and revisionists, partly as a result of differences in the stability of individuals' social worlds.

Internal variations. Variation in religious organizations derives in part from the internal development of the religious system. The elaboration of theological ideas, inventiveness in the field of aesthetics or ritual, and differences in judgment concerning the most effective way to maintain or strengthen the faith all express themselves in different religious organizations. They do so, however, not because of some independent power but because of the responses of possible constituencies. Thus, these internal religious developments help to account for church–sect and other contrasts only as they are connected with the other previously noted factors and with the needs and desires of various audiences. In Weber's thought there is an "elective affinity" between particular religious ideas and the circumstances faced by given groups. This can result either in internal differentiation or in conversion, which may be defined as the shifting of loyalty across a major religious line. Thus, lower caste Hindus, when change and mobility have opened up to their imaginations new religious perspectives, become potential candidates for conversion to Buddhism; and some American Negroes, under similar circumstances, join a variant of the Muslims.

Contextual differentiations. Viewing the question from the perspective of religious leaders, there is a strategic factor to be noted as an important cause of religious differentiation. According to contemporary theories of administration, complex organizations are often faced with dilemmas, both in dealing with their own members —whose allegiances and motives are mixed—and in dealing with the external environment. As a religious organization (or any other group) seeks to maintain or broaden its influence, it often has to win the support or neutralize the opposition of others. The question thus arises: shall it oppose other groups and member motivations that are not supportive of the organization's purposes directly, compromise with them, or try to co-opt them into its own activities? The dilemma of religious organizations is not unlike that of political parties: direct opposition to powerful forces may bring defeat; compromise may require yielding on major values; co-optation raises the question of who will in fact dominate whom. The dilemma is clearly illustrated in the variety of relationships between church and state. According to Yinger:

Dilemmas of complex organizations

> Those who believe that clear separation of church and state increases the power of the church emphasize the freedom from political domination, the freedom to criticize the political process and the secular power structure. There is the danger, however, that such freedoms are closely connected with powerlessness. On the other hand, close institutional connection between church and state scarcely avoids the dilemma, because the union raises the likelihood that the church will be used to lend sanctity to a secular power

> structure. The problem is to **find** a way to be simultaneously in politics [thus to influence it] and beyond politics [thus free to challenge it]. (From J. Milton Yinger, ***Sociology Looks at Religion;*** The Macmillan Co., 1963.)

Those who support the churchlike response believe that compromise is better than isolation, that to press too hard is not to win but rather to alienate potential supporters. By accepting what in any event can scarcely be avoided or directly changed, at least by a religious movement (war, or inequalities of station, for example), churchmen hope to remain in a position of influence from which they can gradually remove the causes. Sectarians disagree with this strategy. They view compromise as a one-way street down which churches move until they have left their original values behind. The way to deal with the dilemma, in the sectarian view, is to maintain the purity of the religious system of values in an uncompromised community of believers. Some sectarians may then define the dilemma as irrelevant, for they seek no influence beyond the group. Others envisage victory for the sectarian ideal by human effort or miraculous event. Still others believe that the vocation of the religious person and group is to maintain the religious ideal in the hope and expectation that it will be a beacon for others.

These several sources of religious differentiation are highly interactive. Those who support a sectarian approach for strategic reasons, for example, are often those who are seriously deprived, and thus their class location is also involved. A society that treats them so poorly is clearly not one with which they want their religious group to compromise. These same persons may be among the most seriously affected by the stresses of social change.

Ecumenism

Contextual **affinities.** If certain cultural and structural facts tend to produce religious divisions, other facts tend to produce ecumenism (religious cooperation). Those concerned with the social aspects of religion must therefore be concerned with fusion as well as with fission, with the social sources of ecumenism as well as with the social sources of denominationalism. Although the forces of division are strong in the 20th century (reflecting the sharp differences in experience and in opinions about the conflicts of the day), tendencies toward ecumenism are also strong. A World Fellowship of Buddhists was formed in 1950; the Roman Catholic second Vatican Council (1962–65) gave serious attention to the question of the relationship of that church to other Christian churches and to other religions; Protestant and Orthodox bodies have extended the scope and the reach of the World Council of Churches; cooperation among Orthodox, Conservative, and Reform congregations in Judaism has increased.

The term ecumenism is thus used in a variety of ways, referring to activities ranging from tentative conversations among formerly separate religious groups to the achievement of full unity. Ecumenism may thus be viewed as a variable rather than as a condition, with points marked along a scale with familiar terms. The scale might therefore range from toleration—through conversation, cooperation, and federation—to integration, indicating progressively stronger ecumenical activity. This range is meaningful, however, only when another scale is used at the same time, a scale that indicates which religious groups are being drawn together. Integration of two Methodist bodies, for example, may be a smaller ecumenical step than serious conversation between a Christian and a Buddhist group.

Viewed sociologically, the trends of this period of relatively active ecumenism are a product of shared experiences, perspectives, and threats. Within the United States, for example, religious differentiation based on national origin, regional isolation, rural–urban contrasts, and language backgrounds has been reduced in the latter half of the 20th century. The appearance of powerful and competitive quasi-religions, communism in particular, has caused traditional groups to view their shared qualities —and their shared competition—more clearly. And the transportation and communication revolution of the 20th century has created and made dramatically visible a powerful ecumenical fact: inhabitants of the earth are vitally interdependent.

RELIGIOUS LEADERSHIP

Types and functions of religious leaders

There are many ways to describe the range of types of religious leaders. Wach distinguishes among the following: founder, reformer, prophet, seer, magician, diviner, saint, priest, and religiosus (a plain man who lives a highly religious life). Studies that focus on the contemporary scene emphasize the range of functions, more than types of leaders, although these may be partially equated by a division of labour. Marshal Sklare, a U.S. sociologist, designates eight functions: priest (conductor of public worship), preacher, cleric (a functionary of the state), rector (administrator of an organization), pastor (counsellor), father (head of a congregation in a psychological sense), parson (representative of the church to the community), and rabbi (teacher and interpreter of religious doctrines). Such diversity of functions is found only in highly differentiated societies in which religious organizations have become complex. Social aspects of religion are strongly influenced by the factors in the recruitment of these various types of leaders (*e.g.*, the social classes to which they belong, their educational levels and personality types), by the degree of self-selection, by the extent and nature of their training, and by the extent to which they are gathered up into or under the direction of complex organizations—*e.g.*, the local Muslim *imām* (religious leader) into the *ʿulamāʾ* (the body of men trained in Muslim law and theology), or the Buddhist monk into a regional or national *saṅgha.*

More analytic studies of religious leadership deal with the relationship of the leader to the surrounding society and to processes of social change. In anthropological work, a distinction is frequently drawn between the priest and the shaman, the former a religious leader trained to fulfill a culturally defined role in a complex organization, the latter a person possessed of personal divine power and involved in less structured, noncalendrical rites. In sociology, the distinction is more often drawn, as by Weber, between the priest and the prophet. Priests are trained functionaries of an established religious system. Prophets are the bearers of charisma—an ability to convince others that they possess supernatural or at least excep tional powers, not by virtue of their office but by virtue of their personal qualities. The concepts of charisma and prophet were not adequately developed by Weber. They have something of an ad hoc (particularistic) quality, making them appear to be designed to help account for drastic change in the face of Weber's emphasis on bureaucratization and rationalization. In view of this, the question as to who is ready to grant charisma to which candidates (for many prophets go unheard) and what their relationship to the tradition from which they come (however much they may challenge it) needs to be asked.

A further analytic approach to religious leadership refers to those persons who give intensive expression to one of the three primary roots of religion and who have become identified with a movement of which that expression is the focus of attention. The mystic promises enlightenment; the ascetic is most concerned with suffering; the prophet seeks justice. These are analytic types, however, not specific positions; individual leaders are likely to combine them. Moreover, they cut across the types of leaders described in terms of organizational structure. Each approach has its value in the study of leadership.

RELIGION AND SOCIETY

The concept of function

Religion as sociofunetional. The universality of religion leads readily to the assumption that it serves essential functions for individuals and society, or both. This observation expresses a theory that has been widely used, and sharply criticized, partly because the concept of "function" has several meanings. Two of these are critical for the student of religion. One meaning is a given structure or process that performs an essential service. In mechanics, for example, a carburetor functions to mix gasoline and oxygen to make combustion possible in an automobile engine. Without it an automobile could not run. Religion, functionally, serves to give men shared goals, thus reducing the sharpness of their competitive goals; it promises later rewards, thus softening the anguish of present frustration; it helps to define the meaning of suffering, thus reducing the threat of chaos. Religion, thus, is a functional prerequisite for society.

But function also means consequence. If religion is a function of society and of individual need, it varies with them, reflecting their changes; it is an effect. Functional theory ties these two meanings together, although some of its advocates have used only the first meaning and wondered why they were criticized; some critics have used only the second meaning and wondered how it could possibly be used to show the effects of religion. When the two meanings are used together, functional investigation focusses on those processes within a system in which a product of the system (in this case religion) helps to maintain that system by reducing or eliminating otherwise destructive processes. This is an influential theory in the biological and social sciences because they work with evolutionary and cybernetic, or "feedback," models. A system becomes what it is partly because of the effects it has had, which help it to adapt to its environment. In evolutionary terms, those societies that did not invent religion did not survive. In psychological terms, the pattern is reinforced because of its consequences. An effect triggers a signal or a process that contributes to adaptation, integration, and development.

Functionalism emphasizes in a valuable way the interdependence of society and religion. If it is narrowly interpreted, however, it leaves several critical questions unanswered. One of these is of special importance for the student of religion: if religion, which in the first instance is a product of certain social and individual forces, serves functions of adaptation and integration for the system out of which it comes, the question as to what are its consequences for smaller and larger systems, which are interdependent with the first and which may have conflicting needs and inclinations, must be asked. If religion integrates a society that is highly repressive for some of its members, its functional aspects for them must be investigated. If it integrates in such a way that it arms a society with righteous anger to attack another "heathen" society, the question concerning its functional aspects for the latter must also be investigated.

Religion as dysfunctional. These questions suggest that functionalism is not only incomplete without conflict theory but that it is one segment of a larger theory, of which the study of conflict is also an integral part. To simply add functional and conflict theories together, eclectically noting that both processes operate in society, is not a sufficient answer for the social scientist. They are best seen as a unit. Lack of conflict can be functional or dysfunctional for a system. (Pain can be a signal that some action is needed; the lack of such a signal can be catastrophic.) Conflict can be functional or dysfunctional. In assessing these various possibilities, it is essential that the system of reference be specified.

Any bland interpretation that religion preserves sociai order or lowers individual anxiety disregards the frequency with which religion expresses the deep rifts in society or increases the possibilities of anxiety. If one person's life is given meaning and coherence by a faith that constrains the life of another or makes him the object of attack, the total level of anxiety may not be lowered.

The role
of conflict
in religion

The conflict potential of religion is expressed in sectarian and reformation movements, in the development of new religions, and in the continuing confrontation of different religious communities within one society. The Levellers and Diggers (religiosocial reform movements of 17th-century England) used sectarian protest to challenge the establishment, both secular and religious. The Black Muslims in contemporary America demonstrate the use of a new religion to challenge a society, not to express integration with it. Catholic–Protestant conflicts for several centuries in Northern Ireland indicate that religious difference can symbolize and strengthen divisive tendencies within a society.

These are nor vaiuarive statements. Whether or no1 the potential of religion to contribute to conflict is desirable can be stated only in terms of specified values and with knowledge of total, long-run consequences. The harsh, antagonistic stance of the Black Muslims may help the members to rid themselves of self-doubt, encourage them to accept disciplines and responsibilities that a "white man's religion" could not do, and alert the dominant society to grave injustices and great suffering that it apparently has disregarded. Whether these will be the long-run outcomes, rather than increased tension and conflict, mainly depends not on the religious doctrines but on the social setting in which they are heard.

Reciprocity in society and religion. The relationships of religion to society, then, are best understood not by separate applications of functional and conflict theories but by consistent application of the whole system, or field, theory.

From the perspectives of the social sciences, religious organizations are part of the social structure, religious values part of the general culture, religious motivation part of individual character. For purposes of analysis, however, the religious element in social life can be separated from the rest in order to study its interactions with the polity, the economy, the stratification system, and other elements of society. These relationships are too complex to examine in detail but will be referred to briefly.

Religion and social organization. Religion everywhere is closely connected with family structures. All societies have culturally designated ways in which sexual behaviour and reproduction are regulated; status assignment is made (indicating who stands up for a child, giving him his name and social position), socialization is carried out, and affection and personal support are made available. Although a variety of structures can serve this complex of functions, they are so vital that no society leaves them simply to chance or to individual initiative. In virtually every instance, moreover, they are reinforced by the religious system. This is particularly true in those societies in which the kinship system is the centre of social organization. Family deities and ancestor worship may be important parts of the religious life in such societies. The ethical norms governing interpersonal behaviour within the family are often given religious sanction (*e.g.*, "Honor thy father and thy mother," as in the Ten Commandments of Judaism and Christianity; marriages, monogamous and permanent, are "made in heaven," as in popular piety). Even in societies in which occupational, locational, recreational, and other associations have modified the pre-eminent place of the family, there continue to be important religious elements in socialization; religious endogamy (marriage within one's group) remains common; and the basic structure of the family — the place of women, the importance of children, the possibility of divorce, and the like—continues to be supported by religious norms and training.

Religion
and social
stratification

Religion and social differentiation. The distinction between church and sect indicates that religion also is involved in social stratification. Whether it be a caste system, a majority–minority system, or a class system, there is religious variation among the strata. In Buddhism, the ways in which one seeks merit—*i.e.*, the means to rebirth in a higher life — vary widely by class because expectations, resources, training, and motivation vary. The wealthy have time and training for meditation, or they may make a large gift to a monastery. The poor also make gifts, perhaps at greater sacrifice than the wealthy; but they also express devotion — in which they are at no disadvantage.

The conflicts among social strata are also expressed, in part, religiously. In some instances this will be in the form of a deflected or displaced attack on the social order by the lower strata, who proclaim that "the last shall be first" in some heavenly kingdom. But religion may arm the lcwly for purely earthly battles (as it often arms the powerful). This happens under various sets of circumstances. In one case, religious protest develops shortly after some independent and prosperous era has ended. A giorious (often partly romanticized j past is seen through the frustrations of an oppressive present. Thus, the Ghost Dance swept through a number of American Indian tribes in 187%-90—particularly among the tribes of the plains—a period when their own independent cultural lives were still a vivid memory, though their contemporary lives were filled with frustration. Although there were several versions of the Ghost Dance, some more conflict-oriented than others, they all envisioned the restoration of the land to Indians, the return of their cultures, and the annihilation or the expulsion of the white man.

Religion may also support a protest movement among members of lower strata who are beginning to experience some improvement of status, perhaps after generations of repression. Their hopes may soar far more rapidly than opportunities open up to them. Their comparisons, then, are with a glorious future, not a glorious past; but these produce the same sense of unjust deprivation, relative to the standard before them. "I have a dream," the American civil rights leader Martin Luther King, Jr., proclaimed, and the dream was the basis of his militant, if nonviolent, attack on racial discrimination. In his "Letter from Birmingham Jail" he declared that civil disobedience and extremism were religiously prescribed:

> Jesus Christ was an extremist for love, truth and goodness, and thereby rose above his environment. Perhaps the South, the nation and the world are in due need of creative extremists.

Religion and economics. No aspect of the relationship between religion and society has been more carefully studied than the reciprocal influence of religion and economic activity. Religion influences an economic system in many ways. Worship and holidays affect the timing and rhythm of work. Occupational assignment, as in the Hindu caste system or, more individualistically, in the Christian doctrine of the "calling," may be religiously prescribed or supported. The economic value of goods and services is partly determined by the religious definition of their value, which can raise or lower both demand and supply. The distribution of wealth is partly governed by religious norms, which may indicate the deserving and the undeserving. Religious organizations, activities, personnel, and buildings may command a substantial proportion of the resources of a society. This is particularly true of technologically underdeveloped societies and of those with a precarious economic existence, for there is a negative correlation between economic productivity and the proportion of the resources of a society spent on religion.

The Protestant Ethic

The relationship between religion and economic development, however, has received the most intensive examination. The issue was raised in a decisive way by Max Weber in his essay ***The Protestant Ethic and the Spirit of Capitalism.*** Unconvinced by the Marxian interpretation of religion and of economic development, Weber carefully examined the relationship between the areas of rapid capitalist advancement and religious allegiance. In countries with both Protestant and Catholic citizens, he noted, business leaders, owners of capital, technically trained persons, and skilled workers were "overwhelmingly Protestant." He did not deny the importance of economic factors:

> . . . we have no intention whatever of maintaining such a foolish and doctrinaire thesis as that the spirit of capitalism . . . could only have arisen as the result of certain effects of the Reformation, or even that capitalism as an economic system is a creation of the Reformation.

Weber did emphasize, however, what he saw as the peculiar spirit of economic enterprise among early Protestants, a spirit characterized as disciplined, rational, and highly ascetic. These qualities expressed the 16th-century Reformer John Calvin's desire to be not simply a "vessel of the Holy Spirit," which expressed Martin Luther's mysticism, but "the tool of the divine will."

> Since Calvin viewed all pure feelings and emotions, no matter how exalted they might seem to be, with suspicion, faith had to be proved by its objective results in order to provide a firm foundation for the *certitudo salutis* [or certainty of salvation].

Religious ethics and economic action

Probably no book in the sociology of religion has aroused so much commentary and criticism as ***The Protestant Ethic.*** A substantial library has been written proclaiming it as a theoretical work of the first rank, denouncing it as absurd, substituting a different religious ethic for Protestantism, or qualifying the thesis in various ways. This is scarcely surprising, considering the complexity of the problem and the difficulty in excluding ideological perspectives. Weber skillfully demonstrated that religious ethics are part of a complex of forces that influence economic action. He less skillfully examined the evolution of the Protestant ethic in its step-by-step modification as it interacted with the economic setting. Or, to put it in another way, he paid insufficient attention to the selectivity of the groups who chose Protestantism (in part precisely because of its congeniality with emerging economic conditions), who modified it and who then were significantly influenced by its doctrines and obligations. Calvinism (Reformed or Presbyterian) had within it various potentialities for development into a religious attitude that would be meaningful to people who were also engaged in, or wanted to be engaged in, capitalist economic activity. These potentialities were much more limited in Lutheranism and Catholicism. The religious spirit of which Weber wrote, however, was not simply a product of economic motivation. It evolved partly as a result of its own "inner dialectic." It helped to shape the life style and the goals of its adherents and thus served to intensify a peculiarly rational and frugal economic pattern that was developing as a result of more mundane forces.

The Protestant Ethic, first published in 1904, was the initial volume in a series of studies in which Weber explored the significance of religion for economic matters. In studies of Confucianism and Taoism, Hinduism and Buddhism, and ancient Judaism, Weber examined the ways in which religious ideas blocked or supported the development of rational economic enterprise. In later writings, he took account of the interactions among economic, political, and religious influences, thus approaching the question from a broader perspective than that employed in ***The Protestant Ethic,*** in which he described only one side of the causal chain. In each of these later works, Weber concluded that the religious influence restrained economic development, although at different levels of intensity. Even in the face of extensive economic opportunity, as in China, traditionalism prevailed, partly as a result of the strength of Confucian traditionalism. Weber accounts for Europe's being freed from an equally or even more restrictive Christian traditionalism by reinterpretations of Protestant prophecy. A major theoretical issue then emerges: why did the prophets appear in Europe and why did Hinduism or Confucianism not have a Reformation? Thus, there is a need for recognition of the gradual and mutual modifications that appear in a situation of rapid change.

The study of the interaction of religion and economic development received renewed attention in the 1960s because of the efforts of many technologically underdeveloped societies to create economies with the capability for self-sustaining growth. The applicability of Weber's thesis to Japan and to contemporary United States has also been studied. The range of issues is too wide to examine here; but the following generalizations are broadly supported by contemporary research. Traditional religions are proving to be only minimally supportive of economic development in the technologically less advanced societies, although most of them are capable of reinterpretations that permit, if they do not promote, economic change. Japan's economic transformation did not require prior religious transformation and may have received some religious stimulation. In the United States, those brought up in the Protestant tradition adapted more quickly to the possibilities of economic achievement than did Catholics, but this contrast subsequently has been sharply reduced if not eliminated entirely. In the technologically underdeveloped world as a whole, the process of making new types of men and new societies has been led mainly by revolutionary quasi-religions, not by reformed traditional religions.

Power, prestige, and possessions

Religion and political development. Political and religious orders are everywhere interactive. Both are involved with questions that arise from the fact that many of the values for which men strive—power, prestige, and possessions—are in scarce supply. If each person pursued them by means of his own choosing, organized societies would be impossible. Political institutions, therefore, are the structures that assign ultimate coercive power--even to the extreme of the administration of death—to certain procedures and certain individuals in order to enforce approved ways of achieving life's values.

In some societies, religious and political structures are coterminous, a characteristic situation in relatively isolated, preliterate societies. The gods of the group guarantee or represent its values; the roles of citizen and believer cannot be separated. This does not mean that conflict is absent. Indeed, conflict often finds religious expression in such societies; but it is handled in such a way that it is less likely to increase or produce a permanent split in the social structure.

When societies become more heterogeneous, when some groups become acquainted through cuiture contact with different sets of values, and when sharper lines of stratification appear, the stage is set for a different pattern of relationship between religion and politics. Because these trends may loosen the hold of social norms, some members of the society will acquire an instrumental attitude toward religion. The ruling class begins to see it as a means of preserving order—*i.e.*, helping to guarantee their positions. This is not so much cynical manipulation as ready belief in a congenial faith. In Islāmic societies, to challenge the ruler may be to challenge the caliph (Islāmic political leader) as a religious leader. A U.S. sociologist, Kai Erikson, has noted that the antinomian (anti-legalistic) controversy in the Massachusetts Bay Colony (in 17th-century America), although couched in religious language, was primarily a political struggle. The elders could fight Anne Hutchinson and her supporters more effectively and more earnestly on doctrinal than on political grounds.

Separation of religious systems and the state

Implicit in the partial separation of religious and political identities is the possibility of a third pattern of relationship—religious systems that are set sharply apart from the state. Religious specialists may develop ideas that contradict secular claims and values. This seems to occur under conditions of persistent social change, social contact, and widespread and prolonged suffering. The religious imagination leaps the boundaries of the society within which that suffering has been felt and propounds a universal system. In the classic case, Yahweh worship was transformed by the 8th-century-BC prophets of Judaism from a tribal religion, with its burnt offerings and sacrifices, into a monotheistic religion that emphasized repentance. And, as Leonard Trelawney Hobhouse, a British social scientist, wrote in comparing the development of Judaism with the development of Buddhism,

> . . . by a very different road and with much difference of implied meaning, we are reaching the Buddhist doctrine of renunciation and humility—those cardinal points of spiritualized religion.

These three levels of relationship between religion and politics do not represent a historical sequence. One is built upon the other, and all three are visible in contemporary societies. *Gott* mit *uns* ("God with us," a phrase found on German army uniforms in World War II) can be written in many languages, to illustrate the first level. Pres. Nguyen Van Thieu of South Vietnam ordered authorities in the 1960s to arrest Buddhist monks and Catholic priests who make "political sermons" to "inflame the people." He thus indicated their opposition and his interest in maintaining a religious neutrality if he could not win active support—illustrative of the second level of interaction. There are elements of universalism—the third level—in ecumenism, pacifism, opposition to discrimination, and the symbolic affirmation of the brotherhood of man in all of the world religions.

The complexity and importance of the issues involved in the various degrees of the separation of church and state is indicated in the sharp separation of the duties of Brahmins (priestly caste) and Kṣatriyas (military caste) in Hinduism, which has institutionalized the separation of church and state and has created a context in which a secular state could emerge. That Brahmins have developed a minimum of ecclesiastical structure supports these trends. In theory, Buddhism equally supports the separation of church and state, but under some conditions this relationship has been extensively modified. When a predominantly Buddhist nation confronts a non-Buddhist imperial power, for example, the nationalist movement may gain strength from religious themes, as in the case of Burma. In most instances, Islām supports the close identity of church and state. Even some contemporary states have an explicitly religious character, as documented by the official title of Pakistan, the Islāmic Republic of Pakistan.

Political and religious structures

Political and religious structures were closely aligned in early Judaism, but through history the pattern changed drastically. There was no likelihood that Jews would identify their religious community with the Assyrian, Babylonian, or Roman empires that held political power over them at various times. Political subordination has continued to be the experience of many Jews through centuries of what some regard as a continuing diaspora (dispersion into foreign lands). The impact of the development of modern Israel—where some 15 percent of the world's Jews live—on the creed and practice of church–state relationships is too recent to measure. Citizenship and religious identity in Israel, however, have once again been brought close together.

Christianity shows perhaps the widest variety of relationships of church and state, from extremely close union (not only in the formal but in the operative sense) to separation tinged with antagonism. This last aspect tends to persist for relatively brief periods, however, as in Mexico and the Soviet Union in the first few decades after their revolutions. The more standard relationship today is formal separation accompanied by numerous points of contact, cooperation, and interpenetration, as in the U.S.

Religion anti *sociocultural* transformation. Almost every issue thus far discussed involves, directly or implicitly, the question of the relationship between religion and social change. There are several possible answers to the question: religion and social change are unconnected; religion is the dependent variable, merely reflecting changes in its environment; religion prevents change (whether as an "opiate" or a "conserver of tested values"); religion is the independent variable, the source of major changes; and religion is part of an interdependent system and thus reflects, carries, and causes changes, depending on the point in a sequence that is being examined and the perspective from which a problem is being studied.

RELIGION AND PERSONALITY

A major connecting link in the study of religion, culture, and society is the field of culture and personality, which relates individual motivation and behaviour to the social context in which socialization and learning take place. An individual learns the religious culture around him just as he learns other parts of culture. Were this the whole truth, however, religious change, conversion to other faiths, withdrawal of allegiance, or the range of individual religious experiences within a given tradition would be difficult to explain.

The significance of the fear of death

In noting individualistic theories of the origin of religion, the most important of the universal experiences connected with religion are the fear and fact of death. Everywhere, the ways in which men meet the problem of death are in the realm of the sacred or holy (the transcendent). In societies in which any one of the world religions is dominant, the religious response to death often proceeds along two paths. One is the reaching upward to what is called the "great tradition," which, however, may be more stern and ascetic than the average man can achieve; the other is a reaching out to what is called the "little tradition" that is more attuned to immediate human need and capabilities. Thus, the Buddha (the 6th-century BC Indian religious reformer) did not make what he felt were false promises about immortality; he stressed instead the strength that could come from recognition of man's common helplessness. Alongside this form of Buddhism, however, are found ancestral and national cults that soften its stern message by dealing with the day-to-day ills that threaten to overwhelm man.

Other individual needs and experiences that are less obviously universal also enter importantly into religion. They require that attention be paid to variation in the direction and intensity of religious inclinations. This variation is partly the result of differences in socialization. Those who need religion are, in some measure, those who have been trained to need it—the training comes first, not the need. The need is partly a consequence of social role assignment. Women may be more religiously inclined in some societies than men because they have been socialized that way, though this disposition is partly an indirect effect of their role and its frustrations. In other societies, however, men's roles are more likely to encourage the public forms of religious worship, as in Buddhist, Jewish, and Islāmic societies.

Social learning and role influences help to account for variation in religious needs and activities, but more individualistic factors also enter in. In ***The Varieties of Religious Experience,*** the U.S. philosopher William James distinguished between the religion of "healthy-mindedness" and the religion of "the sick soul." The healthy-minded individual, in James's terms, views life optimistically; he does not linger over the darker facts of human experience. But the sick soul maximizes evil,

> . . . based on the persuasion that the evil aspects of our life are of its very essence, and that the world's meaning most comes home to us when we lay them most to heart.

This distinction was illustrated more than tested in James's work, and it is considered to be subject to value-laden distortion. Nevertheless, it stimulated an extensive amount of study of the varieties of religious experience, of conversion, ecstasy, possession, and revelation; of joy, terror, wonder, mystical encounter, and prophetic power; and of less exuberant feelings of contentment, enlightenment, and expansion of self. Much of this work is purely descriptive; but the accumulated material for a more analytic treatment of religious experience is being developed in the latter part of the 20th century.

Religious experience

Religious experience, according to social scientists, is not the direct expression of inner forces but is rather a product of a transaction between an individual with certain tendencies and the surrounding social and physical environment. In a study of trance ***(Journal for the Scientific Study of Religion,*** April ***1962)*** by Alexander Alland, a U.S. anthropologist, for example, the interactive influence of heat, high levels of carbon dioxide, loud, rhythmic music that leads to sensory deprivation, the presence of "significant others" to serve as models, lack of information, and isolation are examined. The description of the social setting does not mean that individual motivational factors are uninvolved;

> . . . receptivity to the trance is most certainly influenced by personal differences such as: range of experience, needs of the individual, and tolerance for various physiological stresses.

Religious experiences of this kind are best understood not as sharply different from other experiences but as one possible outcome of tendencies in a particular situation. A different situation can support the expression of those tendencies in another way. Students of comparative psychiatry emphasize that the behavioral significance of individuai anxiety is a function not only of its intensity and form but also of the interpretation given it by others. Consequences as diverse as acute schizophrenia (split personality) and shamanism (psychic transformation) may follow from the same underlying individual tendencies, depending on the way they are acted upon by others. According to the U.S. scholar Julian Silverman,

> In primitive cultures in which such a unique life crisis resolution is tolerated, the abnormal experience (shamanism) is typically beneficial to the individual, cognitively and affectively; he is regarded as one with expanded consciousness. In a culture that does not provide referential guides for comprehending this kind of crisis experience, the individual [schizophrenic] typically undergoes an intensification of his suffering over and above his original anxieties. (From Julian Silverman, "Shamans and Acute Schizophrenia," ***American Anthropologist,*** February 1967.)

An empirically based science of the personality factors in religion requires more reliable and valid measures than have yet been designed. A great deal of work is being done on this topic, however, not only of the case study variety, discussed above, but of a more quantitative sort. Thus, in comparing the levels of educational motivation of Protestants, Catholics, and Jews, for example, care is being taken to see that other variables are controlled, that only those alike on other grounds are compared. The meaning of individual "religiosity" is also being differentiated since it has many dimensions. To compare two "church member" samples is to learn very little if one does not know how much they are alike or different in beliefs, religious knowledge, or tendencies toward particular religious experiences. When the various "dimensions" of religion have been isolated, each can be put on a scale. Church membership, for example, can range from nuclear (dedicated and active participation), to modal (usual), marginal (occasional participation), and dormant (in name only). The importance of religion to the individual can be used as a variable, and variations in concern for suffering, injustice, and meaninglessness, as basic religious categories, can be measured to obtain individual views. Both the causes and the consequences of variations in these concerns are fundamental questions for the student of religion and personality. To explore them fully, he will need to connect the study of personality with the study of society and culture.

Religion, Study of

The study of religion, involving theological, historical, philosophical, literary, anthropological, sociological, psychological, and phenomenological approaches to the subject, has been a matter of scholarly concern from the time of the ancient Greeks until the present, though the subject has been of increasing importance in the second part of the 20th century.

This article is divided into the following sections:

I. Nature and significance

The history of mankind has shown the pervasive influences of religion, and thus the study of religion, involving the attempt to understand its significance and origins, has become increasingly important in modern times. The 19th century saw the rise of the study of religion in the modern sense, in which the techniques of historical enquiry, the philological sciences, psychology, anthropology, sociology, and other human studies were brought to bear on the task of estimating the history, origins, and functions of religion. Rarely, however, has there been unanimity among scholars about the nature of the subject, partly because assumptions about the revealed nature of the Christian (or other) religion or about the falsity of religion become entangled with questions about the historical and other facts of religion. Thus, the subject has, throughout its history, contained elements of controversy.

THE ESSENCE OF RELIGION AND THE CONTEXT OF RELIGIOUS BELIEFS, PRACTICES, AND INSTITUTIONS

Attempts to arrive at a definition of religion

An acceptable definition of religion itself is difficult to attain. Attempts have been made to find an essential ingredient in all religions (*e.g.*, the numinous, or spiritual, experience; the contrast between the sacred and the profane; belief in gods or in God), so that an "essence" of religion can be described. But objections have been brought against such attempts, either because the rich variety of men's religions makes it possible to find counterexamples or because the element cited as essential is in some religions peripheral. The gods play a very subsidiary role, for example, in most phases of Theravāda ("Way of the Elders") Buddhism. A more promising method would seem to be that of exhibiting aspects of religion that are *typical* of religions, though they may not be universal. The occurrence of the rituals of worship is typical, but there are cases, however, in which such rituals are not central. Thus, one of the tasks of a student of religion is to gather together an inventory of types of religious phenomena.

The fact that there is dispute over the possibility of finding an essence of religion means that there is likewise a problem about speaking of the study of religion or of religions, for it is misleading to think of religion as something that "runs through" religions. This brings to light one of the major questions of method in the study of the subject. In practice, a religion is a particular system, or a set of systems, in which doctrines, myths, rituals, sentiments, institutions, and other similar elements are interconnected. Thus, in order to understand a given belief that occurs in such a system, it is necessary to look at its particular context—that is, other beliefs held in the system, rituals, and other aspects. Belief in the lordship of Christ in the early Christian Church, for example, has to be seen in the context of a belief in the Creator and of the sacramental life of the community. This systematic character of a religion has been referred to by the 20th-century Dutch theologian Hendrik Kraemer as "totalitarian"; but a better term would be "organic." Thus, there arises the problem of whether or not one belief or practice embedded in an organic system can properly be compared to a similar item in another organic system. To put the matter in another way, every religion has its unique properties, and attempts to make interreligious comparisons may hide these unique aspects. Most students of religion agree, however, that valid comparisons are possible, though they are difficult to make. Indeed, one can see the very uniqueness of a religion through comparison, which includes a contrast. The importance of setting religions side by side is why the study of religions is sometimes referred to as the "comparative study of religion"—though a number of scholars prefer not to use this phrase, partly because some comparative work in the past has incorporated value judgments about other religions.

Uniqueness and similarities in religions

But even if an inventory of types of belief and practices can be gathered—so as to provide a typical profile of what counts as religion—the absence of a tight definition means that there will always be a number of cases about which it is difficult to decide. Thus, some ideologies, such as Soviet Marxism, Maoism, and Fascism, may have analogies to religion. Certain attempts at an essentialist definition of religion, such as that of the German-American theologian Paul Tillich (1886–1965), who defined religion in terms of man's ultimate concern, would leave the way open to count these ideologies as proper objects of the study of religion. Tillich, incidentally, calls them "quasi-religions." Though there is no consensus on this point among scholars, it is not unreasonable to hold that the frontier between traditional religions and modern ideologies represents one part of the field to be studied.

NEUTRALITY AND SUBJECTIVITY IN THE STUDY OF RELIGION

Discussion about religion has been complicated further by the attempt of some Christian theologians, notably Karl Barth (1886–1968), to draw a distinction between the Gospel (the proclamation peculiar to Christianity) and religion. This distinction depends, to some extent, upon taking a projectionist view of religion as a human product. This tradition goes back in modern times to the seminal work of the German philosopher Ludwig Feuerbach (1804–72), who proposed that God was the extension of human aspirations, and is found in the work of Karl Marx, Sigmund Freud, and others. The distinction attempts to draw a line between the transcendent, as it reveals itself to men, and religion, as a human product involved in the response to revelation. The difficulty of the distinction consists chiefly in a denial that God (*e.g.*, Yahweh or Christ) as the object of man's response is a "religious" being (*i.e.*, God is transcendent, not "religious" in the sense of being a part of the human product), and thus the question about revelation as a religious fact needs to be answered. This account of religion, however, incorporates a theory about it, which is characteristic of a number of definitions of religion and creates a difficulty in that the field—namely, the study of religion—is being defined in terms of a theory within it.

Subjectivity in the study of religion. There are, however, doubts about how far there can be neutrality and objectivity in the study of religion. Is it possible indeed to understand a faith without holding it? If it is not possible, then cross-religious comparisons would mostly break down, for normally it is not possible to be inside more than one religion. But it is necessary to be clear about what objectivity and subjectivity in religion means. Religion can be said to be subjective in at least two senses. First, the practice of religion involves inner experiences and sentiments, such as feelings of the gracious presence of God in the heart, guiding the life of the devotee. Here religion involves subjectivity in the sense of individual experience. Second, religion may be thought to be subjective because the criteria by which its truth is decided are obscure and hard to come by, so that there is no obvious "objective" test in the way in which there is for a large range of empirical claims, such as that there are mountains on the moon. As to the first sense, one of the challenges to the student of religion is the problem of evoking its inner, individual side, which is not observable in any straightforward way. In considering a religion, however, the scholar is not only conceined with individual responses but also with communal ones. In any case, very often he is confronted only with texts describing beliefs and stories, so that he needs to infer the inner sentiments that these both evoke and express. The adherent of a faith is no doubt authoritative as to his own experience, but he is not necessarily so in regard to the communal significance of the rites and institutions in which he participates. Thus, the matter of coming to understand the inner side of a religion involves a dialectic between participant observation and dialogical (interpersonal) relationship with the adherents of the other faith. Consequently, the study of religion has strong similarities to, and indeed overlaps with, anthropology. General agreement upon scholarly methods, however, does not exist, partly because different scholars have come to the study of religion from different disciplines and points of view—such as history, theology, philosophy of religion, and sociology.

Study of individual and communal responses

The other sense of the subjectivity of religion is properly a matter for philosophy of religion and theology (Christian and otherwise). The study of religion can roughly be divided between descriptive and historical enquiries, on the one hand, and normative inquiries, on the other. The latter primarily concern the truth of religious claims, the acceptability of religious values, and other such normative aspects; the former, only indirectly involved with the normative elements of religion, are primarily concerned with its history, structure, and similar descriptive elements. The distinction, however, is not an absolute one, for, as has been noted, descriptions of religion may sometimes incorporate theories about religion that imply something about the truth or other normative aspects of some or all religions. Conversely, theological claims may imply something about the history of a religion. The dominant sense in which one speaks nowadays of the study of religion is the descriptive sense.

Neutrality in the study of religion. The attempt to be descriptive about religious beliefs and practices, without judging them to be valuable or otherwise, is often considered to involve *epochē*—that is, the suspension of belief and the "bracketing" of the phenomena under investigation. The idea of *epochē* is borrowed from the philosophy of the German thinker Edmund Husserl (1859–1938), the father of Phenomenology, and the procedure is regarded as central to the phenomenology of religion.

Phenomenology as a method attempting objectivity

In this context the term phenomenology refers first to the attempt to describe religious phenomena in a way that brings out the beliefs and attitudes of the adherents of the religion under investigation, but without either endorsing or rejecting these beliefs and attitudes. Thus, the bracketing means forgetting about one's own beliefs that might endorse or conflict with what is being investigated. Second, phenomenology of religion refers to the attempt to devise a typology of religious phenomena—to classify religious activities, beliefs, and institutions.

To some extent the emphasis on neutral description arises in modern times as a reaction against "committed" accounts of religion, which were for long the norm and still exist where religion is treated from a theological point of view. The Christian theologian, for example, may see a particular historical process as providential or as providing significance for Christian living. This is a legitimate perspective from the standpoint of faith. But the historical process itself has to be investigated in the first instance "scientifically"—that is, by considering the evidence, using the techniques of historical enquiry and other scientific methods. Conflict sometimes arises because the committed point of view is likely to begin from a more conservative stance—*i.e.*, to accept at face value the scriptural accounts of events—whereas the "secular" historian may be more skeptical, especially of records of miraculous events. The study of religion may thus come to have a reflexive effect on religion itself, such as the manner in which modem Christian theology has been profoundly affected by the whole question of the historicity of the New Testament.

The reflexive effect of the study of religion on religion itself may in practice make it more difficult for the student of religion to adopt the detachment implied by bracketing. Scholars generally agree, however, that the pursuit of objectivity is desirable, provided this does not involve sacrificing a sense of the inner aspect of religion. Thus, the stress on the distinction between the descriptive and normative approaches is becoming more frequent among scholars of religion.

The study of religion may thus be characterized as concerned with man's religious behaviour in relation to the transcendent, to God or the gods, and whatever else is regarded as sacred or holy, and as a study that attempts to be faithful both to the outer and inner facts. Its present-day concern is predominantly descriptive and explanatory and hence embraces such various disciplines as history, sociology, anthropology, psychology, and archaeology. Traditionally, however, the study has been more oriented toward truth claims in religion—these being properly the concern of theology and philosophy of religion. Needless to say, there are different sorts of theology, related to the different religious traditions, such as Christian, Muslim, and Buddhist. But insofar as the theologian expresses and articulates a tradition, he belongs to it and thus is part of the subject matter studied by the student of religion.

II. History of the study of religion

No single history of the study of religion exists since the major cultural traditions (Europe, the Middle East, India, China) have been mutually independent over long periods. The main impulse to study religion, however, happens to be the Western one, especially because other cultural traditions utilized categories other than that denoted in the Western concept of "religion." On the whole, in the ancient world and in the Middle Ages the various approaches to religion grew out of attempts to criticize or defend particular systems and to interpret religion in harmony with changes in knowledge. The same is true of part of the modern period, but increasingly the idea of the nonnormative (descriptive-explanatory) study of religions, and at the same time the attempt to understand the genesis and function of religion, has become established. Viewed thus, the 19th century is the formative period for the modern study of religion. The ensuing accounts here of the history of the subject take it up to the modern period and then consider the various disciplines connected with religion in detail—*i.e.,* in relation to their development since the 19th century.

Western orientation to the study of religion

THE GRECO-ROMAN PERIOD

Early attempts to study religion. An early attempt to systematize the seemingly conflicting Greek myths and thus to bring order into the Greek tradition was the *Theogony* of the Greek poet Hesiod (flourished c. 800 BC), who rather laboriously put together the genealogies of the gods. His work remains an important source book of ancient myth. The rise of speculative philosophy among the Ionian philosophers (*e.g.*, Thales, Heracleitus, and Anaximander) led to a more critical and, to some extent, rationalistic treatment of the gods. Thus, Thales (6th century BC) and Heracleitus (flourished c. 500 BC) considered water and fire, respectively, to be the first substance, out of which everything is made, though Aristotle reported mysteriously in the 4th century BC that Thales believed that everything was full of the gods. Anaximander (6th century BC) called the primary substance the infinite (apeiron). In these various schemes of belief, there is a unitary something that transcends the many clashing forces in the world, including the gods. Heracleitus refers to the controlling principle as logos, or reason, though the philosopher, poet, and religious reformer Xenophanes (6th–5th centuries BC) directly assaulted the traditional mythology as immoral, out of his concern to express a monotheistic religion. This theme of criticism of the myths was taken over and elaborated in the 4th century BC by the philosopher Plato. More conservatively, the poet Theagenes (6th century BC) allegorized the gods, treating them as standing for natural and psychological forces. To some extent, this line was pursued in the works of the Greek tragedians and by the philosophers Parmenides and Empedocles (5th century BC). Criticism of the ancient Greek tradition was reinforced by the reports of travellers as Greek culture penetrated widely into various other cultures. The Greek historian Herodotus (5th century BC) attempted to solve the problem of the plurality of cults by identifying foreign deities with Greek deities (*e.g.*, those of the Egyptian Amon with Zeus). This kind of syncretism was widely used in the merging of Greek and Roman culture in the Roman Empire (*e.g.*, Zeus as the Roman god Jupiter).

Skepticism in the study of religion

The plurality of cults and gods also induced skepticism, as with the Sophist Protagoras (c. 481–411 BC), who was driven from Athens because of his impiety in questioning the existence of the gods. Prodicus of Ceos (5th century BC) gave a rationalistic explanation of the origin of deities that foreshadowed Euhemerism (see below Later attempts to *study* religion), and another Sophist, Critias (5th century BC), considered that religion was invented to frighten men into adhering to morality and justice. Plato was not averse to providing new myths to perform this alleged function—as is seen in his conception of the "noble lie" (*i.e.*, the invention of myths to promote morality and order) in *The* Republic. He was strongly critical, however, of the older poets' (*e.g.*, Homer's) accounts of the gods and substituted a form of belief in a single creator, the Demiurge or supreme craftsman. This line of thought was developed in a stronger way by Aristotle, in his conception of a supreme intelligence that is the unmoved mover. Aristotle combined elements of earlier thinking in his account of the genesis of the gods (coming from the observation of cosmic order and stellar beauty and from dreams).

Later attempts to study religion. Later Greek thinkers tended to vary between the positions adumbrated in the earlier period. The Stoics (philosophers of nature and morality) opted for a form of naturalistic monotheism, while the philosopher Epicurus (341–270 BC) was skeptical of religion as ordinarily understood and practiced, though he did not deny that there were gods who, however, had no transactions with men. Of considerable influence was Euhemerus (c. 330–c. 260 BC), who gave his name to the doctrine called Euhemerism, namely, that the gods are divinized men. Though Euhemerus' own argument was based largely upon fantasy, there are certainly some examples, both in Greek religion (*e.g.*, the god Heracles) and elsewhere, of the tendency to make men into gods, but it is obviously not universal.

Most of the Greek concepts about religion proved to be influential in the Roman world also. The atheistic Atomism of the Roman natural historian Lucretius (*c.* 95–55 BC) owed much to Epicurus. The eclectic thinker and politician Cicero (106–43 BC), in his De *natura deorum* ("Concerning the Nature of the Gods"), criticized Stoic, Epicurean, and later Platonic ideas about religion, but the book remains, however, incomplete. Much of the skepticism about the gods in the ancient world was concerned with the older traditional religions, whether of Greece or Rome. But in the early empire, the mystery cults, ranging fom 'the Eleusinian mysteries of Greece to those of the Anatolian Cybele and the Persian Mithra, together with philosophically based religions such as Neoplatonism and Stoicism, had the greatest vitality. The patterns of religious belief were complex and of different levels, with various types of religion existing side by side. Into this situation Christianity was injected, and in its encounter with classical civilization it absorbed a number of the critiques of the gods of the older thinkers. In particular, Euhemerism was fashionable among the Church Fathers (the religious teachers of the early church) as an account of paganism. On the "pagan" side, there were persistent attempts to justify the popular cults and myths by the extensive use of allegory—a technique well adapted to the attempt to synthesize philosophical and popular religion. Christianity's own contribution to theories of the genesis of polytheism was through the doctrine of the fall of man, in which pure monotheism was believed to have become overlaid by demonic cults of the gods. Such an account could help to explain some underlying similarities between the Judeo-Christian tradition and certain aspects of Greco-Roman paganism. In this view there is the germ of an evolutionary account of religion. On the whole, however, the theories of religion in the ancient world were naturalistic and rationalist in emphasis.

THE MIDDLE ACES TO THE REFORMATION

Theories of the Middle Ages. The spread of Christianity into northern Europe and elsewhere beyond the confines of the Roman Empire presented similar problems to those encountered in the pagan world. Similar solutions were offered—*e.g.*, the identification of northern and Roman and Greek gods, sometimes using etymologies owing much to superficial resemblances of names. Thus, the Icelandic historian Snorri Sturluson (1179–1241) made use of this method in his handbook of Icelandic mythology—a work necessitated by the need to pass on the myth-laden Norse poetic lore that had survived the Christianization of the north—by adding to it Euhemeristic elements.

European contacts with other religions

Meanwhile, Islāmic theology had had an impact on Western Christianity, notably upon medieval Scholastic philosophy, in which the values of both reason and revelation were maintained. Muslim knowledge of other religions was in advance of European knowledge, notably in the work of the theologian Ibn Hazm (994–1064). Nevertheless, the reports of some European travellers, such as the Italian Marco Polo (1254?–?1324) and also Odoric of Pordenone (14th century), gave Westerners some knowledge of Asian religions. This opened the way toward a more inductive treatment of the phenomena of other religions, based on factual knowledge. Though most Christian, as well as Islamic and Jewish, theologians tended to consider the question of whether or not natural religion gives insight in God's nature—treating religion as a relation to the first cause of the universe—the English philosopher Roger Bacon (c. 1220–c. 1292) preferred to categorize the various manifest types of religion as a preliminary effort to establishing a true theology. Theorists of the medieval period continued to accept the thesis that polytheism had its origin in the Fall of man, but two new theories modified attitudes of Christians to other faiths. First, the theory arose that God adapts customs and rites having a pagan style in order to combat paganism itself—as a concession to the human condition. This theory could be used to explain the divergencies of practice within Christendom and to show points of contact between Christianity and paganism. Second, the doctrine of man's innate capacity to know God by reason enabled thinkers to discern some measure of truth in other religions. The questions raised by such theories were intensified during the Renaissance.

Theories of the Renaissance and Reformation. The Renaissance consisted in the invigoration of European culture through the rediscovery of the Greek and Roman classics, art, and architecture and thus was bound to set up tensions among Christians about paganism. The Italian Humanist Giovanni Boccaccio (1313–75) attempted to resolve these tensions in a medieval way by extensively allegorizing the ancient myths. The Dutch Humanist Erasmus (c. 1466–1536) and others, however, went further in stating that the ancient thinkers had a direct knowledge of the highest truth and sometimes in comparing them favourably with Scholastic theologians. One of the interlocutors in his *Convivium* Religiosum suggests that it would be better to lose the Scholastic theologian Duns Scotus than the ancient Roman thinkers Cicero or Plutarch, while another speaker restrains himself with difficulty from praying to the Greek philosopher Socrates (c. 470–399 BC) as though he were a Catholic saint. But a new turn to the arguments about idolatry, which were essentially apologetic, was given by the Protestant Reformers' attack on idolatry within the Roman Catholic Church and by their comparison between what they took to be the Christianity of the New Testament and the religion of Rome.

The need for a comparative study of religion

Thus, the need for a comparative treatment of religion became clear, and this prepared the way for more modern developments. Also preparatory for the modern study of religion was the new trend toward more or less systematic compilations of mythological and other material, stimulated partly by the Renaissance itself and partly by the discovery of America and other lands—conveying to the inhabitants of Europe a new perspective on the richness and variety of man's customs and histories. The most important figures in the exploration of the religions of the non-European world were the Spanish monk Bernardino de Sahagún (c. 1499–1590), who conscientiously gathered information in New Spain, J. Lafitau (1685–1740), a French missionary in Canada, and the Italian Jesuits Roberto de Nobili (1577–1656) and Matteo Ricci (1552–1610). The last two, who brought to bear a deep understanding of Indian and Chinese cultures, were unparalleled in that area of study until modem times. Thus, some of de Nobili's discussions with Brahmins were probably the first profound dialogues between Hindus and Christians. The inquiries of the 16th to 18th centuries thus initiated an accumulation of data about other cultures that stimulated studies of other men's religions and went beyond apologetic concerns, which hitherto had been dominant.

THE BEGINNINGS OF THE MODERN PERIOD

The late 17th and 18th centuries. Attempts at a developmental account of religion were begun in the late 17th and 18th centuries. Notable was the scheme worked out, though not in great detail, by the Italian philosopher Giambattista Vico (1668-1774), who suggested that Greek religion passed through various stages: the divinization of nature, then of those powers that man had come to control (such as fire and crops), then of institutions (such as marriage), and finally the process of humanizing the gods, as in the works of Homer. The English philosopher David Hume (1711–76) gave another account in his Natural History of Religion, which reflected the growing Rationalism of the epoch. For Hume, original polytheism was the result of a naïve anthropomorphism (conceiving the divine in human form) in the assignment of causes to natural events. The intensification of propitiatory and other forms of worship, he believed, led to the exaltation of one infinite divine Being. His "Essay upon Miracles" was also important in posing vital questions about the historical treatment of sacred texts, a set of problems that was to preoccupy 19th- and 20th-century Christian theologians.

The Rationalism of the period often involved a rejection both of paganism and dogmatic Christianity in the name of "natural religion." This natural religion, also called Deism, was the intellectual counterpart of the more emotional antidogmatic faith of the Pietists, who advocated "heart religion" over "head religion." Among the French Philosophes and Encyclopaedists, Voltaire (1694–1778) espoused an anticlerical Deism, which viewed the genesis of polytheism in the work of priests—a point also developed by another Encyclopaedist, Denis Diderot (1713–1784). Voltaire was, incidentally, somewhat influenced and impressed by reports of the ethics of the Chinese social and religious sage Confucius (6th century BC).

The culmination of 18th-century Rationalism was found in the works of the German philosopher Immanuel Kant (1724–1804), but it was a rationalism modified to leave room for religion, which he based essentially on ethics. He held that all men in their awareness of the categorical imperative (*i.e.*, the notion that one must act as though what one does can become the universal law for mankind) and reverence for it share in the one religion and that the pre-eminence of Christianity lay in the conspicuous way in which Jesus enshrined the moral ideal. A series of reactions against the highly influential Kantian account paved the way for the various approaches to religion in the 19th century. In the meantime, the first beginnings of the development of Oriental studies and of ethnology and anthropology were making available more data about religion, though discussion in the 18th century continued, as in earlier centuries, the concern for the problems of religions other than those of the Judeo-Christian tradition largely in terms of the paganism of the ancient world. In this connection, the French scholar and politician Charles de Brosses (1709–77) attempted to explain Greek polytheism partly through the fetishism (belief in the magical powers of certain objects) found in West Africa. This foreshadowed later attempts to use comparative material in the elucidation of Greek myths. The French abbé Bergier (1718–90) explained primitive religions by means of a belief in spirits arising from a variety of psychological causes, which thus was a precursor of animism (a belief in souls in persons or certain natural objects).

One of the critics of Kant's view of religion was the German philosopher Johann Gottfried von Herder (1744–1803), who adopted an evolutionary account of the human race and who saw in mythology something much deeper and more significant for the understanding of human language and thought than a record of follies. His concern with symbolic thinking makes him the first modern student of myth. The German philosopher Friedrich Schelling (1775–1854) continued this positive approach, in the tradition of Romanticism. Furthermore, the advances in the knowledge of non-European, especially Indian, religion gave a wider perspective to discussions of the nature of religion, as was clear in the work of the German philosopher G.W.F. Hegel (1770–1831). The latter's self-confidence, in supposing that his philosophy represented the culmination of the history of philosophy, may amuse present-day scholars in view of the fact that many changes have occurred in philosophical enquiry since his day. Hegel was, nevertheless, immensely influential over a wide range of scholarship, including the study of religion. His followers were in large measure the founders of modern scientific history. Admittedly his theory of the historical dialectic—in which one movement (the thesis) is countered by another (the antithesis), both in interplay giving rise to a third (the synthesis), which now becomes the thesis of a new dialectical interplay, and so on—has been viewed as too artificial. But in providing a theoretical skeleton, it inspired attempts to make sense of the multitude of historical data, so that scholars were driven to the investigation and discovery of particular facts that might exhibit the universal patterns postulated. Hegel also had a modified relativism, which implied that each phase of religion has a limited truth. This, together with his dialectic scheme, led to a general theory of religions, which though dated, much too neat, and based on imperfect information, nevertheless represents an important attempt at a comparative treatment, and one that was evolutionary or developmental.

Beginnings in the modern study of myth and evolutionary theories

The early 19th century. Hegel, as an Idealist, stressed the formative power of the spiritual on human history. By contrast, the French social philosopher Auguste Comte (1798–1857), from a Positivistic and Materialist point of view, devised a different evolutionary scheme in which there are three stages of human history: the theological, in which the supernatural is important; the metaphysical, in which the explanatory concepts become more abstract; and the positivistic—*i.e.*, the empirical. A rather different Positivism was expressed by the English philosopher Herbert Spencer (1820–1903), in which religion has a place beside science in attempting to refer to the unknown, and unknowable, Absolute. Evolutionary accounts were much boosted in the latter part of the 19th century by the new theory of biological evolution and had a marked effect both on history of religions and anthropology.

Meanwhile, the German philosopher Ludwig Feuerbach (1804–72) propounded, in his Lectures on the Essence of Religion, a view of religion as a projection of the aspirations of men, a thesis that was to be taken up in various ways by, among others, Marx, Freud, and Barth.

These various movements were supplemented by the growth of scientific history, archaeology, anthropology, and other sciences, which increased comparative knowledge of civilizations and cultures. The major figures and trends in the relevant disciplines are dealt with below.

Though the 19th-century theories that form the starting point of the modern study of religion were often based directly on metaphysical schemes in competition with Christian and other theologies, there was a notably different atmosphere in comparison with preceding periods, and the stage was set for a more complex and mutual attempt to understand the history and nature of religion.

III. Basic aims and methods

The growth of various disciplines in the 19th century, notably psychology and sociology, stimulated a more analytic approach to religions, while at the same time theology became more sophisticated and, in a sense, scientific as it began to be affected by and thus to make use of historical and other methods. The interrelations of the various disciplines in relation to religion as an area of study can be described as follows.

The various dimensions of religion

Religions. being complex, have different aspects or dimensions. Thus, the major world religions typically possess doctrines, myths, ethical and social teachings, rituals, social institutions, and inner experiences and sentiments. These dimensions lie behind the creation of buildings, art, music, and other such extensions of basic beliefs and attitudes. But not all religions are like Christianity and Buddhism, for example, in possessing institutions such as the church and the *saṅgha* (Buddhist monastic order), which exist across national and cultural boundaries. In opposition to such institutionalized religions, tribal religion, for example, is not usually separately institutionalized but in effect is the religious side of communal life and is not treated as distinct from other things that go on in the community.

The various dimensions of religion noted above represent a cross section of a tradition; but to see the latter in a well-balanced perspective it is necessary to view it as historical—as a religion having a past and the capacity for development in the future ("dead" religions, obviously enough, being the exception). Thus, there are various disciplines that may examine a religion cross-sectionally to find its basic patterns or structures. Psychology views religious experience and feelings and to some extent the myths and symbols that express experience; sociology and social anthropology view the institutions of religious tradition and their relationship to its beliefs and values; and literary and other studies seek to elicit the meanings of myths and other items. These structural enquiries sometimes benefit from being comparative—as when recurrent motifs in the doctrines of different religions are noticed. On the other hand, the aforementioned disciplines need to be supplemented by history, archaeology, philology, and other such disciplines, which have their own various methods of elucidating the past. Philosophy generally has attempted wide-ranging accounts of the nature of religion and of religious concepts, but it is not always easy to disentangle these enquiries from issues raised by normative theology.

HISTORICAL, ARCHAEOLOGICAL, AND LITERARY STUDIES

Historical and literary studies. The expansion of European empires in the early 19th century and the growth of scientific methods in history and philology combined to place Oriental and other non-European studies on a new basis. Another stimulus to the new approach to history and philology was Napoleon's expedition to Egypt, which was accompanied by scholars and scientists; it was a notable attempt to gather knowledge of a culture systematically. The discovery and editing of sacred and other texts from other cultures also had profound effects upon European thinking. A notable publishing venture was the series Sacred Books of *the* East, edited under the leadership of the German Orientalist and philologist Max Miiller (1823–1900), which placed at the disposal of Westerners translations of the major literary sources of the non-Christian world. Earlier, Muller had published translations of the more important Vedic texts (Hindu sacred works), of which the Rgveda was given a complete scholarly edition in 1861–77. Interest in these ancient Indian texts was intense among Europeans and Americans in that earlier reports had suggested that these represented a world outlook from the "dawn of humanity" and that the origin of polytheism lay in nature worship. The Vedas, however, turned out to be of a very different character. The length of human history and prehistory, as implied by evolutionary theory and the growing archaeological discoveries, precluded looking upon the Vedic hymns as anything but late; though the contents showed them to be highly artificial and complex compilations for use in a priest-dominated ritual context, they were not at that time seen as spontaneous outpourings of the human spirit. Muller himself reacted rather sharply by adopting a different theory, which expressed his philological slant—namely, that polytheism was the result of a disease of language, in which the terms for natural phenomena came to be treated as having independent and personal reality: *nomina* ("names") became *numina* ("spirits"). The theory was in vogue for a time but was later replaced by more realistic insights drawn from anthropology. Furthermore, study of the greater part of the corpus of Indian sacred writings, including those in vernacular languages (especially Tamil), gradually modified the preoccupation with the earliest texts—the Vedic hymns and the *Upaniṣads* (philosophical treatises).

Discovery and publication of non-Western sacred writings

Throughout the development of the study of non-European languages there was a supposition that a non-Christian equivalent of the Bible could be found, a sacred writing that would thus provide the authoritative key to the beliefs, practices, and institutions of the religion under consideration. Gradually, however, it became apparent that sacred scriptures play very different roles in different religious cultures. Somewhat later in developing were studies of the Buddhist canon in Pāli (an ancient Indian language), which, through the work of such scholars as the English Orientalist T.W. Rhys Davids (1843–1922) and of the Pāli Text Society, which he founded, had a remarkable impact in revealing to the West the full range of Theravādin (southern Buddhist) religious literature; it tended to make Western scholars look upon the Theravāda as the earlier, "purer" form of Buddhism; but the editing of early Mahāyāna ("Greater Vehicle," or northern Buddhist) texts and the recognition of the different strata in the PBli canon have modified this view. Buddhist studies were enhanced by the growth of Tibetan, Chinese, and Japanese studies. Some of the more important modern scholars of Zen Buddhism (a Mahāyāna sect) have been Japanese, notably the philosopher D.T. Suzuki (1870–1966), sometimes called the apostle of Zen Buddhism to America, whose editions and interpretations have been widely influential.

The productivity of the study of religious literature of the late 19th century was immense, for it was not confined to the foregoing literary and archaeological activities but to the investigation of the Chinese Classics and the roots of Chinese civilization as well. Thus, by the early 20th century, Western scholars were in a position to study the main range of non-Western literary cultures. The wave of interest in these texts and the freeing of their dissemination from some of their traditional constraints (*e.g.*, the restriction of Vedic revelation to the upper classes of the Indian caste system) contributed to the revival of other

Interest in textual studies

religious cultures—notably Hinduism and Buddhism, under the stimulus of the Western challenge. Modern scholarship thus provided the basis for a new self-understanding among such religious traditions.

Meanwhile, the texts of Zoroastrianism, an Iranian religion originating in the 6th century BC, were being discovered and edited (from 1850 onward). The disentangling of different layers of varying antiquity indicated the complex ways in which the religion of Zoroaster had developed.

During the latter part of the 19th and early part of the 20th century, there was a remarkable flowering of ancient Near Eastern studies. Archaeology contributed to the unravelling of non-Jewish and Jewish religious history. The discovery of the *Epic of Gilgamesh,* a major work of Mesopotamian religious literature, and other materials brought a whole new perspective to the development of ideas in Mesopotamia; and in Egypt archaeological and papyrological studies brought to light the famous and revealing Egyptian funerary text, the Book of the Dead. These various ancient Near Eastern discoveries have thrown light on the evolution of Judaism, and Semitic studies have likewise illuminated the origins and background of Islām. Furthermore, classical and European studies assembled data about the pre-Christian religions of the West so that scholars might gain a more detailed and scientific understanding of them. Compilations such as the *Corpus Inscriptionum Graecorum* and the *Corpus Inscriptionum Latinarum,* assembled in the mid-19th century, and the publication of Germanic, Celtic, and Scandinavian texts provided the tools for a reappraisal of these older traditions. Throughout the period intense researches into the composition and milieu of the Old and New Testaments reflected a new and "scientific" spirit of enquiry—which was, however, not without its controversial elements, sometimes because of the intimate tie between religious positions and evaluations of the Bible and sometimes because of the application of speculative patterns in the history of (non-Christian) religions to the New Testament. Meanwhile, the assemblage of materials extended forward into Christian history through the application of classical philological methods to patristic texts (the writing of the early Church Fathers) and to the corpus of Reformation writings.

The significance of 19th-century archaeological discoveries

Archaeological studies. The great archaeological discoveries of Heinrich Schliemann, the German excavator of Troy; the English archaeologists Arthur Evans in Crete and Wm. M. Flinders Petrie in Egypt; the French archaeologist Jacques de Morgan in Elam; the German Orientalist Hugo Winckler in Boğazköy (Anatolia); the French archaeologists Claude Schaeffer and C. Virolleaud in Ras Shamra (Ugarit); and other archaeologists greatly enlightened modem knowledge of the Greco-Roman and ancient Near Eastern worlds. Biblical archaeology, culminating perhaps in the discovery of Masada, the Judaean hill fortress where the Jews made their last stand against the Romans in the revolt of AD 66–73 and that was mainly excavated in 1963, has given a new perspective to Old Testament, intertestamental, and later studies of ancient Judaism. The spectacular discovery by the English archaeologist John Marshall and others of the Indus Valley civilization pushed back knowledge of Indian prehistory to about 3500 BC and called into question the earlier theory of the primacy of Vedic culture in the formation of the Indian tradition, many features of which appear to have their first manifestation in the Indus Valley cities.

Archaeology made another profound impact on the study of religion when in 1841 the discovery of prehistoric human artifacts and later finds gave clues to early man's magico-religious beliefs and practices. These discoveries, notably the cave paintings in the Dordogne, northern and eastern Spain, and elsewhere, gave scholars encouragement to work out the course of man's religious evolution from earliest times. Spectacular as prehistoric archaeology was proving to be, however, it could only yield fragments of a whole that is difficult to reconstruct. Even the famous cave paintings of Trois Frères, in the Dordogne, for example, which portray among other things a dancing human with antlers on his head and a stallion's tail decorating his rear, does not yield an unambiguous interpretation: is the dancing figure a sorcerer, a priest, or what? He very likely is a priest presenting himself as a divine figure connected with animal fertility and hunting rites—but this remains as only an educated guess. Hence, it became attractive to many scholars of religion to try to supplement ancient archaeological evidence with data drawn from contemporary primitive peoples—*i.e.*, to interpret the prehistoric Stone Age through present-day stone age cultures. This procedure has several pitfalls—partly because contemporary "primitives" are themselves the product of a long historical process and because their culture may have changed over the millennia in many and various ways.

The work of the archaeologists has not merely stimulated new thinking about the early stages of religious history but it has also been a factor in drawing attention to the roles of buildings and art objects in religion. During the present century, spectacular religious monuments of the past, such as Angkor Wat (Cambodia), Borobodur (Indonesia), Ellora and Ajantā (India), and the Acropolis (Athens), have been officially preserved for scholarly and public viewing. Though iconography (the study of content and meaning in visual arts) has been better developed among art historians, students of religion are now paying increased attention to the religious decipherment of the visual arts. By contrast, very little has been done in the sphere of music, despite the considerable role it plays in so many religions. This is a further way in which the study of texts and ideas needs to be supplemented by knowledge of the milieu in which they have their meaning.

ANTHROPOLOGICAL APPROACHES TO THE STUDY OF RELIGION

Theories concerning the origins of religion. To draw a clear line between anthropology and sociolonv is difficult, and the two disciplines are divided more–by tradition than by the scholarly methods they employ. Anthropology, however, has tended to be chiefly concerned with nonliterate and technologically primitive cultures and thus has stressed a certain range of techniques, such as the use of participant observation. Much anthropological investigation, however, has been carried out recently in more complex societies, such as in various Hindu areas of India, where there are different layers of society, ranging from an educated elite to illiterate workers who carry out the traditional menial tasks of the lowest castes and the outcastes. Because of the anthropologists' interest in tribal and "primitive" societies, it has not been unnatural for them to try to use the data gained in the study of such societies to speculate about the genesis and functions of religion.

Evolutionary theories about religion

An early attempt to combine archaeological evidence of prehistoric peoples, on the one hand, and anthropological evidence of primitive peoples, on the other, was that of the English anthropologist John Lubbock (1834–1913). His book, *The Origin of Civilization and the Primitive Condition of Man*, outlined an evolutionary scheme, beginning with atheism (the absence of religious ideas) and continuing with fetishism, nature worship, and totemism (a system of belief involving the relationship of specific animals to clans), shamanism (a system of belief centring on the shaman, a religious personage having curative and psychic powers), anthropomorphism, monotheism (belief in one god), and, finally, ethical monotheism. Lubbock recognized a point later made by the German theologian and philosopher Rudolf Otto (1869–1937) in distinguishing between the unique holiness (separateness) of God and his ethical characteristics. Unfortunately, much of his information was unreliable, and his schematism was open to question; he foreshadowed, nevertheless, other forms of evolutionism, which were to become popular both in sociology and anthropology. The English ethnologist E.B. Tylor (1832–1917), who is commonly considered the father of modem anthropology, expounded, in his book *Primitive Culture,* the thesis that animism is the earliest and most basic religious form. Out of this evolves fetishism, belief in demons, polytheism, and, finally, monotheism, which derives from the exaltation of a great god, such as the sky god, in a polytheistic context. A somewhat similar system was advanced by Herbert Spencer (1820–1903) in his *Principles of Sociology,* though he stresses ancestor worship rather than animism as the basic consideration.

The classifications of religion—polytheism, henotheism (*i.e.*, the worship of one god as supreme without necessarily excluding the possibility of other groups' gods), and monotheism—begin from concern with gods and often imply the superiority of monotheism over other forms of belief. Naturally, the anthropologists of the 19th century were deeply influenced by the presuppositions of Western society.

The English anthropologist R.R. Marett (1866–1943), in contrast to Tylor, viewed what he termed animatism as of basic importance. He took his clue from such ideas as mana, mulungu, orenda, and so on (concepts found in the Pacific, Africa, and America, respectively), referring to a supernatural power (a kind of supernatural "electricity") that does not necessarily have the personal connotation of animistic entities and that becomes especially present in certain men, spirits, or natural objects. Marett criticized Tylor for an overly intellectual approach, as though primitive men used personal forces as explanatory hypotheses to account for dreams, natural events, and other phenomena. For Marett, primitive religion is "not so much thought out as danced out," and its primary emotional attitude is not so much fear as awe (in this he is close to Otto, whom he influenced).

Theories of Sir James Frazer

Another important figure in the development of theories of religion was the English folklorist Sir James Frazer (1854–1941), in whose major work, *The Golden Bough,* is set forth a mass of evidence to establish the thesis that men must have begun with magic and progressed to religion and from that to science. He owes much to Tylor but places magic in a phase anterior to belief in supernatural powers that have to be propitiated—this belief being the core of religion. Because of the realization that magical rituals do not in fact work, primitive man then turns, according to Frazer, to reliance on supernatural beings outside his control, beings who need to be treated well if they are to cooperate with human purposes. With further scientific discoveries and theories, such as the mechanistic view of the operation of the universe, religious explanations gave way to scientific ones. Frazer's scheme is reminiscent of that of the French "father of sociology," Auguste Comte.

These and other evolutionary schemes came in for criticism, however, in the light of certain facts about the religions of primitive peoples. Thus, the Scottish folklorist Andrew Lang (1844–1912) discovered from anthropological reports that various primitive tribes believed in a High God—a creator and often legislator of the moral order. Marett and other anthropologists contended that Lang's attempt to argue for an *Urmonotheismus* (primordial monotheism) was contrary both to evolutionary ideas and to the established view of the lack of sophistication and half-animal status of the so-called savage. Since Lang was more of a brilliant journalist than an anthropologist, his view was not taken with as much seriousness as it should have been.

The German Roman Catholic priest and ethnologist Wilhelm Schmidt (1868–1954), however, brought anthropological expertise to bear in a series of investigations of such primitive societies as those of the Tierra del Fuegians (South America), the Negrillos of Rwanda (Africa), and the Andaman Islanders (Indian Ocean). The results were assembled in his *Der Ursprung der Gottesidee* ("The Origin of the Idea of God"), which appeared in 12 volumes from 1912 to 1955. Not surprisingly, Schmidt and his collaborators saw in the high gods, for whose cultural existence they produced ample evidence from a wide variety of unconnected societies, a sign of a primordial monotheistic revelation that later became overlaid with other elements (this was an echo of earlier Christian theories invoking the Fall to similar effect). The interpretation is controversial, but at least Lang and Schmidt produced grounds for rejecting the earlier rather naive theory of evolutionism.

Theories of primordial monotheism

Modern scholars do not, on the whole, accept Schmidt's scheme. Some, such as the Italian anthropologist Raffaele Pettazzoni (1883–1959), have stressed merely that a sky god has a certain natural pre-eminence; others emphasize that the high god is often a *deus otiosus* ("idle god")—*i.e.*, not active in the world and hence not the recipient of a functioning cult. In any event, it is a very long jump from the premise that primitive tribes have high gods to the conclusion that the earliest men were monotheists.

Others who have looked at religions from an anthropological point of view have emphasized the importance, in a number of cultures, of the mother goddess (as distinct from the male sky god). A pioneer work in this direction was that of the Swiss anthropologist and jurist J.J. Bachofen (1815–87), whose *Das Mutterrecht* ("The Mother Right") unravelled some puzzles in ancient law, mythology, and art in terms of a matriarchal society.

Functional and structural studies of religion. The search for a tidy account of the genesis of religion in prehistory by reference to primitive societies was hardly likely to yield decisive results. Thus, anthropologists became more concerned with functional and structural accounts of religion in society and relinquished the apparently futile search for origins.

Notable among these accounts was the theory of the French sociologist Émile Durkheim (1858–1917). According to Durkheim, totemism was fundamentally significant (he wrongly supposed it to be virtually universal), and in this he shared the view of some other 19th-century savants, notably Salomon Reinach (1858–1932) and Robertson Smith (1846–94), not to mention Sigmund Freud. Because Durkheim treated the totem as symbolic of the god, he inferred that the god is a personification of the clan. This conclusion, if generalized, suggested that all the objects of religious worship symbolize social relationships and, indeed, play an important role in the continuance of the social group.

Analyses of social patterns and institutions

Various forms of functionalism in anthropology—which understood social patterns and institutions in terms of their function in the larger cultural context—proved illuminating for religion, such as in the stimulus to discover interrelations between differing aspects of religion. The Polish-British anthropologist Bronisław Malinowski (1884–1942), for instance, emphasized in his work on the Trobriand Islanders (New Guinea) the close relationship between myth and ritual—a point also made emphatically by the "myth and ritual" school of the history of religions (see below *Other studies and emphases).* Furthermore, many anthropologists, notably Paul Radin (1883–1959), moved away from earlier categorizations of so-called primitive thought and pointed to the crucial role of creative individuals in the process of mythmaking.

A rather different approach to myths was made by the 20th-century French anthropologist Claude Levi-Strauss, whose rather formalistic structuralism tended to reinforce analogies between "primitive" and sophisticated thinking and also provided a new method of analyzing myths and stories. His views had wide influence, though they are by no means universally accepted by anthropologists.

Specialized studies. The impact of Western culture, including missionary Christianity, and technology upon a wide variety of primitive and tribal societies has had profound effects and represents a specialized area of study closely related to religious anthropology. One pioneering work is *Religions of the Oppressed* by the Italian anthropologist and historian of religion Vittorio Lanternari. What is striking is the way in which similar types of reaction, creating new religious movements, occur at different points across the world. There are, thus, many possibilities of a comparative treatment.

Among a number of contemporary anthropologists, including the American Clifford Geertz, there is a concern, after a period of functionalism, with exploring more deeply and concretely the symbolism of cultures. The English social anthropologist E.E. Evans-Pritchard (1902–73), noted among other things for his work on the religion of Nuer people (who live in The Sudan), produced in his *Theories* of Primitive Religion a penetrating critique of many of the earlier anthropological stances. Though it has always been difficult to confirm theories in view of the complexity of the data, a statistical approach has been attempted—*e.g.*, by G. Swanson (1922–) in his *Birth* of the Gods, which attempts to exhibit correlations between types of social arrangement and religious beliefs, such as the caste system and belief in reincarnation.

Because of the nature of the societies that typically have come under the scrutiny of anthropology, the discipline has necessarily had to come to terms with religion. In terms of the methods used, the anthropological approach is of considerable interest to historians of religion and is a corrective to overintellectual, text-based accounts of religions. Also, the present concerns for comparative studies and symbolic analysis coincide with existing concerns in the phenomenology of religion (see below History *and* phenomenology of religion).

SOCIOLOGICAL STUDIES OF RELIGION

Theories of stages. Auguste Comte (1798–1857) is usually considered the founder of modem sociology. His general theory hinged substantially on a particular view of religion, and this view has somewhat influenced the sociology of religion since that time. In his *Cours* de *philosophie* positive (The Positive Philosophy of Auguste *Comte)* Comte expounded a naturalistic Positivism and sketched out the following stages in the evolution of thought. First, there is what he called the theological stage, in which events are explained by reference to supernatural beings; next, there is the metaphysical stage, in which more abstract unseen forces are invoked; finally, in the positivistic stage, men seek causes in a scientific and practical manner. To seek for scientific laws governing human morality and society is as necessary, in this view, as to search for those in physics and biology—hence Comte's role in advocating a science of society, namely sociology. Among the leading figures in the development of sociological theories were Spencer and Durkheim (see above *Anthropological approaches to* the study of religion).

Marxist theories of religion

A rather separate tradition was created by the German economic theorist Karl Marx (1818–83). A number of Marxists, notably Lenin (1870–1924) and K. Kautsky (1854–1938), have developed social interpretations of religion based on the theory of the class struggle. Whereas sociological functionalists posited the existence in a society of some religion or a substitute for it (Comte, incidentally, propounded a positivistic religion, somewhat in the spirit of the French Revolution), the Marxists implied the disappearance of religion in a classless society. Thus, in their view religion in man's primordial communist condition, at the dawn of the historical dialectic, reflects ignorance of natural causes, which are explained animistically. The formation of classes leads, through alienation, to a projection of the need for liberation from this world into the transcendental or heavenly sphere. Religion, both consciously and unconsciously, thus becomes an instrument of exploitation. In the words of the young Marx, religion is "the generalized theory of the world . . . , its logic in popular form." The modem intellectualist accounts of religion, tending to ignore the rituals, experiences, and institutions but concentrating rather on the doctrines and myths, have proved something of a problem for later Marxist applications of their theory. Since the theory was a product of a rather early and unsophisticated stage of theorizing about religion, it was not adapted particularly well to deal with other cultures—hence a considerable debate in modem China on the status of Chinese religion in the light of Marxism, some holding that Marx's critique did not, for example, fit Buddhism.

Theories of Max Weber

Comparative studies. One of the most influential theoreticians of the sociology of religion was the German scholar Max Weber (1864–1920). He observed that there is an apparent connection between Protestantism and the rise of capitalism, and in The Protestant Ethic and the Spirit of Capitalism he accounted for the connection in terms of Calvinism's inculcating a this-worldly asceticism—which created a rational discipline and work ethic, together with a drive to accumulate savings that could be used for further investment. Weber noted, however, that such a thesis ought to be tested; and a major contribution of his thinking was his systematic exploration of other cultural traditions from a sociological point of view. He wrote influentially about Islām, Judaism, and Indian and Chinese religions and, in so doing, elaborated a set of categories, such as types of prophecy, the idea of charisma (spiritual power), routinization, and other categories, which became tools to deal with the comparative material; he was thus the real founder of comparative sociology. Because of his special interest in religion, he can also be reckoned a major figure in the comparative study of religion (though he is not usually reckoned so in most accounts of the history of religions). Though he made significant contributions to the study of religion, his judgments on Indian and other religions are not all or mostly accepted now—since he necessarily based his views on secondary sources—and some of his categorial distinctions are open to debate, such as his rather broad use of the category of prophet.

Weber's comparative method in the scientific sociology of religion introduced an analogue to experimentation (*i.e.*, looking at similar patterns in independent cultures with varying contextual conditions). Since the 1950s there has been considerable emphasis on statistical methods, side by side with the more theoretical discussions arising from classical sociology. Typical of the trend is the American sociologist Gerhard Lenski's Religious Factor, which delineates the relations between religious allegiance and other factors in a large city in the United States.

Other sociological studies. An extensive literature on religious sects and similar groups has also developed. To some extent this has been influenced by the German theologian Ernst Troeltsch (1865–1923) in his distinction between church and sect (see below Theological studies). Notable among modem investigators of sectarianism is the British scholar Bryan Wilson (1929–). Church organizations also have attempted to use the insights of sociology in the work of evangelism and other church-related activities—a use of the discipline that is sometimes called "religious sociology" to distinguish it from the more theoretical and "objective" sociology of religion.

Coordination between sociology and the history of religions is not usually very close, since the two disciplines operate as separate departments in most universities and often in different faculties. From the sociological end, Weber represents one kind of synthesis; from the history-of-religions end, the writings of the German-American scholar Joachim Wach (see below The "Chicago school") were quite influential. In his book Sociology of Religion he attempted to exhibit the ways in which the community institutions of religion express certain attitudes and experiences. This view was in accordance with his insistence on the practical and existential side of religion, over against the intellectualist tendency to treat the correlate of the group as being a system of beliefs.

Recent sociological studies

Among the more recent theorists of the sociology of religion is the influential and eclectic American scholar Peter Berger (1929–). In The Sacred Canopy he draws on elements from Marx, Durkheim, Weber, and others, creating a lively theoretical synthesis. One problem is raised by his method, however; he espouses what he calls "methodological atheism" in his work, which appears to presuppose a view about religion. Despite Berger's sympathy in dealing with religious phenomena, the methodological stance adopted in this book seems to imply a reductionist position—namely, one in which religious beliefs are explained by reference to basically nonreligious sentiments, sociopsychological circumstances, and other factors. In itself, this is a theory having possibilities, for the study of religion cannot rule out a priori the thesis that religion is a projection—*e.g.*, that it rests upon an illusion—or other such theses; but the question arises as to whether or not the methods espoused in the scientific study of religion have already secretly prejudged the is-

On the whole, modern sociology is largely geared to dealing with Western religious institutions and practices, though some notable work has been done, especially since World War II, in Asian sociology of religion. Emphasis has been placed upon the process of secularization in a number of Western sociological studies (which have had some impact on the formation of modern Christian theology), notably in *The Secular City* of the American theologian Harvey Cox (1929–). There are indications that the process of secularization does not occur in the same degree or occurs in a different manner in non-Western cultures.

In general, the main question of the sociology of religion concerns the effectiveness with which it can relate to other studies of religion. This question is posed in *The Scientific Study of Religion,* by the American sociologist J. Milton Yinger (1916–). A similar tendency is noted in the synthesis between the history and the sociology of religion in a new-style evolutionism propounded by another American scholar, Robert Bellah (1927–).

THE PSYCHOLOGY OF RELIGION

The study of religious psychology involves both the gathering and classification of data and the building and testing of various (usually rather wide-ranging) explanations. The former activity overlaps with the phenomenology of religion, so it is to some extent an arbitrary decision under which head one should include descriptive studies of religious experience and related subjects.

Investigations of religious experience

Psychological studies. Notable among investigations by psychologists was *The Varieties of Religious Experience,* by the American philosopher and psychologist William James (1842–1910), in which he attempted to account for experiences such as conversion through the concept of invasions from the unconscious. Because of the clarity of his style and his philosophical distinction, the work has had a lasting influence, though it is dated in a number of ways and his examples come fiom a relatively narrow selection of individuals, largely within the ambit of Protestant Christianity. This points to a recurring problem—that of relating individual psychology to the institutions and symbols of different cultures and traditions.

More radical, but drawing from a rather larger range of examples, was the American psychologist J.H. Leuba (1868–1946). In A *Psychological Study of Religion,* he attempted to account for mystical experience psychologically and physiologically, pointing to analogies with certain drug-induced experiences. Leuba argued forcibly for a naturalistic treatment of religion, which he considered to be necessary if one was to look at religious psychology scientifically. Others, however, have argued that psychology is in principle neutral, neither confirming nor ruling out belief in the transcendent. Most scholars would, however, consider the problem to be a complex philosophical one, which goes beyond psychology as such.

Among those who have attempted a fairly detailed classification of mystical experience, but not necessarily from a scientific-psychological point of view, mention should be made of the English scholar Evelyn Underhill (1875–1941), drawing on examples from the Jewish, Christian, and Muslim traditions. Recently, systematic explorations (taking into account Eastern mysticism as well) have been undertaken. Rudolf Otto was important in elucidating the nature of numinous experience, and there has also been a certain amount of scholarly work performed in the description and classification of types of shamanism, spirit possession, and similar phenomena.

Theories of Freud and Jung

Psychoanalytical studies. More influential than James and Leuba and others in that tradition were the psychoanalysts. Thus, Sigmund Freud (1856–1939) gave explanations of the genesis of religion in various of his writings. In *Totem and Taboo* he applied the idea of the Oedipus complex (involving unresolved sexual feelings of, for example, a son toward his mother and hostility toward his father) and postulated its emergence in the primordial stage of human development. This stage he conceived to be one in which there were small groups, each dominated by a father. According to Freud's reconstruction of primordial society, the father is displaced by a son (probably violently), and further attempts to displace the new leader bring about a truce in which incest taboos (proscriptions against intrafamily sexual relations) are formed. The slaying of a suitable animal, symbolic of the deposed and dead father, connected totemism with taboo. In *Moses and Monotheism* Freud reconstructed biblical history in accord with his general theory, but biblical scholars and historians would not accept his account since it was in opposition to the point of view of the accepted criteria of historical evidence. His ideas were also developed in *The Future of an Illusion.* Freud's view of the idea of God as being a version of the father image and his thesis that religious belief is at bottom infantile and neurotic do not depend upon the speculative accounts of prehistory and biblical history with which Freud dressed up his version of the origin and nature of religion. The theory can still stand as an account of the way in which religion operates in individual psychology, though of course it har also attracted criticism on grounds other than historical ones (*e.g.*, Buddhism does not have a father figure to worship).

A considerable literature has developed around the relationship of psychoanalysis and religion. Some argue, despite the atheistic mood of Freud's writing and his critique of religious belief, that the main theory is compatible with faith—on the grounds, for instance, that the theory describes certain mechanisms operative in people's religious psychology that represent modes in which people respond to the challenge of religious truth. Even if this position can be sustained, it is clear, nevertheless, that acceptance of Freudian insights makes a considerable difference to the way in which one views religious experience and behaviour. Questions have arisen about the range of applicability of Freud's ideas—*e.g.*, whether or not his theories apply outside the Western milieu, such as in Theravāda Buddhism, which does not possess a father figure or worship a god. Various attempts have been made to test Freud's theory of religion empirically, but the results have been ambiguous.

The Swiss psychoanalyst C.G. Jung (1875–1961) adopted a very different posture, one that was more sympathetic to religion and more concerned with a positive appreciation of religious symbolism. Jung considered the question of the existence of God to be unanswerable by the psychologist and adopted a kind of agnosticism. Yet he considered the spiritual realm to possess a psychological reality that cannot be explained away, and certainly not in the manner suggested by Freud. Jung postulated, in addition to the personal unconscious (roughly as in Freud), the collective unconscious, which is the repository of human experience and which contains "archetypes" (*i.e.*, basic images that are universal in that they recur in independent cultures). The irruption of these images from the unconscious into the realm of consciousness he viewed as the basis of religious experience and often of artistic creativity. Religion can thus help men, who stand in need of the mysterious and symbolic, in the process of individuation—of becoming individual selves. Some of Jung's writings have been devoted to elucidating some of the archetypal symbols, and his work in comparative mythology, the history of alchemy, and other similar areas of concern has proved greatly influential in stimulating the investigations of other interested scholars. Thus, the Eranos circle, a group of scholars meeting around the leadership of Jung, has contributed considerably to the history of religions. Associated with this circle of scholars have been Mircea Eliade, the eminent Romanian-French historian of religion, and the Hungarian-Swiss historian of religion Karl Kerényi (1897–). This movement has been one of the main factors in the modern revival of interest in the analysis of myth.

Among other psychoanalytic interpreters of religion, the American scholar Erich Fromm (1900–) has modified Freudian theory and has produced a more complex account of the functions of religion. Part of the modification is viewing the Oedipus complex as based not so much on sexuality as on a "much more profound desire°—namely, the childish desire to remain attached to protecting figures. The right religion, in his estimation, can, in principle, foster men's highest potentialities, but religion in practice tends to relapse into being neurotic. Authoritarian religion, according to Freud, is dysfunctional and alienates man from himself.

Other studies. Apart from Jung's work, there have been various attempts to relate psychoanalytic theory to comparative material. Thus, the English anthropologist Meyer Fortes, in his Oedipus and Job in West *African* Religion, combined elements from Freud and Durkheim, and G.M. Carstairs (a British psychologist), in The T ice *Born*, investigated in depth the inhabitants of an Indian town from a psychoanalytic point of view and with special reference to their religious beliefs and practices. Among the more systematic attempts to evaluate the evidences of the various theories is Religious Behaviour, by Michael Argyle, another British psychologist.

A certain amount of empirical work in relation to the effects of meditation'and mystical experience—and also in relation to drug-induced "higher" states of consciousness—has also been carried on. Investigation of religious responses as correlated with various personality types is another area of enquiry; and developmental psychology of religion, largely under the influence of the French psychologist Jean Piaget (1896–), has played a prominent part in educational theory in the teaching of religion. Most scholars agree, however, that more needs to be done to make results in the psychology of religion more precise; and also, for reasons that are unclear, very few people recently have concerned themselves with the field, which thus is in a state of suspension after a flurry of activity in the late 19th and early 20th centuries.

PHILOSOPHY OF RELIGION

Trends in the philosophy of religion

The concerns of the philosophy of religion. The scope of the philosophy of religion has changed somewhat in the last century and a half—that is, in the time since it came to he recognized as a separate branch of philosophy. Its nature is, as is typically the case in philosophy, open to debate. Three main trends, however, can be noted: (1) the attempt to analyze and describe the nature of religion in the framework of a general view of the world; (2) the effort to defend or attack philosophically various religious positions; and (3) the attempt to analyze religious language. Philosophical materials are also often incorporated into theologies—a modern example being the use of Existentialism in the theology of Rudolf Bultrnann, the German New Testament scholar (see below *Neo-orthodoxy and demythologization*), and others; an older example is the medieval theologian Thomas Aquinas' use of Aristotle and of his (Aquinas' own) insights in the service of a systematic Christian theology. The different activities mentioned above overlap substantially. The second of them is usually taken to include the exploration of natural theology (*i.e.*, the truths about God that can be known, as it is claimed, by the aid of men's reasoning and insight, independently of the truths vouchsafed by revelatior'. Metaphysical systems (concerning the nature of reality) sometimes function as analogues to natural theology and thus provide a kind of support for a revealed religious belief system. Thus, much of philosophy of religion is concerned with questions not so much of the description of religion (historically and otherwise) as with the truth of religious claims. For this reason philosophy can easily become an adjunct of theology or of antireligious positions. To this extent, philosophy lies outside the main disciplines concerned with the descriptive study of religion; thus, it is often difficult to disentangle descriptive problems from those bearing on the truth of the content of what is being described. Feuerbach's "projection" theory of religion, for example, possessed a metaphysical framework, but it also included empirical claims about the nature of religion. The following brief account of philosophical trends is necessarily selective, leaning toward those philosophical theories that have a stronger content of, or relevance to, descriptive claims about religion.

Theories of Schleiermacher and Hegel. Immanuel Kant's powerful critique of traditional natural theology appeared to rob religion of its basis in reason and to make it an adjunct to morality. But Kant's system depended on drawing certain distinctions, such as that between pure and practical reason, which were open to challenge. One reaction that attempted to place religion in a more realistic position (*i.e.*, as neither primarily to do with pure nor with practical reason) was that of the German theologian and philosopher Friedrich Schleiermacher (1768–1834) in his On Religion: *Speeches* to *Its Cultured* Despisers. He attempted there to carve out a separate territory for religious experience, as distinct both from science and morality. For him the central attitude in religion is "the feeling of absolute dependence." In drawing attention to the affective and experiential side of religion, usually neglected in preceding philosophical discussions, Schleiermacher set in motion the modem concern to explore the subjective or inner aspect of religion. Schleiermacher's main goal, however, was not the exploration of religion as such but rather the construction of a new type of theology—the "theology of consciousness." In so doing he relegated doctrines to a secondary role, their function being to express and articulate the deliverances of religious consciousness. Thus, incidentally, it became important for New Testament historians who were influenced by Schleiermacher to penetrate the religious consciousness of Jesus—this becoming, in effect, the reputed locus of his divinity.

Philosophical approach to religious experience

G.W.F. Hegel had, as noted above, a profound effect upon the development of historical and other studies. His own system, the system of the Absolute, contained a view of the place of religion in human life. According to this notion, religion arises as the relation between man and the Absolute (the spiritual reality that undergirds and includes the whole universe), in which the truth is expressed symbolically, and so conveyed personally and emotionally to the individual. As the same truth is known at a higher—that is, more abstract—level in philosophy, religion is, for all its importance, ultimately inferior to philosophy. The relationship between abstract and concrete truth was, incidentally, taken up in the 19th-century Hindu renaissance as a parallel to the doctrine of the Absolute in the Hindu philosopher Sankara (c. 780–820), the Advaita (nondualism), the dominant expression of Hindu metaphysics. The Hegelian account of religion was worked out in the context of the dialectical view of history, according to which opposites united in a synthesis, which in turn produced its opposite, and so on. Hegel was influential in the interpretation of Christian history: Jesus as thesis, Paul as antithesis, and early Catholicism as the synthesis, the latter becoming a new thesis that would elicit a new antithesis, Protestantism.

Hegel attracted some radical criticism, however. One such was that of the aforementioned German philosopher Ludwig Feuerbach (1804–72), whose ideas have been sketched above. Another was that of the Danish philosopher and theologian Søren Kierkegaard (1813–55), sometimes regarded as the father of modern Existentialism, who reacted against the metaphysical and "rational" approach to Christianity in Hegel's thought. Kierkegaard's penetrating psychological insights were put to the service of philosophy and theology and threw new light on the nature of religious experience and its relation to features of man's inner life, such as dread and despair. Kierkegaard's main concern, however, was prophetic rather than descriptive. From a very different standpoint (*i.e.*, that of liberal Protestantism), the German theologian Albrecht Ritschl (1822–89) made an apologetic defense of Christianity in his attempt to analyze theological utterances as essentially affirming value judgments.

Schleiermacher's delineation of religious experience was complemented by attempts among the Romantics and by the German philosopher Ernst Cassirer (1874–1945) to exhibit the nature of symbolic thinking and in particular the special character of religious symbolism. This was some distance from the rationalism of Kant, though Cassirer was nevertheless influenced by the Neo-Kantian tradition.

Influence of Existentialism and Linguistic Analysis

Empiricism and Pragmatism. The Hegelian school, very influential in the 19th century, entered a period of rapid decline in the early part of the 20th. The common sense and scientifically oriented philosophy of the English scholars G.E. Moore (1873–1958) and Bertrand Russell (1872–1970) introduced a period of Empiricism in Britain, while William James's Pragmatism had a similar effect in America. Theologically, there was an antimetaphysical revolution during and after World War 1. On the continent of Europe, the increasing Influence of Existentialism was hostile to the old type of metaphysics. British Empiricism was expressed very strongly in Logical Positivism (maintaining the exclusive value of scientific knowledge and the denial of traditional metaphysical doctrines) and its linguistic aftermath. This stimulated the analysis of religious language, and the movement was complicated by the transformation in the thought of the Austrian-English philosopher Ludwig Wittgenstein (1889–1951), who in his later thought was very far removed from his early, rather formalistic treatment of language.

Theoretically, the Analytic attempt to exhibit the nature of religious language could have been a chiefly descriptive task, but, in fact, most analyses have occurred in the context of questions of truth—thus some scholars have been concerned with exhibiting how it is possible to hold religious beliefs in an Empiricist framework, and others with showing the meaninglessness or incoherence of belief. A landmark was the publication, in 1955, of New Essays in Philosophical Theology, edited by the English philosophers A.G.N. Flew and A. MacIntyre. Though Wittgenstein stressed the idea of "forms of life," according to which the meaning of religious beliefs would have to be given a practical and living contextualization, little has been done to pursue the idea empirically. The discovery by the English philosopher J.L. Austin (1911–60) and others of performative uses of language has stimulated some enquiry in this direction. On the whole, however, the Analytic philosophy of religion has been pursued rather independently of the descriptive study and history of religion.

Influence of Heidegger and Sartre

Modern Existentialist and Phenomenological studies. Since linguistic philosophy tends to be considered by its proponents to be a method or a group of methods, internal diversity within the area of concern is not surprising. Similarly, Existentialism, which is less of an "-ism" than an attitude, expresses itself in a variety of ways. The most influential modern Existentialists have been the German philosopher Martin Heidegger (1889–1976) and the French philosopher, dramatist, and novelist Jean-Paul Sartre (1905–80); the former was especially important in the development of modem continental theology, particularly for the use made of some of his ideas by Rudolf Bultmann.

According to Heidegger, man's existence is characterized as "care." This care is shown first in possibility: man makes things instrumental to his concerns and so projects forward. Secondly, there is his facticity, for he exists as a finite entity with particular limitations (his "thrownness"). Thirdly, man seeks to avoid the anxiety of his limitations and thus seeks inauthentic existence. Authenticity, on the other hand, involves a kind of stoicism (positive attitude toward life and suffering) in which death is taken up as a possibility and man faces the "nothing." The structure of man's world as analyzed by Heidegger is revealed, in a sense, affectively—*i.e.*, through care, anxiety, and other existential attitudes and feelings.

Sartre's thought has had less direct impact on the study of religion, partly because his account of human existence represents an explicit alternative to traditional religious belief. Sartre's analysis begins, however, from the human desire to be God: but God is, on Sartre's analysis, a self-contradictory notion, for nothing can contain the ground of its own being. In searching for an essence man fails to see the nature of his freedom, which is to go beyond definitions, whether laid down by God or by other human beings.

The French philosopher Gabriel Marcel (1889–1973) is not individualistic like Sartre (or at least the early Sartre, whose thinking was modified by Marxism); instead, he stresses the communal character of human existence—the highest virtue being fidelity. Marcel also emphasizes the mysterious (as distinguished from the empirically problematic) character of love, evil, hope, freedom, and, above all, being. His work provides a rich analysis and interpretation of the religious dimensions of human experience and thus is a philosophical basis for the study of religious experience.

The Existentialist approach attempts to describe and evoke the way human beings are and thus can lay claim to be phenomenological. It is clear, however, from the divergencies among Existentialists, that they contain speculative and idiosyncratic elements, and one question raised about the general applicability of their characterizations is how far they are bounded by the product of a particular mood in Western culture.

Influence of Phenomenology

The German philosopher Edmund Husserl (1859–1938) has had, as the main exponent of Phenomenology, a wide effect on the study of religion. His program of describing experience and "bracketing" the objects of experience, in the pursuit of essences of types of experience, was in part taken up in the phenomenology of religion. Husserl distinguished Phenomenology from psychology, however, because, in his view, the latter concerns facts in a spatio-temporal setting, whereas Phenomenology uncovers timeless essences. This aspect of Husserl's thinking has not always or wholly been accepted by phenomenologists of religion, who have been much more oriented toward facts, though Husserl's emphasis on essences often has tended to make religious phenomenology lean toward a static typology.

Relationship between Western and non-Western philosophy in regard to religion. Western philosophy has thus had a significant influence on the study of religion. It has also come into contact with non-Western traditions and has thus stimulated concern with the problem of the nature of religious truth in a world perspective. The most influential product of this interplay has most likely been the neo-Advaitin philosophy (a new version of Advaita, or nonduality) espoused by a number of modem Indians, such as Swami Vivekananda (1863–1902), who made a sensational appearance at the Parliament of Religions in Chicago in 1893, and the Indian philosopher Sarvepalli Radhakrishnan (1888–1975). Both of these thinkers attempted to reveal the underlying unity in the great religions—a unity described from a point of view drawing on the thought of Śaṅkara.

The idea of a world faith

The U.S. philosopher William Ernest Hocking (1873–1966) pursued similar interests in the construction of a world faith that he considered might come about through the mutual modification of, and interchange between, the great religious traditions. These concerns have raised important questions about the criteria of truth between religions, the tests of whether one religion is truer than others, and the extent to which valid identifications of belief can be made between one faith and another. The various elements of the philosophical traditions of the last two centuries have thus had a bearing on religious questions, and most scholars consider that though the philosophy of religion tends to be normative rather than descriptive, it is a necessary adjunct to descriptive studies. Philosophical insights and expertise are of significant relevance to the numerous questions of method that arise in the study of religion.

THEOLOGICAL STUDIES

Historical-critical studies. The major feature in the development of Christian theology during the 19th and 20th centuries has been the impact of historical enquiry on the biblical sources of belief (there has also been a similar effect on Jewish and other theologies, but Christian theology has been the most influential in the development of Western culture). A pioneer in the attempt to understand the mythological elements in the New Testament was the German theologian David F. Strauss (1808–74), whose controversial Life of Jesus (published in German, 1835–36) was an attempt to sift out the historical Jesus from the overlay of myth created by the poetic imagination of the early church. Similarly, the German church historian Adolf von Harnack (1851–1930), influenced by Albrecht Ritschl, intended to penetrate the accretions of dogma attached to the historical Jesus. Such attempts were later to come under radical criticism from, among others, the Alsatian philosopher-theologian and Nobel laureate Albert Schweitzer (1875–1965) for describing the alleged Jesus of history in terms tailored to fit the presuppositions of liberal Protestantism. Thus was raised an important methodological question on how to deal with such material as the Gospels.

Principles of historical criticism

Important in trying to spell out principles for dealing with the material was Ernst Troeltsch, who argued that history has to be written in accordance with the following principles: first, the principle of criticism—*i.e.*, the sifting of the evidences and testing of conclusions (thus historical certainty about much in the ancient witnesses to Jesus is impossible); second, the principle of analogy—*i.e.*, in the absence of first-hand experience, scholars must treat reports of miraculous events with skepticism since men do not encounter such events in their own experiences (here Troeltsch adopts the position of David Hume); and third, the principle of correlation—*i.e.*, events in history are continuous with one another in a causal nexus, which rules out irruptions into the causal order by God: if he works in history he is immanently in all of it. Troeltsch, it may be noted, had some effect on the sociology of religion—*e.g.*, in his distinction between church-type and sect-type organizations in the history of Christianity, a distinction that has formed the starting point of considerable researches in recent times, as noted above. The implications of Troeltsch's historical treatment of religion seemed to be relativistic. Christianity, at any rate, is viewed as a part of religious history as a whole, a point that had not always been clearly recognized by theologians. Troeltsch thereby raised some important questions about the relationship between Christianity and other religions and showed how Christian theology was beginning to take a more realistic view of mankind's religious experience and history, in distinction to the earlier rather simplistic dichotomies between special (*i.e.*, Judeo-Christian) and general (*i.e.*, natural) revelation.

Discoveries about ancient Near Eastern religions were also bound to affect biblical studies, and a well-defined school developed in Germany—the Religionsgeschichtliche Schule (History of Religions school)—which was critical of the rather unhistorical treatment of Jesus by Ritschl and others. This school emphasized the degree to which biblical ideas were the product of the ancient cultural milieu. Important in this line of development was Albert Schweitzer, in whose Quest of the Historical Jesus the eschatological teachings (statements about the "last times," or end of the world as it is now understood) of Jesus are emphasized, together with the dissimilarity of his thought world from our own. Criticism of Harnack also came from a different direction. The French theologian Alfred Loisy (1857–1940), from a Catholic point of view but taking into account the work of Protestant biblical critics, found the essence of Christianity in the faith of the developed church, which could not be found simply by trying to discover the nature of the historical Jesus. The founder, in effect, of Catholic Modernism, Loisy was condemned by his own church, and this was a main factor in discouraging some of the livelier Catholic studies of the New Testament until after the epochal ecumenical second Vatican Council (1962–65).

Influence of Barth and Bultmann

Neo-orthodoxy and demythologization. Liberal Protestantism of the Harnack type was severely criticized by Karl Barth (1886–1968), the founder of Neo-orthodoxy; liberalism's optimism, in any event, came under a cloud through the outbreak of World War I. Barth's *Epistle* to the Romans and his later *Church* Dogmatics became highly influential. His theology depended in part on a distinction between the Word (*i.e.*, God's self-revelation as concretely manifested in Christ and in preaching) and religion. The latter, according to Barth, is the product of human culture and aspirations and is not to be identified with saving revelation (for salvation cannot come from man, only from God). This rather uncompromising view made use of the projectionist theory of religion expressed by Feuerbach and others. Barth's conclusion was challenged somewhat by another Swiss theologian, Emil Brunner (1889–1966), who allowed a modicum of insight for fallen man into God's nature. The concession was, however, a slight one. The Dutch theologian Hendrik Kraemer (1888–1965) applied the doctrine of the theology of the Word to non-Christian religions in The *Christian* Message in a Non-Christian Would, which had a wide impact on the overseas mission field. Since man's religions are cultural products and since each system of belief is organic and particular, there are, according to Kraemer, no points of contact between them and the Gospel (even Christianity as an empirical religion must be distinguished from it: its only advantage is to have been continuously under the judgment and influence of the Gospel). Kraemer's position has come under some criticism from students of comparative religion; one of the theological problems it poses is that it seems to shut off the possibilities of dialogue between religions.

After Barth, the most influential theologian in the 20th century has been Rudolf Bultmann (1884–). Though mainly concerned with the presentation of the faith, his project of "demythologization" has a wide significance for the historian of religions, for it involves a theory of myth. Bultmann comes to the New Testament material partly as a historian and partly as a theologian influenced by the Existentialism of Heidegger. He centres his interest on the difference between the style of thinking in the early church, as expressed in the New Testament writings, and modern thought. Modern man, he holds, cannot think in the mythological terms employed in the New Testament presentation of the Gospel. Therefore, it is necessary to demythologize the New Testament message. For Bultmann, the mythological elements are belief in the pre-existence of Christ, the three-layer universe (heaven, earth, and hell), miracles, ascension into heaven, demonology, and various other elements of the Judeo-Christian-Hellenistic world view. The inner meaning of the myths, he claims, has to be explicated in existential terms and purged of the objectifications that they contain. Thus, his theory contains an empirical claim, namely about the original function of myths (expressing existential attitudes through objectified representations). Bultmann's theory, however, has not yet been brought together with anthropological and other theories of myth.

A follower of Bultmann, Fritz Buri (1907–), considers Bultmann's stance to be insufficiently radical, for Bultmann still differentiates between the kerygma (the essential proclamation of the early church) and the myths, desiring to retain the former, but not the latter. Buri has attempted to overcome this distinction. Authentic existence is not, according to Buri, distinctively Christian, and he has been led to a position not altogether different in principle from that of Troeltsch. Buri's views have also led him into considering in some depth the significance of other religions.

Inter-religious dialogue

The relationship of Western Christianity to other religions. Since World War II, Western Christianity has found it difficult, from a cultural point of view, to ignore the challenge of other religions; and the mood has changed somewhat from the more rigorous climate in which the theology of the Word (*i.e.*, Barth's position) was dominant. The "theology of religions" (analogous to the "history of religions") has moved in the direction of dialogue, which sometimes simply refers to mutual acquaintance in charity so that men of differing faiths can come to understand more deeply the meaning of each other's religions. More significantly, it means a kind of mutual theologizing. Among the more prominent writers who have been involved one way or another in the process of dialogue have been the Jewish philosopher Martin Buber (1878–1965), the English Islāmic scholar Kenneth Cragg (1913–), and the Canadian Islāmic scholar Wilfred Cantwell Smith. In effect, modern dialogue continues an earlier tradition that emphasized some continuities between religions, notably the work of the British theologian John Oman (1860–1939), who was influenced both by Schleiermacher and Otto, though critical of the latter. Oman contrasted prophetic and mystical religion and considered that the former had the highest conception of the supernatural. There are analogies between his position and that of the important Swedish theologian, historian of religion, and archbishov Nathan Soderblom (1866–1931).

A rather different theory of myth and symbolism from that of Bultmann was expressed by Paul Tillich, who viewed religion as having to do with what concerns man ultimately. He taught that symbolic and mythological language, used by all religions, points beyond itself to the being in which the symbols participate. Tillich used the term being in an existential sense (one related directly to human experience and commitment) rather than a strictly metaphysical sense. Also, he claimed that it is not possible to dispense with the symbolic, which is essential to the task of speaking about ultimate reality, but the myths are to be "broken"—that is, they are to be seen as not being literally true.

Christian theology, in the 19th and 20th centuries, has been more concerned with intellectual and social challenges, however, than with the analysis of religion, which has been secondary to that concern.

HISTORY AND PHENOMENOLOGY OF RELIGION

The history of religions and the phenomenology of religion are generally understood by scholars to be nonnormative—that is, they attempt to delineate facts, whether historical or structural, without judging them from a Christian or other standpoint. At any rate, their tasks are considered to be different from that of articulating and systematizing a faith. The same, in principle, is true for the comparative study of religion, though this sometimes is thought to cover the theology of other religions, such as the Christian appraisal of Hindu history. Needless to say, the fact that a discipline aims to be nonnormative does not mean that it will succeed in being so. Also, the history and phenomenology of religion tend to raise essentially philosophical questions of explanation, where the issues are often debatable.

Modern origin and development of the history and phenomenology of religion. The history of religions on a cross-cultural basis, though it has quite an ancient pedigree, came into its own in a modern sense from about the time of the German comparative philologist Max Miiller (1823–1900). During the latter part of the 19th century an attempt was made to place comparative methodology on a systematic basis (often called the Science of Religion), and in this connection the work of the Dutch theologians P.D. Chantepie de la Saussaye (1848–1920) and C.P. Tiele (1830–1902) was important. During this period, various lectureships and chairs in the subject were instituted. In The Netherlands, following the reform of the theological faculties in 1876, four chairs in the history of religions were founded. In 1879 a chair was founded at the Collège de France (followed by others elsewhere in France), while a number were created in Switzerland. The subject also spread to Great Britain (where chairs at Manchester and London were instituted), the United States (at Harvard and Chicago), and elsewhere in the Western world. In Germany, on the other hand, there was strong resistance, notably from Adolf von Harnack, who thought that theology should avoid what he regarded as dilettantism and that the subject was sufficiently covered in the study of biblical religion.

The first congress of *Religionswissenschaft* (Science of Religion) took place in Stockholm in 1897, and a similar one in the history of religions at Paris in 1900. Later, the International Association for the History of Religions, dedicated to a mainly nonnormative and nontheological approach, was formed. Also important was the compilation of encyclopaedias, notably Hastings' *Encyclopaedia of Religion and Ethics,* with many distinguished contributions. Thus, there were development and progress in the new subject in the latter part of the 19th and early part of the 20th century. In the 1960s came the next major burst of expansion.

A great amount of the work of scholars in the field has been devoted to exploring particular histories—piecing together, for instance, the history of Gnosticism (a Hellenistic-Christian heretical sect that emphasized dualism) or of early Buddhism. In principle, Christianity is considered from the same point of view, but much significant work has also been comparative and structural. This can range from the attempt to establish rather particular comparisons, such as Otto's comparison (in his *Mysticism East and West)* of the medieval German mystic Meister Eckehart and the medieval Hindu philosopher Śaṅkara, to a systematic typology, as in *Religion in Essence and Manifestation* by the Dutch historian of religion Gerardus van der Leeuw.

The concept of the Holy

There have been many significant scholars in the history and phenomenology of religion since Max Miiller. Rudolf Otto (1869–1937) made a profound impression on the scholarly world with the publication of *The Idea of the Holy* (in its German edition of 1917), which showed the influence of Schleiermacher, Marett, Edmund Husserl, and the Neo-Kantianism of Jakob Fries (1773–1843). More important than the philosophical side of his enterprise, however, was the excellent delineation of a central experience and sentiment and the elucidation of the concept of the Holy. The central experience Otto refers to is the numinous (Latin *numen*, "spirit") in which the Other (*i.e.*, the transcendent) appears as a *mysterium tremendum et fascinans*—that is, a mystery before which man both trembles and is fascinated, is both repelled and attracted. Thus, God can appear both as wrathful or awe inspiring, on the one hand, and as gracious and lovable, on the other. The sense of the numinous, according to Otto, is *sui generis,* though it may have psychological analogies, and it gives an access to reality, which is categorized as holy. Otto stresses what he calls the nonrational character of the numinous, but he does not deny that rational attributes may be applied to God (or the gods or other numinous powers), such as goodness and personality. The impact of Otto's work, however, does not depend on the now rather curious Neo-Kantian scheme into which he presses his data. Not all scholars would agree that the numinous is universal as a central element in religion, as Otto seems to have supposed: early Jainism and Theravāda Buddhism, for example, have other central values. Otto's treatment of mysticism, which is central to Buddhism, wavers somewhat, and the notions of the "wholly Other" and of the *tremendurn* do not easily apply to the experience of Nirvana (the state of bliss) or to other deliverances of the contemplative mystical consciousness.

Friedrich Heiler (1892–1967), like Otto a professor at Marburg (Germany), was a strong proponent of the phenomenological and comparative method, as in his major work on prayer. Heiler, however, went beyond the scientific study of religion in attempting to promote interreligious fellowship, partly through the Religioser Menschheitsbund (Union of Religious Persons), which he helped to found. Heiler believed in the essential unity of religions—a recurring theme in various guises in the period, though open to question because of the widely apparent divergences between prophetic and other religions, such as Theravāda Buddhism and Jainism, which do not believe in a supreme personal being.

The phenomenologist of religion who probably has had the greatest influence after Otto, partly because he is fairly explicit about method, is Gerardus van der Leeuw (1890–1950), who was somewhat influenced by the French anthropologist Lucien Lévy-Bruhl (1857–1939) and his notion of prelogical mentality, which he applied to primitive cultures to distinguish them from civilized cultures. Van der Leeuw emphasized power as being the basic religious conception. His major work, *Religion in Essence and Manifestation,* is an ambitious and wide-ranging typology of religious phenomena, including the kinds of sacrifice, types of holy men, categories of religious experience, and other types of religious phenomena. The work has been criticized, however, as being unhistorical. Partly because of his philosophical presuppositions, borrowed chiefly from Husserl, van der Leeuw held the disputable doctrine that Phenomenology knows nothing of the historical development of religion: it picks out timeless essences of religious phenomena. Apparently it is not necessary, however, to hold this doctrine, since one could as well classify types of religious change (*i.e.*, temporal sequences), as indeed Max Weber attempted to do. Classificatory and historical techniques and conclusions are not incompatible, however. Thus, the work of Nathan Soderblom, who, as well as being a historian of religions, was prominent in the ecumenical movement, combined the two aspects in his Living God.

Emphases of Joachim Wach and Mircea Eliade

The "Chicago school." The phenomenological method was brought to the United States primarily by the German-American historian of religions Joachim Wach (1898–1955), who established *Religionswissenschaft* (Science of Religion) in Chicago and was thus the founder of the modern "Chicago school" (though his successor, Mircea Eliade, has a rather different slant). Wach was concerned with emphasizing three aspects of religion—the theoretical (or mental; *i.e.*, religious ideas and images), the practical (or behavioral), and the institutional (or social); and because of his concern for the study of religious experience, he interested himself in the sociology of religion, attempting to indicate how religious values tended to shape the institutions that expressed them. Wach, however, was not committed to a religious neutralism in his use of the idea of a "science of religion." For him, Religionswissenschaft deepens the sense of the numinous and strengthens, rather than paralyzes, religious impulses.

Mircea Eliade (1907–), a Romanian scholar who emigrated to the United States after World War II, has had a wide influence, partly because of his substantive studies on yoga (a Hindu meditation technique) and on shamanism (both these major works are now regarded as classical studies of their subjects) and partly because of his later writings, which attempt to synthesize data from a wide variety of cultures. The synthesis incorporates a theory of myth and history. Eliade was also a founder of the journal History of Religions, which expresses the "Chicago school" viewpoint. Eliade has been somewhat influenced by Jung, both in his psychological interpretations of certain religious experiences (such as those attained in the practice of yoga) and more importantly in his attempt to give an interpretation in depth to the mythic material over which he ranges so widely. He also affirms strongly the importance of the history of religions in the intellectual world and is thus concerned to emphasize its unique and positive role in providing a "creative hermeneutics" (critical interpretive method) of man's religious and existential condition. Two important elements in the theory of Eliade are, first, that the distinction between the sacred and the profane is fundamental to religious thinking and is to be interpreted existentially (the symbols of religion are, typically, profane in literal interpretation but are of cosmic significance when viewed as signs of the sacred); and, second, that archaic religion is to be contrasted with the linear, historical view of the world. The latter essentially comes from biblical religion; the former viewpoint tends to treat time cyclically and mythically—referring to foundational events, such as the creation, the beginning of the human race, and the Fall of man, on to *illud tempus* (the sacred primordial time), which is re-enacted in the repetitions of the ritual and in the retelling of the myth. Though Christianity has contained archaic elements, in essence it is linear and historical. Thus, faith in Christianity involves a kind of fall from archaic timelessness, and secularization—in which the overt symbolism of religion is driven underground into the unconscious—is a second fall. Eliade is not very explicit about his meaning beyond this point. Not only is he concerned with descriptive phenomenology, in which context his analysis of the religious functions of time and space is most illuminating, but also with a kind of metaphysical speculation (as exemplified in his idea of the "fall").

The myth and ritual school

Other studies and emphases. Though not always giving a detailed account of the correlation between myth and ritual, Eliade is indebted to the so-called myth and ritual school, which has influenced thinking in the history of religions and which was important in the 1930s, especially in the interpretation of Near Eastern mythology. Thus, the *Enuma* elish, the Babylonian creation epic, was discovered to be no mere set of stories but rather a mythic drama re-enacted every year at the spring festival, at which time the foundation of the world is ritually renewed. More generally, it was seen that for a wide range of sacred stories it was important to discover the ritual context. The most influential statement of the school's position is to be found in *Myth* and Ritual (1933), edited by the English biblical scholar and Orientalist Samuel Hooke.

Meanwhile, the categorization of types of religion (*e.g.*, as polytheism, henotheism, or other) continued to stimulate attempts at a deeper understanding of the emergence of monotheism. To some extent scholars remained under the influence of the older evolutionism. An important work in this connection was Dio: Formazione *e sviluppo del monoteismo nella* storia *delle* religioni ("God: Formation and Development of Monotheism in the History of Religions"), by the Italian historian of religion Raffaele Pettazzoni (1883–1959), who emphasized the importance of the divinized sky in the development of monotheism. He was critical of the *Urmonotheismus* of Wilhelm Schmidt, considering that the latter's theory of an original monotheism went very far beyond the evidence. At best, the facts could only support the conclusion that primitive peoples believed in a supreme celestial being. Pettazzoni, in his concern for problems of method, was critical of the sharp division between phenomenology and history. He considered that the former cannot exist without the historical sciences—*e.g.*, history, philology, and archaeology—but that it supplies scholars in the latter fields a sense of the religious significance of what they discover. This point of view has also been more vigorously espoused by the Swedish scholar Geo Widengren (1907–), who has specialized mainly in Iranian religions. The need to integrate historical and structural studies has caused some debate in recent years; and there has also been some contrast made between historical approaches and contemporary sociological and (essentially theological) dialogical approaches to religion. To some extent, such debates represent different ideals of scholarship; but it is difficult to note where the essential incompatibilities lie. For many scholars, the multidisciplinary way of studying religion is difficult to comprehend.

Studies on the sociological functions of deities

Meanwhile, the longstanding interest in the Indo-European group of religions was given a new impetus in the work of the French comparative philologist and mythologist Georges Dumézil (1898–), who broke away from an etymological (analysis of word derivations) approach and sought instead the thematic traits of the gods in the mythical material. This approach, pioneered by others before Dumézil, also was skeptical of the easy identification of gods with natural forces and emphasized the sociological functions of the divinities—without, however, holding to a reductionist theory. Dumézil's theory was partly stimulated by discoveries in the Near East, notably that of Boğazköy (Turkey), which revealed a similarity between some of the chief gods of the Indo-European Mitannians and those of the Aryans of the Indian Vedic tradition. His theory correlated the functions of the gods with the tripartite division of Indo-European societies—namely the priestly regal, the nobility, and the producers (agriculturalists, craftsmen). Though his work has been controversial (there are, for instance, some difficulties about its application to ancient Greece, despite the fact that the analysis seems to apply to the threefold division of society into philosophers, warriors, and producers in Plato's Republic), there is no doubt that the search for correlated functions of the kind Dumézil postulated has been significant in the area of Indo-European mythology.

Dumézil's work is one example of a thematic, comparative study. The interest in such studies has grown since World War II. Examples can be found in the writings of such thinkers as the English scholar S.G.F. Brandon (1907–1971) in his treatment of ideas such as creation and time in different religions, but with special reference to the ancient Near East, and the English Indo-Iranian scholar R.C. Zaehner (1913–), notably in his work on mysticism, as in his *Mysticism Sacred and Profane.* Zaehner's is a definitely Christian approach rather than a scientific-descriptive one; and his concern is to distinguish between theistic and other forms of mysticism, such as monistic mysticism as found, according to him, in Yoga, Advaita, and even Theravāda Buddhism.

Apart from the comparative, phenomenological studies, there has also been a strong growth of historical work in regard to particular religions. This has been most obvious in Indian religions—in Hinduism and Buddhism especially. In part, this is the result of a general growth in non-Christian religions in the post-World War II era and of the need to come to terms with Asian and African cultures after the demise of European hegemony.

IV. **Conclusion**

Problems and directions of the study of religions

The foregoing, a necessarily rather selective account of some of the principal developments and scholars in the various disciplines related to the study of religion, emphasizes the artificiality of some of the divisions between traditional disciplines. Thus, Dumézil's work could as easily fall under sociology or anthropology as under the history of religions; and there are obvious connections between philosophy and sociology in, for example, Marxist interpretations of religion. Again, the description and typology of religious experience belong as much to psychology as to the phenomenology of religion, and the analysis of the nature of symbolism requires a variety of disciplinary approaches. To some extent, the study of religion has suffered from the barriers between disciplines, and this fact is increasingly recognized in the formulations, notably in the United States, of the idea of religion as a subject that should be institutionalized in a university department or program in which historians, phenomenologists, sociologists, and members of other disciplines work together. There are some, however, who consider that there are dangers in such an arrangement; thus Eliade prefers to work rather tightly within the framework of the history of religions, concerned lest the social sciences overwhelm and distract the interpreter of religious meanings. Similarly, the theological tradition in the West remains powerfully operative (quite legitimately) in regard to the articulation of the Christian faith and sometimes resists any attempt to treat Christianity itself in the manner dictated by the history and phenomenology of religion. Thus, the history of religions and the comparative study of religion still tend to mean in practice "the study of religions other than Judaism and Christianity." Educational and social pressures have arisen, however, within a secularistic, increasingly pluralistic society and (in effect) a shrunken world, increasing the tendency toward a pluralism in the study of religion that expands the viewpoints of traditional faculties and departments of theology, both in universities and theological seminaries.

A further problem about the multidisciplinary study of religion is that little has been done to explore the problem of the people to whom religions are interpreted—the clientele for the subject. Hitherto, the main assumption has been that the study is for Westerners, though a number of distinguished Asian and African scholars are working in the field. Until recently, owing to the unequal cultural and political relationship between Western and non-Western religions, however, some of the most vital contributions have been primarily attempts to articulate (for the new apologetic situation) the old traditions. This has been a main concern of scholars of Asian religions such as Sarvepalli Radhakrishnan, T.R.V. Murti, and K.N. Jayatilleke. The prospect is, however, that an intellectual community will be the clientele of the subject. To this extent the study of religions will most likely involve, as it does already to some extent, a complex dialogue between religions.

Another problem is the need to elucidate the basis of a dynamic typology of religion in which phenomenology and history are properly brought together. The tendency toward a rift between the historians and phenomenologists is unnecessary and causes harm to the pursuit of the subject.

Meanwhile, some emergent tendencies within the various disciplines can be perceived. There is an increased concern in anthropological theory for the content of religious symbolism, such as in the work of the English anthropologist Mary Douglas; and the sociology of religion is, in a sense, returning to the method of Max Weber in stressing the comparison of cultures. The important development of Oriental and African studies since World War II has made this task earier—American sociologists have, for example, examined in some detail Japanese culture and religion. The interest in symbolism and mythology coincides with developments in the philosophy of religion, which, under the influence of Wittgenstein (in his later, more open phase), is concerned with explicating different functions of language. One area of the study of religion that is seriously underdeveloped at the present time—other than in respect to the psychoanalytic approaches—is the psychology of religion, although current interest in mysticism and other forms of religious experience has stimulated the collection and interpretation of data. One of the difficult problems to be solved is the extent to which cultural conditioning exerts an influence on the actual content of such experience.

In many ways the present position promises well for an expanding multidisciplinary approach to problems in the study of religion. Historians of religion are recognizing some of the contributions to be made by modern sociology, and sociologists—partly because of the development of the sociology of knowledge—have become more aware of the need for accounting for the particular systems of meaning in religion. An area that may very well exhibit the new synthesis is the study of new religious movements.

After a period of relative unconcern, Christian theology is increasingly aware of the challenge of other religious beliefs, so that there are greater impulses toward blending Christian and other studies—often kept rather artificially apart, though biblical studies, especially Old Testament studies, have usually been quite closely ielated to the history of the relevant religions of the ancient Near East.

Meanwhile, in a number of Western countries (chiefly in Europe, but also to some extent in the United States), the study of religion on a pluralistic and multidisciplinary basis is being increasingly viewed as an important element in the education of secondary school students. This, together with the popularity of the subject in universities, may ensure that the study of religion will increase in significance.

PINARD DE LA BOULLAYE, *L'Étude comparée des religions,* 2 vol. (1922–25), a thorough and excellent account; J. MILTON YINGER, *The Scientific Study of Religion* (1970), a recent attempt to indicate the multidisciplinary approach to the study of religion; J. HASTING~(ed.), *Encyclopaedia of Religion and Ethics,* 13 vol. (1908–26), dated in many respects but still an enormously important reference work; PAUL EDWARDS (ed.), *Encyclopedia of Philosoplty,* 8 vol. (1967), many entries on world religions, doctrines, and religious thinkers; JOHN MACQUARRIE, *Twentieth Century Religious Thought* (1963), a survey, despite its title, of both 19th- and 20th-century thinkers, including many important in the history and phenomenology of religion (also a good general guide to issues about religion in modern Western theology); G. VAN DER LEEUW, *Phänomenologie der Religion* (1933; Eng. trans., *Religion in Essence and Manifestation,* 1938), the most wide-ranging and ambitious attempt at a systematic and classificatory phenomenology of religion; RUDOLF OTTO, *Das Heilige* (1917; Eng. trans., *The Idea of the Holy,* 2nd ed., 1950), a highly influential classic; MIRCEA ELIADE has written widely from a standpoint that combines elements drawn from depth psychology, phenomenology, and the history of religions: his *Sacred and the Profane* (1961) and *The Quest* (1969) give an insight into his general approach; J. WACH, *The Comparative Study of Religion* (1958) and *Sociology of Religion* (1962), still useful compendiums; J. HINNELLS (ed.), *The Comparative Study of Religion in Education* (1970), contains some recent thinking about the comparative method relating it to education; MICHAEL BANTON (ed.), *Anthropological Approaches to Religion* (1966), and E. EVANS-PRITCHARD, *Theories of Primitive Religion* (1965), indicate the main issues about the genesis and function of religion debated by anthropologists; recent work in the sociology of religion is surveyed usefully in THOMAS O'DEA, *The Sociology of Religion* (1966); MAX WEBER, *Religionssoziologie* (1922; Eng. trans., *The Sociology of Religion,* ed. by TALCOTT PARSONS, 1963), a good introduction to the thought of Weber. PETER BERGER, *The Sacred Canopy* (Brit. title, *The Social Reality of Religion,* 1969), more speculative but stimulating example of modern sociological theorizing about religion; V. LANTERNARI, *The Religions of the Oppressed* (1963), an example of comparative sociology of religion; J. HICK, *The Philosophy of Religion* (1963), a useful survey of the issues raised in the philosophy of religion.

(N.Sm.)

Religions, Classification of

The classification of religions, the attempt to systematize and bring order to a vast range of knowledge about man's religious beliefs, practices, and institutions, has been the goal of students of religion for many centuries but especially so with the increased knowledge of the world's religions and the advent of modern methods of scientific inquiry in the last two centuries.

The classification of religions involves: (1) the effort to establish groupings among historical religious communities having certain elements in common or, (2) the endeavour to group similar religious phenomena in categories that serve to reveal the structure of human religious experience as a whole.

FUNCTION AND SIGNIFICANCE

Classification as a tool in understanding religion

The many schemes suggested for classifying religious communities and religious phenomena all have one purpose in common; *i.e.*, to bring order, system, and intelligibility to the vast range of knowledge about human religious experience. Classification is basic to all science as a preliminary step in reducing data to manageable proportions and in moving toward a systematic understanding of a subject matter. Like the zoologist who must distinguish and describe the various orders of animal life as an indispensable stage in the broad attempt to understand the character of such life as a whole, the student of religion also must use the tool of classification in his outreach toward a scientific account of man's religious experience. The growth of scientific interest in religion in Western universities over the past 130 years has compelled most leading students of religion to discuss the problem of classification or to develop classifications of their own.

The difficulty of classifying religions is accounted for by the immensity of religious diversity that history exhibits. As far as scholars have discovered, there has never existed any people, anywhere, at any time, who were not in some sense religious. The individual who embarks upon the arduous task of trying to understand religion as a whole confronts an almost inconceivably huge and bewilderingly variegated host of phenomena from every locale and every era. Empirically, what is called religion includes the mythologies of the preliterate peoples on the one hand and the abstruse speculations of the most advanced religious philosophy on the other. Historically, religion, both ancient and modem, embraces both primitive religious practices and the aesthetically and symbolically refined worship of the more technologically progressive and literate human communities. The student of religion does not lack material for his studies; his problem is rather to discover principles that will help him to avoid the confusion of too much information. Classification is precisely the appeal to such principles; it is a device for making the otherwise unmanageable wealth of religious phenomena intelligible and orderly.

The classification of religions thus has significance for the method of a general science of religion. Broadly speaking, the scientific study of religion comprehends two aspects: assembling information and interpreting the material gathered in order to elicit its meaning. The first aspect involves the psychological and historical study of religious life and must be supplemented by such auxiliary disciplines as archaeology, ethnology, philology, literary history, and other similar disciplines. The facts of religious history and insight into the development of the historical religious communities are the foundation of all else in the study of religion. Beyond the historical basis lies the task of seeing the entirety of human religious experience from a unified or systematic point of view. The student of religions attempts not only to know the variety of beliefs and practices of *homo religiosus* ("religious man"), but also to understand the structure, nature, and dynamics of religious experience. The student of religion attempts to discover principles that operate throughout religious life--on the analogy of a sociologist seeking the laws of human social behaviour—to find out whether there are also laws that operate in the religious sphere. Only with the attempt to discern the system and structure binding together the differentiated historical richness of religion does a true science of religion, or *Religionswissenschaft*, begin.

The endeavour to group religions with common characteristics or to discover types of religions and religious phenomena belongs to the systematizing stage of religious study. According to F. Max Müller, an Anglo-German comparative philologist of the 19th century,

> All real science rests on classification and only in case we cannot succeed in classifying the various dialects of faith, shall we have to confess that a science of religion is really an impossibility.

PRINCIPLES OF CLASSIFICATION

The criteria employed for the classification of religions are far too numerous to catalogue completely. Virtually every scholar who has considered the matter has evidenced a certain amount of originality in his view of the interrelationships among religious forms. Thus, only some of the more important principles of classification will be discussed.

True and false religion

Normative. Perhaps the most common division of religions—and in many ways the most unsatisfactory—distinguishes true religion from false religion. Such classifications may be discovered in the thought of most major religious groups and are the natural, perhaps inevitable, result of the need to defend particular perspectives against challengers or rivals. Normative classifications, however, have no scientific value, because they are arbitrary and subjective, inasmuch as there is no agreed method for selecting the criteria by which such judgments should be made. But because living religions always feel the need of apologetics (systematic intellectual defenses), normative classifications continue to exist.

Many examples of normative classification might be given. The early Church Fathers (*e.g.*, Clement of Alexandria, 2nd century AD) explained that Christianity's Hellenistic (Greco-Roman culture) rivals were the creations of fallen angels, imperfect plagiarisms of the true religion, or the outcome of divine condescension that took into account the weaknesses of men. The greatest medieval philosopher and theologian, Thomas Aquinas, distinguished natural religion, or that kind of religious truth discoverable by unaided reason, from revealed religion, or religion resting upon divine truth, which he identified exclusively with Christianity. In the 16th century Martin Luther, the great Protestant Reformer, forthrightly labelled the religious views of Muslims, Jews, and Roman Catholic Christians to be false and held the view that the gospel of Christianity understood from the viewpoint of justification by grace through faith was the true standard. In Islām, religions are classified into three groups: the wholly true, the partially true, and the wholly false, corresponding with Islām, the Peoples of the Book (Jews, Christians, and Zoroastrians), and polytheism. The classification is of particular interest because, being based in the Qur'ān, (the Islāmic sacred scripture), it is an integral part of Islāmic teaching, and also because it has legal implications for Muslim treatment of followers of other religions.

Although scientific approaches to religion in the 19th century discouraged use of normative categories, elements of normative judgment were, nonetheless, hidden in certain of the new scientific classifications that had emerged. Many evolutionary schemes developed by anthropologists and other scholars, for example, ranked religions according to their places on a scale of development from the simplest to the most sophisticated, thus expressing an implicit judgment on the religious forms discussed. Such schemes more or less clearly assume the superiority of the religions that were ranked higher (*i.e.*, later and more complex); or, conversely, they serve as a subtle attack on all religion by demonstrating that its origins lie in some of humanity's basest superstitions, believed to come from an early, crude stage. A normative element is also indicated in classification schemes that preserve theological distinctions, such as that between natural and revealed religion. In short, the normative factor still has an important place in the classification of religions and will doubtless always have, since it is extraordinarily difficult to draw precise lines between disciplines primarily devoted to the normative exposition of religion, such as theology and philosophy of religion, and disciplines devoted to its description or scientific study.

Geographical categories

Geographical. A common and relatively simple type of classification is based upon the geographical distribution of religious communities. Those religions found in a single region of the earth are grouped together. Such classifications are found in many textbooks on comparative religion, and they offer a convenient framework for presenting man's religious history. The categories most often used are: (1) Near Eastern religions, including Judaism, Christianity, Islām, Zoroastrianism, and a variety of ancient cults; (2) Far Eastern religions, comprising the religious communities of China, Japan, and Korea, and consisting of Confucianism, Taoism, Mahāyāna ("Greater Vehicle") Buddhism, and Shintō; (3) Indian religions, including early Buddhism, Hinduism, Jainism, and Sikhism, and sometimes also Theravāda Buddhism and the Hindu- and Buddhist-inspired religions of South and Southeast Asia; (4) African religions, or the cults of the tribal peoples of black Africa, but excluding ancient Egyptian religion, which is considered to belong to the ancient Near East; (5) American religions, consisting of the beliefs and practices of the Indian peoples indigenous to the two American continents; (6) Oceanic religions—*i.e.*, the religious systems of the peoples of the Pacific islands, Australia, and New Zealand; (7) classical religions of ancient Greece and Rome and their Hellenistic descendants. The extent and complexity of a geographical classification is limited only by the classifier's knowledge of geography and his desire to seek detail and comprehensiveness in his classification scheme. Relatively crude geographical schemes that distinguish Western religions (usually equivalent to Christianity and Judaism) from Eastern religions are quite common.

Although religions centred in a particular area often have much in common because of historical or genetic connections, geographical classifications present obvious inadequacies. Many religions, including some of the greatest historical importance, are not confined to a single region (*e.g.*, Islām), or do not have their greatest strength in the region of their origins (*e.g.*, Christianity, Buddhism). Further, a single region or continent may be the dwelling place of many different religious communities and viewpoints that range from the most archaic to the most sophisticated. At a more profound level, geographical classifications are unacceptable because they have nothing to do with the essential constitutive elements or inner spirit of religion. The physical location of a religious community reveals little of the specific religious life of the group. Though useful for some purposes, geographical classifications contribute minimally to the task of providing a systematic understanding of man's religions and religiousness.

Use of the comparative study of languages

Ethnographic-linguistic. F. Max Miiller, often called the "Father of the history of religions," stated that "Particularly in the early history of the human intellect, there exists the most intimate relationship between language, religion, and nationality." This insight supplies the basis for a genetic classification of religions (associating them by descent from a common origin), which Miiller believed the most scientific principle possible. According to this theory, in Asia and Europe dwell three great races, the Turanians (including the Ural-Altaic peoples), the Semites, and the Aryans, to which correspond three great families of languages. Originally, in some remote prehistory, each of these races formed a unity, but with the passage of time they split up into a myriad of peoples with a great number of distinct languages. Through careful investigation, however, the original unity may be discerned, including the unity of religion in each case. Miiller's principal resource in developing the resulting classification of religions was the comparative study of languages, from which he sought to demonstrate similarities in the names of deities, the existence of common mythologies, the common occurrence of important terms in religious life. and the likeness of religious ideas and intuitions among the branches of a racial group. His efforts were most successful in the case of the Semites, whose affinities are easy to demonstrate, and probably least successful in the case of the Turanian peoples, whose early origins are hypothetical. Miiller's greatest contribution to scholarship, however, lay in his study of Aryan languages, literatures, and comparative mythology.

Because Müller was a scholar of the first rank and a pioneer in several fields, his ethnographic-linguistic (and genetic) classification of religions has had much influence and has been widely discussed. The classification has value in exhibiting connections that had not been previously observed. Miiller (and his followers) discovered affinities existing among the religious perspectives of both the Aryan and Semitic peoples and set numerous scholars on the path of investigating comparative mythology, thus contributing in a most direct way to the store of knowledge about religions.

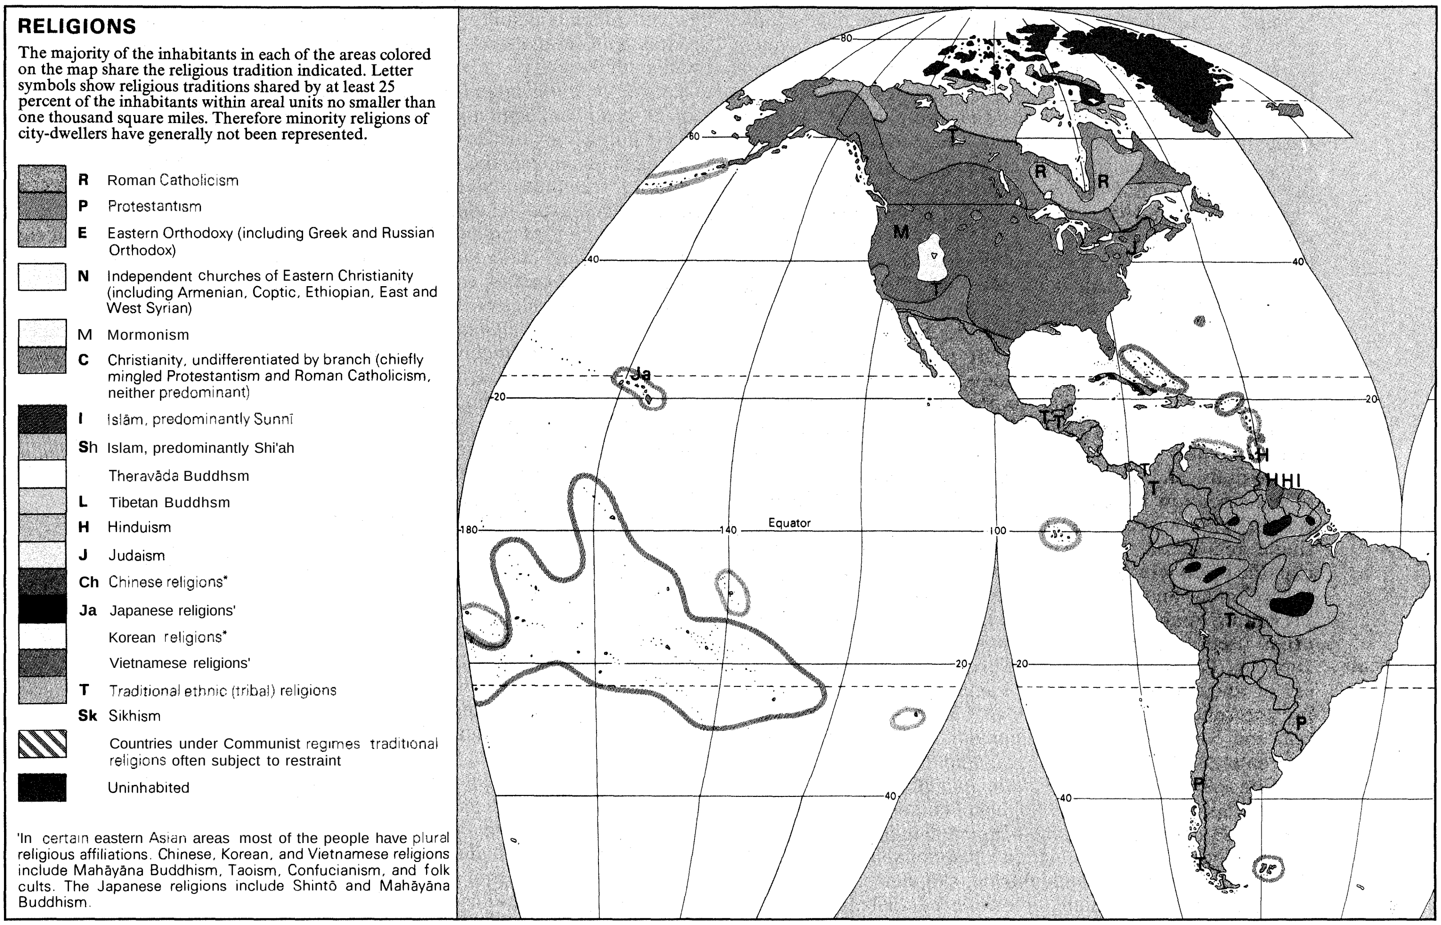
There are, nevertheless, difficulties with the ethnographic-linguistic classification. To begin with, Miiller's evidence was incomplete, a fact that may be overlooked given the state of knowledge in his day. More important is the consideration that peoples of widely differing cultural development and outlook are found within the same racial or linguistic group. Further, the principle of connection among race, language, and religion does not take sufficiently into account the historical element or the possibility of developments that may break this connection, such as the conversion of the Aryan peoples of Europe to a Semitic religion, Christianity.

Other scholars have developed the ethnographic classification of religion to a much higher degree than did Miiller. The German scholar Duren J.H. Ward, for example, in The Classification of Religions (1909) accepted the premise of the connection between race and religion, but appealed to a much more detailed scheme of ethnological relationship. He says: ". . . religion gets its character from the people or race who develop or adopt it . . ." and further that

> . . . the same influences, forces, and isolated circumstances which developed a special race developed at the same time a special religion, which is a necessary constituent element or part of a race . . . .

In order to study religion in its fullness and to bring out with clarity the historical and genetic connections between religious groups, the ethnographic element must thus have adequate treatment. Ward devised a comprehensive "Ethnographico-historical Classification of the Human Races to facilitate the Study of Religions—in five divisions." These major divisions were (1) the Oceanic races, (2) the African races, (3) the American races, (4) the Mongolian races, and (5) the Mediterranean races, each of which has its own peculiar religion. The largest branch, the Mediterranean races, he subdivided into primeval Semites and primeval Aryans, in order to demonstrate in turn how the various Semitic, Indo-Aryan, and European races descended from these original stocks.

Philosophical. The past 150 years have also produced several classifications of religion based on speculative and abstract concepts that serve the purposes of philosophy. The principal example of these is the scheme of G.W.F. Hegel, a seminal German philosopher, in his famous Lectures on the Philosophy of Religion (1832). In general, Hegel's understanding of religion coincided with his philosophical thought; he viewed the whole of



RELIGIONS
The majority of the inhabitants in each of the areas colored on the map share the religious tradition indicated. Letter symbols show religious traditions shared by at least 25 percent of the inhabitants within areal units no smaller than one thousand square miles. Therefore minority religions of city-dwellers have generally not been represented.
R Roman Catholicism
P Protestantism
E Eastern Orthodoxy (including Greek and Russian Orthodox)
N Independent churches of Eastern Christianity (including Armenian, Coptic, Ethiopian, East and West Syrian)
M Mormonism
C Christianity, undifferentiated by branch (chiefly mingled Protestantism and Roman Catholicism, neither predominant)
I Islām, predominantly Sunnī
Sh Islam, predominantly Shi'ah
Theravāda Buddhsm
L Tibetan Buddhsm
H Hinduism
J Judaism
Ch Chinese religions*
Ja Japanese religions*

Hegelian dialectics

human history as a vast dialectical movement toward the realization of freedom. The reality of history, he held, is Spirit, and the story of religion is the process by which Spirit—true to its own internal logical character and following the dialectical pattern of thesis, antithesis, and synthesis (the reconciliation of the tension of opposite positions in a new unity that forms the basis of a further tension)—comes to full consciousness of itself. Individual religions thus represent stages in a process of evolution (*i.e.*, progressive steps in the unfolding of Spirit) directed toward the great goal at which all history aims.

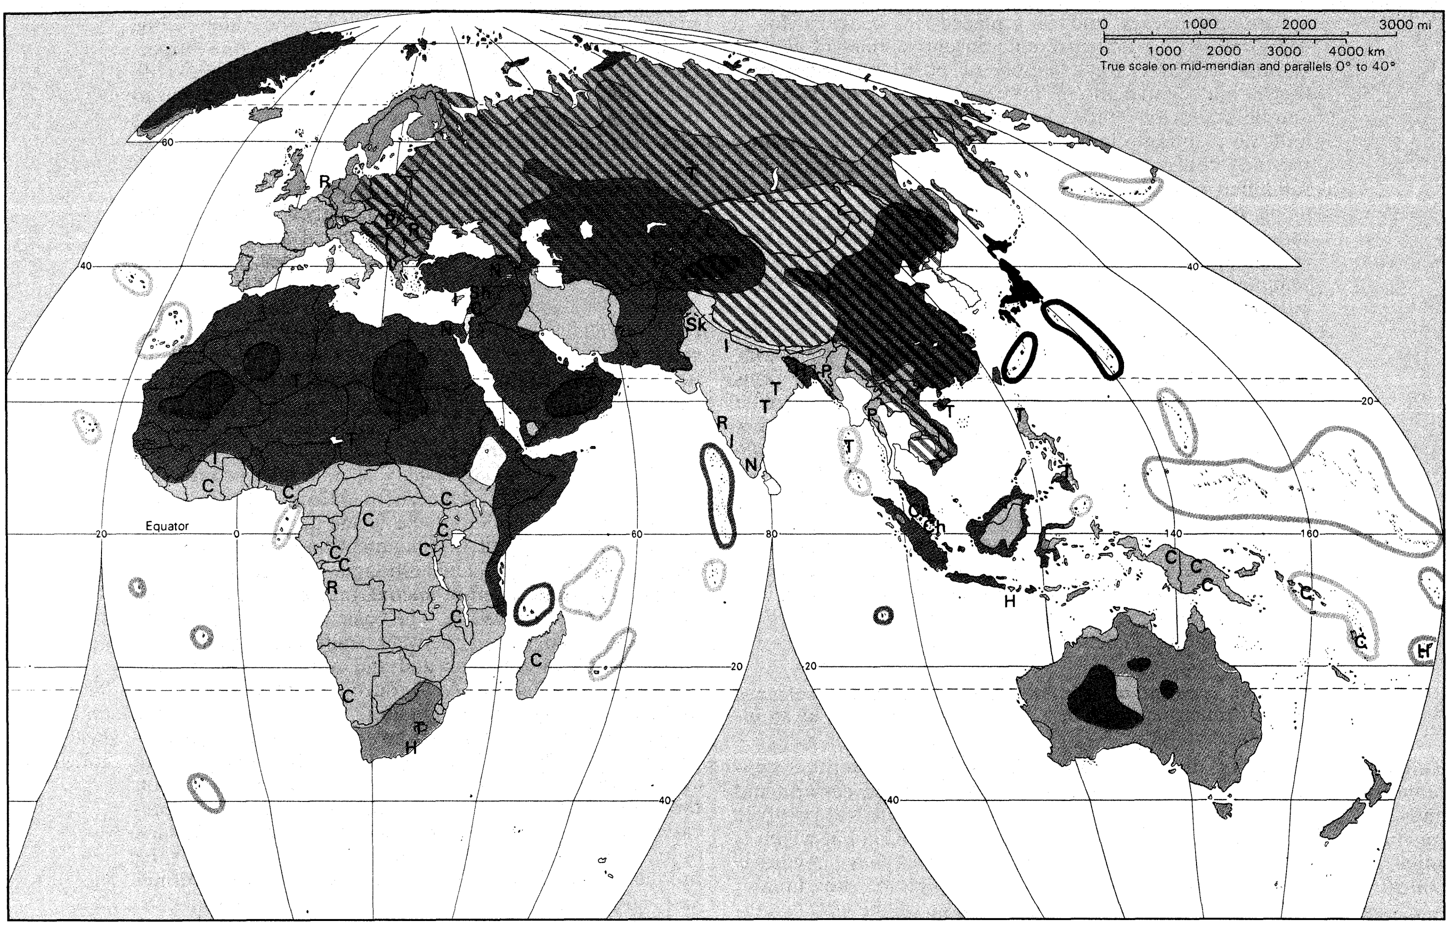
Hegel classified religions according to the role that they have played in the self-realization of Spirit. The historical religions fall into three great divisions, corresponding with the stages of the dialectical progression. At the lowest level of development, according to Hegel, are the religions of nature, or religions based principally upon the immediate consciousness deriving from sense experience. They include: immediate religion or magic at the lowest level: religions, such as those of China and India plus Buddhism, that represent a division of consciousness within itself; and others, such as the religions of ancient Persia, Syria, and Egypt, that form a transition to the next type. At an intermediate level are the religions of spiritual individuality, among which Hegel placed Judaism (the religion of sublimity), ancient Greek religion (the religion of beauty), and ancient Roman religion (the religion of utility). At the highest level is absolute religion, or the religion of complete spirituality, which Hegel identified with Christianity. The progression thus proceeds from man immersed in nature and functioning only at the level of sensual consciousness, to man becoming conscious of himself in his individuality as distinct from nature, and beyond that to a grand awareness in which the opposition of individuality and nature is overcome in the realization of Absolute Spirit.

Many criticisms have been offered of Hegel's classification. An immediately noticeable shortcoming is the failure to make a place for Islām, one of the major historical religious communities, which numbers one-seventh of the human race among its constituents. The classification is also questionable for its assumption of continuous development in history. The notion of perpetual progress is not only doubtful in itself but is also compromised as a principle of classification because of its value implications.

Nevertheless, Hegel's scheme was influential and was adapted and modified by a generation of philosophers of religion in the Idealist tradition. Departure from Hegel's scheme, however, may be seen in the works of Otto Pfleiderer, a German theologian of the 19th century, who held a particular interest in problems of classification. Pfleiderer believed it impossible to achieve a significant grouping of religions unless, as a necessary preliminary condition, the essence of religion were first isolated and clearly understood. Essence is a philosophical concept, however, not a historical one. Pfleiderer considered it indispensable to have conceptual clarity about the underlying and underived basis of religion from which all else in religious life follows. In ***Die Religion, ihr Wesen und ihre Geschickte*** ("Religion, Its Essence and History"), Pfleiderer held that the essence of religious consciousness exhibits two elements, or moments, perpetually in tension with one another: one of freedom and one of dependence, with a number of different kinds of relationships between these two. One or the other may predominate, or they may be mixed in varying degrees.

Religions of freedom and dependence

Pfleiderer derived his classification of religions from the relationships between these basic elements. He distinguished one great group of religions that exhibits extreme partiality for one over against the other. The religions in which the sense of dependence is virtually exclusive are those of the ancient Semites, the Egyptians, and the Chinese. Opposite these are the early Indian, Germanic, and Greek and Roman religions, in which the sense of freedom prevails. The religion of this group may also be



seen in a different way, as nature religions in the less-developed cultures or as culture or humanitarian religions in the more advanced. A second group of religions exhibits a recognition of both elements of religion, but gives them unequal value. These religions are called supernatural religions. Among them Zoroastrianism gives more weight to freedom as a factor in its piety, and Brahmanism and Buddhism are judged to have a stronger sense of dependence. The last group of religions is the monotheistic religions: Islam, Judaism, and Christianity, which are divided again into two sub-groups, *i.e.*, those that achieve an exact balance of the elements of religion and those that achieve a blending and merging of the elements. Both Judaism and Islam grant the importance of the two poles of piety, though there is a slight tendency in Islam toward the element of dependence and in Judaism toward freedom. It is Christianity alone, he claimed, that accomplishes the blending of the two, realizing both together in their fullness, the one through the other.

The intellectual heritage that lies behind this classification will be immediately apparent. The classification reflects its time (19th century) and place (western Europe) of conception in the sense that the study of religion was not yet liberated from its ties to the philosophy of religion and theology.

Morphological. Considerable progress toward more scientific classifications of religions was marked by the emergence of morphological (evolution of religious forms) schemes. These classifications assume that religion in its history has passed through a series of discernible stages of development, each having readily identifiable characteristics and each constituting an advance beyond the former stage. So essential is the notion of progressive development to morphological schemes that they might also be called evolutionary classifications. Recent trends in the comparative study of religions, however, have retained the interest in morphology but have decisively rejected the almost universal 19th-century assumption of unitary evolution in the history of religion. The crude expression of evolutionary categories such as the division of religions into lower and higher or primitive and higher religions has been subjected to especially severe criticism.

Influence of E.B. Tylor

The pioneer of morphological classifications was E.B. Tylor, a British anthropologist, whose *Primitive Culture* (1871) is among the most influential books ever written in its field. Tylor developed the thesis of animism, a view that the essential element in all religion is belief in spiritual beings. According to Tylor, the belief arises naturally from elements universal in human experience (*e.g.*, the phenomena of death, sleep, dreams, trances, and hallucinations), and leads through processes of primitive logic to the belief in a spiritual reality distinct from the body and capable of leading an independent existence. In the development of the idea, this reality is identified with the breath and the life principle; thus arises the belief in the soul, in phantoms, and in ghosts. At a higher stage, the spiritual principle is attributed to aspects of reality other than man, and all things are believed to possess spirits that are their effective and animating elements; it is the spirits, for example, that primitive men generally believe to cause sickness and control their destinies.

Of immediate interest is the classification of religions drawn from E.B. Tylor's animistic thesis. Ancestor worship, a common occurrence among less developed peoples, is obeisance to the spirits of the dead. Fetishism, the veneration of objects believed to have magical or supernatural potency, springs from the association of spirits with particular places or things and leads in turn to idolatry, in which the image is looked upon as the symbol of a spiritual being or deity. Totemism, a system of belief in which there is an association between particular groups of people and certain spirits that serve as guardians of those peoples, arises when the entire world is conceived as peopled by spiritual beings. At a still higher stage, polytheism, the interest in particular deities or spirits, disappears and is replaced by concern for a "species" deity who represents an entire class of similar spiritual realities. By a variety of possible means polytheism may evolve into monotheism, a belief in a supreme and unique deity. Tylor's theory of the nature of religions and the resultant classification were so logical, convincing, and comprehensive that for a number of years they remained virtually unchallenged.

The morphological classification of religions received more sophisticated expression from C.P. Tiele, a 19th-century Dutch scholar and an important pioneer in the scientific study of religion. His point of departure was a pair of distinctions made by the philosophers of religion A.K. Kuenen and W.D. Whitney. In the Hibbert Lectures for 1882, *National Religions and Universal Religions,* Kuenen had emphasized the difference between religions limited to a particular people and those that have taken root among many peoples and qualitatively aim at becoming universal. Whitney saw the most marked distinction among religions as being between race religions ("the collective product of the wisdom of a community") and individually founded religions. The first are the result of nature's unconscious working through long periods of time, and the latter are characterized by a high degree of ethical awareness. Tiele agreed strongly with Whitney in distinguishing between nature and ethical religions. Ethical religion, in Tiele's views, develops out of nature religion,

> But the substitution of ethical religions for nature-religions is, as a rule, the result of a revolution; or at least of an intentional reform.

Religions of nature and spiritualistic–ethical religions

Each of these categories (*i.e.*, nature or spiritualistic–ethical) may be further subdivided. At the earliest and lowest stage of man's spiritual development was polyzoic religion, about which there is no information but which is based on Tiele's theory that man must have regarded natural phenomena as endowed with life and superhuman magical power. The first known stage of the nature religions is called polydaemonistic (many spirits) magical religion, which is dominated by animism and characterized by a confused mythology, a firm faith in magic, and the pre-eminence of fear above other religious emotions. At a higher stage, but still in the type of nature religions, occurs therianthropic polytheism, referring to the form of the deities that are normally of mixed animal and human composition. The highest stage of nature religion is anthropomorphic polytheism, in which the deities appear in human form but have superhuman powers. These religions have some ethical elements, but their mythology portrays the deities as indulging in all sorts of shocking acts. None of the polytheistic religions, thus, was able to raise itself to a truly ethical point of view.

In their further division the ethical religions fall into two subcategories. First are the national nomistic (legal) religions that are particularistic, limited to the horizon of one people only and based upon a sacred law drawn from sacred books. Above them are the universalistic religions, qualitatively different in kind, aspiring to be accepted by all men, and based upon abstract principles and maxims. In both subtypes of ethical religion, doctrines and teachings are associated with the careers of distinct personalities who play important roles in their origin and formation. Tiele could find only three examples of this highest type of religion: Islām, Christianity, and Buddhism.

Influence of Nathan Soderblom

Tiele's classification enjoyed a great vogue and influenced many who came after him. Nathan Soderblom, a Swedish archbishop who devoted much energy to problems of classification, accepted the division of higher religions into two great groups but used a varied terminology that pointed to some of the characteristics of the two types of religion. In addition to natural religion and revealed religion, or religions of nature and religions of revelation, Soderblom spoke of culture religions and prophetic religions, of culture religions and founded religions, and of nature religions and historical religions. The highest expression of the first category is the "mysticism of infinity" that is characteristic of the higher aspects of Hindu and Buddhist religious experience. The apex of genuine prophetic religion is reached in the "mysticism of personality." All these distinctions mean the same thing, and all are indebted to Tiele's thought. In one important matter, however, Soderblom sharply disagreed with Tiele, for he could not accept the thesis of continuous development in the history of religion. In Soderblom's view, the line between nature religion and prophetic religion is a deep and unbridgeable chasm, a qualitative difference so enormous that one type could never evolve by natural historical processes into the other. Prophetic religion can be explained only as a radical and utterly new incursion into history. Soderblom, it must be remembered, was a churchman and theologian as well as a distinguished historian of religions, and there is without doubt an element of theological judgment influencing his stand on this matter. Soderblom was eager to defend the uniqueness of biblical religion, and he believed that his historical and scientific studies provided an objective basis for asserting, not only the uniqueness, but also the superiority of Christianity.

Tiele's enduring influence may also be seen in the classification of religions advanced by Mircea Eliade, a Romanian–American scholar who is one of the most prolific contemporary students of religion. Eliade, who in other respects might be considered among the phenomenologists of religion, is interested in uncovering the "structures" or "patterns" of religious life. The basic division of religions that Eliade recognizes is between traditional religions, in which primitive religions and the archaic cults of the ancient civilizations of Asia, Europe, and America are included, and historical religions. The meaning of the distinction is better revealed, however, in the terms cosmic religion and historical religion. In Eliade's estimation, all of traditional religion shares a common outlook upon the world. The chief element in this outlook is the deprecation of history and the rejection of profane, mundane time. Religiously, traditional man is not interested in the unique and specific, but rather exclusively in those things and actions that repeat and restore transcendental models. Only those things that participate in and reflect the eternal archetypes or the great pattern of original creation by which cosmos came out of chaos are real in the traditional outlook. The religious activities of traditional man are the recurring attempts to return to the beginning, to the Great Time, to trace again and renew the process by which the structure and order of the cosmos were established. Traditional religions may, therefore, find the sacred in any aspect of the world that links man to the archetypes of the time in the beginning; their typical mode of expression is in consequence repetitive. Further, their understanding of history, as far as they are concerned with it at all, is cyclical. The world and what happens in it are devalued, except as they show forth the eternal pattern of the original creation.

Traditional and historical religions

Modem, postarchaic, or historical religions (*e.g.*, Judaism, Christianity, Islām) show markedly other features. They tend to see a discontinuity between God and the world and to locate the sacred not in the cosmos but somewhere beyond it. Moreover, they hold to linear views of history, believing it to have a beginning and an end, with a definite goal as its climax and to be by nature unrepeatable. Thus, the historical religions are world affirming in the double sense of believing in the reality of the world and of believing that meaning for man is worked out in the historical process. By reason of these views, the historical religions alone have been monotheistic and exclusivist in their theologies. Although Eliade outstrips his predecessors in delineating the qualities of traditional religion in particular, much of his thought was anticipated in Soderblom's descriptions of nature religion and prophetic religion.

Phenomenological. The principles thus far discussed have all had reference to the classification of religions in the sense of establishing groupings among historical religious communities having certain elements in common. Attempts have been made to deal with entire religions or religious communities as the units to be classified. In recent times, however, the interest in classifying entire religions has markedly declined, partly because of an emerging interest in the phenomenology of religion.

urposes f the henomnology f religion

This new trend in studies, which dominates the field at the present, claims its origin in the Phenomenological philosophy of Edmund Husserl, a German Jewish–Lutheran scholar, and has found its greatest exponents in The Netherlands. Phenomenology of religion has at least two aspects. It is first of all an effort at devising a taxonomic (classificatory) scheme that will permit the comprehensive cataloging and classifying of religious phenomena across the lines of religious communities, but it is also a method that aims at revealing the self-interpretation by religious men of their own religious responses. Phenomenology of religion thus rejects any overview of religion that would interpret religion's development as a whole, confining itself rather to the phenomena and the unfolding of their meaning for religious men. Phenomenologists are especially vigorous in repudiating the evolutionary schemes of past scholars; whom they accuse of imposing arbitrary semiphilosophical concepts in their interpretation of the history of religion. Phenomenologists also have little interest in history for its own sake, except as a preliminary stage of material gathering for the hermeneutical (critical–interpretive) task that is to follow.

One of the earliest Dutch Phenomenologists, W. Brede Kristensen (1867–1953), spoke of his work as follows:

> Phenomenology of Religion attempts to understand religious phenomena by classifying them into groups . . . . we must group the phenomena according to characteristics which correspond as far as possible to the essential and typical elements of religion . . . .

The material with which Phenomenology is concerned is all the different types of religious thinking and action, ideas about divinity, and cultic acts. Kristensen's systematic organization of religious phenomena may be seen in the table of contents of his *Meaning of Religion* in which he divides his presentation of material into discussions of: (1) cosmology, which includes worship of nature in the form of sky and earth deities, animal worship, totemism, and animism; (2) anthropology, made up of a variety of considerations on the nature of man, his life, and his associations in society; (3) cultus, which involves consideration of sacred places, sacred times, and sacred images; and (4) cultic acts, such as prayer, oaths and curses, ordeals, and other acts. Kristensen was not concerned with the historical development, or the description of a particular religion, or even a series of religions, but rather with grouping the typical elements of the entire religious life, no matter in what community they might occur.

ignifiance f G. van er Leeuw

Probably the best known Phenomenologist is G. van der Leeuw. another Dutch scholar. In his ***Religion in Essence and Manifestation,*** van der Leeuw categorized the material of religious life under the following headings: (1) the object of religion, or that which evokes the religious response; (2) the subject of religion, in which there are three divisions: the sacred man, the sacred community, and the sacred within man, or the soul; (3) object and subject in their reciprocal operation both as regards outward reaction and inward action; (4) the world, ways to the world, and the goals of the world; and (5) forms, which must take into account religions and the founders of religions. Van der Leeuw was not interested in grouping religious communities as such, but rather in laying out the types of religious expression. He discussed distinct religions only because religion in the abstract has no existence. He classified religions according to 12 forms: (1) religions of remoteness and flight (ancient China and 18th-century deism); (2) religion of struggle (Zoroastrianism); (3) religion of repose, which has no specific historical form but is found in every religion in the form of mysticism; (4) religion of unrest or theism, which again has no specific form but is found in many religions; (5) dynamic of religions in relation to other religions (syncretism and missions); (6) dynamic of religions in terms of internal developments (revivals and reformations); (7) religion of strain and form, the first that van der Leeuw characterizes as one of the "great" forms of religion (Greece); (8) religion of infinity and of asceticism (Indian religions, but excluding Buddhism); (9) religion of nothingness and compassion (Buddhism); (10) religion of will and of obedience (Israel); (II) the religion of majesty and humility (Islām); and (12) the religion of love (Christianity). It is apparent that the above is not a classification of religions as organized systems. Categories 3, 4, 5, and 6 relate to elements found in many if not all historical religious communities, and the categories from 7 onward are not classifications but are attempts to characterize particular communities by short phrases that express what van der Leeuw considered to be their essential spirit. This classification leaves out of account altogether the "primitive" religions of less developed peoples.

Psychological and sociological types

Other principles. William James, the American philosopher and psychologist, in his well-known book ***The Varieties of Religious Experience,*** differentiated two types of religion according to the attitude of the individual toward life. There is the religion of healthy-mindedness, which minimizes or ignores the evil of existence, and the religion of morbid-mindedness, which considers evil as the very essence of life. Max Weber, a German sociologist, called attention to the differences between religions that express themselves primarily in mythopoetic ways and those that express themselves in rational forms. The distinction comes very close to that between traditional and historical religions, though its emphasis is somewhat different.

Nathan Soderblom, in his prolific scholarly career, devised several classifications other than the principal one discussed above. In his great work on primitive religions, ***Das Werden des Gottesglaubens*** ("Development of the Belief in God"), Soderblom divided religions into dynamistic, animistic, and theistic types according to the way primitive peoples apprehend the divine. In others of his works (***Einführung in die Religionsgeschichte,*** or "Introduction to the History of Religion," and ***Thieles Kompendium der Religionsgeschichte neu bearbeitet,*** or "Tiele's Compendium of the History of Religion Revised") he contended that Christianity is the central point of the entire history of religions and, therefore, classified religions according to the historical order in which they came into contact with Christianity. A somewhat similar approach was adopted by Albert Schweitzer, the French theologian, medical missionary, and Nobel laureate, in ***Christianity arid the Religions of the World,*** in which he grouped religions as rivals or nonrivals of Christianity. Still another scheme may be seen in Söderblom's Gifford Lectures, ***The Living God,*** in which religions were divided according to their doctrines of the relation between human and divine activity in the achievement of salvation. Thus, among higher religions there are those in which man alone is responsible for salvation (Buddhism), God alone is responsible (the Bhakti cults of India), or God and man cooperate (Christianity).

Attention may also be called to a recent classification of religions by the American sociologist, Robert Bellah. Having in mind the advances of the social sciences in their understanding of religions, Bellah offers a refurbished and more highly sophisticated version of an evolutionary scheme that he thinks to be the most satisfactory possible in the present state of scholarly knowledge. He views religion in its evolution as having passed through five stages, beginning with the primitive, and proceeding through the archaic, the historical, and the early modern to the modern stage. The religious complexes that emerge in each stage of this evolution have identifiable characteristics that Bellah studies and differentiates according to the following categories: symbol systems, religious actions, religious organizations, and social implications. Two basic concepts run through Bellah's classification, providing the instruments for the division of religions along the evolutionary scale. The first is that of the increasing complexity of symbolization as one moves from the bottom to the top of the scale, and the second is that of increasing freedom of personality and society from their environing circumstances or, in other words, the growing secularization of the religious field. Bellah's classification is important because of the wide discussion it has awakened among social scientists.

In addition to those already listed, one may find classifications based upon the content of religious ideas, the forms of religious teaching. the nature of cultus, the character of piety, the nature of the emotional involvement in religion, the character of the good toward which religions strive, the relations of religions to the state, to art, to science, to morality, and a host of others.

CONCLUSION

The classification of religions that will withstand all criticism and serve all the purposes of a general science of religions has not yet been devised. Each of the classifications presented above has been attacked for its inadequacies or distortions, yet each is useful in bringing to light certain aspects of religion. Even the crudest and most subjective classifications throw into relief various aspects of religious life and contribute in this way to the cause of understanding. At the present state of advance in this matter the most fruitful approach for a student of religion appears to be that of employing a number of diverse classifications of religions, each one for the insight that it may yield. Though each may have its shortcomings that must be recognized, each also offers a positive contribution to the store of knowledge and its systematization. The error that must be avoided is that of insisting upon the exclusive validity of any single taxonomic effort. To confine oneself to a single determined framework of thought about so rich and variegated a subject as religion is to risk the danger of missing much that is important. Classification should be viewed as a method and a tool only.

Criteria for making and judging classifications

Although a perfect classification lies at present beyond scholars' grasp, certain criteria may be suggested for building and judging classifications. These are both positive and negative in nature. First, it may be insisted that classifications should not be arbitrary, subjective, or provincial. A first principle of the scientific method is that it should strive for objectivity to the extent possible and that its findings should be capable of confirmation by other observers. Second, an acceptable classification should deal with the essential and typical in the religious life, not with the accidental and the unimportant. The contribution to understanding that a classification may make is in direct proportion to the penetration of the bases of religious life exhibited in its principles of division. A good classification must concern itself with the fundamentals of religion and with the most typical elements of the units it is seeking to order. Third, it may be held that a proper classification should be capable of presenting both that which is common to religious forms of a given type and that which is peculiar or unique to each member of the type. No classification can serve its proper purpose if it ignores the concrete historical individuality of religious manifestations in favour of that which is common to them all, nor can it be approved if it neglects to demonstrate the common factors that are the bases for the very distinction of types of religious experience, manifestations, and forms. Classification of religions involves both the systematic and the historical tasks of the general science of religion. Fourth, it is desirable in a classification that it demonstrate the dynamics of religious life both in the recognition that religions as living systems are constantly changing and in the effort to show, through the categories chosen, how it is possible for one religious form or manifestation to develop into another. Few errors have been more damaging to the understanding of religion than that of viewing religious systems as static and fixed, as, in effect, ahistorical. Adequate classifications should possess the flexibility to come to terms with the flexibility of religion itself. Fifth, a classification must solve the problem of what exactly it is that is to be classified. If the purpose is to develop types of religions as a whole, the questions of what constitutes a religion and what constitutes various individual religions must be asked. Since no historical manifestation of religion is known that has not exhibited an unvarying process of change, evolution, and development, these questions are far from easily solved. With such criteria in mind it should be possible continuously to construct classification schemes that illuminate man's religious history.

BIBLIOGRAPHY. Two monographs dealing specifically with the classification of religions, each of which offers a survey of previous classifications in addition to the author's own scheme, are: DUREN J.H. WARD; *The Classification of Religions: Different Methods, Their Advantages and Disadvantages* (1909); and FRED LOUIS PARRISH, *The Classification of Religions: Its Relation to the History of Religions* (1941), containing a full survey of classification schemes with brief characterizations of each and the best bibliographical guide for one who wishes to pursue the subject in depth. Other books useful for further study are as follows: P.D. CHANTEPIE de la SAUSSAYE, *Lehrbuch der Religionsgeschichte,* 2 vol. (1887–89; Eng. trans. of vol. 1, *Manual of the Science of Religion,* 1891), which includes some pages on classification problems at the beginning of vol. 1; C.P. TIELE, *Elements of the Science of Religion,* 2 vol. (1897–99), a classic work by an important scholar on this subject; and F. MAX MUELLER, *Introduction to the Science of Religion* (1873), another classic work. Of more recent origin is GUSTAV MENSCHING, *Die Religion: Erscheinungsformen, Strukturtypen und Lebensgesetze* (1959), a popular manual of the history of religions that includes a long section on classification problems.

(C.J.A.)

Religious Dress and Vestments

The meaning religious dress and vestments

Religious dress and vestments, broadly understood, include a wide range of attire, accoutrements, and markings used in religious rituals that may be corporate, domestic, or personal in nature. They comprise types of coverings all the way from the highly symbolic and ornamented eucharistic (Holy Communion) vestments of Eastern Orthodox Christianity to tattooing, scarification, or body painting of members of primitive (preliterate) societies. Some types of religious dress may be used to distinguish the priestly from the lay members of a religious group, or they may also be used to signify various orders or ranks within a priesthood. Some religious communities may require that religious personages (*e.g.*, priests, monks, nuns, shamans, priestesses, and others) garb themselves with appropriate types of religious dress at all times, whereas other religious communities may only request that religious dress be worn during rituals.

In theocratic societies, such as Judaism and Islām, religious sanctions govern what may and may not be worn by members of the community; and religious dress embraces not only what is worn by a prayer leader but also what is worn by his congregation outside as well as inside a place of worship. In many traditions, habits serve to identify monastic groups. Indeed, in the latter case, the function of religious dress is more akin to heraldry as a form of symbolic identification than to liturgy, with its ritualistic symbolic motifs.

In a more restricted sense, religious vestments articulate a liturgical language as part of a figurative idiom shared with other religious symbols—*e.g.*, icons (images), statues, drama, music, and ritual. According to the richness of the liturgical or ritual vocabulary employed, the more feasibly can a symbology of vesture be attempted. This is especially the case with Eastern Orthodoxy, whose predilection for symbolical theology has spread from sacraments to sacramentals and everything associated with worship, including dress. With allegory paramount in the Middle Ages, the Western Church could not escape attributing symbolical values to garments whose origin may have owed little to symbolism. From the liturgical writer Amalarius of Metz in the 9th century to the theologian Durandus of Saint-Pourçain in the 13th–14th century sacerdotal vestments, in particular the stole and the chasuble, were viewed as symbols and indeed operated as such in a way that still influences current usage. Thus, because the stole is a yoke around the neck of the priest and he should rejoice in his servitude, on donning or doffing it he kisses the emblem of his servile status.

The notion of dress as a substitute skin and, hence, as an acquired personality temporarily assumed has been widespread in primitive religion; such practices in shamanism have been widely observed in Arctic and Siberian regions. The use of a substitute skin in religious ritual is also explicit in the cultic actions of some advanced cultures, such as in the rite of the Aztec maize goddess Chicomecoátl. A virgin chosen to represent Chicomecoátl, after having danced for 24 hours, was then sacrificed and flayed; and the celebrant, dressed in her skin, re-enacted the same ritual dance to identify with the victim, who was viewed as the goddess.

Religious dress may also serve a memorial function, as in the case of the religious leaders (mullahs) of the Shi'ites (Muslim members of the party of 'Ali), whose black gowns allude to the sufferings of Husayn ('Ali's son by Fāṭimah, Muhammad's only surviving daughter), who was martyred at Karbalā', in modern Iraq, in AD 680. In the Eucharist, which is both a thanksgiving and a re-enactment of the sacrifice of Christ on Golgotha, the chasuble (outer garment) worn by the celebrant depicts scenes from the Passion on the orphrey, the name given to the elaborately embroidered strips stitched on the chasuble. The fringes on the Jewish prayer shawl witness to "the commandments of the Lord" in Numbers, chapter 15, and remind the worshipper that he has covenanted to observe them.

TYPES OF DRESS AND VESTMENTS IN WESTERN RELIGIONS

Judaism. Early sacerdotal dress. Jewish vesture is an amalgam of very ancient and extremely modern religious dress, Originally, sacerdotal dress was probably varied and complex, but, after the destruction of the Second Temple in AD 70 and the subsequent disappearance of the Temple offices, many garments associated with priestly functions passed into oblivion. Chief among these offices was that of the high priest. In addition to the usual Levitical garments (those of the priestly class), the high priest, while officiating, wore the me'il (mantle), the ephod (an upper garment), a breastplate, and a headdress. The *meʿil* was a sleeveless robe of purple the lower hem of which had a fringe of small gold bells alternating with pomegranate tassels in red, scarlet, purple, and violet. The ephod—an object of much controversy—probably consisted of a wide band of material with a belt to secure it to the body, and it was worn over the other priestly garments. Most important was the breastplate (hoshen), which was square in outline and probably served as a pouch in which the divinatory devices of Urim and Thummim were kept. Exodus, chapter 28, verse 15, specifies that it was to be woven of golden and linen threads dyed blue, purple, and scarlet. Because of its oracular function, it was called the "breastpiece of judgment." On the face of the breastplate were set 12 gems in four rows, symbolizing the 12 tribes of Israel. These stones were a sardius, a topaz, and a carbuncle in the first row; an emerald, a sapphire, and a diamond in the second; a jacinth, an agate, and an amethyst in the third; and a beryl, an onyx, and a jasper in the fourth. The identity, sequence, and objects of representation of these stones are matters of controversy. Worn over the ephod, the breastplate was slung from the shoulders of the wearer by golden attachments. On his head the high priest usually wore a mitzenfet (either a tiara or a turban), except on Yom Kippur ("Day of Atonement"), when he wore nothing but white linen garments upon entering the Holy of Holies (the inner sanctuary).

High priestly garments

Later religious dress. Later religious dress of Judaism after the fall of the Temple in AD 70 reflects usages that predate that event but were continued in Judaism at the synagogue. Included among such garments are *tefillin* (phylacteries) and tzitzit (fringes), which have certain features in common. The name phylacteries is sometimes thought to point to a prophylactic origin, but the term is actually a translation of the Hebrew word for "frontlets" (*ṭoṭafot*). Phylacteries are worn in obedience to the commandment found in Deuteronomy, chapter 11, verse 18, and Exodus, chapter 13, verses 9 and 16: "And you shall bind them [*i.e.*, the words of God] as a sign upon your hand, and they shall be as frontlets between your eyes." This implies that there should be two phylacteries: one to be worn on the arm, the other on the head. Both kinds consist of a small black box of hide containing a manuscript and are secured to the respective parts of the body by leather thongs. On the sides of the head *tefilla* is the Hebrew letter ש, the first letter of Shaddai (Almighty). Both boxes are secured by leather thongs. The practice can be dated at least as far back as the 3rd century BC. The knotted thongs indicate a prophylactic purpose—*i.e.*, to protect the wearer against demons. Likewise, the wearer of these objects was, for the prayer's duration, under the protection of the Almighty, whose name he bore. The importance of knots in Semitic magic is also alluded to in the Qur'ān (the Islāmic scripture).

The use of phylacteries and fringes

Something similar obtains in the case of the tzitzit (fringes), or "twisted cords." The wearing of fringes is in obedience to a commandment in Numbers, chapter 15, verses 38–40: "It shall be to you a tassel to look upon and remember all the commandments of the Lord, [and] to do them." The fringes were attached to the outer garment with no attempt at or reason for concealment. Later, because of persecution, they became an inner garment, enabling the wearer to observe the Law clandestinely. This garment, which is not entirely obsolete, is styled *arbaʿkanfot* ("four corners") in allusion to Deuteronomy, chapter 22, verse 12 ("you shall make yourself tassels on the four corners of your cloak with which you cover yourself"), although no literary reference to its use can be traced further back than the 14th century.

The tallith, or prayer shawl, has the four fringes also, but it is confined to synagogal use and, even there, is limited to the morning service, whereas the arba'kanfot is worn all day. Both silk and wool are used, but the woollen tallith is preferable, with white as its ground colour. In the 20th century the tallith is worn like a scarf and is sometimes pulled over the head to aid in concentrating during prayer. Formerly, however, it was always wrapped around the head. In orthodox Judaism, the head is invariably covered during worship, usually by a skullcap known as a yarmulka or *kappel.*

Because a Jewish male is not supposed to walk more than four cubits (six feet) with his head uncovered, a religious Jew will wear the skullcap clipped to his hair, and indeed he may wear it all day because he believes himself to be in the presence of God at all times.

The dress of rabbis never conformed to precise standards. Current practice approximates modern Genevan (Protestant) conventions (gown and bands). The Jewish Reform movement, which began in Germany, further emphasized the Protestant character of rabbinical dress, and Reform rabbis differ little in this respect from ministers of various Protestant churches. Both cantor (*ḥaz*zan) and rabbi now use the black gown and round black hat, which came into use during the 19th century.

Garments used on Yorn Kippur

On Yom Kippur, it was the custom for participants to wear a sargenes, or white garment, emphasizing that Yom Kippur was an occasion not only of repentance but also of grace, for which festal wear was appropriate. Emphasis on the atoning aspect of the occasion, however, led to the sargenes being interpreted as takhrikhim, or graveclothes, which are worn to aid the worshipper toward a mood of repentance, a practice also adopted by the hazzan on two other occasions and by the host at the seder (meal) on Passover (a feast celebrating the Exodus of the Hebrews from Egypt in the 13th century BC). Officiants at the Yom Kippur service still dress in white robes. Shrouds are normally of unadorned white linen, following the sumptuary ruling of the 1st-century-ADrabbi Gamaliel the Elder. To the shroud may be added the tallith used by the deceased, but with the fringes removed or cut, because the prescription governing their use applies only to the living. Both liturgical vesture and everyday clothing must conform to the Mosaic requirement that forbids the combination of linen and wool in the same garment (see also JUDAISM).

Christianity. In the pre-Constantinian church (before the early 4th century), no distinctive liturgical dress was worn, and the Eucharist (Holy Communion) was celebrated by priests whose dress did not differ from that worn by lay members of their congregations. Present liturgical vestments in Roman Catholic and Orthodox churches derive from a common origin—*i.e.*, the garments that were fashionable in the late Roman Empire. After the Schism of 1054, however, they each followed separate courses (see also CHRISTIANITY).

Roman Catholic religious dress. A distinction is made between the insignia of ecclesiastical and sacerdotal office in the hierarchy and the functionally and symbolically significant liturgical robes. After the barbarian invasions of the Roman Empire from the 4th century on, fashions in secular dress changed, and thus the clergy became distinct in matters of dress from the laity. Certain robes indicate a position in the hierarchy; others correspond to function and may be worn by the same individual at different times. The most important vestment among the insignia is the stole, the emblem of sacerdotal status, the origin of which is the ancient *pallium.* The stole originally was a draped garment, then a folded one with the appearance of a scarf, and, finally, in the 4th century, a scarf. As a symbol of jurisdiction in the Roman Empire, the supreme pontiff (the pope, or bishop of Rome) conferred it upon archbishops and, later, upon bishops, as emblematic of their sharing in the papal authority.

Liturgical garb

The distinctive garb of the liturgical celebrant is the chasuble, a vestment that goes back to the Roman *paenula.* The *paenula* also was the Orthodox equivalent of the chasuble, the *phelonion*, and perhaps also the cope (a long mantle-like vestment). In its primitive form the *paenula* was a cone-shaped dress with an opening at the apex to admit the head. Because ancient looms were not wide enough to make the complete garment, it was made in several parts sewn together with strips covering the seams. These strips, of contrasting material, developed into the orphrey (embroidery), on which much attention was later lavished. Next in the hierarchical order after the priesthood were the diaconate and subdiaconate, whose characteristic vestments were, respectively, the dalmatic (*dalmatica*), a loose-fitting robe with open sides and wide sleeves, and the tunic (*tunica*), a loose gown. A priest wore all three, one over another. Under these he wore the alb (a long white vestment), held round the waist by a girdle, and around the neck the amice (a square or oblong, white linen cloth), with the maniple (originally a handkerchief) on the left arm. Although the deacon used a stole, the subdeacon did not. In the formative period of liturgical dress, these practices were in the process of becoming normative. During the 9th to the 13th century the norms now familiar were established. The chasuble became an exclusively eucharistic garment; the cope, excluded from the Eucharist, became an all-purpose festive garment.

Next in importance to the chasuble is the cope, a garment not worn during the celebration of the mass but rather a processional vestment. It is worn by the celebrant for rites of a non-eucharistic character, such as the Asperges, a rite of sprinkling water on the faithful preceding the mass. The origins of the cope are not known for certain by liturgical scholars. According to one theory, it derives from the open-fronted *paenula,* just as the chasuble derives from the closed version of the same garment. (The subsequent wide divergence between the two vestments need not preclude a common origin.) Unlike the chasuble, the form of which has never stopped changing, the evolution of the cope was complete before the end of the Middle Ages. Cope chests, based on the quadrant of a circle and designed to preserve the embroidered surfaces by keeping the copes flat, were a common feature of medieval cathedrals. When it is worn, the two sides of the garment are held together by a morse (a metal clasp). The cope occupied an intermediate position between liturgical and nonliturgical vestments, the most important of which was the cassock, the normal dress of the priesthood outside church ceremonies. When engaged in religious ceremonies, the officiant would wear the liturgical vestments over his cassock.

The tiara, the papal diadem or crown apostolic, emerged in the early medieval period; and the mitre (the liturgical headdress of bishops and abbots), the most conspicuous of the episcopal insignia, began as a mark of favour accorded to certain bishops by the supreme pontiff at a somewhat later date.

Like the cope, the surplice (a white outer robe) entered liturgical usage in the Middle Ages as a late modification of the alb. By the 14th century its present role as a choral or processional garment was established. With the passage of time, the length of the garment grew progressively shorter.

Monastic garb

The surplice was also associated with the monastic orders, but vesture distinguished only the order and not the kind of order. Eremitical (hermitic) monasticism allowed no standard form of dress to develop, and only communal monasticism, beginning with the Rule of St. Benedict of Nursia in the 6th century, enabled standardization to become possible. Monastic dress included habit, girdle or belt, hood or cowl, and scapular (a long narrow cloth worn over the tunic). The salient characteristics of monastic dress have always been sobriety and conservatism. The orders proved even more retentive of archaic fashions than the hierarchy, and, in contrast to the deliberate splendour of ecclesiastical vestments, monastic dress was expressive of a renunciation of luxury. The contrast was functional in origin: the menial tasks of the monk related him sartorially to the peasant, whose humble avocations he often duplicated, rather than to the princes and prelates of the church, whose dress reflected the splendour of the ceremonies in which they engaged.

Because of the diversity of the monastic orders, only a summary account of their vesture may be given. The Benedictine mantle was black, fastened with a leather belt; but the Cistercians—reformed Benedictines—eschewed any dyed material and instead dressed in undyed woollen material, which w.ıs off-white in colour. In the course of time this became white, a tacit relaxation of the primitive austerity adopted as a protest against "luxury." Carthusians, a contemplative order founded in the 11th century, likewise wore white. In the 13th century the mendicant orders (friars) emerged. The Franciscans, founded by St. Francis of Assisi, first used a gray habit, which in the 15th century was exchanged for a brown one; in spite of this change they continued to be known as the Grey Friars. The Carmelites, an order founded in the 12th century, became known as White Friars. Dominicans, founded by St. Dominic from Spain, adhered from the beginning to a black robe over a white gown. Canons regular (communal religious persons living under vows), although ordained, lived like the orders under a rule, and the Augustinians (several orders following the Rule of St. Augustine) are styled Black Canons in contradistinction to the Premonstratensians, oı White Canons, an order founded by St. Norbert in the 12th century. Because the office (prescribed prayers) took up so much of a monk's time, his choir robes were almost as important as his day clothes. Surplices were worn in choir with an almuce over; this last was a lined shoulder cape designed to help the wearer resist the cold of medieval churches.

Nuns' costumes were similar to those of monks, the chief difference consisting in the replacement of the hood by a wimple (collar and bib) and head veil. Habits are white or black or mixed, and this remained unaltered till the 17th century, when the Sisters of St. Vincent de Paul introduced blue. This exception remained unique; nuns' habits retained a markedly medieval aspect until reformed by the second Vatican Council (1962–65).

The cassock has its origin in the barbarian *caracalla,* a robe favoured by the Roman emperor Bassianus (reigned 211–217), who came to be known as Caracalla because of the garment he habitually wore. Worn by the clergy as early as the 5th century, it became in time the standard day wear for prelates and priests, hierarchical rank being indicated by colour: bishops, archbishops, and other prelates wore purple; cardinals, red; the pope, white; and ordinary clergy, black (see also ROMAN CATHOLICISM).

Garb of priests, bishops, and monk

Eastern Orthodox religious dress. The Middle Ages also witnessed the evolution of Eastern Orthodox vestments into approximately their present form. The eucharistic garment corresponding to the chasuble was the *phelonion*, with variant forms in the Greek and Russian churches. The *sticharion,* which is held by the *zōnē*, or girdle, corresponds to the alb. The cuffs, or *epimanikia,* which fit over the *sticharion,* bear little or no resemblance to the maniple. The *epitrachēlion* is the Orthodox equivalent of the stole, but it hangs straight instead of being crossed over the chest, as is the case with the stole in Western churches. On the deacon, the *epitrachēlion* is pinned to the left shoulder and hangs in front and behind; with this exception, the deacon's vesture is identical with the priest's. The bishop wears an *omophorion*, whose shape and manner of wearing are closer to the original *pallium* than either the stole or the *epitrachēlion*. In place of the *phelonion*, since the 16th century, the bishop uses a dalmatic known as the *sakkos*. The *epigonation*, or rhombus-shaped portion of silk hanging to below the right knee, is common both to bishops and archimandrites (head abbots).

The monastic habit of the monk differs according to which of the three grades he occupies. The fully professed monk wears the great, or angelical, habit, which consists of the inner and outer rhasons, girdle, cowl (with veil), *analvos*, and *mandyas* (mantle). The inner rhason corresponds to the cassock and, like it, is used by the secular clergy. The outer rhason, a wide-sleeved garment, is black in the Greek Church but variable in colour in the Russian Church among the secular clergy (*i.e.*, those who minister in parishes). The *analvos* (shaped like the Western scapular, although historically unconnected with it) differentiates the full, or perfect, monk from the other grades, and its substance must be of animal, nonvegetable origin to remind the wearer constantly of death. The *mandyas* is the bishop's cloak (for non-eucharistic occasions), and in the Russian Church its use is granted to monks of the intermediate grade, although this license does not obtain in the Greek Church. In neither church may the *mandyas* or *analvos* be worn by monks of the lowest grade. Unlike Western orders, Orthodox monks dress only in black, but they share the same sartorial conservatism, their habits having remained unchanged in essentials from medieval times to the present (see also EASTERN ORTHODOXY).

Anglican and Lutheran liturgical vesture

Protestant religious dress. The Reformation of the 16th century varied in intensity from one country to another, and the fate of liturgical vesture suffered accordingly. With the rejection of the dogma of transubstantiation (the Roman Catholic teaching that in the Eucharist the substance of the bread and wine is changed into the body and blood of Christ, with the properties of the bread and wine remaining the same), the use of the mass garments might have been expected to be eliminated, but, wherever an altered eucharistic doctrine survived, an attenuated liturgical vesture contrived to survive with it. In the case of the Anglican and Lutheran churches, a paradoxical situation emerged whereby, in the latter, pre-Reformation practices (*e.g.*, use of crucifixes) survived alongside a Reformation theology, whereas, in Anglicanism, a Catholic theology survived along with a repudiation of Catholic rites. The Lutherans rejected the insignia of a celibate clergy but retained the chasuble for Communion services and the surplice and alb for other services.

Bishops in both Lutheran and Anglican communions retained the cope. The different editions of *The Book of Common Pmyer* (the Anglican liturgical book) attest to 16th-century reforms and the rising power of Puritanism, a 17th-century reform movement; the use of vestments declined in consequence. The cathedrals, however, maintained liturgical vestment standards to a certain degree, even when the last vestiges of liturgical propriety had been extinguished in the parishes in the 18th century. The cope became the High Church (liturgically oriented) vestment *par excellence,* worn by bishops not only processionally but even during Communion. Many views about the ceremonial revival of the 19th century have not in all respects been accurate; and followers of Edward Pusey, a leader of the Catholic revival known as the Oxford Movement, and ritualists sometimes blundered not from excess of archaeological zeal as has been commonly supposed but rather because they were inordinately influenced by their sociocultural environment. This may be less immediately obvious in the case of vesture than in architecture, but one result of overreacting was the loss, in the 19th century, of the customary dress of the clergy. The gown and cassock, as street attire, were allowed to fall into desuetude because in Puseyite views the gown was Genevan, whereas in reality it was the reverse. Another instance lay in the adoption of the (local) Roman biretta, introducing an Italian fashion even though adequate indigenous precedents were not lacking.

The gown, now inseparably associated in the popular mind with Genevan (Reformed) divines, was in fact opposed by these same divines in England and Scotland in the 17th century. In spite of this, standard vesture in Presbyterian churches is now the black gown and white linen bands over cassock and cincture, with the academic hood added for preaching services as a mark of learning appropriate to the pulpit, and a stole or scarf (see also PROTESTANTISM).

Moderrz changes in religious dress and vestments. With a change in emphasis, chiefly expressed in the episcopal use of the cope, Episcopalian usage in the first half of the 20th century differed little from Catholic rules except in Anglo-Catholicism, in which deliberate archaism imposed an adhesion to Baroque (17th to early 1Sth century) models, themselves superseded within Roman Catholicism. The Liturgical Movement of the 20th century has exercised an influence beyond the boundaries of the church in which it originated, and modern clerics of different denominations increasingly resemble one another sartorially because all have had recourse to the same sources of liturgical inspiration.

In Roman Catholicism, the formative period of religious dress was over before the Reformation, and Reformation influence was indirect—via the impetus supplied by the Counter-Reformation, which made Baroque its official art style. The emphasis on richness of material, excessive decoration, and preoccupation with surface set in motion a process of decline that was not arrested till the 20th century. The degeneration of the Gothic chasuble with its pointed folds into a stiff fiddle-backed, overembroidered vestment had begun as early as the 13th century with the practice of elevating the Host (sacrificial elements) in the mass. The elevation of the Host entailed the folding back on the celebrant's shoulders of the sides of the chasuble. The flexibility of the early chasuble permitted this, but, to facilitate the elevation, more and more material was removed from the sides until the garment became a caricature of its primitive form, distorted beyond recognition and its vestigial portions—dorsal (back) and pectoral (front)—came to be viewed simply as canvases for the display of virtuoso embroidery. Undergarments also became what is now viewed as effeminate with the addition of lace, and, although the Liturgical Movement began with a new theology of the Eucharist, its repercussions forced a decline of the Baroque style in dress.

The influence of the second Vatican Council

From the late Middle Ages to the 20th century, the history of religious dress in the Roman Catholic Church has been the history of its rubrical evolution: the regional variants of patristic (early church) and early medieval times were eliminated in the interest of ultramontanism (a theory that advocated a greater authority for the papacy), until the second Vatican Council reversed the process of eight centuries, again sanctioning regional divergences. Council rulings also simplified the use of the mitre and suppressed the use of the maniple altogether. Increased lay participation in the liturgy has led to an extension of lay religious dress in more than one communion. To lay offices such as the verger, who wears a gown over cassock, and chorister, who wears a surplice, Anglicans have added that of the lay reader, who vests in cassock and surplice, with a scarf as his ensign.

The upheavals of the 16th, 19th, and 20th centuries have not had much effect on Eastern Orthodox vesture, and the same canons (rules) prevail today in Orthodoxy as obtained prior to the fall of Constantinople in the 15th century. To ascribe this condition in Eastern Orthodoxy solely to the effects of cultural isolation would be an oversimplification. Suppression of vestments or their alteration is less likely to occur in a church in which such vestments have higher symbolic value attributed to them than in other traditions.

Islām. Islām attaches less importance to liturgical vestments than do most religions, but the social emphasis of the Islāmic faith finds expression in the universal application of the regulations governing dress; *e.g.*, all who enter the mosque remove their footwear, and all going on pilgrimage must wear the same habit, the ihrdm, and thus appear in the holy places in the guise of a beggar.

Because Islam recognizes no priesthood in a sense of a class sacramentally set apart, "clerical" functions are discharged by the *ʿulamāʾ*, or "the learned (in the Law)," whose insignia is the 'imdmah (a scarf or turban). The garb of the *ʿulamāʾ* exhibits geographical variations, but the *ʿimāmah* is found everywhere. Two broad regional distributions obtain, with Iraq as the area of confluence between the two. In the western part of the Muslim world, "clerical" dress has tended to become standardized according to the Azhar (Egyptian) pattern: a long, wide-sleeved gown (jubbah) reaching to the feet and buttoned halfway down its total length over a striped garment (caftan); and the headgear consists of a soft collapsible cap (*qalansūwah*) of red felt around which is wound a white muslin 'imdmah. In Syria a hard *ṭarbūsh* of the same red shade replaces the *qalansūwah.* Both the *qalansūwah* and the *ṭarbūsh* are provided with a blue tassel. The jubbah is usually a sober shade of blue, gray, or brown, and seldom black. Among the Sunnites—from Iraq eastward—the jubbah is worn in association with an *ʿabāʾ* (a long, full garment), traditionally of camel's hair and brown or black in colour. This is sometimes secured by a *ḥijām,* or cummerbund. In this second regional variant, the 'imdmah becomes a full turban replacing the cap, or fez. A green turban usually denotes a *sharīf*, or descendant of the Prophet Muhammad; and among the Shi'ites (the party of 'Ali) the entire "clerical garb" is black, as a symbol of mourning for the death of Husayn at Karbalā'.

The Ottoman Turks, as strict Sunnites, preferred turbans of other colours, which, elaborately wound, served to distinguish the wearer from a non-Muslim. On conquering Constantinople in 1453, they adopted the Byzantine cap and wound the turban around it in demonstration of conquest. The elaborately wound turbans of Persia and India also have a skullcap as a foundation for their folds. The art of winding a turban required no small degree of skill, the wearer fitting the cap over his knee and winding it in that position, whereafter the cap kept the folds in place. To the Prophet Muhammad is attributed the saying "What differentiates us [in appearance] from the polytheists is the turban." In India the turban has also been worn by non-Muslims, but the Muslim turban has remained distinguishable from the Hindu by the use of the skullcap as its foundation.

Religious dress **prohibitions**

For all Muslim males, whether Sunnite or Shi'ite, clerical or lay, the wearing of gold or silk is forbidden in consequence of a prescription (Hadith) of the Prophet, whereby the wearing of either was rendered "*ḥarām* [forbidden] to the males of my nation." Footwear must be removed on entering a mosque for fear of defiling the interior with ritually impure substances that may have adhered to the sole of the shoe. This rule applies also to entering a grave; thus, gravediggers and stonemasons must be unshod on such occasions. Because covering the head is a Near Eastern way of showing respect, a head covering should properly be worn in the mosque and even when praying outside the mosque.

When a Muslim purposes to visit the holy city of Mecca at the time of the major pilgrimage (hajj), he enters on a state of consecration and robes himself in two white seamless garments (*iḥrām*), which may not be exchanged for normal dress until he deconsecrates himself after the conclusion of the pilgrimage ceremonies. To these two garments women may add a veil.

Many of the mystical dervish orders (*ṭuruq*) wear distinctive robes, frequently with hierarchical differences. In Turkey, headstones are carved in the shape of the headdress distinctive to the order to which the deceased belonged and are tinctured in the appropriate colours. Particularly interesting are the ceremonial robes of the Mawlawiyah order (popularly known in the West as the Whirling or Dancing Dervishes), in which the symbolism of the robes is central to the mysteries of the order. The dervishes wear over all other garments a black robe (*khirqah*), which symbolizes the grave, and the tall camel's hair hat (sikke) represent3 the headstone. Underneath are the white "dancing" robes consisting of a very wide, pleated frock (*tannūr*), over which fits a short jacket (*destegül*). On arising to participate in the ritual dance, the dervish casts off the blackness of the grave and appears radiant in the white shroud of resurrection. The head of the order wears a green scarf of office wound around the base of his sikke.

For all Muslims of whatever sect the standard graveclothes are the threefold linen shroud, or kafan: the izdr, or lower garment; the *ridāʾ*, or upper garment; and the *lifāfah*, or overall shroud. Martyrs, however, are buried in the clothes in which they die, without their bodies or their garments being washed, because the blood and the dirt are viewed as evidences of their state of glory (see also ISLAM).

TYPES OF DRESS AND VESTMENTS IN EASTERN RELIGIONS

Indian religions. The distinction between ordinary dress and religious dress is difficult to delineate in India because the ordinary members of the various socioreligious groups may often be distinguished by their costumes. For example, Parsi (Zoroastrian) women wear the *sārī* (robe) on the right shoulder, not the left.

Hindu men frequently wear short coats (*angarkhā*), and the women wear a long scarf, or robe (sari), whereas typical Muslim attire for men and women is a long white cotton shirt (kurtah) and trousers (pd'ijamah). Muslim women also wear a veil called the burqah, which not only hides the face but also envelops the entire body. Traditional Sikh (a religion combining Hindu and Muslim elements) dress is an ordinary kurtah and cotton trousers, covered by a long hanging coat (choghah). The male Sikh is recognized especially by his practice of wearing his hair and beard uncut, the former being covered by a particularly large turban and the latter often restrained by a net.

Hindu religious garments

The Brahmin (Hindu priest) is distinguished primarily by the sacred thread ʿ*upavīta*), which is bestowed on him during his boyhood investiture and worn diagonally across the body, over the left shoulder, at all times. During the water offering to saints, it is worn suspended around the neck and, during ancestor rites, over the right shoulder. Devotees may also wear a tonsure that leaves a tuft of hair longer than the rest (*śikhā*). The *pravrajyā* ("going forth") associated with some *Upaniṣads* (Hindu philosophical treatises) involved a ritual rejection not only of homelife but also of the upavita and *śikhā*. Ascetics usually wear the ordinary loincloth, or dhoti, for meditation or yoga (a physical and psychological meditation system), but there is also a tradition of naked asceticism. A teacher (*swāmī*) traditionally wears a yellow robe (see also HINDUISM; SIKHISM; ZOROASTRIANISM AND PARSIISM).

Buddhism. Buddhism became more widespread in Asia than other ascetic and meditational movements, partly because of the strong organization of its monastic communities (sarigha). One of the main outward signs of the sarigha, along with the tonsure and the begging bowl, has always been the monk's robe; "taking the robe" became a regular expression for entering the sarigha. The sarigha was organized in accordance with the traditional code of discipline (vinaya), which includes the basic rules regarding robes in all Buddhist countries. These rules are all linked to the authority of the Buddha himself, but at the same time they allow considerable flexibility to cater to changing circumstances.

The Buddhist robe

The robe (civara) illustrates two main types of religious action, each symbolized by the character of the materials used. First, the wearing of "cast-off rags" was one of the "four resources" of a monk, being an exercise in ascetic humility similar to the other three, which are living on alms, dwelling at the foot of a tree, and using only cow's urine as medicine. The use of rags was later formalized into making the robes out of separate strips or pieces of cloth, but the rough patchwork tradition was carried over into China, where hermit monks in modern times wore robes made of old rags. In Japan, robes have been preserved with designs imitating the effect of patchwork, and robes sewn from square pieces of cloth were nicknamed "paddy-field robe" (*densōe*). This latter term is reminiscent of an old Indian Buddhist tradition according to which the Buddha instructed his disciple Ānanda to provide robes for the monks made like a field in Magadha (in India). which was laid out in "strips, lines, embankments, and squares." In general, whatever the degree of formalization, the rag motif ensured that the robe was to be "suitable for recluses and not coveted by opponents." The second type of religious action associated with the robe stemmed from the permission granted to monks to receive robes or the materials for making them from the laity. This meant that the laity "became joyful, elated, thinking: 'Now we will give gifts, we will work merit. . .' " (*Mahāvagga* VIII, 1, 36). Thus, the presentation of materials for robes was thought to have the same beneficial karmic effects (toward a better birth in the future) as the offering of food. The practice meant that various good materials were offered as well as rags, and in due course six types were allowed on the authority of the Buddha, namely, linen, cotton, silk, wool, coarse hempen cloth, and canvas.

There are three types of civara (*i.e.*, tricivara): the inner robe (Pāli, antaravdsaka), made of five strips of cloth; the outer robe (*uttarāsaṅga*), made of seven strips; and the great robe, or cloak (*saṃghāṭi*), made of nine, 15, or 25 strips.

In order to avoid the primary colours, Buddhist robes are of mixed colours, such as orange or brown. Another common term for the robe, *kasāya*, originally referred to the colour saffron, though this meaning is lost in the Chinese and Japanese derivatives, *chia-sa* and kesa. The robe is normally hung from the left shoulder, leaving the right shoulder bare, though some ancient texts speak of disciples arranging their robes on the right shoulder before approaching the Buddha with a question. In cooler climates, both shoulders may be covered with an inner robe, and the outer robe is hung from the left shoulder, as ın China.

Sandals are allowed if they are simple and have one lining only, or they may have many linings if they are cast-off sandals. The rules for nuns' robes are similar, but they also wear a belt and skirt. Some special vestments are worn by Tibetan Buddhists, including various hats characteristic of the different sects (see also BUDDHISM).

Chinese religions. Court dress, sacrificial dress, and ordinary dress were all influenced in ancient China by the Confucian-inspired civil religion. The classical text for the Confucian ideal of deportment and dress is Book X of the Analects, in which the emphasis is on propriety in every detail, whether at home or in affairs of state or ceremony. The undergarment, for example, was normally cut wide at the bottom and narrow at the top to save cloth, but it had to be made full width throughout for court and sacrificial purposes.

The Influence of the Confucian ideal of propriety

Confucius was also said to have insisted on the primary, or "correct," colours — blue, yellow, red, white, and black — rather than "intermediate" colours, such as purple or puce, and to have avoided red for himself because it was more appropriate for women.

Garments used in sacrifices to former kings and dukes were prepared from silk grown in a special silkworm house. According to the "Doctrine of the Mean," the clothes used by ordinary people at sacrifices were "their richest dresses." The fully developed Imperial costume for sacrifices was a broad-sleeved jacket and a pleated apron around the waist. Decorative symbols represented the universe in microcosm and thus the universal sovereignty of the emperor.

Funeral dress was generally white, although the *Shu Ching* ("Classic of History") refers to a funeral at which those who officiated wore hempen caps and variously coloured skirts. According to the I *Li*, mourning dress consists of "an untrimmed sackcloth coat and skirt, fillets of the female nettle hemp, a staff, a twisted girdle, a hat whose hat string is of cord, and rush shoes." For Mencius, a 4th–3rd-century-BC philosopher, the wearing of a coarse cloth mourning garment was an important aspect of traditional filial piety.

Buddhist robes in China followed Indian tradition fairly closely, though they were noted under the T'ang dynasty (AD 618–907) for being black in colour. Taoist robes, in contrast, were yellow. That this is an old tradition may be seen from the example of the 2nd-century-AD Yellow Turban movement, in which the missionaries and priests wore yellow robes and the followers yellow headdresses (see also CHINESE RELIGION).

Japanese religions. The priestly robes of Shintō are an example of the way in which rather normal garments of a formative age became the specialized religious vestments of later times.

Shintō religious garments

They consist of an ankle-length divided skirt (hakama) in white, light blue, or purple, depending on rank; a kimono in white, symbolizing purity, and of which there are various types; and a large-sleeved outer robe of various colours that is frequently a kariginu, or hunting garment, as used in the Heian period (794–1185). The headgear is a rounded black hat (eboshi). The more elaborate "crown" (kammuri) has a flat base, a protuberance rising forward from the back of the head, and a flat band curving down to the rear. Within a shrine, stiff white socks with a divided toe (*i.e.*, tabi) are worn, and, when proceeding to or from a shrine, officiants wear special black lacquered clogs (asagutsu) of paulownia wood. Shintō priests carry a flat, slightly tapered wooden mace (shaku), which symbolizes their office but otherwise has no precisely agreed upon significance. The dress of *miko* (girl attendants at shrines), whose main function is ceremonial dance, also typically consists of a divided skirt and a white kimono. They carry a fan of cypress wood. Young male parishioners bearing a portable shrine through the streets may wear a kimono marked with the crest of the shrine and a simple eboshi.

Buddhist robes continued the general Buddhist tradition, but of particular interest are the ornate ceremonial robes of high-ranking monks, especially in the Shingon and Nichirenite sects; the white robes worn by devotees in the syncretistic Shugen-db tradition (famous for its yamabushi, or mountain priests) during lustrations and similar rituals, symbolizing purity, as in Shintō; and the deep, inverted bowl-shaped hats of woven straw (*ajiro*-gasa) worn by Zen monks during begging tours.

Many new religions in Japan have carefully manufactured ceremonial vestments based on Shinto or Buddhist models or of mixed or original design. A common feature is the use of fairly simple uniform clothing for all believers during dedicated labour, mass rallies, or acts of worship. In Tenri-kyō, a religion founded in the 19th century by Nakayama Miki, the name of the religion figures prominently on the back of the garment, and, in Nichiren movements, the central symbol *namu Myōhō renge-kyō* ("Homage to the Lotus of the Good Law") may be displayed on a stole hanging from the left shoulder (see also JAPANESE RELIGION).

BIBLIOGRAPHY. HILAIRE and MEYER HILER, *A* Bibliography of Costume (1939, reprinted 1967), furnishes the widest bibliographical account. In the field of Christian dress the best recent works are HERBERT NORRIS, Church *Vestments:* Their Origin and Development (1949), a detailed and reliable historical coverage; and CYRIL E. POCKNEE, Liturgical Vesture: *Its* Origins and *Development* (1960), a succinct, well-illustrated account. All previous research was superseded by JOSEPH BRAUN, Die liturgische Gewandung im *Occident und* Orient...(1907), a publication that marked a turning point in liturgiological studies. JOHN B. O'CONNELL, The *Celebration* of Mass, new ed. (1956), a handbook intended for the priest, is a study of the rubrics and is supplemented by ADRIAN FORTESCUE's invaluable Ceremonies of the *Roman* Rite Described, 12th rev. ed. (1962), recognized as the standard work on Roman Catholic ritual, directing which garments should be used in the appropriate circumstances. Concerning Orthodox vesture, N.F. ROBINSON, Monasticism in the Orthodox Churches (1916, reprinted 1971); and Алексей **Николаевич Свирин,** *Древнерусское шитье* (1963), are descriptive rather than historical or analytical in methodology. Protestant vesture has not attracted the attention of liturgists, but PERCY DEARMER, The Parson's *Handbook*, 13th rev. ed. (1965); and

CHARLES WALKER, ***The Ritual Reason Why,*** new ed. (1931), treat of the subject from a High Anglican standpoint. On religious dress in Judaism, ***The Universal Jewish Encyclopaedia,*** 10 vol. (1939–43); and WILLIAM OESTERLEY and G.H. BOX, ***The Religion and Worship of the Synagogue*** (1907), are useful. On Islāmic dress, nothing has appeared in European languages, but in Persian there is MOHAMMAD BAQIR OL-MAJLISI, *Helyet ol-motaqqīn* (1952). On Far Eastern Religions there are a few relevant works. JEAN HERBERT, ***Shintô*** (1967), is the standard study of the subject and incorporates drawings of priestly attire as does S. ONO, ***Shinto: The Kami Way*** (1960). On Buddhist religious dress and vestments, ***The Book of the Discipline,*** vol. *4*, trans. by I.B. HORNER (1951), gives the early Buddhist traditions about "the robe." HOLMES WELCH, ***The Practice of Chinese Buddhism,*** vol. 1, ***1900–1950*** (1967), contains much incidental material about monastic vestments, with photographs.

Religious Education

Religious education, the teaching or inculcation of spiritual, cultic, and moral precepts and practices, has been of significance to human culture in various ways. Where religion has been the primary shaper of a particular culture (*e.g.*, Hinduism of Indian culture), education in that religion has been essential to the well-being of the culture.

NATURE AND SIGNIFICANCE

Universal religious traditions—such as Buddhism and Christianity—have played significant roles as bridges between cultures. Where a particular religion is but one among others in a culture, religious education is important chiefly in a narrower sense; *i.e.*, for the survival of that particular religion. The significance of religious education to personal development is much debated in modern society, but there can be little doubt that in most societies of the past it has been important in instilling and illustrating the fundamental life models.

Religious education is concerned with morality, cultic practices, world views, myth, and religious experience. It is crucial in the process of socialization in most cultures. In those societies in which an idea of the sacred suffuses all life, all education may be said to be religious, and even the learning of such skills as hunting or planting has religious connotations. In traditional societies, in which a distinction is made between the sacred and the profane, and where formalized education develops, that education is likely to be dominated by religious ends.

Relationship between initiates and noninitiates

The development of a distinction between initiates and noninitiates in the religious community has a number of implications for religious education. Potential initiates must be properly identified and trained so that they may become full-fledged members of the community and may, in turn, play the role of initiators. There is also the question of stance toward noninitiates. Where status is determined solely by heredity that stance is likely to be one of rejection. But where status is dependent upon some criterion other than heredity the relationship to noninitiates is potentially a more positive one. Converts may in fact be openly sought—as in Buddhism and Christianity. Such a procedure will likely entail the elaboration and systematization of teachings and techniques designed to win converts, to educate them in the ways of the faith, and to meet the challenges of nonbelievers.

Functional differentiation within the religious community also has had considerable significance for religious education. Specialists have assumed the central role in religious education, both in shaping the content and techniques and in the actual process of preparing the initiate and educating the faithful. Education within Buddhism, for example, has been almost entirely carried on by monks. There developed in Judaism, on the other hand, a nonpriestly group (rabbis) whose primary function was study, interpretation, and teaching of the Torah.

TYPES OF RELIGIOUS EDUCATION

Religious education centred on the study of sacred scriptures. Many systems of religious education concentrate primarily upon the memorization or study of sacred scriptures or both. The importance of scriptural study in the Vedic (from the scriptures called Vedas) tradition of India is suggested, for instance, in the affirmation that "whatever may be the toils here between heaven and earth, the study of the scriptures is their last stage, their goal, . . ." In the West, scriptural tradition has roots in ancient Israel, from which emerged the Hebrew Bible (Old Testament). For more than 2,000 years this literature has constituted the core content of Jewish education. Christianity added the New Testament to this literature, and the resulting Christian Bible has been the foundation of religious education in that tradition. In some instances, in fact, the Bible has been almost the sole content of religious education. Likewise in Islām, the Qur'ān (sacred scripture) has constituted the core content of religious education in mosque schools.

Elaboration upon sacred scripture has occurred for purposes of explanation, summary, propaganda, and education. To the Hebrew Bible, for example, the Jewish tradition added the Talmud (interpretations of the Torah, or Law), which became the guide to content, method, and goal in Jewish education. Very early in the history of Christianity, creeds and confessions were developed for purposes of summarizing and explaining the faith. Some early Christians prepared special materials (catechisms) for use in the religious education of converts. In Isliim there emerged what is called *Ḥadīth*, that is, authoritative sayings of the prophet concerning revealed matters. These were often expounded in the mosque in connection with tha instruction of the faithful.

The importance of oral tradition

Preliterate peoples, of necessity, depended upon memorization for conveying culture from one generation to the next. Oral traditions also played a crucial role in the formation of sacred scriptures. Memorization of scriptures has been fundamental in certain forms of religious education. Phenomenal feats of memorization generally have been honoured as signs of piety and learning.

Religious education centred on theological issues. Most scripturally based traditions have valued analytical study and discussion as a logical step beyond memorization. Such analysis has tended to produce particular methods and schools of scriptural interpretation. Religious education reached a sophisticated intellectual level in the medieval schools of Europe that focussed attention on discussions of theological issues. These institutions utilized the dialectical method: the presentation of opposing points of view with the conviction that truth would emerge from the skillful use of logic and superior appeal to authority, especially scriptural authority. Religious education focussed upon detached discussions of profound religious-philosophical questions is evident in the Hindu *Upaniṣads* (composed c. 9th–5th century BC).

The role of the Catechetical school of Alexandria

Religious education centred on progressing from "lower" to "higher" sciences. Exposure to the thought forms and educational patterns of alien cultures has constituted a special challenge to religious traditions. An effort may be made to adapt the educational ideologies and methods of the alien culture to the ends of the religious tradition, as Buddhism did with indigenous patterns in China, and as Christianity did with Greek philosophy and practice. This process of adaptation is likely to work both ways. For example, the Christian Catechetical school of Alexandria, Egypt, in the 2nd and 3rd centuries, developed a kind of religious education that progressed from the "lower sciences" (mathematics, music, literature, biological sciences, philosophy, etc.) to the "higher (sacred or theological) sciences"—*i.e.*, those available only through study of the Christian Scriptures.

Religious education centred on experience. The ultimate goal of much text-centred religious education is some type of experience—such as union (with Christ, or God, or the Ineffable), deliverance (from illusion, temporality, etc.), or enlightenment. Some traditions in religious education, however, have more directly stressed experience and have given relatively less attention to sacred texts. Perhaps the most notable in this regard is Zen Buddhism (literally, meditation Buddhism) in which word-centred methods play a subordinate role in the achievement of enlightenment. Correct meditation proceeds through increasing withdrawal from surface realities and intellection to an ineffable experience. This meditation (*zazen*) is facilitated by a cryptic style of teaching that includes directed concentration upon enigmatic sayings (koans). The master, or *roshi* (venerated teacher), does not explain anything in a rational fashion, for it is contrary to his approach to appeal to the intellect.

Some traditions that stress experience speak in terms of stages—some of which may be more akin to psychophysical states than to levels of conceptual knowledge, such as the stages of mysticism: preparation, purgation, illumination, and union. Many religious traditions specifically require the individual to undergo certain physical disciplines to attain some religious knowledge. Fasting is a common technique. The controlled use of chemical substances, such as the Vedic *soma* or the peyote of certain American Indians, is another example of the attempt to facilitate religious knowledge through some prescribed course of action (see also PHARMACOLOGICAL CULTS).

The role of the teacher or master is especially significant in those traditions that emphasize progression in personal experience. Formalization and institutionalization tend to occur around especially adept masters. Since the desired experience is intensely personal in nature, however, the teacher cannot produce it. He is but a skilled midwife.

Religious education centred on myth and ritual. Myth and ritual perform important educational functions for common men in most religious traditions. By story myth communicates and evokes an experience of sacred reality that cannot be expressed by a simple, straightforward prose account. Similarly, ritual may be a method of communicating, hence, of educating. Many forms of expression may be used in ritual practice, including music, dance, drama, drawing, sculpture, and even architecture. Such forms may also be used as aids in formal instruction.

Religious education relies considerably on symbolic forms as teaching devices. Myth and ritual employ symbols that suggest familiar images and concepts. Thus, in Christianity, Baptism can suggest images of death and rebirth, washing and purification, the water that sustains life (drinking water), the water of eternal life, life-giving rain, etc. Through the use of such symbols religious education provides for a deepening understanding of a tradition based on the expansion of individual experience.

The use of verbal and nonverbal methods

Among the rites of passage commonly practiced by preliterate peoples, the rites associated with puberty, which are usually also initiatory rites, combine the verbal and the nonverbal in an especially significant way. "Explanations," chiefly of a mythological character, set the stage for these rites and give them meaning. The rites themselves may be highly dramatic and, in some instances, even painful, involving ordeals of an extraordinary sort. Upon passing through the experience the young man (or woman) is generally more fully exposed to rituals and teachings associated with sacred power and meaning.

Seasonal festivals and holy days, which characterize most religious traditions, are generally both celebrative and educative in nature. For example, the annual winter festival (chalako) among the Zuni Indians of the southwestern United States is an elaborate affair that conveys in dramatic form the basic tribal world view. Ritual and teaching are brought together in a potentially evocative way in the Jewish festival of Passover, which recalls to the child, both through his senses (taste especially) and his intellect, a crucial episode—the Exodus from Egypt in the 13th century BC—in the life of the people with which he is identified.

THE DEVELOPMENT OF RELIGIOUS EDUCATION IN THE RELIGIONS OF THE WORLD

Primitive religions Among primitive or preliterate peoples all activities that relate to survival are believed to have their origins with the gods. All education is related in some way to this sacred context and hence is religious. The world view is communicated through myth, ritual, and other ways. Its importance to group survival is made evident by various devices. In initiation the individual may be told what calamities will befall the group if certain taboos are violated. Every activity is communicated to children by means that tend to emphasize its proper performance and to insure its continuation.

Use of myth and ritual in primitive religion

Perhaps the best known aspects of primitive religions are their creation rites and seasonal festivals, often associated with fertility cults. Through these dramatic and colourful ceremonies, significant episodes in the religiocultural history of the tribe or people are re-enacted. These have both religious and educational value. The young may observe or participate in them. They may also imitate these adult religious activities in their own play activities. Seasonal festivals often utilize or cooperate with events in nature to communicate and reinforce the individual's understanding of the natural cycle of death and rebirth that is basic to his survival and his religious consciousness.

Rites of passage may also perform a religious educational function. In initiation, for example, the sacred secrets of the group are disclosed. The secret nature of this rite may generate curiosity, fear, and a desire for acceptance. all of which heighten the impact of the material presented. As knowledge of sacred things is presented, the novice may be told about exploits and travails of the gods and cultural heroes who provided this knowledge. Thus at the same time that respect and veneration for the sacred objects are inculcated, exemplary heroes may be held up as models of good behaviour and antiheroes may be portrayed to illustrate behaviour to be avoided. An initiatory rite of the aborigines of Arnhem Land in Australia illustrates the techniques used to educate in a primitive setting. The novices are shown the animal dances, and the older men explain their meaning. The novices are also shown the sacred trumpet.

> Each initiate is asked to try to blow the trumpet. Then the old men command all of them to "respect their fathers and mothers," "never to tell lies," "not to run after women who do not belong to them," "not to divulge any of the secrets of the men to the women, men who belong to a lower division of the association, or uninitiated boys," and all in all to live up to the tribal code.

Eventually the young men are circumcised. Then their wounds are steamed over a fire while they are instructed to avoid obscenity and adultery and admonished always to tell the truth.

Graded initiations are common among primitive people. The youth of the tribe may be assembled into "bush schools," where they are progressively initiated into higher levels of secret knowledge. Regular instructions in the form of lectures or memorized dialogues may be given. Advancement often is based on accomplishment, and recognizable "teaching" takes place. A tutor–tutee relationship may be fostered in which one member of the tribe or clan will have a special responsibility for a particular youth. "Wise men" may educate the group in the moral aspects of their religion through communication of "campfire lore" or through the recitation of proverbs. Simple stories for children serve to inculcate moral virtues and common values.

Though religious education among primitives can correctly be classed as being conservative in nature, this is not to say that such systems are necessarily repressive to creativity and innovation.

Religions of ancient peoples and civilizations. Religion was indistinguishable from the state in Egyptian, Mesopotamian, Aztec, and Mayan civilizations, and the cult of their nation-churches was geared to the perpetuation of the cosmic order of nature and society. This state cult itself was an impressive educational device, as can be noted in the annual new year's festival of cosmic renewal in Mesopotamia at which the great epic of creation (*Enuma elish*) was recited in its entirety and much of it was acted out, or in the Egyptian so-called Mystery Play of Succession marking the transition from one Egyptian king to another.

Education under the concepts of sacred kingship

These cultures were the products of significant developments in the technology of agriculture. There developed around this technology a pattern known today as sacred or divine kingship in which the king figure embodied the essential aspects of the civilization by combining in one functionary a responsibility for agriculture, the cosmos, and the political survival of the state. Effective educational transmission was essential to the ongoing life of these civilizations. This education was usually conducted by priests, and the schools were thus most often associated with temples. In the temple schools of Babylonia, for example, youths were taught to read and write the complicated script (cuneiform) and more advanced students pursued the higher branches of priestly learning; *i.e.*, the myths, the arts of divination, the liturgies and incantations, and other aspects of religious knowledge. It is likely that young men selected for official civic posts also received their education in temple schools. Whether designed for the priesthood or for more mundane pursuits, all education was of cosmic import in these ancient civilizations, and all was essential to the survival of the state.

In Egypt the sons of the priests went to the House of Books or to the school located in the "house of life" (temple) of some deity. The sons of nobility and of royalty also attended such schools to learn how to fulfill the religious duties of their particular offices. At lower levels, boys were educated in the many scribal duties that would make them a part of the functioning state. At a still lower level were the "trade schools," but even these instilled moral precepts and had their place in the overall schema of the religious destiny of the state. Life in these schools was not likely to be easy. Precept was not only drummed into the boys' ears but the master's principle was, "A boy's ears are on his back, and he hearkens when he is beaten."

Religious education in ancient American civilizations

In ancient Mexico systematic education took place in two types of institutions, both of which were essential to the religious functions of the state. Instruction in necessary priestly duties was given in *calmecac* schools where little boys chanted strophes from a ritualistic chant while sitting, according to the archaeologist George Vaillant (1901–45), with "their little legs and faces lacerated by maguey spines, their bodies thin from fasts and penance and their eyes dulled by the monotony of self-denial, . . ." The *telpuchalli* (house of youth) schools, where young men were trained in citizenship and the martial arts, offered no less serious an image. There the youths were prepared for ritual combat between the "sons of light" and the "sons of darkness," the object of which was to capture victims for the blood sacrifice that was believed to be required in order that the sun god might continue in his appointed rounds. Other schools trained women to be priestesses.

Glyph systems, alphabets, and the art of writing were introduced in the ancient civilizations discussed above, and this had important implications for religious education. Copying and memorization of texts became important methods in education. Rites and beliefs could be standardized and communicated through means other than human voice and memory, and cultural wisdom could be more surely preserved.

Though the sacred state produced a massive technoreligious culture, it also sowed the seeds of secularization. Class and caste distinctions became determinative of the type of education an individual might receive. Formal education increasingly prepared specialists to fill set roles. Among the increasingly intellectualized priestly classes, speculative and theological reflection became commonplace, but the common man retained the older forms of religion. The great cosmic rites of the sacred king became spectacles to be observed rather than rituals to be joined.

Religions of the East. *Hinduism.* The goal of traditional Hindu education is twofold: to prepare one to do his duty in this life, and to enable one to achieve release from the illusions of this life through realization of the identity of *Ātman* (individual soul) and Brahman (universal soul). The teacher, or guru, is the pivot of the traditional educational system designed to achieve these ends. The importance attached to proper religious education is evident in the fact that the category "student" is the first of the four stages of life according to orthodox Hindu doctrine, the others being the family supporter, the forest hermit, and the religious recluse. Ideally, this student stage is to be experienced by all potentially "twice-born" Hindus; that is, all members of the three upper classes, or castes (Brahmin, Kṣatriya, and Vaiśya, or priestly, warrior, and merchant), who alone may be initiated into the Hindu community. In actuality, Vedic education became the prerogative chiefly of the Brahmin caste and, in all likelihood, of only a minority of that caste in most periods of Indian history.

The role of the guru, or teacher

According to Vedic standards, the Brahmin youth is ready for initiation into the student stage at the age of eight. The initiation ceremony symbolizes the "second birth" of the boy. The initiate is invested with the sacred thread, which he wears for the remainder of his life; his hair is cut in a certain fashion; his chosen guru formally assumes responsibility for his welfare; and the boy, by ritual and vow, puts himself under the care of the guru. This initiation ceremony is not technically a puberty rite; the boy is not admitted to adulthood but to a crucial stage of study in preparation for the adult roles he later assumes. Girls have seldom been encouraged in formal Vedic study and, indeed, were sometimes even prohibited from such study.

The principal duties of the student are study of the Vedas, service to the guru, and chastity. The teacher transmits orally sacred texts and truths. In this learning situation, concentrated, pithy, and sometimes cryptic combinations of words have been devised to compress a maximum of meaning within a minimum of words. The crowning example of this is the sacred syllable *Om*, which is understood to contain within itself a world of meaning. The student assimilates what the guru has communicated and, ideally, through meditation realizes the profounder truths. Study is aided or accompanied by the performance of certain prescribed rites under the guidance of the guru. The teacher is served in a variety of ways in keeping with the dignity and importance of his position. This kind of Brahminic discipleship is given cosmic significance in one of the hymns of the Atharvaveda, which suggests that by the faithful performance of his duties the twice-born student actualizes and harmonizes the gods.

The guru tradition is one of the most long lasting and influential of traditions in a culture that itself has had a relatively long continuous history. As most commonly practiced, it involves one teacher and a few students living and learning together in the guru's home. On occasion, however, groups of learned men may come together for mutual instruction and to teach others, either in withdrawal from society as in the *āśrama* (spiritual or intellectual retreats) or as travelling bands within the world. The close relationship between pupil and guru also continues to exist in the monastic traditions in India.

Buddhism. According to commonly accepted tradition, after having achieved enlightenment, Gautama, the Buddha, out of compassion, taught others before he entered Nirvāṇa (state of enlightenment). First he taught the dedicated seekers after enlightenment—the early monastics. Then he urged his followers to teach other ascetics and those at a greater distance, the common people who did not have the inclination to become monastics but were involved in the daily round of family, farm, and village.

Importance of Buddhist monasticism

The history of Buddhist education is essentially an aspect of the history of Buddhist monasticism. Entrance into monastic life involved from earliest times a regimen of chastity, poverty, and other moral standards, and also submission to discipline and learning under the direction of a teacher. Meditation and study were the two essential methods in Buddhist formation. Principles such as those known as the four noble truths, the eightfold path, and details of the *dharma*, or law, were indispensable elements of study (see also BUDDHISM). In the early years the sayings, stories, and legends of the Buddha were gradually collected together into the canonical scriptures. Frequent repetition and chanting aided in remembering the words of and about the enlightened founder. Debate and discussion on doctrine also seem to have been an important aspect of monastic education.

A famous Indian Buddhist convert, King Aśoka (*c.* 265–238 BC), played a significant role in transforming Buddhism from an Indian sect into a world religion by encouraging the movement of monastic missionaries into all areas of India, and into Ceylon and Kashmir. Aśoka also prepared a number of Buddhist-informed edicts that he commanded to be engraved on rocks and polished stone pillars and to be read to the public on festival days.

Of the major sects of Buddhism, Theravāda (the religion of the Elders) claimed the PHli canon (sacred texts written in the PHli language) as its sole source of authority. The development of Mahāyāna (the Greater Vehicle) was accompanied by the production of additional siitras, or scriptures, that contained advanced doctrines attributed to the Buddha. These scriptures assumed a significant role in the development of Buddhist teaching and practice in China (and through China to Korea, Japan, and Vietnam) and in Tibet.

As the scriptural canons were established, scholarly monastics extended the scope of their learning in their efforts to explain and defend sacred truths while seeking converts. With the monastic community as a base, this expansionist impulse found expression in Buddhist monastic universities beginning in about the 6th century. The most famous of these was Nālandā in northern India, which, according to the accounts of a 7th-century Chinese writer, attracted thousands of monks of various Buddhist sects who engaged in study under the guidance of monks distinguished for their learning. Laymen also received instruction at Nālandā.

The monastic order (*saṅgha*) was the primary bearer of literate culture in Ceylon, Burma, and other regions of Southeast Asia into which Theravāda Buddhism penetrated. In Ceylon, for example, there appeals to have developed, following the introduction of Buddhism in the 3rd century BC, a continuous history of learning that centred especially on Buddhist literature. Schools associated with temples apparently were the only educational institutions until the establishment of Christian missionary schools. Before the Western incursions of recent centuries nearly all Burmese males spent some time in the pagoda schools. Girls received little formal education, although nunneries were an established aspect of Theravāda Buddhism and did attract some followers.

The empirical approach of Ch'an, or Zen, Buddhism

In China, Buddhism encountered a highly developed culture. Buddhist texts were translated and taught by Chinese Buddhist monks who often used the technical terminology of the classical Chinese religiomagical system known as Taoism in rendering the Sanskrit or PHli texts into Chinese. This religiocultural intermixture of Mahāyāna Buddhism and Taoism found institutional expression in the development of Ch'an (or meditation) Bnddhism in China. Ch'an (Japanese Zen) was radically empiricist in approach; it generally eschewed metaphysics (studies of supersensual reality), theory, and abstract reasoning in preference for direct insight produced by primal experience. Its teachers employed unconventional methods in an effort to elicit by indirection the coveted enlightenment. Another major Buddhist sect in China, Pure Land, or Amidism, stressed a universal salvation and utilized a more conventional approach to education than that employed in Ch'an. Scholarship and the study of scriptures were valued along with meditation.

For nearly eight centuries (c. 3rd–10th centuries AD), while Confucianism remained the primary influence upon domestic and civil life, Buddhism dominated the higher culture in China. Some Buddhist temples became great centres of learning, chiefly for monks and members of the upper classes. After the 10th century, however, Buddhism went into decline in China and monastic education tended to deteriorate.

As Chinese influence spread into Korea and Japan it carried the Buddhist imprint upon it. Though the sects that developed in Japan were similar to those that had emerged in China, Japanese Buddhism developed a character of its own and also exerted a much greater influence upon general educational patterns than Buddhism did in China. The village Buddhist temple often became the village school and the priest the teacher. The Zen stress upon effective mind and body control through a life of disciplined simplicity and earnest labour appealed to the military caste of Japan (the samurai), and Zen became influential in the training of warrior statesmen.

By the 9th century, Buddhism had achieved such influence in Tibet that under royal patronage a massive work of translating scriptures from Sanskrit into Tibetan was carried on. This Tibetan canon remains as one of the most significant sources of Buddhist history and thought. For centuries Buddhist monasteries, or lamaseries, were the sole centres of education in Tibet.

In the past century or two Buddhist religious education has been challenged variously by Christian missionary schools, the growth of state schools, and increasing secularization. At the same time, a Buddhist renaissance has occurred, with the encouragement of such Westerners as T.W. Rhys Davids (1843–1922), founder of the PHli Text Society, and Henry Olcott (1832–1907), an American theosophist who did much to promote the revival of Buddhist culture and education in Ceylon, Burma, and India. In recent years the *saṅgha* (monastic order) has been given increasing educational responsibilities, in some places in supervising modern-style private schools and universities and religious education in public school systems. Buddhist educational practices, especially those centred upon meditation, have also exerted an increasing influence in certain Western circles.

Chinese religions. China's educational system was dominated for two millennia by Confucianism, which, following its founder, stressed formal, precept-oriented, and popular education. For the founder of Taoism (Lao-tzu), on the other hand, popular education was a great mistake since it leads men farther and farther from the state of nature that is their only source of salvation. Hence Taoism had little significant influence upon Chinese education, aside from the appeal of its simple and yet paradoxical ideas. Even in its own monastic schools Taoism emphasized the way of direct insight. Though Taoist texts were studied in Chinese schools, they were interpreted in terms of Confucian methods.

Purpose of Confucian education

The system of schools linked the smallest village and its students through a chain of higher institutions and competitive examinations that culminated in the imperial academy. Education maintained a deceptively secular appearance in that its obvious purpose was the preparation of individuals for entrance into government civil service. Government itself, however, was intended to be the vehicle wherein certain basically religious functions might be performed.

Confucian education sought to maintain harmony throughout the cosmos by giving each individual moral training so that he might behave justly and by preparing and selecting those who were most learned in right conduct as most suited to govern. The classic textual guides for proper behaviour were linked to religion, both in terms of their origins and in their function of preserving the state's relationship to heaven through the Son of Heaven; *i.e.*, the emperor.

Japanese religions. The ease with which Japan has assimilated foreign cultural imports and remolded them into distinctively Japanese systems is perhaps nowhere more apparent than in the history of Japanese religions and religious education. At the base of Japanese religion is the ancient and pervasive practice of Shintb, the kami way (the way of the gods), an essentially primitive form of religious experience that has left its mark on all succeeding systems. To this base were added Confucian, Taoist, Buddhist, Christian, and Western secular ideas and practices. Through this eclectic fusion, a real sense of unity—a unique Japanese piety—was maintained. This process is clearly evident in two of the most influential educational systems in Japan, Bushido (Code of Warriors) and that of the Meiji restoration of the 19th century. Bushido was a unique synthesis of various religious and other elements that stresed the martial arts in the training of the samurai (warrior class). The system produced a remarkable combination of learning, piety, ceremonial propriety, military skill, loyalty, self-control, and selflessness. Meiji education fused elements of Shintb mythology, kami faith, Confucian familial ethics, authoritarian statism, and modern educational methods into an impressively effective instrument for the inculcation of devotion to the state.

Shintb traditionally provided little or no formal religious instruction. It was passed on chiefly through ritual participation in home, temple, and community. Confucianism, on the other hand, was a strong force for formal education. Confucian learning was developed most extensively under the Tokugawa shogunate (17th–19th centuries). The traditional curriculum extended through Japan to the courts of the provinces. The temple or parish schools (terakoya) evolved into a semisecular system of popular education. Taught by a priest (either Buddhist, Shintō, a Confucian scholar, or an unattached Samurai), pupils received a watered-down version of samurai education. Morals were inculcated through typical copybook methods for learning to read and write. Traditional texts were memorized and reproduced.

With the demise of the imperial cult of Shintō in 1945, the state schools discontinued their direct inculcation of a particular ideology. Religious groups, including even traditional folk Shintō, became more self-consciously concerned about religious education. Western, especially Christian, institutions of religious education were emulated. Some religious groups even established their own school systems.

Religions of the West. Judaism. Religious education is stressed repeatedly in the Hebrew Bible. The Israelite is commanded to teach the commandments to his children, to recite them faithfully, to wear them upon his person, and to inscribe them on his doorpost. The household is, then, the primary locus of this sacred duty.

Importance of religious teachers in Judaism

Relatively eaily in Israelite history, the community looked to special teachers to reinforce and extend teaching in the family. Levites are referred to as those "who taught all Israel. . . ." (II Chron. 35:3.) Following the Babylonian Exile (6th to 5th centuries BC) there emerged a group of scholars ("scribes") who were especially qualified in the interpretation and transmission of the divine teaching (Torah). Scholar-teachers (rabbis) in this scribal tradition after the destruction of the Second Temple (AD 70) played a decisive role in assuring the survival of Judaism and in the shaping of that religion down to modern times. Among the better known of the early rabbis were Hillel (1st century BC to 1st century AD), and his student, Johanan ben Zakkai (1st century AD), under whom the rabbinic academy at Jabneh (Jamnia) in Palestine became the chief religious-intellectual centre of Jewry after the destruction of the Second Temple; Gamaliel the Elder (1st century AD), who is mentioned in the New Testament as the teacher of St. Paul; and Akiba (1st–2nd centuries AD), who played a significant role in preparing for the codification of the oral law in the Mishna (a part of the Talmud, a commentary on the Torah, or Law). The compilation of the oral law as developed by rabbinic interpreters over four or five centuries was completed around AD 220. There then ensued among the rabbis a period of detailed discussion of the Mishna, a work that entailed an intensive use of a question and answer method and that produced the Gemara (the commentary on the Mishna). The Mishna and the Gemara were put together in the compilation of the Talmuds (commentaries on the Torah) of Palestine (c. AD 400) and Babylonia (*c.* 500 AD). Subsequently the Talmuds played a primary role in Jewish religious education. Each of the Talmuds emerged from the major rabbinic academies of the day—institutions that, along with others of like nature, became authoritative centres of interpretation and practice in the Jewish religion.

The role of the synagogue in Jewish education

The educational work of the rabbi and the family met and merged in the synagogue. This remarkable institution was both a congregational house of prayer and a place of religious instruction. (The Yiddish term for synagogue is *shul* or "school.") It also was of considerable significance in the survival of Judaism beyond the destruction of the Second Temple in AD 70. Its educational work was supplemented from relatively early times by formally established community schools.

The importance attached to formal religious education is attested to in various ways in the history of Judaism. The initiation of the child into formal education outside the family circle became a solemn rite. It took place relatively early in the child's life and preferably on Shavuot, the festival commemorating the giving of the Law to Moses. The child was brought to the synagogue in special dress and there heard the reading of the Decalogue (the Ten Commandments). Then the teacher began to teach him the Hebrew alphabet from a tablet smeared with honey that the child ate as he pronounced the letters in order to encourage the view that learning is sweet. From then on religious education was a concentrated business, with stress upon close study and memorization of the various texts. Public evidence of learning in the Torah was given upon the ceremony of the Bar Mitzwa (literally, "son of the commandment"), at the age of 13. Formal religious education was generally limited to boys and men. Occasionally a woman became an accomplished student of the Torah, but the primary educational role of women was that of example of motherly faithfulness.

The basic object of all religious education was "labouring in the Torah for its own sake," and this life of study has been considered to be the most laudable kind of activity for any pious Jew to follow. Rabbinical guidance of this process was given not only in the synagogue and the attached school but also through the academies of higher learning (called yeshivas—plural of yeshiva). These academies were centres of authoritative interpretation and advanced study of the Talmud. The term Talmud Torah, "Study of the Talmud," became the title of various types of educational institutions in medieval and modem times.

Emancipation from the ghettos

Emancipation from ghettos in the late 18th century brought about profound changes in Jewish religious education. The long-established principles and practices of "labouring in the Torah" had become so systematized and so pervasive in the Jewish community that the introduction of the radically different ideas and practices of the modern, secularized West threatened to undermine the Jewish religion. Though the more orthodox defenders of Jewish belief and practice bitterly resisted the encroachment of secularization, reformers, under the leadership of such men as the great Jewish philosopher of the 18th-century Enlightenment Moses Mendelssohn, endeavoured to adapt Jewish education, and the whole Jewish world view, to the intellectual and institutional realities of the secularized world. Theological schools were founded for the training of rabbis, and efforts were made to strike a mean in these schools between ancient and modern methods and views. After emancipation, which brought civil rights and political equality, many Jews eagerly embraced secularized education as the chief pathway to successful life in the modern world. But disappointment sometimes followed this eagerness, as state schools were used to convert Jews to Christianity or to inculcate a nationalism that also threatened to destroy Jewish identity or both. Since the Nazi virtual extermination of European Jewry in the 1930s and '40s, efforts have beenmade, especially in the United States and Israel, to revive many of the ancient educational principles and practices. At the same time, many rabbis and educators continue the attempt to develop new and viable methods for teaching Hebrew and the Jewish heritage in Western secularized society.

Zoroastrianism and *the Parsis.* The fifth most important duty of a Zoroastrian, a follower of the religion founded by the 6th century BC Iranian Zarathushtra, or Zoroaster, was "to spend a third of [his] days and nights in attending the seminary and consulting the wisdom of holy men, . . ." Schools among the early followers of Zoroaster were most often located on the premises of the temples in which the fire dedicated to the god Ahura Mazdā (the Good Lord) was maintained. Priests served as teachers. Rote learning of sacred texts, training in ritual observances, transmission of arts of reading and writing, and moral instruction by means of maxims and proverbs occurred at an elementary and fairly universal level in ancient Persia. Opportunities for education were apparently extended to all classes and both sexes. Higher education was concerned primarily with religion, medicine, and law. In western Persia a system of military religious education prepared men to engage in what can be termed "holy wars." Zoroastrianism as an educational system was intricately linked with the needs of the state until AD 651 when the last Zoroastrian dynasty was overthrown by the Muslims. Since the beginning of the British Colonial period the Parsis (the term for the Persian Zoroastrians who settled in India) have shown persistent interest both in systems of Western secular education and in the recovery of their own sources.

Christianity. The word teacher is often applied to Jesus in the Gospels. Much early Christian literature is directed toward questions of belief and practice. The most systematic work of this sort is the *Didachē* (or "The Lord's Teaching to the Gentiles by the Twelve Apostles," late 1st century AD), a manual of discipline and instruction for believers and converts.

The importance of catechetical instruction

The most significant educational device developed in early Christian history was the catechumenate, the systematic instruction of converts preparatory to Baptism and full participation in the fellowship and rites of the church. The convert was prepared through formal instruction in morals and doctrine and through liturgical practice, as in the mass of the catechumens that preceded the mass of the faithful. He was admitted to the latter only after his instruction had been satisfactorily completed, his moral character had been established, and he had been baptized. Trained catechists used special catechetical materials prepared by some of the best thinkers in the early church, such as Gregory of Nyssa (c. 335–394). Formal religious education was concerned, then, primarily with the adult convert; the religious education of children was understood to be the responsibility of the family or household.

Catechetical instruction achieved a high level of sophistication in the "catechetical schools," institutions of higher education that evolved in some urban intellectual circles of Christians in the late 2nd century. In their heyday the schools of Alexandria and Antioch (and later Edessa) were rivals, the former being noted as the champion of Neoplatonism, which emphasized idealism and was marked by the extensive use of allegory in scriptural interpretation, while the latter followed the Aristotelian emphasis on matter and form and more literal interpretation of the Bible.

The catechumenate declined in the 5th and 6th centuries. The sacramental focus of instruction shifted from Baptism to penance in the church of the Middle Ages, and symbolism was employed extensively to convey the truths of the faith. The church of the Middle Ages developed a variety of means for conveying and reinforcing the faith among illiterate and semiliterate peoples. Embellishments upon the ancient liturgy, elaboration of festivals and holy days, and use of the arts—including painting, architecture and drama—contributed to this end.

In the early Middle Ages formal religious education was carried on chiefly in monastic and cathedral schools. Under the leadership of Charlemagne (crowned emperor of the Holy Roman Empire in 800) and his educational aide, Alcuin (c. 732–804), a court school system was developed that exerted significant influence in the 8th and 9th centuries. Education within these schools was concerned with the essentials of the faith. But subjects of study ranged beyond scripture and Christian doctrine to include in some instances all or several of the seven liberal arts; *i.e.*, grammar, rhetoric, dialectic, arithmetic, geometry, astronomy, and the theory of music.

Scholasticism, a system of Western Christian philosophy flourishing from the 11th to 15th centuries, and the rise of the universities brought a significant flowering of critical and systematic thought. Under the impact of the rediscovery of the teachings of Aristotle, Scholastics, or the Schoolmen, led by St. Thomas Aquinas (1225/1226–1274), elevated theology to new heights as "queen of the sciences," and hence as significant to all learning.

Reformation emphases

The religious reforms of the 16th and 17th centuries were characterized by a stress upon both moral and common education within a Christian context. Martin Luther (1483–1546) urged that all people be educated in the faith, and he himself contributed significantly to this end by translating the Bible into the vernacular, preparing catechisms that were widely used, and encouraging the extensive use of music in facilitating both worship and education. John Calvin (1509–1564) was equally convinced of the importance of educating all of the faithful, and he too wrote a catechism and promoted the establishment of schools. The followers of these men stressed religiously informed education wherever they went; for example, the early Puritan (Calvinist) settlers of North America who, within less than 20 years of their settlement (1630) in New England, had founded a college (Harvard) and enacted legislation requiring publicly supported education in all communities of 50 householders or more.

The most significant educational development in the Catholic Reformation sprang from the work of Ignatius of Loyola (1491–1556) and the monastic order of the Society of Jesus (Jesuits) that he founded. This highly disciplined movement sought to bring the total man—mind, body, spirit—under control for the faith and the church. To this end it developed a system of religious and secular education without parallel in Christian history.

Significant developments in Christian education since the Reformation include: (1) the establishment of extensive educational systems by the Roman Catholic Church, with or without state support, a development that was directed ideologically by a series of papal encyclicals that stressed that education of the faithful must be carried on under church control; (2) stress upon education of "the heart" as well as the head among such Protestant groups as the Moravians, the German Pietists, the Quakers, and the Methodists; (3) the founding of liberal arts colleges based upon religious impulses, especially by Protestants in the United States; (4) the gradual separation within both Roman Catholicism and Protestantism of clerical from lay education, a trend that was institutionalized in the establishment of theological seminaries separate from colleges or universities; (5) the flourishing of the Sunday school movement in Great Britain and the United States in the 19th and early 20th centuries, a movement that stressed lay religious education separate from state or public schools; (6) the role of missionary schools in carrying both Christian and modem secular ideas into Asia and Africa; and (7) efforts to adjust method and content in Christian education to the realities of a secularized Western culture, such as in the extensive use of the educational theories of John Dewey (1859–1952) by the Religious Education Movement in the United States in the early part of the 20th century.

The importance of the *kuttāb*

Islām. Muhammad (the founder of Islam in the 7th century AD) is reputed to have admonished his followers to attain education even if it entailed "going to China." Historians record that he allowed certain prisoners of war to gain their freedom through teaching a certain number of Muslims to read and write. The ***kuttdb,*** or elementary school, was established early to promote literacy. These schools employed simple poetry and prose ethical maxims as typical copybook texts for teaching literacy. Sometime after the Qur'ān (Koran) was set down in writing it became the only text employed in a student's early years of ***kuttdb*** instruction. Once the Qur'ān was memorized and a semblance of literacy was achieved (often by the age of 10), *kuttāb* education might extend up to the age of 15. This study included some basic ***Hadith,*** or traditional sayings and actions of the Prophet, these being memorized as guides to proper conduct. Some *kuttāb* seem to have provided also a basic exposure to ***fiqh,*** the law as it was derived from the Qur'ān and the ***Hadith.***

Education developed along many lines beyond ***kuttdb*** instruction. A knowledge of classical Arabic was necessary to study the Qur'ān and the ***Hadith.*** Attempts to clarify the Qur'ān and the ***Hadith,*** as well as to validate many ***Hadith*** sayings, also generated study in linguistics and philology, and the development of deductive logic. The study of ***fiqh,*** or jurisprudence, became a methodology for interrelating the various sources of authority. A knowledge of *fiqh* was necessary even on a village level of administration, and hence such studies became relatively extended through society.

Every mosque served as a school of sorts. It was appropriate for men to meet in the courtyard to discuss tradition and the law. Where one man was recognized as an authority, others grouped around him as their teacher and the situation became somewhat formalized. Students often travelled from mosque to mosque to learn at the feet of respected masters. Many mosques built up libraries that served prominently in public education due to their availability. Indeed, the library was a major aspect of Islāmic society. A number of institutions existed with collections ranging to more than 100,000 volumes. Most of the classical literature that spurred the European Renaissance was obtained from translations of Arabic manuscripts in Muslim libraries.

Formal mosque schools gradually developed around recognized teachers. Instruction in these institutions occurred within the context of the normal Muslim day. The *salāts* (prayers) were observed and many schools had their own *imām* (leader). Some were even identical in physical layout to regular mosques and a number came to offer Friday prayer services.

In AD 1066–1067 (or AH 459 in the Islāmic system of dating of years after the Hegira, or flight of Muhammad from Mecca), Niẓām al-Mulk opened the first *nzadrasah* (higher school) in Baghdad. In a very short time there were large numbers of these schools throughout the Muslim world. The original function of these institutions was to provide an educational base for the teaching of Sunnite (followers of the Prophet's way) beliefs to the then predominantly Shīʿite (followers of Ali ibn Abi Ṭālib, cousin of the Prophet Muhammad) populace. Subsequently, they filled a less controversial role as centres of advanced learning throughout the culture.

Muslim education reached a pinnacle in the al-Azhar Mosque in Cairo. Here instruction has been provided in a great variety of subjects and faculties have been maintained in Arabic and in Muslim law and theology. This university has been especially important to Islam since the 13th century when Mongol invasions destroyed many of the centres of higher learning that had developed in Iraq and Persia.

The religion of Islām generated a constant pressure for education and understanding. Many forms of education developed apart from the more formal schools. But the crowning aspect of Islāmic education was the university. Here the teachings of the Prophet were perpetuated within Islām. Here also aspects of Hellenistic culture were continued and passed on to other, non-Islāmic cultures, such as that of Europe.

RELIGIOUS EDUCATION TODAY

Modern challenges to religious education

Religious education is confronted by a variety of challenges today, including those arising from modern science, technology, mass culture, and the increasing centralization of power in the modern state. Perhaps the last of these poses the most obvious institutional challenge. The political revolutions of recent times have thoroughly undermined traditional religious education and instituted state-controlled systems in its place. Religious groups have developed various ways of dealing with this situation: liaisons with state schools, as in Germany and England; the establishment of separate school systems, such as the Roman Catholic parochial school system in the United States; and fugitive efforts where state control has been most rigorous, as in the Soviet Union and China.

The American Revolution (1775–1781) brought about separation of church and state, and in the 19th century the public school assumed the primary role in inculcating common values, similar to the role that had been played by the established church in earlier times. Such practices as Bible reading, hymn singing, and prayer were utilized in the public schools as much for moral and civic as for religious ends. These and other practices, such as the allowance of time for religious education, were generally encouraged by religious groups in their efforts to carry on the religious education of the young. In recent decisions, the Supreme Court of the United States has declared unconstitutional released time for religious education on public school grounds and school-sponsored prayers and devotional Bible reading. One of the most recent of these decisions (*School District of Abington Tp., Pa.* v. *Schcmpp,* 1963), however, apparently encouraged the study of, as contrasted with the practice of, religion in the public schools.

The study of religion has been encouraged in some state colleges and universities in the United States for more than a generation, beginning with religiously affiliated schools of religion (such as at the universities of Iowa and Montana) and continuing more recently in departments of religious studies (such as at the University of California at Santa Barbara). This development has been characterized by an increasing emphasis upon the scholarly study of religion—as illustrated, for example, in the increasing attention given to the various world religions and to an examination of the nature and function of religion itself. A similar shift is gradually occurring in the public schools in the movement from devotional Bible reading and prayer to curricular programs in the study of religion. This sort of change represents a significant departure from common practices in religious education in the past. It may serve an important function in encouraging knowledge about man's religious faith, but how far it can go in inculcating or sustaining faith is not clear.

In recent years religious teaching has also been excluded from or severely limited in the state-controlled schools of such countries as Turkey, India, and Japan. At the same time, in such recently established nations as Burma, Sri Lanka (Ceylon), Israel, and Pakistan the prevailing religious traditions have been used in varying degrees as vehicles for promoting national unity. A kind of religious education or religiously informed communal education has been encouraged in the state schools of these countries. Efforts have been made to bring together traditional and modern teachings and practices.

Trends in religious education

Trends and experiments illustrating the continuing efforts of religious groups and leaders to meet the various modern challenges to religious education include: the continuing establishment of colleges and universities under religious control or direction or both (*e.g.*, Buddhist universities in Sri Lanka, the International Christian University in Japan); attempts to bring theological education into closer relationship with university education; ongoing attempts to develop viable programs in religious and moral education in state schools; a resurgence of religiously sponsored day schools, especially among certain conservative religious groups; experimentation with such techniques as sensitivity training and affective learning; utilization for purposes of evangelization and education of the various electronic and other means afforded by modern technology and mass culture; and the establishment in the West of Eastern or Oriental types of religious education programs (*e.g.*, Zen meditation centres and monasteries). Generalization is hazardous, considering this variety. In fact, stating that there is the wide variety of approaches may be the only adequate generalization.

TOTAH, *The Contribution of the Arabs to Education* (1926), a fairly comprehensive treatment and probably most available in the U.S.; AHMAD SHALABY, *History of Muslim Education* (1954), more up-to-date and complete than Totah but hard to obtain; M.N. DHALLA, *Zoroastrian Civilization* (1922), three chapters on education in each of the three major epochs of Persian history, but does not treat the Parsis; CHRISTOPHER DAWSON, *The Crisis of Western Education* (1961), illuminating treatments of the impact of science, the effects of the French Revolution on education, and the relationships between religion, patriotism, and education in the American common school; ROBERT MICHAELSEN, *Piety in the Public School: Trends and Issues in the Relationship Between Religion and the Public School in the United States* (1970), discussions of the efforts of churches to use the public schools for religious education, relationships between Catholic parochial schools and the public schools, and recent U.S. Supreme Court cases.

(R.S.M./G.C.T.)

Religious Experience

Religious experience is taken here to include such specific experiences as wonder at the infinity of the cosmos, the sense of awe and mystery in the presence of the holy, feelings of dependence on a divine ground (a divine power or being as the basis of all existence) or an unseen order, the sense of guilt and anxiety accompanying belief in a divine judgment, and the feeling of peace that follows faith in divine forgiveness. Some thinkers also point to a religious aspect or dimension of experience in general having to do with the purpose of life as a whole and with the ultimate destiny of the individual. In the first sense, religious experience means an encounter or coming into the presence of the divine in a way analogous to encounters with other persons and things in the world. In the second case, reference is made not to an encounter with a divine being but rather to the apprehension of a quality of holiness or rightness in reality or to the fact that all experience can be viewed in relation to the ground from which it springs. In short, religious experience means both special experience of the divine or ultimate and the viewing of any experience as pointing to the divine or ultimate. Religious experience is sometimes equated with mysticism, but many interpreters have held that the experiences in question need not be understood exclusively in terms of the immediacy and ineffability characteristic of mysticism.

THE STUDY AND EVALUATION OF RELIGIOUS EXPERIENCE

"Religious experience" was not widely used as a technical term prior to the publication of *The Varieties of Religious Experience (1902)* by William James, an eminent U.S. psychologist and philospher, but the interpretation of religious concepts and doctrines in terms of individual experience reaches back at least to 16th-century Spanish mystics and to the age of the Protestant Reformers. A special emphasis on the importance of experience in religion is found in the works of such thinkers as Jonathan Edwards, Friedrich Schleiermacher, and Rudolf Otto. Basic to the experiential approach is the belief that it allows for a firsthand understanding of religion as an actual force in human life, in contrast with religion taken either as church membership or as belief in authoritative doctrines. The attempt to interpret such concepts as God, faith, conversion, sin, salvation, and worship through personal experience and its expressions opened up a wealth of material for the investigation of religion by psychologists, historians, anthropologists, and sociologists as well as by theologians and philosophers. A focus on religious experience is especially important for Phenomenologists (thinkers who seek the basic structures of human consciousness) and Existentialist philosophers.

Four basic issues

A number of controversial issues have emerged from these studies, involving not only different conceptions of the nature and structure of religious experience but also different views of the manner in which it is to be evaluated and the sort of evaluation possible from the standpoint of a given discipline. Four such issues are basic: (1) whether religious experience points to special experiences of the divine or whether any experience may be regarded as religious by virtue of becoming related to the divine; (2) the kinds of differentia that can serve to distinguish religion or the religious from both secular life and other forms of spirituality, such as morality and art; (3) whether religious experience can be understood and properly evaluated in terms of its origins and its psychological or sociological conditions or is *sui generis*, calling for interpretation in its own terms; and (4) whether religious experience has cognitive status, involving encounter with a being, beings, or a power transcending human consciousness, or is merely subjective and composed entirely of ideas and feelings that have no reference beyond themselves. The last issue, transposed in accordance with either a Positivist outlook or some types of Empiricism, which restrict assertible reality to the realm of sense experience, would be resolved at once by the claim that the problem cannot be meaningfully discussed, since key terms, such as "God" and "power," are strictly meaningless.

Proponents of mysticism, such as Rudolf Otto, Rufus Jones, and W.T. Stace, have maintained the validity of immediate experience of the divine; theologians such as Emil Brunner have stressed the self-authenticating character of man's encounter with God; naturalistically oriented psychologists, such as Freud and J.H. Leuba, have rejected such claims, explaining religion in psychological and genetic terms as a projection of human wishes and desires. Philosophers such as William James, Josiah Royce, William E. Hocking, and Wilbur M. Urban have represented an idealist tradition in interpreting religion, stressing the concepts of purpose, value, and meaning as essential for understanding the nature of God. Naturalist philosophers, of whom John Dewey was typical, have focussed on the "religious" as a quality of experience and an attitude toward life that is more expressive of the human spirit than of any supernatural reality. Theologians Douglas Clyde Macintosh and Henry N. Wieman sought to build an "empirical theology" on the basis of religious experience understood as involving a direct perception of God. Unlike Macintosh, Wieman held that such a perception is sensory in character. Personalist philosophers, such as Edgar S. Brightman and Peter Bertocci, have regarded the person as the basic category for understanding all experience and have interpreted religious experience as the medium through which God is apprehended as the cosmic person. Existential thinkers, such as Søren Kierkegaard, Gabriel Marcel, and Paul Tillich, have seen God manifested in experience in the form of a power that overcomes estrangement and enables man to fulfill himself as an integrated personality. Process philosophers, such as Alfred North Whitehead and Charles Hartshorne, have held that the idea of God emerges in religious experience but that the nature and reality of God are problems calling for logical argument and metaphysical interpretation, in which emphasis falls on the relation between God and the world being realized in a temporal process. Logical Empiricists, of whom A.J. Ayer has been typical, have held that religious and theological expressions are without literal significance, because there is no way in which they can be either justified or falsified (refuted). On this view, religious experience is entirely emotive, lacking all cognitive value. Analytic philosophers following the lead of Ludwig Wittgenstein, an Austrian–British thinker, approach religious experience through the structure of religious language, attempting to discover exactly how this language functions within the community of believers who use it.

RELIGIOUS EXPERIENCE AND OTHER EXPERIENCE

Sense experience and beyond

Views of experience in general. Religious experience must be understood against the background of a general theory of experience as such. Experience as conceived from the standpoint of a British philosophical tradition stemming from John Locke and David Hume is essentially the reports of the world received through the standard senses. Experience, as a tissue of sensible content, was set in contrast to reason, understood as the domain of logic and mathematics. The human mind was envisaged as a wax tablet on which the sensible world imprints itself; and the one who experiences is the passive recipient of what is given. It is possible to distinguish, compare, and in other ways relate these sensible items by means of understanding, but the data themselves are available only through experience—*i.e.*, the sensation of things and reflection upon thought and mental activities, feelings, and desires. According to this classical empiricist view, all ideas, beliefs, and theories expressed in conceptual form are to be traced back to their origin in sense if they are to be understood and justified.

The above view of experience came under criticism from two sides. Immanuel Kant, an 18th-century German philosopher, who still retained some of the assumptions of the position he criticized, nevertheless declared that experience is not identical with passively received sensible material but must be construed as the joint product of such material and its being grasped by an understanding that thinks in accordance with certain necessary categories not derived from the senses. Kant opened the way for a new understanding of the element of interpretation in all experience, and his successors in the development of German Idealism, Johann Fichte, Friedrich Schelling, and G.W.F. Hegel, came to characterize experience as the many-sided reflection of man's multiple encounters with the world, other men, and himself.

A second attack on the classical conception came from U.S. Pragmatist philosophers, notably Charles Sanders Peirce, William James, and John Dewey, for whom experience was the medium for the disclosure of whatever there is to be encountered; it is far richer and more complex than a passive registry of sensible data. Experience was seen as a human activity related to the purposes and interests of the one who experiences, and it was understood as an interpreted product of multiple transactions between man and the environment. Moreover, stress was placed on the social and funded character of experience in place of the older conception of experience as a private content confined to the mind of an individual. On this view, experience is not confined to its content but includes modes or dimensions that represent frames of meaning—social, moral, aesthetic, political, religious—through which whatever is encountered can be interpreted. James went beyond his associates in developing the broadest theory of experience, known as radical empiricism, according to which the relations and connections between items of experience are given along with these items themselves.

The expression and interpretation of experience

Critics of the classical view of experience, while not concerned exclusively with religious experience, saw, nevertheless, that if experience is confined to the domain of the senses it is then difficult to understand what could be meant by religious experience if the divine is not regarded as one sensible object among others. This consideration prompted attempts to understand experience in broader terms. Cutting across all theories of experience is the basic fact that experience demands expression in language and symbolic forms. To know what has been experienced and how it is to be understood requires the ability to identify things, persons, and events through naming, describing, and interpreting, which involve appropriate concepts and language. No experience can be the subject of analysis while it is being had or undergone; communication and critical inquiry require that experiences be cast into symbolic form that arrests them for further scrutiny. The various uses of language—political, scientific, moral, religious, aesthetic, and others—represent so many purposes through which experience is described and interpreted.

Views of religious experience. Specifically religious experience has been variously identified in the following ways: the awareness of the holy, which evokes awe and reverence; the feeling of absolute dependence.that reveals man's status as a creature; the sense of being at one with the divine; the perception of an unseen order or of a quality of permanent rightness in the cosmic scheme; the direct perception of God; the encounter with a reality "wholly other"; the sense of a transforming power as a presence. Sometimes, as in the striking case of the Old Testament prophets, the experience of God has been seen as a critical judgment on man and as the disclosure of his separation from the holy. Those who identify religion as a dimension or aspect of experience point to man's attitude toward an overarching ideal, to a total reaction to life, to an ultimate concern for the meaning of one's being, or to a quest for a power that integrates human personality. In all these cases, it is the fact that the attitudes and concerns in question are directed to an ultimate object beyond man that justifies their being called religious. All interpreters are agreed that religious experience involves what is final in value for man and concerns belief in what is ultimate in reality.

Because of their intimate relation to one another, the religious and the moral have often been confused. The problem has been intensified by many attempts—beginning with Kant's treatise on religion (1793)—to interpret religion as essentially morality or merely as an incentive for doing one's duty. Religion and morality are, however, usually taken to be distinguishable; religion concerns the being of a person, what he is and what he acknowledges as the worshipful reality, while morality concerns what the person does and the principles governing his relation to others. While it is generally acknowledged that religion must affect man's conduct in the world, some have maintained that there is no morality without religion, while others deny this claim on the ground that morality must remain autonomous and free of divine sanctions. Religious experience may be distinguished from the aesthetic aspect of experience in that the former involves commitment and devotion to the divine, while the latter is focussed on the appreciation and enjoyment of qualities, forms, and patterns in themselves, whether as natural objects or works of art. Anthropological studies have shown that primitive religions gave birth to many forms of art that, in the course of development, won independence as secular forms of expression. The problem of the relation between religion and art is posed in a particularly acute way when reference is made to religious art as a special form of the aesthetic. Since it is'concerned with the holy and the purpose of human life as a whole, most scholars would hold that religious experience should be related in an intelligible way to all other experience and forms of experience. The task of tracing out these relationships belongs to theology and the philosophy of religion.

THE STRUCTURE OF RELIGIOUS EXPERIENCE

The three basic elements: subjective, objective, social

The self and the other. All religious experience can be described in terms of three basic elements: first, the personal concerns, attitudes, feelings, and ideas of the individual who has the experience; second, the religious object disclosed in the experience or the reality to which it is said to refer; third, the social forms that arise from the fact that the experience in question can be shared. Although the first two elements can be distinguished for purposes of analysis, they are not separated within the integral experience itself. Religious experience is always found in connection with a personal concern and quest for the real self, oriented toward the power that makes life holy or a ground and a goal of all existence. A wide variety of individual experiences are thus involved, among which are attitudes of seriousness and solemnity in the face of the mystery of human destiny; feelings of awe and of being unclean evoked by the encounter with the holy; the sense of a power or a person who both loves and judges man; the experience of being converted or of having the course of life directed toward the divine; the feeling of relief stemming from the sense of divine forgiveness; the sense that there is an unseen order or power upon which the value of all life depends; the sense of being at one with the divine and of abandoning the egocentric self.

In all these situations, the experience is realized in the life of an individual who at the same time has his attention focussed on an "other," or divine reality, that is present or encountered. The determination of the nature of this other poses a problem of interpretation which requires the use of symbols, analogies, images, and concepts for expressing the reality that evokes religious experience in an understandable way. Four basic conceptions of the divine may be distinguished: the divine as an impersonal, sacred order (Logos, Tao, *ṛta*, Asha) governing the universe and man's destiny; the divine as power that is holy and must be approached with awe, proper preparation, or ritual cleansing; the divine as all-embracing One, the ultimate Unity and harmony of all finite realities and the goal of the mystical quest; and the divine as an individual or self transcending the world and man and yet standing in relation to both at the same time.

The two most important concepts that have been developed by theologians and philosophers for the interpretation of the divine are transcendence and immanence; each is meant to express the relation between the divine and finite realities. Transcendence means going beyond a limit or surpassing a boundary; immanence means remaining within or existing within the confines of a limit. The divine is said to transcend man and the world when it is viewed as distinct from both and not wholly identical with either; the divine is said to be immanent when it is viewed as wholly or partially identical with some reality within the world, such as man or the cosmic order. The conception of the divine as an impersonal, sacred order represents the extreme of immanence since that order is regarded as entirely within the world and not as imposing itself from without. The conception of the divine as an individual or self represents the extreme of transcendence, since God is taken as not wholly identical with either the world or any finite reality within it. Some thinkers have described the divine as wholly transcendent of or "wholly other" than finite reality, some have maintained the total immanence of the divine, and still others claim that both concepts can be applied and therefore that the two characteristics do not exclude each other.

"Solitariness" and community

Social forms or expressions. Most enduring, historical religious traditions find their roots in the religious experience and insight of charismatic individuals who have served as founders; the sharing of their experience among disciples and followers leads to the establishment of a religious community. Thus, the social dimension of religion is a primary fact, but it need not be seen as opposed to religious experience taken as a wholly individual affair. There has been some difference of opinion on the point; Whitehead, for example, put emphasis on the "solitariness" of religious experience precisely in order to deny the claim of those who, like Émile Durkheim, a French sociologist, characterized religion as essentially a social fact. The social expression of religious experience results in the formation of specifically religious groups distinct from such natural groups as the family, the local society, and the state. Religious communities, including brotherhoods, mystery cults, synagogues, churches, sects, and monastic and missionary orders, serve initially to preserve and interpret their traditions or the body of doctrine, practices, and liturgical forms through which religious experience comes to be expressed. Such communities play a significant role in the shaping of religious experience and in determining its meaning for the individual through the structure of worship and liturgy and the establishment of a sacred calendar. Communities differ in the extent to which they stress the importance of individual experience of the divine, as distinct from adherence to a creed expressing the basic beliefs of the community. The tension between social and individual factors becomes apparent at times when the individual experience of the prophet or reformer conflicts with the norm of experience and interpretation established by the community. Therefore, although the religious community aims at maintaining its historic faith as a framework within which to interpret experience of the divine, every such community must find ways of recognizing both novel experience and fresh insight resulting from individual reflection and contemplation.

Objective "intention," or reference. Religious experience is always understood by those who have it as pointing beyond itself to some reality regarded as divine. For the believer, religious experience discloses something other than itself; this referent is sometimes described as the "intentional" object that is meant or aimed at by the experiencing person. Analysis of religious experience, interpretations placed upon it, and the beliefs to which it gives rise may result in the denial that there is any such reality to be encountered or that the assertion of it is justified by the experience in question. This conclusion, however, does not change the fact that all religious experience, whether that of the mystic who strives for unity with God or of the naturalist who points to a religious quality in life, purports to be experience "of" something other than itself. The question of the cognitive import or the objective validity of religious experience is one of the most difficult problems encountered in the philosophy of religion. In confronting the question, it is necessary to distinguish between various ways of describing the phenomena under consideration and the critical appraisal of truth claims concerning the reality of the divine made on the basis of these phenomena. Even if describing and appraising are not utterly distinct and involve one another, it is generally admitted that the question of validity cannot be settled on the basis of historical or descriptive accounts alone. Validity and cognitive import are matters calling for logical, semantic, epistemological, and metaphysical criteria—of the principles of rational order and coherence, meaning, knowledge, and reality—and this means that the appraisal of religious experience is ultimately a philosophical and theological problem. The anthropologist will seek to identify and describe the religious experience of primitive peoples as part of a general history and theory of man; the sociologist will concentrate on the social expression of religious experience and seek to determine the nature of specifically religious groupings in relation to other groups—associations and organizations that constitute a given society; the psychologist will seek to identify religious experience within the life of the person and attempt to show its relation to the total structure of the self, its behaviour, attitudes, and purposes. In all these cases attention is directed to religious experience as a phenomenon to be described as a factor that performs certain functions in human life and society. As William Warde Fowler, a British historian, showed in his classic ***Religious Experience of the Roman People*** (*1911*), the task of elucidating the role of religion in Roman society can be accomplished without settling the question of the validity or cognitive import of the religious feelings, ideas, and beliefs in question. The empirical investigator, as such, has no special access to the critical question of the validity of religious experience.

Cognitive import or objective validity

The most radical form of the denial that religious experience has cognitive import is advanced by the Logical Positivists, who hold that all assertions or forms of expression involving a term such as "God" are meaningless because there is no way in which they can be verified or falsified.

Others who hold that religious utterance based on experience is without cognitive import regard it either as the expression of emotions or an indication that the person using religious language has certain feelings that are associated with religion. Those who follow the lead of Wittgenstein regard religious utterances as noncognitive but attempt to determine the way in which religious language is actually used within a circle of believers. Some psychologists have denied cognitive status to religious experience on the ground that it represents nothing more than man's projection of his own insecurity in the face of problems posed by life in the world and therefore has no referent beyond itself.

Immediacy and mediation. ***Revelational and mystical immediacy.*** Among defenders of the validity and cognitive import of religious experience, it is necessary to distinguish those who take such experience to be an immediate and self-authenticating encounter with the divine and those who claim that apprehension of the divine is the result of inference from, or interpretation of, religious experience. Two forms of immediacy may be distinguished: the revelational and the mystical. Christian theologians, such as Emil Brunner and H.H. Farmer, speak of a "divine–human encounter," and Martin Buber, a Jewish religious philosopher, describes religious experience as an "I–Thou" relationship; for all three, religious experience means an immediate encounter between persons. The second form of the immediate is the explicitly mystical sort of experience in which the aim is to pass beyond every form of articulation and to attain unity with the divine.

Mediation through analysis and critical interpretation. A number of thinkers have insisted on the validity of religious experience but have denied that it can be understood as wholly immediate and self-supporting, since it stands in need of analysis and critical interpretation. Some, like Paul Tillich, hold that there are certain "boundary experiences," such as having an ultimate concern or experiencing the unconditional character of moral obligation, that become intelligible only when understood as the presence of the holy in experience. Others, such as H.D. Lewis and Charles Hartshorne, find the divine ingredient in the experience of the transcendent and supremely worshipful reality but demand that this experience be coherently articulated and, in the case of Hartshorne, supplemented by rational argument for the reality of the divine. Dewey envisaged a religious quality in experience pointing to God as an ideal that stands in active and creative tension with the actual course of events. Whitehead identified the presence of the divine with an apprehension of a "permanent rightness" in the scheme of things and based the validity of the experience on the claim that an adequate cosmology requires God as a principle of selection aiming at the realization of the good in the world process. James found the justification of religious experience in its consequences for the life of the individual: valid experience is distinguished by its philosophical reasonableness and moral helpfulness. Finally, some have sought to combine experience and interpretation by taking the traditional proofs of God's existence and pointing to their roots in the experience of perfection, of the contingency of one's own existence, and of the reality of purpose in human life. On this view, the arguments for the reality of God are not wholly formal demonstrations but rather the tracing out of intelligible patterns in experience.

Three forms of preparation: rational dialectic, moral purification, drugs

Preparations for experience. Mystics, prophets, and religious thinkers in many traditions, both East and West, have been at one in emphasizing the need for various forms of preparation as a preliminary for gaining religious insight. The basic idea is that ordinary ways of looking at the world, dictated by the demands of everyday life, stand in the way of the understanding of religious truth; man must pass beyond these limitations by the disciplining of his mind and body. Three classic forms of preparation may be distinguished: first, rational dialectic for training the mind to reach insight (this explains why many mystical thinkers from the Pythagoreans to Nicholas of Cusa and Benedict de Spinoza were deeply involved in mathematics); second, moral preparation aiming at purity of heart, which was sometimes conjoined with bodily discipline, as in the Indian Yoga exercises; third, the use of drugs to expand the range of consciousness beyond that required for ordinary life. It is significant that the great mystics invariably regarded such preparation as necessary, but not sufficient, for experience. The self may be prepared, but the vision may not come; being prepared, as it were, establishes no claim on the divine. The experience described by St. John of the Cross, a 16th-century Spanish mystic, as "the dark night of the soul" points precisely to the experience of failure. The soul in this situation is convinced that God has abandoned it, cast it into darkness, perhaps forever. Mystics in the Taoist and Buddhist traditions have often emphasized the spontaneity of insight and the need to seek it through an "effortless striving" that combines the need to search with the awareness that the insight cannot be compelled. Zen Buddhists are fond of pointing to insights that are already possessed but not recognized as such until their holder is shaken loose from ordinary patterns of thought.

SITUATIONAL CONTEXTS AND FORMS OF EXPRESSION

Cultic and devotional. Religious experience receives its initial, practical expression in the forming of the cult that provides an orderly framework for the worship of the religious object. Worship includes expressions of praise, acknowledgments of the excellency of the divine, communion in the form of prayer, and the use of sacraments or visible objects that signify or represent the invisible sacred beyond them, feelings of joy and of peace expressed often in musical form, and sacrifice or the offering of gifts to the divine or in the name of the divine. Worship is ordered by means of liturgy directing the experience of the worshipper in patterns that combine the written word, the spoken word, and sacred music in a unity aimed at bringing him or her into the presence of the divine.

Life crises and rites of passage. Religious experience has to do with the quality and purpose of life as a whole and with the ultimate destiny of the person. Certain special times and events in the course of life present themselves as occasions that are set apart and celebrated, because they direct man's thought to the divine and the sacred with peculiar forcefulness. These occasions, called life crises, are regarded as dangerous because they are transitional from one stage of life to another and open to view the relation of life as a whole to its sacred ground. Pregnancy and birth, the naming of a child, being initiated into the community—sometimes called "puberty rites"—the choice of a vocation, the celebration of marriage, and the time of death are experienced as special events distinct from the routine happenings of secular life. These events represent "crises"—*i.e.*, turning points—when man's relation to the sacred becomes a matter of special concern. As Gerardus van der Leeuw, a Dutch Phenomenologist and historian of religions, points out, these transitional times are occasions for celebration in every culture because they mark the death of one stage and the birth of another in a universal cycle of life.

Religious experience and secular life

Sacred and secular. The marking off of these crisis occasions from the routine events of daily life points to the all-important distinction between the sacred and the secular. As directed toward the sacred, religious experience finds expression in the specifically religious form of the cult and in the cycle of sacred life. There is, however, a secular as well as a sacred life, and, since religious experience concerns the whole of life, the religious meaning must be related to all the dimensions of secular life—political, economic, moral, technological, and other. The relationship is twofold; on the one hand, there is the bearing of the conception of the divine on standards of behaviour, and, on the other, there is the influence that the religious meaning has upon one's general attitude toward life. The sacred, thus, makes its impact on the secular by providing principles that are to govern the relations between persons and by holding before men a vision of the divine that gives purpose to life as a whole. Although the sacred retains its dynamism by becoming related to secular life, there is the constant danger that it will lose itself in the secular, unless specifically religious forms of life are preserved. The existence in every society of secret and mystery cults, of sacred brotherhoods, of groups of disciples devoted to holy men, of monastic orders, and, on the broadest scale, of established churches and denominations, points to the need felt to retain the sacred as a special domain that can neither be merged into nor contained within secular society.

Verbal, conceptual, and symbolic. In all of the world religions, religious experience receives its most enduring expression in the form of sacred scriptures and the body of commentary through which they are interpreted. Mythological and symbolic forms of expression are older than conceptual forms and systems of doctrine. Myth takes the form of a story and represents the imaginative use of materials drawn from sensible experience in order to express a religious meaning surpassing the sensible world. Myths of creation in many religions give ample evidence of this imaginative function. The task of the theologian using conceptual tools is to elucidate the thought content of the myth and other primary forms of religious expression—legend, parable, confession, lamentation, prophetic vision—and thereby reduce the degree of dependence on the sensible and imaginative elements. It is important to distinguish devotional and liturgical expressions from the theological use of language. Creeds, confessions, psalms and hymns of praise, litanies and scriptures containing a record of the lives and experiences of sacred persons, all give immediate expression to the primary experience upon which a religious tradition is founded. Systems of theology and religious philosophy make their appearance when it becomes necessary to conceptualize and express consistently the body of belief about the divine, the world, and man implied in this primary experience. Tension exists between religious experience and theological expression at two points: first, the pietistic and evangelical spirit in religion, as seen, for instance, in some forms of Protestant Christianity, and the *bhakti* devotional movement in Hinduism, seeks to preserve the primacy of experience at the expense of theology; and, second, those who acknowledge the indispensability of theology will also demand that its formulations remain in accord with the experience it is meant to express and interpret.

Tension between religious experience and theological expression

TYPES OF RELIGIOUS EXPERIENCE AND PERSONALITY

The personal character of religious experience makes it essential to understand its varieties as manifested in different types of personality and the functions they perform. The mystic, a reflective and contemplative type, shuts out the world and all distracting influences in order to reach true selfhood through purification and enlightenment. Although mysticism has social implications, the mystic is primarily an individualist, whereas the prophet, a person of intense but intermittent experience, sees himself called to be a spokesman for the divine to the community or all mankind, and regards his own experience as a message that enables him to interpret the past and the future in the light of the divine will. The priest is a mediator between man and the divine, and his main function is the proper ordering of worship through liturgical forms. By contrast with the prophet, whose insight is spontaneous, the priest attains the authority of his office through education and training; as guardian of the tradition, he must assume administrative responsibilities in addition to his role as spiritual adviser; thus he is both active and contemplative. The reformer is a figure who stands within a religious tradition and seeks to transform or revitalize it in the light of his own experience and insight. The reforms intended may be moral, intellectual, or ecclesiastical, depending on the particular genius of the individual. Common to all reformers is the conviction that some valid and essential feature of traditional faith has been ignored or distorted and that these deficiencies must be overcome if the religion is to be purified. It is characteristic of the reformer to be actively engaged in bringing about the reforms indicated by his renewing experience. The monk or member of a religious order is in search of a special or sacred place set apart from secular life within which a religious life can be lived and moral and religious demands fulfilled to a greater degree than is possible in the world. Different orders stress different aspects of experience: some emphasize ascetic practices and self-discipline; others are devoted to the preservation of learning and the development of theology; still others make missionary zeal uppermost, and the members are impelled by their own experience to seek to convert others. The forerunner of the monk, who lives in a community governed by rule, was the hermit or religious recluse, the type for whom solitary existence, preferably in deserts and barren places, is necessary for communion with the divine and self-purification. The saint is a figure venerated by the religious community as one who embodies perfection in some form. The saint may have been a martyr, exhibiting perfection in faith; a person possessed of intensified capacity for experience and communion with the divine; or one who achieves to a supreme degree the moral and spiritual ideals of the beatific life. The theologian has the task of expressing the historic faith of a community concerning the divine *(tkeos)* in rational or conceptual form (*logos*). The content of his thought, though handed on to him in its essentials by the tradition, will depend on his own experience and his insight into the special relevance of that tradition for his time. The theologian both interprets and reinterprets. The founder, as might be expected, surpasses all others in importance. The founder's experience forms the basis of his own authority and the substance of the religion he establishes. The intensity of his experience and the effect it has upon his personality are decisive factors determining the response of his initial followers and disciples. There is reason to believe that the founders of the great religions, such as Moses, Buddha, and Jesus, did not intend to fill this role; the founding of the religion in each case was the result of the impact of their personalities and of the profundity of their experience on those who gathered around them.

The founder's experience: Moses, Buddha, and Jesus

The nature of religious experience: WILLIAM JAMES, *The Varieties of Religious Experience* (1902), a classic philosophical and psychological study; RUDOLF OTTO, *Das Heilige,* 9th ed. (1922; Eng. trans., *The Idea of the Holy,* 1923; 2nd ed., 1950), a study of the nonrational in religious experience; J.M. MOORE, *Theories of Religious Experience, with Special Reference to James, Otto and Bergson* (1938); JAMES A MARTIN, JR., *Empirical Philosophies of Religion* (1945); and C.C.J. WEBB, *Religious Experience* (1945), contain valuable appraisals and good bibliography; H.E. BRUNNER, *Wahrheit als Begegnung* (1937; Eng. trans., *The Divine-Human Encounter,* 1943); and MARTIN BUBER, *Ich und Du* (1923; Eng. trans., *I and Thou,* 1937 and 1970), express the view that authentic religion is based on personal encounter between man and God; JOHN DEWEY, A *Common Faith* (1934), argues for the "religious" in experience; E.S. BRIGHTMAN, A *Philosophy of Religion* (1940), represents the Personalist view that personhood is the most basic quality of reality; W.T. STACE, *Time and Eternity* (1952); and D.T. SUZUKI, *Mysticisnt: Christian and Bucldhist* (1957), represent the mystical interpretation; W.E. HOCKING, *The Meaning of God in Human Experience* (1912, reprinted 1963); and J.E. sMITH, *Experience and God* (1968), emphasize the experiential basis of the question of God.

Religious experience and other experience: H.D. LEwIs, *Our Experience of God* (1959); and J.E. SMITH, *Religion and Empiricism* (1967), deal with the bearing of different conceptions of experience on religion; JOSIAH ROYCE, *The Sources of Religious Insight* (1912); W.G. DE BURGH, *From Morality to Religion* (1938); and PAUL TILLICH, *Morality and Beyond* (1963), treat the relation between religion and morality; GERARDUS VAN DER LEEUW, *Vom Heiligen in der Kunst* (1957; Eng. trans., *Sacred and Profane Beauty,* 1963), treats the relation beween art and religion.

The structure of religious experience: JOHN MACMURRAY, *The Structure of Religious Experience* (1936, reprinted 1971); J.B. PRATT, *The Religious Consciousness* (1920); PAUL TILLICH, *The Dynamics of Faith* (1957); and A.N. WHITEHEAD, *Religion in the Making* (1926), deal with psychological, theological, and metaphysical aspects; JOACHIM WACH, *The Sociology of Religion* (1944), is an indispensable study of the social expression of religious experience; WILLIAM A. CHRISTIAN, *Meaning artd Truth in Religion* (1964); F. FERRE, *Basic Modern Philosophy of Religion* (1967); NINIAN SMART, *Philosophers and Religious Truth* (1964); and J.E. SMITH, *Reason and God* (1961), deal with the issue of the cognitive import of religious experience; J.H. LEUBA, *The Psychology of Religious Mysticisnz* (1925), argues against its cognitive import; W.E. HOCKING, *Science and the Idea of God* (1944); W.T. STACE, *Religion and the Modern Mind* (1960); and H.N. WIEMAN, *The Wrestle of Religion with Truth* (1927), discuss the relation between religion and science; J. MACQUARRIE, *God-Talk* (1967); I.T. RAMSEY, *Christian Discourse* (1965) and *Models and Mystery* (1964), represent the linguistic approach to religious experience; MIRCEA ELIADE, *Le Mythe de l'éternel retour* (1949; Eng. trans., *Cosmos and History: The Myth of the Eternal Return,* 1954; rev. ed., 1965) and *The Sacred and the Profane: The Nature of Religion* (1959), interpret religious experience through myth, symbol, and ritual.

Situational contexts and forms of expression: EVELYN UNDERHILL, ***Worship*** (1936, reprinted 1957), invaluable for the meaning of worship and its forms; P. EDWALL *et al.* (eds.), ***Ways of Worship*** (1951), an account of the liturgies of the major Christian communities; EMILE DURKHEIM, ***Les Formes élémentaires de la* vie *religieuse*** (1912; Eng. trans., ***The Elementary Forms of the Religious Life,*** 1915, paperback 1961), presents the "group theory" of religion; C.C.J. WEBB, ***Group Theories of Religion and the Individual*** (1916), a critique of Durkheim; MIRCEA ELIADE, ***Birth and Rebirth*** (1958); ARNOLD VAN GENNEP, ***Les Rites de passage*** (1909; Eng. trans., 1960); and GERARDUS VAN DER LEEUW, ***Phänomenologie der Religion*** (1933; Eng. trans., ***Religion in Essence and Manifestation,*** 1938), contain a wealth of information about initiation rites and the cycle of sacred life; JOACHIM WACH, ***The Sociology of Religion*** (1944), the best source for the relation between religious and nonreligious groupings.

Types of religious experience and personality: GERARDUS VAN DER LEEUW, ***Religion in Essence and Manifestation (op. cit.)***; and JOACHIM WACH, ***The Sociology of Religion*** (1944) and ***Types of Religious Experience*** (1951), invaluable for the analysis of religious roles and personalities; ALFRED GUILLAUME, ***Prophecy and Divination Among the Hebrews and Other Semites*** (1938); RUDOLF OTTO, ***Religious Essays*** (1931); and JOHN SKINNER, ***Prophecy and Religion*** (1922; paperback ed., 1961), deal with the meaning of prophecy in the Semitic traditions.

(J.E.Sm.)

Rembrandt

Rembrandt Harmenszoon van Rijn was the most creative and influential Dutch artist of the 17th century, and his brilliant production is equal to that of the greatest artists from all periods and countries. His works, whether they be paintings, drawings, or etchings, display an unsurpassed control of technique, of light and shadow, and of colour intensities and a profound knowledge of body movements, gestures, and facial expressions that impart to the viewer the very essence of the subject matter. One experiences his images on a variety of psychological levels never before achieved by an artist. His deep concern with humanity has been a source of inspiration for artists of his own and later generations and has made his work universally understandable and appreciated.

Rembrandt, self-portrait, oil on canvas, c. 1659–60. In the Iveagh Bequest, Kenwood House, London.

FORMATIVE YEARS

On July 15 of the year 1606 Rembrandt was born in the university city of Leiden. His father, Harmen Gerritszoon, was a fifth-generation miller whose windmill was located on the outskirts of Leiden on the northern branch of the Rhine River. Rembrandt's father, who appended van Rijn to his own name, was the only member of his family to convert from Catholicism to Calvinism late in the 16th century. In 1598 he was married in the Reformed Church to Neeltje van Suydtbroeck, the daughter of a Leiden baker. Her family, as did Rembrandt's father's, remained Catholic even after Leiden had joined the Calvinist side of Prince William of Orange. The couple had nine children of whom Rembrandt was the second youngest. At the age of seven, he was sent to the Leiden Latin School to prepare for the university. This was a departure from the family practice, as his other brothers were sent out to learn a trade. This suggests that at an early age Rembrandt showed a more than average intelligence and that his parents were willing to educate him for a profession, very likely as a city administrator.

Departure from Leiden University

The Latin School curriculum stressed writings of Cicero, Terence, and Virgil studied in the original. Greek was also mandatory and, in the final years, geography, history, and mathematics. The actual textbooks used by Rembrandt and his contemporaries are not known, but it is clear that when he left Latin School, at 14, he must have been well trained as a Latinist and very much exposed to classical literature. Calvinism was also a very important subject, and the Bible was carefully studied by the young pupils. It was with such a strong religious and classical background that Rembrandt enrolled in Leiden University on May 20, 1620. Just what Rembrandt accomplished at the university is not known, however, for he soon left. Fortunately, the reason for his departure is to be found in the second edition (1641) of J. Orlers' *Beschrijvinge der Stad Leyden,* p. 375 ("Description of the City of Leiden"). Here the mayor of Leiden provides a reliable biography of Rembrandt up until 1641. Orlers reports that Rembrandt matriculated at Leiden University in order to prepare for city administration, but that his "natural emotion" was for painting and drawing. Consequently, his parents removed him from the university and sent him to a painter to learn the fundamentals of art. Orlers goes on to say that Rembrandt's parents

> took him to the well painting Mr. Jacob Isaacxsz. van Swanenburch in order that he be taught and educated by him; with whom he remained about three years, and during this time he progressed so remarkably well that Art Lovers were greatly astonished, and one could note with satisfaction that in time he would become an excellent painter.

Rembrandt learned the fundamentals of art from van Swanenburch but was not apparently greatly influenced by his teacher's artistic style. Van Swanenburch had, however, just returned from 15 years in Italy, where he had worked in Venice, Rome, and Naples. He may have passed on his knowledge of Michelangelo da Caravaggio's new earthy realism, combined with chiaroscuro (light and shadow) lighting, to the young Rembrandt. These two elements were to become an important part of Rembrandt's artistic vocabulary.

Apprenticeship in Amsterdam. After "about three years" with van Swanenburch, according to Orlers, Rembrandt's

> Father found it good to apprentice him and take him to the Renowned Painter P. Lastman, residing in Amsterdam, so that he might advance himself and be better trained and educated.

Why Rembrandt's family chose Pieter Lastman as the young man's second teacher presents an interesting question. It seems most likely that because of Rembrandt's earlier Latin School education, he wanted to learn to paint historical scenes—that is, classical, mythological, and religious subjects. In Leiden, there was no one at that time proficient in this category of art. The choice, therefore, was between the cities of Utrecht and Amsterdam. Rembrandt chose the latter in order to work with Lastman, and not Utrecht, perhaps because Abraham Bloemaert, the leading artist of that city, had not been ιo Italy. Lastman was in Italy from 1603 until 1605, the period of the great stylistic innovations of Caravaggio, Adam Elsheimer, and the Carracci family. With this background, Lastman was creating "modern" historical paintings in the 1620s that, more than others, would have attracted a young student interested in this type of subject matter. It is surprising that Rembrandt stayed only six months with an artist who had such a strong

Influence of Lastman

influence upon him. Lastman taught Rembrandt how to arrange colourful figures in scale and in planes parallel to the picture surface, like an antique relief. Even more important, Lastman showed Rembrandt how to shift the dramatic accents in a scene by means of light and shadow, gestures, expressions, the position of the figures (human and animal), and the arrangement of parts of the landscape and architecture. How well Rembrandt learned his lessons from Lastman and how he improved upon them early in his career can be seen when one compares Rembrandt's "David Kneeling Before Saul with the Head of Goliath" (1626?; Kunstmuseum, Basel), with Lastman's "Coriolanus and the Roman Women" (Dublin University). In his painting, Rembrandt has mastered and even surpassed his teacher in his subtle use of composition and light effects to evoke a highly dramatic atmosphere.

Rembrandt's early works not only reflect his contact with Pieter Lastman, but they also indicate a knowledge and study of his forerunners and contemporaries. Seventeenth-century artists like Jacques Callot of France and Peter Paul Rubens of Antwerp touched Rembrandt upon occasion, but of even greater interest to him were 16th-century themes. In a number of cases, Rembrandt virtually copied earlier compositions by northern artists. For example, when Rembrandt painted "The Angel and the Prophet Balaam" he did not use Lastman's 1622 arrangement of the same subject, now in the Palmer Collection, England, but an early-16th-century one by Dirk Vellert. The latter's composition very likely appealed to Rembrandt because it emphasized the dramatic representation of the beating in terms of the individual's physical and emotional actions and not just the literal interpretation of Lastman and his late-16th-century precursors.

During these formative years Rembrandt also, upon occasion, combined 16th-century and early-17th-century Dutch imagery in his work. The "Tobit and Anna with the Kid," although filled with motifs borrowed from several sources, signals an important change in his use of light. For the first time the figures are placed in a darker setting and the light intensity fades, making the wall space less distinct and the room more intimate and isolated from the world. It was also at this time that Rembrandt began to paint chiaroscuro scenes; that is, pictures with strong contrasts between the light and dark areas of the composition. This manner of composing in terms of light and shadow was not favoured in Lastman's Amsterdam atelier but was introduced into Dutch art by the Utrecht painter Gerrit van Honthorst. He had returned from Italy in 1620 and was famous for his candlelight scenes based upon Caravaggesque and north Italian ideas. His paintings of this type were very popular in the early 1620s and were often engraved by Cornelis Bloemaert. These single-figured scenes illuminated by a candle or lantern must have been in Rembrandt's mind when he painted his "Money Changer" ("Avarice"). Rembrandt, however, adds to this and other scenes like it (compare "The Artist in His Studio," Museum of Fine Arts, Boston) an intense study of the individual's emotion. Rembrandt's early mastery of chiaroscuro light effects is not restricted to moralizing subjects but is also marvellously rendered in his first known outdoor night scene—"The Flight into Egypt."

First chiaroscuro scenes

During his early years Rembrandt also began to etch, and it was in this technique that he would create some of his most extraordinary works of art. His development as an etcher followed much the same pattern as did his development as a painter. From his forerunners (Albrecht Diirer, Martin Schongauer, Lucas van Leyden, etc.) he received ideas of comaosition and the aossibilities of mixing techniques (engraving, drypoint, and etching), while from his contemaoraries, specifically Hercules Seghers, he learned to use the etching technique in a free and imaginative manner. Other than that of Hercules Seghers, early-17th-century etching still resembled the more laboured and detailed engraver's approach, which is also evident in Rembrandt's earliest etchings of around 1626, "The Rest on the Flight into Egypt" and "The Circumcision." As in his early paintings, the same need and ability to portray emotions are present, as well as an awkwardness in the compositions and figures. Within a short time, however, these disturbing elements are eliminated, as in his 1627 "Flight into Egypt." This etching is a simple rendering of a family wearily traversing a shadowy, desolate road. His previous insecurity with the etching needle is eliminated, and now the technique is free and the line rendered with the spontaneity of a pen drawing like the "Study of a Man Wearing a High Cap" (c. 1627; Louvre, Paris).

Return to Leiden. By 1627 Rembrandt had mastered the fundamentals of painting, drawing, and etching and was forming his own distinctive style. Under normal circumstances a Dutch artist who had reached this stage in his career would have already visited Italy. Rembrandt, however, left Lastman in Amsterdam and immediately returned home to Leiden to work closely with another young Lastman pupil, Jan Lievens. The reasons for Rembrandt and Lievens' provincial attitude are explained in the autobiography written by Constantijn Huygens between 1629 and 1631. Huygens, one of the most remarkable Dutch personages of the 17th century, visited the young Rembrandt in 1626, when the former was secretary to the stadholder, Prince Frederik Hendrik of the House of Orange. In his autobiography Huygens writes that he suggested to Rembrandt and Lievens that they should study in Italy, "for if they became familiar with Raphael and Michelangelo, they would reach the heights of painting." Huygens reports that the two young artists said

> that now, in the flower of their youth, they had no time for travel. Moreover, the finest Italian works can be seen in Holland; paintings which one would have to look for in Italy in many different places are massed together in great abundance outside of Italy.

Huygens also provides an astute insight into the progress of the young Rembrandt and a comparison between the latter and his colleague Jan Lievens, with whom he worked closely from 1626 to 1631. It is even possible that they shared the same studio. Huygens writes that

> For myself, I'll wager to pass this superficial judgement on them, that Rembrandt surpasses Lievens in taste and liveliness of feeling, but that the latter exceeds the former in a certain imaginative grandeur and boldness of subjects and figures. For while [Lievens] already strives in his young heart for everything elevated and beautiful, he paints the forms before him life-size or preferably even larger; the other [Rembrandt], completely absorbed in his own work, likes to concentrate on smaller paintings and to achieve in a little space an effect that one seeks for in vain in the colossal canvases of others.

In still another passage from his autobiography, Huygens writes about a specific painting by Rembrandt, "Judas Returning the 30 Pieces of Silver" (1629; Normanby Collection, Mulgrave Castle, Yorkshire), giving a precise idea of what the contemporary intelligentsia thought of the young Rembrandt's work. Huygens says that he was

> impressed by Rembrandt's ability to depict expression, appropriate gestures and movement, particularly in the central figure of Judas who bewails his crime and implores for the pardon which he knows he will not receive.

Huygens, in still another passage, states that the aforementioned painting can be compared favourably with any Italian or ancient picture.

It was also during these years (1627 to 1629) that Rembrandt executed numerous studies of himself. These early self-portraits, done in etching, drawing, and painting, vividly depict Rembrandt's physiognomy. They must be seen, however, as studies of moods and emotions that he would later incorporate into his history pictures. They are not yet the penetrating studies of human character that Rembrandt concentrated upon later in his career. These early self-portraits range from the more violent images like the one painted c. 1628 (in the Rijksmuseum, Amsterdam, on loan from the Cevat Collection), where he is presented with untidy hair and a deeply emotional face three-quarters in shadow, to the calmer, more elegant portrait of c. 1629 (in the Mauritshuis, The Hague), where for the first time Rembrandt shows an interest in depicting himself in a carefully detailed costume. This same attention to detail is also evident in his history

Early self-portraits

paintings of this time and can be beautifully seen in a number of small panels like "The Tribute Money" and the "Presentation of Christ in the Temple." His early style was highly esteemed at this time, and Rembrandt very likely had a number of pupils and ***gezellen*** (journeymen). On February 14, 1628, for example, the 14%-year-old Gerrit Dou came to work with the 21%-year-old Rembrandt. Jan Orlers, writing in 1641, states that Dou was apprenticed to the "artful and renowned Mijnheer Rembrandt" for three years, after which time Dou "had grown into an eminent master, particularly skilled in small, subtle and curious things." Dou, well after Rembrandt left for Amsterdam late in 1631, continued to work in and perfect Rembrandt's late Leiden style. The former founded the school of "fine painters" in Leiden, which had an enormous success both at home and abroad during and after Dou's lifetime.

MATURITY

Move to Amsterdam. Sometime after June 1631 Rembrandt left the quiet university town of Leiden for the cosmopolitan city of Amsterdam. At this time Amsterdam was one of the great trade centres of Europe, and contemporary descriptions reveal that the Stock Exchange, for example, was populated with people from all over Europe. Businessmen from Poland, Russia, Hungary, Greece, and Turkey traded with the western Europeans. In Amsterdam people of all political and religious persuasions could trade and work, and this led to a freedom of inquiry that was unique for Europe.

Rembrandt's reasons for moving to Amsterdam were certainly based, in part, upon the new intellectual life, and, even more important, upon the economic advantages offered by such a city. Orlers notes that

> because his [Rembrandt's] portraits and other pictures pleased the citizens of Amsterdam, and because they paid him well, he moved there around 1630.

Association with van Uylenburgh

Rembrandt must have earned large sums at this time, as it is known that on June 20, 1631, while still living with his parents in Leiden, he loaned 1,000 guilders to the Amsterdam art dealer Hendrick van Uylenburgh. In doing this, Rembrandt bought into van Uylenburgh's successful business, which also had as shareowners a number of wealthy Amsterdam businessmen and artists. Van Uylenburgh was an art dealer who also ran an art school where rich children could learn to paint for a large tuition. They copied the masterpieces in van Uylenburgh's shop, and these copies were sold to the public. In any case, Rembrandt moved into the van Uylenburgh house sometime shortly after June 1631, but how long he stayed there is not clear. He very likely taught in van Uylenburgh's academy for a short time. Of even greater importance is the fact that Rembrandt became an immediate success in Amsterdam. His earliest known important Amsterdam commission was the "Portrait of Nicolaes Ruts," the subject a wealthy Amsterdam businessman. Whether or not he actually painted him in Leiden or Amsterdam is open to question; but the success of this lively and natural portrait composed in terms of light and shadow, and in which the sitter directly engages the spectator, is a marked departure from the more formal and linear style of contemporary Amsterdam portraiture. This portrait and the one of Maarten Looten, completed on January 11, 1632, must have established Rembrandt's position as the leading portrait painter of Amsterdam in the early 1630s. This surely was the reason for his having received one of the most important commissions granted at that time: "The Anatomy Lesson of Dr. Nicolaes Tulp." It was traditional that the presiding professor of anatomy in the Amsterdam Surgeon's Guild personally select the artist. The anatomy lesson was an annual event and considered the high point of the social season. Actually the anatomy paintings were not executed during the actual dissection but were commemorative works. The records of the Amsterdam Surgeon's Guild indicate that

> Adiaan Adiaansz., alias the Kid, was born a boilermaker at leijden in hollant [and] in [his] 28 year was executed with the rope an [no] 1632 the 31 January was dissected by those of this guild.

When one compares Rembrandt's composition with the traditional type, it is not difficult to see why his painting has long been held in such high esteem. The earlier group portraits of this subject consisted of a series of stiff, unrelated, realistic heads placed to the side of or behind the cadaver or skeleton. Rembrandt changes this radically and presents a group of individuals placed in a pyramidal structure above-andto the side of the corpse.

Upon the completion of "The Anatomy Lesson of Dr. Nicolaes Tulp," Rembrandt received numerous portrait commissions in the 1630s, and his success was assured. His close association with the art dealer Hendrick van Uylenburgh certainly helped to further Rembrandt's career and also led to his meeting of his future wife, Hendrick's Frisian cousin Saskia van Uylenburgh. Saskia belonged to the regent class. Her father held numerous important government positions including that of pensionary and mayor of Leeuwarden. Saskia received a respectable inheritance upon his death, in 1624, as her mother had died six years earlier. Rembrandt, although socially inferior to Saskia, married her on June 22, 1634, in the Reformed Church in the village of Sint Annaparochie near Leeuwarden. The couple returned to Amsterdam and remained for several months with Hendrick van Uylenburgh before renting a house on the fashionable Nieuwe Doelenstraat.

Marriage to Saskia van Uylenburgh

During the 1630s, Rembrandt lived on a very high level, and it was at this time that he began his art collection. It is known that in 1637 he purchased a very expensive painting by Rubens. Furthermore, the Italian biographer Filipo Baldinucci, writing in 1686, provides an interesting account of Rembrandt's behaviour in the public auction rooms. He notes that Rembrandt "bid so high at the outset that no one else came forward to bid; and he said that he did this in order to emphasize the prestige of his profession."

Rembrandt's change in status beginning in the early 1630s is evident in his portraits of himself and his wife. The 1634 "Self Portrait" shows a fashionably dressed young man wearing an embroidered silk scarf, a fur collar, and an elegant beret. In the same year he painted a charming "Portrait of Saskia as Flora," where his beautiful young wife is clothed in a richly decorated costume, and her hair is capped by a glorious garland of flowers. Rembrandt's "Portrait of Saskia" from the same time clearly reflects the affluence of the young couple in her rich robes, fur cape, and jewels. This new opulence came from Rembrandt's success as a portrait painter of the wealthy upper class Amsterdam society. His ability to capture magnificently in paint the character of his sitters --like the well-known Remonstrant preacher Johannes Uytenbogaert, the master shipbuilder of the East India Company Jan Rijcksen and his wife Griet Jans, or the two canvases representing Maerten Soolmans and his wife Oopjen Coppit—was responsible for his success. His religious works were also in demand, and as early as about 1632 he received a commission from Prince Frederik Hendrik in The Hague to paint five scenes from the Passion of Christ, which was completed in 1639. This clearly indicates the high esteem in which Rembrandt was held and places him on an equal level with such court painters as Rubens and Van Dyck.

Letters to Huygens

From one of seven preserved letters written by Rembrandt to Constantijn Huygens, Frederik Hendrik's secretary, concerning these pictures, Rembrandt himself gives an idea of what he was attempting to do. In the letter of January 12, 1639, Rembrandt writes about the "Entombment" and "Resurrection" saying:

> These same two pieces through studious application are now both completed. . . these two are the ones in which the most and the most natural movement is observed, which is also the main reason why the same have been so long in the making.

This letter also relates that the young Rembrandt concentrated upon attaining the greatest inward emotion. The other letters reveal that Rembrandt originally wanted 1,000 guilders for each picture but that he settled for 600 plus 44 guilders to cover the costs of framing and packing. Rembrandt also writes that he is very much in need of money and pleads for a speedy payment.

Rembrandt's mythological paintings and his religious scenes were much in demand during these years and until 1636 were characterized by a highly dramatic and exciting style, culminating in "The Abduction of Ganymede" and "The Blinding of Samson."

It was also in the 1630s that Rembrandt made numerous genre sketches vividly illustrating his absorption and interest in the commonest of activities. The wonder of these sketches is found in his free and spontaneous reaction to numerous impressions at home and in the street. He drew many private moments from family life. Nothing escaped his eye, whether it be the breast-feeding of a child, a screaming child, one learning to walk, or his wife confined to her bed. Rembrandt's drawing of Saskia in bed with a woman in attendance contains the anxiety and tension of a mother awaiting labour or perhaps in shock after a tragic event. This drawing and another equally as poignant in Amsterdam, Rijksprentenkabinet, records Saskia's difficult and tragic personal life beginning late in 1635. Her first child, Rumbartus, was baptized on December 15, 1635, in the Oude Kerk, Amsterdam, and exactly two months later was buried in the Zuiderkerk. On July 22, 1638, their daughter Cornelia was baptized and died within a month on August 14. A second daughter, also named Cornelia after Rembrandt's mother, was baptized on July 29, 1640, and hardly survived a month. Their last child, Titus, was baptized on September 22, 1641, and lived twenty-seven years. Saskia, herself, lived only a few months after the birth of her only surviving child. She died on June 14,1642.

Sketches of Amsterdam

Rembrandt not only made moving sketches of his home-life but also marvellous studies of the life going on about him in Amsterdam. The picturesque figures who walked the streets, their special gestures and their exotic costumes, did not escape his pen and often appeared again later as details in his history scenes. Public events were also recorded, and when a travelling circus visited Amsterdam in 1637, Rembrandt made two marvellous black chalk drawings of the elephants (Albertina, Vienna). A year later he used one of them in the background of his etching "Adam and Eve." The imaginative world of pageantry and theatre also served as a source of information for his fertile imagination. He made several drawings of beautifully costumed mummers (British Museum, London; Pierpont Morgan Library, New York) who very likely had participated in the procession just prior to the tilting competition held in The Hague on February 11, 1638, to celebrate the wedding of Wolfert van Brederode and Louise Christine van Solms, a princess of Orange. Rembrandt also appears to have been interested in the Amsterdam theatre, which was experiencing a strong revival at this time. He made a number of vivid sketches of actors in a variety of moods and costumes. His pen also captured the drama and tension of biblical scenes and, of course, quick sketches of individuals such as the pensive "Portrait of Saskia" (1633; Staatliche Museen Preussischer Kulturbesitz, Berlin). The latter is inscribed as follows: "This is counterfeited after my wife as she was 21 years old the third day after we married on June 8, 1633." (The text refers to the date of engagement.)

At the same time that Rembrandt produced his remarkable drawings, he achieved magnificent results with the etcher's needle. The uncertainty, awkwardness, and lack of unity in his Leiden etchings disappear almost immediately upon his arrival in Amsterdam; his new etchings, like his paintings, are conceived on a grander scale. Shortly before or after he revolutionized group portraiture with "The Anatomy Lesson," Rembrandt cut the plate for "The Raising of Lazarus." The arrangement of the participants around Lazarus recalls the grouping of the surgeons around the corpse. The variety of individual reactions to the event are similar in both, although one is violent and the other calm. Rembrandt's strong contrast of light and shadow boldly emphasizes the gestures and facial expressions in the etching and foreshadows his more dramatic scenes of the 1630s that culminate in the 1634 etching of "The Angel Appearing to the Shepherds," This etching is one of the high points in Rembrandt's career, both technically and aesthetically. Contrary to his normal procedure of first outlining all the details of the scene, here he began by working out the dark areas, and then, in the second and third states, he etched in the details of the light parts. He also, for the first time, combined the drypoint and burin with the etching needle (see *PRINTMAKING)*, resulting in his glorious chiaroscuro effects. This combination of techniques on one plate he continued to use throughout his career, bringing it to even greater perfection by the 1650s in the famous "Three Crosses."

Portrait etchings

In the early 1630s Rembrandt also etched numerous portraits that, as in his paintings and drawings, contain a baroque splendour similar to his historical scenes. In 1636, however, just after reaching a pinnacle in dramatic exuberance in the etching of "The Angel Appearing to the Shepherds" and the painting of "The Blinding of Samson," Rembrandt moved toward an introspective and quiet style in his etchings and painted portraits. This is especially noticeable in the etching of "The Return of the Prodigal Son," where the artist concentrated on facial expressions to create **an** incredibly human concept. All is focussed on the individual in an attempt to render visually the inner emotions of man. Rembrandt reduced the number of participants to the most essential characters in order to concentrate on the essence of the story as well as to simplify his etching style. This new, quieter style is also evident in his religious paintings of the late 1630s, an example being "The Risen Christ Appearing to the Mary Magdalen."

Although Rembrandt's earliest landscape drawings of 1636 show a similar restfulness and are drawn from nature, his landscape paintings from this time are dramatic and highly imaginative. Such landscapes as the "Baptism of the Eunuch" (1636; Niedersachsisches Landesmuseum, Hannover) or the "Stormy Landscape" clearly display Rembrandt's debt to Hercules Seghers and the 16th-century tradition of artfully composed landscapes.

Sources of Rembrandt's income in the 1630s

In spite of the fact that there are changes in Rembrandt's style and choice of themes during the 1630s, it is impossible to relate them to alterations in his personality. Any suppositions of this type are purely subjective and place one on very insecure ground. There are, however, several contemporary sources that present an interesting picture of Rembrandt as a teacher and man of finance. There is no question that in the 1630s Rembrandt earned large sums of money from the sale of his works, especially the commissioned portraits and prints. Still another important source of revenue came from his numerous pupils and journeymen (*gezellen*), from whom he collected fees and whose work, often painted and drawn copies of Rembrandt compositions, was sold by the master, who kept the proceeds. Rembrandt's-relationship with his pupils is documented by their works, especially the drawings, and by the writings of the German artist Joachim von Sandrart, who worked in Amsterdam from 1637 until around 1645. Von Sandrart undoubtedly knew Rembrandt and visited his studio on more than one occasion. In his biography of Rembrandt, published in the *Teutsche Akademie* of 1675, Von Sandrart says

> he was a very diligent and indefatigable man; consequently, Fortune awarded him with considerable cash and filled his residence in Amsterdam with nearly innumerable children of good family for training and education, each of whom paid him annually about 100 guilders, not counting the profits he gained from the paintings and copper-pieces made by these his pupils, which also ran to 2,000 or 2,500 guilders cash, in addition to what he obtained by the work of his own hand.

Although it is difficult to ascertain from this statement just how many pupils studied with Rembrandt, there must have been considerably more than the 24 to 25 described by Von Sandrart as studying each year with Gerrit van Honthorst in Utrecht. Rembrandt's pupils remained with him for varied periods of time, and some of the more accomplished ones had been fully trained by lesser masters before entering the studio. In the 1630s Rembrandt's more famous pupils included Govert Flinck, Ferdinand Bol, and Gerbrand van den Eeckhout, while the majority of the well-known artists who worked with Rembrandt after 1640 were already trained. These men served as *gezellen* and included such people as Samuel van Hoogstraten, Carel Fabritius, Nicolaes Maes, and Aert de Gelder.

Drawings of the Rembrandt studio

Several drawings executed in the Rembrandt studio by Rembrandt and unknown pupils provide some idea of what it was like to study with the master. One sheet in Darmstadt, Hessisches Landesmuseum, shows Rembrandt in the midst of his pupils, old and young, sketching a nude. Other drawings of nudes confirm the fact that Rembrandt's pupils made figure drawings after living models. The Darmstadt drawing also includes plaster casts that the pupils copied. Furthermore, the same drawing reveals that the students held their drawing paper vertically, following the advice set down by Rembrandt's pupil Samuel van Hoogstraten in his handbook for artists published in 1678. It is also known that Rembrandt corrected his pupils' drawings as well as their paintings. A good example of the latter is "The Sacrifice of Isaac" (Alte Pinakothek, Munich), attributed to Govert Flinck and inscribed "Rembrandt changed and overpainted 1636."

A large portion of the money that Rembrandt earned as a teacher and artist was spent in the auction rooms of Amsterdam. Mention has been made of the collection that Rembrandt began to form in the early 1630s and his reputation as a high bidder. From the documentation it is known, for example, that on February 9, 1638, Rembrandt spent 224 guilders at the auction, at which the artist bought prints by Lucas van Leyden, Albrecht Dürer, Hendrik Goltzius, and others as well as a variety of drawings. A little over a year later, on April 9, 1639, Rembrandt was present at a sale at which he bought nothing but studied and sketched Raphael's "Portrait of Balthasar Castiglione," now in the Louvre, Paris, which was purchased by the Amsterdam financier and collector Alphonso Lopez. This drawing and Titian's "Portrait of Ariosto" (?), now in National Gallery, London, but then in Lopez's collection, which Rembrandt knew, provide an interesting insight into the latter's stylistic development and thoughts about painting and poetry. Titian's portrait was the compositional source for Rembrandt's etched self-portrait of 1639 and the painted one of 1640 (National Gallery, London), which marked an important change in Rembrandt's portraiture from the earlier flamboyant style to a new dignified and quiet presentation. Furthermore, Rembrandt's copy of Raphael's "Portrait of Castiglione" was influenced by the former's etched self-portrait in which Rembrandt posed himself as the poet Ariosto to affirm the ascendancy of painting over poetry.

Success and problems of the 1640s. Although Rembrandt's style of the 1640s is characterized by a new classical calm and dignity, as late as 1642 he painted his last really explosive and dynamic work—"Nightwatch." The title itself is deceiving, as it first came into use in the 19th century, when the picture was covered with boiled oil and varnish. A cleaning in 1946–47, however, removed the old varnishes and revealed a brilliantly coloured work with Captain Frans Banning Cocq and Lieutenant Willem van Ruytenburch in the foreground. A hint as to what this picture really represents can be found in a text opposite a watercolour of the picture in Banning Cocq's family album on display in the Rijksmuseum, Amsterdam:

> This sketch of the painting in the great hall of the Kloveniersdoelen [headquarters of the civic guards], showing the young Squire of Purmerlandt [Banning Cocq], as captain, ordering his lieutenant, the Squire of Vlaardingen [Van Ruytenburchl, to move off with his civic guard company.

This text also states that the picture was hung in the recently built Kloveniersdoelen. It was one of a number of such pieces executed by the most fashionable painters of the time: Nicolaes Eliasz., Jacob Backer, Govert Flinck, Joachim von Sandrart, and Bartholomeus van der Helst. Rembrandt, however, did not follow the traditional imagery for such a subject as did the others. Beginning around 1530 such group portraits contained figures that were either seated or standing stiffly in rows parallel to the picture plane. Because Rembrandt broke so radically with tradition, a myth grew up in the 19th century that the painting was badly received by the members of the company—furthermore, that it was this picture that marked Rembrandt's fall from favour and that thereafter he lived the life of a rejected artist. This tale has recently been disproved, and it is known from contemporary sources that the picture was, in fact, well received. In 1678 Samuel van Hoogstraten wrote that

> No matter how much this work is reproached, however, I feel it will outlast all its competitors, being so picturesque of conception, so dashing in action, and so powerful that, as some people think, [it makes] all the other pieces there look like playing cards. Still, I do wish he lit more lights in it.

Myth of the "Nightwatch"

Van Hoogstraten's appreciation of the painting is echoed by Bernhardt Keil, a Rembrandt pupil of 1642–44, whose thoughts were published in 1686 by the Italian Filippo Baldinucci. The latter wrote that Rembrandt's contemporaries thought very highly of the painting and that Rembrandt received 4,000 scudi for it. Other sources, notarized statements of two guardsmen of 1658–59, indicate that "sixteen of them had each paid 100 guilders, some a little more, others a little less, according to the place they occupied in the painting." The escutcheon on the archway gives the names of 18 guardsmen in the painting, although there are at least ten more figures very likely included to fill the space. Whatever Rembrandt received for this highly original and magnificent composition, it is clear that the painting was as well thought of in the 17th century as it is today.

Three years before Rembrandt completed the "Nightwatch," he bought a large and expensive house in the Sint Anthonisbreestraat for 13,000 guilders. At this time his credit was still excellent, as seen by the terms of the loan granted to him by Christoffel Thijs. Thijs gave Rembrandt six years to pay off three-quarters of the purchase price and did not stipulate when the payments were due and how much they should be. Two years later, on September 22, 1641, Rembrandt's son Titus was born, but to counteract this happy event came the death of his wife within a year. On June 5, 1642, a very ill Saskia drew up her last will and testament. In keeping with Dutch law, she bequeathed one-half of her possessions to Rembrandt and the other to their baby, Titus. She gave Rembrandt the usufruct of the entire estate until his death or remarriage. Saskia did not ask Rembrandt to make out an inventory of their common holdings, "trusting that her aforesaid husband will very conscientiously acquit himself in this matter." Saskia also did not wish to have Titus' legacy administered by the Orphan's Chamber in Amsterdam. All of this clearly attests to her complete faith and trust in her husband. Saskia died on June 14 and was buried in Amsterdam's Oude Kerk on June 19.

Relationship with Geertghe Dircx

At an unknown date, shortly before or after Saskia's death, Geertghe Dircx, the widow of a ship's bugler, entered Rembrandt's household as Titus' nurse. It was not long before she became Rembrandt's common-law wife. Rembrandt presented her with Saskia's jewelry, and among the pieces there was a "rose" ring set with diamonds and a "marriage medallion." Rembrandt's relationship with Geertghe changed radically in 1649, very likely because of the presence of Hendrickje Stoffels, who had entered the household, perhaps as a servant, at an unknown date before 1649.

This 23-year-old soon commanded Rembrandt's affections, and Geertghe left the latter's house in June 1649. She immediately sued the artist for breach of promise. After an unpleasant court action, Rembrandt was forced to pay her 200 guilders a year until death, but Geertghe was not permitted to sell the jewelry that she had willed to Titus in 1648. Within a year, however, she broke her part of the agreement. Rembrandt learned of this and in July 1650 brought charges against her. She was sentenced to the reformatory in Gouda, and Rembrandt paid her transportation there. In 1655, after much opposition from Rembrandt, Geertghe was freed through the efforts of her friends living in Edam.

From all of this it can be concluded that Rembrandt's personal life, beginning with Saskia's illness in the late 1630s, was extremely difficult and unsettling. Furthermore, he was having financial problems caused, in the main, by his inability to meet the large payments due on his house. This ultimately led to his bankruptcy in the 1650s. It has been suggested that these difficulties were responsible for his stylistic changes beginning around 1639–40. This romantic notion has recently been discarded. It has been pointed out that around 1640 Dutch art underwent a general change from the more dramatic Baroque to a quieter, more classical style in representations of landscape, portraiture, still life, allegorical genre, history, and so on. Rembrandt responded to this new spirit, and his works of the 1640s become more introspective, quiet, and structured. His portraits of the period stress the sitters and not their attributes, but this does not lessen the animation or naturalism of his subjects. This begins with the "Self Portrait" (1640; National Gallery, London) and becomes more and more evident in the following decades. His sitters are placed in a quiet balance, and the canvas is filled with soft, atmospheric light that suggests an inner mood. This same emphasis upon balance and structure dominates his religious works, which were still held in high esteem whether they were in graphics ("The 100 Guilder Print") or paint. On November 29, 1646, Rembrandt was paid 2,400 guilders by Prince Frederik Hendrik for two paintings, an "Adoration of the Shepherds" (now in Alte Pinakothek, Munich) and a "Circumcision" (lost).

Landscapes of the 1640s

During the 1640s Rembrandt continued to paint landscapes, and they, too, became more architectonic, although remaining imaginary in subject matter except for the "Winter Landscape." This work might very well have been observed from nature. Beginning in the early 1640s Rembrandt began to walk in and draw the countryside around Amsterdam. Perhaps he turned toward the peaceful landscape as an escape from the hectic problems of life that engulfed him at this time. In any case, these drawings made from nature and the etchings executed after the walks are marvellous observations of nature done in a simple and direct style. The structured, calm, and harmonious style of his portraits and history scenes is also most evident in his drawn and etched views of the Amstel and Bullewijk rivers, the Diemer dike, and the environs of Haarlem and Rhenen in Gelderland made during the 1640s and early 1650s. His ability to catch vividly and preserve the atmosphere of the Dutch countryside was due, in part, to his masterful combination of line and wash or the etcher's needle and drypoint.

Work and life during the 1650s. During the 1650s Rembrandt created many of his most impressive works. He continued to develop the more structural quiet style of the 1640s, but with a more monumental effect. His brush became broader and more powerful, and he built up the colours in layers, thereby giving the viewer an even greater sense of form. His colour range became warmer and more intense, and he established a greater tonal harmony. Although contemporary taste had changed in favour of the brighter hues and the cool tonality of Anthony Van Dyck's elegant courtly style, as practiced in Amsterdam by such able and successful artists as Bartholomeus van der Helst, Rembrandt's sombre and heroic style of the 1650s was still very much appreciated, both at home and abroad. In 1653, for example, he created two of his great masterpieces, the visionary "Three Crosses" in drypoint and burin and the majestic painting of "Aristotle Contemplating the Bust of Homer." The latter was commissioned by the Sicilian nobleman Don Antonio Ruffo, who paid Rembrandt 500 guilders, which, Ruffo himself said, was eight times more than he paid for similar works by the most well-known Italian painters. Moreover, Ruffo commissioned the famous Italian artist Guercino to paint a pendant for the "Aristotle." The letter of acceptance, dated June 13, 1660, gives some idea of Rembrandt's reputation in contemporary Italian art circles. Guercino, after praising Rembrandt's prints, says that "I sincerely consider him a great artist." Ruffo must have been more than pleased with the "Aristotle," as he ordered two more pictures from Rembrandt in the early 1660s, an "Alexander the Great" and a "Homer," and 189 etchings in 1669.

Important commissions of the 1650s

Rembrandt continued to receive important commissions from distinguished Amsterdam citizens such as the publisher and print dealer Clement de Jonghe, the patrician Jan Six, the inspector of Amsterdam's Medical College, Dr. Arnold Tholinx, and the silversmith Johannes Lutma the Elder. Rembrandt also obtained one of his most important public commissions at this time, the 1656 "Anatomical Lesson of Dr. Joan Deyman." Other works of this decade, whose 17th-century provenances are unknown but which are also magnificent in execution, are "The Polish Rider," "Bathsheba," and "Jacob Blessing the Sons of Joseph." In spite of the fact that Rembrandt earned respectable sums of money at this time, his financial situation deteriorated rapidly, and by 1656 he declared bankruptcy. As noted, the management of his finances had been a constant source of difficulty for Rembrandt since he purchased the large house on the Sint Anthonisbreestraat. In 1653 the mortgage holder sent Rembrandt an itemized account of the latter's debt, which amounted to 8,470 guilders (at that time the rector of the Amsterdam Athenaeum received a yearly salary of 1,500 guilders and a rent-free house). Rembrandt paid the debt immediately, but not before he had obtained a one-year interest-free loan of 4,180 guilders from the mayor of Amsterdam, Dr. Cornelis Witsen, while Rembrandt's patrician friend Jan Six and a cosigner loaned him 1,000 guilders. Rembrandt received another 4,000-guilder loan at 5 percent interest from a merchant and art dealer. A year later Rembrandt bought a smaller house, but he had not paid for it by December 1655. In this same month, Rembrandt sold a large amount of his belongings at seven public auctions, perhaps to satisfy his creditors or because he was moving into smaller quarters. In spite of these auctions and the continued sales of his pictures, Rembrandt was unable to extricate himself. On May 17, 1656, he transferred ownership of his house to Titus and shortly thereafter petitioned the High Court in The Hague for "cessio bonorum." From this petition one learns the names of his main creditors and the reasons for his bankruptcy, which were "losses suffered in business as well as damages and losses by Sea." This suggests that Rembrandt very likely was an art dealer and also invested in Dutch commercial ventures abroad, which in the early 1650s had suffered setbacks because of the naval war with England. Rembrandt's petition was granted, and he kept his freedom and such personal belongings necessary for him to earn his living. On the other hand, Titus' affairs were placed in the hands of a court-appointed guardian and Rembrandt had to make an inventory of his belongings, which were to be sold at auction for the benefit of his creditors. The inventory for the municipal auctioneer is dated July 25/26, 1656, and presents a formidable list that, among other things, reveals the extent of Rembrandt's activities as a collector. This collection shows Rembrandt to be a gentleman-virtuoso and that, according to 17th-century ideals, he possessed all the symbols of success—that is, riches, honour, and fame. Unhappily, this magnificent collection was sold in two parts. The first sale took place in the Emperor's Crown Inn beginning on December 4, 1657, and lasted three weeks, earning 3,094 guilders. The second sale, in the fall of 1658, contained his etchings and drawings and brought a disappointing 596 guilders. In February of the same year, the Sint Anthonisbreestraat house was sold, but Rembrandt was not forced to move out until December 18, 1660.

Sale of Rembrandt's collection

Rembrandt's complicated financial situation also affected his domestic life. It must be remembered that if he remarried, he would forfeit his share of Saskia's estate, which was his only dependable source of income. As a result, he was unable to marry either Geertghe Dircx or Hendrickje Stoffels. Around 1649 Hendrickje replaced Geertghe as his mistress, and this situation was fully acceptable to the church until she became pregnant. Because of this she and Rembrandt were called to appeal before the Council of the Reformed Church of Amsterdam and accused of having illicit relations. The couple ignored the first two calls, and Hendrickje answered the third summons on July 23. The council's discussion is preserved in the following statement:

> Hendrickie Jaghers having appeared before the sitting, admits that she has engaged in concubinage with Rembrandt the painter, is therefore severely reprimanded, exhorted to penitence, and forbidden the table of the Lord.

At the end of October, Hendrickje gave birth to Cornelia, who was baptized on October 30. Because the baptism was permitted, it can be concluded that Hendrickje repented sufficiently and that the church recognized Rembrandt's difficult circumstances. Furthermore, it becomes clear that Rembrandt must have been a nonpracticing member of the Reformed Church and not a Mennonite as stated in Baldinucci's biography of Rembrandt and suggested by choice of subject matter. Certainly the Mennonites would never have allowed a member of their community to live with a mistress and have an illegitimate child baptized in the Reformed Church.

FINAL YEARS

Partnership with Titus

After 1654 Rembrandt and Hendrickje had, as far as is known, no more problems with the church authorities. They lived and worked together in harmony, and on December 15, 1660, three days before moving to a new house on the Rozengracht, they formalized a business partnership with Titus that already had been in force for two years. The document states that all the household effects were owned in equal shares by Titus and Hendrickje. They also divided in half all profits and losses resulting from the sale of Rembrandt's work. The latter acted as adviser to the firm and received free room and board. He also agreed to repay a loan of 1,750 guilders that he owed to Titus and Hendrickje.

In the following year, 1661, Rembrandt's production showed a decided increase. In fact, he painted more in that year than in any other year before or after, including a commission to paint "The Conspiracy of Claudius Civilis" for the public gallery of the new Amsterdam Town Hall. This great canvas was hung in the town hall in 1662, and a document from August of that year notes that Rembrandt was still owed money for the painting and changes that he had made. Sometime thereafter, very likely because the alterations were not approved, the painting was returned to Rembrandt. This reverse does not mark a fall in Rembrandt's popularity, however. In the following year he received an important public commission to paint "The Sampling Officials of the Drapers' Guild." Portraits like this, the numerous self-portraits, and the poignant Bible scenes, such as "The Return of the Prodigal Son," display an even broader and more freely applied paint composed of warm, rich yellows, reds, and browns. Although Rembrandt executed fewer works during the years after Hendrickje's death in 1663, he rose to even greater heights as an artist who truly spoke to mankind on all levels.

During the final years of his life, Rembrandt attained the apex of his creative powers. With the bankruptcy of 1656 and the death of Hendrickje in July 1663, Rembrandt did not, as some writers and film makers have asserted, become more and more of a poverty-stricken recluse. His circle of friends, however, did change during the last decade of his life and no longer included members of the patrician or influential strata of Amsterdam society. He now associated with lower middle class citizens who, nonetheless, were very much concerned and involved in the intellectual and artistic life of the period. Rembrandt's friends included such people as the apothecary, merchant, and collector Abraham Francen, the dyer and portraitist Christiaen Dusart, the poets Jeremias de Decker and H.F. Waterloos, the painter and poet Heiman Dullaert, the artists Gerbrand van den Eeckhout and Roelant Roghman, and the Reformed theologian and poet Jacobus Heyblock. This group formed a loose circle of intellectuals who critically followed the tenets of Reformed Christianity based on a deep knowledge of the Bible. Their poems and essays exhibit a real understanding of Rembrandt's importance as an interpreter of the Bible. Not only did Rembrandt continue to have friends during.the last decade of his life, but he also appears to have been financially solvent. He was still able to function as a collector, a fact that is known from a notebook kept by the shopkeeper and amateur genealogist Pieter van Brederode. In an entry dated October 2, 1669, the latter writes about "Antiquities and Rarities collected over a course of time by Rembrandt van Rijn." Two days after this was written, very likely on the occasion of Van Brederode's visit to Rembrandt, the artist died and was buried on October 8 in Amsterdam's Westerkerk. Rembrandt's funeral was not that of a forgotten pauper. It is known that, among others, his colleagues from the painters' Guild of St. Luke attended, that he had 16 pallbearers, and that the costs amounted to 20 guilders. Titus, his only son, had been interred in the same church 11 months earlier on September 7, 1668, and his funeral was half as expensive as his father's.

Death and funeral

REMBRANDT CRITICISM

At the time of his death Rembrandt had attained an international renown and was very much praised by his countrymen. He had pupils and followers at home and abroad and, as noted, did not die a penniless hermit. Within six years after his death, however, his reputation fell victim to classicistic art theory. He was condemned for following nature instead of the ideal beauty within nature, for being against the academies and their study of perspective, the imitation of the antique, rules of anatomy and proportion. He was, in short, considered a vulgar painter. This negative evaluation began with Joachim von Sandrart's *Teutsche Akademie* of 1675. This type of criticism grew in the late 17th and early 18th centuries and reached a climax in Arnold Houbraken's biography of 1718. The latter filled his Rembrandt biography with anecdotes depicting him as a man governed by avarice and vanity. During these years, Rembrandt must have been considered one of the most important and influential Dutch artists of the older generation to warrant such violent attacks. This classicistic appraisal of Rembrandt continued in the Netherlands well after Houbraken. In the 18th century Rembrandt's vulgar nature was still stressed, and he continued to be considered an outcast whose great talent was never fulfilled. Outside of academic circles, however, especially in France, his works, particularly the etchings, were very much sought after. Artists such as Jean-Honor6 Fragonard, Jean-Baptiste Chardin, and Jean-Baptiste Greuze copied his work, while the aristocratic painter Antoine Coypel praised Rembrandt highly. In 18th-century Italy, Rembrandt's paintings and etchings were especially appreciated in Venice, where they were collected and very much influenced the most important artists working there—G.B. Piazzetta and G.B. Tiepolo. In Germany and eastern Europe, Rembrandt's works were also collected. In England, at the end of the century, Sir Joshua Reynolds praised Rembrandt, copied him, and purchased his works. Reynolds started the English interest in Rembrandt that initiated a new criticism of the artist, an example of which appeared in the 1817 edition of the *Encyclopædia Britannica.* William Hazlitt wrote "Rembrandt might be said to have created a style of his own, which he also perfected." The 19th century saw Rembrandt turned into a hero. The age of Romanticism considered him a genius, a revolutionary, and a hero of the middle class, Protestant, Dutch society. Houbraken's estimates of Rembrandt's character were, at long last. disregarded and Rembrandt's social position elevated because–of his marriage to the socially prominent Saskia. Around 1850, however, there was still another change, and he was once again viewed as a man of weak character. This was excused as a handicap under which a genius must work. Rembrandt was also seen as a man who loved liberty because of his so-called predilection for low company. In the early 20th century, the romanticized version of Rembrandt's character continued. Following late-19th-century romantic myth, his life was divided into two periods: an early, outgoing successful one and a later one of failure and introversion living in seclusion. This change of status from fortune to misfortune was attributed to the mythical rejection of the "Nightwatch" in 1642. Rembrandt's patrons were believed to have been dissatisfied, the picture reduced in size and hung in a dark out-of-the-way place. Dime novelists

Romanticized version of Rembrandt's life had a field day elaborating on this tale, which culminated in the film starring Charles Laughton as the forgotten, alcoholic Rembrandt. It has only been within the last years that these myths have been disproved and that Rembrandt's true position in his own period has been clarified.

MAJOR WORKS

Paintings

PORTRAITS: "Self Portrait" (c. 1628: Rijksmuseum, Amsterdam, on loan from Daan Cevat Collection, England); "Self Portrait" (c. 1629; Mauritshuis, The Hague); "Rembrandt's Mother" (1631; Rijksmuseum, Amsterdam); "Portrait of Nicolaes Ruts" (1631; Frick Collection, New York); "Portrait of Maarten Looten" (1632; Los Angeles County Museum of Art); "The Anatomy Lesson of Dr. Nicolaes Tulp" (1632; Mauritshuis, The Hague); "The Noble Slav" (1632; Metropolitan Museum of Art, New York); "Portrait of Johannes Uytenbogaert" (1633; Earl of Rosebery Collection, Mentmore, Buckinghamshire); "The Shipbuilder and His Wife" (1633; Buckingham Palace, London); "Portrait of Maerten Soolmans" (1634; Robert de Rothchild Collection, Paris); "Portrait of Oopjen Coppit, Wife of Maerten Soolmans" (1634; Robert de Rothchild Collection, Paris); "Portrait of Saskia as Flora" (1634; Hermitage, Leningrad); "Self Portrait" (1634; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Portrait of Saskia" (c. 1633–34; Staatliche Kunstsammlungen, Kassel, West Germany); "Rembrandt and Saskia" ("Prodigal Son[?]"; c. 1635; Gemaldegalerie, Dresden, East Germany); "Rembrandt's Mother" (1639; Kunsthistorisches Museum, Vienna); "Maria Trip" (1639; Rijksmuseum, Amsterdam, on loan from the Van Weede Family Foundation); "Self Portrait at the Age of 34" (1640; National Gallery, London); "The Mennonite Minister Cornelis Claesz. Anslo Conversing with a Woman" (1641; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Nightwatch" ("The Company of Captain Frans Banning Cocq and Lieutenant Willem van Ruytenburch"; 1642; Rijksmuseum, Amsterdam); "A Girl at the Window" (1645; Dulwich College Picture Gallery, London); "The Man with the Golden Helmet" (*c.* 1650; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Self Portrait" (1652; Kunsthistorisches Museum, Vienna); "Portrait of Nicolaes Bruyningh" (1652; Staatliche Kunstsammlungen, Kassel); "A Woman Bathing in a Stream" (*c.* 1654 or 1655?; National Gallery, London); "Jan Six" (1654; Six Collection, Amsterdam); "Titus at His Desk" (1655; Museum Boymans-van Beuningen, Rotterdam); "Portrait of Dr. Arnold Tholinx" (1656; Musée Jacquemart-André, Paris); "The Anatomical Lesson of Dr. Joan Deyman" (1656; Rijksmuseum, Amsterdam); "Portrait of Hendrickje Stoffels[?]" (c. 1656–58; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Self Portrait" (1657; National Gallery of Scotland, Edinburgh, on loan from the Duke of Sutherland); "Portrait of Titus Reading" (c. 1657; Kunsthistorisches Museum, Vienna); "Self Portrait" (1658; Frick Collection, New York); "Self Portrait" (c. 1659–60; Iveagh Bequest, Kenwood House, London); "Self Portrait" (1659; National Gallery of Art, Washington, D.C.); "Portrait of Titus" (c. 1659; Louvre, Paris); "Hendrickje Stoffels" (1660; Metropolitan Museum of Art, New York); "Self Portrait" (1660; Louvre, Paris); "Portrait of Himself as St. Paul" (1661; Rijksmuseum, Amsterdam); "The Sampling Officials of the Drapers' Guild" ("Staalmeesters"; 1662; Rijksmuseum, Amsterdam); "Portrait of Gerard de Lairesse" (1665; Robert Lehman Collection, New York); "Self Portrait" (c. 1668; Wallraf-Richartz Museum, Cologne); "Family Group" (c. 1668; Herzog-Anton-Ulrich-Museum, Braunschweig, West Germany); "Self Portrait" (1669; Mauritshuis, The Hague); "The Bridal Couple" ("The Jewish Bride"; c. 1665; Rijksmuseum, Amsterdam).

RELIGIOUS PAINTINGS: "The Angel and the Prophet Balaain" (1626; Musée Cognacq-Jay, Paris); "Tobit and Anna with the Kid" (1626; Rijksmuseum, Amsterdam, on loan from Baroness Bentinck-Thyssen); "The Flight into Egypt" (1627; Musée des Beaux-Arts, Tours, France); "Christ at Emmaus" (*c.* 1629; Musée Jacquemart-André, Paris); "The Tribute Money" (1629; National Gallery of Canada, Ottawa); "Presentation of Christ in the Temple" (1631; Mauritshuis, The Hague); "The Passion Cycle," five paintings (c. 1632/33–39; Alte Pinakothek, Munich); "The Sacrifice of Abraham" (1635; Hermitage, Leningrad); "The Blinding of Samson" (1636; Stadelsches Kunstinstitut, Frankfurt am Main); "The Risen Christ Appearing to the Mary Magdalen" (1638; Buckingham Palace, London); "Samson's Wedding Feast" (1638; Gemäldegalerie, Dresden); "The Visitation" (1640; Detroit Institute of Arts); "The Reconciliation of David and Absalom" (1642; Hermitage, Leningrad); "The Holy Family with Angels" (1645; Hermitage, Leningrad); "The Holy Family," with painted frame and curtain (1646; Staatliche Kunstsammlungen, Kassel); "Rest on the Flight into Egypt" (1647; National Gallery of Ireland, Dublin); "Susanna and the Elders" (1647; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Bathsheba Holding King David's Letter" (1654; Louvre, Paris); "Jacob Blessing the Sons of Joseph" (1656; Staatliche Kunstsammlungen, Kassel); "St. Peter's Denial" (1660; Rijksmuseum, Amsterdam); "The Return of the Prodigal Son" (c. 1668–69; Hermitage, Leningrad); "Simeon Holding the Christ Child in the Temple" (1669; Nationalmuseum, Stockholm).

ALLEGORY, HISTORY, AND MYTHOLOGY: "The Money-Changer" ("Avarice"; 1627; Staatliche Museen Preussischer Kulturhesitz, Berlin); "The Abduction of Ganymede" (1635; Gemaldegalerie, Dresden); "Danae" (1636 and reworked c. 1645–50; Hermitage, Leningrad); "Aristotle Contemplating the Bust of Homer" (1653; Metropolitan Museum of Art, New York); "The Polish Rider" (*c.* 1655; Frick Collection, New York); "The Conspiracy of Claudius Civilis" (1661; Nationalmuseum, Stockholm); "Homer" (1663; Mauritshuis, The Hague); "Lucretia" (1664; National Gallery of Art, Washington, D.C.); "Lucretia" (1666; Minneapolis Institute of Arts, Minnesota).

LANDSCAPES: "The Stone Bridge" (c. 1638; Rijksmuseum, Amsterdam); "Stormy Landscape" (c. 1638; Herzog-Anton-Ulrich-Museum, Braunschweig); "Winter Landscape" (1646; Staatliche Kunstsammlungen, Kassel).

Etchings

"Self Portrait Bareheaded" (1629); "The Raising of Lazarus" (c. 1632); "The Angel Appearing to the Shepherds" (1634); "The Return of the Prodigal Son" (1636); "The Death of the Virgin" (1639); "Rembrandt Leaning on a Stone-Sill" (1639); "View of Amsterdam" (c. 1640); "The Three Trees" (1643); "Six's Bridge" (1645); "Jan Cornelis Sylvius Preacher" (1646); "Study of Two Male Nudes and Baby Learning to Walk" (c. 1646); "Jan Six" (1647); "Self Portrait Drawing at a Window" (1648); "The 100 Guilder Print" (c. 1639–49); "The Shell" (1650); "Clement de Jonghe" (1651); "The Goldweigher's Field" (1651); "Faust" (c. 1652); "Christ Preaching" ("La Petite Tombe"; c. 1652); "The Three Crosses" (1653); "St. Jerome Reading in an Italian Landscape" (c. 1653); "Christ Presented to the People" (1655); "Thomas Jacobszoon Haringh" (1655); "Arnold Tholinx" (c. 1656); "Abraham Francen" (*c.* 1657); "Negress Lying Down" (1658); "Jupiter and Antiope" (1659).

Drawings

"Self Portrait" (c. 1627–28; British Museum); "Seated Old Man" (1631; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Watchdog Asleep in His Kennel" (c. 1633; Museum of Fine Arts, Boston); "Saskia Looking Out of a Window" (c. 1635; Museum Boymans-van Beuningen, Rotterdam); "Study for the Etching 'The Great Jewish Bride'" (c. 1635; Nationalmuseum, Stockholm); "A Woman Carrying Child Downstairs" (c. 1636; Pierpont Morgan Library, New York); "A Row of Trees in an Open Field" (c. 1636; Kupferstichkabinett der Akademie der bildenden Künste, Vienna); "Elephant" (1637; British Museum); "Woman Seen from Behind Wearing a North Holland Costume" (c. 1638; Teyler Museum, Haarlem); "Saskia in Bed, a Woman Sitting at Her Feet" (*c.* 1635–40; Staatliche Graphische Sammlung, Munich); "Portrait of Titia van Uylenburch" (1639; Nationalmuseum, Stockholm); "Study for Etched Portrait of J.C. Sylvius" (1646; British Museum); "Young Man Pulling a Rope" (c. 1645; Rijksprentenkabinet, Amsterdam); "Turn in the Amstel River near Kostverloren Estate" (c. 1649–50; Louvre, Paris, Edmond de Rothschild Bequest); "View of the River IJ near Amsterdam" (c. 1649–50; Chatsworth Settlement, Derbyshire); "View of the Amstel River" (c. 1648; Rijksprentenkabinet, Amsterdam); "The Amstel River at the Omval" (c. 1652; Chatsworth Settlement, Derbyshire); "St. Jerome Reading in a Landscape" (c. 1652; Kunsthalle, Hamburg); "Jael and Sisera" (c. 1655–60; Rijksprentenkabinet, Amsterdam); "Sleeping Woman" (c. 1655; British Museum); "Christ on the Mount of Olives" (c. 1657; Kunsthalle, Hamburg); "Portrait of a Man" (c. 1655–60; Louvre, Paris); "Female Nude Seated on a Stool" (c. 1658; Art Institute of Chicago); "Self Portrait" (c. 1656–59; Museum Boymans-van Beuningen, Rotterdam); "Study for the Conspiracy of Claudius Civilis" (1661; Staatliche Graphische Sammlung, Munich).

BIBLIOGRAPHY. O. BENESCH, *Rernbrandt: Werk und Forschung* (1935), a fundamental work studying in detail Rembrandt's life and oeuvre and containing a complete and methodical bibliography; *Bibliography of the Netherlands Institute for Art History* (annual since 1943), a complete and systematic compilation of everything published on Rembrandt for each year issued; E. HAVERKAMP BEGEMANN, "The Present

State of Rembrandt Studies," *The Art Bulletin,* 53:88–104 (1971), excellent critical analysis of Rembrandt publications in 1968–71.

Biographies, documents, and history of criticism: A. HOUBRAKEN, *De Groote Schouburgh der Nederlantsche Konstschilders en Schilderessen . . .* , 3 vol. (1718–21), a long biography of Rembrandt containing many anecdotes as well as facts that became the basis for 18th- and 19th-century Rembrandt criticism; C. HOFSTEDE DE GROOT, *Die Urkunden über Rernbrandt* (1575–1721), new ed. (1906), a basic work that includes all documents concerning Rembrandt known at that time with careful annotations; S. SLIVE, *Rembrandt and His Critics,* 1630–1730 (1953), a study of critical and biographical works on Rembrandt written during his lifetime and up until 1730, informing us of what Rembrandt's contemporaries and near contemporaries thought of him; C. WHITE, *Rernbrandt and His World* (1964), an excellent study of Rembrandt's life and his environment, including works to illustrate the biography; J.A. EMMENS, *Rembrandt en de regels van de Kunst* (1968), a brilliant and fundamental work clarifying the false image of Rembrandt created by 17th-century classicistic critics, which continued well into the 20th century—English summary; R.W. SCHELLER, "Rembrandt en de encylopedische verzameling," *Oud-Holland,* 84:81–147 (1969), a splendid and new interpretation of Rembrandt as a collector—English summary; ART INSTITUTE OF CHICAGO, *Rembrandt After Three Hundred Years: An Exhibition of Rembrandt and His Followers* (1969–70), contains an excellent discussion in the introduction by E. HAVERKAMP BEGEMANN on Rembrandt as a teacher.

Monographs and catalogs of works: (Paintings): A.M. HIND, *Rembrandt*, 2nd ed. (1938), a good general discussion of all phases of Rembrandt; A. BREDIUS, *The Paintings of Rembrandt,* 3rd ed. rev. by HORST GERSON (1968), a catalog of all known works by Rembrandt completely illustrated with important short entries about each painting; J. ROSENBERG, *Rembrandt*, 2nd rev. ed. (1964), a sensitively written survey and catalog; K. BAUCH, *Rembrandt Gemälde* (1966), a catalog of paintings with short comments; H. GERSON, *Rembrandt Paintings* (Eng. trans. 1968), an excellent general discussion of Rembrandt's development and position in Dutch art and a catalog of the paintings (rejects a number of works generally considered to be by the artist); B. HAAK, *Rernbrandt: His Life, His Work, His Time* (Eng. trans. 1969), illustrated biography of Rembrandt with an especially good discussion of contemporary Dutch history, including documents concerning Rernbrandt's life. *(Drawings):* O. BENESCH, *The Drawing.of Rembrandt,* 6 vol. (1954–57), a fundamental catalog of all known Rembrandt drawings, completely illustrated; *Rernbrandt As a Draughtsman* (1960), a sensitive introduction including additions to drawing oeuvre not known in 1957; C. WHITE, *The Drawings of Rembrandt* (1962), an excellent concise essay on Rembrandt as a draughtsman. *(Etchings)*: A.M. HIND, *Catalogue of Rembrandt's Etchings,* 2nd ed., 2 vol. (1923), a fundamental work; L. MUNZ, *Rembrandt's Etchings,* 2 vol. (1952), an entirely new study of Rembrandt's etchings with catalog and illustrations; G. BIORKLUND and O.H. BARNARD, *Rembrandt's Etchings, True and False* (1955), a careful discussion of various states of the etchings; C. WHITE and K.F. BLOON, *Rernbrandt van Rijn* (1969), a most important catalog of Rembrandt etchings; C. WHITE, *Rembrandt As an Etcher: A study of the Arfist at Work* (1969), a very well written discussion of Rembrandt as an etcher, with special emphasis upon his technique and the connections between the etchings, drawings, and paintings.

Rembrandt and religion: H.M. ROTERMUND, *Handzeichnungen urid Radierungen zur Bibel* (1963; Eng. trans., *Rembrandt's Drawings and Etchings for the Bible,* 1969), considers the biblical texts as the main source for Rembrandt's imagery.

Critical sturlies: K. CLARK, *Remhrandt and the Italian Renaissance* (1966), a discussion of the change in Rembrandt's style as seen by the author as a result of his study of antique and Italian Renaissance art; J.S. HELD, *Rembrandt's Aristotle and Other Rembrandt Studies* (1969), an excellent volume of essays that includes new and scholarly iconological studies of Rembrandt's *Aristotle* and *Juno*, reprints of Held's book *Rembrandt and the Book of Tobit,* and his well-known articles on *The Polish Rider* and *Rembrandt: Truth and Legend;* R.H. FUCHS, *Rembrandt in Amsterdam* (1969), essays on Rembrandt's connections with Amsterdam and with the art of his contemporaries; *Otto Benesch, Collected Writings*, vol. 1, *Rembrandt,* ed. by EVA BENESCH and German translations by GILLIAN MULLINS (1970), an important collection of articles for the understanding of many aspects of the artist.

(J.R.J.)

Renaissance

The term Renaissance is widely understood to denote a new age in the history of Western civilization at the end of the Middle Ages. The term derives from the "rebirth" (French *renaissance,* from Italian *rinascenza,* more commonly *rinascimento*) or "revival" of learning or of the arts, supposed to separate the Middle Ages and the modern period.

HISTORIOGRAPHICAL PROBLEMS

This concept of a new age derives mainly from the 19th-century writers Jules Michelet, John Addington Symonds, and above all Jacob Burckhardt, whose classic essay, *The Civilization of the Renaissance in Italy* (1860), continues to exercise an enormous influence.

The early view. The concept of a revival of culture, however, began much earlier, with the Italian writers and scholars of the 14th, 15th, and 16th centuries, who, because they occupied themselves with *studia humanitatis*, or the humanities, came to be called Humanists.

The Italian Humanists. The 14th-century poet and classical scholar Petrarch was probably the first to conceive of the 1,000 years from late Roman antiquity down to and including his own day as an age of darkness, marked by the extinction of excellence in both literary culture and public virtue. Petrarch was not optimistic that this state of affairs could really be altered, so deeply ingrained was the modern barbarism, but he called for a revival of the study of antiquity—its speech, literary style, and moral thought. A true *imitatio* of the ancients would be no superficial aping of their ways but instead a grasping of the mystery of their genius and, thus, the beginning of a great recovery. Addressing himself to the younger generation, Petrarch expressed the hope that "this slumber of forgetfulness" would soon be dispelled and that man would be able "to walk forward in the pure radiance of the past."

Classical revival

Thus, Petrarch introduced some of the main elements of the Renaissance idea, particularly the twin myths that antiquity was the zenith and the "Dark Ages" the nadir of human creativity and that a revival of culture and an improvement of society were dependent upon a revival of classical learning. These notions became the deepest convictions of the 15th-century Humanists. Moreover, success in gaining attention for their ideals and programs made them far more optimistic than Petrarch had been; wherever Humanist influence ran, it was commonplace to think that this was a time of revival not of Latin studies alone but of all of man's intellectual and creative powers.

The rise of the new style in painting and sculpture in 14th-century Italy, with its new treatment of space and its attention to human proportions, seemed to be a part of the same revival. Lorenzo Ghiberti, designer of the "Gates of Paradise" of the Florentine baptistery, wrote that after the destruction of ancient art following the spread of Christianity, Giotto had discovered methods buried some 600 years, thereby enabling him to abandon the crudeness of "the Greeks" (*i.e.,* the Byzantine style). This view was to receive its classic formulation by Giorgio Vasari in his *Lives of the Most Eminent Italian Painters, Sculptors and Architects . . .* (1550), with which the term rebirth—in Italian *la rinascita*—came into general usage. For Vasari, as for other writers of the time, the rebirth was both an imitation of ancient models and a recovery of the ability to observe and imitate nature. The inherent contradiction between imitation of antiquity and the spontaneous revival of creative impulses has plagued much of the thinking about the Renaissance ever since.

Humanism outside Italy. Outside Italy the idea of a rebirth of art and learning was absorbed as part of the Humanist movement that had conceived it. Understandably, Humanists of other countries were eager to demonstrate that the Italians did not have a monopoly of eloquence and belles lettres. Erasmus of Rotterdam, the "Prince of Humanists," who was, more than any other intellectual leader of the 16th century, a citizen of all Christendom, emphasized the European-wide scope of the Humanist movement and linked the classical revival to an attack upon scholastic philosophy and a reform of religion. Writing to Pope Leo X in 1517, he predicted the imminent beginning of a golden age under Leo's reign, marked by the restoration of peace, belles lettres, and piety.

The Reformation and the Enlightenment

The Reformation, which began that very year, was not the golden era envisioned by Erasmus. Nevertheless, while the Protestant Reformers were hostile to what they considered the paganizing aspects of the Humanist movement, they shared the Humanists' detestation of medieval culture, and they adopted the Erasmian view that the revival of classical literature was the prelude to the restoration of true piety. Indeed, the Reformers saw this as a part of God's plan for the opening of the new era of which they themselves were the prophets. For the most part, however, interest in the classical revival was now overshadowed by other more pressing issues in Reformation historiography. In the 17th century the enthusiasm generated by the great advances in the physical and biological sciences also tended to put the classical revival in the shade. References to "la renaissance des beaux arts" and "renaissance des lettres" in 17th-century French dictionaries conveyed nothing more than a fairly narrowly conceived event in literary and art history. The textbooks of the German writer Christoph Keller (Cellarius), which divided history into the three periods—Antiquity, Middle Ages, and Modern Times—had only a passing reference to the restoration of learning in Italy. Cellarius also retailed the mistaken notion that the revival was due to the influence of Greek scholars who had fled to Italy after the fall of Constantinople to the Turks in 1453.

The 19th-century view. With the coming of the Enlightenment, interest in the revival of learning increased. But of the Renaissance as a distinct epoch with its own characteristic culture there were as yet few hints. The idea that the age of classical revival had something positive and creative to contribute to Western civilization made headway in the early 19th century. Broadening views of intellectual and cultural history led historians of art and literature to think about the relations between their fields and Italian society as a whole. With critics like John Ruskin, the use of the term Renaissance to describe a definite period in the history of art became common, while the term humanism (*Humanismus*) was coined in Germany to refer to an intellectual movement the importance of which went far beyond the mere revival of classical style. Georg Voigt's monumental study of Italian Humanism, The Revival of Classical Antiquity (1859), treated the Humanists as representatives of a new lay literary culture characterized by a sense of individualism. Important as Voigt's book was for the history of Humanism, it was a step backward for the concept of the Renaissance, toward the old tradition of the Humanists themselves, who had attributed everything positive in their society to the revival of letters for which they, of course, were responsible. But the new trend of historical thinking, partly under the influence of G.W.F. Hegel, was to conceive of the classical revival as but one expression of a new, liberating historical epoch.

Michelet's idea of the Renaissance as an antithesis of the Middle Ages

Michelet. This trend reached maturity in 1855, when Jules Michelet published the seventh volume of his History of France, entitling it The Renaissance. Here Michelet introduced most of the themes present in the modern idea of the Renaissance. He viewed the period as the absolute antithesis of the Middle Ages, when nature and science had been proscribed and man had abdicated his freedom (a condition that had persisted until the close of the 15th century). Then, from Columbus to Copernicus and Galileo, man went from the discovery of the Earth to the discovery of the heavens and in the process rediscovered his own true spirit. In Michelet's view, Martin Luther and John Calvin, who penetrated man's moral nature, were as much men of the Renaissance as were Filippo Brunelleschi and Leonardo da Vinci, who reconciled nature and reason with art, or as were the Humanists, who recovered the wisdom of antiquity. He saw them all as imbued with the same impulse, "the discovery of the world and the discovery of man," which he regarded as the essence of the modern spirit. Michelet's discovery of an all-inclusive Renaissance spirit was congenial to the historical thinking of his time, and it provided a solution to the old problem of "la renaissance des lettres," demonstrating how the impulse for the revival of antiquity could be viewed as part of a more fundamental cultural transformation. But as to what, in turn, caused this cultural transformation, Michelet seems to have believed that it was self-generating. Moreover, his shift of emphasis from 15th-century Italy to 16th-century France was an overcompensation, a reaction to the excessively Italian focus of earlier theories. Writing in the full flush of 19th-century liberal French nationalism, Michelet's depiction of a youthful French nation leading Europe out of the clerical and feudal bondage of the Middle Ages was an obvious reference to the contemporary struggles with which he identified himself.

Burckhardt. Jacob Burckhardt, the conservative, detached Swiss historian of culture, shared neither Michelet's enthusiasm for nationalism nor his antipathy toward the Middle Ages. Although he borrowed some of Michelet's concepts and terminology (he once apologized for adopting, "for want of something better," the term Renaissance, which sounded "as if during the Middle Ages all cultural life had been sleeping as though dead"), the Renaissance he fashioned was fundamentally different from Michelet's. Burckhardt's Renaissance was exclusively Italian, thus representing a return to the older historical tradition. Neither medieval nor yet merely the beginning of the modern era, it was a distinct epoch that began in the 14th century and ended in the 16th—a civilization (Kultur) that was "the mother of our own." Although Burckhardt was chiefly interested in the mental traits of this new civilization, he saw a close connection between the new spirit and the social and political experience of the Italians. As he explained it, the political situation in Italy at the beginning of the 14th century provided the conditions for the development of the new mentality. The long struggle between the popes and the emperors, just ended, had exhausted both powers and had left Italy, the main scene of the conflict, in a new situation. While elsewhere in the West feudalism was being transformed into centralizing monarchies, Italy found itself with a multitude of independent states: some old, some of recent origin; some republican, some ruled by despots; but all free of any higher authority or sanction. In these states, where only power counted, Burckhardt detected the appearance of "the modern political spirit of Europe," which, though too frequently displaying the "worst features of an unbridled egotism," was also capable of creating a wholly new fact—"the state as a work of art." Where power was a function of individual ability rather than of legitimate authority, where political forms were what men and occasions rather than law and tradition made them, the state was the product of reflection and calculation, of the deliberate adaptation of means to ends.

Burckhardt's emphasis on the importance of individualism

"In the character of these states, whether republics or despotisms," Burckhardt wrote, "lies not the only but the chief reason for the early development of the Italian." The main feature of this development and the central characteristic of the Renaissance for Burckhardt was, indisputably, individualism. This, he thought, was a psychological fact that had profound implications for man's intellectual and social existence. Thus, "the development of the individual" made possible "the discovery of the world and the discovery of man"; Michelet's phrase, originally intended to describe the intellectual conquests of the 16th century, was given roots by Burckhardt in the social and political experience of the 14th- and 15th-century Italians. In other words, the revival of classical antiquity was an important feature but not the cause of the Renaissance. As Burckhardt put it in what he called one of the chief propositions of his book, "it was not the revival of Antiquity alone, but its union with the genius of the Italian people which achieved the conquest of the Western world."

The chief mediators between their own age and "a venerated Antiquity" were the Humanists, "poet-scholars," who, according to Burckhardt, constituted a virtual class that determined the forms of education and culture and often took the lead in political affairs as well. Although he recognized that Humanism first became "an indispensable element in daily life" in the city republics, he chose to emphasize the natural alliance between the poet-scholars and the despots by whom they were employed to sing praises and embellish the courts. Laymen rather than clerics and dependent upon the patronage of princes and wealthy burghers, the Humanists fell into disfavour in the 16th century; victims of their own reputation for profligacy and irreligion, they were also rendered superfluous by the new technology of printing, which made classical literature readily available to the reading public at large. Moreover, the unusual political situation, which, in Burckhardt's view, had made the Italian cities the matrix of a unique civilization, was being transformed. Beginning with the French invasion in 1494, Italy was overrun by foreign armies. In religion the new spirit of the Counter-Reformation was loosed upon the land, nurtured by a resurgent papacy. While many aspects of the new culture were becoming a part of the permanent endowment of the European mind, in Italy the Renaissance was over; the first prototype of modern civilization had passed into history.

The continuing influence of Burckhardt

Twentieth-century views. Burckhardt's Renaissance has become, to a remarkable degree, *the* Renaissance. This is no mere figure of speech: for most people, that particular historical landscape is first viewed with the configurations and colours that Burckhardt gave it, and for many it is all they ever see. Even scholars who take issue with Burckhardt's interpretation are obliged to fight on his ground—to formulate their own findings in terms of the validity or invalidity of his concepts. These concepts—"the State as a Work of Art"; "the Development of the Individual"; "the Discovery of the World and of Man"; "the Revival of Antiquity"—are the central features of what still deserves to be called the ruling paradigm of Renaissance studies.

In the manner of paradigms, Burckhardt's conception of the Renaissance has stimulated both an immense amount of further research and a great deal of controversy. Whether a new synthesis is in the offing—whether, indeed, there is a need for a new interpretation—is as much a matter of controversy as is the question of what this interpretation might be. Some leading scholars insist that while there are "oversights and errors" in the Burckhardtian vision, "the central insights . . . remain essentially unimpaired," and that "his book exhibits a reality that subsequent scholarship, however reluctantly, has been compelled to affirm." Others accept certain parts of his picture but would revise it in important ways. For example, Hans Baron agrees that Renaissance Italy was the prototype of modern civilization and that the revival of classical antiquity was an expression of the new culture rather than its cause; but he is wholly un-Burckhardtian in his own assessment of the originality of Humanist political, social, and historical thought and in his theory that Renaissance culture owed more to the experience of republican liberty than to the patronage of the despots. Some scholars accept the idea of a Renaissance more or less in Burckhardt's terms but insist that there were parallel developments of other national cultures so that there existed a French and a German as well as a Northern Renaissance. Others, sensing a different spirit and purpose in Humanist culture beyond the Alps, speak of a Christian Renaissance in the North in contrast to the secular Renaissance in Italy. A frequent criticism of Burckhardt's Renaissance is that it emerges too suddenly and is too sharply differentiated from the Middle Ages. Wallace K. Ferguson describes the Renaissance as a period of transition between the Middle Ages and the modern era, during which the feudal and ecclesiastical elements of the medieval world were gradually but steadily transformed, first in Italy, then in the rest of Europe, by the development of capitalism and urban society.

The Renaissance as a period of transition

The notion of an epoch whose distinguishing feature is that it was an age of transition between two other eras is not very illuminating, yet it represents an effort to cope with a historical record that is far more complicated and intractable than the one with which Burckhardt had to work. The impression of a static, solid, faith-bound Middle Ages has given way to a complex image of a variegated, changing, and creative civilization, scarcely recognizable in Burckhardt's poetic description of medieval consciousness lying "dreaming or half awake beneath a common veil" before its Renaissance awakening. The rise of economic and social history has provided new ways of looking at society and has created new challenges for Renaissance historians. The fact that capitalism and urban society are of medieval if not of ancient origins makes it difficult to accept without qualification Burckhardt's idea of the Renaissance as "a civilization which is the mother of our own."

At least one economic historian, Armando Sapori, has grasped the nettle, declaring that the really decisive Renaissance of the West began in the late 11th century with the advent of the Crusades, when the Italian coastal towns took the lead in the reconquest of the Mediterranean from Islām. In the 12th century, according to Sapori, a new society emerged in Italy, characterized by urban centres, merchant capitalism, the autonomous city-state, and a new culture of laymen. While the heyday of this civilization was the 12th and 13th centuries, it lasted until the 16th, when it was overtaken and bypassed by the new political and economic forces whose centre of gravity was the Atlantic and the North rather than the Mediterranean and the East. Frederick C. Lane has proposed a similar periodization on the ground that, between the 12th and the 16th centuries, the character of Italian society was uniquely shaped by its experiment in republican, representative government. From these perspectives the Renaissance would appear to have been an end phase rather than a revival and a beginning—the last glow of the fading medieval Italian communal society. Whether this new periodization or some other interpretation will prevail over the classic Burckhardtian view is impossible to predict. But it seems clear that, despite strenuous objections from scholars who believe that it has exercised a pernicious influence on historical thinking, neither the term nor the idea of a Renaissance shows any sign of disappearing from the historical vocabulary.

THE ITALIAN RENAISSANCE

Urban growth

Development of the Italian cities. Medieval Italy was a land of cities. The urban imprint of .Roman times, never totally erased during some 500 years of barbarian invasions and settlement, began to reassert itself in Italy by the 10th century. New towns and old ones newly revived began to dot the spiny Italian landscape—striking creations of a population that was burgeoning in numbers and brimming with new energies. As in Roman times, the medieval Italian town lived in close relation to its surrounding rural area, or *contado;* Italian city folk seldom relinquished their ties to the land from which they and their families had sprung. Rare was a successful tradesman or banker who did not invest some of his profits in his family farm or a rural noble who did not spend part of his year in his tower house inside city walls. In Italian towns, nobles, merchants, *rentiers,* and skilled craftsmen lived and worked side by side, fought in the same militia, and married into each other's families. Social hierarchy there was, but it was a tangled system with no simple division between noble and commoner, between landed and commercial wealth. That nobles took part in civic affairs helps explain the early militancy of the townfolk in resisting the local bishop, who was usually the principal claimant to power in the community. Political action against a common enemy tended to fuse townspeople with a sense of community and civic loyalty. By the end of the 11th century civic patriotism began to express itself in literature; city chronicles combined fact and legend to stress a city's Roman origins and, in some cases, its inheritance of Rome's special mission to rule. Such motifs reflect the cities' achievement of autonomy from their respective episcopal or secular feudal overlords and, probably, the growth of rivalries between neighbouring communities.

The city-states. This in turn was part of the expansion into the neighbouring countryside, with the smaller and weaker towns submitting to the domination of the larger and stronger. As the activity of the towns became more complex, sporadic political action was replaced by permanent civic institutions. Typically, the first of these was an executive magistracy, named the consulate (to stress the continuity with republican Rome). In the late 11th and early 12th centuries, this process--consisting of the establishment of juridical autonomy, the emergence of a permanent officialdom, and the spread of power beyond the walls of the city to the *contado* and neighbouring towns—was completed for about a dozen Italian centres and underway for some dozens more; the loose urban community was becoming a corporate entity, or ***commune;*** the city was becoming a city-state. The typical 13th century city-state was a republic administering a territory of dependent towns; whether it was a democracy is a question of definition. The idea of popular sovereignty existed in political thought and was reflected in the practice of calling a ***parlamento,*** or mass meeting, of the populace in times of emergency; but in none of the republics were the people as a whole admitted to regular participation in government. On the other hand, the 13th century saw the establishment, after considerable struggle, of assemblies in which some portion of the citizenry, determined by property and other qualifications, took part in debate, legislation, and the selection of officials. Most offices were filled by citizens serving on a rotating, short-term basis. If the almost universal obligation of service in the civic militia is also considered, it becomes clear that participation in the public life of the commune was shared by a considerable part of the population. Moreover, most of the city republics were small enough (in 1300 Florence, one of the very largest, had perhaps 100,000 people; Padua, nearer the average, had about 15,000) so that public business was conducted by and for citizens who knew each other, and civic issues were a matter of widespread and intense personal concern.

Enmity between nobles and the people

A darker but ever-present side of this intense community involvement was conflict. It became a cliché of contemporary observers that when the citizens were not fighting wars with their neighbours they were fighting each other. Machiavelli explained this as the result of the natural enmity between nobles and "the people—the former desiring to command, the latter unwilling to obey." Although this is too simple, it contains an essential truth: the basic problem was the unequal distribution of power and privilege, complicated by the persistence of violent feudal ways (the nobles' militant style was widely imitated as a standard of behaviour). The inability to contain conflict within peaceable limits resulted in bloody strife between members of rival factions, such as the Guelfs and Ghibellines, with those on the losing side often forced into exile and suffering the confiscation of their property.

Signoria. During the 14th century a number of cities, despairing of finding a solution to the problem of civic strife, were turning from republicanism to ***signoria,*** the rule of one man. The ***signore,*** or lord, was usually a member of a local feudal family that was also a power in the commune; thus, lordship did not appear to be an abnormal development, particularly if the ***signore*** chose, as most did, to rule through existing republican institutions. Sometimes a ***signoria*** was established as the result of one noble faction's victory over another, while in a few cases a feudal noble who had been hired by the republic as its ***condottiere,*** or military captain, became its master. Whatever the process, hereditary lordship had become the common condition and free republicanism the exception by the late 14th century. Contrary to what Burckhardt believed, Italy in the 14th century had not shaken off feudalism. In the south, feudalism was entrenched in the loosely centralized Kingdom of Naples, successor state to the Hohenstaufen and Norman kingdoms. In central and northern Italy, feudal lordship and knightly values merged with medieval communal institutions to produce the typical state of the Renaissance—a state that was a compromise between conflicting tendencies. Where the nobles were excluded by law from political participation in the commune, as in the Tuscan cities of Florence, Siena, Pisa, and Lucca, parliamentary republicanism had a longer life; but even these bastions of liberty had their intervals of disguised or open lordship. The great maritime republic of Venice reversed the usual process by increasing the powers of its councils at the expense of the doge (Latin ***dux,*** leader). But Venice never had a feudal nobility, only a merchant aristocracy that called itself noble and jealously guarded its hereditary sovereignty against incursions from below.

Wars of erpansion. There were new as well as traditional elements in the Renaissance city-state. Changes in the political and economic situation affected the evolution of government, while the growth of the Humanist movement influenced conceptions of citizenship, patriotism, and civic history. The decline in the ability of both the empire and the papacy to dominate Italian affairs as they had done in the past left each state free to pursue its own goals within the limits of its resources. These goals were, invariably, the security and power of each state vis-B-vis its neighbours. Diplomacy became a skilled game of experts; rivalries were deadly, and warfare was endemic. Because the costs of war were all-consuming, particularly as mercenary troops replaced citizen militias, the states had to find new sources of revenue and to develop methods of securing pubic credit. New officials were required to administer these revenues and to gather information and keep records. The city-state came to take over many of the functions formerly performed by associations of private citizens—the kinship groups, tower consortiums, guilds, and political parties that had regulated social relations—leaving individuals to confront the state alone and without intermediaries. If Renaissance man became conscious of himself as an individual, as Burckhardt declared, he also became inescapably conscious of his relation to the state, which became father, mother, and family to everyone under its jurisdiction.

Emergence of regional powers

In place of the prevailing anarchy, the Italian states had begun to evolve a new pattern by the 14th century. In place of the dual orbits of empire and papacy in which most of them had revolved, regional powers emerged, with the stronger or more ambitious from time to time bidding for domination of the peninsula. The most sustained effort of aggrandizement was that of Milan under the lordship of the Visconti. In the 1380s and 1390s Gian Galeazzo Visconti pushed Milanese hegemony eastward as far as Padua, at the very doorstep of Venice, and southward to the Tuscan cities of Lucca, Pisa, and Siena and even to Perugia in papal territory. Some believed that Gian Galeazzo meant to be king of Italy; whether or not this is true, he would probably have overrun Florence, the last outpost of resistance in central Italy, had he not died suddenly in 1402 leaving a divided inheritance and much confusion. In the 1420s, under Filippo Maria, Milan began to expand again; but by then Venice, with territorial ambitions of its own, had joined with Florence to block Milan's advance, while the other Italian states took sides or remained neutral according to their own interests. The mid-15th century saw the Italian peninsula embroiled in a turmoil of intrigues, plots, revolts, wars, and shifting alliances, of which the most sensational was the reversal that brought the two old enemies, Florence and Milan, together against Venetian expansion. This "diplomatic revolution," engineered by Cosimo de' Medici (1389–1464), the unofficial head of the Florentine republic, is the most significant illustration of the emergence of balance of power diplomacy in Renaissance Italy.

Italian Humanism and scholarship. As seen above, the notion that ancient wisdom and eloquence lay slumbering in the Dark Ages until awakened in the Renaissance was the creation of the Renaissance itself. The idea of the revival of classical antiquity was one of those great myths, comparable to the idea of the universal civilizing mission of imperial Rome or to the idea of progress in a modern industrial society, by which an era defines itself in history. Like all such myths, it was a blend of fact and invention. Classical thought and style permeated medieval culture in ways past counting. Most of the authors known to the Renaissance were known to the Middle Ages as well, while the classical works "discovered" by the Humanists were not originals but medieval copies preserved in monastic or cathedral libraries. Moreover, the Middle Ages had produced at least two earlier revivals of classical antiquity. The so-called Carolingian Renaissance of the late 8th and 9th centuries saved many ancient works from destruction or oblivion, passing them down to posterity in its beautiful minuscule script (which influenced the Humanist scripts of the Renaissance). A 12th-century Renaissance saw the revival of Roman law, Latin poetry, and Greek science, including almost the whole corpus of Aristotelian writings known today.

Earlier revivals of classical antiquity

Growth of literacy. Nevertheless, the classical revival of the Italian Renaissance was so different from these earlier movements in spirit and substance that the Humanists understandably felt it was original and unique. During most of the Middle Ages, classical studies and virtually all intellectual activities were carried on by churchmen, usually members of the regular orders. In the Italian cities this monopoly was partially breached by the growth of a literate laity with some taste and need for literary culture. New professions reflected the growth of both literary and specialized lay education—the *dictatores,* or teachers of practical rhetoric, and lawyers, and the ever present notary (a combination of accountant, solicitor, and public recorder). These, and not Burckhardt's wandering scholar-clerics, were the true predecessors of the Humanists.

In Padua a kind of early Humanism emerged, flourished, and declined between the late 13th and early 14th centuries. Paduan classicism was a product of the vigorous republican life of the commune, and its decline coincided with the loss of the city's liberty. A group of Paduan jurists, lawyers, and notaries—all trained as *dictatores*—developed a taste for classical literature that probably stemmed from their professional interest in Roman law and their affinity for the history of the Roman republic. The most famous of these Paduan classicists was Albertino Mussato, a poet, historian, and playwright, as well as lawyer and politician, whose play *Ecerinis,* modelled on Seneca, has been called the first Renaissance tragedy. By reviving several types of ancient literary forms and by promoting the use of classical models for poetry and rhetoric, the Paduan Humanists helped make the 14th-century Italians more conscious of their classical heritage; in other respects, however, they remained close to their medieval antecedents, showing little comprehension of the vast cultural and historical gulf that separated them from the ancients.

Language and eloquence. It was Petrarch who first understood fully that antiquity was a civilization apart and, understanding it, outlined a program of classically oriented studies that would lay bare its spirit.,The focus of Petrarch's insight was language: if classical antiquity was to be understood in its own terms it would be through the speech with which the ancients had communicated their thoughts. This meant that the languages of antiquity had to be studied as the ancients had used them and not as vehicles for carrying modern thoughts. Thus, grammar, which included the reading and careful imitation of ancient authors from a linguistic point of view, was the basis of Petrarch's entire program.

Eloquence as the union of elegance, power, and virtue

From the mastery of language one moved on to the attainment of eloquence. For Petrarch, as for Cicero, eloquence was not merely the possession of an elegant style, nor yet the power of persuasion, but the union of elegance and power together with virtue. One who studied language and rhetoric in the tradition of the great orators of antiquity did so for a moral purpose—to persuade men to the good life—for, said Petrarch in a dictum that could stand as the slogan of Renaissance Humanism, "it is better to will the good than to know the truth."

The humanities. To will the good, one must first know it; and so there could be no true eloquence without wisdom. According to Leonardo Bruni, a leading Humanist of the next generation, Petrarch "opened the way for us to show in what manner we might acquire learning." Petrarch's union of rhetoric and philosophy, modelled on the classical ideal of eloquence, provided the Humanists with an intellectual dignity and a moral ethos lacking to the medieval *dictatores* and classicists. It also pointed the way toward a program of studies—the *studia humanitatis* —by which the ideal might be achieved. As elaborated by Bruni, Pier Paolo Vergerio, and others, the notion of the humanities was based on classical models—the tradition of a liberal arts curriculum conceived by the Greeks and elaborated by Cicero and Quintilian. Medieval scholars had been fascinated by the notion that there were seven liberal arts, no more and no less, although they did not always agree as to which they were. The Humanists had their own favourites, which invariably included grammar, rhetoric, poetry, moral philosophy, and history, with a nod or two toward music and mathematics. They also had their own ideas about methods of teaching and study. They insisted upon the mastery of Classical Latin and, where possible, Greek, which began to be studied again in the West in 1397, when the Greek scholar Manuel Chrysoloras was invited to lecture in Florence. They also insisted upon the study of classical authors at first hand, banishing the medieval textbooks'and compendiums from their schools. This greatly increased the demand for classical texts, which was first met by copying manuscript books in the newly developed Humanistic scripts and then, after the mid-15th century, by the method of printing with movable type. Thus, while it is true that most of the ancient authors were already known in the Middle Ages, there was an all-important difference between circulating a book in many copies to a reading public and jealously guarding a single exemplar as a prized possession in some remote monastery library.

The term humanist (Italian *umanista,* Latin *humanista*) first occurs in 15th-century documents to refer to a teacher of the humanities. Humanists taught in a variety of ways. Some founded their own schools, as Vittorino da Feltre did in Mantua in 1423 and Guarino Veronese in Ferrara in 1429, where students could study the new curriculum at both elementary and advanced levels. Some Humanists taught in universities, which, while remaining strongholds of specialization in law, medicine, and theology, had begun to make a place for the new disciplines by the late 14th century. Still others were employed in private households, as was the great Politian (Angelo Poliziano), who was tutor to the Medici children as well as a university professor.

Literary works of the Humanists

Formal education was only one of several ways in which the Humanists shaped the minds of their age. Many were themselves fine literary artists who exemplified the eloquence they were trying to foster in their students. Renaissance Latin poetry, for example, nowadays dismissed—usually unread—as imitative and formalistic, contains much graceful and lyrical expression by such Humanists as Politian, Giovanni Pontano, and Jacopo Sannazzaro. In drama, Politian, Pontano, and Pietro Bembo were important innovators, and the Humanists were in their element in the composition of elegant letters, dialogues, and discourses. By the late 15th century, Humanists were beginning to apply their ideas about language and literature to composition in Italian as well as in Latin, demonstrating that the "vulgar" tongue could be as supple and as elegant in poetry and prose as was Classical Latin.

Classical scholarship. Not every Humanist was a poet, but most were classical scholars. Classical scholarship consisted of a set of related, specialized techniques by which the cultural heritage of antiquity was made available for convenient use. Essentially, in addition to searching out and authenticating ancient authors and works, this meant editing--comparing variant manuscripts of a work, correcting faulty or doubtful passages, and commenting in notes or in separate treatises on the style, meaning, and context of an author's thought. Obviously, this demanded not only superb mastery of the languages involved and a command of classical literature but also a knowledge of the culture that formed the ancient author's mind and influenced his writing. Consequently, the Humanists created a vast scholarly literature devoted to these matters and instructive in the critical techniques of classical philology, the study of ancient texts.

The Humanists' conception of man. Beginning with Petrarch, Humanist thought approached the subject of man through introspection and an examination of actual behaviour rather than through doctrinaire formulas. Striving for the good life, yet torn by selfish passions, caught between desires for immortality and for earthly fame, alternating between glory and despair—this was man as Petrarch knew him because the subject of his inquiry was himself. As orators, poets, historians, and moralists the Humanists dealt with man acting, willing, creating his own beauty and his own worldly destiny. Humanist psychology tended to stress the volitional and emotional rather than the rational side of man's nature. Reason was important but limited; it could neither master the passions nor grasp the ultimate mysteries. Reason was subordinate to the will, and the will was free to determine man's destiny. To quote Petrarch again, "It is better to will the good than to know the truth."

The study of man through his behaviour

This voluntarist, moralist conception of man reflects the Humanists' function as spokesmen of an urban, literate laity. To those who had found rewarding social roles in the public world of the city-state, the conception of human life elaborated by medieval theologians was no more useful than an educational system in the service of monastic and priestly values. The Humanists' conception of man as actor and creator was the counterpart of their definition of a new curriculum of liberal studies, with its emphasis upon the relation between culture and the good life. Here the Renaissance myth of antiquity served the Humanists in two ways: first, as a summation of, or way of access to, an extraordinary range of experience (since they believed that the ancients had achieved everything worthwhile in this life); second, as a legitimating authority for modes of thought and action that were unknown or disapproved of in traditional Christian doctrine.

The Humanists were secularists who found in classical antiquity a conception of human life that was congenial and supportive; but they were also Christians, and in their use of ancient thought they showed an independent judgment that belies the old notion of a "pagan Renaissance." In fact, some of their favourite sources were post-classical and Christian. Even the most celebrated of Renaissance themes, the idea of "the dignity of man," best known in the *Oration* of Pico della Mirandola, was derived in part from St. Augustine and other Church Fathers. Created in the image and likeness of God, man was free to shape his own destiny; but the definition of that destiny was very much in the Christian tradition:

> You will have the power to sink to the lower forms of life, which are brutish. You will have the power, through your own judgment, to be reborn into the higher forms, which are divine.

Political thought. Pico envisioned the potential divinity of man; Niccolb Machiavelli looked unblinkingly at his actual behaviour; Francesco Guicciardini saw him as a victim of that behaviour.

Machiavelli. The author of ***The Prince,*** a treatise on how to get power and keep it, Machiavelli so shocked his readers—not because he described behaviour that was unfamiliar to them but because he dared to advocate it—that they coined his name into synonyms for the devil (Old Nick) and for crafty, unscrupulous tactics (Machiavellian). No other name but that of Borgia so invariably evokes the image of the wicked Renaissance, and, indeed, Cesare Borgia was Machiavelli's chief model for ***The Prince.*** Yet Machiavelli, too, was influenced by Humanism, by Humanist voluntarist psychology and faith in human freedom. He was also a devotee of the cult of antiquity, which he reverenced chiefly in the ancient historians for their examples of political wisdom and military valour. From the example of Rome he derived the laws of political behaviour by which, he believed, his countrymen must live if they were to recover their civic virtue and free themselves from the yoke of the "barbarians" who were overrunning Italy.

Machiavelli's ideas of the uses of the ancient past were indebted to a Florentine tradition of Civic Humanism that, by his time, was a century old. A line of Humanists had expounded the ideals of republican citizenship and the meaning of classical studies for the public life. In the years of Milanese aggression against Florence, Coluccio Salutati, serving as chancellor of the republic, had rallied the Florentines by reminding them of the legend that their city was "the daughter of Rome" and urging upon them the Roman legacy of justice and liberty. Salutati's pupil, Leonardo Bruni, who also served as chancellor, expounded many of the tenets of Civic Humanism in his ***History of the Florentine People*** and his panegyrics of Florence. The roots of Florentine liberty, he maintained, were deep in the soil of Tuscany, where, even before the rise of Rome, the Etruscans had founded free cities. In Florence, declared Bruni, equality was recognized in justice and opportunity for all citizens, while the claims of individual excellence were rewarded by preferment to public office and in public honours. Thus, the relation between freedom and achievement was close, and this explained Florence's pre-eminence in culture as well as in political liberty. Florence, observed Bruni, was the home of Italy's greatest poets, the pioneer in both vernacular and Latin literature, and the seat of the Greek revival as well as of eloquence. It was, in short, the centre of the ***studia humanitatis,*** those studies by and for a free man.

Civic Humanism

As a theory of political life, Civic Humanism represented the ideal rather than the reality of 15th-century communal politics. Even in Florence, where, after 1434, the Medici family took a grip on the city's republican institutions, the emphasis shifted from activism to the kind of Utopian mysticism represented by Pico's ***Oration*** and to the millennialist fantasies most vividly expressed in the late-15th-century preaching of Fra Girolamo Savonarola. Nevertheless, in providing ways of thinking about the republic and its history, the Humanist chancellors had contributed to a tradition of civic thought that the Medici had failed to extinguish. Machiavelli, himself a secretary in the chancellery of the anti-Medicean republic of 1494–1512 and a member of the group of Florentine patricians and Humanists that met in the Rucellai gardens to talk about politics, was deeply influenced by it. In his ***Florentine History,*** in the ***Art of War,*** and above all in the ***Discourses on Livy,*** Machiavelli is best seen in the context of the Florentine Humanist tradition. In the ***Discourses,*** where Machiavelli examines the whole range of political possibilities, it is clear that his own preference in forms of government is for republics. The key to this preference is his idea of man as a political being, a conception he shared with Bruni and indeed with Bruni's source—Aristotle. To participate in the public life, to interact with one's fellowmen in making decisions, was to fulfill one's human nature. For this the best setting was the well-ordered republic, in which no one had a monopoly of power and citizens were devoted to the welfare and service of the community. But well-ordered republics were scarce in 16th-century Italy, as scarce as *virtù,* the political energy that made them possible.

Machiavelli believed that this scarcity was because of the modern disposition to follow the precepts of conventional Christian morality rather than the more relevant example of ancient political experience. He said that in politics antiquity was more admired than imitated, whereas the teachings of religion had made states weak and sluggish. His solution was to expound Livy, the classical historian of the Roman Republic, in order to determine which examples were applicable to his own time. In this, he saw himself as setting out on a new route, but one that paralleled the paths already taken by modern jurisprudence and medicine, which had already created science by studying ancient laws and the knowledge of the ancient physicians; he proposed to do the same for politics. Thus, for Machiavelli, statecraft was a discipline based on timeless rules or laws and was no more to be subordinated to Christian ethics than were jurisprudence or medicine. The simplest example of the conflict between Christian and political morality is in warfare, where the use of deception, so detestable in every other kind of action, is necessary, praiseworthy, and even glorious. Machiavelli's political morality may be summed up in the ***Discourses,*** where, commenting upon a Roman defeat, he writes,

Conflict between Christian and political morality

> This is worth noting by every citizen who is called upon to give counsel to his country, for when the very safety of the country is at stake there should be no question of justice or injustice, of mercy or cruelty, of honour or disgrace, but putting every other consideration aside, that course should be followed which will save her life and liberty.

Guicciardirzi. Machiavelli's own country was Florence; when he wrote that he loved his country more than he loved his soul, he was consciously forsaking Christian ethics for the morality of civic virtue. His friend and countryman Francesco Guicciardini shared his political morality and his concern for politics but lacked his faith that a knowledge of ancient political wisdom would redeem the liberty of Italy. Guicciardini was an upper class Florentine who chose a career in public administration and devoted his leisure to writing history and reflecting on politics. He was steeped in the Humanist traditions of Florence and was a dedicated republican, despite the fact —or perhaps because of it—that he spent his entire career in the service of the Medici and rose to high positions under them. But Guicciardini, more skeptical and aristocratic than Machiavelli, was also half a generation younger, and he was schooled in an age that was already witnessing the decline of Italian autonomy.

In 1527 Florence revolted against the Medici a second time and established a republic. As a confidant of the Medici, Guicciardini was passed over for public office and retired to his estate. One of the fruits of this enforced leisure was the so-called *Cose fiorentine (Florentine Affairs),* an unfinished manuscript on Florentine history. While it generally follows the classic form of Humanist civic history, the fragment contains some significant departures from this tradition. No longer is the history of the city treated in isolation; Guicciardini was becoming aware that the political fortunes of Florence were interwoven with those of Italy as a whole and that the French invasion of Italy was a turning point in Italian history. He returned to public life with the restoration of the Medici in 1530 and was involved in the events leading to the tightening of the imperial grip upon Italy, the humbling of the papacy, and the final transformation of the republic of Florence into a hereditary Medici dukedom. Frustrated in his efforts to influence the rulers of Florence, he retired to his villa to write; but instead of taking up the unfinished manuscript on Florentine history, he chose a subject commensurate with his changed perspective on Italian affairs. The result was his *History of Italy.* Though still in the Humanist form and style, it was in substance a fulfillment of the new tendencies already evident in the earlier work---criticism of sources, great attention to detail, avoidance of moral generalizations, shrewd analysis of character and motive.

Guicciardini's pessimism

The *History of Italy* has rightly been called a tragedy by Felix Gilbert, for it demonstrates how, out of stupidity and weakness, men make mistakes that gradually narrow the range of their freedom to choose alternative courses and thus to influence events until, finally, they are trapped in the web of Fortune. This was already far from the world of Machiavelli, not to mention that of the Civic Humanists. Where the Humanists believed that *virtù* could master Fortune, Guicciardini was skeptical about men's ability to learn from the past and pessimistic about their power to influence the course of their own destinies. All that was left, he believed, was to understand. Guicciardini wrote history to show what men were like and to explain how they had reached their present circumstances. Man's dignity, then, consisted not in the exercise of his will to shape his destiny but in the use of his reason to contemplate and perhaps to tolerate his fate. In taking a new, hard look at the human condition, Guicciardini represents the decline of the Humanist view of man.

Arts and letters. As pointed out above, classicism and the literary impulse went hand in hand. From Lovato Lovati and Albertino Mussato to Politian and Pontano, Humanists wrote Latin poetry and drama with considerable grace and power (Politian wrote in Greek as well), while others composed epistles, essays, dialogues, treatises, and histories on classical models. In fact, it is fair to say that the development of an elegant, nonclassical style of prose writing was the major literary achievement of Humanism and that the epistle was its typical literary form. Petrarch's practice of collecting, reordering, and even rewriting his letters—of treating them as works of art—was widely imitated.

For lengthier discussions the Humanist was likely to compose a formal treatise or a dialogue—a classical form that provided the opportunity to combine literary imagination with the discussion of weighty matters. The most famous example of this type is *The Courtier,* published by Baldassare Castiglione in 1528; a graceful discussion of love, courtly manners, and the ideal education for a perfect gentleman, it had enormous influence all over Euroye. Castiglione had a Humanist education, but he wrote *The Courtier* in Italian, the language Bembo chose for his dialogue on love, the *Asolani* (1505), and Ludovico Ariosto chose for his delightful epic, *Orlando furioso,* completed in 1516. The vernacular was coming of age as a literary medium.

According to some a life-and-death struggle between Latin and Italian began in the 14th century, while the mortal enemies of Italian were the Humanists, who impeded the natural growth of the vernacular after its brilliant beginning with Dante, Petrarch, and Boccaccio. In this view, the choice of Italian by such great 16th-century writers as Castiglione, Ariosto, and Machiavelli represents the final "triumph" of the vernacular and the restoration of contact between Renaissance culture and its native roots. The reality is somewhat less dramatic and more complicated. Most Italian writers regarded Latin as being as much a part of their culture as the vernacular, and most of them wrote in both languages. It should also be remembered that Italy was a land of powerful regional dialect traditions; until the late 13th century, Latin was the only language common to all Italians. By the end of that century, however, Tuscan was emerging as the primary vernacular, and Dante's choice of it for his *Divine Comedy* ensured its pre-eminence. Of lyric poets writing in Tuscan (hereafter called Italian), the greatest was Petrarch. His *canzoni,* or songs, and sonnets in praise of Laura are revealing studies of the effect of love upon the lover; his *Italia mia* is a plea for peace that evokes the beauties of his native land; his religious songs reveal his deep spiritual feeling.

Emergence of Tuscan as the vernacular

Petrarch's friend and admirer Giovanni Boccaccio is best known for his *Decameron;* but he pioneered in adapting classical forms to Italian usage, including the hunting poem, romance, idyll, and pastoral, whereas some of his themes, most notably the story of Troilus and Cressida, were borrowed by other poets, including Chaucer and Tasso.

The scarcity of first-rate Italian poetry throughout most of the 15th century has caused a number of historians to regret the passing of "il buon secolo," the great age of the language, which supposedly came to an end with the ascendancy of Humanist classicism. For every Humanist who disdained the vernacular, however, there was a Leonardo Bruni to maintain its excellence or a Poggio Bracciolini to prove it in his own Italian writings. Indeed, there was an absence of first-rate Latin poets until the late 15th century, which suggests a general lack of poetic creativity in this period and not of Italian poetry alone. It may be that both Italian and Latin poets needed time to absorb and assimilate the various new tendencies of the preceding period. Tuscan was as much a new language for many as was Classical Latin, and there was a variety of literary forms to be mastered.

With Lorenzo de' Medici the period of tutelage came to an end. The Magnificent Lorenzo, virtual ruler of Florence in the late 15th century, was one of the fine poets of his time. His sonnets show that he had felt Petrarch's influence but transformed it with his own genius. His poetry epitomizes the Renaissance ideal of *l'uomo universale,* the many-sided man. Love of nature, love of women, love of life are the principal themes reflecting the experience of the man. The woodland settings and hunting scenes of his poems suggest how he found relief from a busy public life; his love songs to his mistresses and his bawdy carnival ballads show the other face of a devoted father and affectionate husband. The celebration of youth in his most famous poem was etched with the sad realization that time passes swiftly:

> Oh, how fair is youth, and yet how fleeting!
> Let yourself be joyous if you feel it:
> Of tomorrow there is no certainty—

Florence was only one centre of the flowering of the vernacular. Ferrara saw literature and art flourish under the patronage of the ruling Este family and before the end of the 15th century counted at least one major poet, Matteo Boiardo, author of the *Orlando innamorato,* an epic of Roland. A blending of the Arthurian and Carolingian epic traditions, Boiardo's *Orlando* inspired another resident of the Ferrarese court, Ludovico Ariosto, to take up the same themes. The result was the finest of all Italian epics, *Orlando furioso.* The ability of the medieval epic and folk traditions to inspire the poets of such sophisticated centres as Florence and Ferrara suggests that Humanist disdain for the Dark Ages notwithstanding, Renaissance Italians did not allow classicism to cut them off from their medieval roots.

THE NORTHERN RENAISSANCE

Political, economic, and social background. In 1494 King Charles VIII of France led an army southward over the Alps, seeking the Neapolitan crown and glory. Many believed that this barely literate. gnome of a man, hunched over his horse, was the Second Charlemagne, whose coming had been long predicted by French and Italian prophets. Apparently, Charles himself believed it; it is recorded that when he was chastised by the fiery preacher Savonarola for delaying his divine mission of reform and crusade in Florence, the King burst into tears and soon went on his way. He found the Kingdom of Naples easy to take and impossible to hold; frightened by local uprisings, by a new Italian coalition, and by the massing of Spanish troops in Sicily, he left Naples in the spring of 1495, bound not for the Holy Land, as the prophecies had predicted, but for home, never to return to Italy. In 1498 Savonarola was tortured, hanged, and burned as a false prophet for predicting that Charles would complete his mission. Conceived amid dreams of chivalric glory and crusade, the Italian expedition of Charles VIII was the venture of a medieval king—romantic, poorly planned, and totally irrelevant to the real needs of his subjects. This should be pondered, while noting that kings would continue to behave in this way for centuries to come, before accepting the judgment of those historians who maintain that the French invasion of Italy marked the beginning of modem times.

French invasions of Italy. The invasion did, however, mark the beginning of a new phase of European politics, during which the Valois kings of France and the Habsburgs of Germany fought each other, with the Italian states as their reluctant pawns. For the next 60 years the dream of Italian conquest was pursued by every French king, none of them having learned anything from Charles VIII's misadventure except that the road southward was open and paved with easy victories. For even longer Italy would be the keystone of the arch that the Habsburgs tried to fling across Europe from the Danube to the Strait of Gibraltar in order to link the Spanish and German inheritance of the emperor Charles V. In destroying the autonomy of Italian politics, the invasions also ended the Italian state system, which was absorbed into the larger European system that now took shape. Its members adopted the balance of power diplomacy first evolved by the Italians as well as the Italian practice of using resident ambassadors who combined diplomacy with the gathering of intelligence by fair means or foul. In the art of war, also, the Italians were the schoolmasters of Europe, with their innovations in the use of mercenary troops, cannonry, bastioned fortresses, and field fortifications, although they were soon outstripped by their eager pupils. French artillery was already the best in Europe by 1494, whereas the Spaniards developed the *tercio,* an infantry unit that combined the most effective field fortifications and weaponry of the Italians and Swiss.

New phase of European politics

The New Monarchs. Thus, old and new ways were fused in the bloody crucible of the Italian Wars. Rulers who lived by medieval codes of chivalry adopted Renaissance techniques of diplomacy and warfare to satisfy their lust for glory and dynastic power. Even the lure of Italy was an old obsession; only the size and vigour of the 16th-century expeditions were new. Rulers were now able to command vast quantities of men and resources because they were becoming masters of their own domains. The nature and degree of this mastery varied according to local circumstances; but all over Europe the New Monarchs, as they are called, were reasserting kingship as the dominant form of political leadership after a long period of floundering and uncertainty.

By the end of the 15th century the Valois kings of France had expelled the English from all their soil except for the port of Calais, concluding the Hundred Years' War (1453); had incorporated the fertile lands of the duchy of Burgundy to the east and of Brittany to the north; and had extended the French kingdom from the Atlantic and the English Channel to the Pyrenees and the Rhine. To rule this vast territory they created a professional machinery of state, converting wartime taxing privileges into permanent prerogative, freeing their royal council from supervision by the States General, appointing a host of officials who crisscrossed the kingdom in the service of the crown, and establishing their right to appoint and tax the French clergy. They did not achieve anything like complete centralization; but in 1576 Jean Bodin was able to write, in his *Six Books of the Commonweal,* that the king of France had absolute sovereignty because he alone in the kingdom had the power to give law unto all of his subjects in general and to every one of them in particular.

Absolute sovereignty

Bodin might also have made his case by citing the example of another impressive autocrat of his time, Philip II of Spain. Though descended from warrior kings, Philip spent his days at his writing desk poring over dispatches from his governors in the Low Countries, Sicily, Naples, Milan, Peru, Mexico, and the Philippines and drafting his orders to them in letters signed "I the King." The founding of this mighty empire went back more than a century to 1469, when Ferdinand II of Aragon and Isabella of Castile brought two great Hispanic kingdoms together under a single dynasty. Castile, an arid land of sheepherders, great landowning churchmen, and crusading knights, and Aragon, with its Catalan miners and its strong ties to Mediterranean Europe, made uneasy partners; but a series of rapid and energetic actions forced the process of national consolidation and catapulted the new nation into a position of world prominence for which it was poorly prepared. Within the last decade of the 15th century the Spaniards took the kingdom of Navarre in the north; stormed the last Muslim stronghold in Spain, the kingdom of Granada; and launched a campaign of religious unification by pressing tens of thousands of Muslims and Jews to choose between Baptism and expulsion, at the same time establishing a new Inquisition under royal control. They also sent Columbus on voyages of discovery to the Western Hemisphere, thereby opening a new frontier just as the domestic frontier of Reconquest was closing. Finally, the crown linked its destinies with the Habsburgs by a double marriage, thus projecting Spain into the heart of European politics. In the following decades Castilian *hidalgos* (lower nobles), whose fathers had crusaded against the Moors in Spain, streamed across the Atlantic to make their fortunes out of the land and sweat of the American Indians, while others marched in the armies and sailed in the ships of their king, Charles I, who, as Charles V, was elected Holy Roman emperor in 1519 at the age of 19. In this youth the vast dual inheritance of the Spanish and Habsburg empires came together. The grandson of Ferdinand and Isabella on his mother's side and of the emperor Maximilian I on his father's, Charles was duke of Burgundy, head of five Austrian dukedoms (which he ceded to his brother), king of Naples, Sicily, and Sardinia, and claimant to the duchy of Milan as well as king of Aragon and Castile and German king and emperor. To

The empire under Charles V

administer this enormous legacy, he presided over an ever-increasing bureaucracy of viceroys, governors, judges, military captains, and an army of clerks. The New World lands were governed by a separate Council of the Indies after 1524, which, like Charles' other royal councils, combined judicial, legislative, military, and fiscal functions.

The yield in American treasure was enormous, especially after the opening of the silver mines of Mexico and what is now Bolivia halfway through the 16th century. The crown skimmed off a lion's share—usually a fifth—which it paid out immediately to its creditors because everything Charles could raise by taxing or borrowing was sucked up by his wars against the French in Italy and Burgundy, the Protestant princes in Germany, rhe Turks on the Austrian border, and the Barbary pirates in the Mediterranean. By 1555 both Charles and his credit were exhausted, and he began to relinquish his titles—Spain and the Netherlands to his son Philip, Germany and the imperial title to his brother Ferdinand I. American silver did little for Spain except to pay the wages of soldiers and sailors; the goods and services that kept the Spanish armies in the field and the ships afloat were largely supplied by foreigners, who reaped the profits. But for the rest of the century Spain continued to dazzle the world, and few could see the chinks in the armour; for this was an age of kings, in which bold deeds, not balance sheets, made history.

Recovery of creative energy. The growth of centralized monarchy claiming absolute sovereignty over its subjects may be observed in other places, from the England of Henry VIII on the extreme west of Europe to the Muscovite kingdom of Ivan III the Great on its eastern edge, for the New Monarchy was one aspect of a more general phenomenon—a great recovery of energy that surged through Europe in the 15th century. No single cause, whether economic, social, or demographic, can be adduced to explain it; it was the interaction of all such forces. Some historians believe it was simply the upturn in the natural cycle of growth: the great medieval population boom had overextended Europe's productive capacities; the depression of the 14th and early 15th centuries had corrected this condition through famines and epidemics, which had led to depopulation; now the cycle of growth was beginning again.

The effects of increased food production and new technology

Once more, growing numbers of people, burgeoning cities, and ambitious governments were demanding food, goods, and services—a demand that was met by both old and new methods of production. In agriculture, the shift toward commercial crops such as wool and grains, the investment of capital, and the emancipation of servile labour completed the transformation of the manorial system already in decline. (In eastern Europe, however, the formerly free peasantry was now forced into serfdom by an alliance between the monarchy and the landed gentry, as huge agrarian estates were formed to raise grain for an expanding Western market.) Manufacturing boomed, especially of those goods used in the outfitting of armies and fleets—cloth, armour, weapons, and ships. New mining and metalworking technology made possible the profitable exploitation of the rich iron, copper, gold, and silver deposits of central Germany, Hungary, and Austria, affording the opportunity for large-scale investment of capital.

One index of Europe's recovery is the spectacular growth of certain cities. Antwerp, for example, more than doubled its population in the second half of the 15th century and doubled it again by 1560. Under Habsburg patronage Antwerp became the chief European entrepôt for English cloth, the hub of an international banking network that financed imperial operations, and the principal Western market for German copper and silver, Portuguese spices, and Italian alum. By 1500 the Antwerp Bourse was the central money market for much of Europe. Other cities profited from their special circumstances, too: Lisbon as the home port for the Portuguese maritime empire; Seville, the Spaniards' gateway to the New World; London, the capital of the Tudors and gathering point for England's clothmaking and banking activity; Lyons, favoured by the French kings as a market centre and capital of the silk industry; Augsburg, the principal north–south trade route in Germany and the home city of the Fugger merchant-bankers.

Northern Humanists. Cities were also markets for culture. The resumption of urban growth in the second half of the 15th century coincided with the diffusion of Renaissance ideas and educational values. Humanism offered linguistic and rhetorical skills that were becoming indispensable for nobles and commoners seeking careers in diplomacy and government administration, while the Renaissance ideal of the perfect gentleman was a cultural style that had great appeal in this age of growing courtly refinement. At first those who wanted a Humanist education had to go to Italy, and many foreign names appear on the rosters of the Italian universities and schools. By the end of the century, however, such northern cities as London, Paris, Antwerp, and Augsburg were becoming Humanist centres in their own right. The development of printing, by making books cheaper and more plentiful, also helped to quicken the diffusion of Humanism.

Christian Humanism

A textbook convention, heavily armoured against truth by constant reiteration, states that northern Humanism —*i.e.*, Humanism outside Italy—was essentially Christian in spirit and purpose, in contrast to the essentially secular nature of Italian Humanism. In fact, however, the program of Christian Humanism had been laid out by Italian Humanists of the stamp of Lorenzo Valla, one of the founders of classical philology, who showed how the critical methods used to study the classics ought to be applied to problems of biblical exegesis and translation as well as church history. That this program only began to be carried out in the 16th century, particularly in the countries of northern Europe (and Spain), is a matter of chronology rather than of geography. In the 15th century the necessary skills, particularly the knowledge of Greek, were possessed by a few scholars; a century later, Greek was a regular part of the Humanist curriculum, and Hebrew was becoming much better known, particularly after Johannes Reuchlin published his Hebrew grammar in 1506. Here, too, printing was a crucial factor, for it made available a host of lexicographical and grammatical handbooks and allowed the establishment of normative biblical texts and the comparison of different versions of the Bible.

Christian Humanism was more than a program of scholarship, however; it was fundamentally a conception of the Christian life that was grounded in the rhetorical, historical, and ethical orientation of Humanism itself. That it came to the fore in the early 16th century was the result of a variety of factors, including the spiritual stresses of rapid social change and the inability of the ecclesiastical establishment to cope with the religious needs of an increasingly literate and self-confident laity. By restoring the gospel to the centre of Christian piety, the Humanists believed they were better serving the needs of ordinary people. They attacked Scholastic theology as an arid intellectualization of simple faith, and they deplored the tendency of religion to become a ritual practiced vicariously through a priest. They also despised the whole late-medieval apparatus of relic mongering, hagiology, indulgences, and image worship, and they ridiculed it in their writings, sometimes with devastating effect. According to the Christian Humanists, the fundamental law of Christianity was the law of love as revealed by Jesus Christ in the Gospel. Love, peace, and simplicity should be the aims of the good Christian and the life of Christ his perfect model. The chief spokesman for this point of view was Desiderius Erasmus, the most influential Humanist of his day. Erasmus had the gift of presenting his conception of "the philosophy of Christ" with gentle humour or biting satire as the occasion demanded. Both are evidenced in his ***Praise of*** Folly (1509), which begins as a defense of the foibles of everyday life, becomes an attack upon the vicious follies of society's leaders, and ends in praise of the Gospel. Erasmus and his colleagues had the typical Humanist belief that an eloquent appeal would convince people of the truth of their message, and they relied heavily upon education as a means of reforming Christendom. As moralists, they were uninterested in dogmatic differences and were early champions of religious toleration. In this they were not in tune with the changing times, for the outbreak of the Reformation polarized European society along confessional lines, with the paradoxical result that the Christian Humanists, who had done so much to lay the groundwork for religious reform, ended by being suspect on both sides—by the Catholics as subversives who (as it was said of Erasmus) had "laid the egg that Luther hatched," and by the Protestants as hypocrites who had abandoned the cause of reformation out of cowardice or ambition. Toleration belonged to the future, after the killing in the name of Christ sickened and passions had cooled.

Spread of mysticism

Christian mystics. The quickening of the religious impulse that gave rise to Christian Humanism was also manifested in a variety of forms of religious devotion among the laity, including mysticism. In the 14th century a wave of mystical ardour seemed to course down the valley of the Rhine, enveloping men and women in the rapture of intense, direct experience of the divine Spirit. It centred in the houses of the Dominican order, where friars and sisters practiced the mystical way of their great teacher, Meister Eckehart. This wave of Rhenish mysticism radiated beyond convent walls to the marketplaces and hearths of the laity. Eckehart had the gift of making his abstruse doctrines understandable to a wider public than was usual for mystics; moreover, he was fortunate in having some disciples of a genius almost equal to his own —the great preacher of practical piety, Johann Tauler, and Heinrich Suso, whose devotional books, such as *The Little Book of Truth* and *The Little Book of Eternal Wisdom,* found eager readers among laymen and laywomen hungry for spiritual consolation and religious excitement. Some found it by joining the Dominicans; others, remaining in the everyday world, joined with like-spirited brothers and sisters in groups known collectively as the Friends of God, where they practiced methodical contemplation, or, as it was widely known, mental prayer. Probably few reached, or even hoped to reach, the ecstasy of mystical union, which was limited to those with the appropriate psychological or spiritual gifts. Out of these circles came the anonymous work called *The German Theology,* from which Luther was to say that he had learned more about man and God than from any book except the Bible and the writings of St. Augustine.

In the Netherlands the mystical impulse awakened chiefly under the stimulus of another great teacher, Gerhard Groote. Not a monk nor even a priest, Groote gave the mystical movement a different direction by teaching that true spiritual communion must be combined with moral action, for this was the whole lesson of the Gospel. At his death a group of followers formed the Brethren of the Common Life. These were laymen and laywomen, married and single, earning their livings in the world but united by a simple rule that required them to pool their earnings and devote themselves to spiritual works, teaching, and charity. Houses of Brothers and Sisters of the Common Life spread through the cities and towns of the Netherlands and Germany, and a monastic counterpart was founded in the order of Canons Regular of St. Augustine, known as the Windesheim Congregation, which, in the second half of the 15th century numbered some 82 priories. The Brethren were particularly successful as schoolmasters, combining some of the new linguistic methods of the Humanists with a strong emphasis upon Bible study. Among the generations of children who absorbed the New Piety *(devotio moderna)* in their schools were Erasmus, and, briefly, Luther. In the ambience of the *devotio moderna* appeared one of the most influential books of piety ever written, *The Imitation of Christ,* attributed to Thomas à Kempis, a monk of the Windesheim Congregation.

One man whose life was changed by *The Imitation* was the 16th-century Spaniard Ignatius Loyola. After reading it Loyola converted from a soldier of the king to a soldier of Christ, founded the Society of Jesus, and wrote his own book of methodical prayer, *Spiritual Exercises.* Thus, Spanish piety was in some ways connected with that of the Netherlands; but the extraordinary outburst of mystical and contemplative activity in 16th-century Spain was mainly an expression of the intense religious exaltation of the Spanish people themselves as they confronted the tasks of reform, Counter-Reformation, and world leadership. Spanish mysticism belies the usual picture of the mystic as a withdrawn contemplative, with his or her head literally in the clouds. Not only Loyola but also St. Teresa of Avila and her disciple, St. John of the Cross, were tough, activist Reformers who regarded their mystical experiences as means of fortifying themselves for their practical tasks. They were also prolific writers who could communicate their experiences and analyze them for the benefit of others. This is especially true of St. John of the Cross, whose mystical poetry is one of the glories of Spanish literature.

The growth of vernacular literature. In literature, medieval forms continued to dominate the artistic imagination throughout the 15th century. Besides the vast devotional literature of the period—the books on *The Art of Dying Well,* the saints' lives, and manuals of methodical prayer and spiritual consolation—the most popular reading of noble and burgher alike was the 13th-century love allegory, the *Roman de le rose.* Despite a promising start in the late Middle Ages, literary creativity suffered from the domination of Latin as the language of "serious" expression, with the result that if the vernacular attracted writers, they tended to overload it with Latinisms and artificially applied rhetorical forms. This was the case with the so-called *grande rhetoriqueurs* of Burgundy and France. One exception is 14th-century England, where a national literature made a brilliant showing in the works of William Langland, John Gower, and, above all, Geoffrey Chaucer; but the troubled 15th century produced only feeble imitations. Another exception is the vigorous tradition of chronicle writing in French, distinguished by such eminently readable works as the chronicle of Jean Froissart and the memoirs of Philippe de Commynes. In France, too, around the middle of the 15th century there lived the vagabond François Villon, about whom next to nothing is known except that he was a great poet. In Germany *The Ship of Fools,* by Sebastian Brant, was a lone masterpiece.

Renaissance of national literatures

The 16th century saw a true renaissance of national literatures. In Protestant countries the Reformation had an enormous impact upon the quantity and quality of literary output. If Luther's rebellion destroyed the chances of unifying the nation politically, his translation of the Bible into German created a national language. Biblical translations, vernacular liturgies, hymns, and sacred drama had analogous effects elsewhere. For Catholics, the Reformation was a time of deep religious emotion expressed in art and literature. Spanish mystical poetry is mentioned above; Spanish drama flowered later in the century. On all sides of the religious controversy, chroniclers and historians writing in the vernacular were recording their versions for posterity.

While the Reformation was providing a subject matter, the Italian Renaissance was providing literary methods and models. The Petrarchan sonnet inspired French, English, and Spanish poets, while the Renaissance Neoclassical drama finally began to end the reign of the medieval mystery play. Ultimately, of course, the works of real genius were the result of a crossing of native traditions and new forms. The Frenchman François Rabelais assimilated all the intellectual, literary, and religious themes of his day—and mocked them all—in his story of the giants Gargantua and Pantagruel. The Spaniard Miguel de Cervantes, in *Don Quixote,* drew a composite portrait of his countrymen, which caught their exact mixture of idealism and realism. In England, Christopher Marlowe and William Shakespeare used the forms of Renaissance drama to probe the deeper levels of their countrymen's character and experiences.

RENAISSANCE SCIENCE AND TECHNOLOGY

To the medieval mind, matter was composed of four elements—earth, air, fire, and water—whose combinations and permutations made up the world of visible objects. The cosmos was a series of concentric spheres in motion, the farther ones carrying the stars around in their daily courses; and at the centre of all was the globe of Earth, heavy and static. Motion was either perfectly circular, as in the heavens, or irregular and naturally downward, as on the Earth. The Earth was made up of three landmasses—Europe, Asia, and Africa—and was unknown and uninhabitable in its southern zones. Man, the object of all creation, was composed of four humours—black and yellow bile, phlegm, and blood—and his personality and health were determined by the relative proportions he had of each. The cosmos was alive with a common consciousness, and the stars influenced the course of events as well as the fortunes of men (although the church frowned on this denial of free will). Man might influence the spirits in nature through magic—black for demons, white for the benevolent spirits—although the church preferred that the Christian seek his well-being through faith, the sacraments, and the intercession of Mary and the saints.

New concepts of natural phenomena

These views were an amalgam of Aristotelian physics, Galenic medicine, Ptolemaic astronomy, and Christian theology. Together they ruled man's understanding and directed his experience of phenomena, until they all were overthrown and replaced by the new mechanistic conceptions of Copernicus, William Harvey, Galileo, and Isaac Newton. Only the first of these great scientists was born in the period discussed here as the Renaissance; the Scientific Revolution was largely the achievement of the 17th century. The persistence of the medieval model of the cosmos through the Renaissance ought not, however, to obscure the period's real contributions to the revolution that came later. Humanist scholarship provided both originals and translations of ancient Greek scientific works—which enormously increased the fund of knowledge in physics, astronomy, medicine, botany, and other disciplines—and presented as well alternative theories to those of Ptolemy and Aristotle. Thus, the revival of ancient science brought heliocentric astronomy to the fore again after almost two millennia. Renaissance philosophers, most notably Jacopo Zabarella, analyzed and formulated the rules of the deductive and inductive methods by which scientists worked, while the rediscovery of certain ancient philosophies enriched the ways in which scientists conceived of phenomena. Pythagoreanism, for example, conveyed a vision of a harmonious geometric universe that helped form the mind of Copernicus.

In mathematics the Renaissance made its greatest contribution to the rise of modern science. Humanists included arithmetic and geometry in the liberal arts curriculum; artist experimenters furthered the geometrization of space in their work on perspective; Leonardo da Vinci perceived, however faintly, that the world was ruled by "number." The interest in algebra in the Renaissance universities, according to the 20th-century historian of science George Sarton, "was creating a kind of fever." It was a benign illness that produced some mathematical theorists of the first rank, including Niccolb Tartaglia and Girolamo Cardano. If they had done nothing else, Renaissance scholars would have made a great contribution to the cause of mathematics by translating and publishing, in 1544, some previously unknown works of Archimedes, perhaps the most important of the ancients in this field.

Development of printing

Technological advances. If the Renaissance role in the rise of modern science was more of midwife than of parent, in the more practical realm of technology the proper image is the Renaissance *magus,* manipulator of the hidden forces of nature. Working within the confines of the medieval world view, engineers and technicians of the 15th and 16th centuries achieved remarkable results, which in some ways had more to do with changing the social environment than the theories of pure science. The most important technological advance of all, because it underlay progress in so many other fields, strictly speaking had little to do with nature at all. This was the development of printing, with movable metal type, around the mid-15th century in Germany. Johann Gutenberg is usually called its inventor, but in fact many people and many steps were involved. Block printing on wood came to the West from China between 1250 and 1350, papermaking also came from China by way of the Arabs in 12th-century Spain, whereas the Flemish technique of oil painting was the origin of the new printers' ink. Three men of Mainz—Gutenberg and his contemporaries Johann Fust and Peter Schoffer—seem to have taken the final steps, casting metal type and locking it into a wooden press. The invention spread like the wind, reaching Italy by 1467, Hungary and Poland in the 1470s, and Scandinavia by 1483. By 1500 the presses of Europe had produced some 6,000,000 books. Without the printing press it is impossible to conceive that the Reformation would have ever been more than a monkish quarrel or that the Scientific Revolution, which was a cooperative effort of an international community, would have occurred at all. In short, the development of printing amounted to a communications revolution of the order of the invention of writing; and like that prehistoric discovery it transformed the conditions of life.

Geographical discoveries. Within the same half century that saw the spread of printing, explorers sailing under the flags of Portugal and Castile reached India by rounding the Cape of Good Hope and the New World by sailing westward across the Atlantic. As with printing, geographical discovery was the fruit of a long, complicated process that involved the technical ingenuity of several European peoples and three cultures. Navigational instruments that derived from the Arabs, astronomical tables and sea charts drawn up by Hispanic and North African Jews, square-rigged ships designed by Spaniards and, like as not, sailed by Italian mariners were some of the factors in the spectacular successes of the great voyages.

Renaissance discovery began when the Portuguese conquest of Ceuta in Morocco (1415) gave Prince Henry the Navigator a base from which to send ships down the west coast of Africa. By the year of his death (1460) Henry's ships had reached the Guinea coast, and by 1487 Bartholomeu Dias had doubled the Cape of Good Hope, so named because this achievement gave a fair prospect of reaching the Indian Ocean. In 1498 Vasco da Gama dropped anchor off the Malabar coast in India, seeking "Christians and spices."

Meanwhile, Spain, having entered the race late, hurried to catch up. In 1492 Ferdinand and Isabella sent the Genoese Christopher Columbus on a voyage to the Indies by way of the Atlantic Ocean. Columbus made four voyages to the Caribbean, steadfastly believing he had found the route to the Far East. But other voyages, especially those of Amerigo Vespucci in 1501–03, made map makers and scholars aware-dimly at first, because they had to overthrow the accumulated images of centuries—that between Europe and Asia lay a great landmass that was not India but, as Rodrigo de Santaella wrote in 1503, "opposite-India, in a part of the world hitherto unknown." In the same year, Vespucci, having failed to find a southern route around that barrier, described it as a New World. In 1513 Vasco Núñez de Balboa sighted the Pacific Ocean. Finally, in 1521, Ferdinand Magellan found the western passage by sailing around the southern tip of South America, through the straits that now bear his name. Magellan himself was killed in the Philippines, but his men completed the circumnavigation of the globe. With the mapping out of the Western Hemisphere and the Pacific, the tripartite world of the ancient geographers was abandoned once and for all and with it much of the authority that antiquity had exercised over European minds.

CONCLUSION

Emerging awareness of the growth of the Renaissance

The foregoing discussion was intended to convey the impression that the concept of the Renaissance is no longer as clear-cut as it was to Michelet and Burckhardt and to the Renaissance Humanists themselves. As knowledge of the Middle Ages as a period of creative achievements has increased, so has an awareness that the Renaissance did not emerge suddenly out of medieval darkness but organically out of the urban setting and sophisticated intellectual environment of medieval society. At the same time, the sharp demarcation between Italy and the rest of Europe, first posited by the Humanists and maintained by Burckhardt, has somewhat given way. Any conception of the Renaissance as a period that does not include the growth of the New Monarchies, the development of printing, the discovery of the Western Hemisphere, and the economic boom of the 16th century seems almost trivial. Italy retains pride of place in the development of new intellectual and literary forms, which, despite the current emphasis upon the history of institutions and material culture, should not be underestimated; the influence of Italian Humanism upon the formation of early modern culture is almost too pervasive to trace out in all its ramifications. Humanism was the manifestation of a wider social trend that, again, had its roots in the earlier period but became dominant in the Renaissance—first in Italy, then in the rest of Europe. This might be called the coming of age of lay culture. With the growth of urban society the ecclesiastical leadership of intellectual, artistic, and even religious life declined. A literate laity found the values of monastic or priestly culture too restrictive. Scholasticism was a theology that did not speak to the human condition in a voice that ordinary men and women could understand. Education was the preserve of clerics. The liturgy reduced laymen to spectators. Devotional exercises were the special concern of monks—"the Religious." Humanism, in both its classicizing and religious forms, was a peaceful revolt against all this, an assertion of the claims of secular life and the vocations of laymen. In a sense the Humanist ideal of eloquence and the emphasis upon the exercise of the will epitomize the distinctiveness of Renaissance culture: the ideal of eloquence refers to the new awareness of man as a social being who interacts with his fellows through the arts of communication; the emphasis upon the will refers to the heightened sense of man as actor, shaping his destiny and creating his own environment. Cultural ideals and social realities merged in the technological achievements and the widening of the world's frontiers through the voyages of discovery, for there man's ability to communicate and to act led him to create a whole new setting for the future. If he did not remain mindful of the Humanist admonition to unite eloquence and wisdom in order to act virtuously, it was not, as Burckhardt and other moralists have said, because the Renaissance contained some special capacity for evil but because in all his actions man seldom lives up to his own ideals.

CLARK, *The Great German Mystics: Eckhart, Tauler and Suso* (1949), a good introduction to the three founders of the German school; J.H. ELLIOTT, *Imperial Spain, 1469–1716* (1963), the best short account in English; JOHAN HUIZINGA, *Herfsttij der middeleeuwen* (1919; Eng. trans., *The Waning of the Middle Ages,* 1924, reprinted 1955), a classic—France and the Low Countries on the eve of their Renaissance; H.A. MISKIMIN, *The Economy of Early Renaissance Europe, 1300–1460* (1969), a brief, up-to-date survey; E. ALLISON PEERS, *Studies of the Spanish Mystics,* 3 vol. (1927–60), the classic work in the field; GUSTAVE REESE, *Music in the Renaissance* (1954), an excellent, comprehensive introduction to the subject.

Renaissance science and technology: PIERCE BUTLER, *The Origin of Printing in Europe* (1940), a standard work on the subject; HERBERT BUTTERFIELD, *The Origins of Modern Science, 1300–1800* (1949), the best non-technical introduction; CARLO M. CIPOLLA, *Guns, Sails and Empires: Technological Innovation and the Early Phases of European Expansion, 1400–1700* (1966), explores the technological origins of Western supremacy; J.H. PARRY, *The Age of Reconaissance,* 2nd ed. (1966), full of information on navigation, shipbuilding, and exploration.

(D.We.)

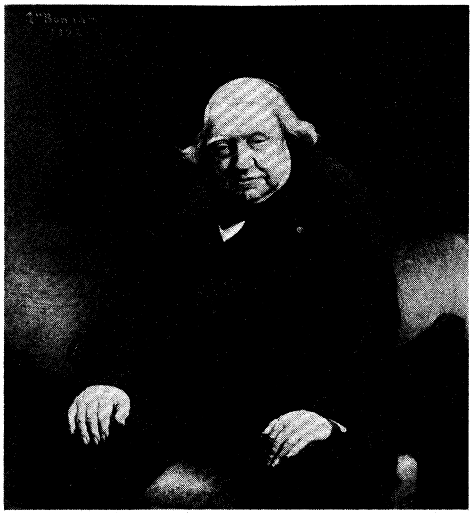
Renan, Ernest

Ernest Renan, a significant 19th-century philosopher, historian, and scholar of religion, anticipated in his life and writings the anxiety of the existential quest for authentic existence and the totalitarian messianism of the 20th century. Born of peasant stock on February 28, 1823, at Tréguier, Côtes-du-Nord, France, Renan was educated at the ecclesiastical college in his hometown. He began training for the priesthood, and in 1838 he was offered a scholarship at the seminary of Saint-Nicolas-du-Chardonnet. He later went on to the seminary of Saint-Sulpice, where he soon became involved in a crisis of faith that finally led him, reluctantly, to leave the Roman Catholic Church in 1845.

Ecclesiastical training

In his view, the church's teachings were incompatible with the findings of historical criticism; but he kept a quasi-Christian faith in the hidden God, revealed to him both in the 17th-century religious writings of Blaise Pascal and in experience, as well as in himself as a kind of intellectual messiah.

Early works. For Renan, the February revolution of 1848 in France and other parts of Europe was a religion in the making. Sometimes enthusiastic, sometimes critical, he participated in the revolution's messianic expectations and carried this ambiguous attitude over into *L'Avenir de la science (The Future of Science,* 1891)—a work that, in allusion to the works of the philosopher René Descartes, he called his "Discourse on Method." The main theme of this work, not published until 1890, is the importance of the history of religious origins, which he regarded as a human science having equal value to the sciences of nature. Though he was now somewhat anticlerical, the French government sent him in 1849 to Italy, where the papacy was still politically important, to help classify manuscripts previously inaccessible to French scholars. In Rome he was transformed, for a while, from



Renan, oil painting by Léon Bonnat, 1892. In the Musée Renan, Tréguier.
Archives Photographiques

an austere scholar into an artist alive to the pageantry and naïveté of popular religion.

Renan returned to Paris in 1850 to live with his sister, Henriette, on her savings and the small salary attached to his own post at the Bibliothèque Nationale. He began to make a name for himself with his doctoral thesis ***Averrobs et l'Averroïsme*** (1852; "Averroës and Averroism"), concerning the thought of that medieval Muslim philosopher. He continued his scholarly writings with two collections of essays, ***Études d'histoire religieuse*** (1857; ***Studies of Religious History,*** 1864) and ***Essais de morale et de critique*** (1859; "Moral and Critical Essays"), first written for the ***Revue des Deux Mondes*** and the ***Journal des Dkbats.*** The ***Etudes*** inculcated into a middle class public the insight and sensitivity of the historical, humanistic approach to religion. Many of the ***Essais*** denounce the materialism and intolerance of the Second Empire (1852–70) in the name of Renan's aristocratic ideal: the intellectuals, acting as "bastions of the spirit," must, he affirms, resist tyranny by intellectual and spiritual refinement; that is, by the humanism exemplified throughout these essays.

In 1856 Renan proposed marriage to Cornélie Scheffer, niece of the painter Ary Scheffer. When Henriette discovered that she herself meant less to her brother than his work, even less than another woman, her jealousy knew no bounds. As related by Renan with more art than truth in his tribute to her (1862), Henriette gave way to his benevolent egoism and agreed to live with him and his wife. Yet, the beginnings of his marriage were unhappy, the more so as he was still dependent on Henriette's savings.

Investigations concerning the life of Jesus

In October 1860 Renan was entrusted with an archaeological mission to the Lebanon. The Phoenician inscriptions that he discovered were published in his ***Mission de Phénicie*** (1864–74; "Phoenician Expedition"). They were later included in the ***Corpus Inscriptionum Semiticarum*** ("Corpus of Semitic Inscriptions"), which he helped to bring out through the Académie des Inscriptions et Belles-Lettres. But archaeology was not his main interest. In April 1861, with his wife and sister, he visited the Holy Land in search of materials and inspiration concerning a life of Jesus that he was bent on writing. He finished a first draft of it in the Lebanon but at tragic cost, for Henriette died of malaria at ʿAmshīt on September 24, 1861, while he himself fell desperately ill.

Religious controversies. Renan had counted on the writing of his life of Jesus to secure election to the chair of Hebrew at the College de France. He was elected, before the book was ready, on January 11, 1862. But in his opening lecture, on February 21, he referred to Jesus in the words of Jacques Bossuet, a French bishop and historian of the 17th and 18th centuries, as "an incomparable man." Though this was, in his eyes, the highest praise one could bestow on a man, it was not sufficient for the clericals, who took advantage of its implied atheism and the uproar caused by the lecture to have Renan suspended. Contemptuously refusing an appointment to the Bibliothèque Imperiale (June 1864), Renan decided to live by his pen for the next few years. He had to wait until 1870, however, before the chair was restored to him. He was thus pushed into opposition to the church but had already begun to frequent such dissident salons as that of Princess Mathilde, niece of Napoleon Bonaparte, and to associate with such literary notables as Gustave Flaubert, Charles Augustin Sainte-Beuve, Hyyyolyte-Adolyhe Taine, and the Goncourt brothers (Edmond and Jules).

When the ***Vie de Jésus (Life of Jesus,*** 1869) did appear in 1863 it was virulently denounced by the church. Though not Renan's best historical work, it can still claim the attention of 20th-century readers because it presents a "mythical" account of the making of Christianity by the popular imagination, and thus has a place, like his other historical works, in the literature of messianism. After a journey in Asia Minor in 1864–65 with his wife, he published ***Les Apôtres*** (1866; ***The Apostles,*** 1869) and ***Saint Paul*** (1869), to follow the ***Vie de Jésus*** as parts of a series, ***Histoire des origines du christianisme (The History of the Origins of Christianity).*** Both these volumes, containing brilliant descriptions of how Christianity spread among the rootless proletariat of the cities of Asia Minor, illustrate his preoccupation with the question: would the intellectuals of the 19th century lead the masses toward a new enlightenment?

Interest in politics. Renan began to interest himself increasingly in politics. In 1869, at the beginning of the "liberal" phase of the Second Empire, he stood unsuccessfully for Parliament. In the same year he defended constitutional monarchv in an article, "La Monarchie constitutionnelle en Fiance" ("Constitutional Monarchy in France"). Thus far he was a liberal. In the same spirit he tried, during the Franco-German War of 1870–71, to work across frontiers: he corresponded with David Friedrich Strauss, a German theologian, and tried to persuade the Prussian crown prince (later German emperor as Frederick III) to stop the war. But the bitterness of France's defeat and his anger with democracy caused him to become authoritarian. Thus, ***La Réforme intellectuelle et morale*** (1871), concerning intellectual and moral reform, argues that France, to achieve national regeneration, must follow the example set by Prussia after the Battle of Jena in 1806. By taking his advice, however, France would have become the sort of clerical monarchy that Renan soon found he did not want. He had to resign himself to accepting the Third Republic (1870–1940), but he withdrew from public life. Though he continued to travel zestfully all over Europe, visiting surviving Bonapartists, such as Prince Jérôme Napoléon, his life became more and more identified with his writings. He was elected to the Acadkmie Française in 1878.

Concerns for **apocalypticism** and death

Later writings. Renan's ironical yet imaginative vision of the "festival of the universe" found expression in ***L'Antéchrist*** (1873; ***The Antichrist,*** 1896; vol. iv of the ***Histoire des origines),*** with its satirical portrait of Nero and its apocalyptic atmosphere—replete with expectations of a cataclysmio consummation of history—assuredly the most impressive of his historical narratives. The "festival of the universe" provides a visionary end to the ***Dialogues et fragments philosophiques*** (1876; ***Philosophical Dialogues and Fragments,*** 1899). In the first of these, however, Renan is more ironically skeptical about the hidden God than he had been. In fact, the Epicureanism of his later years masks an anxiety about death and the hereafter. His more superficial side is illustrated in the "philosophic dramas" (collected edition 1888), which trace his acceptance of the Republic, especially ***Caliban*** (written 1877) and ***L'Eau de jouvence*** (written 1879; "The Water of Youth"). In the former, the aristocracy (Prospero and Ariel) loses to democracy (Caliban) because alchemical spells (traditional sanctions) are powerless against a people infected by positivism; scientific power politics would be an effective answer, but this is out of the question because in practice it would mean a clerical monarchy.

As to the remaining volumes of the ***Histoire des origines,*** if Renan's Epicureanism is hard to find in ***Les Évangiles*** (1877; ***The Gospels,* 1889**), it is present in *L'Église chrétienne* (1879; "The Christian Church") in the portrait of the Roman emperor Hadrian; but in ***Marc-Aurèle*** (1882; ***Marcus Aurelius,* 1904**), the study of Marcus Aurelius (a Roman emperor and philosopher), again a self-portrait, is dominated by the author's preoccupation with death. Since 1876 Renan had been working on his memoirs, ***Souvenirs d'enfance et de jeunesse*** (1883; ***Recollections of My Youth,* 1883**), in which he reconstructs his life so as to show that he was predestined to become a *prêtre manqué* (failed priest) and that, in spite of heavy odds, his wager on the hidden God had "paid off' in terms of happiness.

In the ***Souvenirs*** Renan is too serene for some tastes, though his irony keeps his complacency in check. In *L'Ecclésiaste* (1882; "Ecclesiastes") and two articles on Amiel (**1884**), he is above all an ironist combatting the Pharisees (religious legalists). On the other hand, in some of his speeches at the Académie Française, on Claude Bernard, a French physiologist (**1879**), and Emile Littré, a French philologist (**1882**), he reveals his anguish in moments of doubt. Thus, he manifests a baffling variety of characteristics, but the moral heart of the man is to be found in one of the later dramas, ***Le Prêtre de Némi*** (1885; "The Priest of Némi"), and above all in his ***Histoire du peuple d'Israël*** (1887–93; "History of the People of Israel," 1888–91). For him, the history of Jewish messianism bore witness to man's capacity for faith when the odds are against him. Thus, it revived his own faith. He could therefore hope that, though Judaism would disappear, the dreams of its prophets would one day come true, so that "without a compensatory Heaven justice will really exist on earth." Having exhausted himself in an effort to finish the work, he died shortly after its completion on October 2, 1892.

With his leanings toward liberalism and authoritarianism in politics and faith and skepticism in religion, Renan embodied the contradictions of the middle class of his time. Politically, his influence after his death was far-reaching, on nationalists, such as Maurice Barrès and Charles Maurras, on republicans, such as Anatole France and Georges Clemenceau. He succeeded in assuaging one of the great anxieties of his time, the antagonism between science and religion, but he very much felt this anxiety.

Henriette Psichari's definitive edition of Renan's works appeared in ten volumes in 1947–61.

BIBLIOGRAPHY. J.M. POMMIER, ***Renan, d'après des documents inédits*** (**1923**), may be regarded as the definitive hiography; the same author's ***La Jeunesse cle'ricale d'Ernesi Renan*** (**1933**), is indispensable for a detailed knowledge of Renan's seminary years. HENRIETTE PSICHARI, ***Renan d'après lui-même*** (1937) and ***Renan et la guerre de '70*** (**1947**), constitute an important appraisal of Renan by one of his granddaughters. R. DUSSAUD, ***L'Oeuvre scientifique &Ernest Renan*** (1951), is the most exhaustive assessment of Renan's scholarly work. R.M. CHADBOURNE, ***Ernest Renan As an Essayist*** (1957), breaks new ground in Renan criticism, and the same author's ***Ernest Renan*** (**1968**), condenses ***an*** impressive amount of analysis. H.W. WARDMAN, ***Ernest Renan*** (1964), is a critical biography that stresses Renan's interest in the psychology and politics of messianism. HENRI PEYRE (ed.), ***Sagesse de Renan*** (**1968**), is a discriminating anthology by a leading scholar. K. GORE, ***L'Idée de progrès dans la pensée de Renan*** (1970), is a sound scholarly study of his political philosophy.

(H.W.W.)

Renoir, Jean

Born virtually at the same time as motion pictures were invented, Jean Renoir was to achieve a place in the forefront of the creators of the art of the film. His fame is based largely on the deeply moving films he made in France in the 1930s, such as ***La Règle du jeu*** and ***La Grande Illusion,*** but he also wrote and directed films—in France, in Hollywood, and elsewhere—that are outstanding for their entertainment values alone. All his works are distinguished for their strong pictorial sense, and his best are of a quality equalling the most sublime art in their humanity, grace, and style.

Artistic influences

The son of the Impressionist painter Auguste Renoir and the younger brother of the actor Pierre Renoir, Jean Renoir was born in the Montmartre section of Paris on September 15, 1894. In an environment in which art predominated, among painters and their models, he spent a happy childhood, which was richer in the carefree appreciation of beauty than in formal studies. Nevertheless, he received a degree in 1913 from the University of Aix-en-Provence, where he wrote poetry, and joined the cavalry to begin a military career.

World War I broke out in 1914, and Renoir was wounded in the leg. During his convalescence, he spent his time in Paris movie houses, where he discovered the serials and Charlie Chaplin. After he recovered, he rejoined the service in the air force and finished the war with the rank of lieutenant.

Undecided on a career, he studied ceramics with his brother at Cagnes-sur-mer, near Nice, where his family had settled. Early in 1920, he married one of his father's models, Andrée Heurschling, a few months after the painter's death, and went with her to live in the Paris area in Marlotte, a village in which his father had once painted.

Intending to set up a ceramics factory, Jean Renoir was joined by his friend Paul Cézanne, the son of the painter. Having come into contact with theatrical circles through his sister-in-law, the actress Vera Sergine, Renoir was attracted by the evolving art of the film and decided to write a screenplay. It was made into the the film ***Catherine,*** or ***Une vie sans joie,*** in 1923, with his wife appearing under the name of Catherine Hessling. Another film was made on Cézanne's property, ***La Fille de l'eau*** (released **1924**), which again starred Renoir's wife. All of his early films were produced in a makeshift way, with a technical clumsiness, a lack of means, and an amateurishness. Nevertheless, the instinctive genius of the film maker found expression in them. These early films, which reveal a strong pictorial influence, have taken on with time a particular charm. In the late 1920s, he found his inspiration in the writings of Emile Zola, Hans Christian Andersen, and others, but made of them personal films in the style of the French avant-garde of the period.

These films had no commercial success, and Renoir and his backers were almost ruined. The advent of sound in motion pictures brought new difficulties, but Renoir passed the test with ***On purge bkbk*** (1931) and proved himself with ***La Chienne*** (**1931**), a fierce and bitter film adapted from a comic novel by Georges de la Fouchardière.

Freedom of composition

During the 1930s, Jean Renoir produced many of his most notable works, but their freedom of composition was confusing to critics of the period, and the films achieved only middling success. These films include ***La Nuit du carrefour*** (**1932**), based on a novel by Georges Simenon; ***Boudu sauvk des eaux*** (**1932**), an anarchistic and unconstrained comedy; ***Madame Bovary*** (1934), based on Flaubert's classic novel; and ***Le Crime de M. Lange*** (1936), which, in contrast to the rather stilted manner of the first years of sound films, foretells a reconquest of the true moving-picture style, especially in use of improvisation and of montage—the art of editing, or cutting, to achieve certain associations of ideas.

In 1936, in sympathy with the social movements of the French Popular Front, Renoir directed the Communist propaganda film La ***Vie est à nous***, but the film was not commercially successful. The same year he recaptured the flavour of his early works with a short film, ***Une partie de campagne*** (released 1946), which he finished with great difficulty. A masterpiece of Impressionist cinema, this film presents all the poetry and all the charm of the pictorial sense that is, far more than is his technique, the basis of Renoir's art as a film maker. The late 1930s saw such major works as ***La Grande Illusion*** (1937), a moving story of World War I prisoners of war; La ***Bête humaine*** (1938), an admirable free interpretation of Zola; and especially La ***Règle du jeu*** (1939), his masterpiece. Cut and fragmented by the distributors, this classic film was also regarded as a failure until it was shown in 1965 in its original form, which revealed its astonishing beauty.

During World War II, at the time of the Nazi invasion of France in 1940, Jean Renoir, like many of his friends, went to Hollywood. His American period includes films of varying merit, which mark a departure from his previous style: ***Swamp Water*** (1941), ***The Southerner*** (1945), ***Diary of a Chambermaid*** (1946), and ***The Woman on the Beach*** (1947). In 1944, after being divorced from Catherine Hessling, he married Dido Freire, the daughter of the Brazilian film maker Alberto Cavalcanti. He made ***The River*** (1951) in India, his first colour film.

Mature style

Now in full command of a mature style that reflected the qualities of the man himself—sensitivity, fervour, and humanity—he returned to Europe by way of Italy, where he made ***Le Carrosse d'or*** (released 1953). A sumptuous work, combining the talents of both a painter and a dramatist, this film shows Renoir's love of actors and their profession. He often played roles in his own films, and he allowed his actors a great deal of initiative. Subsequently, he made ***French-Cancan*** (1955), a fabulous evocation of the Montmartre of the 18th century, and ***Eléna et les hommes*** (1956), a period fantasy swept along in a prodigious movement. His last works, of the 1960s, do not achieve the same beauty, nor does his television work.

A powerful personality, having been deeply impressed by the artistic environment of his youth, Renoir was also extremely open to later influences both in his art and in his ideas. A naturalized American citizen, settling in Los Angeles, he nevertheless kept his French nationality and maintained connections in Paris.

In addition to his films, Renoir also wrote a play, *Orvet* (first performed 1955), which was presented in Paris; a novel, ***Les Cahiers du capitaine Georges*** (1966); and an invaluable book of memories about his father, ***Renoir*** (1962). His autobiography, ***Ma Vie et mes films***, was published in 1974 (English translation, ***My Life and My Films***, also 1974). He died at Los Angeles on February 12, 1979.

MAJOR WORKS

La Chienne (1931); Boudu sauvé des eaux (1932; Boudu Saved from Drowning); La Nuit du carrefour (1932); Toni (1934); Le Crime de M. Lange (1936; The Crime of Monsieur Lange); Une Partie de campagne (made in 1936, released in 1946; A Day in the Country); La Grande Illusion (1937; Grand Illusion); La Bête humaine (1938); La Règle du jeu (1939; The Rules of the Game); The River (1951); Le Carrosse d'or (1953; The Golden Coach); French-Cancan (1955).

(P.Le.)

Renoir, Pierre-Auguste

During the last quarter of the 19th century, Impressionism had the greatest effect on the methods and goals of painting, and to that Impressionism Pierre-Auguste Renoir brought an accent of pleasing sensuality that gave his work its particular force. His background (he belonged to a family of simple artisans), his subjects (much more than his contemporaries, he was drawn to the human figure), and lastly his technique (he did not use for long the divided colour and juxtaposition of small, separate strokes that characterized the other Impressionists) all set him apart from his fellow painters and at the same time helped make him one of the most brilliant members of that school.

Renoir, self-portrait, oil painting, 1910. In the Durand-Ruel Collection, Paris.

Early work

Renoir was born at Limoges on February 25, 1841, into a family of small artisans. His father, a tailor who had seven children, moved with his family to Paris about 1845. Renoir demonstrated his talent for painting at a very early age. Quickly recognizing his talents, his parents apprenticed him, at the age of 13, to work in a porcelain factory, where he learned to decorate plates with bouquets of flowers. Shortly after that, he was painting fans and then cloth panels representing religious themes for missionaries to hang in their churches. His skill and the great pleasure he took in his work soon persuaded him to study painting in earnest. Having saved a little money, he decided, in 1862, to take evening courses in drawing and anatomy at the École des Beaux-Arts as well as painting lessons at the studio of Charles Gleyre, a Swiss painter who had been a student of the 19th-century Neoclassical painter J.-A.-D. Ingres. Although the academic style of his teacher did not suit Renoir, he nevertheless accepted its discipline in order to acquire the elementary knowledge needed to become a painter. He felt a much greater affinity with three students who entered the studio a few months later: Alfred Sisley, Claude Monet, and Frederic Bazille. All four students dreamed of an art that was closer to life and free from past traditions. The shared ideals of the four young men quickly led to a strong friendship. At the same time in another workshop at the Académie Suisse, the young artists Paul Cezanne and Camille Pissarro were preoccupied with the same problems. With Bazille as the intermediary, the two groups met frequently.

Fontainebleau period

Association with the Impressionists. Circumstances encouraged Renoir to attempt a new freedom and experimentation in his style. The tradition of the time was that a painting—even a landscape—had to be executed in the studio. In the spring of 1864, however, Gleyre's four students moved temporarily to the forest of Fontainebleau where they devoted themselves to painting directly from nature. The Fontainebleau forest had earlier attracted other artists, among them Theodore Rousseau and Jean-François Millet, who demanded that art represent the reality of everyday life, even though they had not yet completely renounced the constraints imposed by the traditional school. In 1863 Édouard Manet took a much bolder step: his picture "Le Déjeuner sur l'herbe" ("Luncheon on the Grass"; Louvre, Paris) provoked a resounding scandal because its subject and technique affirmed the need for a revival of painting through the observation of reality. Manet's daring made him the leader of a new movement in the eyes of these young artists.

Conditions were ripe for the birth of a new pictorial language; and Impressionism, bursting upon the scene, made quite a scandal in the first Impressionist exposition of 1874, held independently of the official Salon exhibition. It took ten years for the movement to acquire its definitive form, its independent vision, and its unique perceptiveness. But one can point to 1874 as the year of departure for the movement that subsequently spawned modern art.

Renoir's work is a perfect illustration of this new approach in thought and in technique. Better than any other artist, he suggested by small multicoloured strokes the vibration of the atmosphere, the sparkling effect of foliage, and especially the luminosity of a young woman's skin in the outdoors. Renoir and his companions stubbornly strove to produce light-coloured paintings from which black was excluded, but their pursuits led to many disappointments: their paintings, so divergent from traditional formulas, were constantly rejected by the juries of the Salon and were extremely difficult to sell. On the other hand, despite the continuing criticisms, some of the Impressionists were making themselves known, as much among art critics as among the lay public. Renoir, because of his interest in the human figure, separated himself from the others who were more tempted by landscape. Thus he obtained several orders for portraits and was introduced, thanks to the publisher Georges Charpentier, to an upper middle-class society, whose women and children he painted.

Renoir was now a master of his craft, and his paintings showed great vitality despite the grave financial worries that troubled him. Several of his masterpieces date from this period: "La Loge," "Le Moulin de la galette," "The Luncheon of the Boating Party," "Mme Charpentier and Her Children." Charpentier organized a personal exposition for the works of Renoir in 1879 in the gallery La Vie Moderne.

Rejection of Impressionism. In 1881 and 1882 Renoir made several trips to Algeria, Italy, and Provence, which eventually had a considerable effect on his art and on his life. He became convinced that the systematic use of the Impressionistic technique was no longer sufficient for him and that small brush strokes of contrasting colours placed side by side did not allow him to convey the satiny effects of the skin. He also discovered that black did not deserve the opprobrium given to it by his comrades and that, in certain cases, it had a striking effect and gave a great intensity to the other colours. During his journey to Italy, he discovered Raphael and the fascinations of classicism: the beauty of drawing, the purity of a clear line to define a form, and the expressive force of smooth painting to enhance the suppleness and modelling of a body. At this same time, he happened to read *Il libro dell'arte* (1437; *A Treatise on Painting*, 1844) by Cennino Cennini, which confirmed his new ideas. What he learned from all of these revelations was so powerful, brutal, and unexpected that it provoked a crisis, and he was tempted to break with Impressionism, which he had already begun to doubt. He felt that until now he had been mistaken.

The Ingres period

Most of his works executed from 1883–84 on are so marked by a new discipline that art historians have grouped them under the title "the Ingres period" to signify their vague similarity with the technique of Ingres. Renoir's experiments with Impressionism were not wasted, however, because he retained a palette that was bursting with colours.

His strong reaction against Impressionism continued until around 1890. During these years he made several trips to southern France: Aix-en-Provence, Marseille, and Martigues. The nature of this sunlit region gave greater encouragement to his separation from Impressionism, which to him was associated with the landscapes of the valley of the Seine. Southern France offered him scenes bursting with colour and sensuality. At the same time, the seemingly joyous spontaneity of nature gave him the desire to depart from the very strict rules of classicism. While in southern France, he recovered the instinctive freshness of his art; he painted women at their bath with the same healthful bloom he would give to bouquets of flowers.

Marriage and fame

His financial situation was appreciably improved; he was married in 1890 to Alice Charigot, and the exposition that was organized for him in 1892 by Durand-Ruel was a great success. Renoir's future was assured, and his work of that period reflected his new security and also his confidence in the future.

Later years. Two years later, he had his first attack of rheumatism, and, as the attacks became more and more frequent, he spent more and more time in southern France where the climate was better for his health. About 1899 he sought refuge in the small village of Cagnes; in 1907 he settled there permanently, buying the estate of Les Collettes, where he spent the rest of his life. In 1910 he was no longer able to walk. But in spite of his infirmity, which was more and more constraining, Renoir never ceased to paint; when his fingers were no longer supple, he continued by attaching his paintbrush to his hand.

In spite of his misfortune, his paintings still embodied a cheerful attitude toward life. He was no longer satisfied with topical themes or with smiling portraits of the Parisian bourgeoisie but turned instead to portraits of his wife, his children, and of Gabrielle his maid, who often also posed for his nude paintings. His still lifes were composed of flowers and fruits from his own garden, and the landscapes were those that surrounded him. The nudes, especially, reflect the serenity that he found in the joy of working throughout his life. He attempted to embody his admiration for the female form in sculpture, with the assistance of young Richard Guino. Since Renoir was no longer able to do sculpture himself, Guino became, about 1913, the skillful instrument who willingly followed his directions. He yielded before the personality of Renoir and succeeded so well in this difficult enterprise that the works born of this union have all the qualities of Renoir's style.

Mme Renoir died in 1915, after having returned from Gérardmer, where she had gone to see their son Jean, who had been seriously wounded in the war. Renoir survived her for four years, until his death on December 3, 1919, at Cagnes. Several months earlier—in August—he had been able to go to Paris to see his "Portrait de Mme Georges Charpentier," which had been recently acquired by the state. On that occasion, several friends had wheeled him for the last time to view the Louvre's masterpieces that he had venerated throughout his life.

MAJOR WORKS

"Le Carabet de la mère Anthony" (1866; Nationalmuseum, Stockholm); "Diana" (1867; National Gallery of Art, Washington, D.C.); "Portrait du peintre Bazille" (1867; Louvre, Paris); "Lise" (1867; Museum Folkwang, Essen); "The Painter Sisley and His Wife" (1868; Wallraf-Richartz-Museum, Cologne); "La Grenouillère" (1869; Nationalmuseum, Stockholm); "Chalands sur la Seine" ("Barges on the Seine," *c.* 1869; Louvre); "Odalisque" (1870; National Gallery of Art, Washington, D.C.); "Captain Darras" (1871; Gemäldegalerie, Dresden); "The Breakfast" (1872; Barnes Foundation, Merion, Pennsylvania); "Monet Painting in His Garden" (1873; Wadsworth Atheneum, Hartford, Connecticut); "Horsewoman in the Bois de Boulogne" (1873; Hamburger Kunsthalle); "Dancer" (1874; National Gallery of Art, Washington, D.C.); "La Loge" ("The Theatre Box," 1874; Courtauld Institute Galleries, London); "Mme Chocquet" (1875; Staatsgalerie, Stuttgart); "La Premiere Sortie" (1875–76; Tate Gallery, London); "Le Moulin de la galette" (1876; Louvre); "Mme Charpentier and Her Children" (1878; Metropolitan Museum of Art, New York); "Oarsmen at Chatou" (1879; National Gallery of Art, Washington, D.C.); "Little Blue Nude" ("Petit Nu Bleu," 1879–80; Albright-Knox Art Gallery, Buffalo, New York); "The Luncheon of the Boating Party" ("Le Déjeuner des canotiers," 1881; Phillips Collection, Washington, D.C.); "Bather" (1881: Sterling and Francine Clark Art Institute, Williamstown, Massachusetts); "Le Bal à Bougival" ("The Dance at Bougival," 1883; Museum of Fine Arts, Boston); "Les Parapluies" (c. 1883; National Gallery, London); "Bathers" (1884–87; Mrs. C.S. Tyson Collection, Philadelphia); "Mount Sainte-Victoire" (1889; Barnes Foundation, Merion, Pennsylvania); "Bather" (1892; Robert Lehman Collection, New York);

"Young Girl Reading" (1892; Durand-Ruel Collection, Paris); "Berthe Morisot and Her Daughter" (1894; Mme Ernest Rouart Collection, Paris); "After the Bath (*c.* 1895; E.C. Vogel Collection, New York); "The Artist's Family" (1896; Barnes Foundation, Merion, Pennsylvania); "Sleeping Bather" (1897; Sammlung Oskar Reinhart, Winterthur, Switzerland); "Le Lever" (1899; Barnes Foundation, Merion, Pennsylvania).

BIBLIOGRAPHY. The principal work on Renoir is the *Catalogue raisonné de l'oeuvre peint*, ed. by FRANCOIS DAULTE, vol. 1, *Figures, 1860–1890* (1971), the first volume of a projected four-volume work. Other important studies are: JULIUS MEIER-GRAEFE, *Auguste Renoir* (1911) and *Renoir* (1929). in German; ALBERT C. BARNES and VIOLETTE DE MAZIA, *The Art of Rerzoir* (1935); MICHEL DRUCKER, *Renoir* (1944), the most complete critical and biographical study in French; and HENRI PERRUCHOT, *La Vie de Renoir* (1964), a good and skillful use of the best documented sources. Among the numerous monographs, the principal ones are: AMBROISE VOLLARD, *La Vie et I'oeuvre de Pierre-Auguste Renoir* (1919; Eng. trans., 1925); ALBERT ANDRE, *Renoir,* new ed. (1923); THEODORE DURET, *Renoir* (1924; Eng. trans., 1937); GUSTAVE COQUIOT, *Renoir* (1925); MICHEL FLORISOONE, *Renoir* (1937); CLAUDE ROGER-MARX, *Renoir* (1937); and FRANCOIS FOSCA, *Renoir, I'homme et son oeuvre* (1961; Eng. trans., 1970). Works on more specialized aspects include: ALBERT ANDRE and MARC ELDER, *L'Atelier de Renoir* (1931); PAUL HAESAERTS, *Renoir, sculpteur* (1947; Eng. trans., 1947); CLAUDE RENOIR, "Souvenirs sur mou père," in AUGUSTE RENOIR, *Seize aquarelles et sanguines* (1948); JEAN RENOIR, *Renoir,* My *Father* (Eng. trans. 1962); CLAUDE ROGER-MARX, *Les Lithographies de Renoir* (1951); and JOHN REWALD (ed.), *Renoir Drawings* (1946, reprinted 1958). Recent studies in English include PARKER TYLER, *Renoir* (1969); and LAWRENCE HANSON, *Renoir: The Man, the Painter, and His World* (1968).

(R.Cog.)

Reproduction

In a general sense reproduction is one of the most important concepts in biology: it means making a copy, a likeness. Although reproduction is often considered solely in terms of the production of offspring in animals and plants, the more general meaning has far greater significance to living organisms. To appreciate this fact, the origin of life and the evolution of organisms must be considered. One of the first characteristics of life that emerged in primeval times must have been the ability of some primitive chemical system to make copies of itself. At its lowest level, therefore, reproduction is chemical replication. As evolution progressed, cells of successively higher levels of complexity must have arisen, and it was absolutely essential that they had the ability to make likenesses of themselves. In unicellular organisms, the ability of one cell to reproduce itself (along with its parts) means the reproduction of a new individual; in multicellular organisms, however, it means growth (the enlargement of the organism by cell multiplication) and regeneration (the replacement of lost parts). Multicellular organisms also reproduce in the strict sense of the term—that is, they make copies of themselves in the form of offspring.

LEVELS OF REPRODUCTION

Transmittal of genetic information

Molecular **replication.** The characteristics that an organism inherits are largely stored in cells as genetic information in very long molecules of deoxyribonucleic acid (DNA). In 1953, it was established that DNA molecules actually consist of two complementary strands, each of which can make copies of the other. The strands are like two sides of a ladder that has been twisted along its length in the shape of a double helix (spring). The lungs, which join the two sides of the ladder, are made up of two terminal bases. There are four bases in DNA: thymine, cytosine, adenine, and guanine. In the middle of each rung a base from one strand of DNA is linked by a hydrogen bond to a base of the other strand. But they can only pair in certain ways: adenine always pairs with thymine, and guanine with cytosine. This is why one strand of DNA is considered complementary to the other.

The double helices duplicate themselves by separating at one place between the two strands and becoming progressively unattached. As one strand separates from the other, each acquires new complementary bases until eventually each strand becomes a new double helix with a new complementary strand to replace the original one. Because adenine always falls in place opposite thymine and guanine opposite cytosine, the process is called a template replication—one strand serves as the mold for the other. It should be added that the steps involving the duplication of DNA do not occur spontaneously; they require catalysts in the form of enzymes that promote the replication process.

Genetic code

Molecular reproduction. The sequence of bases in a DNA molecule serves as a code by which genetic information is stored. Using this code, the DNA synthesizes one strand of ribonucleic acid (RNA), a substance that is so similar structurally to DNA that it is also formed by template replication of DNA. RNA serves as a messenger for carrying the genetic code to those places in the cell where proteins are manufactured. The way in which the messenger RNA is translated into specific proteins is a remarkable and complex process. (For more detailed information concerning DNA, RNA, and the genetic code, see the articles GENE; NUCLEIC ACID.)

The ability to synthesize enzymes and other proteins enables the organism to make any substance that existed in a previous generation. Proteins are reproduced directly; however, such other substances as carbohydrates, fats, and other organic molecules found in cells are produced by a series of enzyme-controlled chemical reactions, each enzyme being derived originally from DNA through messenger RNA. It is because all of the organic constituents made by organisms are derived ultimately from DNA that molecules in organisms are reproduced exactly by each successive generation.

Cell reproduction. The chemical constituents of cytoplasm (that part of the cell outside the nucleus) are not resynthesized from DNA every time a cell divides. This is because each of the two daughter cells formed during cell division usually inherits about half of the cellular material from the mother cell (see CELL AND CELL DIVISION), and is important because the presence of essential enzymes enables DNA to replicate even before it has made the enzymes necessary to do so.

Cells of higher organisms contain complex structures, and each time a cell divides the structures must be duplicated. The method of duplication varies for each structure, and in some cases the mechanism is still uncertain. One striking and important phenomenon is the formation of a new membrane. Cell membranes, although they are very thin and appear to have a simple form and structure, contain many enzymes and are sites of great metabolic activity. This applies not only to the membrane that surrounds the cell but to all the membranes within the cell. New membranes, which seem to form rapidly, are indistinguishable from old ones.

Thus, the formation of a new cell involves the further synthesis of many constituents that were present in the parent cell. This means that all of the information and materials necessary for a cell to reproduce itself must be supplied by the cellular constituents and the DNA inherited from the parent cell.

Binary fission. Of the various kinds of cell division, the most common mode is binary fission, the division of a cell into two separate and similar parts. In bacteria (prokaryotes) the chromosome (the body that contains the DNA and associated proteins) replicates and then divides in two, after which a cell wall forms across the elongated parent cell. In higher organisms (eukaryotes) there is first an elaborate duplication and then a separation of the chromosomes (mitosis), after which the cytoplasm divides in two. In the hard-walled cells of higher plants, a median plate forms and divides the mother cell into two compartments; in animal cells, which do not have a hard wall, a delicate membrane pinches the cell in two, much like the separation of two liquid drops. Budding yeast cells provide an interesting exception. In these fungi the cell wall forms a bubble that becomes engorged with cytoplasm until it is ultimately the size of the original cell. The nucleus then divides, one of the daughter nuclei passes into the bud, and ultimately the two cells separate.

Mitosis and meiosis

In some instances of binary fission, there may be an unequal cytoplasmic division with an equal division of the chromosomes. This occurs, in fact, in a large number of higher organisms during meiosis—the process by which sex cells (gametes) are formed: originally each chromosome of the cell is in a pair (diploid); during meiosis these diploid pairs of chromosomes are separated so that each sex cell has only one of each pair of chromosomes (haploid). During the two successive meiotic divisions involved in the production of eggs, a primordial diploid egg cell is converted into a haploid egg and three small haploid polar bodies (minute cells). In this instance the egg receives far more cytoplasm than the polar bodies.

Multiple fission. Some algae, some protozoans, and the true slime molds (Myxomycetes) regularly divide by multiple fission. In such cases the nucleus undergoes several mitotic divisions, producing a number of nuclei. After the nuclear divisions are complete, the cytoplasm separates, and each nucleus becomes encased in its own membrane to form an individual cell. In the Myxomycetes, the fusion of two haploid gametes or the fusion of two or more diploid zygotes (the structures that result from the union of two sex cells) results in the formation of a plasmodium—a motile, multinucleate mass of cytoplasm. The nuclei are in a syncytium, that is, there are no cell boundaries, and the nuclei flow freely in the motile plasmodium. As it feeds, the plasmodium enlarges, and the nuclei divide synchronously about once every 24 hours. The plasmodium may become very large, with millions of nuclei, but, ultimately, when conditions are right, it forms a series of small bumps, each of which becomes a small, fruiting body (a structure that bears the spores). During this process the nuclei undergo meiosis, and the final haploid nuclei are then isolated into uninucleate spores (reproductive bodies).

Development of a plasmodium

Many algae (*e.g.*, the Siphonales and related groups) are multinucleate. In most instances the nuclei are in one common cytoplasm within a large and elaborate organism surrounded by a hard cell wall. As the wall becomes extended, the nuclei, which wander freely in the central cavity, undergo repeated mitoses. Again, either during the formation of zoospores (asexual reproductive cells) or after meiosis during gamete formation, a massive progressive division occurs. The most unusual of such organisms is the marine alga Acetabularia; many nuclei stay clumped together in one compound nucleus in the rootlike base, which often is as much as two inches (five centimetres) away from the tip of the plant. The compound nucleus breaks up just before gamete formation, and the minute individual nuclei undergo meiosis and wander to the elaborate tip structures, where they are released as uninucleate gametes.

Syncytial organisms raise the question of whether or not cells, in the strict sense, are necessary for the development of large organisms. Syncytia are also found in animals—*e.g.*, in the early stages of development of fishes and insects—and in the voluntary muscles of man. The proposal of the 19th-century botanist Julius von Sachs is generally considered a satisfactory answer to this question; he suggested that the important matter was the existence not of a cell membrane but of a certain amount of cytoplasm surrounding a nucleus and acting as a unit of metabolism, which he called an energid. Cell reproduction, therefore, might be considered a special case of energid reproduction.

Reproduction of organisms. In single-celled organisms (*e.g.*, bacteria, protozoans, many algae, and some fungi), organismic and cell reproduction are synonymous, for the cell is the whole organism. Details of the process differ greatly from one form to the next and, if the higher ciliate protozoans are included, can be extraordinarily complex. It is possible for reproduction to be asexual, by simple division, or sexual. In sexual unicellular organisms the gametes can be produced by division (often multiple fission, as in numerous algae) or, as in yeasts, by the organism turning itself into a gamete and fusing its nucleus with that of a neighbour of the opposite sex, a process that is called conjugation. In ciliate protozoans (*e.g.*, Paramecium), the conjugation process involves the exchange of haploid nuclei; each partner acquires a new nuclear apparatus, half of which is genetically derived from its mate. The parent cells separate and subsequently reproduce by binary fission. Sexuality is present even in primitive bacteria, in which parts of the chromosome of one cell can be transferred to another during mating.

Vegetative reproduction

Multicellular organisms also reproduce asexually and sexually; asexual, or vegetative, reproduction can take a great variety of forms. Many multicellular lower plants give off asexual spores, either aerial or motile and aquatic (zoospores), which may be uninucleate or multinucleate. In some cases the reproductive body is multicellular, as in the soredia of lichens and the gemmae of liverworts. Frequently, whole fragments of the vegetative part of the organism can bud off and begin a new individual, a phenomenon that is found in most plant groups. In many cases a spreading rhizoid (rootlike filament) or, in higher plants, a rhizome (underground stem) gives off new sprouts. Sometimes other parts of the plant have the capacity to form new individuals; for instance, buds of potentially new plants may form in the leaves; even some shoots that bend over and touch the ground can give rise to new plants at the point of contact (see REPRODUCTIVE SYSTEMS, PLANT).

Among animals, many invertebrates are equally well endowed with means of asexual reproduction. Numerous species of sponges produce gemmules, masses of cells enclosed in resistant cases, that can become new sponges. There are many examples of budding among coelenterates, the best known of which occurs in freshwater Hy*dra.* In some species of flatworms, the individual worm can duplicate by pinching in two, each half then regenerating the missing half; this is a large task for the posterior portion, which lacks most of the major organs—brain, eyes, and pharynx. The highest animals that exhibit vegetative reproduction are the colonial tunicates (*e.g.*, sea squirts), which, much like plants, send out runners in the form of stolons, small parts of which form buds that develop into new individuals. Vertebrates have lost the ability to reproduce vegetatively; their only form of organismic reproduction is sexual (see REPRODUCTIVE SYSTEMS, ANIMAL).

In the sexual reproduction of all organisms except bacteria, there is one common feature: haploid, uninucleate gametes are produced that join in fertilization to form a diploid, uninucleate zygote. At some later stage in the life history of the organism, the chromosome number is again reduced by meiosis to form the next generation of gametes. The gametes may be equal in size (isogamy), or one may be slightly larger than the other (anisogamy); the majority of forms have a large egg and a minute sperm (oogamy). The sperm are usually motile and the egg passive, except in higher plants, in which the sperm nuclei are carried in pollen grains that attach to the stigma (a female structure) of the flower and send out germ tubes that grow down to the egg nucleus in the ovary. Some organisms, such as most flowering plants, earthworms, and tunicates, are bisexual (hermaphroditic, or monoecious)—*i.e.*, both the male and female gametes are produced by the same individual. All other organisms, including some plants (*e.g.*, holly and the ginkgo tree) and all vertebrates, are unisexual (dioecious) : the male and female gametes are produced by separate individuals.

Some sexual organisms partially revert to the asexual mode by a periodic degeneration of the sexual process. For instance, in aphids and in many higher plants the egg nucleus can develop into a new individual without fertilization, a kind of asexual reproduction that is called parthenogenesis.

Parthenogenesis

Liie-cycle reproduction. Although organisms are often thought of only as adults, and reproduction is considered to be the formation of a new adult resembling the adult of the previous generation, a living organism, in reality, is an organism for its entire life cycle, from fertilized egg to adult, not for just one short part of that cycle. Reproduction, in these terms, is not just a stage in the life history of an organism but the organism's entire history. It has been pointed out that only the DNA of a cell is capable of replicating itself, and even that process requires specific enzymes that were themselves formed from DNA. Thus, the reproduction of all living forms must be considered in relation to time; what is reproduced is a series of copies that, like the frames of a motion picture, change through time in an exact and orderly fashion.

A few examples serve to illustrate the great variety of life cycles in living organisms. They also illustrate how different parts of the life cycle can change, and the fact that these changes are not confined solely to adult structures. One variation is that of minimum size—that is to say, the differences in the sizes of gametes (mature sex cells) and asexual bodies. An even greater variation in life cycles, however, involves maximum size; there is an enormous difference between a single-celled organism that divides by binary fission and a giant sequoia. Size is correlated with time. A bacterium requires about 30 minutes to complete its life history and divide in two (generation time); a giant sequoia bears its first cones and fertile seeds after 60 years. Not only is the life cycle of the sequoia 10,000,000 times longer than that of the bacterium, but the large difference in size also means that the tree must be elaborate and complex. It contains different tissue types that must be carefully duplicated from generation to generation.

Life cycles of plants. Most life histories, except perhaps for the simplest and smallest organisms, consist of different epochs. A large tree has a period of seed formation that involves many cell divisions after fertilization and the laying down of a small embryo in a hard resistant shell, or seed coat. There then follows a period of dormancy, sometimes prolonged, after which the seed germinates, and the adult form slowly emerges as the shoots and roots grow at the tips and the stem thickens. In some trees the leaves of the juvenile plant have a shape that is quite different from that of the taller, more mature individuals. Thus, even the growth phase may be subdivided into epochs, the final one being the flowering or gamete-bearing period. Some of the parasitic fungi have much more complex life histories. The wheat rust parasite, for example, has alternate hosts. While living on wheat, it produces two kinds of spores; it produces a third kind of spore when it invades its other host, the barberry, on which it winters and undergoes the sexual part of its life cycle.

In plants, variations in the epochs of the life cycle are often centred around the times of fertilization and meiosis. After fertilization the organism has the diploid number of chromosomes (diplophase); after meiosis it is haploid (haplophase). The two events vary in time with respect to each other. In some simple algae (*e.g.*, *Chlamydomonas*), for example, most of the cycle is haploid; meiosis occurs immediately after fertilization. Yet in other algae, such as the sea lettuce (Ulva), two equal haploid and diploid cycles alternate. The outward morphological structures of mature Ulva are indistinguishable; the two cycles can be differentiated only by the size of the cell or nucleus, those of the haploid stage being half the size of those of the diploid stage.

In many of the higher algae, there is a progressive diminution of the haplophase and an increase in the importance of the diplophase, a trend that is especially noticeable in the evolution of the vascular plants (*e.g.*, ferns, conifers, and flowering plants). In mosses, the haplophase, or gametophyte, is the main part of the green plant; the diplophase, or sporophyte, usually is a spore-bearing spike that grows from the top of the plant. In ferns, the haplophase is reduced to a small, inconspicuous structure (prothallus) that grows in the damp soil; the large spore-bearing fern itself is entirely diploid. Finally, in higher plants the haploid tissue is confined to the ovary of the large diploid organism, a condition that is also prevalent in most animals.

Metamorphosis

Life cycles of animals. Invertebrate animals have a rich variety of life cycles, especially among those forms that undergo metamorphosis, a radical physical change. Butterflies, for instance, have a caterpillar stage (larva), a dormant chrysalis stage (pupa), and an adult stage (imago). One remarkable aspect of this development is that, during the transition from caterpillar to adult, most of the caterpillar tissue disintegrates and is used as food, thereby providing energy for the next stage of development, which begins when certain small structures (imaginal disks) in the larva start growing into the adult form. Thus, the butterfly undergoes essentially two periods of growth and development (larva and pupa–adult) and two periods of small size (fertilized egg and imaginal disks). A somewhat similar phenomenon is found in sea urchins; the larva, which is called a pluteus, has a small, wartlike bud that grows into the adult while the pluteus tissue disintegrates. In both examples it is as if the organism has two life histories, one built on the ruins of another.

Another life-cycle pattern found among certain invertebrates illustrates the principle that major differences between organisms are not always found in the physical appearance of the adult but in differences of the whole life history. In the coelenterate Obelia, for example, the egg develops into a colonial hydroid consisting of a series of branching Hydra-like organisms called polyps. Certain of these polyps become specialized (reproductive polyps) and bud off from the colony as free-swimming jellyfish (medusae) that bear eggs and sperm. As with caterpillars and sea urchins, two distinct phases occur in the life cycle of Obelia: the sessile (anchored), branched polyps and the motile medusae. In some related coelenterates the medusa form has been totally lost, leaving only the polyp stage to bear eggs and sperm directly. In still other coelenterates the polyp stage has been lost, and the medusae produce other medusae directly, without the sessile stage. There are, furthermore, intermediate forms between the extremes.

NATURAL SELECTION AND REPRODUCTION

The significance of biological reproduction can be explained entirely by natural selection (see EVOLUTION: Natural selection). In formulating his theory of natural selection, Charles Darwin realized that, in order for evolution to occur, not only must living organisms be able to reproduce themselves but the copies must not all be identical; that is, they must show some variation. In this way the more successful variants would make a greater contribution to subsequent generations in the number of offspring. For such selection to act continuously in successive generations, Darwin also recognized that the variations had to be inherited, although he failed to fathom the mechanism of heredity (*q.v.*). Moreover, the amount of variation is particularly important. According to what has been called the principle of compromise, which itself has been shaped by natural selection, there must not be too little or too much variation: too little produces no change; too much scrambles the benefit of any particular combination of inherited traits.

Of the numerous mechanisms for controlling variation, all of which involve a combination of checks and balances that work together, the most successful is that found in the large majority of all plants and animals—*i.e.*, sexual reproduction. During the evolution of reproduction and variation, which are the two basic properties of organisms that not only are required for natural selection but are also subject to it, sexual reproduction has become ideally adapted to produce the right amount of variation and to allow new combinations of traits to be rapidly incorporated into an individual.

The evolution of reproduction. An examination of the way in which organisms have changed since their initial unicellular condition in primeval times shows an increase in multicellularity and therefore an increase in the size of both plants and animals. After cell reproduction evolved into multicellular growth, the multicellular organism evolved a means of reproducing itself that is best described as life-cycle reproduction. Size increase has been accompanied by many mechanical requirements that have necessitated a selection for increased efficiency; the result has been a great increase in the complexity of organisms. In terms of reproduction this means a great increase in the permutations of cell reproduction during the process of evolutionary development.

Size increase also means a longer life cycle, and with it a great diversity of patterns at different stages of the cycle. This is because each part of the life cycle is adaptive in that, through natural selection, certain characteristics have evolved for each stage that enable the organism to survive. The most extreme examples are those forms with two or more separate phases of their life cycle separated by a metamorphosis, as in caterpillars and butterflies; these phases may be shortened or extended by natural selection, as has occurred in different species of coelenterates.

Efficiency of reproduction

To reproduce efficiently in order to contribute effectively to subsequent generations is another factor that has evolved through natural selection. For instance, an organism can produce vast quantities of eggs of which, possibly by neglect, only a small percent will survive. On the other hand, an organism can produce very few or perhaps one egg, which, as it develops, will be cared for, thereby greatly increasing its chances for survival. These are two strategies of reproduction; each has its advantages and disadvantages. Many other considerations of the natural history and structure of the organism determine, through natural seiection, the strategy that is best for a particular species; one of these is that any species must not produce too few offspring (for it will become extinct) or too many (for it may also become extinct by overpopulation and disease). The numbers of some organisms fluctuate cyclically but always remain between upper and lower limits. The question of how, through natural selection, numbers of individuals are controlled is a matter of great interest; clearly, it involves factors that influence the rate of reproduction.

The evolution of variation control. Because inherited variation is largely handled by genes in the chromosomes, organisms that reproduce sexually require a single-cell stage in their life cycle, during which the haploid gamete of each parent can combine to form the diploid zygote. This is also often true in organisms that reproduce asexually, but in this case the asexual reproductive bodies (*e.g.*, spores) are small and hence are effectively dispersed.

The amount of variation is controlled in a large number of ways, all of which involve a carefully balanced set of factors. These factors include whether the organism reproduces asexually or sexually; the mutation (gene change) rate; the number of chromosomes; the amount of exchange of parts of chromosomes (crossing over); the size of the individual (which correlates with complexity and generation time); the size of the population; the degree of inbreeding versus outbreeding; and the relative amounts and position of haploidy and diploidy in the life cycle. It is clear, therefore, that the mode of reproduction influences the amount of variation and vice versa; the two together permit natural selection to operate, and selection in turn modifies the mechanisms of reproduction and variation.

Reproductive Behaviour

Reproductive behaviour in animals includes all the events and actions that are directly involved in the process by which an organism generates at least one replacement of itself. In an evolutionary sense, the goal of an individual in reproduction is not to perpetuate the population or the species; rather, relative to the other members of its population, it is to maximize the representation of its own genetic characteristics in the next generation. The dominant form of reproductive behaviour for achieving this purpose is sexual rather than asexual, although it is easier mechanically for an organiam simply to divide into two or more individuals. Even many of the organisms that do exactly this—and they are not all the so-called primitive forms--every so often intersperse their normal asexual pattern with sexual reproduction.

This article considers the modes of behaviour directly involved in the asexual and sexual reproduction of invertebrates and vertebrates; it does not include man. For a discussion of man's behaviour as it relates to his reproductive activities, the reader should refer to the article SEXUAL BEHAVIOUR, HUMAN. The articles BEHAVIOUR, ANIMAL and SOCIAL BEHAVIOUR, ANIMAL also contain information related to the subject of reproductive behaviour. For more complete details concerning the anatomical, physiological, neurological (nervous), and mechanical aspects of reproduction, see REPRODUCTION; and REPRODUCTIVE SYSTEMS, ANIMAL.

GENERAL FEATURES

The dominance of sexual reproduction. Two explanations have been given for the dominance of sexual reproduction. Both are related to the fact that the environment in which an organism lives changes in location and through time; the evolutionary success of the organism is determined by how well it adapts to such changes. The physiological and morphological aspects of an organism that interact with the environment are governed by the organism's germ plasm—the genetic materials that determine hereditary characteristics. Unlike asexual methods, sexual reproduction allows the reshuffling of the genetic material, both within and between individuals of one generation, resulting in an array of offspring, each with a genetic makeup different from that of its parents.

According to proponents of the so-called long-term theory for the dominance of sexual reproduction, sexual reproduction will replace asexual reproduction in the evolutionary development of an organism because it assures greater genetic variability, which is necessary if the species is to keep pace with its changing environment. According to proponents of the short-term theory, however, the above argument implies that natural selection acts on groups of organisms rather than on individuals, which is contrary to the Darwinian concept of natural selection (see EVOLUTION: Natural selection). They prefer to view the advantages of sexual reproduction on a more immediate and individual level: an organism employing sexual reproduction has an advantage over one employing asexual means because the greater variety of offspring produced by the former results in a larger number of genes being transmitted to the next generation. The latter view is probably more nearly correct, especially in violently fluctuating and unpredictable environments. The former theory is probably correct when viewed in terms of its advantage to individuals that are spreading in geographic range, thereby increasing the likelihood of encountering different environments.

Natural selection and reproductive behaviour. Natural selection places a premium on the evolution of those physiological, morphological, and behavioral adaptations that will increase the efficiency of the exchange of genetic materials between individuals. Organisms will also evolve mechanisms for sensing whether or not the environment is always permissive for reproduction or if some times are better than others. This involves not only the evolution of environmental sensors but also the concurrent evolution of mechanisms by which this information can be processed and acted upon. Because all seasons are not usually equally conducive, individuals whose genetic backgrounds result in their reproducing at a more favourable rather than less favourable period will eventually dominate succeeding generations. This is the basis for the seasonality of reproduction among most animal species.

Natural selection also results in the evolution of systems for transmitting and receiving information that will increase the efficiency of two individuals' finding each other. These attraction systems are usually, but not always, species specific (see SPECIES AND SPECIATION).

Need for genetic variability

Once the proper individuals have found each other, ıt is clearly important that they are both in a state of reproductive readiness. That their sensory receptors are tuned to the same environmental stimuli is usually sufficient to achieve this synchrony (proper timing) in the lower organisms. Apparently, however, this is not enough in the more complex organisms, in which the fine tuning for reproductive synchrony is accomplished chiefly by a process called courtship. Another evolutionary necessity is a mechanism that will guide the partners into the proper orientation for efficient copulation. Such mechanisms are necessary for both internal and external fertilization, especially the latter, where improper orientation could result in a complete waste of the eggs and sperm.

In most organisms, the period of greatest mortality occurs between birth or hatching and the attainment of maturity. Thus, it is not surprising that some of the most elaborate evolutionary adaptations of an organism are revealed during this period. Natural selection has favoured an enormous variety of behaviour in both parents and offspring that serves to ensure the maximum survival of the young to maturity. In some animals this involves not only protecting the young against environmental vicissitudes and providing them with adequate nutrition but also giving them, in a more or less active manner, the information they will need to reproduce in turn.

External and internal influences **on** reproductive behaviour. As mentioned at the beginning of this article, the anatomical, physiological, and neurological aspects of reproduction and behaviour are dealt with in other articles. It is useful here, however, to consider briefly the external and internal factors that initiate reproductive behaviour.

Environmental influences. Light, usually in the form of increasing day length, seems to be the major environmental stimulus for most vertebrates and many invertebrates, especially those living in areas away from the Equator. That this should be such an important factor is quite reasonable in an evolutionary sense: increasing day length signifies the onset of a favourable period for reproduction. In equatorial regions, where changes in day length are usually insignificant throughout the year, other environmental stimuli, such as rain, predominate.

Superimposed on day length are usually several other factors, which, if lacking, often override the stimulating effect of light. Many insects, for example, will not initiate a reproductive cycle if they lack certain protein foods. Many animal groups have an internal cycle of cellular activity that must coincide with the external factors before reproduction can occur; a familiar example is the estrous cycle in most mammals except primates. Females display sexual behaviour (are "in heat") only during a brief period when they have ovulated an egg.

Hormonal influences. Although the exact way by which light affects the reproductive cycle is still disputed, it undoubtedly varies from group to group. In birds, light passes either through the eyes or through the bony tissue of the skull and stimulates the development of certain cells in the forepart of the brain. These cells then secrete a substance that stimulates the anterior pituitary gland, which is located at the base of the brain, to produce an array of regulatory substances (hormones), called gonadotropins, that are carried by the blood to the gonads (ovaries and testes), where they directly stimulate the development of eggs and sperm. The gonads, in turn, produce the sex hormones—estrogen in the female and testosterone in the male—that directly control several overt aspects of reproductive behaviour.

Insect pheromones

Unlike the higher animals, the gonads of insects apparently do not themselves secrete hormones. Instead, stimulation by the corpus allatum, an organ in insects that corresponds in function to the pituitary gland, causes the secretion of liquid substances on the body surface. These substances are transmitted as liquids, or, even more significantly, as gases, to the recipient, in which they are usually detected by olfaction or taste. Such substances, which are called ectohormones or pheromones, may serve as the major regulation and communication system for reproduction as well as other behaviour in insects.

In the absence of all other stimuli, many types of sexual behaviour can be induced simply by an injection of the appropriate gonadal hormone. Conversely, removal of the gonads usually inhibits most sexual behaviour. The apparent failure of complete hormonal control over reproductive behaviour has been a subject of much investigation and dispute. There is much evidence that many types of reproductive behaviour are or can be controlled solely by neural mechanisms, bypassing the hormonal system and any effect that it might exert on the nervous system to produce behaviour. Several types of reproductive behaviour controlled solely or almost solely by neural mechanisms are involved in or triggered by the processes that are initiated by courtship.

MODES OF SEXUAL **ATTRACTION**

The chief clues by which organisms advertise their readiness to engage in reproductive activity are visual, auditory, and olfactory in nature. Most animals use a combination of two modes; sometimes all three are used.

Visual clues. The appearance of many higher vertebrates changes with the onset of reproductive activity. The so-called prenuptial molt in many male birds results in the attainment of the nuptial plumage, which often differs radically from that possessed by the bird at other times of the year or from that possessed by a nonreproductive individual. The hindquarters of female baboons become bright red in colour, which indicates, or advertises, the fact that she is in estrus and sexually receptive. Such changes in appearance are less common in the lower animals but do occur in many fishes, crabs,, and cephalopods (*e.g.*, squids and octopuses).

The role of aggressive behaviour

Often associated with changes in appearance are changes in behaviour, particularly the increase in aggressive behaviour between males, often a prime feature in attracting females; such changes have interesting evolutionary implications. In certain grouse, for example, females are most attracted to males that engage in the greatest amount of fighting. No doubt, fighting in some groups of mammals also serves this function as well as others (see AGGRESSIVE BEHAVIOUR).

In many animals the rise in aggression takes the form of territoriality, in which an individual, usually a male, defends a particular location or territory by excluding from it all other males of his own kind. Occasionally, other species are also excluded when it is to the advantage of the defending individual to do so. Territorial behaviour involves many functions, not all of which are directly concerned with reproduction. For purposes of advertising, however, aggression probably reduces the amount of interference between males and also makes it easier for females to find males at the proper time.

Auditory clues. The fact that sound signals can travel around barriers, whereas visual signals cannot, accounts for their widespread use in indicating sexual receptiveness, especially in frogs, insects, and birds. Like visual signals, a sound for advertising purposes usually encodes several pieces of information; for example, the signals usually reveal to the receiver the caller's species, its sex, and, in some cases, whether or not it is mated. The vocalizations of one type of frog also reveal the number of other males located nearby. This information, a critical clue for females, is a measure of how good the habitat is for depositing eggs. The sounds produced by the wings of mosquitoes attract females and are species specific. Humans have taken advantage of this signal by using artificial sound generators to eradicate certain mosquitoes. Advertising signals also serve to repel other males; a classical example is the territorial song of many songbirds.

Olfactory clues. Researchers have now become aware of the enormous amount of information that is passed between animals bv chemical means. Well-known are the urine, feces, anh scent markings employed by most mammals to delimit their breeding territories and to advertise their sexual state. Males of a number of mammals are capable of determining if a female will be sexually receptive simply by smelling her urine markings. A substance in the urine of male mice, on the other hand, actually induces and accelerates the estrous cycle of females. A female gypsy moth is able to attract males thousands of metres downwind of it simply by releasing minute quantities of its sex pheromone each second. It has been calculated that one female silkworm moth carries only about 1.5 micrograms (0.0015 gram) of its sex attractant, called bombykol, at any given moment; theoretically, this is enough to activate more than 1,000,000,000 males, surely more than exist in any one place at any time. The sex attractant of barnacles, which are rather sessile (sedentary) organisms, causes individuals to aggregate during the breeding period.

The potency of pheromones

One other possible channel of communication occurs in a few fishes, namely electric discharge. Evidence now accumulating suggests that weak electrical fields and discharges in the Mormyridae of Africa and the Gymnotidae of South America represent the major mode of social interaction in these families.

COURTSHIP

Synchrony is the major factor in achieving fertilization in the lower animals, particularly in aquatic forms. In most of these groups, the eggs and sperm are simply discharged into the surrounding water, and fertilization occurs externally. The parents may never meet, so to speak. It might be assumed that this procedure would be roughly the same in the higher animals, with perhaps more overt behaviour to achieve synchrony, and that, after the two individuals found each other, fertilization would proceed fairly quickly. This is usually not the case, however. Although fertilization in the higher terrestrial forms involves contact during copulation, it has been suggested that all of the higher animals may have a strong aversion to bodily contact. This aversion is no doubt an antipredator mechanism: close bodily contact signifies being caught. Since females are in an especially helpless situation during copulation, they are particularly wary about bodily contact. In addition, males are particularly aggressive during the breeding period, which further increases the uncertainty of both individuals. These difficulties were solved by the evolution of a collection of behaviours called courtship. Courtship has been defined as the heterosexual reproductive communication system leading to the consummatory sexual act.

Courtship behaviour has many advantages and functions, not the least of which is the reduction of hostility between the potential sex partners, especially in species in which the male actively defends a territory. The major aspects of such behaviour seem to be appearance, persistence, appeasement, persuasion, and even deception. Because courtship behaviour involves the transmission of information by means of signals, it is useful to define at this point a peculiar and important group of social signals called displays.

A social signal may be considered any behavioral pattern that effectively conveys information from one individual to another. The term display has been restricted by some authorities to social signals that not only convey information but that, in the course of evolution, have also become "ritualized." In other words, such signals have become so specialized and exaggerated in form or function that they expressly facilitate a certain type of communication. The visual, auditory, olfactory, tactile, or other patterns by which organisms advertise their readiness to engage in reproductive activity provide examples of displays. Clearly, the kinds of displays utilized by organisms depend on the sensory receptors of the receiver. Whereas higher vertebrates tend to use visual and auditory displays, insects tend toward olfactory and tactile displays.

In animals in which the male takes on a wholly different appearance during the breeding period, natural selection has eliminated from the female's appearance the "aggressive badges" of males that provoke fighting. It is not without significance that the appearance of the adult female in many species is much like that of the juvenile; this implies to the male a friendly, nonaggressive relationship. When one male approaches another that has intruded into the former's territory, the outsider may either return the aggressive display or flee. Females, however, usually quietly back up slightly and then slowly move forward again. With each approach the male's hostility lessens toward this appeasing, increasingly familiar individual. Often, as in many birds, the females resort to displays that resemble the food-begging behaviour normally seen in the young. Males frequently respond to this display by actually regurgitating food. Male spiders of some species offer the larger and more aggressive females food as bait, and copulation occurs while the female is eating the food rather than her potential mate. Mutual feeding displays, often with nonedible items, are engaged in by a number of insects and birds. In the courtship behaviour of several birds, extremely elaborate displays are utilized to hide the bill from the potential partner, because the bills of these birds are their chief weapons. Some aspects of nest building have been incorporated into the displays of such birds as penguins. Early in the relationship between the individuals, one or both may offer the other stones that are placed in a pile. The actual nest is not constructed until much later, however.

The common denominator in courtships is that the displays resemble functional behaviours that are appropriate to friendly, bonded situations, such as those between parents and between parents and their offspring. The degree of elaborateness of the display is governed by a number of factors. One is to prevent cross-mating between different species, an occurrence that usually results in the waste of the eggs and sperm. Any specific aspect—*i.e.*, one or more displays—used by an organism in species discrimination is called an isolating mechanism. In many species, the majority of the displays between individuals are a series of identity checks.

Species discrimination

Another factor governing the complexity of displays is the length of time that the pair bond will endure. Brief relationships are usually, but not always, associated with rather simple courtship activity. In a number of insects, birds, and mammals, the males display on a common courtship ground called a lek or an arena. Females visit these courtship areas, copulate, and leave. The males do not participate in any aspect of parental care; the bond lasts but a few seconds. Yet despite the brevity of this relationship, in no other courtship system is there the development of such elaborate and almost fantastic displays in both the movements and appearances of the males.

POST-FERTILIZATION BEHAVIOUR

Various types of behaviour ensure that a maximum number of fertilized eggs or young will survive to become reproductive adults. Clearly, the number of eggs produced and their size represents a balance achieved by natural selection. This balance conforms to some optimum compromise between producing many eggs containing little food for the development of young or fewer eggs with more provisions.

There has been considerable controversy about the factors that limit the number of offspring an organism can produce. It has been suggested that, among animals in which the offspring are dependent on the parents for varying lengths of time, clutch or litter size has been adjusted through natural selection to the maximum number of offspring that the parents, on the average, can feed. There are, on the other hand, organisms that do not practice parental care and produce millions of eggs. According to one popular school of thought, these species have such a high fecundity (productivity) because the eggs and larvae suffer a very high mortality rate. Hence, it is necessary for such animals to produce thousands, even millions, of eggs just to obtain a few reproductive adults. An opposing school of thought, however, says that such species have high mortality rates because of their great fecundities. Similarly, low death rates would be the consequence of low fecundity.

Protective adaptations. Several adaptations have evolved to protect the eggs and larvae of species not attended by adults. In one such adaptation, the eggs or larvae are distasteful, inedible, or apparently harmful to potential enemies. The eggs of the jellyfish *Bougainvillia*, for example, contain stinging cells on the surface that deter predators. Many female butterflies deposit their eggs on plants that contain poisonous compounds, which the larvae incorporate into their bodies, making them distasteful. When disturbed many insect larvae, especially those that are camouflaged, give a so-called startle display; several caterpillars, for example, raise their heads as if to bite or their hindparts, in the manner of a wasp, as if to sting. Others suddenly present striking colour patterns previously hidden. Most of these displays have been shown experimentally to be effective deterrents against predators.

Caring for offspring. Animals that do not care for their young must provide for the nutritional needs of their offspring. One way of doing so is by producing an egg with a sufficiently large yolk supply that the young, when hatched, are already at an advanced, almost independent state. **A** peculiar example of this is found in the incubator birds (Megapodiidae), which cover their large eggs with soil and debris to create a mound of considerable depth, effectively providing heat for the developing eggs. After a very long incubation period, the young emerge as fully feathered miniature adults and are capable of flying in 24 hours. Before sealing the nest that they make for their eggs, many insects, such as certain solitary wasps, stock the nest with food. In a more bizarre manner, other solitary wasps place one egg in the body of an insect or spider previously paralyzed by the wasp. Upon hatching, the larva eats the still living host.

Social parasitism

Social parasitism, another fascinating aspect of post-fertilization behaviour, is found in certain insects and birds. In this case, the true parents do not care for their eggs or offspring; rather, they place them under the foster care of other species, often, but not always, to the detriment of the foster parents' offspring. In certain parasitic species of cuckoos, the females are divided into groups, or gentes, each of which lays eggs with a colour and pattern unlike those of the other groups. The females of each group usually select a particular species as the host, and, more often than not, the eggs of the parasite closely resemble those of the potential foster parent. This mimicry has evolved because many host species throw eggs not resembling their own out of the nest. Some young cuckoos also exhibit a behaviour called backing, in which they push out the other nestlings and monopolize the food supply.

Parental *care*. Among the organisms that remain with the eggs or offspring, one particular behaviour is striking —that of nest construction to keep the eggs and larvae in one spot and to protect them against predators as well as such environmental factors as sun and rain. The placement of a nest usually serves an antipredatory purpose, as in birds that put their nests near those of social wasps or stinging ants. Although they are not normally thought to do so, many mammals, particularly rodents and carnivores, construct special nests, dens, or burrows solely for reproductive purposes.

A number of fishes build nests made of bubbles that not only hold the eggs together but also provide the oxygen necessary for the developing embryos. Other fishes, particularly those that live in oxygen-poor waters, display elaborate fanning behaviour to keep the water moving around the eggs. In some fishes, the female incubates the egg in her mouth, thus providing protection against predators as well as constant aeration. The fry (young) of some of these mouthbreeders travel in a school near the parent. When danger approaches, they flee into the parent's mouth and later swim out after the danger passes.

Birds have the problem of keeping the eggs at an optimum temperature for development of the embryo. With the onset of egg laying in many species, the feathers of the lower abdomen are lost, and the skin in that area becomes thickened and highly vascularized (filled with blood vessels), forming the so-called brood patches. Usually the female develops these patches, which serve to transfer more effectively to the eggs the warmth from the adult's body. It has been shown that, like much of parental behaviour in the higher vertebrates, brood patches and "broodiness" are controlled by several hormones, combined with visual and tactile stimuli. Chief among these hormones is prolactin, which also controls the production of pigeon milk, a cheeselike substance produced only in the crops of adult doves and pigeons and fed to the nestlings by regurgitation.

Although there are some outstanding exceptions, most young mammals are completely helpless at birth. This helplessness is most striking in the marsupials (*e.g.*, opossums and kangaroos), in which the young are born at a very early stage of development; they crawl through the mother's hair to the brood pouch, where they attach themselves to a nipple and their development continues for many more months.

Licking of newborn

An early characteristic behaviour in mammals following birth is that of the mother licking the newborn. This serves at least two functions--one is general cleanliness to avoid infections or the attraction of parasites; the other would appear to be purely social. If a newborn mammal is removed from its mother and cleaned elsewhere before she can lick it, she usually will not accept it. Thus, licking behaviour also serves, in some manner, to establish a unique relationship between the mother and her offspring. Another characteristic mammalian behaviour is the suckling response of the newborn. Although this behaviour has been claimed to be the perfect instinctive response, it apparently is not so in many species; the trial-and-error period during which the newborn discovers the nipple, however, is quite short.

In birds, especially those that nest on the ground, one of the first adult responses to the hatching of the eggs is to remove the conspicuous eggshells from the area of the nest. It has been shown experimentally that, in gulls at least, this is an important antipredatory measure. When birds hatch, they have the ability to stretch their heads and to gape for food in response to any mechanical disturbance, such as that produced when the parent lands on the nest. Later in development, they stretch and gape only when the parents appear. This is another type of adaptive, antipredatory behaviour, as it would be dangerous for the nestlings to gape and vocalize in response to any environmental disturbance.

Group care. The ability of an animal to identify its own offspring at an early stage is apparently not important in animals that nest or are solitary breeders; offspring in the nest belong to that parent. In colonially breeding species or in those where the offspring of different parents are likely to become mixed, however, natural selection has favoured the evolutionary development of behaviour that makes possible the recognition by the parent of its own offspring, thereby avoiding the danger of expending energy on offspring that do not possess the parent's genes.

There is, on the other hand, the situation in which the offspring are cared for by individuals who are not the parents. This phenomenon occurs among the social insects in particular and also among several groups of birds and mammals; future investigations may show it to be even more widespread. In such birds as the anis, the effective breeding group consists of several females and males. One nest is constructed in which all the females deposit their eggs, and all individuals participate in the care of the resulting offspring. In certain jays (Corvidae), the offspring of one generation participate in the care of the offspring of the next or another generation, but the exact family relationships among the participants are not clear.

In the social insects, this type of parental behaviour apparently results from the peculiar genetic relationships between the individuals in most social-insect colonies (termites are among the exceptions). The female and, in the termites, both the male and the female can control by chemical means the kinds (called castes in ants and termites) and sexes of the offspring. An outstanding feature of such colonial insects as the honeybee is that the majority of the individuals produced by the queen are sterile; these are the workers, the individuals who care for and feed both the queen and her offspring, the sibs of the workers.

The queen is diploid in genetic makeup; that is to say, half of her genes are derived from her mother and half from her father. The males (drones) are haploid; that is, they have only half the genes possessed by the queen, all of them derived from the mother. A queen produces eggs fertilized by sperm she has retained in her body from the mating flight; thus the individuals produced are diploid, but, unlike the queen, they are sterile. This sterility results indirectly from a chemical secreted by the queen, called the queen substance. It inhibits the workers from building special brood cells that give rise to sexually developed individuals. If the queen fails to secrete this substance because of age or death, the workers immediately construct special brood cells with a substance they secrete; called royal jelly, it is necessary for the development of a larva then destined to be a queen.

How can the evolution of sterility in workers and their care of offspring not their own be accounted for? One possible explanation concerns the coefficient of relationship (the number of genes on the average shared in common) among the individuals of a colony. Because of the peculiar haplodiploid mode of sex determination, the workers (sisters) share all the genes from their father and, on the average, half of those from their mother. Since each worker receives half of its genes from the father and half from the mother, the average genes shared between any two workers (sisters) is three-fourths. But between mother (the queen) and daughter (a worker) this average is only one-half. The offspring (the sterile workers), therefore, may contribute more to their fitness (the maximum representation of their genes in the next generation) by caring for their sisters than by providing an equal amount of care to their "own" offspring, had they been fertile rather than sterile. A drone, on the other hand, has a coefficient of relationship with one of his sterile sisters of only one-fourth, but retains a relationship of one-half with his mother and daughters (future sterile workers). This explains why workers provide more care for their sisters than for their brothers, and why the workers eventually drive off the almost useless drones, which are relatively scarce (having resulted from unfertilized eggs), from the colony. Because sisters share more genes with each other than with their brothers, they maximize the chances of these genes surviving into the next generation by providing more care for their sisters.

This explanation of group care and extreme sociality does not account for all cases. Indeed, termites are perhaps the most extreme among animals in these respects but lack the haplodiploid sex determination mechanism. In addition, several groups having this mechanism have not evolved extreme brood care and sociality. Other factors have to interact for these systems to evolve, but it is not yet clear what they are.

REPRODUCTIVE BEHAVIOUR IN INVERTEBRATES

Protozoans and sponges. Most protozoans (one-celled organisms) reproduce asexually, usually by fission (splitting in two); in some species, however, sexual as well as asexual reproduction occurs and may be complex. The colonial organism *Volvox*, which may be either of one "sex" or composed of cells of both sexes, produces true eggs and sperm. **A** chemical substance released by "females" induces the production of sperm packets; following the union of the egg and sperm, the parent colony dissolves, and the zygote (fertilized egg) is released.

Conjugation

Another form of reproduction in protozoans is conjugation, in which organisms such as *Paramecium* fuse together briefly to exchange nuclear products. This results in a reshufflingof hereditary characteristics just as occurs in true sexual reproduction in higher animals. In some species of *Paramecium*, there are mating types, and an individual is of one type or the other. Opposite types apparently recognize each other by a chemical (pheromone) that is released on their body.

In the lower metazoans (multicellular organisms), reproduction is also by both asexual and sexual means. As befits their sessile life-style and low population densities, sponges that reproduce sexually are usually hermaphroditic; that is, each individual is capable of producing both sperm and eggs, but often at different times to prevent self-fertilization. The sperm are swept by water currents into another sponge, where they are picked up by specialized cells called choanocytes and carried to the egg. Fertilization takes place when a choanocyte fuses with the egg. The free-swimming larval stage that is produced is of short duration, after which the organism settles on the bottom and becomes a new adult sponge.

Coelenterates. Hydroids, jellyfishes, sea anemones, and corals of the phylum Coelenterata, or Cnidaria, reproduce by a variety of mechanisms. A familiar coelenterate animal, the freshwater *Hydra*, usually reproduces asexually by budding, a process by which small portions of the adult structure become new, but genetically identical, individuals. Hydras are also dioecious; that is, each individual produces either sperm or eggs. In many temperate-zone species of *Hydra*, sexual reproduction occurs during the autumn; the fertilized eggs enable the species to survive the winter.

Most of the other hydrozoans are colonial organisms, often occurring in polyp and medusal (umbrella-shaped) forms. In a colony, reproductive individuals called gonophores develop into free-swimming organisms (medusae) that reproduce sexually. Fertilization can be either external or internal; if external, the eggs are shed directly into the water. Internal fertilization results in larvae that swim out of the parent and soon settle on a surface, where they develop into another hydroid colony.

Sea anemones and the polyps of corals reproduce asexually by budding or sexually. In the sexual mode, sea anemones have both dioecious and hermaphroditic species. One interesting aspect of sea anemones, which undergo internal fertilization, is that they are among the first lower animals to provide parental care. The larvae remain inside the adult until they are ready to metamorphose (change in form), at which time they swim from the parent's mouth and settle on its base, remaining there until they develop tentacles, after which they move away from the parent's protection.

Flatworms **and** rotifers. The reproductive structures of flatworms (phylum Platyhelminthes) resemble those found in the higher groups. Such flatworms as the land and freshwater planarians are hemaphrodites. Although some species can reproduce asexually by splitting in two, most engage in copulation. Some freshwater planarians can produce both thin-shelled summer eggs, which hatch in a short time, and thick-shelled winter eggs, which are resistant to freezing and hatch in the spring. An apparently unique situation in many planarians is that nutrition for the embryo is supplied by the addition of separate cells to the zygote, after which the entire mass is enclosed in the shell; more commonly, the yolk is incorporated within the structure of the zygote itself.

In the rotifers (phylum Aschelminthes), small but abundant freshwater animals, reproduction is usually sexual, and the sexes are separate. Copulation occurs by injection of sperm anywhere in the body wall of the female. Many species found in temporary ponds and streams exhibit a peculiar reproductive behaviour that is well adapted to their transient environment: they produce different kinds of eggs at different times of the year. One egg type, called amictic, is produced in the early spring. These eggs apparently cannot be fertilized, and the embryo develops without fertilization (parthenogenesis); the result is females with a life-span no longer than two weeks. When the population reaches a peak in the early summer, a second type of egg is produced. If unfertilized, this egg, which is called mictic, results in males. As the male population increases, most mictic eggs become fertilized, resulting in the production of a heavy-shelled dormant egg with much yolk. The dormant egg survives the winter and gives rise to the amictic females of the next spring. Thus, despite the many generations produced in the summer by so-called sexual means, the reshuffling and recombination of genetic material occurs only once a year.

Parthenogenesis

Segmented worms. The marine worms of the class Polychaeta (*e.g.*, clam worms and lugworms of the phylum Annelida) provide the first examples of a kind of courtship behaviour involving both visual and chemical displays initiated by some rather subtle environmental stimuli. Most polychaetes reproduce sexually, and there are two distinct sexes in most species. Either by transformation or budding, many polychaetes produce a reproductive form (epitoke). At a certain time of the year, the epitokes swarm to the ocean surface and engage in mass shedding of eggs and sperm. Some female epitokes of clam worms (Nereis) produce a chemical substance called fertilizin that attracts the male epitokes and stimulates the shedding of sperm. Male epitokes of a polychaete found in the Atlantic Ocean emit a flashing light; females emit a steady light. The light may serve to attract male and female and to aid in species discrimination. The swarming of the palolo worm Eunice in parts of the South Pacific is apparently triggered by an annual and a lunar cycle; the epitokes separate from the parent (atoke) in October or November, during the last part of the lunar cycle.

The class Oligochaeta (phylum Annelida) contains a diversity of both aquatic and terrestrial worms, among which is the familiar earthworm, Lumbricus. Although some aquatic oligochaetes reproduce asexually, the majority are sexual, and all of these are hermaphrodites. At mating, two oligochaetes lie side by side so that the head of one is opposite the tail of the other. Sperm then pass reciprocally into small sacs, where they are temporarily stored. This transfer is more complex in the earthworms, however, because the respective male pores are not in direct opposition; each individual forms a temporary skin canal through which the sperm flow to their respective sacs for storage. The body of oligochaetes has a swollen girdle-like structure, the clitellum, which serves an important function in reproduction. After the eggs have matured, a mucous tube, secreted from the clitellum, slides along the body as the worm moves backward. The stored sperm are discharged into this tube, as are the eggs when the tube slides along the section containing them. As the worm literally passes out of the tube, a mucous, lemon-shaped cocoon forms around the now-fertilized eggs. This cocoon serves as a kind of primitive nest, in which the young hatch.

Many leeches (class Hirudinea), all of which are hermaphrodites, have copulatory behaviour much like that of earthworms. Cocoons are formed in a manner similar to that described above, but in some leeches the cocoon is transparent and remains attached to the parent in which the eggs were developed. After hatching, the young leeches remain attached to the "mother" until they become independent. One African leech gives birth to live young and even possesses a special incubating chamber in its body for the developing embryos.

Mollusks. The animals in the phylum Mollusca (*e.g.*, clams, snails, and squid) display a diversity of reproductive behaviour. The majority of the amphineurans (chitons) and pelecypods (*e.g.*, clams, oysters) are dioecious —*i.e.*, individuals are either male or female. Because most species simply shed their eggs and sperm directly into the sea, individuals tend to form dense aggregations during the breeding period. The environmental factor that triggers the release of eggs and sperm has not yet been established with certainty, but, at least in a few species, after one individual has shed its sex products, the others follow in a kind of chain reaction that is clearly chemical in nature. In some mollusks, however, such as the European oyster, the eggs are retained and brooded.

The snails and slugs include hermaphroditic as well as dioecious species. Copulation in the hermaphroditic land snail Helix is preceded by a curious courtship involving a bizarre tactile stimulation. When the two partners come together, each drives a calcareous dart (the so-called love dart) into the body wall of the other with such force that it is buried deep in the other's internal organs.

The love dart

To avoid predators, some arboreal slugs copulate in mid. air while each partner is suspended by a viscous thread, In the slipper-shell snails (Crepidula), which are rather sessile, all the young are males; their subsequent sex, however, is determined by their nearest neighbour. They remain males as long as they are near a female but change into females if isolated or placed near another male.

Remarkably advanced courtship behaviour in the cephalopods, particularly the squids, involves complex visual displays of movement and changes in colour pattern. Males signify that they are ready for breeding by assuming a distinctive zebra-striped pattern, displaying their fourth arm in a flattened manner, and approaching other individuals with a jerky motion. This fourth arm in squids and the third arm in octopods, called a hectocotylus, is structurally modified for carrying spermatophores, or balls of sperm. The male cuttlefish (Sepia) places the spermatophores in a pocket near the female's mouth, from which the sperm subsequently make their way to the tubes that carry eggs (oviducts). In no squid studied thus far do either of the sexes care for the fertilized eggs, which are laid on vegetation. This is not the case with octopuses, however; at least in Octopus vulgaris, the female broods her large number of eggs (about 150,000) for as long as six weeks. During this period she aerates the egg clusters and keeps them free of detritus, exhibiting remarkable behaviour for an animal that produces so many eggs. Brood care such as this is usually associated only with organisms that produce a small number of eggs.

From *California Fish and Game (1954)*

Arthropods. Crustaceans. With a few exceptions, barnacles are the only hermaphroditic members of the class Crustacea in the phylum Arthropoda. This is in agreement with the theory that a sessile mode of life tends to be correlated with hermaphroditism. Thus, it is not important for the organism to be near an individual of the opposite sex, but simply to be near any individual of the same species.

Some barnacles are parasitic and have undergone a radical degeneration in form. One, Sacculina, is an example of the way in which the reproductive necessities of one species can profoundly affect the reproductive behaviour of another—in this case, the host. Several cells from a larval barnacle penetrate a crab's body and migrate through the bloodstream until they reach the lower portion of its stomach. The cells then send rootlike projections throughout the crab's body. When the crab molts, the barnacle protrudes a large bulbous portion of its body through the ventral (bottom) surface of the crab. If the crab is a female, its broad shell protects this structure, which contains the barnacle's reproductive organs. The body shape of the male crab, however, is much narrower and does not provide such protection. If the host is a male, therefore, the barnacle first consumes the host's testes; at its next molt, the crab assumes the shape of a female. Should the parasite be removed, the crab regains a male appearance and regenerates its testes.

In the copepods (*e.g.*, sea lice, Cyclops) and the amphipods (*e.g.*, beach fleas), the sexes are mostly separarate, copulation is brief and without elaboration, and the female of both groups broods the fertilized eggs. The eggs of copepods are usually attached in two clusters to the rear of the female; many amphipods have a special pouch on their ventral surface for brooding the eggs. Many copepods and some amphipods are parasitic on fish and on such marine mammals as whales.

In the crustacean order Decapoda, which includes shrimp, crayfish, lobsters, and crabs, the sexes are separate, fertilization is mostly internal, and egg laying usually occurs shortly after copulation. In terrestrial crabs, however, the females of which migrate to salt water to expel the eggs, the sperm are stored, and fertilization and egg laying are delayed for several months after copulation.

Fiddler crabs of the genus ***Uca*** and several other decapods show territorial behaviour, an act that is not very common among invertebrates. As in many groups in which males defend territories, male crabs often differ in appearance from the females. Males are much more brightly coloured than the females, and one of their front claws is greatly enlarged; the mostly dull-coloured females have two small front claws. Depending on the species, males perform either simple or complex rhythmic dances in front of their sand burrows. The waving and vertical movement of the large claw is apparently species specific.

The necessity of spermatophores

As in squids and octopuses, the sperm of primitive terrestrial arthropods—millipedes, centipedes, springtails, and silverfish—are often transferred from males to females in structures called spermatophores. During the transition from an aquatic to a terrestrial mode of life, spermatophores became necessary, particularly for those species that had not developed copulatory organs for direct transmission of sperm. Because sperm transfer in these animals is often complicated and takes considerable time, the delicate sperm would be in danger of drying up, were it not for the moisture contained in the spermatophores. It would appear, therefore, that all species that exhibit indirect sperm transfer in which spermatophores are utilized have not achieved complete independence of water.

Males of most primitive soil-dwelling arthropod species place sperm drops on threads in damp locations or use threads or chemical products to guide females to externally placed spermatophores. Most male millipedes have secondary genital appendages called gonopods, by which they transfer the spermatophore directly to the genital opening of the female. One millipede actually uses a "tool" in sperm transfer; the male rounds a fecal pellet, places a drop of sperm on it, and, using its legs, passes the pellet back along its body to a point opposite the female's genital pore. Paired body projections then are used to inject the sperm into the female, and the pellet is dropped. Males of the common bark-inhabiting millipede ***Polyxenus*** transfer sperm by spinning thin threads on which they place sperm drops; they then construct two parallel thicker threads on which they place a pheromone to attract the female. This chemical and tactile guidance system causes the sperm to become attached to the female's vulva (the external part of the female's genital organs). Males eat the sperm not picked up and replenish it with fresh sperm.

Arachnids. The arachnids (*e.g.,* spiders and scorpions) exhibit the earliest pattern of classical courtship behaviour during which rather ritualized movements are involved. In the true scorpions this behaviour takes the form of the ***promenade à deux,*** in which the male holds the female by her front claws and apparently stings her in a joint near the base of the claw. The ensuing dancelike pattern apparently results from the male seeking a suitable surface upon which to deposit his spermatophore. After he deposits the spermatophore, the male drags the female over it, releasing her after the spermatophore has passed into her genital pore.

Behaviour of male spiders

As mentioned above, many male spiders have a particular problem in approaching the aggressive and predatory female in order to deposit a spermatophore. The hunting behaviour of most spiders is adapted to react to the slightest movement or vibration of the web, causing the spider to rush forward and bite its prey as quickly as possible. Thus, it is not surprising that male spiders have evolved fairly elaborate display movements and patterns to convey their identity. Many males are quite strikingly coloured, providing additional information about their identity. Some males approach the female only at night and vibrate her web in a highly characteristic manner, different from that caused by the struggling of a trapped animal.

Insects. One puzzling aspect about the courtship behaviour of insects is its sporadic nature. Most insects should exhibit behaviour involving approach, identification, and copulation. Yet, whereas male fruit flies (*Drosophila*) often have elaborate displays preceding copulation, male houseflies and blowflies ***(Musca)*** simply fly at any object of the proper size and attempt to copulate with it. The reason for these differences in behaviour may be that some insects do not require courtship. Males of some butterflies and moths, for example, simply wait by the pupa and copulate with the female immediately after she emerges.

It is more likely, however, that the majority of insects have fairly elaborate displays, but man is unable to sense them. The pheromones are, in fact, rather elaborate displays used as sex attractants by many insects; such sensory mechanisms are not usually perceived by man. It has been experimentally demonstrated that the reproductive behaviour of some butterfly species depends heavily on visual clues; similar experiments with other species have failed to show such behaviour. It must be realized, however, that insect vision is quite different from that of vertebrates. Most insects have vision that is sensitive to ultraviolet light, which man and the other vertebrates cannot normally perceive. Butterflies may appear to have identical wing colour patterns under normal light, but, when viewed under ultraviolet light, the patterns differ drastically. Thus, insects that mimic each other in order

Figure 2: Reproductive behaviour in mecopterans.
(Top) With his hind tarsi a male mecopteran, Harpobittacus australis, captures an insect. Suspending himself he everts two abdominal sacs that release a pheromone that "calls" females. The female, who approaches upwind, is presented with the prey, and copulation follows. (Bottom) Protruding sacs as they appear in magnified view of male abdomen.

to appear identical to a vertebrate predator actually possess an unbreakable code by which each species is able to distinguish its own kind.

A reproductive behaviour that is usually misunderstood by those who have observed it is the copulation process in dragonflies. The actual copulatory organ of the male is located close to the thorax, not, as in most insects, near the tip of the abdomen. After a male alights on a plant and transfers sperm from the terminal genital opening to the copulatory organ, he seeks out a female and grasps her behind the head with claspers on his abdomen. Although the two fly in a tandem position, actual copulation occurs only when they alight, and the female bends her abdomen to receive the sperm from the male's organ. Colour, pattern, and movement are important in species recognition. In experiments, it has been found that artificial models acceptable to male *Platycnemis* dragonflies must consist of a female head, thorax, and one wing; the model also must be moved from side to side about once every four seconds to be effective. Complete aerial mating in insects is rare, but it does occur in mayflies, houseflies, ants, wasps, and bees.

Sound displays

Among the cicadas, crickets, and some grasshoppers, females normally mate after they have been attracted to a male by vocalizations of the latter, which, in most cases, are species specific. It has been demonstrated that deafened female grasshoppers do not permit copulation. In many crickets, the specific stridulations (noises) that occur after each copulation keep the female near the male until he is ready to produce another spermatophore. These stridulations also prevent the female from removing the spermatophores before insemination has been completed.

Even some butterflies incorporate sounds into their reproductive displays; in some manner, the butterfly Ageronia makes a loud cracking sound when engaged in courtship. Many other insects may incorporate sound into their reproductive displays, perhaps utilizing sounds beyond the sensitivity of the human ear.

Research has revealed that olfactory displays are widespread in insects. The sex attractants for this purpose are usually volatile pheromones. Among certain species of butterflies, such as the queen butterfly (Danaus *gilippus*), the males possess "hair pencils" that project from the end of the abdomen and emit a scent when swept over the female's antennae during courtship behaviour. Copulation does not occur in the absence of this chemical display.

During some stage of their development, a number of insects are either external or internal parasites on a wide variety of animals, including other insects. A particularly bizarre pattern is found in the stylopids, which belong to the order Strepsiptera. Though seldom seen, these insects may be common internal parasites of wasps and bees. The abdomen of the adult females, which never leave their hosts, consists of a bag of eggs that is concealed in the host. The forepart of the parasite, which projects from between abdominal segments of the host, is usually concealed by the host's wings. The females of one stylopid group are apparently unique among animals in having two genital openings—both in the head—in the form of membranous windows. The larvae emerge through these openings, crawl onto a plant, and seek another host. When the host molts its old cuticle (hard skin), the larvae penetrate the soft body. Females extend their heads through the host's abdomen and mature within the host. The males, however, leave the host, pupate in the host's cast-off cuticle, and emerge several days later as adults. The male stylopid then seeks out a host insect and taps it on the side of the abdomen. If no female is present, the male leaves; if a female is present, she somehow signals her presence. The male then inserts his abdomen under the host's wing and enters the genital window of the female.

It is in the orders Isoptera (termites) and Hymenoptera (bees, wasps, and ants), however, that the reproductive behaviour of insects attains its highest level of sophistication. Although dung beetles and some other insect species brood their eggs and care for the young, extreme insect sociality, with its peculiar brood-care system, is found only among the isopterans and the hymenopterans. The principal criterion for such behaviour would appear to be that the female must remain with her brood until after they begin to hatch. Although the phenomenon has been intensively studied, the explanation for the evolution of extreme brood care in ants, many wasps and bees, and termites remains one of the more challenging problems in biology.

Most colonies of social insects reproduce in two ways: either sexual individuals are produced that mate and start new colonies, or the colony breaks up after reaching a certain size. Some species reproduce in both ways. In the first case, the chances of finding new sites are maximized by providing as many individuals of different sexes as possible, each equipped with appropriate guidance mechanisms. In the second, members of the parent colony explore the environment and establish a new colony where suitable.

Another example of reproduction in social insects is that practiced by many ants. Most larvae in an ant colony develop into wingless, sterile workers. Some, however, may get more food (a point that is controversial) and grow more rapidly. These do not pupate when the other larvae do; instead, they become king-sized individuals that eventually metamorphose into sexually mature males or females with wings. Their sex, like that of the wasps and bees, depends upon whether or not the egg was fertilized by the queen.

Mating swarms

The winged sexual forms, or alates, are produced at certain times during the year and swarm in mating flights to establish a new colony, which may actually be no more than a few hundred feet from the old colony. Actual copulation may occur either during flight or after landing on a surface. For most species of ants, it is not known whether a male will copulate with more than one female or if a female will copulate with more than one male. After copulation, the female seeks a location for a new nest and loses her wings within three to five days. Generally, two months are required to rear the first daughter workers. Some females carry a live mealybug with them on the mating flight and take it to the new colony site, where the mealybug's offspring provide the honeydew to feed the ant's initial offspring. Generally, however, the female ant does not provide food for her first offspring; instead, the larvae eat many of the first 100 or so eggs. This egg cannibalism decreases when there are sufficient workers to feed the larvae.

REPRODUCTIVE BEHAVIOUR IN VERTEBRATES

Fishes. The reproductive behaviour of fishes is remarkably diversified: they may be oviparous (lay eggs), ovoviparous (retain the eggs in the body until they hatch), or viviparous (have a direct tissue connection with the developing embryos and give birth to live young). All cartilaginous fishes—the elasmobranchs (*e.g.*, sharks, rays, and skates)--employ internal fertilization and usually lay large, heavy-shelled eggs or give birth to live young. The most characteristic features of the more primitive bony fishes is the assemblage of polyandrous (many males) breeding aggregations in open water and the absence of parental care for the eggs. Many of the species in this group, such as herrings, make what appear to be completely chaotic migrations to their breeding areas. Actually, however, each of these huge spawning aggregations is made up of small, coordinated parties consisting of one female and one or more males. On the other hand, a number of fishes are monogamous, form pairs, and care for the eggs or young. In courtship behaviour, in which they utilize all potential stimuli including sound, chemical, and electrical stimuli, the range and complexity of their displays are not exceeded by any other vertebrate group.

Hermaphroditism in fishes

Although the sexes are usually separate, hermaphroditism is much more common among the bony fishes than in any other group of vertebrates. The reasons for this condition are both physiological and ecological. Whereas the developing gonads of all other vertebrates have an outer and inner layer of tissue, those of bony fishes have a simple origin that lacks any male or female elements. In terms of the evolutionary process, this type of development is likely to be more adaptable to pressures that favour hermaphroditism. When, because of one or several interacting factors, a population density reaches a low point in some species, reproduction may be limited to a low probability of contact with another sexually active individual. In such situations (*e.g.*, very deep sea habitats, tide or stream pools) the evolution of even temporary self-fertilizing hermaphrodites would have the greatest advantage.

From W. Wickler, *Mimicry in Plants and Animals* copyright (1968); Weidenfeld and Nicolson Co . Ltd.

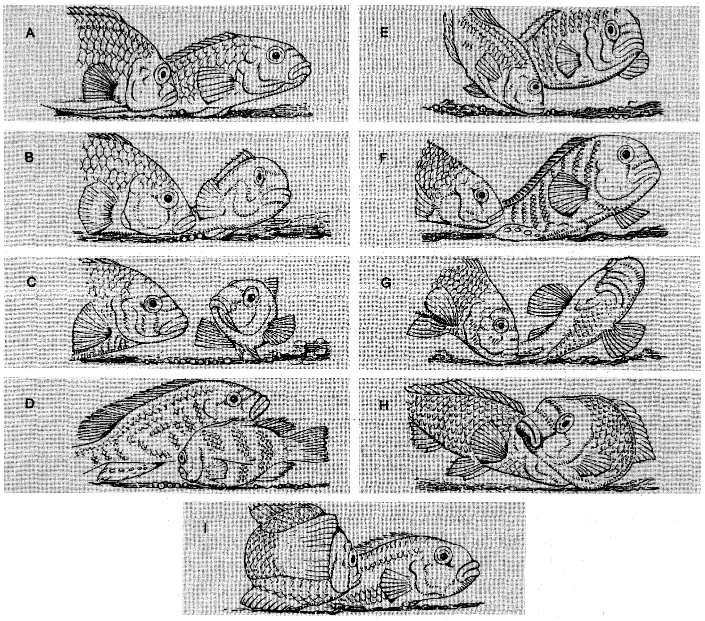

Figure 3: Phases in the spawning sequence of Haplochromis burtoni.
(A–C) Female on right deposits batch of eggs; (D,E) female collects eggs in her mouth, where she broods them; (F–H) male emits sperm onto bare surface while female attempts to take up dummy eggs (conspicuous spots near the base of the anal fin of the male) into her mouth; semen enters her mouth in the process and fertilizes the eggs; (I) female deposits another batch of eggs.

One form of hermaphroditism fairly common in bony fishes is the protogynous type, in which the individual functions first as a female and later as a male; it is much more frequent than the reverse situation (protandrous hermaphroditism). The selective reasons for the predominance of the former are presumably associated with the relationship between smaller body size in females and the greater energy requirements needed to produce eggs. In addition, in some promiscuous mating systems, it may be selectively advantageous to be a male when the body size is large and the individual experienced, rather than small and young. Most sea basses, parrot fishes, and wrasses have this sort of hermaphroditism.

Amphibians. Although true viviparity has been described in the African frog Nectophrynoides, most amphibians lay eggs. Some salamanders, however, retain the eggs within their body and give birth to live young. Courtship displays in frogs are almost entirely vocal, although in salamanders they may involve tactile, visual, and chemical stimuli. In the European newt *Triturus,* for example, in which mating takes place in the water, the male places himself in front of a female with his back to her. Suddenly, he executes a leap, directs a current of water at her, faces her, and bends his tail forward alongside his body; by waving his tail, he sends toward her a gentle current of water that probably carries a chemical stimulant. If the female responds by approaching the male, he turns and faces away, whereupon she touches his tail and he deposits a spermatophore, which she takes into her cloaca, a common passageway into which waste products and reproductive cells are discharged.

Lack of
brood
care

Most frogs and salamanders do not show brood care, but there are exceptions. In the European midwife toad the male rather than the female carries the sticky eggs on its hindlimbs. In a number of Neotropical frogs, the male carries the eggs under a flap of skin on its back. In some species, the young (tadpoles) cling to the back of the male by using their sucker-like mouths.

Reptiles. Reptiles are the first vertebrates that, in an evolutionary sense, have evolved an egg that is truly independent of water. Indeed, many snakes and lizards have even gone beyond this stage and have attained complete viviparity. It is difficult to generalize about reproductive behaviour in the reptiles because the various groups differ from each other in the sensitivity of their receptor organs. In many turtles, for example, the males are territorial and are very aggressive during the breeding period. Courtship behaviour involves mainly tactile stimuli, but olfactory clues are also important. It has been recorded that the wood turtle (*Clemmys*) actually emits a low whistle during courtship. Turtles usually bury their eggs and do not brood them.

Lizards appear to use almost every sensory mechanism in their reproductive activities. The nocturnal geckos employ vocalizations, in addition to tactile and olfactory stimuli. Skinks such as Eumeces rely heavily on olfactory clues. Lizards of the large family Iguanidae, on the other hand, are almost entirely diurnal creatures and utilize, in the main, visual displays, some of which are the equal in complexity to any known among the vertebrates. Many, such as the anoles, are equipped with a throat flap (dewlap) that is often brightly coloured and specifically marked; it is utilized both in courtship and territorial defense. The skinks and a number of other lizards are known to guard their eggs.

In general, the reproductive behaviour of snakes is not well known. The tongue is apparently an important sense organ for receiving olfactory and other chemical stimuli. The males of some snakes have characteristic skin papillae (nipple-like projections) on the throat; the fact that they rub the papillae over the female's body suggests that tactile stimuli are also important to reproduction. In boas, the rudimentary pelvic bones serve as "claws" for lifting the hind end of the female and for producing a vibration that is said to be important in the process of copulation. Some snakes, the pythons in particular, incubate and guard their eggs.

The bellowing roars of male alligators serve to establish breeding territories and apparently also to attract the females. Female crocodiles remain in the vicinity of their nest and will defend it vigorously.

Birds. Although all birds lay eggs, it is curious that they do so, because the time of highest mortality in most birds usually occurs during the egg-laying period. Apparently, birds lack some adaptation that would permit them to become viviparous.

Number
of eggs
laid

Most birds build a nest and incubate their eggs, but the incubator birds and such brood parasites as cuckoos are among the exceptions to this rule. Many females that lay a fixed number of eggs are referred to as determinant layers. The pigeons and doves are outstanding examples of this behaviour; for some as yet unknown reason, they never lay more than one or two eggs. Other species are often referred to as indeterminate layers because, in the absence of a suitable stimulus, they continue to produce eggs. More often than not, this stimulus is the presence in the nest of a certain number of eggs. Such behaviour is clearly adaptive—if eggs are lost for some reason and if other environmental stimuli are present, the missing eggs are replaced. The distinction between determinate and indeterminate layers is often blurred, for many indeterminate layers will not replace more than one or two missing eggs.

The duration of egg incubation varies from as little as nine days in some tropical perching birds to as long as 80 days in some albatrosses. In most species that form pairs, both individuals incubate and feed the young, but the female usually has the greater share of the burden. Among the exceptions to this behaviour pattern are the tinamou (partridge-like game birds), ostriches, some gallinaceous species (*e.g.*, pheasant, grouse, turkeys), and phalaropes. In the phalaropes, the role of the sexes is largely reversed: the females are more brightly coloured than the males and, not surprisingly, are the aggressive ones in courtship and in territorial defense; incubation is carried out solely by the male, but the female aids in feeding the young.

Because many birds begin incubation with the laying of the first egg in the clutch, the eggs hatch at different times. This strategy is often employed by species whose food supply for the young may vary in abundance over a fairly short period. Hence, should food suddenly become scarce, only the smallest chick or chicks will starve rather than the entire clutch. Species in which the young hatch in a relatively well developed, almost independent state tend to have very large clutches, as in many gallinaceous birds. In this case, it might be said that the ultimate size of the clutch is regulated by the abundance and quality of the food available to the female as she produces eggs. The same explanation also accounts for clutch size in parasitic birds—*i.e.*, those that lay eggs in the nests of other species. The breeding densities of birds vary from one pair in many square miles, as in some birds of prey, to such species as the fulmar, which forms colonies numbering as many as 250,000. Some colonies of the African weaverbird (Quelea) have been estimated to exceed 1,000,000 individuals.

One interesting aspect of reproductive behaviour in birds, possibly peculiar to them and to some mammals, is that many courtship displays are learned, or at least perfected through practice, from the parents. An example is the learning of birdsongs. It has been shown in some cases that when chicks are switched from the nest of one species to that of another, they learn some and perhaps all of the songs of the foster parents and do not develop their own species' vocalizations. When mature, such birds often prefer to choose as mates individuals of the same species as their foster parents' rather than those of their own species.

Courtship stimuli in birds are mostly visual and auditory, but it is possible that odour may he important in some petrels and shearwaters. As previously mentioned, most birds form pairs. In these and in many that do not, the males engage in communal, or lek-type, displays on a common courtship ground, such as the familiar strutting grounds of turkeys and many grouse. In addition, there are the incredibly bizarre communal dances of the birds of paradise; the jungle-floor dancing of the cock of the rock; the pasture display grounds of the shorebird, the ruff; and the forest arenas cleared for displaying purposes by the tiny manakins. Many of these display areas are used for many years; in some manakins, for example, certain cleared arenas have existed continuously for at least 30 years. In most lek species, the males are usually brightly coloured, and the females are rather dull in appearance. An exception occurs in some hummingbirds, the so-called hermits, in which both sexes are rather dull in coloration and in which the males group together in singing assemblies.

Mammals. Most mammals give birth to live young. The outstanding exceptions are the egg-laying monotremes of Australia, the platypus (*Ornithorhynchus*) and the echidnas (spiny anteaters). In the duckbill platypus, a brief courtship involving a chase in the water precedes copulation. The two eggs that are produced are placed in a burrow and hatch in eight to ten days. In the reproductive behaviour of the spiny anteater (*Tachyglossus*), the female apparently lays her single egg directly into her pouch.

Estrous cycle

As already mentioned, another general aspect of reproductive behaviour in mammals is the estrous cycle, knowledge of which is essential to an understanding of the mechanisms involved in the reproduction of any mammalian species. Females are usually responsive to males only during that portion of the estrous cycle when they are in heat; that is, when one or more eggs have broken out of the ovary and are in the process of descending to the uterus. The factors causing this event vary greatly, hut in some such as rabbits and cats, copulation itself is the main stimulus. In general, however, those mammals, particularly the large ones, that live in temperate areas—*e.g.*, bears, dogs, wolves, foxes, seals, and some deer and antelopes—have one estrous cycle per year. Mammals that live in warmer zones, such as some areas of the tropics, tend to have more than one estrous cycle per year. The sexual cycle in males, the height of which in some forms is referred to as the rut, is, not surprisingly, usually correlated with that of the females. The males of many species of domestic mammals, however, seem to be capable of copulating at almost any time of the year.

Another general aspect of mammalian reproductive behaviour is that they do not normally form pairs. Exceptions occur in certain carnivores and in some primates, in which parental care is divided between the sexes. As in many insects, the courtship behaviour of most mammals does not appear to be elaborate; but, just as in the former group, most mammals (humans are an exception) have an acute sense of smell. It is possible, therefore, that many of the chemical attractants wafted into the air by receptive females are actually courtship displays that are more complex than has been realized. This is not to say, of course, that visual, auditory, and tactile displays do not occur. Many deer and antelopes, for example, have rather complex ritualized visual displays employing such movements as strutting and arching of the heads, as well as conspicuous colour patterns. Males in many species discharge urine on females as a preliminary to copulation. Tactile and auditory displays have been shown to be important in aquatic mammals, such as porpoises and whales.

Additional effects of odours

In addition to a number of mammalian pheromones, other odour effects occur in mammals that, aside from their simple advertising value, have an important influence on reproductive behaviour. It has been shown that, when a recently impregnated female mouse is exposed to the odour of a male other than the one with which she has mated, implantation of the egg in the uterus often fails; as a result, there is a rapid return to estrus. The odour of a strange male may signify to a female rodent an unfavourable situation in which to raise young, inasmuch as a number of male rodents attempt to attack offspring not their own. Although it is not yet certain, there might he an adaptive explanation for this behaviour. The population fluctuations of rodents have attracted much attention, and, perhaps correctly, studies have focussed on the ecological parameters of these fluctuations; for example, it has been demonstrated in the laboratory that certain behavioral mechanisms involving odours exercise profound control over the reproduction and population levels of rodents. It has also been shown that the odour of mice can stimulate the production of hormones that cause a decrease in the reproductive capacity of other mice. In another study, estrus was suppressed, and many pseudopregnancies developed when four or more female mice were grouped together in the absence of a male. These results offer a partial explanation for the well-known phenomenon of reduction of population growth in rodent colonies that have high population densities.

THE EVOLUTION OF REPRODUCTIVE BEHAVIOUR

There is a popular tendency to think of primitive animals (in a phylogenetic or descent sense) as lacking "elaboration"; *i.e.,* that the animals of earlier geological periods had simpler displays or perhaps lacked crests or pheromones or elaborate communal displays in comparison with the reproductive systems of their present-day counterparts. There is no a priori reason for this belief. The fossil record indicates that the societies of which these animals were a part were as diverse and complex as those in which their relatives now live; certainly their display repertoires should have been equally complete. This is not to say, however, that the primitive forms of reproductive behaviour used the same displays for courtship as do the modem forms.

Displays. It has been pointed out that, in general, animals have relatively few displays; in addition, it has been deduced that the relative stability of displays is a dynamic equilibrium—that is, new ones are gained and old ones are lost at about the same frequency. Displays are lost when they no longer convey a selective advantage to the individual animals using them; that is, when the displays are no longer effective in promoting the behaviour that seeks to maximize gene survival in the next generation.

New displays, on the other hand, generally arise by ritualization of previously existing behaviours or functions; that is, when a selective advantage accrues to those individuals who, to convey information, use certain behaviours or functions in a manner that is either partly or totally different from their original purpose. Pheromones, for example, are usually derived from compounds that are natural breakdown products of body metabolism, such as the compounds in urine. Thus, urine, as the precursor of these chemical sex attractants in mammals, functions for display purposes, which is far removed from its basic excretory function.

Darwin's theory of sexual selection

Darwin proposed a theory of sexual selection to account for the presence in animals of displays and functions that apparently were not related to survival. He pointed out that two general concepts were involved. First, the evolution of such characteristics as the larger size of males in many species and the development of horns and antlers in mammals could be accounted for by their usefulness in fights between males for the sexual possession of females. This concept has been termed intrasexual selection. For such colourful male structures as the plumes of birds of paradise and the tails of peacocks, Darwin suggested that they resulted from the cumulative effects of sexual preference exerted by the females of the species at the time of mating. This second concept has been termed epigamic selection.

A displaying male has been known to convey information about his relative fitness; that is, his ability, with respect to other displaying males, to maximize the survival of his genes into the next generation. Both the brightness of his coloration and the frequency with which he struts say something about the effectiveness of his genes to produce a "healthy" individual. Once this correlation takes place, selection favours those females who perceive the differences between males and choose the "most fit" ones. Correspondingly, sexual selection intensifies the signals up to the point at which any further elaboration of those signals would result in a loss of fitness. When selection goes beyond this point, the male, because of his elaborate ornamentation and other displays, is more likely to suffer from predation before he has the opportunity to reproduce.

Sexual selection. The discussion concerning courtship displays leads naturally to the concept of sexual selection. Why do the males of some species possess elaborate displays? Why, in fact, do some species "elect" to utilize one mating system, say a monogamous one, while others "choose" a polygamous one? It has been suggested that many courtship displays and mating systems, particularly those involving polygamous systems with communal displays in a common courtship area, have an epideictic function—that is, they provide information as to the number of like individuals in a locality. The animals then act according to the information received, often by reducing their reproductive output. Because this concept implies that natural selection is acting for the good of the species rather than for the good of the individual, it has been called group selection. This concept has provoked considerable controversy for two reasons: first, there is no known mechanism by which group selection can function; second, as mentioned earlier, the pertinent behaviours involved can be more simply explained in terms of Darwinian selection dealing with individuals rather than groups.

Polygynous mating systems

In a number of polygynous (mating of one male with more than one female) and promiscuous species, adult females outnumber adult males, sometimes by a factor of five or more. It has been erroneously suggested that this sexual imbalance is the cause of the polygynous mating system, in which one male has several female partners. It has been demonstrated, however, in all polygynous species so far studied, that the ratio of males to females is 50:50 at the time of birth; in many cases, this ratio persists until the cessation of parental care. Therefore, it is the polygynous relationship that causes the imbalance, not vice versa: because sexual selection is the dominant factor in a polygynous and promiscuous species, it results in a greater (but not intolerably greater) mortality of males than of females.

Because one male can impregnate many females, thus lowering the selective value of an individual male, females are more valuable than males in an evolutionary sense. It can be seen, therefore, that sexual selection always favours a polygynous and promiscuous system unless it is disadvantageous to the females, as is the case with most birds. In most mammals, however, polygyny is the dominant mating system because the male is not needed for parental care. Therefore, monogamy is favoured over polygamy only when some environmental resource (food, for example) is limited and when the maximum survival of the young requires that they receive the care of both parents. As in all other aspects of reproductive behaviour, the type of mating system that is employed by a given species is the result of natural selection.

Reproductive System, Human

Man belongs to that group of mammals characterized by the bearing of live offspring that have attained considerable development within the uterus, or womb. Provided all organs are: present, normally constructed, and functioning properly, the essential features of human reproduction are (1) liberation of an egg from the ovary at the right time in the reproductive cycle; (2) internal fertilization by spermatozoa (sperm, or male sex cells) of the ovum in the uterine tube; (3) transport of the fertilized ovum along the uterine tube to the uterus; (4) implantation of the blastocyst, the early embryo that develops from the fertilized ovum, in the wall of the uterus; (5) formation of a placenta and maintenance of the intra-uterine existence of the unborn child; *(6)* birth of the child and expulsion of the placenta; and (7) suckling and care of the child, with an eventual return of the maternal organs virtually to their original state.

For this biological process to be carried out, certain organs and structures are required in both male and female bodies. The source of the ova, the female germ cells, is the female gonad or ovary; that of spermatozoa is the testis. In human beings, the two ovaries are situated in the pelvic cavity, and the two testes are enveloped in a sac of skin, the scrotum, lying below and outside the abdomen. Besides producing the germ cells, or gametes, the ovaries and testes are the source of hormones that cause full development of secondary sexual characteristics and also the proper functioning of the genital (reproductive) tracts. These tracts comprise the uterine tube, the uterus, vagina, and associated structures in females, and, in males, the penis, the sperm channels—epididymis, ductus deferens, and ejaculatory ducts—and other related structures and glands. The function of the uterine tube is to convey an ovum, which is fertilized in the tube, to the uterus, where gestation (development before birth) takes place. The function of the male ducts is to convey spermatozoa from the testis, to store them, and, when ejaculation occurs, to eject them with secretions from the male glands through the penis.

At copulation the erect penis is inserted into the vagina and spermatozoa contained in the seminal fluid are ejaculated into the female genital tract. Spermatozoa then pass from the vagina through the uterus to the uterine tube to fertilize the ovum in the outer part of the tube. Human females exhibit a periodicity in the activity of their ovaries and uterus, which starts at puberty and ends at the menopause. The periodicity is manifested by menstruation at intervals of about 28 days; important changes occur in the ovaries and uterus during each reproductive or menstrual cycle. Periodicity is suppressed during pregnancy and lactation.

This article describes the component parts of the reproductive system in humans, with an indication of the functions of the various organs. Some comparisons are made with arrangements in other mammals, and, where helpful to understand relationships, a brief account of the embryology of a particular region is given. Endocrine and other physiological factors in human reproduction are mentioned briefly.

THE SEXES: MALE AND FEMALE

The sex of a human child is determined at the time of fertilization of the ovum by the spermatozoon. The differences between a man and a woman are genetically determined by the chromosomes that each possesses in the nuclei of the cells. This stage in the development of the individual is detailed in the article EMBRYOLOGY, HUMAN.

Development of sexual differences in embryo

Once the genetic sex has been determined there normally follows a succession of changes that will result, finally, in the development of an adult male or female. There is, however, no external indication of the sex of a human embryo during the first eight weeks of its life within the uterus. This is a neutral or indifferent stage during which the sex of an embryo can be ascertained only by examination of the chromosomes in its cells. The next phase, one of differentiation, begins first in gonads that are to become testes, and a week or so later in those destined to be ovaries. Embryos of the two sexes are initially alike in possessing similar duct systems linking the undifferentiated gonads with the exterior and in having similar external genitalia, represented by three simple protuberances. The embryos each have four ducts, the subsequent fate of which is of great significance in the eventual anatomical differences between men and women. Two ducts closely related to the developing urinary system are called mesonephric, or wolffian, ducts. In males, each mesonephric duct becomes differentiated into four related structures: a duct of the epididymis, a ductus deferens, an ejaculatory duct, and a seminal vesicle (see below). In females, the mesonephric ducts are largely suppressed. The other two ducts, called the paramesonephric or müllerian ducts, persist, in females, to develop into the uterine tubes, the uterus, and part of the vagina; in males they are largely suppressed. Differentiation also occurs in the primitive external genitalia, which in males become the penis and scrotum, and in females the clitoris and labia.

At birth the organs appropriate to each sex have developed and are in their adult positions but are not functioning. Various abnormalities can occur during development of sex organs in human embryos, leading to hermaphroditism, pseudohermaphroditism, and other chromosomally induced conditions (see BIRTH DEFECTS AND CONGENITAL DISORDERS). During childhood until puberty there is steady growth in all reproductive organs and a gradual development of activity. Puberty marks the onset of increased activity in the sex glands and the steady development of secondary sexual characteristics. Puberty is brought about primarily by increased output of hormones from the anterior lobe of the pituitary gland at the base of the brain, but other endocrine organs are also involved.

Changes at puberty

In males at puberty the testes enlarge and become active, the external genitalia enlarge, and the capacity to ejaculate develops. Marked changes in height and weight occur as hormonal secretion from the testes increases. The larynx, or voice box, enlarges, with resultant deepening of the voice. Certain features in the skeleton, as seen in the pelvic bones and skull, become accentuated. The hair in the armpit and the pubic hair becomes abundant and thicker. A beard, a moustache, and cheek hair develop, as well as hair on the chest, abdomen, and limbs. Hair at the temple recedes. Skin glands become more active, especially apocrine glands (a type of sweat gland that is found in the armpit and groin and around the anus).

These secondary sex characteristics do not develop in individuals castrated before puberty, but the administration of androgens (male sex hormones) to such persons and to males having poorly developed testes can correct, in large measure, some of the poorly developed secondary characteristics. Large amounts of androgen, however, by preventing production of the hormone gonadotrophin by the pituitary, suppress testicular activity, thus depressing formation and release of sperm. Some derivatives of the male sex hormone testosterone can promote general bodily development.

In females at puberty, the external genitalia enlarge and the uterus commences its periodic activity with overt menstruation. The mammary glands develop, and there is a deposition of body fat in accordance with the usual contours of the mature female. Growth of axillary (armpit) and pubic hair is more abundant, and the hair becomes thicker. In a female receiving androgens, the typical male secondary sex characteristics may develop, menstruation may be suppressed, and the mammary glands may atrophy.

MALE REPRODUCTIVE SYSTEM

The male gonads are the testes; they are the source of spermatozoa and also of male sex hormones called androgens. The other genital organs are the epididymides, the ductus or vasa deferentia, the seminal vesicles, the ejaculatory ducts, and the penis, as well as certain accessory structures, the prostate and the bulbourethral (Cowper's) glands. The principal functions of these structures are to transport the spermatozoa from the testes to the exterior, to allow their maturation on the way, and to provide certain secretions that help form the seminal fluid.

The penis. The penis, the male organ of copulation, is partly inside and partly outside the body. The inner part, attached to the bony margins of the pubic arch (that part of the pelvis directly in front and at the base of the trunk), is called the root of the penis. The second, or outer, portion is free, pendulous, and enveloped all over

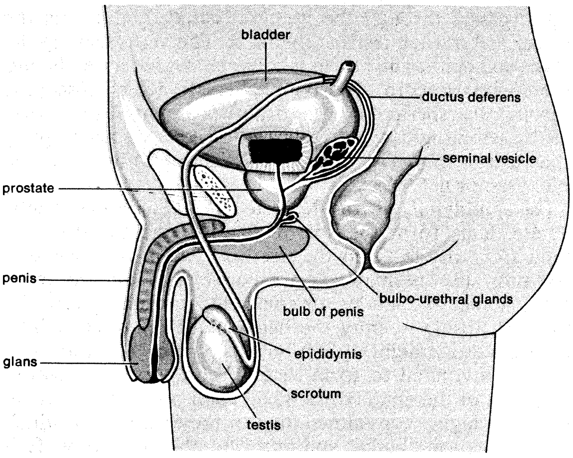

Figure 1: Male reproductive organs.

in skin; it is termed the body of the penis. The organ is composed chiefly of cavernous or erectile tissue that becomes engorged with blood to produce considerable enlargement and erection. The penis is traversed by a tube, the urethra, which serves as a passage both for urine and for semen.

The corpus spongiosum and the corpora cavernosa

The body of the penis, sometimes referred to as the shaft, is cylindrical in shape when flaccid but when erect is somewhat triangular in cross section, with the angles rounded. This condition arises because the right and left corpora cavernosa penis, the masses of erectile tissue, lie close together in the dorsal part of the penis, while a single body, the corpus spongiosum penis, which contains the urethra, lies in a midline groove on the under surface of the corpora cavernosa. The dorsal surface of the penis is that which faces upward and backward during erection.

The slender corpus spongiosum reaches beyond the extremities of the erectile corpora cavernosa, and at its outer end is enlarged considerably to form a soft, conical, sensitive structure called the glans penis. The base of the glans has a projecting margin, the corona, and the groove where the corona overhangs the corpora cavernosa is referred to as the neck of the penis. The glans is traversed by the urethra, which ends in a vertical, slitlike, external opening. The skin over the penis is thin and loosely adherent and at the neck is folded forward over the glans for a variable distance to form the prepuce or foreskin. A median fold, the frenulum of the prepuce, passes to the under surface of the glans to reach a point just behind the urethral opening. The prepuce can usually be readily drawn back to expose the glans.

The root of the penis comprises two crura, or projections, and the bulb of the penis. The crura and the bulb are attached respectively to the edges of the pubic arch and to the perineal membrane (the fibrous membrane that forms a floor of the trunk). Each crus is an elongated structure covered by the ischiocavernosus muscle, and each extends forward, converging toward the other, to become continuous with one of the corpora cavernosa. The oval bulb of the penis lies between the two crura and is covered by the bulbospongiosus muscle. It is continuous with the corpus spongiosum. The urethra enters it on the flattened deep aspect that lies against the perineal membrane, traverses its substances, and continues into the corpus spongiosum.

The two corpora cavernosa are close to one another, separated only by a partition in the fibrous sheath that encloses them. The erectile tissue of the corpora is divided by numerous small fibrous bands into many caverncus spaces, relatively empty when the penis is flaccid but engorged with blood during erection. The structure of the tissue of the corpus spongiosum is similar to that of the corpora cavernosa, but there is more smooth muscle and elastic tissue. A deep fascia, or sheet of connective tissue, surrounding the structures in the body of the penis, is prolonged to form the suspensory ligament, which anchors the penis to the pelvic bones at the mid point of the pubic arch.

The penis has a rich blood supply from the internal pudendal artery, a branch of the internal iliac artery, which supplies blood to the pelvic structures and organs, the buttocks, and the inside of the thighs. Erection is brought about by distension of the cavernous spaces with blood, which is prevented from draining away by compression of the veins in the area.

The penis is amply supplied with sensory and with autonomic (involuntary) nerves. Of the autonomic nerve fibres the sympathetic fibres cause constriction of blood vessels, and the parasympathetic fibres cause their dilation. It is usually stated that ejaculation is brought about by the sympathetic system, which at the same time inhibits the desire to urinate and also prevents the seminal fluid from entering the bladder.

Septum and raphe

The scrotum. The scrotum is a pouch of skin lying below the pubic symphysis and just in front of the upper parts of the thighs. It contains the testes and lowest parts of the spermatic cord. **A** scrotal septum or partition divides the pouch into two compartments and arises from a ridge, or raphe, visible on the outside of the scrotum. The raphe turns forward onto the under surface of the penis and is continued back onto the perineum (the area between the legs and as far back as the anus). This arrangement indicates the bilateral origin of the scrotum from two genital swellings that lie one on each side of the base of the phallus, the precursor of the penis or clitoris in the embryo. The swellings are also referred to as the labioscrotal swellings because in females they remain separate to form the labia majora, while in males they unite to form the scrotum.

The skin of the scrotum is thin, brown, devoid of fatty tissue, and more or less folded and wrinkled. There are some scattered hairs and sebaceous glands on its surface. Below the skin is a layer of involuntary muscle, the dartos, which can alter the appearance of the scrotum. On exposure of the scrotum to cold air or cold water, the dartos contracts and gives the scrotum a shortened, corrugated appearance; warmth causes the scrotum to become smoother, flaccid, and less closely tucked in around the testes. Beneath the dartos muscle are layers of fascia continuous with those forming the coverings of each of the two spermatic cords, which suspend the testes within the scrotum and contain each ductus deferens, the testicular blood and lymph vessels, the artery to the cremaster muscle (which draws the testes upward), the artery to each ductus deferens, the genital branch of the genitofemoral nerve, and the testicular network of nerves.

The scrotum is supplied with blood by the external pudendal branches of the femoral artery, which is the chief

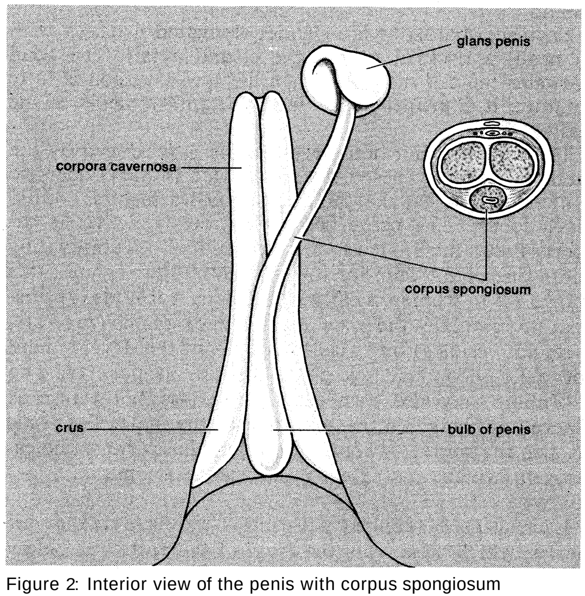

Figure 2: Interior view of the penis with corpus spongiosum detached and turned to one side.

artery of the thigh, and by the scrotal branches of the internal pudendal artery. The veins follow the arteries. The lymphatic drainage is to the lymph nodes in the groin.

The testes. The two testes, which usually complete their descent into the scrotum from their point of origin on the back wall of the abdomen in the seventh month after conception, are suspended in the scrotum by the spermatic cords. Each testis is four to five centimetres (about one to one and one-half inches) long and is enclosed in a fibrous sac, the tunica albuginea. This sac is lined internally by the tunica vasculosa, containing a network of blood vessels, and is covered by the tunica vaginalis, which is a continuation of the membrane that lines the abdomen and pelvis. The tunica albuginea has extensions into each testis that act as partial partitions to divide the testis into approximately 250 compartments, or lobules.

Adapted from H. Gray, *Anatomy of the Human Body*, 28th ed. by C.M. Goss (1966); Lea & Febiger

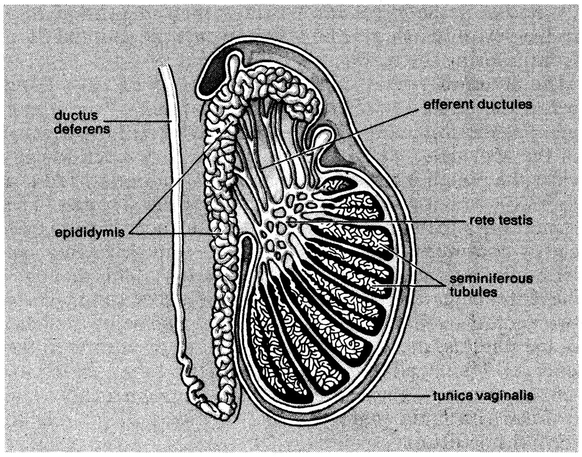

Figure 3: Longitudinal cross section of testis.

Each lobule contains one or more convoluted tubules, or narrow tubes, where sperm are formed. The tubules, if straightened, would extend about 70 centimetres (about 30 inches). The multistage process of sperm formation, which takes about 60 days, goes on in the lining of the tubules, starting with the spermatogonia, or primitive sperm cells, in the outermost layer of the lining. Spermatozoa (sperm) leaving the tubules are not capable of independent motion, but undergo a further maturation process in the ducts of the male reproductive tract; the process may be continued when, after ejaculation, they pass through the female tract. Maturation of the sperm in the female tract is called capacitation; little is known about it.

Each spermatozoon is a slender elongated structure with a head, a neck, a middle piece, and a tail. The head contains the cell nucleus. When the spermatozoon is fully mature, it is propelled by the lashing movements of the tail.

Production of hormones

The male sex hormone testosterone is produced by the cells of Leydig. These cells are located in the connective (interstitial) tissue that holds the tubules together within each lobule. The tissue becomes markedly active at puberty under the influence of the interstitial-cell-stimulating hormone of the anterior lobe of the pituitary gland; this hormone in women is called luteinizing hormone. Testosterone stimulates the male accessory sex glands (prostate, seminal vesicles) and also brings about the development of male secondary sex characteristics at puberty. The hormone may also be necessary to cause maturation of sperm and heighten the sex drive of the male. The testis is also the source of some of the female sex hormone estrogen, which may exert an influence on pituitary activity.

Each testis is supplied with blood by the testicular arteries, which arise from the front of the aorta just below the origin of the renal (kidney) arteries. Each artery crosses the rear abdominal wall, enters the spermatic cord, passes through the inguinal canal, and enters the upper end of each testis at the back. The veins leaving the testis and epididymis form a network, which ascends into the spermatic cord. The lymph vessels, which also pass through the spermatic cord, drain to the lateral and preaortic lymph nodes. Nerve fibres to the testis accompany the vessels; they pass through the renal and aortic nerve plexuses, or networks.

The epididymis, ductus deferens, and ejaculatory ducts. These ducts form the sperm canal. Together they extend from the testis to the urethra, where it lies within the prostate. Spermatozoa are conveyed from the testis along some 20 ductules, or small ducts, which pierce the fibrous capsule to enter the head of the epididymis. The ductules are straight at first but become dilated and then much convoluted to form distinct compartments within the head of the epididymis. They each open into a single duct, the highly convoluted duct of the epididymis, which constitutes the "body" and "tail" of that structure. It is held together by connective tissue but if unravelled would be nearly six metres (20 feet) long. The duct enlarges and becomes thicker walled at the lower end of the tail of the epididymis, where it becomes continuous with the ductus deferens.

The ductules from the testis have a thin muscular coat and a lining that consists of alternating groups of high columnar cells with cilia (hairlike projections) and low cells lacking cilia. The cilia assist in moving spermatozoa toward the epididymis. In the duct of the epididymis the muscle coat is thicker and the lining is thick with tufts of large nonmotile cilia. There is some evidence that the ductules and the first portion of the duct of the epididymis remove excess fluid and extraneous debris from the testicular secretions entering these tubes. The blood supply to the epididymis is by a branch from the testicular artery given off before that vessel reaches the testis.

The ductus deferens is the continuation of the duct of the epididymis. It commences at the lower part of the tail of the epididymis and ascends along the back border of the testis to its upper pole. Then, as part of the spermatic cord, it extends to the deep inguinal ring. Separating from the other elements of the spermatic cord—the blood vessels, nerves, and lymph vessels—at the ring, the ductus deferens makes its way through the pelvis toward the base of the prostate, where it is joined by the seminal vesicle to form the ejaculatory duct. A part of the ductus that is dilated and rather tortuous, near the base of the urinary bladder, is called the ampulla.

The ductus deferens has a thick coat of smooth muscle that gives it a characteristic cordlike feel. The longitudinal muscle fibres are well developed, and peristaltic contractions (contractions in waves) move the spermatozoa toward the ampulla. The mucous membrane lining the interior is in longitudinal folds and is mostly covered with nonciliated columnar cells, although some cells have nonmotile cilia. The ampulla is thinner walled and probably acts as a sperm store.

The prostate, seminal vesicles, and bulbourethral glands. These structures are the male accessory reproductive organs and provide secretions to form the bulk of the seminal fluid of an ejaculate. The prostate is in the lesser or true pelvis, centred behind the lower part of the pubic arch. It lies in front of the rectum. The prostate is shaped roughly like an inverted pyramid; its base is directed upward and is immediately continuous with the neck of the urinary bladder. The urethra traverses its substance. The two ejaculatory ducts (see below) enter the prostate near the upper border of its posterior surface. The prostate is of a firm consistency, surrounded by a capsule of fibrous tissue and smooth muscle. It measures about 4 centimetres across, 3 centimetres in height, and 2 centimetres front to back (about 1.6 by 1.2 by 0.8 inch) and consists of glandular tissue contained in a muscular framework. It is imperfectly divided into three lobes. Two lobes at the side form the main mass and are continuous behind the urethra. In front of the urethra they are connected by an isthmus of fibromuscular tissue devoid of glands. The third, or median, lobe is smaller and variable in size and may lack glandular tissue. There

Structure of prostate

are three clinically significant concentric zones of prostatic glandular tissue about the urethra. A group of short glands that are closest to the urethra and discharge mucus into its channel are subject to simple enlargement. Outside these is a ring of submucosal glands (glands from which the mucosal glands develop), and farther out is a large outer zone of long branched glands, composing the bulk of the glandular tissue. Cancer of the prostate is almost exclusively confined to the outer zone. The glands of the outer zone are lined by tall columnar cells that secrete prostatic fluid under the influence of androgens from the testis. The fluid is thin, milky, and slightly acid.

The seminal vesicles are two structures, about 5 centimetres (2 inches) in length, lying between the rectum and the base of the bladder. Their secretions form the bulk of the seminal fluid. Essentially, each vesicle consists of a much-coiled tube with many diverticula or outpouches that extend from the main tube, the whole being held together by connective tissue. At its lower end the tube is constricted to form a straight duct or tube that joins with the corresponding ductus deferens to form the ejaculatory duct. The vesicles are close together in their lower parts but are separated above where they lie close to the deferent ducts. The seminal vesicles have longitudinal and circular layers of smooth muscle, and their cavities are lined with mucous membrane, which is the source of the secretions of the organs. These secretions are ejected by muscular contraction during ejaculation. The activity of the vesicles is dependent on androgen production by the testes; castration causes atrophy of the seminal vesicles. The secretion is thick, sticky, and yellowish: it contains the sugar fructose and is slightly alkaline.

The bulbourethral glands, often called Cowper's glands, lie on the underside of the urethra between the prostate and the bulk of the penis. They are hardly larger than a pea. Each has a slender duct that runs forward and toward the centre to open on the floor of the spongy portion of the urethra. These glands are poorly developed in man. Their secretion is liberated during sexual excitement and may help to lubricate and coat the urethra to assist passage of the ejaculate.

Ejaculatory ducts

The two ejaculatory ducts lie on each side of the midline and are formed by the union of the duct of the seminal vesicle, which contributes secretions to the seminal fluid, with the end of the ductus deferens at the base of the prostate. Each duct is about 2 centimetres (about 0.8 inch) long and passes between a lateral and the median lobe of the prostate to reach the floor of the prostatic urethra. This part of the urethra has on its floor (or posterior wall) a longitudinal ridge called the urethral crest. On each side is a depression, the prostatic sinus, into which open the prostatic ducts. In the middle of the urethral crest is a small elevation, the colliculus seminalis, on which the opening of the prostatic utricle is found. The prostatic utricle is a short diverticulum or pouch lined by mucous membrane; it may correspond to the vagina or uterus in the female. The small openings of the ejaculatory ducts lie on each side of or just within the opening of the prostatic utricle. The ejaculatory ducts are thin walled and lined by columnar cells.

THE FEMALE REPRODUCTIVE SYSTEM

The female gonads or sexual glands are the ovaries; they are the source of ova and also of the female sex hormones estrogens and progestogens. The uterine tubes conduct ova to the uterus, which lies within the lesser or true pelvis. The uterus connects through the cervical canal with the vagina. The vagina opens into the vestibule about which lie the external genitalia, collectively known as the vulva.

The external genitalia. The female external genitalia include the structures placed about the entrance to the vagina and external to the hymen, the membrane across the entrance to the vagina. They are the mons pubis (also called the mons veneris), the labia majora and minora, the clitoris, the vestibule of the vagina, the bulb of the vestibule, and the greater vestibular glands.

The mons pubis is the rounded eminence, made by fatty tissue beneath the skin, lying in front of the pubic symphysis. A few fine hairs may be present in childhood; later, at puberty, they become coarser and more numerous. The upper limit of the hairy region is horizontal across the lower abdomen.

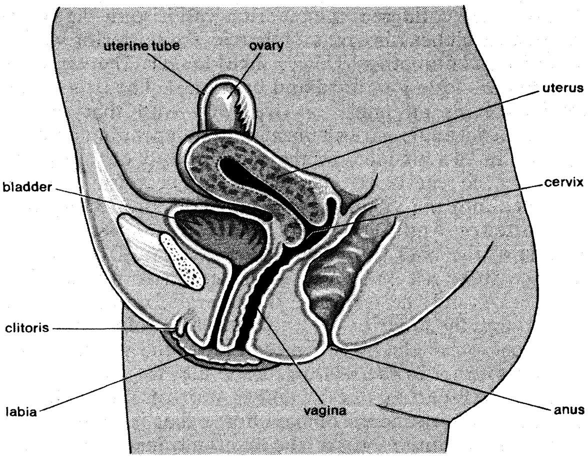

Figure 4: Female reproductive system.
Adapted from H. Gray, *Anatomy of the Human Body*, 28th ed. by C.M. Goss (1966); Lea & Febiger

The labia majora are two marked folds of skin that extend from the mons pubis downward and backward to merge with the skin of the perineum. They form the lateral boundaries of the vulval or pudendal cleft, which receives the openings of the vagina and the urethra. The outer surface of each labium is pigmented and hairy; the inner surface is smooth but possesses sebaceous glands. The labia majora contain fat and loose connective tissue and sweat glands. They correspond to the scrotum in the male and contain tissue resembling the dartos muscle. The round ligament (see below ***The uterus)*** ends in the tissue of the labium. The labia minora are two small folds of skin, lacking fatty tissue, that extend backward on each side of the opening into the vagina. They lie inside the labia majora and are some 4 centimetres (about 1.6 inches) in length. In front, an upper portion of each labium minus passes over the clitoris—the structure, in the female, corresponding to the penis (excluding the urethra) in the male—to form a fold, the prepuce of the clitoris, and a lower portion passes beneath the clitoris to form its frenulum. The two labia minora are joined at the back across the midline by a fold that becomes stretched at childbirth. The labia minora lack hairs but possess sebaceous and sweat glands.

Clitoris and hymen

The clitoris is a small erectile structure composed of two corpora cavernosa separated by a partition. Partially concealed beneath the forward ends of the labia minora, it possesses a sensitive tip of spongy erectile tissue, the glans clitoridis. The external opening of the urethra is some 2.5 centimetres (about 1 inch) behind the clitoris and immediately in front of the vaginal opening.

The vestibule of the vagina is the cleft between the labia minora into which the urethra and vagina open. The hymen vaginae lies at the opening of the vagina: it is a thin fold of mucous membrane that varies in shape. After rupture of the hymen, the small rounded elevations that remain are known as the carunculae hymenales. The bulb of the vestibule, corresponding to the bulb of the penis, is two elongated masses of erectile tissue that lie one on each side of the vaginal opening. At their posterior ends lie the greater vestibular glands, small mucous glands that open by a duct in the groove between the hymen and each labium minus. They correspond to the bulbourethral glands of the male.

The blood supply and nerve supply of the female external genital organs are similar to those supplying corresponding structures in the male.

The vagina. The vagina (the word means "a sheath") is the canal that extends from the cervix (outer end) of the uterus within the lesser pelvis down to the vestibule between the labia minora. The orifice of the vagina is guarded by the hymen. The vagina lies behind the bladder and urethra and in front of the rectum and anal canal.

Its walls are collapsed; the anterior wall is some 7.5 centimetres (3 inches) in length, whereas the posterior wall is about 1.5 centimetres (over ½ inch) longer. The vagina is directed obliquely upward and backward. The axis of the vagina forms an angle of over 90° with that of the uterus. This angle varies considerably, depending on conditions in the bladder, in the rectum, and during pregnancy. The cervix of the uterus projects for a short distance into the vagina and is normally pressed against its posterior wall. There are, therefore, recesses in the vagina at the back, on each side, and at the front of the cervix. These are known as the posterior fornix (behind the cervix and the largest), the lateral fornices (at the sides), and the anterior fornix (at the front of the cervix). The position of the uterus in relation to the vagina is described further in the section on the uterus.

The upper part of the posterior wall of the vagina is covered by peritoneum or membrane that is folded back onto the rectum to form the recto-uterine pouch. The lower part of the posterior vaginal wall is separated from the anal canal by a mass of tissue known as the perineal body.

Mucous membrane and muscle coat of vagina

The vagina has a mucous membrane and an outer smooth muscle coat closely attached to it. The mucous membrane has a longitudinal ridge in the midline of both the anterior and posterior walls. The ridges are known as the columns of the vagina; many rugae or folds extend from them to each side. The furrows between the rugae are more marked on the posterior wall and become especially pronounced before birth of a child. The membrane undergoes little change during the menstrual cycle (except in its content of glycogen, a complex starchlike carbohydrate) ; this is in contradistinction to the situation in many mammals in which marked exfoliation (shedding of the surface cells) can occur. No glands are present in the vaginal lining, and mucus present has been secreted by the glands in the cervical canal of the uterus. The smooth muscle coat consists of an outer longitudinal layer and a less developed inner circular layer. The lower part of the vagina is surrounded by the bulbospongiosus muscle, a striped muscle attached to the perineal body.

The blood supply to the vagina is derived from several adjacent vessels, there being a vaginal artery from the internal iliac artery and also vaginal branches from the uterine, middle rectal, and internal pudendal arteries, all branches of the internal iliac artery. The nerve supply to the lower part of the vagina is from the pudendal nerve and from the inferior hypogastric and uterovaginal plexuses.

The uterus. The uterus, or womb, is shaped like an inverted pear. It is a hollow, muscular organ with thick walls, and it has a glandular lining called the endometrium. The human uterus is normally a single structure, termed unicornuate; in the majority of mammals there are two horns or pouches to the uterus (bicornuate). In an adult virgin the uterus is 7.5 centimetres (3 inches) long, 5 centimetres (2 inches) in breadth, and 2.5 centimetres (1 inch) thick, but it enlarges to four to five times this size in pregnancy. The narrower, lower end is called the cervix; this projects into the vagina. The cervix is made of fibrous connective tissue and is of a firmer consistency than the body of the uterus. The two uterine tubes enter the uterus at opposite sides, near its top. The part of the uterus above the entrances of the tubes is called the fundus; that below is termed the body. The body narrows towards the cervix, and a slight external constriction marks the juncture between the body and the cervix.

Adapted from H. Gray Anatomy *of* the Human *Body*, 28th ed. by C.M. Goss (1966); Lea & Febiger

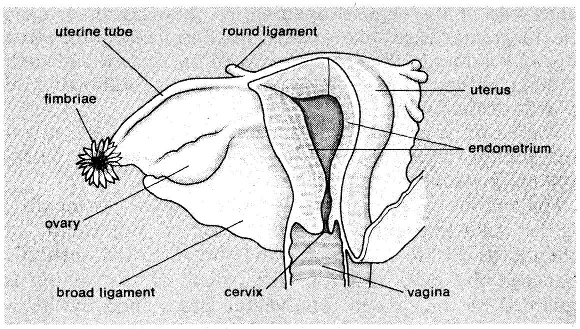

Figure 5: The uterus.

The uterus does not lie in line with the vagina but is usually turned forward (anteverted) to form approximately a right angle with it. The position of the uterus is affected by the amount of distension in the urinary bladder and in the rectum. Enlargement of the uterus in pregnancy causes it to rise up into the abdominal cavity, so that there is closer alignment with the vagina. The nonpregnant uterus also curves gently forward; it is said to be anteflexed. The uterus is supported and held in position by the other pelvic organs, by the muscular floor or diaphragm of the pelvis, by certain fibrous ligaments, and by folds of peritoneum. Among the supporting ligaments are two double-layered broad ligaments, each of which contains a uterine tube along its upper free border and a round ligament, corresponding to the gubernaculum testis of the male, between its layers. Two ligaments—sometimes called Mackenrodt's ligaments—at each side of the cervix are also important in maintaining the position of the uterus.

The cavity of the uterus is remarkably small in comparison with the size of the organ. Except during pregnancy, the cavity is flattened, with front and rear walls touching, and is triangular. The triangle is inverted, with its base at the top, between the openings of the two uterine tubes, and with its apex at the internal os, the opening into the cervix. The canal of the cervix is flattened from front to back and is somewhat larger in its middle part. It is traversed by two longitudinal ridges and has oblique folds stretching from each ridge in an arrangement like the branches of a tree. The cervical canal is 2.5 centimetres (about 1 inch) in length; its opening into the vagina is called the external os of the uterus. In virgins the external os is small, almost circular, and often depressed. After childbirth, the external os becomes bounded by lips in front and in back and is thus more slitlike. The cervical canal is lined by a mucous membrane containing numerous glands that secrete a clear, alkaline mucus. The upper part of this lining, in the region called the isthmus, undergoes cyclical changes resembling, but not as marked as, those occurring in the body of the uterus. Numerous small cysts (Naboth's follicles) are found in the cervical mucous membrane. It is from this region that cervical smears are taken in order to detect early changes indicative of cancer.

The tissue layers in the uterus

The uterus is composed of three layers of tissue. On the outside is a serous coat of peritoneum (a membrane exuding a fluid like blood minus its cells and the clotting factor fibrinogen) which partially covers the organ. In front it covers only the body of the cervix; behind it covers the body and the part of the cervix that is above the vagina and is prolonged onto the posterior vaginal wall; from there it is folded back to the rectum. At the side the peritoneal layers stretch from the margin of the uterus to each side wall of the pelvis, forming the two broad ligaments of the uterus.

The middle layer of tissue is muscular (the myometrium) and comprises the greater part of the bulk of the organ. It is very firm and consists of densely packed, unstriped, smooth muscle fibres. Blood vessels, lymphatics, and nerves are also present. The muscle is more or less arranged in three layers of fibres running in different directions. The outermost fibres are arranged longitudinally. Those of the middle layer run in all directions without any orderly arrangement; this layer is the thickest. The innermost fibres are longitudinal and circular in their arrangement.

The innermost layer of tissue in the uterus is the mucous membrane, or endometrium. It lines the uterine cavity as far as the internal os, where it becomes continuous with the lining of the cervical canal. The endometrium contains numerous uterine glands that open into the uterine cavity and that are embedded in the cellular framework or stroma of the endometrium. Numerous blood vessels and lymphatic spaces are also present. The appearances of the endometrium vary considerably at the different stages in reproductive life. It begins to reach full development at puberty and thereafter exhibits dramatic changes during each menstrual cycle. It undergoes further changes before, during, and after pregnancy; during the menopause; and in old age. These changes are for the most part hormonally induced and controlled by the activity of the ovaries.

To understand the nature of the changes in the endometrium during each menstrual cycle it is usual to consider the endometrium to be composed of three layers. They blend imperceptibly but are functionally distinct: the inner two layers are shed at menstruation; the outer or basal layer remains in position against the innermost layer of the myometrium. The three layers are called, respectively, the stratum compactum, the stratum spongiosum, and the stratum basale. The stratum compactum is nearest to the uterine cavity and contains the lining cells and the necks of the uterine glands; its stroma is relatively dense. Superficial blood vessels lie beneath the lining cells. The stratum spongiosum is the large middle layer. It contains the main portions of uterine glands and accompanying blood vessels; the stromal cells are more loosely arranged and larger than in the stratum compactum. The stratum basale lies against the uterine muscle; it contains blood vessels and the bases of the uterine glands. Its stroma remains relatively unaltered during the menstrual cycle.

The menstrual cycle

The menstrual cycle extends over a period of about 28 days (normal range 21–34 days), from the first day of one menstrual flow to the first day of the next. It reflects the cycle of changes occurring in the ovary, which is itself under the control of the anterior lobe of the pituitary. The menstrual cycle is divided into four phases; menstrual, postmenstrual, proliferative, and secretory phases.

In the menstrual, or bleeding, phase the stratum compactum and most of the stratum spongiosum are shed, become liquefied, and, with a quantity of blood, flow out of the uterus through the cervical opening. During the postmenstrual phase, a process of repair takes place, and the lining, or endometrium, is re-established. In the proliferative phase the endometrium thickens, and its glands begin their secretion of mucus. The secretory, or premenstrual, phase is a period of continued endometrial growth and of active secretion by the endometrial glands. These states are discussed in more detail in the article MENSTRUATION.

The secretory phase reaches its climax about a week after ovulation. Ovulation occurs in midcycle, about 14 days before the onset of the next menstrual flow. The endometrium has been prepared and has been stimulated to a state of active secretion for the reception of a fertilized ovum. The stage has been set for the attachment of the blastocyst, derived from a fertilized ovum, to the endometrium, and for its subsequent embedding. This process is called implantation; its success depends on the satisfactory preparation of the endometrium in both the proliferative and secretory phases. When implantation occurs, a hormone from certain cells of the blastocyst causes prolongation of the corpus luteum and its continued activity. This causes suppression of menstruation and results in the maintenance of the endometrium and its further stimulation by progesterone, with consequent increased thickening. The endometrium of early pregnancy is known as the decidua.

In a cycle in which fertilization of the ovum has not taken place, the secretory phase terminates in menstruation.

The phenomenon of menstruation occurs also in the great apes and in the Old World monkeys, but in New World monkeys, uterine changes are not as dramatic and bleeding is slight. It does not occur in other mammals (except perhaps in modified form in the elephant shrew); and the slight bleeding that may occur in some mammals at about the time of ovulation, caused by high levels of estrogen, is distinct from menstruation. Menstruation may seem a wasteful process, with its loss of tissue and of blood and the iron contained in the blood. If not excessive or abnormally frequent, this loss can be readily made good by a healthy woman. The endometrium needs to be in a certain state of preparedness before implantation can occur. When this stage has been passed, menstruation occurs. Repair then re-establishes an endometrium capable of being stimulated again to the critical stage when implantation can occur.

The uterus is supplied with blood by the two uterine arteries, which are branches of the internal iliac arteries, and by ovarian arteries, which connect with the ends of the uterine arteries and send branches to supply the uterus. The nerves to the uterus include the sympathetic nerve fibres, which produce contraction of uterine muscle and constriction of vessels, and parasympathetic (sacral) fibres, which inhibit muscle activity and cause dilation of blood vessels.

The uterine tubes. The uterine tubes, often called the fallopian tubes, carry ova from the ovaries to the cavity of the uterus. Each opens into the abdominal cavity near an ovary, at one end, and into the uterus, at the other. Three sections of the tubes are distinguished: the funnel-shaped outer end, or infundibulum; the expanded and thin-walled intermediate portion, or ampulla; and the cordlike portion, the isthmus, that opens into the uterus. The infundibulum is fringed with irregular projections called fimbriae. One fimbria, somewhat larger than the others, is usually attached to the ovary. The opening into the abdomen is at the bottom of the infundibulum and is small. Fertilization of the ovum usually occurs in the ampulla of the tube. Normally the fertilized egg is transported to the uterus, but occasionally it may adhere to the tube and start developing as an ectopic or tubal pregnancy. The tube is unable to support this pregnancy, and the conceptus may either be extruded through the abdominal opening or may cause rupture of the tube, with ensuing hemorrhage.

The uterine tube is covered by peritoneum except on its border next to the broad ligament. There are inner circular and outer longitudinal layers of smooth muscle fibres continuous with those of the uterus. The inner lining has numerous longitudinal folds that are covered with ciliated columnar and secretory cells. Muscular contraction, movement of the hairlike cilia, and the passage of the watery secretions all probably assist in the transport of spermatozoa to the ampulla and of a fertilized ovum toward the uterus.

The ovaries. The female gonads, or primary sex organs, corresponding to the testes in a male, are the two ovaries. Each is suspended by a mesentery, or fold of membrane, from the back layer of the broad ligament of the uterus. In a woman who has not been pregnant, the almond-shaped ovary lies in a vertical position against a depression, the ovarian fossa, on the side wall of the lesser pelvis. This relationship is altered during and after pregnancy. Each ovary is somewhat over 2.5 centimetres (1 inch) in length, 1.25 centimetres (½ inch) across and slightly less in thickness, but the size varies much with age and with the state of activity.

Shape, position, structure, of ovaries

The mesentery of the ovary helps to keep it in position, and within this membrane lie the ovarian artery and vein, lymphatics, and nerve fibres. The uterine tube arches over the ovary and curves downward on its inner or medial surface.

Except at its hilum, the point where blood vessels and the nerve enter the ovary and where the mesentery is attached, the surface of the ovary is smooth and is covered by cubical cells. Beneath the surface, the substance of the ovary is divided into an outer portion, the cortex, and an inner portion, or medulla. The outermost part of the cortex, immediately beneath the outer covering, forms a thin connective tissue zone, the tunica albuginea. The rest of the cortex consists of stromal or framework cells, contained in a fine network of fibres, and also the follicles and corpora lutea.

The ovarian follicles, sometimes called graafian follicles, are rounded enclosures for the developing ova in the cortex near the surface of the ovary. At birth and in childhood they are present as numerous primary or undeveloped .ovarian follicles. Each contains a primitive ovum, or oocyte, and each is covered by a singie iayer of

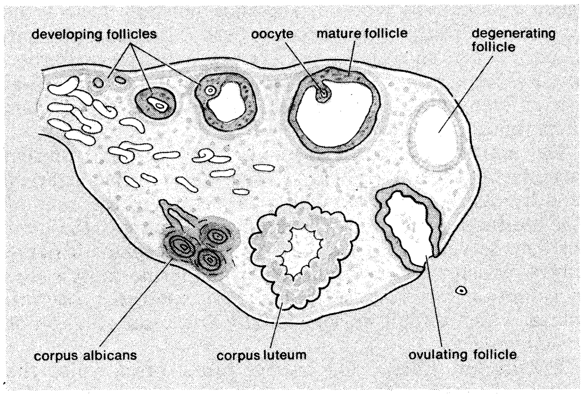

Figure 6: Cross section of the ovary.

flattened cells. As many as 700,000 primary follicles are contained in the two ovaries of a young child. Most of these degenerate before or after puberty.

Cyclical development of follicles

During the onset of puberty and thereafter until the menopause (except during pregnancy), there is a cyclic development of one or more follicles each month into a mature follicle. The covering layer of the primary follicle thickens and can be differentiated into an inner membrana granulosa and an outer vascularized theca interna. The cells of these layers (mostly the theca interna) produce estrogenic steroid hormones that exert their effects on the endometrium of the uterus and on other tissues. The maintenance and growth of the follicle to maturity is brought about by a follicle-stimulating hormone (FSH) from the anterior lobe of the pituitary gland. Another hormone, called luteinizing hormone (LH), from the anterior lobe, assists FSH to cause the maturing, now fluid-filled follicle to secrete estrogens. LH also causes a ripe follicle (1.0–1.5 centimetres in diameter) to rupture, causing the liberation of the oocyte into the peritoneal cavity and thence into the uterine tube.

This liberation of the oocyte is called ovulation; it occurs at about the midpoint of the human reproductive cycle, on the 13th–14th day of a 28-day cycle as measured from the first day of the menstrual flow.

Corpus luteum

After ovulation the ruptured follicle collapses because of loss of its follicular fluid and rapidly becomes transformed into a soft, well-vascularized glandular structure known as the corpus luteum. The human corpus luteum ("yellow body") is not yellow but is a creamy gray on section. It develops rapidly, becomes vascularized after about four days, and is fully established by nine days. The gland produces the steroid hormone progesterone and some estrogens. Its activity is both stimulated and maintained by luteinizing hormone. Progesterone stimulates glandular proliferation and secretion in an endometrium primed by estrogens.

While the ovarian follicle matures, the primary oocyte divides into a secondary oocyte and a small rudimentary ovum called the first polar body. This occurs at about the time when the follicle develops its cavity; the oocyte also gains a translucent, acellular covering or envelope, the zona pellucida. The secondary oocyte is liberated at ovulation: it is 120–140 microns in diameter and is surrounded by the zona pellucida and a few layers of cells known as the corona radiata. The final maturation of the oocyte, with the formation of the rudimentary ovum called the second polar body, occurs at the time of fertilization.

If fertilization does not occur, then the life of the corpus luteum is limited to about 14 days. Degeneration of the gland starts toward the end of this period and menstruation occurs. The corpus luteum shrinks, fibrous tissue is formed, and it is converted into a scarlike structure, called a corpus albicans, which persists for a few months. Should fertilization occur and be followed by implantation of the blastocyst, hormones (particularly chorionic gonadotrophin) are produced by cells of the blastocyst to prolong the life of the corpus luteum. It persists in an active state for at least the first two months of pregnancy until the placental tissue has taken over its endocrine (hormone-producing) function. The corpus luteum of pregnancy then also retrogresses and is becoming a fibrous scar by the time of parturition.

The ovarian arteries arise from the front of the aorta, in a manner similar to the testicular arteries, but at the brim of the lesser pelvis they turn down into the pelvic cavity. Passing in the suspensory ligament of the ovary, each artery reaches the broad ligament below the uterine tube and then passes into the mesovarium to divide into branches distributed to the ovary. One branch continues in the broad ligament to anastomose with the uterine artery. The ovarian veins emerge from each ovary as a network that eventually becomes a single vein; the terminations are similar to those of the testicular veins. The nerves are derived from the ovarian nerve network on the ovarian artery.

Reproductive System Diseases

The human reproductive system is made up of the organs, glands, and secretions required for the development and maintenance of the male and female characteristics and the production of the sex cells, or gametes (spermatozoa and ova), responsible for reproduction.

The system in the male includes (1) the testes (testicles), gonads, or sex glands, that produce spermatozoa (sperm) and male sex hormones and are enclosed in the pouch of skin called the scrotum; (2) the penis, the shaft of which is made up of erectile tissue called the corpora cavernosa and the structure known as the corpus spongiosum, capped by the sensitive glans penis; (3) the sperm channels—the epididymides, the ductus deferentus, or vasa deferentia, the ejaculatory ducts, and the urethra, which also carries urine; and (4) the glands that secrete the greater part of the seminal fluid; these are the prostate, which encircles the urethra close to the bladder, the seminal vesicles, and the bulbourethral glands.

The reproductive system in the female includes (1) the ovaries, which are the source of ova and of female sex hormones; (2) the uterine (Fallopian) tubes, which carry the ova to the uterus, and normally are the site for the fertilization of the ova; (3) the uterus, or womb, in which the fertilized ovum is normally implanted and the embryo and the fetus develop; and (4) the vagina, or pouch, in which semen is deposited during sexual intercourse. The lower end of the uterus, the cervix, is a projection that opens into the vagina.

The reproductive system in the human male and female is described at more length and illustrated in the article REPRODUCTIVE SYSTEM, HUMAN. The menstrual cycle is set forth in MENSTRUATION and the development of the offspring in the uterus in DEVELOPMENT, HUMAN. Pregnancy is covered in the article PREGNANCY and childbirth in PARTURITION, HUMAN.

The human reproductive system may be affected by abnormal hormone production coming from the ovaries or the testes or from other endocrine glands, such as the pituitary, thyroid, and adrenals. Reproductive-system diseases can also be caused by genetic abnormalities, congenital anomalies (abnormalities), infections, tumours, and disorders of unknown cause.

The main sections of this article are concerned with (1) genetic and congenital abnormalities; *(2)* functional genital disorders; (3) infections; (4) structural changes of unknown cause; and (5) tumours.

GENETIC AND CONGENITAL ABNORMALITIES

In the male. Congenital anomalies of the prostate and seminal vesicles are rare; they consist of absence, hypoplasia (underdevelopment), or the presence of fluid- or semisolid-filled sacs, called cysts. Cysts of the prostatic utricle (the uterine remnant found in the male) are often found in association with advanced stages of hypospadias (a defect in the urethra, see below) and pseudohermaphroditism (in which sex glands are present but bodily appearance is ambiguous as to sex; *i.e.*, the secondary sexual characteristics are underdeveloped). Cysts may also cause urinary obstructive symptoms through local pressure on the bladder neck.

Abnormalities of the penis

Severe anomalies of the penis are rare and are generally associated with urinary or other systemic defects that are incompatible with life. Anomalies are those of absence, transposition, torsion (twisting), and reduplication of the penis. An abnormally large penis frequently is present in boys affected by precocious puberty, in congenital imbeciles, in dwarfs, in men with overactive pituitaries, and in persons affected by adrenal tumours. A small penis is seen in infantilism and in underdevelopment of the genitals, or undersecretion of the pituitary or pineal gland, and failure of development of the corpora cavernosa.

The only anomaly of the foreskin of grave concern is congenital phimosis, characterized by a contracture of the foreskin, or prepuce, sufficient to prevent its retraction over the glans; the preputial opening may be pinhole in size and may impede the flow of urine. The condition is easily remedied by circumcision, a permanent cure.

There is a considerable variety of urethral anomalies. Stenosis (contracture) of the external opening (meatus) is the most common, but congenital stricture of the urethra occasionally occurs at other points. Valves (or flaps) across the anterior or posterior part of the urethra may cause congenital urethral obstruction in boys. Posterior urethral valves are more common than anterior valves and consist of deep folds of mucous membrane, often paper-thin and usually attached at one end to the verumontanum, a small prominence in the back wall of that part of the urethra that is surrounded by the prostate gland. If too tight, the valves may obstruct the urethra and destroy the kidneys.

There are various defects associated with incomplete closure of the urethra. One of the commonest is hypospadias, in which the underside (ventral side) of the urethral canal is open for a distance at its outer end. Frequently the hypospadiac meatus is narrowed, and the penis also has a downward (ventral) curvature beyond the meatus. The posterior part of the urethra is never involved; therefore, the muscle that closes the urethra, the sphincter, functions normally, and urinary control exists. Although the condition occurs in both sexes, it is seen predominantly in the male. There is a high incidence of partial or complete failure of the testes to develop, cryptorchism (failure of the testes to descend into the scrotum), and small external and internal genitalia; variable male–female admixtures may be associated with this deficiency. Epispadias, an opening in the upper (dorsal) side of the penis, is considerably less common than hypospadias. Dorsal curvature may also be present, but the disabling aspect is that the defect usually extends through the urinary sphincter and causes urinary incontinence. Other less common urethral anomalies include complete absence of the urethra, double urethra, urethra fistula (an opening in the urethra), urethrorectal fistula (an opening between the urethra and the rectum), and urethral diverticulum (a pouch in the wall of the urethra). Most of the above conditions are correctable by surgery.

Absence or excessive number of testes

Anorchism (absence of one or both testes) is rare; it may be associated with the absence of various other structures of the spermatic tract. Generally, if one testis is absent, the other is found to be within the abdomen rather than in the scrotum. Congenitally small testes may be a primary disorder or may occur because of underactivity of the pituitary. In both disorders, there is a lack of development of secondary sexual characteristics and some deficiency in libido and potency. Supernumerary testicles are extremely rare; when present, one or more of the supernumerary testicles usually shows some disorder such as torsion of the spermatic cord. Synorchism, the fusion of the two testicles into one mass, may occur within the scrotum or in the abdomen. Cryptorchism is the term applied to all forms of imperfectly descended testes, the commonest anomaly of the spermatic tract. Testicular descent is arrested in about 3 percent of boys at puberty; the sex gland may be found anywhere between the kidney and the scrota1 area. The majority of undescended testes are in the groin (70 percent), whereas about 25 percent are in the abdomen or in the retroperitoneal space (the space behind the membrane lining the back wall of the abdomen). The condition is often bilateral, and in the unilateral cases there is no preponderance between the left or right side. Hormonal treatment may be useful in correcting the condition, but usually surgery is necessary for correction. Cryptorchism is often associated with congenital hernia and less often with hydrocele—a collection of fluid in the membranous sac that encloses the testes—or with torsion of the spermatic cord. Tumours are more common in undescended testes.

In the female. The female external genitalia are less complex than those of the male but have anomalies that can at times severely interfere with the functioning of the female urogenital tract. The clitoris, an erectile structure that corresponds to the penis, except that it does not contain the urethra, may be absent but in other cases may be enlarged on either a congenital or a hormonal basis. Fusion of the labia minora (small folds of skin covering the clitoris, the urethral opening, and the opening of the vagina) is a midline "sealing together" of the labia minora; usually a minute unfused area is left just below the clitoris, through which the child urinates and later menstruates. The chief difficulty with this anomaly is concerned with obstruction to the flow of urine and associated urinary-tract infection. An imperforate hymen (the membrane closing off the opening of the vagina) causes distension of the uterus and vagina with fluid other than blood before puberty and with blood after puberty (the two conditions are called hydrometrocolpos and hematocolpometra, respectively). The distended vagina compresses the urethra enough to interfere with urination and commonly may even cause complete retention of urine in the bladder and distension of the entire upper urinary tract. Fusion of the urethra and the hymen is characterized by a dense hymenal ring and a stenosed urethral opening. The consequent urinary obstruction commonly results in persistent urinary infection. Most of the conditions are readily remedied by surgery.

Anomalies of vagina and uterus

Anomalies of the vagina and uterus consist of complete absence, incomplete development, and duplication. The female urethra may have a congenitally narrow opening, or meatus; may be distended; may have an abnormal pouch, or diverticulum, in its wall; or may open abnormally into the vagina. Hypospadias may occur in the female but is far less common than in the male. Epispadias is also present in the female. Reconstructive surgery is the only method of treatment. One of the rarest and most severe of the urogenital-tract anomalies, called persistent cloaca, consists in congenital intercommunication between the rectum and the bladder and vagina or between the rectum and the urethra and vagina.

Intersexuality. Intersexuality (having both male and female characteristics) may be noticeable at birth or may become apparent after puberty. Intersexuality noticeable at birth may be classified as female or male pseudohermaphroditism or true hermaphroditism. Female pseudohermaphroditism, or female intersex, may be of adrenal or nonadrenal type. The adrenal type develops because of an inborn error in the metabolism of the adrenal hormone cortisol that leads to an increased secretion of corticotropin (ACTH) and consequent excessive secretion of androgens (male sex hormones). The newborn female with this condition is a chromosomal female and resembles a normal female, but an excess male hormone has a masculinizing effect on the external genitalia; the vagina tends to be connected to the urethra; the clitoris is enlarged, as are the labia (the labia majora are prominent folds of skin, corresponding to the scrotum in the male). Effective treatment can be achieved by administration of adrenal hormones (*e.g.*, cortisone, hydrocortisone), which suppress the pituitary so that its stimulus to adrenal production of androgenic hormones is minimized. The nonadrenal type of intersex is seen in infants whose mothers have been administered synthetic androgens or progestational compounds (substances that stimulate changes in the uterus that further the implantation and growth of the fertilized ovum) during pregnancy. Rarely, the condition is associated with the presence in the mother of a masculinizing tumour of the ovary or the adrenal gland. The newborn infant is a female with varying degrees of ambiguous genitalia; no treatment is necessary, and normal female development occurs at puberty.

Male pseudohermaphrodites are males with varying deficiencies of internal and external virilization. Most commonly, the male intersex has a markedly hypospadiac penis, undescended testes, a cleft scrotum, and an enlarged prostatic utricle; a complete uterus and Fallopian tubes may be found, with the vagina opening into the posterior wall of the urethra. (Such persons are pseudohermaphrodites in that they do not have ovaries.)

True hermaphrodites have recognizable ovarian and testicular tissue. **A** uterus is always present, but the internal genitalia otherwise vary greatly, often including both male and female structures. The external genitalia are usually ambiguous, but in **75** percent of the reported cases the children have been raised as males. At puberty, over 80 percent of them develop enlarged breasts, and approximately half menstruate. Most hermaphrodites are chromatin positive—that is, they have, within and near the periphery of the nuclei of their cells, a substance, chromatin, that is normally found in the cells of females but not in those of males—and over half have a characteristically female set of chromosomes in their peripheral blood cells.

Surgical and hormonal therapy directed to producing either a male or a female configuration of the body is based on the existing physical and psychological findings.

Inter-sexuality syndromes associated with puberty

Klinefelter's, Turner's, and testicular feminizing syndromes are intersexuality syndromes that become apparent prior to or after puberty. Klinefelter's syndrome is a disorder of phenotypic males (persons who have a male body configuration) who do not produce sperm, have small testes, and have varying degrees of eunuchoidism. The essential genetic abnormality is the presence of an extra sex chromosome. Thus, instead of the X and Y and total of 46 that would be anticipated from their appearance, affected persons have two X's and a Y and a total of **47** chromosomes. Patients with this syndrome have various associated medical problems, such as chronic disease of the lungs, varicose veins, thrombophlebitis (inflammation of the blood vessels), obesity, diabetes mellitus, hyperlipemia (abnormally high blood levels of fats), and enlarged breasts at the time of puberty. Mental retardation and antisocial behaviour are also associated with this syndrome. Treatment consists of the administration of androgens to prevent eunuchoid symptoms and osteoporosis (a condition characterized by lightness, porosity, and fragility of the bones). Removal of the breasts is occasionally necessary.

Turner's syndrome is a disorder of phenotypic females —persons who are female in physical configuration. Characteristically, such persons are short, do not menstruate, and show estrogen (a female sex hormone) deficiency; there is a distinctive cluster of congenital anomalies. In the typical cases, the ovary is an undifferentiated streak of cells inside the body, with no evidence of activity related to secretion or production of ova. Internal genital development is female, with a uterus and Fallopian tubes, and external development is immaturely female, with no virilization except for occasional enlargement of the clitoris. Treatment consists of administration of estrogens.

The disorder known as the testicular feminizing syndrome is inherited. Affected persons seem to be of normally developed females but have a chromosomal sex that is that of the normal male. The gonads are well-developed testes, and evidence indicates that there is a normal production of testosterone (male hormone), but there is cellular resistance to the action of this hormone, and therefore the affected person becomes female in appearance. Because these gonads are apt to form malignant tumours, they are usually removed surgically. Female sexual characteristics are then maintained by the administration of estrogenic hormones.

FUNCTIONAL GENITAL DISORDERS

Affecting both male and female systems. Delayed puberty. The term delayed puberty may be a misnomer, because puberty delayed beyond age **19** is in fact a permanent failure of sexual development because of an abnormally low secretion by the pituitary gland of gonadotropic hormone, the hormone that stimulates growth and activity of the sex glands; this condition is called hypogonadotropic eunuchoidism. The term delayed puberty is usually applied to boys who develop more slowly than the average but who still eventually undergo full sexual development. Only in retrospect—*i.e.*, after the affected person reaches the age of 20—can one clearly differentiate these cases from the classic or incomplete forms of hypogonadotropic eunuchoidism. If there are social and psychological problems related to the sexual underdevelopment, therapy may consist of a course of chorionic gonadotropin, a hormone produced by the placenta and secured from the urine of pregnant women. If puberty is merely delayed, it will usually progress normally after this treatment. If it fails to progress, the patient does not have delayed puberty but rather has hypogonadotropic eunuchoidism.

Precocious puberty. In healthy girls living in a temperate climate, the earliest sign of puberty occurs at a mean age of 10.6 years (standard deviation of 1.2 years), whereas, in boys, testicular growth begins at a mean age of 11.8, with a standard deviation of one year. The average age of menstruation is **13.5** years (range, **9–17** years). What is called true precocious puberty is a condition in which normal pituitary–gonadal function is activated at an abnormally early age. It is always isosexual with the sex gonads (*i.e.*, it is always in keeping with the sex of the gonads) and with development of the secondary sexual characteristics and production of spermatozoa or ova. Pseudoprecocious puberty includes development of secondary sexual characteristics but not production of spermatozoa or ova and may be isosexual or may be heterosexual (*i.e.*, it may involve virilization in the female or feminization in the male).

Pseudo-precocious puberty

The causes of true precocious puberty are several—including brain lesions and hypothyroidism (abnormally low secretion by the thyroid glands); the largest proportion of cases are of unknown cause. Precocious pseudopuberty in females may be caused by ovarian tumours, a cyst of the ovary, a tumour of the adrenal cortex (outer substance of the adrenal gland), or congenital overdevelopment of the adrenal gland. In males, the causes include congenital overdevelopment of the adrenal glands, tumour of the adrenal cortex, tumour involving the Leydig cells of the testes, and teratoma (a tumour containing numerous types of tissue; in these circumstances it includes adrenal-cortical tissue).

The diagnosis of precocious puberty is warranted when sexual maturation begins before the age of eight in girls or ten in boys. The condition is twice as common in girls as in boys but in girls is far less indicative of serious disease. Most prematurely developed girls (80 percent) have no demonstrable structural abnormality of brain, pituitary gland, or ovary; more than 60 percent of sexually precocious boys have serious organic disease. In girls, ovarian tumours account for **15** percent of the cases of precocious development and intracranial lesions for only **4** percent. In boys, 20 percent of the cases of precocious development are due to intracranial disease, **25** percent to adrenal disease, and less than 10 percent to lesions of the testicle. Precocious puberty of unknown cause is four to ten times as common in girls than in boys.

Infertility. At least 10 percent of marriages are barren, and deficiencies of sperm production in the male are the causal factor in 40 percent of these. The common causes of male infertility are deficiencies in maturation of germ cells (sperm); orchitis (mumps), with destruction of the testes; obstruction of the passageways for sperm; abnormally low thyroid or high adrenal secretion; varicocele (enlargement of the veins of the spermatic cord); or formation of antibodies to sperm by the male or the female. The most important steps in the evaluation of male infertility are examination of the semen and of a specimen of the tissue of the testes. Evaluation also includes chromatin analysis and observation of thyroid, adrenal, and pituitary function. The results of treatment of infertility in the male are usually unsatisfactory, except when a varicocele or obstruction in the sperm passageways is the cause, in which case surgical correction may be beneficial.

Causes of infertility in females

Infertility in the female is related to the faulty production of ova or to interferences with their union with spermatozoa. Vaginal causes are usually uncommon, but obstruction may be due to an unruptured hymen or may be functional and arise from enlargement and contraction of the levator ani muscles (these muscles form a supporting sheet under the pelvic cavity, with openings for structures such as the anus and the vagina). Abnormalities of the cervix are among the most important causes obstructing the passage of sperm. (The sperm normally enter the uterus through the cervix and, from the uterus, move into a uterine or Fallopian tube, where fertilization of an ovum takes place.) During the few days prior to ovulation—release of an ovum from the ovary—the glands within the cervix normally secrete a thin, watery mucus that is beneficial to sperm survival and migration. Various factors, such as infection or estrogen deficiency, may decrease the quality of the mucus.

Uterine anomalies such as a bicornuate (double) uterus may play a role in infertility. Total or partial blocking of the uterine tubes can result from inflammation due to infection (*e.g.*, gonorrhea) or from endometriosis, a condition involving the presence of tissue resembling that which lines the uterus elsewhere in the pelvic cavity. Thyroid, pituitary, adrenal, or ovarian disease may interfere with ovulation, as may the presence of large numbers of cysts in the ovaries (the condition known as polycystic ovaries).

Finally, emotional factors may play a role in causing infertility. Treatment consists of the use of various hormones, surgical correction of tubal blockage, and psychotherapy. With the advent of new hormone preparations, the results in achieving pregnancy have been vastly improved.

Affecting female system. ***Menstrual disorders.*** Amenorrhea (failure to menstruate) may be caused by congenital abnormalities of the female reproductive system and disturbances of the pituitary, thyroid, and adrenal glands and the ovaries. The pituitary may be affected by cancer (adenoma or carcinoma), by cysts, by an acute infection, by the functional disorder known as Frölich's syndrome, or by anorexia nervosa (a condition in which aversion to eating, itself caused by some underlying emotional disorder, leads to emaciation and other abnormal effects). Both overactivity and underactivity of the thyroid may cause either amenorrhea or excessive uterine bleeding. Abnormally high secretion by the adrenal glands causes amenorrhea as a secondary effect of the virilization that results, but low adrenal secretions (Addison's disease), when present for some time, also causes amenorrhea as a typical symptom. Amenorrhea may be caused by masculinizing tumours of the ovaries, by polycystic ovaries (Stein-Leventhal syndrome), or by infections; radiation of the ovaries may decrease production of estrogens (female sex hormones) enough to cause amenorrhea.

There is also spontaneous premature failure of the ovaries (in women in their early 30s), which is similar to the normal menopause in its effects. Lastly, debilitating diseases such as tuberculosis or severe malnutrition may cause amenorrhea.

Abnormal uterine bleeding

Abnormal uterine bleeding may be excessive menstrual bleeding, scanty menstrual bleeding, too frequent menstruation, or bleeding other than at the time of menstruation. The causes include lesions in the uterus, pregnancy disorders, endometriosis, lesions in the ovaries, systemic diseases, administration of hormones, or underactivity or overactivity of the thyroid. Dysfunctional uterine bleeding—that is, irregular, excessive, or prolonged menstrual bleeding from nonorganic or endocrine causes—is most frequently seen in women who are near 40 years of age. Dysmenorrhea is of two types, called primary and acquired. Primary dysmenorrhea is usually not associated with any organic pelvic abnormality. Characteristically, there are severe cramps during menstruation, accompanied by pain in the pelvis, nausea, vomiting, and tension. Acquired dysmenorrhea usually accompanies some organic pelvic abnormality, such as endometriosis or cervical stenosis—narrowing of the opening in the cervix.

Affecting the male system. ***Impotence.*** Impotence is inability of the male to have satisfactory sexual intercourse and varies in form from the inability to gain an erection to weak erections, premature ejaculation, or loss of normal sensation with ejaculation. Almost all of these complaints are psychogenic in origin, but impotence may be caused by subnormal functioning of the testes, by arteriosclerosis (hardening of the arteries), diabetes mellitus (a metabolic disease in which there is inadequate secretion or utilization of insulin), or by some disease of the nervous system. Certain medications prescribed for the treatment of such diseases as peptic ulcer, hypertension, or psychiatric illnesses may adversely affect sexual ability. Therapy, usually limited in its success, includes administration of sex hormones and psychotherapy.

Priapism. Priapism is prolonged penile erection that is painful and unassociated with sexual stimulation. The blood in the spaces of the corpora cavernosa becomes sludgelike and may remain for hours or even for days. About 25 percent of the cases are associated with leukemia (a disease of the blood-forming tissues that results in extremely high numbers of white blood cells), sickle-cell anemia (an inherited disease in which red blood cells are abnormal in shape and function and the hemoglobin is of a particular type), metastatic carcinoma (cancerous development at a distance from the primary site), and diseases of the nervous system, but in the majority of cases the causation is not clear. There have been many forms of therapy, but prompt surgical treatment with evacuation of the blood from the corpora appears to be the best. Regardless of treatment, impotence is common after an episode of priapism and even more common after repeated episodes of priapism.

INFECTIONS

Venereal infections. The principal venereal infections are syphilis, gonorrhea, chancroid, lymphogranuloma venereum, and granuloma inguinale.

Syphilis. Syphilis is caused by infection with ***Treponema pallidum.*** Two to four weeks after sexual exposure, a painless lump develops on the skin or mucous membranes of the genitalia, the region around the anus, or the oral cavity and then breaks down, forming a hard, punched-out ulcer (called the primary chancre). The diagnosis is made early by identifying the organism on microscopic examination. Several weeks after exposure, syphilis can be identified by standard tests of the blood serum. The genitalia of both male and female may be affected by flat, raised nodules in the secondary state of syphilis. In the tertiary state, the testes or epididymides may be affected with nodule (gumma) formation. Treatment with massive doses of penicillin is extremely effective, and, if treatment is early, the chances of cure are excellent. A female with syphilis can transmit the disease to a fetus for an undetermined period of years. Infection of the fetus usually occurs after the fifth month of pregnancy and may result in spontaneous abortion, miscarriage, a stillborn fetus, or a fatally ill infant.

Syphilitic infection of fetus

Gonorrhea. Gonorrhea, commonest of the venereal diseases, is caused by the organism *Neisseria gonor-*

rhoeae. Pain or a burning sensation on urination is an early symptom. The infection tends to spread. In the male, it may include the posterior portion of the urethra, the prostate, and the seminal vesicles. Involvement of the epididymides may lead to sterility. In the female, a large, painful abscess may form near the opening into the vagina; spread to the uterine tubes may lead to sterility. Other possible effects include inflammation of the heart lining and arthritis. Identification of the disease depends upon finding the organism in smears from the urethral or vaginal discharge. Treatment is with antibibtics.

Chancroid. Chancroid, a common venereal disease caused by *Haemophilus ducreyi*, first becomes evident two to 14 days after sexual intercourse, with the appearance of a small red papule, or pimple, on the genitals or surrounding skin. During the next few days a series of changes occur. Pus forms in the lesion; it then goes through a necrotic stage (death of tissue), followed by ulceration. Other lesions may develop. Identification of the disease is by examination of a smear, culture (growth of the organism in the laboratory), and skin test. Treatment is with antibiotics or sulfonamide drugs.

Other venereal diseases. Lymphogranuloma venereum, an infection with an organism of the group that cause psittacosis (parrot fever, or ornithosis) and the eye disease trachoma, inflames the lymph nodes and channels of the genitals and rectum, with eventual formation of fistulas (open channels) and scar tissue. It is treated with antibiotics, usually a tetracycline or chloramphenicol. Surgical treatment may also be required.

Granuloma inguinale, a slowly developing and relatively painless disease, causes scar tissue and ulcers in the skin and subcutaneous tissues of the genitalia and adjacent regions. The micro-organism responsible, ***Donovania granulomatis,*** is transmitted during sexual intercourse. Cure is usually effected by use of tetracyclines or chloramphenicol.

Types of puerperal infection

Nonvenereal infections. ***Puerperal infection.*** Puerperal infection, one of the commonest causes of death in childbearing, is an infection of a wound in the birth canal (usually in the endometrium, the lining of the uterus). The infection may be divided into two main categories: (1) local involvement of the vagina, cervix, endometrium, and adjacent tissues and (2) extensions of the original process to the veins, to the lymph vessels, to the membranes lining the abdomen, and to the uterine tubes. The vast majority of puerperal infections are caused by the ***Streptococcus,*** but any of a number of other organisms may be iesponsible. The treatment consists chiefly of antibiotics, supportive therapy, and, occasionally, surgical drainage of an abscess.

Tuberculosis. Tuberculosis of the reproductive system usually is brought from another part of the body by way of the bloodstream. In the male, the kidney and possibly the prostate are the primary sites of tuberculosis infection in the genitourinary tract, and from these sites the infection can invade the seminal vesicles, the epididymides, and the testes. Tuberculosis of the prostate and seminal vesicles may not cause any symptoms; the first indication of involvement of these organs is the onset of epididymitis — inflammation of the epididymides — with subsequent scrotal abscess and sinus formation. The diagnosis is made by finding the tuberculosis bacilli in urine or semen or by examining a specimen of tissue from the genitourinary tract. The semen has been known to infect the vagina.

In the female, the uterine tubes are usually first infected; then the endometrium, ovaries, **cervix,** and vulva.

The treatment in both sexes is basically medical and consists of the administration of antituberculotic drugs in various combinations for periods of up to at least two years. Surgical excision of an infected organ may also be necessary. The outlook is good with early diagnosis and treatment, except that sterility may possibly result.

Other infections. Balanitis, or inflammation of the glans penis, and posthitis, or infection of the prepuce, is usually caused by retention of secretions and bacteria beneath the foreskin.

Elephantiasis of the scrotum, a chronic disease caused by interruption of the lymphatic drainage of the scrotum, leads to massive hypertrophy (enlargement) of the skin and collection of fluid subcutaneously.

Prostatitis

Acute prostatitis is an inflammation of the prostatic tissue caused by bacterial invasion or by toxins produced by these bacteria. Infection is usually associated with inflammation of the posterior part of the urethra and the seminal vesicles. Chronic prostatitis can occur at any age but is probably the most common chronic infection in the reproductive system of men over 50 and usually follows acute inflammation of the prostate. Inflammation of the epididymis (epididymitis) is the most common disease of the scrotal contents and is commonly a sequel to prostatitis, the usual pathway of invasion being the vas deferens. Herpes progenitalis is a common lesion of the penis caused by a virus; it is manifested by groups of small blisters on the surface of the glans or prepuce along the pathway of the dorsal penile nerve. In the female, similar vesicles (blisters) may appear in the area of the vulva, and in many cases its occurrence coincides with the onset of menstruation.

Condylomata acuminata are soft, painless, cauliflower-like growths caused by a virus. They appear on the prepuce, glans penis, within the adjacent part of the urethra, and on the female perineum (the area between the external genitals and the anus). Other infections that occur in the genital organs of women include Bartholinitis, or inflammation of Bartholin's glands, near the opening of the vagina; trichomonas vaginitis, infection with the parasite *Trichomonas vaginalis*; and monilia vulvovaginitis, a common inflammation caused by the fungus ***Candida*** *albicans.*

STRUCTURAL CHANGES OF UNKNOWN CAUSES

In the female: endometriosis. Endometriosis, a disease occurring only during a woman's menstrual life, is the growth of endometrial tissue in an abnormal location. This may occur in the uterus or elsewhere. The most common location of the implants of endometrial tissue are the ovaries; other areas and organs affected (in order of incidence) are uterosacral ligaments (thickened portions of the sheet of connective tissue covering the pelvic organs), the rectovaginal septum (the membrane dividing the rectum from the vagina), the sigmoid colon (that portion of the large intestine that leads into the rectum), the lower genital tract, the round ligaments of the uterus, and the peritoneum (membrane) lining the pelvis. Characteristic symptoms associated with this disease include (1) progressive, severe pain associated with menstruation or occurring just before it; (2) dyspareunia (painful intercourse); (3) painful defecation; (4) slight bleeding before menstruation and excessive flow during menstruation; (5) painful urination and blood in the urine; and (6) infertility. The treatment includes suppression of ovulation by administration of hormones, and surgical treatment. Although endometriosis is a progressive disease in most instances, pain relief following conservative surgery (surgery that preserves ability to bear children) has occurred in an estimated 80 percent of patients, and 40–50 percent were able to become pregnant.

Symptoms of endometriosis

In the male: benign hypertrophy of the prostate. Benign prostatic hypertrophy, an overgrowth of normal glandular and muscular elements of the prostate gland, arises in the immediate vicinity of the urethra and is the most frequent cause of urinary obstruction. The enlarged prostate usually causes symptoms after the age of 50. If undetected, the obstruction may cause bladder and kidney damage. The diagnosis is made by rectal examination, excretory urography (X-raying the urinary tract while an opaque substance is being excreted in the urine), and cystourethroscopy (direct viewing of the bladder and urethra). Treatment is by surgical removal of the excess tissue. The prognosis is good if detection is early and treatment is given before the kidneys are damaged.

TUMOURS

In the male. ***External genitalia.*** Tumours of the penis are almost all of epithelial (covering or lining) origin and usually involve the foreskin or glans. Cancer of the penis (epithelioma) is rarely found in men who have been circumcised during infancy. The growth arises on the glans or inner surfaces of the prepuce, and metastases (secondary growths at distant parts) occur through lymph channels that lead to the inguinal (groin) and iliac nodes (nodes along the aorta and iliac arteries). The diagnosis is made by examination of a specimen of the lesion. Treatment for small lesions consists of surgical removal of a part of the penis or by X-ray therapy, while spread to inguinal nodes may be treated by removal of the node. The outlook is good if the cancer is small and there has been no metastasis.

Tumours of the scrotal skin are rare; most are thought to arise from occupational exposure to various carcinogens (cancer-causing substances), such as the soot in chimney sweeps' clothing. Primary tumours of the epididymis are also uncommon, and most are benign.

Testicular tumours. Testicular tumours are usually malignant; the peak incidence is between the ages of *20* and 40 years. This type of cancer accounts for about 0.5 percent of all malignant growths in men and about 4 percent of all tumours affecting the genitourinary tract. The great majority of testis tumours (greater than 95 percent) are of types that do not reproduce cells resembling those of the tissue of origin. The major route of metastases is via the lymphatics. The lymph nodes in the loins and the mediastinum—the region between the lungs—are most commonly involved, but the lungs and liver are also frequent sites of tumour spread. The remaining 5 percent of the testicular tumours, which usually resemble the cells from which they arise, include the hormone-secreting tumours. In general, these tumours have been described in all age groups, have usually been benign in behaviour, and have been most frequent in poorly developed or undescended testes.

The most common symptom first observed in all groups is painless enlargement of the testis. If, after careful examination, tumour cannot be ruled out, the testicle is removed for microscopic examination. Further treatment may consist of removal of the retroperitoneal lymph nodes (the lymph nodes in the region behind the peritoneum, the membrane lining the abdomen), X-ray therapy, or chemotherapy.

Carcinoma of the prostate. Carcinoma (cancer) of the prostate is rare before the age of 60 but increases in frequency every decade thereafter. It is the second most common cause of death from cancer in the male, second to cancer of the lung. In men over *60,* it is the commonest cause of cancer deaths. Like most tumours, prostatic cancer has no known cause, but it is clear that its growth is strikingly influenced by sex hormones or their withdrawal. Viruses may also play a role. The progress of the cancer is so slow that, by the time it produces symptoms of urinary obstruction, metastasis has occurred in many cases, most frequently to the spine, the pelvic bones, or the upper portions of the thigh bones. The diagnosis is made by finding cancer cells in a specimen of tissue taken from the prostate. Elevated levels of acid phosphatase (an enzyme of the prostate) are found in the blood (in *75* percent of cases) when the cancer has extended outside the prostate capsule and metastases are present.

Slow growth of prostate cancer

If the tumour is discovered before it has extended beyond the prostate, the gland is removed. If spread has occurred, various palliative measures offer the affected person much relief.

In the female. *Carcinoma of the vulva.* Primary carcinoma of the vulva (the external female genital organs) usually occurs in women over *50* and usually arises from the labia majora or labia minora. Most patients first notice a lump on the vulva or perineum; the diagnosis is made by examination of a specimen of tissues. Treatment consists of surgical removal of the vulva and of regional lymph nodes.

Cancer of the cervix of the uterus. Cancer of the cervix is the most common malignant tumour of the female genital tract; it is second only to cancer of the breast as a cause of death from cancer in women. The average age of occurrence for cancer of the cervix is the 45th year. The initial diagnosis is made by screening with such tests as those developed by Papanicolaou and Traut. (These consist of staining smears from vaginal and other secretions and examining them for cancer cells.) The final diagnosis rests on examining specimens of tissue from the cervix. Treatment now is usually irradiation instead of surgery because of the uncertainties of total surgical excision and the illness associated with extreme surgery. The prospect of five-year survival is as good as 85 percent if the cancers have not spread beyond the cervix.

Uterine fibromyomas. Uterine fibromyomas (fibroids) are the most frequent cause of enlargement of the uterus. They are most common in Negroes and in persons who have not borne children and are most often identified in women aged 30–45 years. New tumours do not originate after the menopause, and existing ones usually regress at that time but do not disappear. The tumours, which are benign, originate from the smooth muscle cells of the uterus wall and may be single but usually are multiple, pseudoencapsulated nodules. The symptoms are quite variable and depend largely on the location and size of the tumour. Excessive menstrual bleeding is often caused by fibroids. The diagnosis is tentatively made by pelvic examination and confirmed at surgery. Small asymptomatic fibromyomas need not be treated; the larger ones are dealt with by total or partial removal of the uterus or by irradiation.

Diagnosis of fibromas

Carcinoma of the body of the uterus. Cancer of the endometrium (the lining) of the body of the uterus is the second most common malignant tumour of the uterus and the female genital tract. The peak incidence is in the mid-50s, and there is also a strikingly high incidence in women who have not borne children. The chief symptom of the cancer is postmenopausal uterine bleeding. The Papanicolaou smear is not a reliable screening test, and an examination of a specimen of endometrial tissue must be performed. The treatment is primarily surgical but is often supplemented with preoperative intrauterine radium application or preliminary deep X-ray therapy to the pelvis. The survival rate from this disease is relatively good if the tumour is confined to the uterine body.

Ovarian tumours. No other organ in the body develops such a variety of tumours as does the ovary. The symptoms and signs may be due to the hormones secreted or may be only those of an enlarging mass in the pelvis. The final diagnosis is usually made at abdominal exploration. The treatment consists of surgery, X-ray therapy, or chemotherapy. The prognosis is variable and depends on the type of tumour that is present as well as the extent of metastatic spread.

Periodic pelvic and rectal examinations for both men and women, before any symptoms have occurred, would save almost all of those who now die from genital cancers.

BIBLIOGRAPHY. P.B. BEESON and W. MCDERMOTT (eds.), *Cecil-Loeb Textbook of Medicine,* 13th ed. (1971); and M.M. WINTROBE *et al.* (eds.), *Harrison's Principles of Internal Medicine,* 6th ed. (1970), are two excellent general textbooks of medicine that cover many of the subjects in this article in a short concise manner. "The Male Reproductive System" in *Christopher's Textbook of Surgery,* 9th ed. (1968), is one of the best summaries of the diseases of the male reproductive system. F.H. NETTER, *A Compilation of Paintings on the Normal and Pathological Anatomy of the Reproductive System* (1954), is one of the best books for anatomical illustrations on the reproductive system. M.F. CAMPBELL and J. HARTWELL HARRISON (eds.), *Urology,* 3rd ed., 3 vol. (1970), represents one of the most complete textbooks in the field of urology; D.R. SMITH, *General Urology,* 6th' ed. (1969), is well written and quite complete. D.D. FEDERMAN, *Abnormal Sexual Development* (1967), presents in complete detail all aspects of abnormal sexual development. E. STEWART TAYLOR, *Essentials of Gynecology,* 4th ed. (1969); and R.W. KISTNER, *Gynecology* (1964), cover the field of gynecology in detail; W.D. and D.W. BEACHMAN, *Synopsis of Gynecology,* 7th ed. (1967), is a good outline on female reproductive diseases. N.J. EASTMAN and L.M. HELLMAN (eds.), *Williams' Obstetrics,* 13th ed. (1966), is a classic in the field of obstetrics. R.H. WILLIAMS (ed.), *Textbook of Endocrinology,* 4th ed. (1968), covers in detail the endocrine aspects of the male and female reproductive systems.

(N.A.Ro./J.K.La.)

Reproductive Systems, Animal

The role of reproduction is to provide for the continued existence of a species; it is the process by which living organisms duplicate themselves. Animals compete with other individuals in the environment to maintain themselves for a period of time sufficient to enable them to produce tissue nonessential to their own survival, but indispensable to the maintenance of the species. The additional tissue, reproductive tissue, usually becomes separated from the individual to form a new, independent organism.

This article describes the reproductive systems in metazoans (multicelled animals) from sponges to mammals, exclusive of man. It focusses on the gonads (sex organs), associated ducts and glands, and adaptations that aid in the union of gametes—*i.e.*, reproductive cells, male or female, that are capable of producing a new individual by union with a gamete of the opposite sex. Brief mention is made of how the organism provides for the development of embryos and of the regulatory role of gonads in vertebrate cycles. (Human reproduction is treated in REPRODUCTIVE SYSTEM, HUMAN.)

This article is divided into the following major sections:

I. General features

Unlike most other organ systems, the reproductive systems of higher animals have not generally become more complex than those of lower forms. Asexual reproduction (*i.e.*, reproduction not involving the union of gametes), however, occurs only in the invertebrates, in which it is common, occurring in animals as highly evolved as the sea squirts, which are closely related to the vertebrates. Temporary gonads are common among lower animals; in higher animals, however, gonads are permanent organs. Hermaphroditism, in which one individual contains functional reproductive organs of both sexes, is common among lower invertebrates; yet separate sexes occur in such primitive animals as sponges, and hermaphroditism occurs in animals more highly evolved —*e.g.*, the lower fishes. Gonads located on or near the animal surface are common in the lowest invertebrates, but in higher animals they tend to be more deeply situated and often involve intricate duct systems. In echinoderms, which are among the highest invertebrates, the gonads hang directly into the sea and spill their gametes into the water. In protochordates, gametes are released into a stream of respiratory water that passes directly into the sea. Duct systems of the invertebrate flatworms (Platyhelminthes) are relatively complex, and those of specialized arthropods (*e.g.*, insects, spiders, crabs) are more complex than those of any vertebrate. Copulatory organs occur in flatworms, but copulatory organs are not ubiquitous among vertebrates other than reptiles and mammals. The trend toward fewer eggs and increased parental care in higher animals may account for the relative lack of complexity in the reproductive systems of some advanced forms. As trends toward increasing structural complexity have often been reversed during evolution, however, reproductive behaviour patterns in many phylogenetic (*i.e.*, evolutionary) lines have become more complicated in order to enhance the opportunity for fertilization of eggs and maximum survival of offspring (see SEX AND SEXUALITY).

A direct relationship exists between behaviour and the functional state of gonads. Reproductive behaviour induced principally but not exclusively by organic substances called hormones promotes the union of sperm (spermatozoa) and eggs, as well as any parental care accorded the young. There are a number of reasons why behaviour must be synchronized with gonadal activity. Chief among these are the following:

Synchronization of behaviour and gonadal activity

Individuals of a species must congregate at the time the gonads contain mature gametes. This often entails migration, and some members of all major vertebrate groups migrate long distances to gather at spawning grounds or rookeries.

Individuals with gametes ready to be shed must recognize members of the opposite sex. Recognition is sometimes by external appearance or by chemical substances (pheromones), but sex-linked behaviour is often the only signal.

Geographical territories frequently must be established and aggressively defended.

The building of nests, however simple, is essential reproductive behaviour in many species.

When fertilization of aquatic forms is external, sperm and eggs must be discharged at approximately the same time into the water, since gametes may be quickly dispersed by currents. Courtship, often involving highly intricate behaviour patterns, serves to release the gametes of both mating individuals simultaneously.

When fertilization is internal, willingness of the female to mate is often essential. Female mammals not in a state of willingness to mate not only will not mate but may injure or even kill an aggressive male. The unwillingness of a female mammal to mate when mature eggs are not present prevents loss of sperm needed to preserve the species.

Parental care of fertilized eggs by one parent or the other has evolved in many species. Parental behaviour includes fanning the water or air around the eggs, thereby maintaining appropriate temperature and oxygen levels; secretion of oxygen from a parent's gills; transport of eggs on or in the parental body (including the mouth of some male parents); and brooding, or incubation, of eggs.

Some species extend parental care into the postnatal period, feeding and protecting the offspring. Such behaviour patterns are adaptations for survival and thus are essential; all are induced by the nervous and endocrine systems and are typically cyclical, because gonadal activity is cyclical (see also REPRODUCTIVE BEHAVIOUR).

II. Reproductive systems of invertebrates

GONADS, ASSOCIATED STRUCTURES, AND PRODUCTS

Although asexual reproduction occurs in many invertebrate species, most reproduce sexually. The basic unit of sexual reproduction is a gamete (sperm or egg), produced by specialized tissues or organs called gonads. Sexual reproduction does not necessarily imply copulation or even a union of gametes. As might be expected of such a large and diverse group as the invertebrates, many variations have evolved to ensure survival of species. In many lower invertebrates, gonads are temporary organs; in higher forms, however, they are permanent. Some invertebrates have coexistent female and male gonads; in others the same gonad produces both sperm and eggs. Animals in which both sperm and eggs are produced by the same individual (hermaphroditism) are termed monoecious. In dioecious species, the sexes are separate. Generally, the male gonads ripen first in hermaphroditic animals (protandry); this tends to ensure cross-fertilization. Self-fertilization is normal, however, in many species, and some species undergo sex reversal.

Sponges, coelenterates, flatworms, and aschelminths. Sponges are at a cellular level of organization and thus do not have organs or even well-developed tissues; nevertheless, they produce sperm and eggs and also reproduce asexually. Some species of sponge are monoecious, others are dioecious. Sperm and eggs are formed by aggregations of cells called amoebocytes in the body wall; these are not considered gonads because of their origin and transitory nature.

In hydrozoan coelenterates, temporary gonads are formed by groups of cells in either the epidermis (outer cell layer) or gastrodermis (gut lining), depending on the

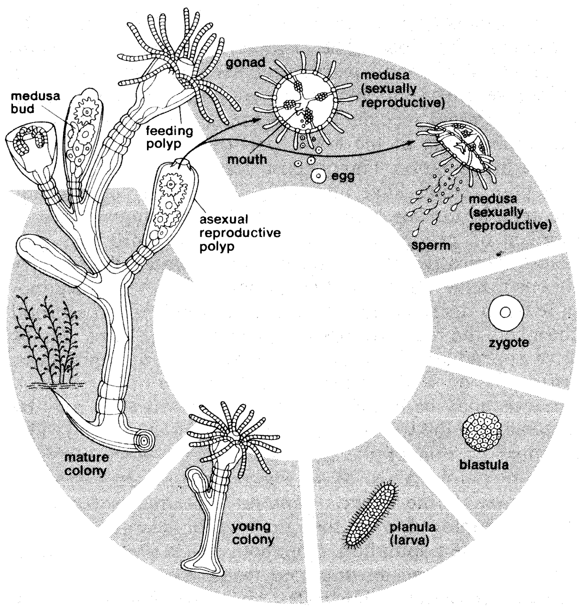

Figure 1: Life cycle of the colonial hydrozoan *Obelia*.

species; scyphozoan and anthozoan coelenterates generally have gonads in the gastrodermis. The origin and development of gonads in coelenterates, particularly freshwater species, are often associated with the seasons. Freshwater hydrozoans, for example, reproduce asexually until the onset of cold weather, which stimulates them to form testes and ovaries. Colonial hydrozoans asexually produce individuals known as polyps. Polyps, in turn, give rise to free swimming stages (medusae), in which gonads develop (Figure 1). The body organization of sponges and coelenterates is such that most of their cells are in intimate contact with the environment; consequently, gametes are shed into the water, and no ducts are necessary to convey them to the outside.

Polyps

In contrast to sponges and coelenterates, platyhelminths generally have well-developed organ systems of a permanent nature and, in addition, have evolved secondary reproductive structures to convey sex products. One exception is the acoels, a group of primitive turbellarians; they lack permanent gonads, and germinal cells develop from amoebocytes in much the same manner as in sponges. The majority of flatworms, however, are monoecious, the primary sex organs consisting of one or more ovaries and testes (Figure *2)*. The tube from the ovary to the outside is called the oviduct; it often has an outpocketing (seminal receptacle) for the storage of sperm received during copulation. In many species the oviduct receives a duct from yolk (vitelline) glands, whose cells nourish the fertilized egg. Beyond the entrance of the duct from the yolk glands the oviduct may be modified to secrete a protective capsule around the egg before it is discharged to the outside. The male organs consist of testes, from which extend numerous tubules (vasa efferentia) that unite to form a sperm duct (vas deferens); the latter becomes an ejaculatory duct through which sperm are released to the outside. The sperm duct may exhibit expanded areas that store sperm (seminal vesicles), and it may be surrounded by prostatic cells that contribute to the seminal fluid. The sperm duct eventually passes through a copulatory organ. The same basic structural pattern, somewhat modified, is found in most higher invertebrates.

Reproductive organs of nematodes

Aschelminthes (roundworms) are mostly dioecious; frequently there are external differences between males and females (sexual dimorphism). The males are generally smaller and often have copulatory spicules. Nematodes have relatively simple reproductive organs, a tubular testis or ovary being located at the end of a twisted tube. The portion of the female tract nearest the ovary forms a uterus for temporary storage of fertilized eggs. Some species lay eggs, but others retain the egg in the uterus until the larva hatches. The sperm are released into a cavity called the cloaca. A number of free-living nematodes are capable of sex reversal—if the sex ratio in a given population is not optimal or if environmental conditions are not ideal, the ratio of males to females can be altered. This sometimes results in intersexes; *i.e.*, females with some male characteristics. Hermaphroditism occurs in nematodes, and self-fertilization in such species is common. Unisexual reproduction among rotifers is described below (see Parthenogenesis).

Annelids and mollusks. Annelids have a well-developed body cavity (coelom), a part of the lining of which gives rise to gonads. In some annelids, gonads occur in several successive body segments. This is true, for example, in polychaetes, most of which are dioecious. Testes and ovaries usually develop, though not invariably, in many body segments; and the sperm and eggs, often in enormous numbers, are stored in the coelom. Fertilization is external. In oligochaetes (all of which are monoecious) on the other hand, the gonads develop in a few specific segments. Sperm are stored in a seminal vesicle and eggs in an egg sac, rather than in the coelom. A portion of the peritoneum, the membrane lining the coelom, becomes a saclike seminal receptacle that stores sperm received from the mate. The earthworm, *Lumbricus* terrestris, is an example of a specialized annelid reproductive system. Female organs consist of a pair of ovaries in segment 13; a pair of oviducts that open via a ciliated funnel (*i.e.*, with hairlike structures) into segment 13 but open to the exterior in segment 14; an egg sac near each funnel; and a pair of seminal receptacles in segment 9 and another in segment 10. Male organs consist of two pairs of minute testes in segments 10 and 11, each associated with a ciliated sperm funnel leading to a tiny duct, the vas efferens. The two ducts on each side lead to a vas deferens that opens in segment 15. Testes and funnels are contained within two of three pairs of large seminal vesicles that occupy six body segments.

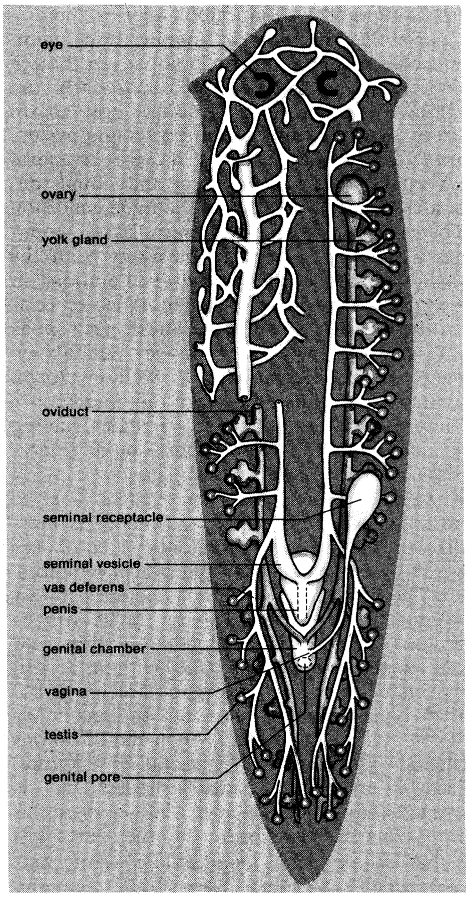

Figure 2: Reproductive system of a planarian flatworm, a monoecious animal.

Leeches (Hirudinea), also monoecious, have one pair of ovaries and a segmentally arranged series of testes with duct systems basically similar to those of earthworms.

Differences between mollusk and annelid systems

Although mollusks have a close evolutionary kinship to annelids, they have reduced or lost many structures characteristic of segmented worms. The coelom persists only as three regional cavities: gonadal, nephridial (kidney), and pericardial (heart). In ancestral forms these were interconnected so'that gametes from the gonad passed through the pericardial cavity, the nephridial cavity, then to the outside through a nephridial pore. The various groups of mollusks have tended to modify this arrangement, with the result that gonads have their own pore; among amphineurans, for example, the sexes are usually separate, and there is one gonad with an associated pore. Gastropods show considerable variability, but generally one gonad (ovary, testis, or ovotestis—a structure combining the functional gonads of both sexes) is located in the visceral hump and connected to the outside by a remnant of the right kidney. In hermaphroditic forms, one duct carries sperm as well as eggs. The gonadal ducts of gastropod females often secrete a protective capsule around the fertilized eggs; in males, the terminal portion of the duct is sometimes contained in a copulatory organ. Pelecypods may be either monoecious or dioecious, but the gonads are usually paired. In mussels and oysters, the gonads open through the nephridial pore, but in clams the reproductive system opens independently. The cephalopods are all dioecious. The single testis or ovary releases its products into the pericardiai cavity and this, in turn, leads to a gonopore, the external opening. The oviduct of the squid is terminally modified to form a shell gland. The male system is more complex—the gonoduct leads into a seminal vesicle where a complicated torpedo-shaped sperm case (spermatophore) is secreted and contains the sperm. Spermatophores are then stored in a special structure (Needham's sac) until copulation occurs.

A remarkable characteristic of some mollusks is the ability to alter their sex. Some species are clearly dioecious; however, among the monoecious species there is considerable variability in their hermaphroditic condition. In some species, male and female gonads, although in the same individual, are independent functionally and structurally. In others, an ovotestis produces both sperm and eggs. Oysters display a third condition; young oysters have a tendency toward maleness, but, if water temperature or food availability is altered, some individuals develop into females. Later, a reversal to the male condition may occur. The sexual makeup of an entire oyster population also has a seasonal aspect; in harmony with the group, an individual may undergo several alterations in the course of a year. A similar phenomenon, called consecutive sexuality, occurs in limpets. These gastropods stack themselves in piles, with the younger animals on top. The animals on top are males with well-developed testes and copulatory organs; those in the middle are hermaphroditic; those on the bottom are females, having lost the testes and copulatory organ (penis) by degeneration. A decrease in the number of females in a stack induces males to assume female characteristics, but the transition is retarded when an excess of females is present. The degree of maleness or femaleness is probably controlled in part by environmental and internal factors.

Arthropods. The phylum Arthropoda includes a vast number of organisms of great diversity. Most arthropods are dioecious, but many are hermaphroditic, and some reproduce parthenogenetically (*i.e.*, without fertilization). The primary reproductive organs are much the same as in other higher invertebrates, but the secondary structures are often greatly modified. Such modifications depend on whether fertilization is internal or external, whether the egg or zygote (*i.e.*, the fertilized egg) is retained or immediately released, and whether eggs are provided some means of protection after they have left the body of the female. The mandibulate arthropods (*e.g.*, crustaceans, insects) include more species than any other group and have invaded most habitats, a fact reflected in their reproductive processes.

Crustaceans (*e.g.*, crabs, crayfish, barnacles) are for the most part dioecious. The primary reproductive organs generally consist of paired gonads that open through paired ventral (bottom side) gonopores. Females often have a seminal receptacle (spermatheca) in the form of an outpocketing of the lower part of the female tract or as an invagination (inpocketing) of the body near the gonopore. Males have appendages modified for clasping the female during copulation or for guiding sperm.. A number of groups have members that reproduce parthenogenetically. Branchiopods (*e.g.*, water fleas, fairy shrimp) have simple paired gonads. The female gonopore often opens dorsally (on the back side) into a brood chamber; the male gonopore opens near the anus. Males have appendages for clasping females during copulation. Ostracods, or seed shrimp, have paired, tubular gonads. The eggs may be brooded by the female, or they may be released into the water via a gonoduct aad gonopore. The terminal portion of the male gonoduct is enclosed in a single or paired penis. Many species reproduce parthenogenetically. Some experts contend that this is the only method employed, even though functional males may be present in the population. Copepods (*e.g.*, ***Cyclops)*** have paired ovaries and an unpaired testis. The terminal portion of the oviduct constitutes an ovisac for storage of eggs. The male deposits sperm in a spermatophore that is transferred to the female. Sexual dimorphism is particularly evident among parasitic copepods. Frequently, parasitic females can hardly be recognized as copepods except for the distinctive ovisacs. Males, on the other hand, are free-living and are recognizable as copepods.

Reproductive variation among arthropod groups

The hermaphroditic Cirripedia (*e.g.*, barnacles) are among the exceptions to the generalization that crustaceans are dioecious. It has been suggested that hermaphroditism in barnacles is an adaptation to their sessile, or stationary, existence, but cross-fertilization is more common than self-fertilization. The ovaries lie either in the base or in the stalk of the animal, and the female gonopore is near the base of the first pair of middle appendages (cirri). The testes empty into a seminal vesicle through a series of ducts; from the vesicle extends a long sperm duct within a penis that may be extended to deposit sperm in the mantle cavity of an adjacent barnacle. The terminal portion of the oviduct secretes a substance that forms a kind of ovisac within the mantle cavity, where fertilized eggs undergo early development. Although most barnacles are hermaphrodites, some display a peculiar adaptation in that they contain parasitic dwarf or accessory males. Dwarf males are much smaller than the host barnacle in which they live and are degenerate, except for the testes. In some species they live in the mantle cavity of hermaphroditic forms and produce accessory sperm; in other species only the female organs persist in the host animal, and the accessory male is a necessity.

Amphipods and isopods (*e.g,* pill bugs, sow bugs), like most crustaceans, are dioecious and have paired gonads. Females of both groups have a ventral brood chamber (marsupium) formed by a series of medially directed (*i.e.*, toward the body midline) plates (oostegites) in the region of the thorax, the region between head and abdomen. Many isopods are parasitic and have developed unusual sex-related activities. Certain species are parasitic on other crustaceans. After a series of molts (*i.e.*, shedding of the body covering) a parasitic larval (immature) isopod attaches to the shell of a crab. If it is the only larva to do so, it increases in size and develops into an adult female. If another larva subsequently attaches, the new arrival becomes a male. It has been demonstrated that the testes of the functioning male larva will change to ovaries if the larva is removed to a new, uninfected host. Thus, the larvae of these species apparently are intersexual and can develop into either sex. This phenomenon, reminiscent of that in mollusks, demonstrates the way in which similar adaptations have evolved in diverse groups of organisms.

The gonads of crabs and lobsters are paired, as are the gonopores. The females of many species have external seminal receptacles on the ventral part of the thorax;

those of other species have internal receptacles in the same region. In some species, seminal receptacles are absent, and the male simply attaches a spermatophore to the female. Thus, males either have appendages (gonopods) by which sperm are inserted in the body of the female or produce spermatophores for sperm transfer. The sexual dimorphism of many decapods can be altered by parasitism. An example of this is the crab that is parasitized by a barnacle. A barnacle infection in male crabs induces the secondary sex characters of the crab to resemble those of a female; however, masculinization does not occur in parasitized females. At each molt a parasitized male crab increasingly resembles a female even though the testes may be completely unaffected. Feminization results from a hormonal alteration of the parasitized crab.

Parthenogenesis in insects

Insects are rarely hermaphroditic, but many species reproduce parthenogenetically (without fertilization). The insect ovary is composed of clusters of tubules (ovarioles) with no lumen, or cavity (Figure 3). The upper portion of each ovariole gives rise to oocytes (immature eggs) that mature and are nourished by yolk from the lower portion. The oviduct leads to a genital chamber (copulatory bursa, or vagina), with which are often associated accessory glands and a seminal receptacle. Some accessory glands form secretions by which eggs become attached to a hard surface; others secrete a protective envelope around the egg. The eighth and ninth body segments are often modified for egg-laying. The paired testes consist of a series of seminal tubules that form primary spermatogonia (immature spermatozoa) at their upper ends. As the spermatogonia mature a covering is secreted around them. Eventually they enter a storage area (seminal vesicle). The terminal portion of the male system is an ejaculatory duct that passes through a copulatory organ. A pair of accessory glands, often associated with the ejaculatory duct, contributes to the semen (fluid containing sperm) or participates in spermatophore formation. The ninth body segment and sometimes the tenth bear appendages for sperm transfer. Scorpions and spiders have tubular or saclike gonads; the female system is equipped to receive and store sperm, and, in some species, the female retains the eggs long after fertilization has occurred. Male spiders may have a cluster of accessory glands associated with the terminal portion of the reproductive system for the manufacture of spermatophores, or they may have expanded seminal vesicles for the retention of sperm until copulation takes place. Often specific appendages are adapted for sperm transfer.

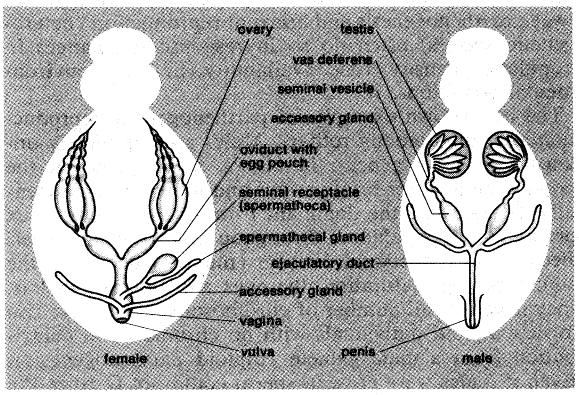

Figure 3: Reproductive organs of insects.

Echinoderms and protochordates. Echinoderms (*e.g.*, sea urchins), hemichordates (including acornworms), urochordates (*e.g.*, sea squirts), and cephalochordates (amphioxus) are restricted to a marine habitat. As with many other marine animals, their gametes are shed into the water. In echinoderms, the gonads are generally suspended from the arms directly into the sea; with few exceptions, the sexes are separate. Female starfishes have been known to release as many as 2,500,000 eggs in two hours; 200,000,000 may be shed in a season. Males produce many times that number of sperm. Acornworms reproduce only sexually, and the sexes are generally separate. The gonads lie on each side of the gut as a paired series of simple or lobed sacs. Each opens to the exterior, either directly or via a short duct. The eggs, when shed, are in coiled mucous masses, each of which contains 2,500 to 3,000 eggs.

Gonads in urochordates and cephalochordates

In urochordates and cephalochordates the gonads develop in the wall of a cavity (atrium) that receives respiratory water after it passes over the gills. Gametes are released into the cavity, then carried into the sea by the water flowing from the cavity. Most urochordates are hermaphroditic. One ovary and one testis may lie side by side, each with its own duct to the atrium; some species have many pairs of ovaries and testes. The eggs develop in so-called ovarian follicles consisting of two layers of cells, as in many vertebrates. The inner layer remains with the ovulated, or shed, egg, and the cells become filled with air spaces, which apparently help the eggs to float. Amphioxus, the highest animals lacking vertebral columns, are dioecious. They have 24 or more pairs of ovaries or testes lacking ducts. When ripe, the gonads rupture, spilling their gametes directly into the atrium.

MECHANISMS THAT AID IN THE UNION OF GAMETES

Sponges, coelenterates, flatworms, and aschelminthes. The processes of sperm transfer and fertilization have been documented for only a few species of sponges. Flagellated (*i.e.*, bearing a whiplike strand) sperm are released from the male gonad and swept out of the body and into the water by way of an elaborate system of canals. A sperm that enters another sponge, or the one from which it was released, is captured by a flagellated collar cell (choanocyte). The choanocyte completely engulfs the sperm, loses its collar and flagellum (or "whip"), and migrates to deeper tissue where the egg has matured. The choanocyte containing the sperm cell fuses with the egg, thus achieving fertilization. In freshwater coelenterates, sperm are also released into the water and carried by currents to another individual. Unlike the mechanism in sponges, however, coelenterate eggs arise in the epidermis, or surface tissue, and are exposed to sperm that may be nearby in the water; thus, no intermediate transport cell is needed. Many species of marine coelenterates expel both sperm and eggs into the water, and fertilization takes place there. Some medusoid coelenterates (jellyfish), however, offer some protection to the egg. After leaving the gonad, the egg becomes temporarily lodged in the epidermis on the underside of the organism, where fertilization and early development occur.

In all flatworms, fertilization is internal. Among species with no female duct, sperm are injected, and fertilization occurs in the inner layer of tissue. Most flatworms, however, have an elaborate system of male and female ducts. Generally, the male gonoduct passes through a penis-like organ, and sperm are transferred during copulation. In parasitic species, which often cannot find a mate, self-fertilization serves as the means for reproduction. Sperm and ova unite in the oviduct, which then secretes yolk around the zygote.

Male nematodes (roundworms) are usually equipped with a pair of copulatory structures (spicules) that guide the sperm during copulation. The posterior end of some males also exhibits a lateral (sideward) expansion (copulatory bursa) that clasps the female during copulation. Other males loop their tail around the female in the region of her gonopore. Unlike many other aschelminthes, nematodes have sperm cells that are amoeboid; *i.e.*, their cell contents seem to flow. Some male rotifers have a copulatory organ.

Annelids and mollusks. In some species of annelid polychaetes (marine worms) reproductive activity is synchronized with lunar cycles. At breeding time the body of both sexes differentiates into two regions, an anterior atoke and a posterior epitoke, in which gonads develop. When the moon is in a specific phase, the epitoke separates from the rest of the body and swims to the surface. The female epitoke apparently stimulates the male epitoke to release sperm, and sperm release, in turn, evokes expulsion of eggs. Fertilization is external. So well coordinated is this phenomenon that tremendous numbers of epitokes appear on the surface at about the same time.

Sexually mature oligochaetes have a clitellum, which is a modification of a section of the body wall consisting of a glandular, saddlelike thickening near the gonopores. During copulation, the clitellum secretes a mucus that keeps the worms paired while sperm are being exchanged. Following copulation, the clitellum secretes substance for a cocoon, which encircles the worm and into which eggs and sperm are deposited. The worm then manipulates the cocoon until it slips off over the head. Thereupon, the ends of the cocoon become sealed, and fertilization and development take place inside. Many leeches also form a cocoon; but the males of some species have a penis that can be inserted into the female gonopore. In other leeches, a spermatophore is thrust into the body of the mate during copulation.

Union of gametes among mollusks is effected in a number of ways. Marine pelecypods synchronously discharge sperm and eggs into the sea; some freshwater clams are apparently self-fertilizing. One of the more unusual types of reproductive diversity occurs in marine gastropods of the family Scalidae that produce two kinds of sperm cells. A large sperm with a degenerate nucleus acts as a transport cell for carrying numerous small fertilizing sperm through the water and into the oviduct of another individual. Cephalopod males have modified arms for the transfer of spermatophores. The right or left fourth arm of the squid, for example, is so modified. Following an often elaborate courtship, the male squid uses the modified appendage to remove spermatophores from their storage place in his body and place them in the mantle cavity of the female. A cementing substance, which is released from the spermatophore, firmly attaches the spermatophore to the female's body near the oviduct. In some species, the male loses the arm. Manipulation of the eggs by the female's arms may also occur.

Sexual behaviour among mollusks

Some unusual behaviour patterns have evolved in conjunction with sperm transfer in mollusks. Prior to copulation of certain land snails, a dart composed of calcium carbonate is propelled forcefully from the gonopore of each of the mating individuals and lodges in the viscera of the mate. Even though the snails have assumed a mating posture, sperm transfer cannot occur until each snail has been stimulated by a dart.

Arthropods. Arthropods are as varied as mollusks in their methods of effecting union of sperm and eggs. They have relatively few devices for sperm transfer, but many display a high degree of behavioral complexity.

The male and female scorpion participate in a courtship ritual involving complicated manoeuvres. In some species the male produces spermatophores that are anchored to the ground. In the course of the ritual dance the female is positioned over the spermatophore. The male then presses her down until the sperm packet is forced into her genital chamber, where it becomes attached by means of small hooks. Thus, ultimately, fertilization takes place internally.

Among some spiders the male's pedipalp, a grasping or crushing appendage, contains a bulb and an extensible, coiled structure (embolus). As mating begins, the male dips the pedipalp into semen from his gonopore. The embolus is then placed in the female gonopore, and the sperm are transferred to her seminal receptacle. The female deposits the sperm along with her eggs into a silken cocoon, which she attaches to her body or to an object such as a rock or a leaf.

Sperm transfer in copepods, isopods, and many decapods, often preceded by courtship, is effected by modified appendages, gonopods, or spermatophores. Copepods clasp the female with their antennae while placing a spermatophore at the opening of the seminal receptacle. In some decapods fertilization occurs as eggs are being released into the water.

Fertilization among insects is always internal; there is much variation in the manner in which sperm are transferred to the female. Males of some species form spermatophores that are deposited in a copulatory bursa (vagina) of the female; the wall of the spermatophore breaks down, and the sperm swim to the seminal receptacle. In other species, sperm are introduced directly into the seminal receptacle by an intromittent organ. In still others, sperm, but no spermatophores, are deposited in the copulatory bursa and migrate to the seminal receptacle. In all instances, sperm are retained in the seminal receptacle until after fertilization. An exception to the usual route of sperm transfer occurs in insects that inject sperm into the female's hemocoel (*i.e.*, the space between the body organs). The sperm then migrate to the ovary and oviduct and unite with eggs before the eggshell is formed.

PARTHENOGENESIS

Most frequently, parthenogenesis is the development of a new individual from an unfertilized gamete. Often referred to as unisexual reproduction, it has been observed in almost every major invertebrate group, with the exception of protochordates (including hemichordates), and frequently occurs alternately with bisexual reproduction (reproduction by union of gametes). Some species, in which males are completely unknown, apparently reproduce only by parthenogenesis. Species that alternate between parthenogenesis and bisexual reproduction (heterogenetic species) often do so in response to changes in population density, food availability, or other environmental conditions.

Examples of parthenogenetic reproduction

The best known examples of parthenogenetic reproduction are found among rotifers. Males are completely unknown in some genera; in others, they appear in the population only for brief periods and more or less seasonally. Females are the dominant form or are the only sex present in a population throughout most of the year. Because no reductional division (meiosis) occurs in the course of egg maturation, the eggs are diploid—that is, they have the full number of chromosomes; they give rise to new diploid individuals with no chromosomal contribution from a male gamete (diploid parthenogenesis). Even if males were present, sperm could not fertilize the eggs because the latter are already diploid. Under conditions of environmental stress such as seasonal changes, some females form eggs that undergo reductional division, resulting in eggs with the haploid number of chromosomes; such eggs must be fertilized by a male gamete to produce a new female. When the new individual matures, it will probably reproduce parthenogenetically. If, however, there are no males in the population, the haploid eggs can develop into haploid males (haploid parthenogenesis), which then participate in bisexual reproduction. Bisexually produced eggs are often referred to as winter eggs since they have a thick covering that protects the embryo during adverse environmental conditions. Summer eggs, produced parthenogenetically, are thin shelled. Bisexual reproduction occurs, therefore, only often enough to ensure survival of the species.

Nematodes, especially free-living species such as some dioecious soil nematodes, exhibit a type of parthenogenesis known as gynogenesis. In this type of reproduction, the sperm produced by males do not unite with the haploid female egg but merely activate it to begin development. The result is haploid females.

Parthenogenesis, which apparently occurs only rarely in the annelids and mollusks, is found more frequently among the arthropods. The cladocerans (*e.g.*, water fleas), for example, have a reproductive cycle much like that of rotifers—so long as environmental conditions are optimal and food is plentiful, females produce other females by diploid parthenogenesis. When conditions become adverse, males begin to appear in the population, and bisexual reproduction follows. The precise trigger for the appearance of males is not yet known. Fertilized eggs, covered with a highly resistant case, enter a resting stage (ephippium) and can withstand severe temperatures and drying out. The return of favourable conditions leads to the emergence of females that reproduce parthenogenetically. The ability to form a resting stage regulates population density. Whenever the food supply becomes short because of overpopulation by parthenogenetic females, bisexual reproduction is induced, and a dormant stage ensues. During periods of food shortage, the excess females die from lack of food, but the ephippia remain to restore the population.

Insects provide numerous examples of parthenogenesis of varying degrees of complexity. One of the most notable is that of the honeybee. Unfertilized eggs develop into drones, which are males. Fertilized eggs become worker females, which are kept in a nonreproductive state by secretions from the reproductive female, the queen bee.

Life cycles involving alternation between parthenogenesis and bisexual reproduction can be found in many species of Homoptera and Diptera (flies). Aphids (Homoptera) have a seasonal cycle consisting of a bisexual winter phase and a parthenogenetic summer phase; some species spend each phase on a different host plant. Temperature change, length of day, and food availability play major roles in initiating the phases. In the midge, a type of fly, the bisexual phase occurs in adults, and parthenogenesis takes place among the larvae (paedogenesis). Adult female midges deposit fertilized eggs, from which hatch larvae whose ovaries develop while the rest of the body retains a larval form. The ovaries of the larvae release eggs that enter the larval hemocoel (the space between body organs), where they undergo development while feeding on larval tissue. When sufficiently developed, the parthenogenetically produced young emerge either as larvae that continue parthenogenetic reproduction, forming larvae like themselves, or as male or female larvae that mature to become bisexually reproducing adults.

PROVISIONS FOR THE DEVELOPING EMBRYO

Differences in amount of yolk

Invertebrates have developed a great many methods for protecting the fertilized egg and young embryo and for providing nutrients for the developing young. This is especially true of freshwater and terrestrial forms. Sponges and freshwater coelenterates, exposed to seasonal drying out, provide a tough covering for the eggs that prevents water loss. Many turbellarians envelop the eggs with a capsule and attach it to a hard surface, where it remains until the young emerge. Other turbellarians retain encapsulated eggs in the body until development is complete and the young emerge. All parasitic flatworms enclose their eggs in a protective capsule within which development occurs after it has left the parent's body. Most nematodes and rotifers do likewise, but a few species are ovoviviparous; *i.e.*, the egg hatches in the mother's body. In many forms the amount of yolk provided in the egg and the nature of the egg capsule are correlated with annual seasons—summer eggs generally have less yolk and thinner capsules than do winter eggs. This is true also in a number of crustaceans. Freshwater and terrestrial annelids provide a cocoon for their young and often deposit it in a moist place. One group of leeches, however, does not form a cocoon; instead, the egg, surrounded by a protective membrane, is attached to the underside of the parent. As the young develop, the adult leech undulates its body so that water currents flow over the young. Presumably this serves as a means of aeration. Mollusks that live in freshwater may provide a protective covering for the eggs, or the eggs may be brooded by the female. Some pelecypods (bivalves) release mature eggs into their gill chambers; here the eggs are fertilized, and embryonic development is completed in a protected location. Cephalopods (*e.g.*, squid, octopus) attach the eggs to a surface, then continuously force jets of water over the egg masses, thereby keeping them free of debris and perhaps aerating them. Some echinoderms also brood the eggs until the young emerge.

Arthropods have a particularly wide range of methods for ensuring offspring survival. Brood pouches, common in branchiopods, isopods, and amphipods, are sometimes part of the carapace, or back plate. In other instances, expanded plates on the lower side (sternum) form the pouches. Crayfish cement the fertilized eggs to their swimmerets (modified appendages) and carry them about as they are brooded by the female. The most elaborate provisions for the embryo are found among terrestrial arthropods, especially insects. Although some species simply deposit their eggs and abandon them, many retain the encapsulated egg within the body during early development. Some are viviparous; that is, they Gear living young. The eggs of certain species of scorpions have little or no yolk; the embryo is nourished by the parent in a manner similar to that in mammals—part of the scorpion oviduct becomes modified as a uterus for the embryo; another part lies close to the female's gut and absorbs nutritive substances that are conveyed to the developing young. A similar arrangement has evolved in some insects. Other viviparous insects nourish the larvae ky glandular secretions from the uterine lining.

III. Reproductive systems of vertebrates

GONADS, ASSOCIATED STRUCTURES, AND PRODUCTS

The reproductive organs of vertebrates consist of gonads and associated ducts and glands. In addition, some vertebrates, including some of the more primitive fishes, have organs for sperm transfer or ovipository (egg-laying) organs. Gonads produce the gametes and hormones essential for reproduction. Associated ducts and glands store and transport the gametes and secrete necessary substances. In addition to these structures, most male and female vertebrates have a cloaca, a cavity that serves as a common terminal chamber for the digestive, urinary, and reproductive tracts and empties to the outside. In lampreys and most ray-finned fishes in which the cloaca is small or absent, the alimentary canal has a separate external opening, the anus. In some teleosts the alimentary, genital, and urinary tracts open independently. Hagfishes, which are closely related to the lampreys, have a short cloaca. In many vertebrates other than mammals, especially reptiles and birds, the cephalic, or head, end of the cloaca is partitioned by folds into a urinogenital chamber (urodeum) and an alimentary chamber (coprodeum) that open into a common terminal chamber (proctodeum). Above monotremes (*e.g.*, platypus, echidna) the embryonic cloaca becomes completely partitioned into a urinogenital sinus conveying urine and the products of the gonads, and an alimentary pathway; the two open independently to the exterior.

Embryonic development of gonads

Gonads arise as a pair of longitudinal thickenings of the coelomic epithelium and underlying mesenchyme (unspecialized tissue) on either side of the attachment of a supporting membrane, the dorsal mesentery, to the body wall. At first, gonadal ridges bulge into the coelom and are continuous with the embryonic kidney. The germinal epithelium covering the gonadal ridges gives rise to primary sex cords (medullary cords) that invade the underlying mesenchyme. These cords establish within the gonadal blastema (a tissue mass that gives rise to an organ) a potentially male component, the medulla. Secondary sex cords grow inward, spreading just beneath the germinal epithelium to form a cortex. If the gonad is to become a testis, only the medullary component differentiates. If the gonad is to become an ovary, only the cortex differentiates (see DEVELOPMENT, ANIMAL).

The length of an adult gonad depends, in part, upon the extent of gonadal-ridge differentiation. In cyclostomes (lampreys and hagfish), elasmobranchs (sharks, skates, and rays), and teleosts most of it differentiates, and the gonads extend nearly the length of the body trunk. In tetrapods (amphibians, reptiles, birds, and mammals), the cranial portion, at the anterior end, generally does not differentiate; in toads only the more caudal, or posterior, portion does so. The middle segment in toads of both sexes gives rise to a Bidder's organ containing immature eggs. In anurans (frogs and toads) and some lizards of both sexes, one segment of the gonadal ridge gives rise to yellow fat bodies that, especially in anurans, diminish in size just prior to the breeding season. In mammals, only the middle portion of the gonadal ridge differentiates.

Some vertebrate species have only one gonad, which may lie in the midline or on one side; the condition is more common among females. Adult cyclostomes of both sexes have one gonad. In lampreys it is in the middle of the body; in hagfishes it is on the right side. Birds are the only other major group of vertebrates in which most females have one gonad, the right ovary being typically absent. Male birds have a pair of testes, however. Exceptions to the condition of single ovaries among birds include members of the falcon family, in which more than 50 percent of mature hawks have two well-developed ovaries. In all bird species a small percentage of females probably have two ovaries; reported instances include owls, parrots, sparrows, and doves, with estimates for doves ranging from 5 percent to 25 percent. A few teleosts and viviparous elasmobranchs have only one ovary; in sharks the right one is usually present, in rays, the left. In amniotes (*i.e.*, reptiles, birds, and mammals) unpaired gonads are unusual. Some lizards have one testis, and some female crocodiles have one ovary. Among mammals, the platypus usually has only a left ovary, and some bat species (family Vespertilionidae) have only the right.

Theories about unpaired gonads

One of two explanations may account for unpaired gonads: the paired embryonic gonadal ridges may fuse to form a median gonad—as in lampreys and the perch--or only one gonadal ridge may receive immigrating primordial germ cells (immature sperm or eggs), with the result that the opposite gonad does not develop—as in chickens and ducks. Both gonadal ridges have been reported to exhibit an equal number of primordial germ cells in embryonic hawks, and these typically have two ovaries.

Among lower vertebrates, mature gonads sometimes produce both sperm and eggs. Hermaphroditism is more general in cyclostomes and teleosts than in other fishes. A teleost may function as a male during the early part of its sexual life and as a female later. In some teleost families sperm and eggs mature simultaneously but in different regions of the gonad. These fish normally function as males during one season and as females the next. Cyclostomes generally are ambisexual during juvenile life—*i.e.*, immature male and female sex cells exist side by side, or, as in *Myxine*, the anterior part of the immature gonad may be ovary and the caudal part, the testis. It is thought that cyclostomes normally become unisexual at maturity. Hermaphroditism is uncommon among amphibians, although it frequently occurs as an anomaly. In vertebrates above amphibians, true hermaphroditism probably does not exist.

Both male and female duct systems are occasionally absent. In cyclostomes, a few elasmobranchs, and some teleosts, such as salmon, trout, and eels, the gametes are propelled toward the posterior within the coelom, often by cilia (minute hairlike structures), and exit via a pair of funnel-like genital pores near the base of the tail. In cyclostomes, the pores lead to a sinus, or cavity, within a median papilla (*i.e.*, a fingerlike structure) and are open only during breeding seasons.

Seminiferous tubules

Male systems. Testes. In anurans, amniotes (reptiles, birds, and mammals), and even some teleosts, testes are composed largely of seminiferous tubules--coiled tubes, the walls of which contain cells that produce sperm—and are surrounded by a capsule, the tunica albuginea. Seminiferous tubules may constitute up to 90 percent of the testis. The tubule walls consist of a multilayered germinal epithelium containing spermatogenic cells and Sertoli cells, nutritive cells that have the heads of maturing sperm embedded in them. Seminiferous tubules may begin blindly at the tunic, or outermost tissue layer, and pass toward the centre, becoming tortuous before emptying into a system of collecting tubules, the rete testis. Such an arrangement is characteristic of frogs. In certain amniotes—the rat, for example—the tubules may be open ended, running a zigzag course from the rete to the periphery and back again. The average length of such tubules is 30 centimetres (12 inches), and they seldom communicate with each other. In many mammals the tubules are grouped into lobules separated by connective-tissue septa, or walls. The arrangement permits the packing of an extensive amount of germinal epithelium into a small space. In immature males and in adult males between breeding seasons, the tubules are inconspicuous and the epithelium is inactive; in some species, however, spermatogenesis, or production of sperm, proceeds at a variable pace throughout the year. An active epithelium may exhibit all stages of developing sperm. The lumen, or tubule cavity, contains the tails of many sperm (the heads of which are embedded in Sertoli cells), free sperm, and fluid that is probably resorbed. In mammals, in any single zone along a tubule, all sperm are at the same stage of maturation; adjacent zones contain different generations of sperm, and a period of sperm formation and discharge is followed by an interval of inactivity.

In cyclostomes, most fishes, and tailed amphibians the germinal epithelium is arranged differently. Instead of seminiferous tubules there are large numbers of spermatogonial cysts (also called spermatocysts, sperm follicles, ampullae, crypts, sacs, acini, and capsules) in which sperm develop, but in which the epithelium is not germinal. Spermatogenic cells migrate into the cysts from a permanent germinal layer, which, depending on the species, may lie among cysts at the periphery of the testes or in a ridge along one margin of the testis. After invading the thin nongerminal epithelium of a cyst, spermatogenic cells multiply, producing enormous numbers of sperm. The cysts become greatly swollen and whitish in colour; the entire testis also swells and has a granular appearance. As sperm mature, they separate from the epithelium and move freely in the cystic fluid. Finally, the cysts burst, and the sperm are shed into ducts. In the case of cyclostomes and a few teleosts the sperm are shed into the coelom. The cysts, totally emptied, collapse. Then either they are replaced by new ones, or they become repopulated by additional spermatogenic cells. It is not yet known which of these processes occurs.

Testicular stroma, which fills the spaces between seminiferous tubules or spermatogenic cysts, consists chiefly of connective tissue, blood and lymphatic vessels, and nerves; it is more abundant in some vertebrates than in others. Leydig (interstitial) cells, which are undifferentiated connective-tissue cells, are also present in most, if not all, vertebrates. Thought to be a primary source of androgens, or male hormones, Leydig cells are not always readily distinguishable, and, in some bird species, they may be seen only with the electron microscope. The capillary system of the rat testis, and probably that of many other vertebrates, is such that blood that has bathed the Leydig cells flows to the tubules; it is thus probable that Leydig cell hormones have an immediate effect on the germinal epithelium.

Location of testes in mammalian orders

Testes in vertebrates below mammals lie within the body. This is also true of many, sometimes all, members of the mammalian orders Monotremata, Insectivora, Hyracoidea, Edentata, Sirenia, Cetacea, and Proboscidea. Some male mammals—most marsupials, ungulates, carnivores, and primates after infancy—have a special pouch (scrotum) that the testes occupy permanently. A few mammals have a pouch into which the testes descend and from which they can be retracted by muscular action. These include a few rodents such as ground squirrels; most, if not all, bats; and some primitive primates (loris, potto). The scrotum consists of two scrota1 sacs, each connected to the abdominal cavity by an inguinal canal lined with the peritoneal membrane. The canals are the path of descent (and retraction) of the testes to the sacs. In descending, the testes carry along a spermatic duct, blood and lymphatic vessels, and a nerve supply wrapped in peritoneum and constituting, collectively, the spermatic cord. Rabbits, most rodents, and some insectivores, which lack scrotal sacs, have instead a wide inguinal canal into which the testes may be drawn and from which they are retracted when in danger of injury. In these mammals, descended testes cause a temporary bulge in the perineal region (*i.e.*, between the anus and the urinogenital opening). In a small number of mammals, the testes permanently occupy the perineal location.

The scrotum is a temperature-regulating device. Warm blood approaching the testis comes close to the vessels carrying cool blood leaving the testis, so that the blood approaching the testis is cooled; the vessels form an intricate vascular network (pampiniform plexus) within the spermatic cord. Failure of both testes to enter the scrotal sacs (cryptorchidism) results in permanent sterility. In cold weather two sets of muscles, the dartos and cremasteric, pull the testes close to the body. The dartos lies between the two scrotal sacs and is attached to the scrotal skin. The cremaster, wrapped around the spermatic cord, is an extension of the abdominal wall musculature. It retracts the testis. Birds, like mammals, are homoiothermic (warm-blooded), and their testes are near air sacs (extensions of incurrent respiratory tubes). Air in the sacs may help regulate the temperature of the testes.

Ducts. The male duct system begins as the rete testis, a network within the testis of thin-walled ductules, or minute ducts, that collects sperm from the seminiferous tubules. The rete is drained by a number of small ducts—usually fewer than ten—called the vasa efferentia, which are modified kidney tubules. In some fishes and amphibians the vasa efferentia connect the testes with the cranial (anterior) end of the kidneys (Figure 4). In anamniotes (*e.g.*, fish and amphibians), therefore, except teleosts, the ducts that drain the kidneys usually drain the testes also. In most amphibians these ducts pass caudad, or posteriorly, to empty independently into the cloaca; in some fishes they pass through a median urinogenital papilla.

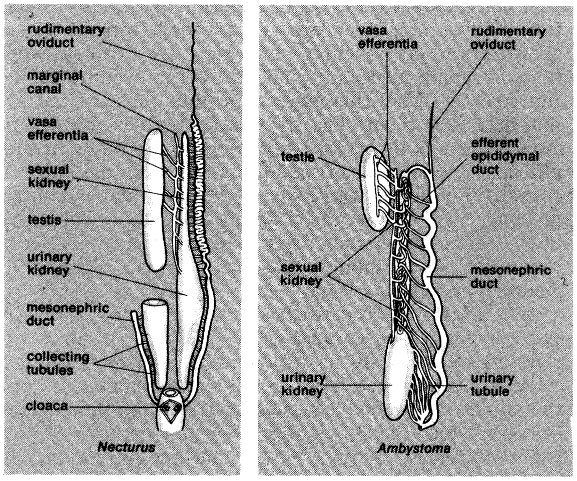

Figure 4: Reproductive systems of two male amphibians. (Left) The sexual kidney is composed of one row of modified tubules that are ciliated for sperm transport and drain into the adult (mesonephric) kidney duct. This duct also collects urine from the kidney. (Right) The mesonephric duct collects only sperm.

Although drainage of the testis and the kidney by the same duct is a basic pattern, there has been a tendency in many vertebrates toward separate spermatic and urinary ducts. This tendency is manifested in one of two ways among anamniotes. In many sharks and in some amphibians (Plethodontidae, Salamandridae, Ambystomatidae), the embryonic kidney duct ultimately drains the testis, and one or more new ducts (ureters) drain the adult kidney. On the other hand, in the primitive fish Polypterus and in most teleosts, the embryonic kidney duct drains the adult kidney, and a new duct arises to drain the testis. Many degrees of separation of the two ducts occur in anamniotes, from the condition of the sturgeon, in which the spermatic duct unites with the urinary duct far toward the head, to the condition in Esox (a pike), in which spermatic and urinary ducts empty independently to the exterior.

In amniotes, the mesonephric kidney is a temporary structure confined to the embryo, but the mesonephric duct persists in the adult male as a sperm duct. A separate ureter drains the adult kidney. The spermatic and urinary ducts empty independently into the cloaca except in mammals above monotremes, in which they are confluent with the urethra. The epididymis of amniotes, a highly tortuous duct draining the vasa efferentia, usually serves as a temporary storage place for sperm; it is small in birds and large in turtles. In mammals, the first part of the epididymis consists of a head, body, and tail that wrap around the testis; it gradually straightens to become the spermatic duct. The epididymis secretes substances that prolong the life of stored sperm and increase their capacity for motility.

In all vertebrates certain regions of the spermatic duct are lined by cilia and a variety of secretory epithelial cells. One end may enlarge to form a sperm reservoir or secrete seminal fluid. In the catfish Tmchycorystes *mirabilis* secretions of the spermatic duct form a gelatinous plug in the female similar to the vaginal plug of mammals. A seminal glomulus in birds functions as a sperm reservoir. In some mammals an enlargement of the spermatic duct called the ampulla contributes to the seminal fluid and stores sperm. Small mucous glands (of Littré) and other glandular structures open into the urethra along its length. Cloacal glands in basking sharks and many salamanders form a jelly that encloses sperm in a spermatophore. Cloacal glands of some lizards produce secretions called pheromones. The siphon sac of elasmobranchs is one of the few accessory sex glands that is a separate organ in animals below mammals. It extends as an elongated pocket into the pelvic fin and secretes a nutritive mucus that enters the female reproductive tract with sperm.

Accessory glands. Accessory sex glands that are conspicuous outgrowths of the genital tract are almost uniquely mammalian. The major mammalian sex glands include the prostate, the bulbourethral, and the ampullary glands, and the seminal vesicles. All are outgrowths of the spermatic duct or of the urethra (Figure 5) and all four occur in elephants and horses and in most moles, bats, rodents, rabbits, cattle, and primates. A few members of these groups lack ampullary glands, or ampullary glands and seminal vesicles. Cetaceans (whales, porpoises) have only the prostate, as do some carnivores, including dogs, weasels, ferrets, and bears.

The prostate gland

The prostate, the most widely distributed mammalian accessory sex gland, is absent only in Echidna (a marsupial) and a few carnivores. It empties into the urethra by multiple ducts. Many rodents, insectivores, and lagomorphs have three separate prostatic lobes; in a few mammals (some primates and carnivores) the prostate is a single mass with lobules and encircles the urethra at the base of the bladder. In a few mammals (*e.g.*, opossum), the prostate is not a compact mass but a partly diffuse gland. In many rodents (*e.g.*, rat, guinea pig, mouse, hamster) and some other mammals, the semen coagulates quickly after ejaculation as a result of a secretion from a male coagulating gland, which is usually considered part of the prostatic mass. Coagulated semen forms a vaginal plug that temporarily prevents copulation.

From George C. Kent Jr., Comparative Anatomy of the Vertebrates, 2nd ed. (1969); The C.V. Mosby Co., St. Louis

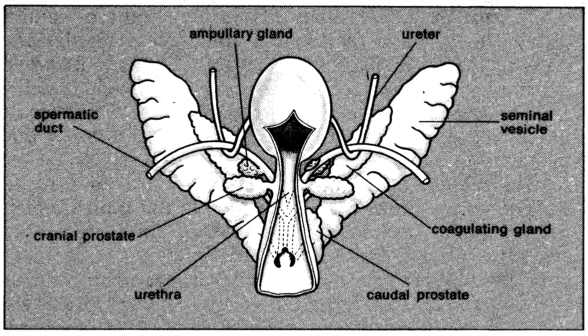

Figure 5: Accessory sex organs of a male golden hamster. Bulbourethral glands arise more toward the tail end and are not shown. The bladder and urethra have been opened to show entrances of ducts.

Bulbourethral (Cowper's) glands arise from the urethra near the penis and are surrounded by the muscle of the urethra or penis. Typically, there is one pair, but as many as three (marsupials) may be found. The glands, small in man, large in rodents, elephants, and some ungulates including pigs, camels, and horses, are absent in cetaceans, mustelids (*e.g.*, mink, weasel), sirenians (manatees, dugongs), pholidotans (pangolins), some edentates, and carnivores such as walrus, sea lion, bear, and dog.

Although many mammals have an ampullary swelling on the spermatic duct near the urethra, only a small number form a separate ampullary gland as an outgrowth of the duct. It is very large in some bats, absent in many mammalian orders, and variable in the rest. Although common in rodents, it is absent in guinea pigs and some strains of mice.

Seminal vesicles are paired, typically elongated and coiled fibromuscular sacs that empty into either the spermatic duct or the urethra. Absent in monotremes, marsupials, carnivores, cetaceans, and in some insectivores, chiropterans, and primates, seminal vesicles are exceptionally large in rhesus monkeys and small in man. They are absent in domesticated rabbits, small or rudimentary in cottontails, large in armadillos, and variable in sloths. They contribute the sugar fructose and citric acid to the semen but do not serve as sperm reservoirs.

Female systems. Ovaries. Ovaries lie within the body cavity and are suspended by a dorsal mesentery (mesovarium), through which pass blood and lymph vessels and nerves. Primitive vertebrate ovaries occur in the hagfish, in which a mesentery-like fold of gonadal tissue stretches nearly the length of the body cavity. Unique in the hagfish is the fact that functional ovarian tissue occupies only the forward half of the gonadal mass, the rear part containing rudimentary testicular tissue. In most fishes except very primitive forms, the ovaries are similarly elongated. In tetrapods other than mammals, the ovaries are usually confined to the middle third or half of the body cavity, particularly during nonbreeding seasons. The ovaries of mammals undergo moderate caudal displacement, finally coming to lie between the kidney and the pelvis.

Characteristicsof the ovary

The appearance of an ovary depends on many factors —*e.g.*, whether one egg or thousands are discharged (ovulated); whether the eggs are immature or ripe; whether mature eggs are small or large; or whether pigments occur in the egg cytoplasm, such as those responsible for yellow yolk. Other factors also affect the appearance of the ovary: the season of the year in seasonal breeders (the ovary enlarges during breeding seasons, diminishes in size between seasons); the age of the animal (whether juvenile, reproductively active, or senile, particularly in birds and mammals); and the fate of ovulated, or discharged, egg follicles, or sacs.

The ovaries are covered with a germinal epithelium that is continuous with the peritoneum lining the body cavity. The term germinal epithelium is inappropriate because in most adults it contains no germ cells, these having moved deeper into the ovary. In hagfishes and amphibians, cells that give rise to eggs are known to occur in the germinal epithelium, and it may be that the germinal epithelium in a few other vertebrates contains similar cells. The germinal epithelium undergoes cell division, however. This is particularly true of species in which enormous expansion of the ovary occurs each breeding season. Beneath the epithelium is a layer of connective tissue, the tunica albuginea, which is much thinner than that surrounding the testes.

A typical vertebrate ovary consists of cortex and medulla. The cortex, immediately internal to the tunica albuginea, contains future eggs and, at one time or another, eggs in ovarian follicles (*i.e.*, developing eggs); it undergoes fluctuations in size and appearance that correlate with stages of the reproductive cycle. The cortex also contains remnants of ovulated follicles and, in mammals, clusters of interstitial cells that, in some species, are glandular. The cortical components are embedded in a supportive framework of connective, vascular, and neural tissue constituting the stroma. Internal to the cortex is the medulla, consisting of blood and lymph vessels, nerves, and connective tissue. The medulla, which contains no germinal elements, exhibits no significant cyclical activity, is usually inconspicuous, is continuous with the dorsal mesentery, and, in cyclostomes, is hardly distinguishable from the latter. The mammalian medulla, on the contrary, is almost completely surrounded by cortex and converges on the mesovarium (*i.e.*, the part of the peritoneum that supports the ovary) at a narrow hilus, at which nerves and vessels enter the ovary. In the medulla of the mammalian ovary near the hilus are small masses of blind tubules or solid cords—the rete ovarii—which are homologous (*i.e.*, of the same embryonic origin) with the rete testis in the male. The microscopic right ovary of birds usually consists only of medullary tissue.

Ovaries are characterized as saccular, hollow, lacunate (*i.e.*, compartmented), or compact. The ovary of many teleosts, especially viviparous ones, contains a permanent cavity, which is formed during ovarian development when an invagination of the ovarian surface traps a portion of the coelom. The cavity is therefore unique in that it is lined by germinal epithelium. The lining develops numerous ovigerous folds that project into the lumen and greatly increase the surface area for proliferation of eggs. In most other teleosts, a temporary ovarian cavity develops after each ovulation, when the shrinking cortex withdraws from the outside ovarian wall along one side of the ovary. The resulting cavity is obliterated as eggs of the next generation enlarge. The permanent and temporary cavities of teleost ovaries and a similar cavity in garfish ovaries are continuous with the lumen of the oviduct, and eggs are shed into them. The ovaries of other fishes lack cavities and are characterized as compact. The amphibian ovary, which contains six or more central, hollow sacs that give it a lobed appearance, is characterized as saccular. The sacs are formed when the embryonic medullary and rete cords become hollow and coalesce. Maturing eggs bulge into the sacs but are not shed into them. The ovaries of reptiles, birds, and monotremes have cavities homologous to those in amphibians; the number of medullary spaces in the adults is considerably larger, however, so that the ovaries contain an extensive network of fluid-filled cavities (lacunae). Such ovaries are characterized as lacunate. The ovaries of mammals above monotremes are compact, having no medullary cavities.

Formation and fate of ovarian follicles

An ovarian follicle consists of an oocyte, or immature egg, surrounded by an epithelium, the cells of which are referred to variously as follicular, nurse, or granulosa cells. In cyclostomes, teleosts, and amphibians, the epithelium is one layer thick. In the hagfish and those vertebrates in which the oocyte receives heavy deposits of yolk (elasmobranchs, reptiles, birds, and monotremes), the epithelium appears to be two cells thick, apparently the result of layering of nuclei in a simple columnar epithelium (*i.e.*, epithelium consisting of relatively "tall" cells). Above monotremes the follicular epithelium appears to be many cells thick; in at least one species, however, this is considered an artifact, and all granulosa cells are said to extend between the outer boundary of the epithelium and the oocyte.

The follicular epithelium originates as a few flattened cells derived from the germinal epithelium. Primary follicles are usually situated just under the tunica albuginea; secondary follicles lie deeper in the cortex. The primitive role of the follicular cells appears to be the secretion of the yolk-forming material onto or into the oocyte. Evidence from mammals indicates that the follicular cells may also have a role in converting substances produced elsewhere into female hormones, or estrogens. In some hibernating bats the granulosa cells are filled with glycogen, or animal starch, which may be a source of energy. Mammalian follicles above monotremes are unique in that they develop a fluid-filled cavity (antrum) within the granulosa layer. During antmm formation cell division of the granulosa cells increases, and fluid-filled spaces develop among the cells. The spaces coalesce to form the antrum. Under the influence of pituitary gonadotropic hormones, many antral follicles thereafter continue to grow, forming large so-called Graafian follicles—less than 400 microns, or 0.4 millimetre (0.02 inch), in diameter in large mammals, 150–200 microns, or 0.15–0.2 millimetre (0.006–0.008 inch), in small ones. Graafian follicles contain mature eggs and appear as large blisters on the ovary. At this stage the ovum, suspended within the fluid of the antrum (liquor folliculi) by a slender stalk of granulosa cells, is surrounded by a cluster of these cells, the cumulus oophorus, or discus proligerus. The remaining follicular cells form a thin wall surrounding the antrum. Antra are lacking in a few insectivores (Hemicentetes, *Euriculus*) because the granulosa cells swell and multiply to form corpora lutea, masses of yellow tissue. In the bat Myotis the antrum is likewise compressed and disappears just before discharge of the egg, or ovulation.

In all vertebrates, oocytes that have begun to grow and mature may, at any time until just before ovulation, cease development and undergo atresia, or degeneration. This is a normal process that reduces the number of eggs ovulated. In small laboratory rodents, atresia takes place in 50 percent of the Graafian follicles in each ovary one or two days before ovulation, thus reducing the number of ovulatable eggs by 50 percent. A similar reduction takes place in hagfish prior to ovulation. Atretic follicles eventually become lost in the stroma of the cortex of the ovary. In mammals especially, follicles lacking oocytes and antra, called anovular follicles, as well as polyovular follicles (*i.e.*, containing more than one oocyte), occasionally occur.

The theca

The ovarian follicle of vertebrates, commencing with hagfish, is surrounded by a theca, or sheath, composed of two concentric layers of stromal cells. The outer layer (theca externa) is chiefly connective tissue but may contain smooth muscle fibres. The inner layer (theca interna) has more blood vessels and, in vertebrates that produce heavily yolked eggs, the largest vessels carry venous blood. In these species the cell membranes of the oocyte and granulosa cells have many microvilli (*i.e.*, fingerlike projections), which probably facilitate transport of substances important in yolk formation from the blood vessels to the egg. Mature follicles in the marsupial Dasyatus are said to lack theca, and in some bats only one thecal layer has been described.

During the growth phase, eggs in species with massive amounts of yolk may increase in size 106 (1,000,000) or more times as a result of vitellogenesis (deposit of yolk). In goldfish, on the other hand, when vitellogenesis commences, the egg has a diameter of 150 microns (0.15 millimetre [0.006 inch]); that of the mature egg is only 500 microns (0.5 millimetre [0.02 inch]). Mammalian eggs contain little yolk and vary little in size. Oogonia (*i.e.*, cells that form oocytes) of the golden hamster average 15 microns (0.015 millimetre [0.0006 inch]) in diameter, and eggs in Graafian follicles average 70 microns (0.07 millimetre [0.003 inch]). The mature eggs of horses and humans are approximately the same size—somewhat less than 150 microns. In seasonally breeding oviparous fishes and amphibians, all eggs are usually in the same stage of development, and the ovary grows to a mature state quite rapidly as a result of growth of the eggs, which frequently number more than 1,000,000. Such ovaries distend the body wall when mature; following spawning, the ovaries shrink rapidly to inconspicuous bodies consisting mainly of oogonia, immature oocytes, and a few stromal cells. In reptiles and birds, ovarian weight also is high in proportion to body weight during egg-laying seasons. The weight of the ovary of the starling, for example, may increase from eight milligrams in early winter to 1,400 milligrams immediately before ovulation. The mature eggs of reptiles and birds are unique in that they are suspended from the ovary by a short stalk (pedicle). The stalk contains a cortex with additional oocytes in various stages of development and extensions of vessels and nerves. Full growth of the follicle in reptiles and birds requires only a few days or weeks (nine days in the domestic hen). In mammals, the ratio of ovarian weight to body weight varies insignificantly throughout the reproductive life of the female, and follicles in many stages of development are constantly present.

Vertebrate eggs are almost universally shed into the coelom or into a subdivision thereof, from which they enter the female reproductive tract. Even in those teleosts in which the eggs are shed into an ovarian cavity, the latter is often of coelomic origin. In many mammals a membranous sac of peritoneum, the ovarian bursa, traps part of the coelom in a chamber along with the ovary. The bursal cavity (periovarian space) may be broadly open to the main coelom, completely closed off from the coelom, or in communication with the coelom by a narrow, slitlike passage. The bursa, moderately developed in lower primates and catarrhines (Old World monkeys), is poorly developed in man. In horses, one edge of the ovary contains a long groove (ovulation fossa) into which all eggs are shed; the groove is found in a cleftlike ovarian bursa. The ovarian bursa increases the probability that all ovulated eggs will enter the oviduct.

Ovulation

The process of ovulation has been described for all vertebrate classes. Elasmobranchs, reptiles, and birds have massively yolked eggs. As ovulation approaches, the fimbria (*i.e.*, frills, or fringes) of the membranous and muscular funnel surrounding the entrance to the oviduct wave in a gentle, undulating motion. An egg that is nearly free of the ovary is grasped and partially encompassed by the fimbria; when the egg is freed, the fimbria draw the egg into the funnel. At this time, the egg has little shape and is partly squirted and partly flows into the oviduct; never completely free in the coelom, its chances of not entering the oviduct are small. In the case of moderately or poorly yolked eggs cilia help to sweep the eggs into the ostium, or opening, of the oviduct. During ovulation in Japanese rice fish, Oryzias *latipes*, a tiny papilla, or fingerlike process, develops on the surface of a bulging mature follicle in the centre (stigma) of the follicle. The follicle becomes thin at the stigma, an aperture appears, and the egg rolls out. In rabbits this process differs only in detail. During the final 20 minutes before ovulation in rabbits, some of the tiny blood vessels surrounding the stigma rupture, and a small pool of blood forms under the apex of the cone-shaped papilla. The follicular wall shortly gives way at the apex, and follicular fluid oozes from the opening, followed soon after by the egg. The ovulated mammalian egg typically is surrounded by a layer of columnar follicular cells, the corona radiata; but it is naked in some insectivores and some marsupials. Following ovulation in all vertebrates, the ovary may become smaller, become modified for maintenance of pregnancy, or proceed to form additional eggs.

The process of ovulation in vertebrates has been documented, but the immediate causes remain to be clarified. It is almost certain that an ovulatory hormone is secreted by the pituitary gland (*i.e.*, the so-called master endocrine gland) of all vertebrates. It is highly probable that breakdown of very small fibres that bind the follicular cells together may occur at the stigma, weakening the follicular wall at that location. Hormones from the ovary and other sources may play a role, as may neurohormones, which are hormones released at nerve endings. Rhythmic contractions of the entire ovary occur at ovulation in many vertebrates and have been described in rabbits. The role of mechanical pressure within the follicle, however, is not understood. Ovulation in most mammals (spontaneous ovulators) occurs cyclically as a result of the spontaneous release of the ovulatory hormone. In a few mammals (reflex ovulators) the stimulus of copulation is essential for release of the ovulatory hormone.

Striking postovulatory changes take place in the follicles of mammals and, to lesser degrees, of lower vertebrates. Blood vessels from the theca interna invade the ovulated follicles; the granulosa cells divide, enlarge, accumulate fats, and obliterate any remnants of the collapsed antra. Thereafter, they are known as lutein cells. Theca interna cells undergo changes identical to those of the granulosa cells. The result in mammals is the formation of solid masses called corpora lutea, recognizable as prominent reddish-yellow bulges on the ovary. Corpora lutea produce the hormone progesterone, which is essential for the maintenance of pregnancy. The conversion of postovulatory follicles into structures more or less resembling mammalian corpora lutea has been demonstrated in numerous viviparous reptiles, amphibians, and elasmobranchs; in certain other fishes, including cyclostomes; and in some oviparous amphibians and reptiles. In birds, the postovulatory follicle shrinks, and identifiable corpora lutea do not develop, although some granulosa cells accumulate lipids of unknown significance.

Tracts. The female reproductive tract consists of a pair of tubes (gonoducts) extending from anterior, funnel-like openings (ostia) to the cloaca (Figure 6), except as noted below. The gonoducts are specialized along their length for secretion of substances added to the eggs; for transport, storage, nutrition, and expulsion of eggs or the products of conception; and, in species with internal fertilization, for receipt, transport, storage, and nutrition of inseminated sperm. The predominately muscular tracts are lined by a secretory epithelium and ciliated over at least part of their length. Fusion of the caudal (tail) ends of the paired ducts may occur. Gonoducts are absent in cyclostomes and a few gnathostome fishes that have abdominal pores. A few vertebrates have only one functional gonoduct.

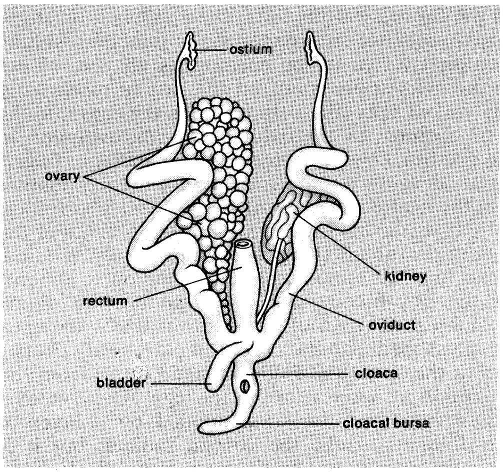

Figure 6: Reproductive tract of female turtle, *Trionyx euphraticus*. One ovary has been removed.

Gonoducts of fishes and amphibians

Gonoducts in lungfishes and amphibians are coiled muscular tubes that are ciliated over most of their length. Only occasionally do they unite caudally in a genital papilla before opening into the cloaca. During breeding seasons their diameter increases severalfold because of the highly active secretory epithelium. Between breeding seasons they are small. In some anurans (frogs, toads), such as *Rana*, the lower end of each gonoduct is expanded to form an ovisac, in which ovulated eggs are stored until spawning; the tube between the ostium (funnel-like opening) and ovisac is the oviduct. In viviparous amphibians the young develop in the ovisac. In amphibians, numerous multicellular glands extend deep into the lining of the female tract. Six successive glandular zones have been described in some urodeles, and these secrete six different gelatinous substances upon the egg. Female urodeles often have convoluted tubular outpocketings of the cloaca called spermatheca; they temporarily store sperm liberated from the male spermatophore.

The two gonoducts of elasmobranchs share a single ostium, a trait found only in Chondrichthyes. The ostium is a wide caudally directed funnel supported in the falciform ligament, which is attached to the liver. The role of the fimbria of the ostium at ovulation has been described (see above Ovaries). Two oviducts pass forward from the ostium to the septum transversum (*i.e.*, between the heart and abdominal cavities), curve around one end of the liver, then pass posteriorly on each side. Approximately midway between ostium and uterus each oviduct has a shell (nidamental) gland. Fertilization takes place above the shell gland, which may be immense or almost undifferentiated. Half of the shell gland secretes a substance high in protein content (albumen), and the other half secretes the shell—delicate in viviparous forms, thick and horny in most oviparous species. Horny shells may have spiral ridges and many long tendrils, which entwine about an appropriate surface after the egg is deposited. In the viviparous shark *Squalus* acanthias several eggs pass one after the other through the shell gland, where they are enclosed in one long delicate membranous shell that soon disintegrates. Beyond the shell gland the oviducts terminate in an enlargement, which, in viviparous species, serves as a uterus. An oviducal valve may be found at the junction of oviduct and uterus. Although the two uteri usually open independently into the cloaca, they occasionally unite to form a bicornuate (two-horned) structure. In immature females, the uterus may be separated from the cloaca by a hymen, or membrane. The tract enlarges enormously during the first pregnancy and does not thereafter fully regress to its original size.

The gonoducts of most lower ray-finned fishes resemble those of lungfish, but those of gars and teleosts are exceptional in that the oviducts are usually continuous with the ovarian cavities. A median genital papilla receives the oviducts in teleosts, and the papilla is sometimes elongated to form an ovipositor. European bitterlings deposit their eggs in a mussel by means of the ovipositor. and female pipefish and sea horses deposit them in the brood pouch of a male.

Gonoducts of reptiles, birds, and mammals

With certain modifications, the gonoducts of reptiles and birds are comparable to those of lower vertebrates. Crocodilians, some lizards, and nearly all birds have one gonoduct; the other is not well developed. Even in birds of prey having two functional ovaries, the right oviduct is sometimes undeveloped. The tracts of reptiles generally show less regional differentiation than do those of birds. The oviduct funnel (ostium) in birds forms the chalazae—two coiled, springlike cords extending from the yolk to the ends of the egg. In both reptiles and birds, much of the length of the female tract is oviduct. This region, called the magnum in birds, secretes albumen; lizards and snakes do not form albumen. Behind the albumen-secreting region is a shell gland. In lizards, the gland is midway along the tract. In birds, the shell gland is at the posterior end, has thick muscular walls, and is often inappropriately called a uterus. It is preceded by a narrow region, or isthmus, which secretes the noncalcareous, or soft, membranes of the shell. The shell gland leads to a narrow muscular vagina that empties into the cloaca. The vagina secretes mucus that seals the pores of the shell before the egg is expelled. Special vaginal tubules (spermatheca) store sperm over winter in some snakes and lizards; seminal receptacles have been described in the oviduct funnel in some snakes. In birds, sperm storage glands (sperm nests) often occur in the funnel and at the uterovaginal junction. In lizards and birds, ovulation does not usually occur into a tract already containing an egg. Some lizards shed very few eggs per season; the gecko, for example, sheds only two.

The female reproductive tracts of monotremes, the egg-laying mammals, consist of two oviducts, the lower ends of which are shell glands. These open into a urinogenital sinus, which, in turn, empties into a cloaca. Marsupials have two oviducts, two uteri (duplex uterus), and two vaginas. The upper parts of the vaginas unite to form a median vagina that may or may not be paired internally. Beyond the median vagina, the vaginas are again paired (lateral vaginas) and lead to a urinogenital sinus. The posterior end of the pouchlike median vagina is separated from the forward end of the urinogenital sinus by a partition. When the female is delivering young, the fetuses are usually forced through the partition and into the urinogenital sinus, bypassing the lateral vaginas. The ruptured partition may remain open thereafter, resulting in a pseudovagina. It closes in opossums, and in kangaroos both the median and lateral routes may serve as birth canals. The lateral vaginas in marsupials receive the forked tips of the male penis. Fertilization in all mammals takes place in the oviducts (Fallopian tubes).

In eutherian mammals (*i.e.*, all mammals except monotremes and marsupials), with exceptions noted below, female reproductive tracts beyond the ostia (oviduct funnels) consist of two narrow and somewhat tortuous Fallopian tubes, two large uterine horns (each of which receives a Fallopian tube), a uterine body, and one vagina. Fallopian tubes often have a short dilated ampulla, or saclike swelling, just beyond the ostium. Implantation of the egg occurs only in the uterine horns; the embryos become spaced equidistant from one another in both horns even if only one ovary has ovulated. In some species one horn is rudimentary—the left in the impala (an African antelope)—and the embryos become implanted in the other horn, even though both ovaries ovulate. The body of the uterus in some mammals (*e.g.*, rabbits, elephants, aardvarks; some rodents, bats, insectivores) contains two separate canals (bipartite uterus). In other mammals (ungulates, many cetaceans, most carnivores and bats) the body of the uterus has one chamber into which the two horns empty (bicornuate uterus). There are numerous intermediate conditions between the bipartite and bicornuate condition. Apes, monkeys, and man have no horns, and the Fallopian tubes empty directly into the body of the uterus (simplex uterus). In all mammals, the uterine body tapers to a narrow neck (cervix). The opening (os uteri) into the vagina is guarded by fleshy folds (lips of the cervix). The vagina in eutherian mammals other than rodents and primates terminates in a urinogenital sinus that opens to the exterior by a urinogenital aperture. In some rodents and in higher primates the vagina opens directly to the exterior. In the young of many species a membrane, the hymen, closes the vaginal opening. In guinea pigs the hymen reseals the opening after each reproductive period. Sperm are stored over winter in the uterus of some bats and in vaginal pouches in others.

Accessory glands. Female mammals have fewer accessory sex glands than males, the most prominent being Bartholin's glands and prostates. Bartholin's (bulbovestibular) glands are homologues of the bulbourethral glands of males. One pair usually opens into the urinogenital sinus or, in primates, into a shallow vestibule at the opening of the vagina. Prostates develop as buds from the urethra in many female embryos but often remain partially developed. They become well developed, however, in some insectivores, chiropterans, rodents, and lagomorphs, although their function is obscure. A variety of glands (labial, preputial, urethral) are found in the mucosa, or mucous membrane. Glands in the uterine mucosa provide nourishment for embryos before implantation. Cervical uterine glands secrete mucus that lubricates the vagina, which has no glands (see also REPRODUCTIVE SYSTEM, HUMAN).

ADAPTATIONS FOR INTERNAL FERTILIZATION

Fertilization among vertebrates may be external or internal, but internal fertilization is not always correlated with viviparity or the presence of intromittent (copulatory) organs. The latter, uncommon among fishes, amphibians, and birds, are present in all reptiles (except Sphenodon) and mammals.

Copulatory organs in fishes and amphibians

A considerable number of fishes are viviparous; in them, fertilization is internal, and the males have intromittent organs. The claspers of most male elasmobranchs are usually paired extensions of pelvic fins that are inserted into the female's uterus for transfer of sperm. The clasper, supported by modified fin cartilages, contains a groove along which sperm are conveyed into the uterus and is raised, or erected, by muscles at its base. Gonopodia of male teleosts are fleshy, often elongated modifications of pelvic or anal fins that are directed posteriorly, have a genital pore at the end, and often serve as intromittent organs. In some teleosts, a large penis-like papilla located under the throat is supported by bones. The spermatic duct opens on one side of the papilla. In a few teleosts, hemal spines (ventral projections of vertebrae) form the skeleton of an intromittent organ. Occasionally, the intromittent organ is an asymmetrical tube that matches the asymmetrical genital opening of the female. Still other teleosts have uncomplicated fleshy genital papillae that can be erected. In at least one teleost species, the female has a copulatory organ that she inserts into the genital pore of the male for receiving sperm.

Certain amphibians have internal fertilization but no intromittent organs. The muscular cloaca of the male coecilian, however, can be everted (turned outward) to protrude into that of the female. The male urodele deposits a spermatophore that the female picks up with the lips of her cloaca. Among anurans, Nectophrynoides (a viviparous frog) and Ascaphus (a toad) have internal fertilization, but only Ascaphus has an intromittent organ. It is a permanent tubular extension of the cloaca and resembles a tail. Other anurans have external fertilization and no intromittent organs.

Copulatory organs in reptiles, birds, and mammals

The provision of an eggshell in reptiles requires that fertilization be internal, and all reptiles have intromittent organs except Sphenodon. Reptilian intromittent organs are of two types. Crocodilians and chelonians (turtles) have a penis (phallus), a median thickening in the floor of the cloaca consisting of two parallel cylinders of spongy vascular erectile tissue, the corpora spongiosa (Figure 6). The caudal tip of the penis protrudes into the cloaca as a genital tubercle, or glans penis. The penis is held in the cloacal floor by retractor muscles. When the blood vessels within the spongy bodies are filled with blood, the penis swells, the retractor muscle relaxes, and the genital tubercle protrudes from the vent to serve as an intromittent organ. A longitudinal groove on the surface of the penis directs the flow of sperm. When the spongy bodies are no longer filled with blood, the retractor muscle returns the penis to the cloacal floor. Snakes and lizards have hemipenes, paired elongated outpocketings of the caudal wall of the cloaca that extend under the skin at the base of the tail. Each hemipenis is held in place by a retractor muscle. During copulation the muscle relaxes, the pocket turns inside out and protrudes through the vent in an erect condition. Semen passes along grooves on its surface. Except in pythons, erectile tissue is lacking in hemipenes. Hemipenes protrude independently of each other and are often covered with spines. Very small hemipenes of unknown function are usually present in females.

All birds have internal fertilization, although they are not viviparous; most lack intromittent organs. Male swans, ducks, geese, tinamous, ostriches, and some other ratites (flightless birds), however, have an erectile median penis like that of crocodiles and turtles. Chickens have an organ consisting of a small amount of erectile tissue, but lymph vessels, rather than blood vessels, become engorged. Some birds have a vestigial penis.

All mammals have internal fertilization and an erectile penis. That of monotremes is of the reptilian type, nonprotrusible and in the cloacal floor. In higher mammals the penis has been modified. The groove on the surface of the embryonic penis becomes enclosed in a tube along with the corpus spongiosum and two additional erectile masses, the corpora cavemosa. The proximal ends (crura) of the corpora cavernosa are anchored laterally to the pubic and ischial bones by various muscles and constitute the root of the penis. The crura converge in the midline to enter the body of the penis, which also contains the urethra, surrounded by the corpus spongiosum. The latter begins on the pelvic floor as the bulb of the penis and contains a dilation of the urethra (urethral bulb). The body of the penis extends a variable distance beyond the body of the mammal, in contrast to the short genital tubercle of reptiles. Except in ruminants (*i.e.*, cud-chewing animals, such as cattle and deer), cetaceans, and some rodents, the penis terminates in a glans penis, a swelling of the corpus spongiosum that caps the ends of the corpora cavernosa and contains the urinogenital aperture. The glans is supplied with nerve endings and is partly or wholly sheathed, except during erection, by a circular fold of skin, the prepuce. The inner surface of the prepuce is moistened by preputial glands, and the external surface is sometimes covered with spines or hard scales, as in the cat, guinea pig, and wombat. The glans penis of the male Virginia opossum (Didelphis *virginiana*), the bandicoot, and some other species is bifid (*i.e.*, with two equal tips), correlated with the paired vaginas of females. In boars, the glans penis is corkscrew-shaped, and in goats, rams, and many antelopes a urethral (vermiform) process of much smaller diameter extends three or four centimetres (about an inch to an inch and a half) beyond the glans. In some cattle, a sigmoid, or S-shaped, flexure bends the penis, which otherwise would be too long to fit into the preputial sac. The penis of marsupials is directed backward, and that of cats and rodents is directed backward, except during copulation. In some mammals (*e.g.*, bats) it is pendulous; and in armadillos it may extend one third the length of the body during copulation.

Erection of the mammalian penis is initiated typically by an increase in the volume of blood reaching the cavernous and spongy bodies, engorgement of the vessels, and consequent compression of the veins leaving the organ. When a retractor muscle is present (wolf, fox, dog), it relaxes as erection occurs. The amount of erectile tissue in bovines (cattle) is small, and the penis has much fibroelastic tissue. Erection in such species results primarily from relaxation of the retractor muscle, and vascular engorgement provides only rigidity. Among mechanisms that reverse the erectile state are disgorgement of blood from the cavernous spaces, elasticity of the walls of the spaces, and action of a retractor muscle. A penis bone (baculum, os priapi) is present in various degrees of development in many mammals.

Female mammals have an erectile penile organ known as the clitoris in the floor of the urinogenital sinus or vagina. In the young spider monkey ***Ateles,*** the clitoris is six or seven centimetres long. In a few mammals (some rodents, insectivores, lemurs, and hyenas) the urethral canal becomes enclosed within the clitoris, as in males. In hyenas, the clitoris is large and often mistaken for a penis, and female scrotal pouches, lacking gonads, are present. So much do the male and female external genitalia resemble each other that the ancients regarded the hyena as a hermaphrodite. The clitoris of female mammals often contains cartilage or bone. A specialized clitoris is present in female turtles, crocodiles, alligators, and a few species of birds in which the male has a penis.

The spermatic duct of male mammals between the seminal vesicle and the prostatic urethra has a heavy muscular coat and serves as an ejaculatory duct. In mammals in which the seminal vesicles empty directly into the urethra, the latter is ejaculatory. In birds, the terminal segments of the spermatic ducts are erectile and ejaculatory, and in fish the posterior end of whatever duct transports sperm may be ejaculatory.

ROLE OF GONADS IN HORMONE CYCLES

Neurosecretions formed in the brain in response to environmental stimuli regulate the synthesis and release of hormones known as gonadotropins, which, in turn, stimulate the gonads. Cyclical intervals of illumination (photoperiods) may be the principal environmental factor regulating gonadal activity. Although cyclical temperature changes are experienced by many species, as are fluctuations in food supply, rainfall, and salinity, their precise effects and those of many other stimuli, independently or in combination, have not yet been defined for any species. Photoperiodicity, temperature, and perhaps all other cycles are attributable to the seasons, and to the 24-hour day.

As a result of rhythmic stimulation by gonadotropins secreted by the pituitary gland, the gonads grow, mature, and produce gametes and hormones. Certain of these hormones, known as androgens, are thought to be produced chiefly by interstitial cells and are more abundant in males. Hormones known as estrogens are probably produced chiefly by ovarian follicles and their thecas. Circulating progestins are produced in greatest quantities by corpora lutea. Although the gonadal hormones of different species vary somewhat in structure, their effects are essentially the same. As the quantity of pituitary gonadotropins decreases, the activity of the gonads slows and may temporarily cease.

Effects of gonadal hormones

The effects of gonadal hormones may be summarized as follows:

Gonadal hormones induce growth of and maintain the cyclical function of the reproductive tracts, accessory sex glands, and copulatory or ovipository organs. They thereby provide for the storage, nutrition, and transport of gametes; the secretion of necessary substances onto the surface of gametes; and the ultimate extrusion of sperm, eggs, or the products of conception. In mammals, therefore, they prepare the vagina for copulation and the uterus for implantation of eggs; in addition, gonadal hormones maintain pregnancy until birth or until placental hormones can take over their function. The hormonal basis for the maintenance of viviparity in vertebrates below mammals is almost unknown.

Gonadal hormones participate in the maturation of gametes still in the gonads by augmenting the metabolic effects of other hormones.

Gonadal hormones are essential for the differentiation of manv secondarv sex characters—the physical differences between the sexes—facilitate amplexus (copulatory embrace) and provide for the protection or nutrition of young. Secondary sex characters include scent glands; sexually linked pigmentation of the skin or its appendages; the nature of any vocal apparatus; hardened areas on the appendages that facilitate amplexus; distribution of hair; body size; mammary gland development; and other features.

Gonadal hormones participate in the induction of behaviour necessary for the union of sperm and eggs; this includes migratory phenomena, heat (estrus) in mammals, courtship, territorial defense, mating, and care of eggs or young.

Gonadal hormones participate in a mechanism that affects the pituitary, thereby imposing certain restraints on the secretion of gonadotropins.

The role of light in establishing periodic reproductive activity

The effects of a cyclical environment on gonads is illustrated in mammals that ovulate spontaneously. Ovulation is induced by ovulatory hormones released rhythmically from the pituitary gland. Newborn mice maintained during the first week of life in regular, natural photoperiods will, on reaching maturity, ovulate regularly. Newborn mice kept in continuous light during this interval will not ovulate regularly. The photoperiods in which these animals live as neonates, or newborn, establish an intrinsic brain rhythm that subsequently results in cyclical reproductive activity. If mature female mice that have been ovulating regularly are subjected to continuous light, ovulation ultimately becomes arrhythmical. This suggests that the rhythmical environment is the ultimate regulator of the gonads. Because of the effects of cyclical photoperiods, spontaneous ovulation occurs about the same time of day or night in all members of species intensively studied thus far. Golden hamsters ovulate shortly after midnight; chickens and Japanese rice fish ovulate in the morning. Not all mammals ovulate spontaneously, however. In those that do not (*e.g.*, reflex ovulators), including some cats, rodents, weasels, shrews, rabbits, the act of mating substitutes for the environmental effects on the pituitary gland in releasing ovulatory hormones (see HORMONE).

PROVISIONS FOR THE DEVELOPING EMBRYO

Among the requirements of developing embryos are nutrients, oxygen, a site in which to discharge metabolic wastes, and protection from the environment. These needs exist whether the embryo is developing outside the body of the female parent (oviparity), or within, so that she delivers living young (viviparity). Combinations of yolk, albumen, jellies, and shells contributed by the female parent, as well as membranes constructed from the tissues of the embryo meet the embryo's needs.

Oviparous eggs are usually supplied with enough nutrients to last until the new individual is able to obtain food from the environment. The alternative, postnatal parental feeding, is uncommon. Oviparous animals that develop from yolk-laden eggs are not hatched until they resemble adults. Those that develop from eggs with moderate amounts of yolk hatch sooner, usually into free-living larvae; in this case the larvae transform, or undergo metamorphosis, into adults. The eggs of amphioxus, an oviparous protochordate, contain almost no nutrients; the embryos hatch in an extremely undeveloped but self-sustaining state as few as eight hours after fertilization. The yolk mass is large in some animals and becomes surrounded by a membrane called the yolk sac, the vessels of which convey yolk to the embryo. In some species, yolk also passes from the yolk sac directly into the fetal intestine.

Oviparous fishes and amphibians develop in an aquatic environment, and exchange of oxygen and carbon dioxide and elimination of metabolic wastes occur through the egg membranes. Oviparous reptiles, birds, and monotremes develop on land, and gaseous exchange is accomplished by two membranes (allantois, chorion) applied closely to the shell. The allantois also receives some wastes. Drying out or mechanical injury of embryos of reptiles, birds, and mammals is prevented by still another membrane, the amnion, which is a fluid-filled sac immediately surrounding the embryo.

Types of viviparity

Viviparity has evolved in some members of all vertebrate classes except birds. When eggs heavily laden with yolk and surrounded by a well-formed shell develop within the female, the parent may provide the developing young only with shelter and oxygen (ovoviviparity). At the opposite extreme, if eggs contain only enough nutrients to supply energy for a few cell divisions after fertrlization, the female provides shelter, oxygen, and nourishment, and, in addition, excretes all metabolic wastes produced by the developing organism (euviviparity). Between these extremes are numerous intermediate degrees of dependence on the parent.

Teleosts have evolved many unusual adaptations for viviparity. In some viviparous teleosts the eggs are fertilized in the ovarian follicle, where development occurs. The granulosa cells either form a membrane that secretes nutrients and assists in respiratory and excretory functions or they may be ingested along with follicular fluid, nearby eggs, and other ovarian tissue. A common site for development is the ovarian cavity, which may become distended with as many as nine series of embryos of different ages. Embryos in this location are bathed with nutritive fluids secreted by the epithelium of the cavity. In some species, mortality rates of intraovarian young are high, and surviving individuals ingest those that die. In still other species, extensions of villi in the ovarian lining invade the mouth and opercular (gill) openings of the embryo, filling the opercular chamber, mouth, and pharynx with surfaces that secrete nutrients. The embryos also develop specialized surfaces for nutrition, respiration, and excretion. An enlarged pericardial (heart) sac or an expansion of the'hindgut of the embryo may occur next to the blood-vessel containing (vascular) follicular wall. Vascular extensions may grow out of the anus, urinogenital pore, or gills of the embryo. Other embryonic surfaces —including ventral body wall, fins, and tail—may participate in the support of viviparity. These embryonic surfaces may lie in contact with the follicular or ovarian epithelium, or they may simply be bathed by ovarian fluids. One or more combinations of the maternal and embryonic specializations described above, as well as many others, make viviparity possible among teleost fishes. In a number of teleosts the eggs are incubated, or brooded, in the mouth of the male for periods as long as 80 days. The oral epithelium becomes vascular and highly glandular. In sea horses and pipefish the female deposits her eggs in a ventral brood pouch of the male, and the embryos develop there.

In viviparous elasmobranchs development takes place in the uterus, the lining of which develops parallel ridges or folds covered with villi or papillae (trophonemata) that constitute a simple placenta (site of fetal–maternal contact). In contact with this region is the yolk sac of the embryo, which serves as a respiratory and nutritive membrane. Trophonemata secrete uterine fluids that supplement the yolk as a source of energy. In one shark (Pteroplatea micrura), trophonemata extend into the spiracular chamber (an opening for the passage of respiratory water) of the young and secrete nutrients into the fetal gut. In another (Mustelus antarcticus), the uterine folds form fluid-filled compartments for each embryo. The yolk sac may lie in contact with the uterine lining, or projections of the sac may extend into uterine pits. When the stored yolk is used up before birth, the yolk sac may serve far the absorption of nutrients; *i.e.*, as a placenta. In a few species, immature eggs that enter the oviduct are eaten by the developing young.

Very few amphibians bear living young. In the viviparous frog Nectophrynoides, all development, including larval stages, occurs in the uteri and the young are born fully metamorphosed; *i.e.*, except for size they resemble adults. N. occidentalis, an African species, has a nine-month gestation period. There is almost no yolk in the egg and no placenta, so it is probable that uterine fluids provide nourishment and oxygen. In N. vivipara there are as many as 100 larvae in the uteri, each with long vascular tails that may function as respiratory membranes. *Gastrotheca* marsupiata is an ovoviviparous anuran with a gestation period of three to four months. In certain viviparous salamanders the extent of the nutritional dependence on the mother varies. After depleting their own yolk supply, the larvae of some forms eat other embryos and blood that escapes from the uterine lining. Conventional viviparity is rare among amphibians; however, they have evolved unusual alternatives. In some anurans the young develop in such places as around the legs of the male (Alytes), or in pouches in the skin of the back (some females of the genera Nototrema, Protopipa, and *Pipa*). In *Pipa*, vascular partitions in the skin pouch separate developing young, and the larvae have vascular tails that absorb substances. In Nototrema larval gills have vascular extensions with a similar function. The male Chilean toad (Rhinoderma darwinii) carries developing eggs in the vocal sac until the young frogs emerge.

Some snakes and lizards and all mammals except monotremes exhibit viviparity to some degree. The same extra-embryonic membranes found in oviparous reptiles and mammals (yolk sac, chorioallantoic membrane, amnion) function in viviparous ones. Here, the extra-embryonic membranes lie against the uterine lining instead of against an egg shell. At special sites of fetal–maternal contact (placentas), viviparous young receive oxygen and give up carbon dioxide; metabolic wastes are transferred to maternal fluids and tissues; and, in euviviparous species, the young receive all their nutrients. Yolk-sac placentas are common in marsupials with short gestation periods (opossum, kangaroo) and in lizards. Chorioallantoic placentas (*i.e.*, a large chorion fused with a large allantois) occur in certain lizards, in marsupials with long gestation periods, and in mammals above marsupials. The yolk-sac placenta does not invade maternal tissues, but intimate interlocking folds may occur between the two. The chorioallantoic membranes of reptiles and mammals exhibit many degrees of intimacy with maternal tissues, from simple contact to a deeply rooted condition (deciduate placentas). Chorioallantoic or chorionic placentas represent specializations in a chorionic sac surrounding the embryo. The entire surface of the sac may serve as a placenta (diffuse placenta, as in pigs); numerous separate patches of placental thickenings may develop (cotyledonary placenta, as in sheep); a thickened placental band may develop at the equator of the chorionic sac (zonary placenta, as in cats); or there may he a single oval patch of placental tissue (discoidal placenta, as in higher primates).

Reproductive Systems, Plant

In plants, as in animals, the end result of reproduction is the continuation of a given species, and the ability to reproduce is, therefore, rather conservative, or given to only moderate change, during evolution. Changes have occurred, however, and the pattern is demonstrable through a survey of plant groups. Reproduction is basically either asexual or sexual. Asexual reproduction in plants involves a variety of widely disparate methods for creating new plants identical in every respect to the parent plant. Sexual reproduction, on the other hand, depends on a complex series of basic cellular events, involving chromosomes and their genes, that take place within an elaborate sexual apparatus evolved precisely for the creation of new plants in some respects different from the two parents that played a role in their production. (See REPRODUCTION for an account of the common details of asexual and sexual reproduction and the evolutionary significance of the two methods.)

In order to describe the modification of reproductive systems, plant groups must be identified. One convenient classification of organisms sets plants apart from lower forms such as bacteria, algae, fungi, and protozoans. Under such an arrangement, the plants, as separated, comprise two great divisions (or phyla)—the Bryophyta (mosses and liverworts) and the Tracheophyta (vascular plants). The vascular plants include four subdivisions: the three entirely seedless groups are the Psilopsida, Lycopsida, and Sphenopsida; the fourth group, the Pteropsida, consists of the ferns (seedless) and the seed plants (gymnosperms and angiosperms).

A comparative treatment of the two patterns of reproductive systems will introduce the terms required for an understanding of the survey of those systems as they appear in selected plant groups.

GENERAL FEATURES

Asexual systems. Asexual reproduction involves no union of cells or nuclei of cells and, therefore, no mingling of genetic traits, since the nucleus contains the genetic material (chromosomes) of the cell. Only those systems of asexual reproduction that are not really modifications of sexual reproduction are considered below. They fall into two basic types: systems that utilize almost any fragment or part of a plant body; and systems that depend upon specialized structures that have evolved as reproductive agents.

Two basic asexual processes

Reproduction by fragments. In many plant groups, fragmentation of the plant body, followed by regeneration and development of the fragments into whole new organisms, serves as a reproductive system. Fragments of the plant bodies of liverworts and mosses regenerate to form new plants. In nature and in laboratory and greenhouse culture, liverworts fragment as a result of growth; the growing fragments separate by decay at the region of attachment to the parent. During prolonged drought, the mature portions of liverworts often die, but their tips resume growth and produce a series of new plants from the original parent plant.

In mosses, small fragments of the stems and leaves (even single cells of the latter) can, with sufficient moisture and under proper conditions, regenerate and ultimately develop into new plants.

It is common horticultural practice to propagate desirable varieties of garden plants by means of plant fragments, or cuttings. These may be severed leaves or portions of roots or stems, which are stimulated to develop roots and produce leafy shoots. Naturally fallen branches of willows *(Salix)* and poplars *(Populus)* root under suitable conditions in nature and eventually develop into trees. Other horticultural practices that exemplify asexual reproduction include budding (the removal of buds of one plant and their implantation on another) and grafting (the implantation of small branches of one individual on another).

Reproduction by special asexual structures. Throughout the plant kingdom, specially differentiated or modified cells, groups of cells, or organs have, during the course of evolution, come to function as organs of asexual reproduction. These structures are asexual in that the individual reproductive agent develops into a new individual without the union of sex cells (gametes). A number of examples of special asexual agents of reproduction from several plant groups are cited in this section.

Spores and vegetative organs

Airborne spores characterize most nonflowering land plants, such as mosses, liverworts, and ferns. Although the spores arise as products of meiosis, a cellular event in which the number of chromosomes in the nucleus is halved, such spores are asexual in the sense that they may grow directly into new individuals, without prior sexual union.

Among liverworts, mosses, lycopods, ferns, and seed plants, few to many celled, specially organized buds, or gemmae, also serve as agents of asexual reproduction.

The vegetative, or somatic, organs of plants may, in their entirety, be modified to serve as organs of reproduction. In this category belong such flowering-plant structures as stolons, rhizomes, tubers, corms, and bulbs, as well as the tubers of liverworts, ferns, and horsetails, the dormant buds of certain moss stages, and the leaves of many succulents (Figure 1). Stolons are elongated runners, or horizontal stems, such as those of the strawberry, which root and form new plantlets when they make proper contact with a moist soil surface. Rhizomes, as seen in iris, are fleshy, elongated, horizontal stems that grow within or upon the soil. The branching of rhizomes results in multiplication of the plant. The enlarged, fleshy tips of subterranean rhizomes or stolons are known as tubers, examples of which are potatoes. Tubers are fleshy storage stems, the buds ("eyes") of which, under proper conditions, can develop into new individuals. Erect, vertical, fleshy, subterranean stems, which are known as corms, are exemplified by crocuses and gladiolas. These organs tide the plants over periods of dormancy and may develop secondary cormlets, which give rise to new plantlets. Unlike the corm, only a small portion of the bulb, as in lilies and the onion, represents stem tissue. The latter is surrounded by the fleshy, food-storage bases of earlier

formed leaves. After a period of dormancy, bulbs develop into new individuals. Large bulbs produce secondary bulbs through development of buds, resulting in an increase in number of individuals.

Sexual systems. In most plant groups both sexual and asexual methods of reproduction occur. Some species, however, seem secondarily to have lost the capacity for sexual reproduction. Such cases are described below (see Variations in reproductive cycles).

The cellular basis. Sexual reproduction at the cellular level generally involves the following phenomena: the union of sex cells and their nuclei, with concomitant association of their chromosomes, which contain the genes, and the nuclear division called meiosis. The sex cells are called gametes, and the product of their union is a zygote. All gametes are normally haploid (having a single set of chromosomes) and all zygotes, diploid (having a double set of chromosomes, one set from each parent). Gametes may be motile, by means of whiplike hairs (flagella) or of flowing cytoplasm (amoeboid motion). In their union, gametes may be morphologically indistinguishable (*i.e.*, isogamous) or they may be distinguishable only on the criterion of size (*i.e.*, heterogamous). The larger gamete, or egg, is nonmotile; the smaller gamete, or sperm, is motile. The last type of gametic difference, egg and sperm, is often designated as oogamy. In oogamous reproduction, the union of sperm and egg is called fertilization. Isogamy, heterogamy, and oogamy are often considered to represent an increasingly specialized evolutionary series (Figure *2).*

In the plants included in this article—bryophytes (mosses and liverworts) and tracheophytes (vascular plants)—sexual reproduction is of the oogamous type, or a modification thereof, in which the sex cells, or gametes, are of two types, a larger nonmotile egg and a smaller motile sperm. These gametes are often produced in special containers called gametangia, which are multicellular. In cases in which special gametangia are lacking, every cell produces a gamete. In oogamy, the male gametangia are called antheridia and the female oogonia or archegonia. A female gametangium with a sterile cellular jacket is called an archegonium although, like an oogonium, it produces eggs. In most of the plants dealt with in this article the eggs are produced in archegonia and the sperms in antheridia with surface layers of sterile cells.

The plant basis. Individual plants may be either bisexual (hermaphroditic), with male and female gametes produced by the same organism, or unisexual, producing either male or female gametes but not both. A bisexual individual, however, may not be capable of fertilizing its own eggs. In certain ferns, for example, male gametes of one individual are not compatible with the female gametes of the same individual, so that cross-fertilization (with another individual) is obligatory. This, of course, is similar in adaptive significance to cross-pollination (which leads to cross-fertilization) among seed plants.

The "alternation of generations"

Among the liverworts, mosses, and vascular plants, the life cycle involves two different phases, often called generations, although only one plant generation is, in fact, involved in one complete cycle. This type of life cycle is often said to illustrate the "alternation of generations" in which a haploid individual (*i.e.*, with one set of chromosomes), or tissue, called a gametophyte, at maturity produces gametes that unite in pairs to form diploid (*i.e.*, containing two sets of chromosomes) zygotes. The latter develop directly into individuals, or tissues, called sporophytes, in which the nuclei of certain fertile cells, called spore mother cells, or sporocytes, give rise to haploid spores (sometimes called meiospores). These spores are lightweight and are borne by air currents; they germinate to form the haploid, sexual, gamete-producing phase, usually designated the gametophyte.

There are several variations in the above described life cycle. The haploid gametophyte and sporophyte may be free-living, independent plants (*e.g.*, certain algae and yeasts), in which case the life cycle is said to be diplobiontic; or the sporophyte may be physically attached to the gametophyte, as it is in liverworts and mosses. By contrast, the gametophytic phases develop as parasites on the sporophytes of the seed plants, as in certain algae. In further variation, the alternating phases may be similar morphologically except for the type of reproductive cells, gametes or spores they produce (isomorphic life cycle); or they may be strikingly dissimilar, as in some algae, mosses, ferns, and seed plants (heteromorphic life cycle). Only heteromorphic life cycles occur in liverworts, mosses, vascular plants, and certain fungi.

The differences between the gametophyte and sporophyte are often great, especially those of the diplobiontic types, so that the alternates seem to be two different, unrelated individuals rather than different manifestations of the same organism.

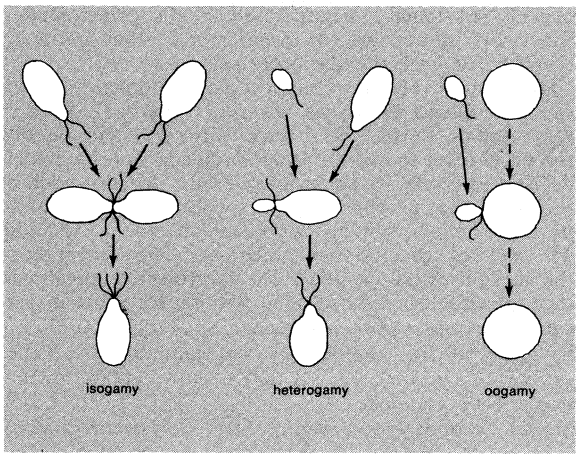

Figure 2: Patterns of fertilization based on gamete types. In isogamy and heterogamy all gametes are motile; in oogamy oniy the smaller is motile, and moves to the larger.

BRYOPHYTE REPRODUCTIVE SYSTEMS

Liverworts and hornworts. The plant bodies of liverworts and hornworts represent the gametophytic (sexual) phase of the life cycle, which is dominant in these plants. In the liverworts, the sporophyte is borne upon or within the gametophyte but is transitory. Liverwort and hornwort plants, depending on the species, may be bisexual or unisexual, and the sex organs may be distributed on the surface (Riccia, Ricciocarpus, *Sphaerocarpos, PelIia*) or localized in groups and borne on special branches (antheriodiophores and archegoniophores) as in *Marchantia*; the sperms are biflagellate (Figure 3).

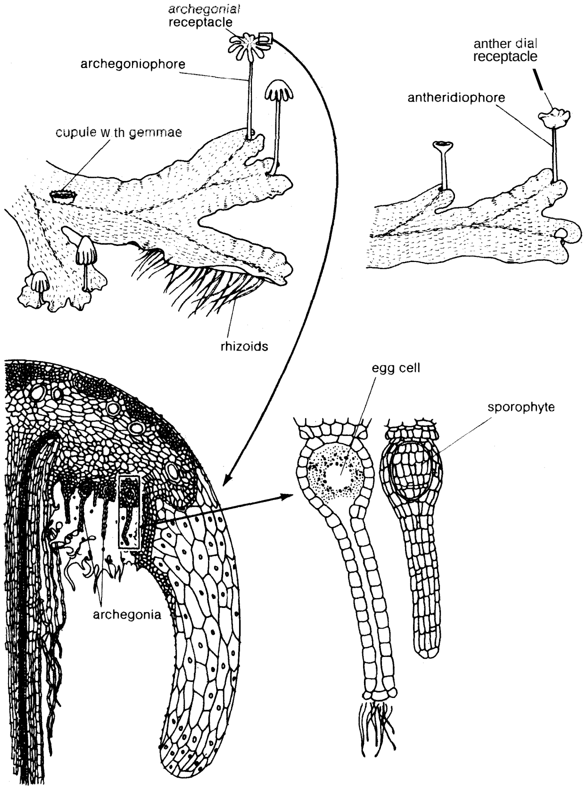

Figure 3: Archegonia and antheridia in the liverwort Marchantia.

Release of the mature sperm and the process of fertilization require moisture in the form of heavy dew or raindrops. In all but a few genera (Riccia, Ricciocarpus), the developing sporophytes are actively photosynthetic—*i.e.,* capable of utilizing light energy to form organic substances. They are, however, dependent on gametophytic tissues for water (and the inorganic salts dissolved in it) and probably derive and utilize in their nutrition some organic substances manufactured by the gametophytes. Liverwort spores are meiospores; *i.e.,* they arise by meiosis from cells called sporocytes.

The sporophytes may consist almost completely of fertile (sporogenous) tissues (Riccia, Oxymitra), or they may contain sterile cells (nurse cells or elaters) among the developing spores. In Marchantia and Porella, a sterile foot and seta, or stalk, are present; the foot anchors the spore-bearing capsule (sporangium) to the gametophyte and also probably serves an absorptive function. The seta connects the foot and capsule. The elongation of the seta raises the capsule from its protective envelopes, thus, placing it in a favourable position for spore dispersal. The capsules of liverworts may shed their spores only by decay of the capsule wall and gametophytic tissues (Riccia, Oxymitra), or they may open irregularly or into two or four segments.

Spore germination in some species may occur immediately after deposition if the spores are in a favourable environment; or, as in other species, the spores may require a period of dormancy before germination.

Mosses. In mosses, as in liverworts and hornworts, the leafy shoots belong to the gametophytic phase and produce sex organs when they mature (Figure 4). The leafy shoots (often called gametophores, because they bear the sex organs) arise from a preliminary phase called the protonema, the direct product of spore germination. Filamentous, straplike, or membranous, it grows along the soil surface. A protonema of a moss may proliferate, apparently indefinitely, under favourable conditions and thus increase the population of leafy shoots that arise as buds. Under adverse conditions, certain buds and branches of the protonema may thicken their walls and thus serve to tide the species over an unfavourable growing period.

The gametophores of mosses

The antheridia and archegonia may be borne at the tips (apices) of the main shoots or on special, lateral branchlets. Both bisexual and unisexual leafy shoots occur, depending on the species. In a number of mosses (*Mnium, Polytrichum,* Funaria), the sexually mature shoots become recognizable through the production of special, prominent leaves that form an apical cup around the sex organs. If brightly coloured, the cup is often flowerlike. In species with bisexual leafy gametophores, the archegonia and antheridia may be present on the same apex (as can be seen, for example, in *Bryum*) or at the apices of separate branches as is evidenced in the moss *Funaria.*

The archegonia and antheridia of mosses are large enough in many species to be just barely visible to the unaided eye. The jacket cells of the antheridia are often coloured bright orange or rust; their sperm are biflagellate. As in liverworts and hornworts, rains and even heavy dews evoke the liberation of sperm and the opening of the mature archegonia so that fertilization may be accomplished.

The moss sporophyte, which is attached to the gametophyte, photosynthesizes during much of its development and is more or less self-supporting. It is, to a certain degree, dependent upon the gametophyte for nutrients

such as water and mineral salts and, in some cases, even for elaborated foods.

After elongation of the moss sporophyte has ceased, the distal portion (farthest away) enlarges to form the capsule (sporangium), or spore-bearing region. The spores (meiospores), which arise by meiosis, are shed from the capsules gradually through a variety of mechanisms. After the operculum (cover) of the capsule has been shed, its mouth is usually partially closed by the peristome (teeth) and sometimes by associated structures. These teeth absorb moisture, and their resultant swelling and contraction open spaces through which the spores are shed.

TRACHEOPHYTE REPRODUCTIVE SYSTEMS

Dominance of the gametophyte

Spore plants. In liverworts, hornworts, and mosses, the dominant phase in the life cycle is the sexual gametophyte. In the tracheophytes (vascular cryptogams and seed plants), on the other hand, the sporophyte is the dominant phase in the life cycle. The gametophytes of the vascular cryptogams mature after the spores that initiated them have been shed from the parent plant, so that the gametophytes are free-living. In the seed plants the garnetophytes mature as parasites on the sporophytes.

Psilopsids. The trilobed sporangia of the whisk fern *Psilotum*—not a true fern but a psilopsid—are borne terminally on short lateral branches. During development, some of the potentially spore-bearing tissue is used as nutrient by the sporocytes as they complete the meiotic divisions that result in colourless kidney-shaped spores. The latter, which are shed as the sporangia open along three lines, germinate and slowly develop into cylindrical, sparingly branched gametophytes, about 0.5 to two millimetres (0.02 to 0.08 inch) in diameter and several millimetres long. They presumably derive nourishment from decaying matter and occur in humus-rich soil, in rock fissures, or among roots on the trunks of tree ferns. The cells of the gametophyte contain fungal structures (hyphae) that probably are involved in some type of nutritional relation with the gametophyte.

The gametophytes are bisexual and the sperms multiflagellate. The embryonic sporophyte is not easily distinguished from the gametophyte that bears it. At first anchored to the gametophyte by an absorptive foot, the sporophyte ultimately becomes separated from both the foot and the gametophyte.

Lycopsids. In the genus Lycopodium, the sporangia are closely associated with the leaves. In some species (L. *lucidulum*), the sporangium-bearing leaves (sporophylls) occur in zones among the vegetative portions of the stems. In most, however, the sporophylls occur in specialized compressed stems, called cones, or strobili (Figure 5). Each sporophyll is associated with one yellow to orange, kidney-shaped sporangium.

From Biolooical Science: An Inquiry into Life, 2nd ed. (1968): Harcourt Brace Jovanovich, Inc., New York; by permission of the Biological Sciences Curriculum Study

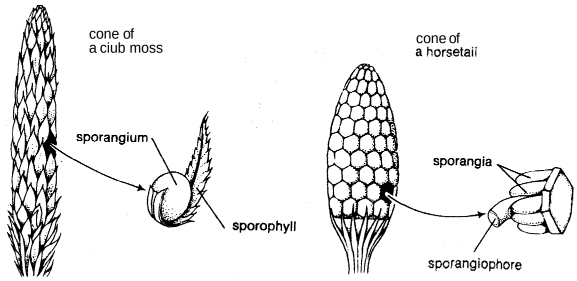

Figure 5: Sporangial protection of a club moss and a horsetail.

In several species the spores develop rapidly on the soil surface into ovoid-cylindrical gametophytes about two to three millimetres (0.08 to 0.12 inch) long, with green lobes and colourless bases; they usually contain a fungus. In other species, development of a colourless gametophyte is slow, so that at maturation, which may require up to eight years, the fleshy gametophyte will have become buried in successive layers of humus. These subterranean gametophytes, which contain fungi, are long-lived and are larger (up to two centimetres) than the surface types.

The gametophytes of Lycopodium are bisexual, although the antheridia and archegonia may develop into separate groups. The sperms are biflagellate and apparently more than one egg of the same gametophyte may be fertilized.

The zygote divides at a right angle to the long axis of the archegonium. The inner cell gives rise to the embryo, which thus is oriented as if it will develop within the gametophyte; it turns 180" during later development, however, and the axis grows vertically outward from the gametophyte.

The heterosporous condition

In contrast to *Lycopodium*, all *Selaginella* sporophytes have sporophylls localized in strobili, and all species of *Selaginella* are heterosporous: that is, they produce spores of two sizes, the larger designated as megaspores and the smaller as microspores. The megaspores develop into female gametophytes and the microspores into male gametophytes. Accordingly, strobili bear megasporophylls that contain megasporangia, which will produce megaspores, and microsporophylls that contain microsporangia, which will yield microspores. Although the evolutionary origin of two kinds of spores (dimorphism) is unknown, the development of megaspores in living plants suggests that differences in nutrition in the two kinds of sporangia are significant. In a microsporangium, most of the microsporocytes undergo meiosis, forming four spores each; by contrast, all but one or, occasionally, several of the sporocytes in the megasporangium do not complete development. As a result, only four megaspores usually mature in such a sporangium, enlarging as they become gorged with the nutrients made available by disintegration of the other cells. The megaspores, accordingly, are much larger than microspores, although both contain stored food. Both types of spores are thick walled, and both have prominent three-part (triradiate) ridges.

Unlike the homosporous spores of most liverworts, hornworts, mosses, ferns, and Lycopodium, the spores of *Selaginella* begin to develop into gametophytes before they have been shed from their sporangia and attain maturity on a suitable, moist substrate.

The microscopic male gametophyte is composed essentially of a single antheridium, which produces biflagellate sperm. The female gametophyte, which protrudes after the megaspore wall cracks open in the region of the triradiate ridge, consists of vegetative cells, has several archegonia at maturity, and usually has three groups of rhizoids. Both male and female gametophytes lack the chlorophyll (green pigment) necessary for photosynthesis; they utilize nutrients stored in the spores.

After fertilization, one zygote of each female gametophyte develops into an embryonic sporophyte. There is considerable variation in details of development among the species of *Selaginella.* In some, the spores may develop mature gametophytes before they are shed from their sporangia, and fertilization may occur, so that female gametophytes with embryos may be found in the strobili (compressed stems, or cones). The megaspores of *Selaginella,* containing female gametophytes with still-attached juvenile sporophytes, have the superficial appearance of germinating seeds, from which, however, they differ in many significant respects.

Zsoetes, like *Selaginella,* is monoecious and heterosporous. Most of the leaves are fertile; some bear one large megasporangium each, and others support a single microsporangium on the inner surface of a spoonlike leaf base. The microsporangia can produce enormous numbers of microspores—as many as 1,000,000—and the megasporangia give rise to 50 to 300 megaspores. The spores are liberated as the older sporophylls decay. Unlike those of *Selaginella,* the spores of Zsoetes do not germinate until they have been shed from their sporangia. The unisexual garnetophytes are much like those of *Selaginella,* but the sperm are multifiagellate. The embryonic sporophyte is nourished by food stored in the megaspore and transported through a massive foot.

Sphenopsids. The perennial sporophytes of horsetails (Equisetum species) produce strobili once during every growing season. They ma, be borne at the tips of green shoots (E. *hyemale*, E. kansanum); at the tips of nongreen shoots that become green after the spores have been shed (E. *fluviatile*, E. sylvaticum); or on special nongreen branches that wither and die after the spores have been shed (E. arvense, E. talmateia). The appendages of the strobilus are often called sporangiophores and have been considered to be both stem branches and of leafy origin; in the latter case, they are called sporophylls (Figure 5). Each sporangiophore bears a number of fingerlike sporangia, which produce large numbers of thin-walled, green spores. The outermost wall layer of the spore breaks down into four appendages, which, by their sensitivity to moisture, coil and uncoil, thereby disseminating the spores.

The spores of *Equisetum* germinate rapidly and grow into green, pincushion-like gametophytes anchored to the surface by rhizoids. Apparently, two types of gametophytes are produced from the homosporous spores; some mature slowly, are smaller than others, and always produce antheridia, never archegonia. Others are larger and hermaphroditic, producing archegonia at first and, later, antheridia. The ratios of male to hermaphroditic gametophytes vary among species but are relatively uniform within a species. The ratios are altered by changes in environmental conditions; for example, at certain temperatures (*e.g.*, 32° C, or 90° F) only male gametophytes develop from the spores of five species; whereas at 15" C (59° F) approximately 50 percent are male and 50 percent hermaphroditic gametophytes.

Environmental influences on sex ratios

Self-fertilization of hermaphroditic gametophytes can occur, and several sporophytes may be produced on one gametophyte. The embryo consists of an absorptive foot, a primary root or radicle, and a shoot with whorled appendages.

Ferns. As they mature, many fern sporophytes begin to produce spores in clusters of sporangia on the undersurfaces of their vegetative "leaves." Others produce their sporangia on highly modified leaves or portions thereof.

The site of origin of the sporangia is the receptacle; the latter, with its groups of sporangia, is called a sorus. In many ferns each sorus is covered with a special outgrowth, the indusium; in others, the sporangia are covered during development by the margin of the leaf. In a few ferns (*e.g.*, Polypodium), the sori remain uncovered.

In primitive ferns, such as Ophioglossum and *Botrychium*, the spores are borne upon a specialized axis, the fertile spike. The sporangia of such primitive ferns are massive, with several layeis of cellular walls, and produce an Indefinite but large number of spores. In most other ferns, the sporangia are smaller, long stalked, with single-layered walls and a definite number of spores. The spores of the latter are shed explosively by breakage and shrinking as the sporangia open and then slam shut.

Homospory and heterospory in ferns

Most ferns produce one kind of spore (homospory), but a few genera of aquatic and amphibious ferns (Marsilea, Salvinia, and Azolla) produce two kinds (heterospory), small microspores and much larger megaspores. In either case, after being shed from the parent sporophyte, the spores that have suitable environmental conditions germinate and develop into the gametophytic phase. The ribbonlike, filamentous or heart-shaped gametophytes of most ferns contain chlorophyll, are anchored to some surface—moist soil, moist rocks, or tree bark—by unicellular root-like rhizoids, and rarely exceed one-half inch (13 millimetres) in diameter. In a few ferns (*Ophioglossum*, Botrychium, and certain species of Schizaea), the gametophytes are subterranean, lack chlorophyll, are cylindrical or tuberous, and contain the filamentous structures (hyphae) of an associated fungus.

Fern gametophytes, often called prothalli (singular, prothallus) are one cell layer thick except in the centre. Most fern prothalli are bisexual—*i.e.*, have both male (antheridia) and female (archegonia) sex organs, which develop usually on the undersurface of the prothallus.

Although the eggs of several archegonia may be fertilized, only one zygote usually develops into a juvenile sporophyte. The latter consists of an absorbing foot; a primary root, or radicle, which promptly penetrates the surface; a prominent first leaf; and a rudimentary, slow-growing stem. As the juvenile sporophyte becomes established, the parental gametophyte dies. The series of leaves formed from the stem of the juvenile sporophyte gradually attain the form and vein pattern that characterize the mature sporophyte.

In most ferns, the antheridia appear before the archegonia and continue to develop as the latter mature; furthermore, the archegonial necks curve toward the mature antheridia so that fertilization can readily occur. Both gametes may be derived from one individual, or from different individuals. In the bracken fern (*Pteridium* aquilinum), although the gametophytes are bisexual, self-incornpatability factors reduce self-fertilization. In Onoclea *sensiblis*, the gametophytes are unisexual in early development, thus favouring cross-fertilization; but, later, the gametophytes become bisexual so that, if cross-fertilization fails, the species can still be maintained.

Seed plants. In the two great groups of seed plants, gymnosperms and angiosperms, the sporophyte is the dominant phase in the life cycle, as it is also in the vascular cryptogams; the gametophytes are microscopic parasites on the sporophytes (Figure *6)*.

Reprtnted from The Spectrum of *Life* by Harold A. Moore and John R. Carlock; Copyright © 1970. Harper & Row, Publtshers. Inc.

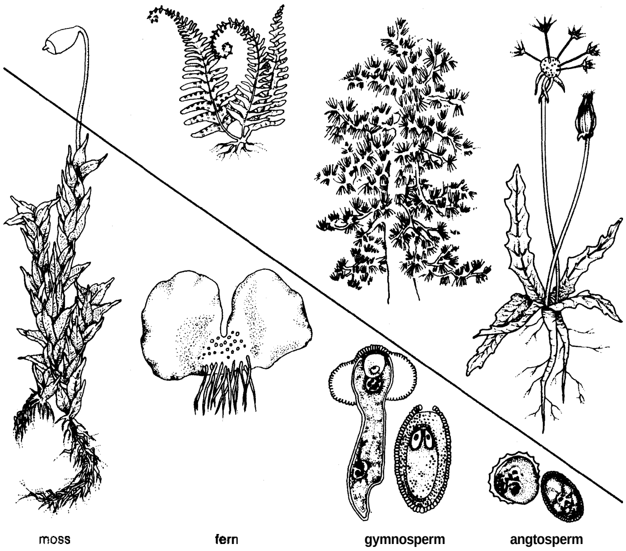

Figure 6: Change in relative size of the gametophyte (below the line) and sporophyte (above the line) in the course of plant evolution. In the moss, the sporophyte is entirely dependent upon the gametophyte.

In the gymnosperms, the seeds occur individually, exposed at the ends of stalks, sometimes in whorls on an axis, or on the scales of a cone, or megastrobilus. In angiosperms, or flowering plants, by contrast, the seeds are enclosed during development in a structure variously termed a pistil or carpel, which is sometimes considered to represent an enfolded megasporophyll.

Events in the reproductive process

A number of parts of the reproductive process are common to both angiosperms and gymnosperms: (1) they produce seeds at maturity; (2) the megasporangium, unlike that of heterosporous seedless plants, is covered by one or two cellular layers called integuments and is termed an ovule; (3) there is a minute passageway, or micropyle, through the integuments; (4) the ovule matures as a seed; (5) only one megasporocyte is present and undergoes meiosis in the megasporangium to produce four megaspores, only one of which usually is functional; *(6)* the megaspore is never discharged from its megasporangium and ovule; (7) one female gametophyte is produced within each megasporangium and ovule; (8) the microspores begin their development into male gametophytes while still enclosed in the microsporangia; (9) as they mature, the male gametophytes, which are contained within the microspore wall and are termed pollen grains, develop a tube that conveys sperm to the egg cell;

(10) union of sperm and egg and development of an embryonic sporophyte from the zygote occur within the female gametophyte (sometimes called the "embryo sac"), which is covered by the remains of the megasporangium and by integuments; (11) as the embryo develops, the ovule matures as a seed.

In contrast to this impressive list of similarities are important differences, which, in addition to seed position, serve to distinguish angiosperms from gymnosperms. The reproductive cycle in most angiosperms is completed quicker than that in gymnosperms, and the gametophytes are smaller and simpler and, unlike those of most gymnosperms, lack archegonia. The pollen in angiosperms is transferred to the surface of the megasporophyll, whereas in gymnosperms it is brought to the micropyle of the ovule itself. Two sperm are involved in the sexual union in angiosperms: one unites with the egg to form a zygote; the other unites with two nuclei of the female gametophyte to form the primary endosperm nucleus. The latter divides to form a postfertilization storage tissue, which serves as a food source for the embryo; the embryo of gymnosperms is nourished by the somatic (nonreproductive) tissues of the female gametophyte. The angiosperm ovule increases to mature seed size after fertilization, whereas in gymnosperms, this enlargement occurs prior to fertilization.

The general features of the reproduction of seed plants having now been summarized, certain special aspects of the reproduction in representative seed plants are described below.

Gymnosperms. The cycads are slow-growing dioecious gymnosperms, the microsporangia (potential pollen) and megasporangia (potential ovules) occurring on different individual sporophytes. In all cycads except the genus Cycas, the ovules are borne on megasporophylls in megastrobili; in Cycas the ovules develop on individual, leaflike megasporophylls in what is regarded as a primitive arrangement. The microspores of all cycads develop in microstrobili.

The microspores reach the three-celled stage of development of the male gametophyte before they are shed as pollen grains from the microsporangia. At this time, elongation of the megastrobilus separates the megasporophylls, and the wind-borne pollen grains have access to the micropyles of the ovules. At the time of pollination each ovule exudes a mucilaginous droplet, the pollination droplet, through the micropyle; some of the pollen grains become engulfed in this droplet and are drawn into the ovule.

The interval between pollination and fertilization is several months in cycads. The sperm are multiflagellate and are among the largest (about 300 microns, or 0.01 inch) in the plant kingdom. Each pollen tube may contain from two to 22 sperm, depending on the genus. The pollen tubes, which develop from the pollen grains, work their way through the megasporangium of the ovule to the archegonia of the female gametophyte. Fertilization of the eggs of the several archegonia is followed by the early development of several embryos (polyembryony), only one of which survives in the mature seeds. Cycad embryos produce two seed leaves, or cotyledons. The seeds are brightly coloured (yellow or scarlet) and covered by an outer fleshy layer and a stony layer of the integument. The seeds of some cycads (*e.g.*, Cycas) may germinate in the megastrobilus without a period of dormancy.

Systems of the ginkgo and the conifers

The maidenhair tree, or ginkgo (Ginkgo biloba), is sometimes classified with the conifers (see below) or separately in a group of which it is the sole living representative. The mature ginkgo (sporophyte) produces microstrobili and ovules each spring as the buds unfold. They occur on the spur shoots among the bases of the young leaves. The ginkgo, like the cycads, is strictly dioecious, so that some trees produce ovules and others produce pollen. The ovules occur in pairs at the tips of stalks that emerge among the leaf bases.

Ginkgo pollen, like that of pines, is four-celled at the time of pollination (spring season), which is accomplished by wind. Development of male and female gametophytes is similar to that in cycads, and the sperm are also multiflagellate. The female gametophyte, within the ovule of Ginkgo, is unique among seed plants in containing chlorophyll. The ovules enlarge tremendously after pollination, and as the seeds mature the integument differentiates into several coats, of which a stony layer and outer fleshy layer are most prominent. The latter becomes mottled, purplish green and foul smelling. Its tissues may cause nausea or skin eruptions in man. The inner tissues of the seed (the embryo and the female gametophyte) are palatable and prized among some peoples. Fertilization often occurs after the ovules have fallen from the trees, three or four months after pollination. The ginkgo embryo has two cotyledons.

The sporophytes of most of the species of living conifers, like those of the ginkgo, are woody trees at maturity. They usually grow for a number of years beyond the seedling stage before they mature and produce seeds.

The sporophyte of a typical conifer, such as a pine, may become a large tree. Unlike the cycads and ginkgo, a pine is monoecious, both microstrobili and megastrobili occurring on the same tree. At the beginning of each growing season, the microstrobili enlarge and emerge from their bud scales; they are borne at the base of the terminal bud, which is destined to develop into the current season's growth. The megastrobili, by contrast, arise singly or in a whorl near the apex of the current season's growth.

The microstrobili are called simple strobili because the microsporangia are borne in pairs on the appendages (microsporophylls) that emerge from the axis of the strobilus. The megastrobili, however, are compound, for the ovules are borne in pairs upon the upper (adaxial) surface of scales, which, in turn, are borne on bracts attached to the megastrobilus.

The pollen of pine, four-celled when shed, is characterized by two lateral, air-filled "wings," enlarged cavities between two layers of the pollen-grain wall. The pollen is produced in large amounts and may be transported great distances by air currents. During the time of pollination, the ovuliferous scales on the megastrobili separate slightly, and pollen can be trapped in the pollination droplet of the micropyles of the ovules. Pollen grains that make contact with a droplet are transferred by its subsequent contraction through the micropyle and to the surface of a small depression (pollen chamber) at the tip of the megasporangium.

As the pollen grain germinates, forming a tube that works its way through the megasporangium, it arrives at the female gametophyte as the latter matures its several archegonia. The pollen tubes discharge their sperm nuclei into the archegonia, and fertilization is accomplished. As in the cycads and ginkgo, the zygotes of several archegonia may initiate embryogeny. Furthermore, in pine and certain other conifers, the young embryos may form several embryos. At maturity of the seed, however, only one embryo is normally present, embedded in the remains of the female gametophyte and megasporangium, all surrounded by the seed coat (the former integument).

The reproductive process in pine occupies two full growing seasons: ovules pollinated in the spring of a given year do not mature as seeds until the late summer of the next year. The interval between pollination and fertilization is about 14 months.

Reproductive variations in gymnosperms

Among the numerous other gymnosperm species are many different reproductive processes. Some gymnosperms, for example, are dioecious, with microstrobili and megastrobili being borne on separate plants, as in junipers (Juniperus), plum yews (Cepkalotaxus), yews (*Taxus*), and podocarps (Podocarpus). Furthermore, in larches (Larix) and other groups the pollen grains lack wings. The pollen grains in larches become attached at pollination to a special receptive enlargement of the integument. In podocarps, the megasporangium bulges through the micropyle at pollination and receives the pollen directly. The interval between pollination and fertilization may be as short as four to five weeks in firs (Abies). The number of ovules formed on the ovuliferous scale varies, as does the number of microsporangia on the microsporophyll. There may be only one ovule in a megastrobilus, as in some junipers, and the megastrobili may become fleshy, also in junipers. In yews the solitary ovules are terminal on dwarf shoots; each ovule is surrounded by a cuplike structure called an **aril,** which becomes fleshy and brightly coloured as the seed matures. The number of sperm produced in each male gametophyte varies also—from two in pine to 20 in some cypresses (*Cupressus*).

The genera Ephedra, Gnetum, and Welwitschia, which are often grouped together in one category (Gnetales, or Gnetophyta), differ among themselves and from other gymnosperms with respect to several details of reproduction. The microsporangia and ovules of both Ephedra and Welwitschia are produced in compound strobili; those of Gnetum are borne in a series of whorls on elongated axes sometimes called misleadingly "inflorescences." The ovules of these genera, unlike those of other gymnosperms, have two integuments instead of one, as in angiospermous ovules. Archegonia are present in the female gametophytes of Ephedra, but only eggs occur in those of Gnetum and Welwitschia. The sperm, like those of the conifers, lack flagella.

Angiosperms. Although the angiosperms are known as flowering plants, they are difficult to distinguish from gymnosperms solely on the basis of bearing flowers, for, like the strobilus, a flower is a compressed stem, with crowded, spore-bearing appendages. The occurrence of coloured petals and attractive scents is not essential and is by no means characteristic of all flowers. The most important distinguishing feature separating flowering plants from gymnosperms is that the ovules of flowering plants are produced within enclosed contaniers called carpels (Figure 7).

Flowers may occur singly at the ends of stems (*e.g.,* tulip, poppy, rose), or they may be grouped in various clusters or inflorescences (gladiolus, sunflower, delphinium, and yucca).

An individual flower may be complete, in that a given floral receptacle produces sepals (often greenish and leaflike), petals (often white or coloured other than green), stamens, and a pistil (or pistils). The sepals are collectively known as the calyx, and the petals as the corolla; the calyx and corolla comprise the perianth. If sepals or petals are lacking, the flower is said to be incomplete. Although incomplete, a flower that has both stamens and a pistil is said to be perfect; lacking either of these parts, it is imperfect.

In practice, groups of solitary flowers are not easily distinguished from inflorescences; the latter seemingly evolved from a system of branches, each with a terminal, solitary flower. The inflorescence may be few flowered or have up to **6,000,000** flowers, as in certain palms. Inflorescences vary also in their position, being terminal, axillary, or intercalary. Terminal inflorescences are at the tips of the major or dominant branches; axillary ones are at the tips of axillary, or side, branches. In intercalary inflorescences, the stem continues beyond the inflorescence, which may result in alternating fertile and sterile areas of the axis.

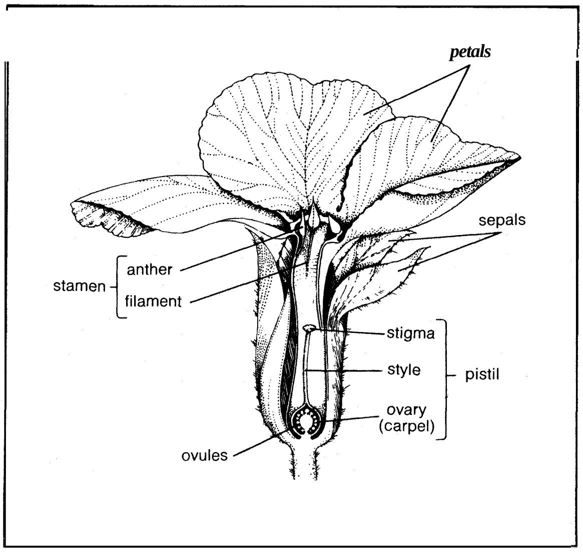

Figure 7: Gross morphology of the flower.

Types of floral clusters

Inflorescences can be distinguished by their growth patterns as determinate or indeterminate. In determinate inflorescences the first formed flower at the tip of the dominant stem matures first, and younger flowers develop on lower lateral branches; the cyme of the forget-me-not (Myosotis) is a typical example. In indeterminate inflorescences the growing region of the axis functions for extended periods so that as the older flowers mature and set fruit near the base of the inflorescence axis, younger buds develop and continue to expand into flowers at the apex. This is exemplified in the spikes of yucca and the racemes of delphinium, in which the youngest flowers are farthest away from the root. Other types of indeterminate inflorescences include umbels and capitula, or heads. The youngest flower is terminal or central in umbels and in heads.

The head is the type of inflorescence that characterizes the composite, or aster family. It may be few to many flowered and usually has at its base one or more series of leaflike bracts. The small individual flowers arise in spiral order on the receptacle, the youngest being at the centre. The basal calyx of each flower, known as a **pappus,** is bristle-like, scaly, or feathery and borne at the top of the ovary. The corolla, formed of the petals, may be: (1) tubular, with five petal lobes, sometimes split open; (2) ligulate, or tonguelike, with a very short basal tube; or (3) bilabiate, with the tube split into two tips. In some genera, all of the flowers are ligulate, whereas in others, the marginal flowers are ligulate (ray flowers) and the others tubular or all are tubular. The marginal ray flowers are either female (pistillate) or sterile. The tubular flowers are characterized by male and female parts: five united pollen-bearing stamens and a pistil, which matures as a one-seeded fruit (achene).

The position of the floral organs with reference to each other and to the tip of the floral receptacle varies in different flowers; in some, the perianth (sepals and petals) and stamens are attached to the receptacle below the pistil; such flowers are hypogynous (*e.g.,* buttercup and magnolia). In others (rose, cherry, peach), the perianth and stamens are borne on the rim of a concave structure in the depression of which the pistil is borne; such flowers are perigynous. Finally, there are flowers in which the ovary is enclosed by a tissue composed of the fused bases of the perianth and stamens (apple, pear, aster); the blossom seems to arise upon or above the ovary and is called epigynous.

The stamen, seemingly the equivalent of the gymnospermous microsporophyll, consists of an anther (a group of two to four microsporangia) borne at the tip of a blade stalk, or filament. The pistil, most often composed of an enlarged basal ovary, a columnar style, and distal stigma, is the ovule-producing organ of the flower. It is often considered to have evolved from enfolded megasporophyll or some other ovuliferous structure with enclosed ovules (angiospermy); alternatively, it is thought to have arisen from the cuplike bracts of extinct seed-bearing plants on which the leafy bracts grew together and thus enclosed the ovules.

There may be one or more pistils on the floral receptacle, depending on the species. Furthermore, pistils may be simple (composed of one ovule-bearing unit, megasporophyll, or carpel) or compound (composed of more than one carpel). Compound pistils are thought to have arisen as a result of crowding of simple pistils on the floral axis; for example, variation in the degree of fusion may be observed in members of the saxifrage family. The ovary —which matures as the fruit—usually reveals by the number of ovule-containing chambers (locules) the number of carpels it contains. The stigma is a specially adapted portion of the pistil modified for the reception of pollen. It may be feathery and branched or elongated, as in such wind-pollinated flowers as those of the grasses, or it may be compact and with a sticky surface. The ovary may contain one ovule (*e.g.*, buckwheat, avocado), a few ovules (*e.g.*, grape, bean) or a large number of ovules (tobacco, begonia, snapdragon).

In some angiosperms (*e.g.*, corn, hickory, walnut, pecan, oak) both types of imperfect flower are borne on the same plant, which is, therefore, called monoecious. By contrast, staminate flowers may occur on one plant and pistillate flowers on another, as in willows, poplars, and mulberries, which are said to be dioecious. In common parlance (and unfortunately in some botanical textbooks) staminate flowers and plants that bear them are often designated "male," and pistillate flowers and the plants that bear them are called "female." This may be traced back at least as far as to the time of Linnaeus (1753), who interpreted stamens and pistils as sex organs. Comparative morphology indicates clearly, however, that stamens and pistils are the spore-bearing structures of the sporophyte and not actually the gamete-bearing organs of the gametophyte. The terms "male" and "female," applied to angiosperm plants and their flowers, is often condoned because the gametophytic phase is so condensed in angiosperms. The designations suggest to the uninitiated, however, that pollen grains and sperm, on the one hand, and eggs and ovules, on the other, are identical, which is not the case.

Floral organization

Among the vast number of species of angiosperms there is considerable variation in floral organization. The perianth may be absent or present; clearly differentiated as calyx and corolla (*e.g.*, pea); or the perianth segments may be similar (magnolia, tulip tree). The number of stamens and pistils may be large and separately attached to the receptacle in a spiral pattern (buttercup), or the numbers may be reduced and the attachment cyclic or whorled (lily). The stamens may be fused together by their anthers (daisy) or their filaments (peas, beans). The filaments may be petallike (water lilies) or stalklike. Opening of the anther may be by longitudinal or transverse fissures or by terminal pores.

The reproductive cycle in angiosperms can be traced from before the shedding of pollen (Figure 8). The microspores begin their development of male gametophytes, which involves formation of a small generative cell and a tube cell. The generative cell may divide to form two sperm before the pollen grain (developing male gametophyte) is shed, or while the pollen tube is growing during germination. The pollen grains of angiosperms have variously, and often elaborately, ornamented walls characteristic of the species.

Pollination in angiosperms is the transfer of the pollen grains from the anther of a stamen to the stigma of a pistil. It may be accomplished by the force of gravity, wind, or water or by agency of insects, birds, or bats. A pollen grain that is trapped on the stigma may germinate, the pollen tube growing rapidly through stigma and style into the ovary, where it enters an ovule.

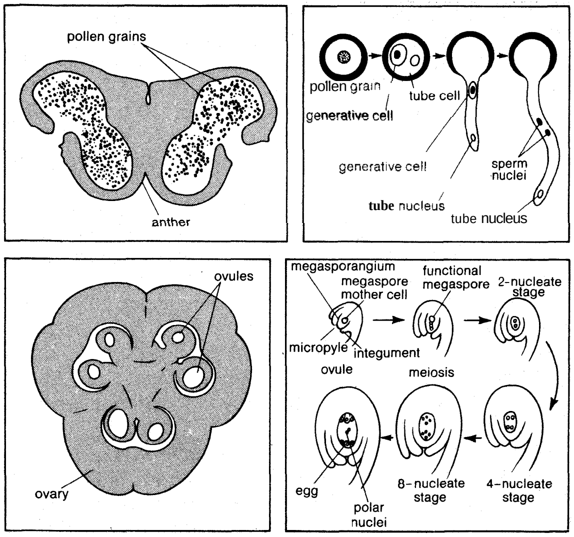

Figure 8: Gametophyte development in a flowering plant (lily). (Top left) Cross section through the anther of a lily. (Top right) Microgametophyte from the microspore. (Bottom left) Cross section through the ovary of a lily. (Bottom right) megagametophyte from the megaspore.

The pistil of a flower may receive pollen from the stamens of the same flower, in self-pollination (*e.g.*, peas and tomatoes). In many other flowers, however, pollen from one or more flowers is transferred to the stigmas of other flowers. A number of specialized relationships have evolved between floral organization and animal pollinators such as insects (see POLLINATION).

In the majority of angiosperms one megasporocyte develops in the megasporangium (often called the nucellus) of the ovule, and a tetrad of megaspores is formed as a result of meiosis. Three megaspores (nearest the micropyle) degenerate; only one enlarges, and then undergoes divisions to form the eight-nucleate, seven-celled female gametophyte ("embryo sac"). Of the three cells of this gametophyte near the micropyle, one functions as an egg. As the pollen tube discharges its contents into the female gametophyte, the egg nucleus is fertilized by one of the sperm, the other unites with the two nuclei (polar nuclei) within the large central cell of the female gametophyte. The resultant nucleus, which has three sets of chromosomes, is the primary endosperm nucleus. This process, double fertilization, occurs only in angiosperms.

Pattern of development

Both pollination and fertilization stimulate cell division in the ovary, ovules, and zygotes, all of which enter upon a period of rapid enlargement. In most angiosperms, the primary endosperm nucleus divides to form endosperm tissue, the cells of which become filled with stored food, such as starches, oils, and proteins. As the rate of embryonic development decreases, the seeds of most angiosperms enter a period of dormancy, accompanied by dehydration and hardening of the integuments, which form seed coats. At this period, the enlarged ovary (and sometimes adjacent structures) matures as fruit.

Angiosperm seeds may germinate as soon as they reach maturity, or they may undergo various kinds of dormancy. In some cases (*e.g.*, coconut) the embryo is rudimentary and undifferentiated when the seed is shed, so that a period of preparation, or after-ripening, is required. In other types of dormancy, germination is retarded by the hardness and impermeability of the seed coat or by special requirements of light, temperature, and moisture.

Some representative variations occur in the reproductive process of angiosperms. In violets (Viola), in addition to the ordinary flowers produced first during the usual flowering season, less conspicuous flowers later develop; called cleistogamous flowers, they do not open but are self-pollinated, thus insuring augmentation of the population during a period less favourable for the usual blossoms.

The pollen grains of most angiosperms separate from each other, but in some cases (*e.g.*, Rhododendron) they remain attached in original groups of four, called tetrads. The very tiny pollen grains of orchids, certain mimosas, and milkweeds are clustered in waxy masses called pollinia (singular pollinium).

A number of variations in pattern of development of the female gametophyte occur in various angiosperms; for example, in certain species of evening primrose (*Oenothera*), the female garnetophyte contains only four nuclei, whereas, in Peperomia, as many as 16 may be present. In lily, all four megaspore nuclei are involved in the formation of the female gametophyte.

Pollen may germinate immediately after contact with a stigma (sugar cane), within five minutes (corn), in two hours (beet), or after one or two days. The pollen grains of most plants produce only one pollen tube, but ten or more pollen tubes have been observed to develop from one pollen grain in plants of the mallow family. The pollen tubes usually enter through the micropyle (porogamy), but they may also enter through the base of the ovule (chalazogarny).

The interval between pollination and fertilization varies. It may be as long as 12 to 14 months in certain species of oak, five to seven months in witch hazel; two to 20 weeka among the orchids; three to four hours in lettuce and as little as 15 to 45 minutes in dandelions.

The postfertilization endosperm fails to develop in orchid seeds but is present at least during early embryogeny in most others. The endosperm may arise by nuclear divisions and become cellular as nuclear divisions terminate, or its development may involve both nuclear and cell divisions from the beginning. In a number of cases (*e.g.*, legumes) the embryo consumes the endosperm during its development, resulting in mature seeds with massive embryos and no endosperm. Most angiosperm embryos have two seed leaves (are dicotyledonous), some have one lateral cotyledon (are monocotyledonous), and a few (*e.g.*, Degeneria) have three to four cotyledons.

In seed germination, the cotyledons may remain below the soil surface within the seed (hypogean germination) and may function in digesting and absorbing endosperm (corn), may serve as sources of stored food themselves (pea!, or may rise above the soil surface (epigean germination) by elongation of the hypocotyl, the embryonic axis between the root, the growing stem, or epicotyl. Cotyledons that emerge above the soil may wither and drop off as their food is used (*e.g.*, bean), or they may persist and function as photosynthetic leaves (*e.g.*, castor bean).

An even greater range of variation occurs in angiospermous fruits. The fruit may arise from one pistil (simple or compound) of one flower (*i.e.*, the simple fruits of pea and peach), from several pistils of one flower (*i.e.*, the aggregate fruits of strawberry and raspberry), or from the pistils of several flowers (*i.e.*, the multiple fruits of pineapple, mulberry, and corn). Simple fruits may be dry (legumes) or fleshy (peach, apple, tomato) at maturity. Dry fruits may open (dehisce; many legumes) or remain closed about the seed (be indehiscent; grasses and sunflower).

The manner of ovular attachment is known as placentation. The ovary may contain one to many ovules, which may be attached to the ovary wall (parietal placentation) or to the central axis (axial, or free-central placentation). Despite these and other variations in the morphology of flower parts, the reproductive process is, with minor diversities, remarkably uniform.

VARIATIONS IN REPRODUCTIVE CYCLES

The life cycles and reproductive processes described above characterize the vast majority of their respective plant groups.

Among the liverworts it has been demonstrated that small fragments of the stalk of the sporophyte are capable of regenerating diploid gametophytes. In the mosses, both haploid and diploid apospory have been experimentally evoked. As in the liverworts, injury and regeneration of fragments of the sporophytic seta result in diploid gametophytes. By contrast, fragments of moss leaves, stems, and rhizoids (and even the sterile tissues of the sex organs) can regenerate haploid gametophytes.

In certain strains of mosses, the gametophyte can give rise to clusters of presumably haploid sporophytes without the functioning of gametes; such apogamous formation of sporophytes may also be chemically induced (by application of a solution containing a specific amount of chloral hydrate to both the protonema and leafy shoots).

Apogamy, apospory, and apomixis

Among the vascular plants both natural and induced apogamy and apospory are known. In certain ferns, gametophytes may develop at the leaf margins or in sori from transformed sporangia. Certain other ferns reproduce apogamously in nature; thus, for example, in the holly fern (*Crytomium falcatum*), the gametophytes give rise directly to sporophytes by nuclear and cell division on vegetative cells of the gametophyte. In almost every group, however, variations of the usual reproductive process occur. These may involve substitution of asexual reproduction for sexual or the direct production of plants by cells other than the usual ones (apomixis). Apomictic phenomena—which are in the strictest sense asexual—include apospory, in which the gametophyte phase is produced without the need of spores, and apogamy, in which the sporophyte phase is produced without the need of gametes, or sex cells.

Apogamy may be induced in normally sexual ferns by withholding water from the gametophytes, which prevents the liberation and functioning of sperm. Similarly, when gametophytes are grown in inorganic culture media supplemented by a variety of sugars, they produce sporophytes apogamously. Colourless roots removed from the bracken fern (Pteridium aquilinum) have been induced to develop diploid gametophytes aposporously, as have the injured juvenile leaves of a number of ferns.

Apomictic phenomena occur also among many angiosperms. In some species, haploid sporophytes may develop either from the unfertilized egg or from some other cell of the gametophyte. Such apogamy occurs, for example, after stimulation of one species with the pollen of a related one (*e.g.*, *Solanum nigrum* by the pollen of S. *lu*teum). Apogamy involving an unfertilized egg (a phenomenon termed parthenogenesis) occurs in certain orchids. Male parthenogenesis, or the production of a sporophyte from a sperm, has been detected in tobacco hybrids. Finally, a form of haploid apogamy is known in which a cell of the female gametophyte other than an egg may develop into an embryo.

In certain species of hawkweed, the embryo develops from a certain cell of the ovule or the megasporangium. In others, the female gametophyte is diploid through an impairment of the meiotic process; in this case, the egg (diploid parthenogenesis) or one of the related cells may form an embryo. In citrus trees a number of embryos (polyembryony) arise from diploid cells of the megasporangium or integuments.

PHYSIOLOGY OF REPRODUCTION

The maturation of sporophytes and gametophytes, as manifested by their ability to produce spores and gametes respectively, involves both internal and environmental factors. With respect to the former, the organism must have completed a certain minimum period of vegetative development before environmental factors are able to stimulate formation of spores and gametes.

Effects of light and temperature

Among environmental factors affecting reproduction, the duration, intensity, and quality of light, as well as temperature, have primary roles; for example, the liverwort Marchantia polymorpha continues in the vegetative state indefinitely under daily fluorescent illumination of 16 hours. Control plants exposed to daily incandescent lighting of 16 hours become sexually mature after 30 days. Addition of the sugar sucrose hastens the development of the sexual phase, an indication that chemical factors also play a role. In hornworts (*e.g.*, Anthoceros and Phaeoceros), antheridia develop under daily light periods (photoperiods) of four to 12 hours; none develop when the plants are illuminated for longer periods.

Temperature also affects sexual maturation. In mosses, for example, initiation of sex organs in bacteria-free laboratory cultures of *Funaria* occurs at 10° C (50" F) when cultures are illuminated six, 12, or 20 hours daily. On the other hand, the moss Polytrichum is seemingly not affected by duration of light but forms sex organs best at 21° C (70° F).

Among vascular cryptogams little is known about the various environmental factors that affect development of sex organs in nature, and, except for certain ferns and horsetails, experimental studies of rigidly controlled laboratory cultures are lacking. It has been shown that laboratory cultures of gametophytes of certain horsetails derived from single spores produce sex organs 40 to 60 days after the spores germinate. In horsetails generally, conditions favouring vegetative growth evoke a preponderance of initially female gametophytes; less favourable conditions induce the production of male gametophytes.

Considerable information is available about the physiology of reproduction in ferns, especially with respect to the gametophyte generation. Spore germination occurs if adequate moisture is present and in temperatures between 15° and 35° C (59° and 95" F). The spores germinate and the young gametophytes do best under neutral or slightly acid conditions. Most fern spores require light for germination. Some fern spores remain viable for as long as 20 years.

Spores germinating in darkness or in the absence of blue wavelengths of light remain in the protonemal, or filamentous, condition. Growth to the mature gametophyte requires light of blue wavelengths in most species.

An interesting aspect of fern reproductive physiology was the discovery that antheridial production is under hormonal control. Several types of antheridiurn-evoking substances (hormones) have been recognized, and there is some evidence that they are specific. The sperm of ferns are attracted chemically to the vicinity of the maturing archegonia, where they become trapped in extruded mucilage. Although only one sporophyte usually develops on a gametophyte, as many as five may be induced to form if the gametophyte is repeatedly exposed to sperm.

The preceding paragraphs, dealing with vascular cryptogams, have emphasized the influence of environmental factors on the expression of sexual reproduction; the remaining account deals with the angiosperms. Because the gametophytic phase of angiosperms is abbreviated and because it is parasitic on the sporophyte, the maturation of the sporophyte, as manifested by flowering, has received more intensive study in angiosperms than has that of the gametophyte.

Durations of life cycles

Angiosperms that complete their life cycles within one growing season (in the temperate zone) are known as annuals. Perhaps the shortest angiospermous life cycle known is that of *Plantago insularis,* a southern California species, that can grow from seed to the production of its own seed in four to six weeks under domestication; the cycle of most annuals, however, is longer. A number of angiosperms are biennial in the temperate zone: they grow vegetatively for one season, but their flowering and seed production are delayed until a second growing season, after which the plants die (*e.g.*, beets, carrots). Still other angiosperms are perennial: they continue growing, flowering, and producing seeds for a number of growing seasons (*e.g.*, irises, roses, oaks).

It has been demonstrated that duration and wavelength of light are of paramount importance in controlling the flowering of angiosperms. Based on extensive experimental studies, flowering plants have been classified as "long-day," "short-day," or "day-neutral" with respect to their requirements of light for flowering (see PHOTOPERIODISM).

Temperature also plays an important role in flowering. Thus, members of the cabbage family can be grown without flowering when high enough temperatures are maintained. A number of perennial and biennial plants (bulbous plants, beets) require a prior period of low temperature before they flower. In addition to internal (*i.e.*, genetic factors), therefore, temperature and light are of paramount importance for many plants in evoking maturation.

Several other physiological aspects of reproduction in angiosperms are noteworthy. Once transported to the stigma, the germination of the pollen grains is markedly affected by the chemical composition of the stigmatic exudate; *e.g.*, pollen of an unrelated species will not germinate on the stigma. There is evidence also that the directional growth of the pollen tubes through the style toward the ovular micropyle is stimulated by a chemical substance produced by the style, ovules, and probably other tissues of the pistil.

It is also clear that both pollination and fertilization have physiological effects on fruit production. In a number of cases pollination alone (not followed by fertilization) is sufficient stimulus to evoke enlargement of the pistil to form a seedless (parthenocarpic) fruit. This phenomenon occurs in the banana and in certain varieties of citrus fruits, grapes, and cucumbers. Parthenocarpy can also be induced by exposure of the stigma to indoleacetic acid, naphthoxyacetic acid, indole butyric acid, naphthaleneacetic acid, or other synthetic hormones. The hormone gibberellin is effective in producing seedless grapes and is the active component in preparations used to prevent premature dropping of fruit.

Also significant in the reproduction of flowering plants are the phenomena of self-sterility and self-incompatibility, which prevail in certain plants with perfect flowers (having both stamens and pistils). Pollen from one flower or from another flower of the same plant or from a plant with identical genetic constitution, when applied to the stigma, fails to germinate or grows so slowly that fertilization does not occur. For example, sweet cherries are self-incompatible: a number of groups of genetically intrasterile types are known, but cross-pollination of trees of different genetic groups results in fruit production. Self-incompatibility occurs also in certain strains of garden plants and in plum, apple, pear, and tobacco.

Self-sterility, usually associated with differences in chromosome number, often occurs in hybrids from widely divergent parents. This is true of cultivated varieties of blackberry and raspberry. Such chromosomal imbalance creates irregularities in meiosis during formation of the pollen, which results in infertility.

Reptilia

Reptilia is a class of vertebrate animals that includes the snakes, lizards, crocodiles, alligators, turtles, and the tuatara, among the living forms, and a great many extinct types such as dinosaurs, pterosaurs, and ichthyosaurs.

Intermediate between amphibians and the warm-blooded vertebrates, reptiles may be described as those air-breathing vertebrates with internal fertilization and a scaly body covering instead of hair or feathers.

GENERAL FEATURES

Importance to man. The economic and ecological importance of reptiles to man is not great, particularly in comparison to the other major vertebrate groups—birds, fishes, and mammals. Locally, some species are eaten on occasion if not regularly. Turtles, in particular, are popular. The green turtle (*Chelonia rnydas)* is the most widely eaten species of reptile. The giant Galápagos tortoise was especially popular as food among 19th-century seafarers and, for this reason, nearly became extinct. Among the lizards, iguanas are perhaps the most popular as a local food. Many species of snakes are eaten locally; canned rattlesnake meat has limited popularity as a delicacy.

Leather goods, including luggage, gloves, belts, handbags, and shoes, are made from the skins of lizards, crocodilians, and snakes. This has led to the virtual extinction of several species of crocodilians and to severe reduction of populations of large lizards, snakes, and turtles. As living subjects for biological research, lizards in particular have been useful to the scientist. Venomous species constitute little hazard to man except in limited rural areas.

Size range. The maximum size of the largest snake or largest crocodile is considerably less than estimated by excitable and gullible travellers. Persistent but unsubstantiated reports have been made of 12-metre (40-foot) anacondas. This gigantic South American snake, although it probably is the largest living species, does not usually exceed nine metres (30 feet) in length. The reticulated python of Southeast Asia and the East Indies has been recorded at 8.4 metres. The rock python *(Python sebae)* of Africa reaches 7.5 metres. No other group of living

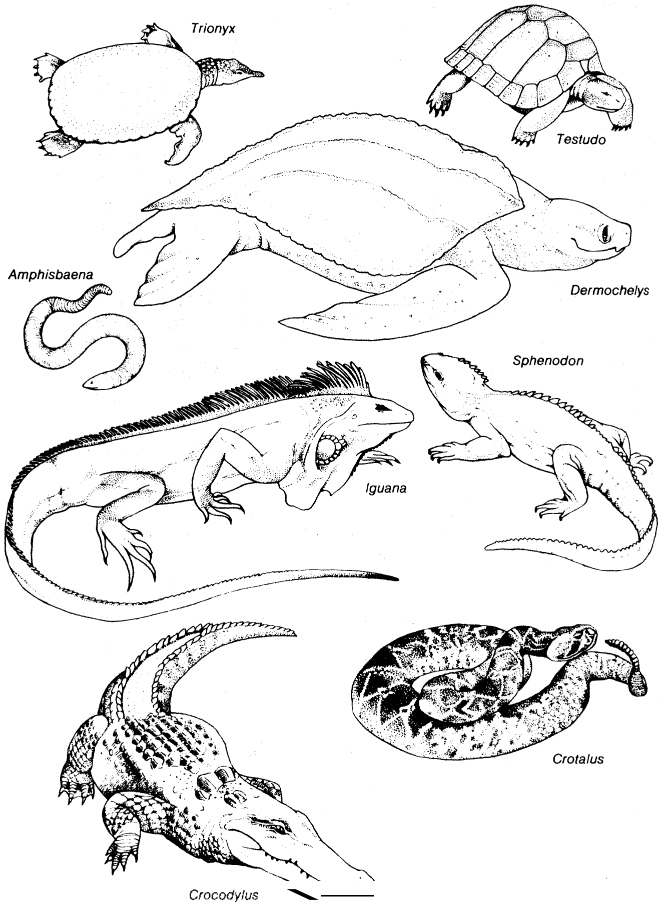

Figure 1: Body plans of living reptiles.

snakes approaches the pythons and boas in weight, although the king cobra of Asia and the East Indies comes close in length (5.4 metres) and is the longest venomous snake. The heaviest venomous snake is probably the eastern diamondback rattlesnake (Crotalus *adamanteus*), which, though not exceeding 2.4 metres, may weigh as much as 15.5 kilograms (34 pounds). The largest of the common nonvenomous snakes of the family Colubridae is probably the Oriental rat snake, Ptyas carinatus (3.73 metres).

Four living species of crocodilians grow larger than six metres: the American crocodile (Crocody*lus* acutus), the Orinoco crocodile (C. *intermedius*), the saltwater crocodile (C. porosus), and the gavial (*Gavialis* gangeticus). The last two may approach nine metres.

The giant among living turtles is the marine leatherback (*Dermochelys*), which reaches a total length of about 2.7 metres and a weight of about 680 kilograms (1,500 pounds). The largest of the land turtles is a Galápagos tortoise weighing 255 kilograms (560 pounds).

The largest modern lizard is a monitor, the Komodo dragon of the East Indies; it attains a length of three metres (ten feet). Two or three other species of monitors reach 1.8 metres. The common iguana comes close to that size, but no other lizard does.

None of the living reptiles, with the possible exception of snakes, is as large as the largest extinct representative of its particular group. The 2.7-metre leatherback turtle is smaller than the extinct 3.6-metre marine turtle *Arche*lon, and no modern crocodile approaches the estimated 15-metre length of Phobosuchus. The Komodo dragon does not compare with the six-metre or more mosasaur Tylosaurus. Extinct dinosaurs such as Brontosaurus (Apatosaurus), Diplodocus, and Brachiosaurus grew to about 24 metres (80 feet) and probably weighed close to 45,000 kilograms (100,000 pounds).

The smallest reptiles

The smallest reptiles are the geckos, some of which grow no longer than three centimetres (slightly more than one inch). Certain blind snakes (Typhlopidae) are less than ten centimetres (four inches) in length when fully grown. The smallest turtles weigh less than 450 grams (one pound) and reach a maximum length of 12.5 centimetres (about five inches). The smallest crocodilians are the dwarf crocodile (Osteolaemus tetraspis) and the smooth-fronted caiman (Paleosuchus), which grow to about 1.7 metres in length.

Distribution and ecology. North Temperate Zone. Although living reptiles, which number some 6,000 species, are primarily tropical animals, many inhabit the temperate zones. The northernmost ranges are those of the lacertid lizard (Lacerta vivipara) and the common viper (Vipera berus), both of Europe and Asia. These ovoviviparous (live-bearing, but the unborn snakes develop within eggs) species live north of the Arctic Circle, at least in Scandinavia. Two other lizards, the slowworm (*Anguis fragilis*) and the sand lizard (Lacerta agilis), and two snakes, the grass snake (Natrix natrix) and the smooth snake (Coronella austriaca), reach 60° N in Europe. Of the six northern species, all but the grass snake are ovoviviparous. Across Siberia only Lacerta vivipara and Vipera berus live north of 60".

In North America no reptile reaches the 60th parallel. Two species of garter snakes live as far north as 55° in western Canada. In North America and Eurasia the northern limit of turtles is about 55° N.

It is only south of 40° N that reptiles become abundant. In the eastern United States and eastern Asia, water snakes (Natrix), rat snakes (*Elaphe*), racers (Coluber), green snakes (Opheodrys), northern skinks (*Eumeces*), glass "snakes" (lizards of the genus Ophisaurus), and soft-shelled turtles (Trionyx) are common. One of the two living species of Alligator lives in southeastern United States; the other lives in China. Even though both regions are characterized by many species of emydid turtles (family Emydidae), the genera to which the species belong are found in only one region or the other. Many lizards of temperate Eurasia belong to the families Agamidae and Lacertidae, which do not occur at all in the Americas. On the other hand, many lizards of North America are in the families Iguanidae and Teiidae, which do not live in Eurasia.

The fauna of the eastern United States is almost as distinct from that of western United States and northern Mexico (which is faunistically part of the same region) as it is from that of eastern Asia. The eastern United States has many genera and species of emydid turtles; the western United States (defined by a diagonal line running southeast to northwest through Texas, then northward along the Continental Divide) has only four or five species. Few genera and species of iguanid lizards inhabit the eastern United States, whereas the western United States has many. Although the eastern United States has more species of water snakes, the western United States contains more garter snakes. More species of snakes appear in the eastern United States than in the western areas, while the converse is true of lizard species.

Ecological types of the North Temperate Zone

Reptiles of the North Temperate Zone include many ecological types. Aquatic groups are represented in both hemispheres by the water snakes, many emydid turtles, and the two alligators. Terrestrial groups include tortoises, ground-dwelling snakes, and many genera of lizards. Arboreal snakes are few, and arboreal lizards are almost nonexistent. Burrowing snakes are common. Specialized burrowing lizards are few.

Central and South America. In Central America the reptile fauna becomes richer. Besides several turtle families found in eastern United States, Central America has three genera of turtles (*Dermatemys, Claudius,* and *Stau*rotypus) not living elsewhere. Crocodilians become more numerous both in species and individuals. Lizards and snakes are particularly more abundant.

Many of the genera of iguanid lizards occurring in western United States have species in Mexico; one genus of spiny lizards (Sceloporus) reaches its peak of numbers of species in Mexico. South of Mexico the North American iguanid genera disappear and are replaced by tropical groups such as the black iguanas (*Ctenosaura*), the helmeted iguanids (*Corythophanes*), the casque-headed iguanids (Laemanctus), and the basilisks (Basiliscus). The lizard family Teiidae, though represented in the United States by the race-runner genus (*Cnemidophorus*), is tropical, and its real development begins in Central America with the large, conspicuous, and active ameivas (Ameiva) and several small genera that live in concealment.

Among snakes, the fer-de-lance genus Bothrops, the coral snakes (Micrurus), the rear-fanged snakes such as the cat-eyed snakes (Leptodeira), and nonvenomous genera such as the tropical green snakes (Leptophis) either appear for the first time or begin their proliferation of species in Central America.

Reptiles become increasingly numerous in northern South America. Vine snakes (Oxybelis and *Imantodes*), false coral snakes (Ery*throlamprus*), slender ground snakes (Drymobius), and the burrowing spindle snakes (*Atractus*) are most abundant there. Most of the genera of the lizard family Teiidae occur in this area. Iguanid lizards of the anole genus (Anolis) are represented in northern South America by approximately 165 species. Other iguanid genera—*e.g.*, the long-legged Polychrus—make their appearance.

Crocodilians, in terms of species, are more numerous in South than in Central America, and turtles are also abundant. Some of the North American groups—for example, the mud turtles (Kinosternon) and sliders (*Chrysemys*)—are represented, but the majority of species are members of genera and even families (*e.g.*, the side-necked turtles, families Pelomedusidae and Chelidae) unknown in temperate North America.

Several groups that form important, if not dominant, elements of the fauna of the Eastern Hemisphere are largely or completely absent from the American tropics: the lizard families Scincidae, Lacertidae, Chamaeleontidae, and Agamidae and the snakes of the cobra (Naja) and water snake (Natrix) genera.

South of the tropics, in the temperate zone of South America, the reptilian fauna diminishes rapidly. Crocodilians and turtles do not occur south of northern Argentina. An ovoviviparous pit viper reaches almost 50° S there; two iguanid lizards range almost to 55° S.

Asia. Apart from the genera of reptiles listed above as common to the eastern United States and eastern Asia, the temperate zone of Eurasia is noted for its many lizards of the families Agarnidae, Lacertidae, and to lesser degrees Gekkonidae and Scincidae. Most of the lizards are terrestrial; extremely specialized burrowers include desert-dwelling skinks (*Ophiomorphus* and *Scincus*). Most of the snakes characteristic of this vast area are also terrestrial. Arboreal snakes are represented almost exclusively by the rat snakes (*Elaphe*). The leaf-nosed snakes (Lyterkynchus) and the sand boas (Eryx) are the distinctive burrowing snakes of the region. Except for the Chinese alligator and the Indian gavial, temperate Eurasia lacks crocodilians. A few species of turtles are found.

A few types characteristic of the Oriental tropics extend into the temperate zone—*e.g.*, several rear-fanged snakes (Boiga *trigonata* and Psammodynastes), a cobra or two (*Naja*), several species of soft-shelled turtles (Trionyx), and some species of true chameleons (*Chamaeleo*).

In the Oriental tropics the reptilian fauna is extremely rich in species and diverse types. Aquatic groups are represented by snakes of various genera (*e.g.*, Natrix, *Enhydris*, Acrochordus), several groups of lizards (*Tropidophorus* among the skinks and Hydrosaurus among the agamids), many emydid and soft-shelled turtles, and five species of crocodiles. The numerous terrestrial reptiles include the small kukri snakes (*Oligodon*), the big Oriental rat snakes (Ptyas), cobras, monitor lizards (Varanus), many species and genera of skinks, some geckos, and several land turtles (Cuora, Geochelone). Specialized burrowing snakes (*e.g.*, the family Uropeltidae and the colubrid genus Calamaria) and lizards (*e.g.*, the family Dibamidae and the skink genus *Brachymeles*) are also abundant.

Arboreal reptiles of tropical Asia

The distinctive life-forms of reptiles in tropical Asia are arboreal. They include pythons and Oriental pit vipers (Trimeresurus), vine snakes (Ahaetulla), slug-eating snakes (Pareas), "flying" snakes (Chrysopelea), and tree racers (*Gonyosoma*). Some lizards climb only with the aid of claws (*e.g.*, the monitors), a few with the help of prehensile, or grasping, tails (*e.g.*, the deaf agamids, Cophotis), and many with the help of clinging pads under the digits (*e.g.*, many geckos). The most striking arboreal reptiles of this area are the flying lizards (Draco) and the parachuting gecko (Ptychozoon), which has fully webbed digits, a fringed tail, and wide flaps of skin along its sides.

Australia. Because New Guinea, although geographically part of the East Indies, has a reptilian fauna more akin to that of Australia, the two areas are considered here as one. The Australian region is the only area in the world in which venomous species of snakes outnumber harmless ones. The family Colubridae, comprising the majority of the nonvenomous or slightly venomous snakes of the world, is poorly represented in Australia, which has only 12 species. The Australian region has many snakes of the cobra family (family Elapidae), but no vipers. The fauna also include several pythons and minute blind snakes (family Typhlopidae); a variety of geckos, skinks, and agamid lizards; side-necked turtles; and three species of crocodiles.

Africa. The reptilian fauna of Africa forms two main divisions. The first, the fauna of the North African coast, is akin to that of central and southwestern Asia and southern Europe and is therefore mainly a temperate-zone fauna. The racers, the burrowing sand skink (*Scincus*), and the emydid turtle (Mauremys caspica) are elements of temperate fauna in North Africa. Some species of the great tropical fauna lying south of the Sahara Desert occur in North Africa and in Southwest Asia. Examples are the sand snakes (Psammophis), cobras, and chameleons (family Chamaeleontidae). As is true of the temperate fauna of Eurasia, the North African reptiles, though representing many families, are principally terrestrial and burrowing. Many lacertid and agamid lizards scamper over rocks and sand by day; they are replaced at night by small geckos and are preyed upon by the racers (*Coluber*) and sand snakes (*Psammophis*). In addition to cobras, the venomous snakes of North Africa include the common vipers, the saw-scaled viper (Echis carinatus), and the horned vipers (Cerastes). The last two are true desert animals. Land tortoises (Testudo) are common in the semi-arid land.

Reptiles of tropical Africa

The second and much larger division of the African fauna is the great tropical assemblage that ranges from the Sahara southward to the Cape of Good Hope. In common with tropical Asia, this vast area has cobras, many skinks, and many geckos. Its fauna differs from that of Asia in the absence of pit vipers (subfamily Crotalinae), the near absence of emydid turtles, and the poor representation of agamid lizards. These groups are replaced in tropical Africa by the many true vipers (subfamily Viperinae), the side-necked turtles (family Pelomedusidae), and the lacertid and cordylid lizards. Chameleons and land tortoises are abundant. Three species of crocodiles occur in Africa.

In Africa are found all of the diverse reptilian types characteristic of a tropical area: aquatic turtles, crocodiles, and snakes; terrestrial turtles, snakes, and lizards; burrowing snakes of the blunt-headed and auger types; limbless and virtually blind burrowing lizards; and a profusion of arboreal snakes and lizards.

Unique reptile fauna of Madagascar

The large island of Madagascar, off the eastern coast of Africa, has a peculiar fauna that appears in part as a collection of castoffs, groups that in Africa have not been able to meet the competition of more advanced forms. With few exceptions the reptiles of Madagascar belong to genera found only there.

NATURAL HISTORY

Reproduction and life cycle. Courtship. Courtship in some form is such a widespread prelude to mating among modern reptiles that it must have characterized many extinct groups as well. When courting, the male of some freshwater turtles, such as the red-eared turtle (*Chrysemys scripta* elegans) of the eastern United States, orients himself in the water so that he is directly in front of a female and facing her. With his forefeet close together, the male vibrates his claws against her head. If the female is receptive, she swims forward slowly while the male backs away. Finally the female sinks slowly down. The male then mounts her from behind, clutching her shell with all four feet. His tail is brought under hers and his penis introduced into her cloaca.

The male of some terrestrial turtles of North America (*e.g.*, the gopher tortoises, Gopherus) begins courtship by extending his neck and bobbing his head up and down. The courted female may bob her head in return. The male advances, nips at the female, and then circles her as she turns away from him. As soon as she shows signs of response, the male mounts her from the rear and begins a series of pumping movements that hump the rear of his shell against the ground. Finally the female extends her tail, and copulation begins. Males of the smaller box turtles (*Terrapene*) nip and butt at the female.

Mating behaviour of crocodilians

Male crocodilians bellow during the mating season, and in many cases the females respond with an answering call. The male American alligator, which copulates in water, grasps the female's neck with his jaws and slips the rear part of his body under hers to enable him to insert his penis into her cloaca.

Lizards have rather elaborate courtship patterns usually involving display and posturing by the males, who often have distinctive patches of colour on their throats or low on their sides. The male bobs up and down, thus exposing the patches of colour, which may be blue, orange, red, or black depending on the species. Males of some species, such as the green anole (Anolis carolinensis) of the southeastern United States, have brightly coloured folds of skin at the throat (dewlaps) that are expanded during courtship. If the female seems receptive, the male straddles her back, often gripping her back or legs with his jaws. Just before copulation, his tail is bent under hers.

The courtship patterns of snakes are simpler; they usually consist of the male's crawling over the back of the female and adopting every curve her body takes, then vibrating against her body or nudging it with waves of his own. Male boas and pythons stroke or scratch the female's body with their vestigial hind limbs. The male water snake rubs his chin against the female's back. The male rattlesnake (Crotalus) frequently nudges the female with his head. The male bull snake (*Pituophis*) grasps the female's neck with his jaws during copulation.

When the male king cobra (*Ophiophagus* hannah) crawls onto the back of a receptive female, he flicks his tongue against her repeatedly. The female raises her head and spreads her hood. The male nudges her neck and head with his snout and lifts the rear of her body with his tail. Copulation between cobras may last more than two hours.

The amnion

The embryo. The embryo of a reptile develops a thin sac, the amnion, that envelops the embryo and becomes filled with a watery fluid. The entire structure serves to protect the embryo from desiccation and mechanical injury. A parchment-like shell, which also contributes mechanical protection, is produced by the female parent and surrounds the amnion; between the shell and the amnion a second sac, the allantois, becomes inserted. The allantois, which is supplied with many fine blood vessels, serves as a respiratory organ, absorbing the oxygen and emitting the carbon dioxide that pass through the somewhat porous shell.

Egg laying. The typical mode of reptilian reproduction is oviparous (*i.e.*, the female lays eggs in which the young develop). The eggs are laid shortly after fertilization, and development of the embryos takes place largely after the eggs have been laid. This pattern characterizes crocodilians, turtles, the tuatara, most lizards and snakes, and many extinct reptiles. The size of eggs laid by lizards and snakes varies according to the size of the females. The banded rock lizard (Petrosaurus mearnsi) of the western United States, which ranges from 7.5 to ten centimetres (three to four inches) in length, lays eggs that are about one centimetre (0.4 inch) long; those of the 30- to 60-centimetre ringneck snake (Diadophis *punctatus*) from the eastern United States are 1.25 centimetres long. Eggs of the three-metre Komodo dragon lizard (Varanus komodoensis) and of the six-metre Indian python (Python *molurus*) are about 11.25 centimetres long.

A minority of modern and extinct reptiles are (and were) live-bearing, or viviparous. Strictly speaking, most of this minority are not truly viviparous but ovoviviparous, because the embryos develop with their shells or shell membranes intact and are nourished wholly by the yolk. In a few modern reptiles the embryonic membranes and the tissues lining the oviducts of the females come into close contact and are modified in one of several ways to provide a temporary organ, through which food and respiratory gases are exchanged; *i.e.*, a structure similar to the placenta of mammals. In the simplest reptilian "placenta," the most superficial layer (the epithelium) of the outer embryonic membrane and of the lining of the oviduct partially degenerates, thereby bringing the blood vessels of embryo and mother closer together. The approximation of the two bloodstreams facilitates the exchange of oxygen and carbon dioxide, this gas exchange being the only function of the organ at this stage of evolution. Several Australian snakes (Denisonia superba and D. *suta*) and a number of lizards—*e.g.*, the common East Indian brown-sided skink (Mabuya multifasciata) and the cylindrical skink (Chalcides ocellatus) of southern Europe and North Africa—are known to have this type of organ, as presumably do many ovoviviparous reptiles.

The best developed reptilian "placentas" consist of apposed, thickened, folded elliptical areas of the outer embryonic membrane and lining of the oviduct. The ridges of the oviductal areas are filled with blood vessels, and the epithelium between ridges is thickened and glandular. Usually, eggs developing with this type of "placenta" have less yolk; food and oxygen are transmitted from mother to embryo. Several species of Australian lizards, American water snakes, and the common European viper (Vipera berus) are known to provide this type of internal environment for their developing young.

Oviparity and ovoviviparity in lizards and snakes

The line between oviparity (egg laying) and ovoviviparity (hatching of eggs in the mother's body) is arbitrary. Females of some lizards and snakes retain the fertilized eggs in their bodies for a few days before laying them. Other species retain the eggs for most of the developmental period, hatching occurring shortly after laying. For the grass snake of England (Natrix natrix), the lapse of time between copulation and egg laying is usually two months; the young hatch six to ten weeks later. The interval between mating and egg laying is one month in the Texas horned lizard (Phrynosoma cornutum). A given species may be ovoviviparous in parts of its range and oviparous elsewhere.

The nest. The eggs of modern reptiles may be deposited in a nest prepared by the female or simply laid under some convenient cover, such as a rock or log. Crocodilians invariably prepare a nest, and the female invariably does the work. Most turtles dig their nests, scooping out a flask-shaped cavity in the ground with their hindfeet. When the hole has reached the proper size, the oval or spherical eggs, 1.5 to 3.75 centimetres (0.5 to 1.5 inches) in diameter depending on the species, are dropped into the nest from the female's cloaca. The female scratches soil over the eggs, usually obliterating the nest site. Crocodilians either dig a nest along the bank of a river or lake or heap together a mass of dead vegetation in which the eggs are laid; their oval eggs are usually about five centimetres (two inches) long.

Most oviparous lizards merely hide their eggs under some convenient cover such as under a rock or in a hole in a tree. Nest construction among lizards, though appearing in such diverse families as the iguanids, skinks, and true chameleons, is neither so elaborate nor so rigid in pattern as among turtles. The nest consists of a small hole made by either the snout or the limbs. Soil or leaves usually are pushed on top of the eggs to hide the nest, although the entrance to the nest cavity is kept open in a few species. Snakes, like lizards, usually lay their eggs under natural, pre-existing cover. The king cobra, one of the very few nest-building snakes, drags dead vegetation into a low heap by bending its body. The eggs are laid in a cavity at the centre. Other snakes deposit their eggs in holes they have scooped out of sand or soft earth with their snouts.

Number of offspring. The number of eggs in a clutch or offspring in a brood varies from one to 200 among living reptiles; presumably similar variation occurred among the extinct types. Crocodilians lay from 20 to 70 eggs, turtles from one to 200. In turtles, more so than in crocodiles, the number varies with the species and roughly with the size attained by the females. The big marine turtles have the largest clutches (usually more than 100); the smaller land and freshwater turtles have much smaller ones. The number of eggs or young is not so closely related to the size of mature females in species of lizards and snakes. With few exceptions, lizards of the family Gekkonidae lay two eggs at a time, regardless of the size of the female. Lizards of the family Scincidae have broods varying from two to about 30; one of the largest members of this family, the 30-centimetre-long (12-inch) stump-tailed skink (Tiliqua rugosa) of Australia, has only two young at a time, whereas the Great Plains skink (*Eumeces* obsoletus) of the United States usually lays between ten and 20 eggs in a clutch.

Relationship of brood size to adult size

Clutch size in the 1.5-metre (five-foot) bull snake (*Pi*tuophis catenifer) of western United States is usually ten or 12; in the grass snake of England and Europe, which measures 60 to 90 centimetres (two to three feet), it is 30 to 40; in the giant reticulated python of Southeast Asia and the East Indies, it may reach 100.

Parerttal care. Parental care of eggs and newborn young is neither well developed nor elaborated among reptiles. Female crocodilians generally remain in the vicinity of their nests and chase would-be predators from the site. In a few lizards the female returns to the nest between feeding excursions to coil around the eggs and turn them at intervals. The male and female king cobra remain in the vicinity of the nest, and one of the parents usually is coiled above the egg cavity.

Female pythons coil around their eggs and pull them into a heap. Females of some species remain with the eggs for the entire two-month incubation period; others leave the eggs only to drink. In at least one species (Python *molurus*) the female provides heat by muscular contraction to keep the eggs at incubation temperature on cool nights. Turtles and the majority of egg-laying lizards andsnakes abandon their eggs after they are laid.

Incubation period. The incubation (or gestation) period of reptilian eggs is affected by many factors and to such an extent that it is difficult to assign a figure characteristic of a given species. One source of complication is the combination of oviparous and ovoviviparous habits by certain species. The developmental period of the embryo, whether it occurs within the female's body or outside it, is referred to as the gestation period.

In general, the gestation period lasts from 60 to 105 days in most American and European reptiles. The eggs of the American alligator hatch about 63 days after they are laid, those of the small Eastern fence lizards (*Sceloporus* undulatus) in about the same time. The gestation period in the common European viper lasts from 60 to 90 days. Eggs of marine turtles hatch between 30 and 75 days after they are laid, depending on the site. The temperatures to which a brood is subjected shorten or lengthen gestation according to whether the temperatures are high or low.

Growth and longevity. Giant Galápagos tortoises kept under nearly ideal conditions have been known to increase their weight from 3.2 to six kilograms (seven to 13 pounds) to about 82 kilograms (180 pounds) in nine years. Smaller species also grow rapidly. The box turtle of the United States has a shell about 3.75 centirnetres long at the end of its first year; at the end of five years, the length has doubled.

Under favourable conditions a one-year-old American alligator is about 60 centimetres long and weighs about 1.8 kilograms (four pounds). At the end of six years, males average about 190 centimetres (about six feet) and about 36 kilograms (80 pounds). The red diamond rattlesnake is about 30 centimetres long at birth, grows to about *65* centimetres in its first year, reaches about 85 centimetres by the end of its second year, and grows more slowly after that. The pattern for lizards is much the same: rapid growth early in life and slow growth afterward. The significant difference between growth in reptiles and that in mammals is that a reptile has the potential of growing throughout its life, whereas a mammal reaches a terminal size and grows no more, even though it may subsequently live many years in ideal conditions.

The length of time needed to attain sexual maturity varies greatly among reptiles and, although roughly related to the size usually attained by the species, is even more closely related to the climate in which the animal lives. The red diamond rattlesnakes in southern California, for example, bear their first young when three years old; on the other hand, the northern Pacific rattlesnake (Crotalus viridis oreganus) bears its first litter when four years old. The much smaller common garter snake is sexually mature shortly before the age of two years.

Achievement of sexual maturity

The 12.5- to 15-centimetre (five- to six-inch) northwestern sagebrush lizard (Sceloporus graciosus gracilis), living in the Sierra Nevada range of California at an elevation (about 1,800 metres [6,000 feet]) where it has, at most, six months of activity each year, requires two years or more to reach sexual maturity. Another lizard, the green anole (Anolis carolinensis), similar in size to the sagebrush lizard but living in the lowlands of the southern United States, may reach maturity in four or five months in Florida.

Turtles mature at a slower rate. Females of the red-eared turtle of the central United States lay their first eggs when they are from three to eight years old, depending upon how long it takes them to reach a shell length of 15 centimetres. Females of the musk turtle, or stinkpot (Sternotherus odoratus), in Michigan require nine to 11 years to mature, at which time their shells are 7.5 to ten centimetres long. Presumably, turtles living in the tropics mature more rapidly.

The maximum age, meaning the potential longevity, of modern reptiles varies greatly and can be determined only from records of captive animals. Turtles as a group seem capable of Jiving longer than the others, and about 30 species have been kept in captivity more than 20 years. Several species, said to have lived 150 years or more, may be cases of two individuals whose periods of captivity overlapped. There is no reliable evidence for believing that the giant land tortoises live much longer than some smaller species. Two crocodilians (Alligator *mississippiensis* and A. sinensis) have survived in zoos for more than 50 years. Several species of pythons and boas have lived longer than 20 years. Lizards seem to have an upper limit near that of snakes. A slowworm, Anguis *fragilis,* has been kept in captivity for more than 30 years.

BEHAVIOUR

Defense. Avoidance and noise. Avoidance, the commonest form of defense in the animal kingdom, is also the commonest one in reptiles. At the first recognition of danger, most snakes and lizards crawl or scamper away into the undergrowth; turtles and crocodilians plunge into water and sink out of sight. But should the danger arise so suddenly and so close at hand that flight may be hazardous, other expedients are adopted.

Crocodiles, some lizards, turtles, and some snakes hiss loudly when confronted by an enemy. Rattlesnakes rapidly vibrate the tip of the tail, which consists of loose, dry, horny rings. A few snakes without rattles (*e.g.,* the fox snake, Elaphe vulpina, of the United States) vibrate the ends of their tails rapidly, and if, as often happens, the tail hits dry leaves, it makes a sound deceptively like the rattle of a rattlesnake.

Hissing and tail rattling

Body form and posturing. Change in body form, which is relatively common in snakes, usually involves spreading the neck, as in cobras (family Elapidae), or the whole body, as in the harmless hognose snakes (*Heterodon*) and DeKay's snake (Storeria dekayi) of the United States. Some snakes inflate the forward parts of their bodies; inflation is one of the defensive actions of the large South American tree snake Spilotes and of the African boomslang (Dispholidus).

Threatening postures may be assumed by snakes as they change their body form. A cobra raises the forepart of its body and spreads its hood when endangered. The typical defensive posture of a viper is with the body coiled and the neck held in an S-curve, the head poised to strike.

Some lizards flatten their bodies, puff out their throats, and turn broadside to the enemy. The helmeted iguanids (Corythophanes) of Central America and the chameleons of Africa increase their apparent size in this way when approached by snakes. The Australian bearded lizard (Amphibolurus barbatus) spreads its throat downward and outward. The Australian frilled lizard (*Chlamydosaurus* kingi) suddenly raises a wide membrane, or frill, which extends backward from the throat. Many lizards and snakes open their mouths when threatened, but do not strike. A common African lizard, Agama atricollis, faces an enemy with head held high and mouth open to show the brilliant orange interior.

Display of colour. Display of colour in Agama *atricollis* may not be part of a threatening mechanism, but it is so in the instances of certain red- or yellow-bellied snakes that turn over or curl up their tails, exposing the brightly coloured undersurface. This behaviour, known in harmless (*e.g.*, the American ring-necked snake, *Diadophis*) as well as venomous snakes (*e.g.*, the coral snake, Micrurus frontalis), is displayed only by snakes having red, orange, or yellow undersides. These colours must have some significance, as yet not fully understood, to predacious animals, for they are also the common colours in insects having warning coloration.

The defense mechanism of camouflage involving form and colour is common. Many arboreal snakes and lizards (*e.g.*, chameleons) are green; some of the green snakes (*e.g.*, the vine snakes of South America, Oxybelis, and of southern Asia, Ahaetulla) are very slender, resembling plants common in the habitat. Lizards of semi-arid and rocky country frequently are pale in colour and blotched in pebble fashion—*e.g.*, the leopard lizard (Crotaphytus *wislizeni*) of the southwestern United States.

Mimicry

Mimicry of dangerous species by harmless snakes is a passive defense. Its validity as an actual mechanism of defense is, however, sometimes challenged. The venomous coral snakes (Micrurus) of the Western Hemisphere are ringed with bright red, yellow, and black. A series of relatively harmless snakes, such as *Erythrolamprus* and *Anilius* of South America and the scarlet king snake, Lampropeltis *triangulum* doliata, of southeastern United States, have similar colours and patterns that may confer some protection against predators.

Striking and biting. If a threatening posture does not succeed in driving off an enemy, many reptiles become more aggressive. Some snakes (*e.g.*, DeKay's snake) strike, but with their mouths closed. Others (*e.g.*, the hognose snakes) strike with their mouth open but do not bite. Still others strike and bite viciously. Among the nonvenomous snakes of North America, few are as quick to bite as the water snakes (Natrix). The sole danger from the bites of these snakes is infection of the wound.

Most of the dangerously venomous snakes (vipers, pit vipers, and cobras) bite in self-defense. Vipers and pit vipers usually strike from a horizontally coiled posture. From this position the head can be shot forward, stab the enemy, and be as rapidly pulled back in readiness for the next strike. From the typical raised posture a cobra sweeps its head forward and downward to bite. To strike again it raises its head and neck once more; such aggressive, defensive movements of cobras are slower than those of pit vipers.

Many lizards, regardless of family and size, bite in defense. Gekko gecko of Southeast Asia bites if sufficiently threatened. Although small lizards have a bite effective against only the smallest predators, a large monitor lizard (Varanus) can inflict a painful wound with its large teeth and strong jaws. Some turtles, particularly the soft-shelled turtles (Trionyx), bite frequently, vigorously, and effectively.

Spitting. The spitting of venom by certain African cobras, the ringhals (Hemachatus haemachatus), and the black-necked cobra (*Naja nigricollis*) is a purely defensive act directed against large enemies. A fine stream of venom is forced out of each fang, which, instead of having a straight canal ending in a long opening near the tip as in most cobras, has a canal that turns sharply forward to a small round opening on the front surface well away from the tip. At the moment of ejection the mouth is opened slightly, and venom is forced out of the fangs by contraction of the muscle enveloping the poison gland. Usually a spitting cobra raises its head and the forepart of its body in the characteristic cobra defensive posture prior to spitting, but venom can be ejected from any position. The effect on skin is negligible; the eyes, however, may be severely damaged, and blindness can result unless the venom is washed out quickly.

Use of the tail. A few lizards, representing different families, have in common thick tails covered by large, hard, spiny scales. Such a tail swung vigorously from side to side is an effective defense against snakes, especially when the head and body of the lizard are in a burrow or wedged between rocks.

Voluntary tail shedding

Lizards' tails are useful in defense in another way. When captured, many lizards voluntarily shed their tails, which wriggle violently, temporarily confusing the predator and allowing the lizard to escape. Each vertebra of the tails of lizards with this capacity has a fracture line and can be split on that line when tail muscles contract violently. Simultaneous stimulation of the nerves in the severed portion keeps it twitching for a few seconds after separation. Usually the tail is broken in only one place, but a few lizards, particularly the so-called glass snakes (*Ophisaurus*), break their tails into several pieces. The stump heals quickly, and a new tail grows; often, however, the regenerated tail is not so long as the original and has simpler scales.

Snakes, turtles, and crocodiles may have their tails bitten off by predators, but they cannot break them voluntarily or regenerate them. Some snakes use their tails in diversionary tactics by raising them and moving them slowly. Species with this habit commonly have thick, blunt, brightly coloured tails. The small African python Calabaria and the Oriental venomous snake Maticora wave their tails in the air as they move slowly away from a threat.

Balling. Many snakes, both harmless and venomous, attempt to hide their heads under coils of their bodies. The body may be coiled loosely, as it is in most species with this habit, or tightly so that it forms a compact ball with the head in the centre. Balling, as the latter habit is called, is a characteristic response of Calabaria and another African python, Python regius.

The African armadillo lizard (*Cordylus* cataphractus), a species with heavy scales on its head and hard spiny scales covering its body and tail, rolls on its back and grasps its tail in its mouth. It thus presents a ring of hard spines to a predator.

Odours. Some reptiles use musk-secreting glands when other defensive measures fail. The water snakes (Natrix), the garter snakes (*Thamnophis*), the alligator lizards (Gerrhonotus), and the musk turtles (Sternotherus) emit a foul-smelling substance from anal glands.

Feeding habits. With few exceptions, modern reptiles feed on some form of animal life: insects, mollusks, birds, frogs, mammals, fishes, or other reptiles. Land tortoises are vegetarians, eating leaves, grass, and in some cases even cactus. The big green iguana (Iguana iguana) of Central and South America, its relative the chuckwalla (Sauromalus obesus) of southwestern United States and northern Mexico, and the spiny-tailed agamids (*Uromastix*) of North Africa and southwestern Asia also are herbivorous. The marine iguana (*Amblyrhynchus cristatus*) of the Galapagos Islands dives into the sea for seaweed.

The majority of carnivorous reptiles have nonspecial-

Man-eating reptiles

ized diets, feeding on a variety of animals. In general, the smaller the reptile, the smaller is its prey. Only the very largest of living snakes—the reticulated python (*Python* reticulatus), the Indian python (P. *molurus*), and the anaconda (*Eunectes murinus*)—are capable of eating large mammals such as small pigs and deer. Among crocodiles the largest species—the Nile crocodile (*Crocodylus* niloticus), the East Indian saltwater crocodile (C. *porosus*), and the Orinoco crocodile (C. *intermedius*)—have been known to attack and to eat men. Presumably, even larger prey was devoured by the great carnivorous dinosaurs such as *Allosaurus* and *Tyrannosaurus*, which were almost certainly capable of killing the largest of their herbivorous contemporaries.

Locomotion. Walking and crawling. The majority of reptilian orders are quadrupedal—*i.e.*, four-legged. Among the land vertebrates, the limbs gradually shifted from a lateral to a ventral position. In most amphibious reptiles the limbs projected out to the side and then bent downward to the ground at the knee and elbow. With few exceptions, the quadrupedal reptiles have the same awkward position. With such an orientation, the centre of gravity of the body is not in the same axis as the hands and feet, resulting in a sideways as well as a forward component of thrust when the animal walks. The typical reptile throws its body into a slight horizontal curve to progress straight forward. In mammals the limbs are directly underneath the body, the centre of gravity is in the axis of the limbs, and all of the thrust of the limbs is directed forward. The latter position and type of motion are more efficient. The lateral orientation of the limbs in amphibians and reptiles also makes it more difficult to raise the body off the ground.

Despite the awkwardness of the orientation of their limbs, some reptiles are (and many extinct forms probably were) capable of moderate speeds. Crocodilians raise their bodies off the ground and make short, fast rushes. Short-bodied lizards also can move fast for short distances; longer bodied lizards have greater difficulty in raising their bodies. They usually have short legs and proceed in a serpentine fashion, with the body, thrown in horizontal curves, doing much of the work.

A snake moves by pushing backward against rocks, sticks, or any relatively fixed point—a lump of earth or a small depression in uneven ground—with the rear surface of the horizontal curves of its body. Each joint of the body passes through the same curves, pressing against the same object and thrusting the forepart of the body forward. Heavy-bodied snakes such as pythons and certain rattlesnakes can move forward without throwing their bodies into curves. This rectilinear movement depends on the ability of snakes to stretch or contract their bodies in the longitudinal axis. By raising a part of its belly, stretching that part forward, lowering it to the ground, and repeating the process alternately with other parts of the body, a heavy snake moves forward smoothly in a straight line.

Bipedal locomotion

Some modern lizards have adopted semi-bipedal locomotion. The collared lizard (Crotaphytus collaris) of the United States and the frilled lizard (*Chlamydosaurus kingi*) of Australia show the early stages of bipedalism, a phenomenon widespread among the dinosaurs and therefore important in reptilian history. These lizards run on their long hindlegs with the forward parts of their bodies at an angle of about 60° off the horizontal.

Presumably, bipedalism among the dinosaurs began as it did among modern lizards, as an occasional means of obtaining bursts of speed. Because the centre of gravity is in front of the hips, modern bipedal lizards must move forward continuously in order to maintain a semi-erect posture; they can stand still in that position only for very short periods.

The awkward sideways orientation of the limbs forces bipedal lizards to swing each leg outward as it is brought forward and to push the body sideways and forward when each leg thrusts backward against the ground. Bipedal dinosaurs eliminated this inefficient rocking motion, for during the course of evolution their hind limbs were rotated forward so that they were directly under their bodies. Thus, they delivered their full force in the forward direction. So successful was this mode of locomotion that dinosaurs utilizing it dominated terrestrial life for millions of years.

Clinging and climbing. Associated with arboreal life are groups of anatomical features mainly concerned with clinging. The commonest clinging structures in vertebrates are claws; they seem to be the only arboreal adaptations of some lizards, such as the common iguana (*Iguana* iguana). Similar structures appear in many lizards of the family Gekkonidae, in the anoles (Anolis) of the family Iguanidae, and in some skinks of the family Scincidae.

Pads on the feet consist of wide plates or scales under the fingers and toes. The outer layer of each plate or scale is composed of innumerable tiny hooks formed by the free, bent tips of cells. These minute hooks catch in the slightest irregularities and enable geckos to run up apparently smooth walls and even upside down on plaster ceilings. Because the hooklike cells are bent downward and to the rear, a gecko curls its toes upward to disengage them. Thus, when walking or running up a tree or wall, a gecko must curl and uncurl its toes at every step.

Prehensile tails

The giant Solomon Islands skink (Corucia), true chameleons (Chamaeleontidae), arboreal vipers, boas, and pythons use prehensile tails—that is, tails capable of supporting most of the weight of the animal or used habitually for grasping—for clinging to their aerial supports. For this purpose, however, true chameleons rely mainly on a tonglike arrangement of their digits, which are ucited into two opposed bundles on each foot—three on the inside and two on the outside of the front foot, and two on the inside and three on the outside of the hindfoot.

Slender vine snakes of several genera of the family Colubridae are capable of extending half the body length in a horizontal plane without support; they do so habitually in bridging the gap between branches. Most snakes can reach across an open space, but all except the vine snakes can extend only a short length of the body, and that portion invariably sags like a cable. The vine snakes bridge an open space like an I-beam. This ability is based partly on reduced body weight and partly on deepened and strengthened vertebrae.

Swimming. In water, of course, neither bipedal nor quadrupedal locomotion is very effective. Aquatic reptiles, with few exceptions, use the same means of propulsion as do fish and whales—that is, powerful beats of the tail. Crocodilians and aquatic lizards such as some monitors (Varanidae) lash their tails from side to side while holding the limbs against the body. The same method was used by the ancient mesosaurs (Mesosauria) and ichthyosaurs (Ichthyosauria). The marine ichthyosaurs, which were the reptilian counterpart of the porpoises, may have used their very short limbs for steering.

A fishlike method of swimming requires a flexible body and at least a moderately long tail. Turtles propel themselves by using their feet as paddles—the hindfeet, which have webbed toes, in the case of freshwater turtles, and the forefeet, which are modified into large paddles, in the case of marine turtles.

The extinct marine plesiosaurs (suborder Plesiosauria), with their short bodies and tails and their large paddle-like limbs, swam the way marine turtles do, although they may have used their hindlimbs for more than just steering. Both pelvic and pectoral (shoulder) girdles were modified in the plesiosaurs into structures having small upper portions and very large lower portions. As the upper element, especially that of the pelvic girdle, has the important function of transferring the weight of the body to the limbs, it is likely that the limbs of plesiosaurs could not support the body weight on land and that the plesiosaurs never came out of water.

Most plesiosaurs had long necks. By moving toward their prey with the neck curved, they probably could strike suddenly. The heavy trunk would provide the inertia against which the neck could move, thus preventing a significant backward shift of the animal as the head shot forward. The modern sea snakes (Hydrophidae) show the same adaptation. Though they swim with an eel-like

Locomotion of sea snakes

undulation of the body, the sea snakes have relatively small heads, slender necks, and very heavy middle and rear sections. With most of the body mass concentrated in the second half of the animal, almost all of the force of the strike is used to drive the head forward.

Flying. Three groups of reptiles have experimented with flight. Thecodontia, a group of Archosauria (the so-called ruling reptiles, which included dinosaurs and crocodilians), became highly successful at this means of locomotion and evolved into birds.

A second group of archosaurs, the Pterosauria, developed wings that were supported along the front margin by the arm and an extremely elongated finger. The pterosaur wing was made of skin; since it lacked both internal supports and feathers, it probably lacked the flexibility or durability of a bird wing. Flight of the pterosaurs presumably amounted to soaring and gliding. It is not understood how they moved when not flying and how they managed to take off if they happened to land on level ground. Since most remains have been found in marine deposits, it is assumed that they lived along ocean shores, probably roosting on cliffs from which takeoff would have been easy.

"Flying" lizards

The third experiment with flight was made by a group of modern lizards *(Draco)*. The "wing" of these small lizards consists of skin supported by five or six elongated ribs between the arm and leg. At rest the ribs and the wings are folded against the sides of the body. In flight the wings form broad semicircles from arm to leg on each side. These flying lizards, which live in the forested country of Southeast Asia and the East Indies, are capable only of gliding. A flying lizard launches itself from a tree into the air and glides toward another tree, turning upward sharply just before lighting on the new perch. Since the arms and legs are not modified, this lizard is capable of scampering about like any strictly arboreal lizard.

FORM AND FUNCTION

External covering. The external covering of reptiles is characteristically dry. It bears few glands or none at all and differs in this respect from the skin of amphibians and mammals. The so-called malpighian layer of the epide mis secretes the outer layer, which is tough and horny. Bony plates develop in the dermis, which lies just below the epidermis. The arrangement of scales is usually characteristic for each species.

Internal features. *Skeletal system and dentition.* The skeleton of reptiles fits the general pattern of vertebrates. They have a bony skull, a long vertebral column that encloses the spinal nerve cord, ribs that form a bony basket around the viscera, and a framework of limbs.

Each group of reptiles developed its own particular variations on this major pattern in accord with the general adaptive trends of the group. Snakes, for example, have lost the limb bones, although a few retain vestiges of the hindlimb. The limbs of several types of marine reptiles became modified into fins or flippers with obvious functional significance. In groups such as the extinct ichthyosaurs and plesiosaurs, the bones of the limbs, no longer supporting the weight of the body against the pull of gravity, became much shortened. At the same time the bones that in other reptiles composed the digits multiplied in number, forming a long flipper.

Groups of reptiles whose modes of life came to depend heavily on passive defense also developed specializations of the skeleton. The bony and horny shell of turtles and rows of bony plates on the back of ankylosaurs (Cretaceous dinosaurs) are cases in point.

The skulls of the several subclasses and orders vary in the ways mentioned below. In addition to differences in openings on the side of the skull and in general shape and size, the most significant variations in reptilian skulls are those affecting movements within the skull.

Reptilian skulls as a group differ from those of early amphibians, the vertebrates from which reptiles arose, in lacking on otic notch (an indentation at the rear of the skull) and several small bones at the rear of the skull roof. The skulls of modern reptiles are sharply set off from those of mammals in many ways, but the clearest differences are in the lower jaw and adjacent regions. Reptiles have a number of bones in the lower jaw, only one of which, the dentary, bears teeth. Behind the dentary a small bone, the articular, forms a joint with the quadrate bone near the rear of the skull. In mammals the lower jaw consists of a single bone, the dentary, and the articular and quadrate have become part of the chain of little bones in the middle ear. An almost complete transition between these two very different arrangements is known from fossils of mammal-like reptiles (order Therapsida).

Differences between reptile and mammal skulls

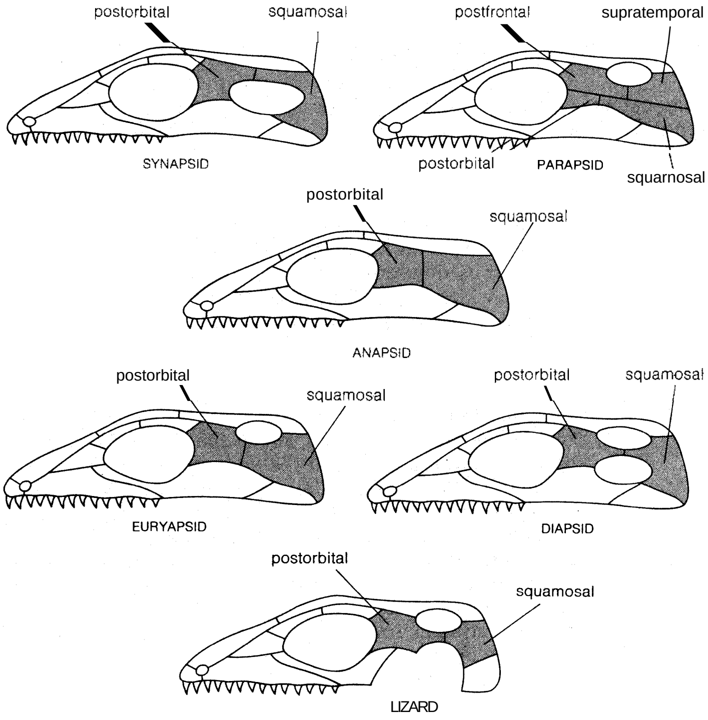

Figure 2: Diagrammatic reptilian skulls.

The dentition of most reptiles shows little specialization along the tooth row. **A** division into distinctive bladelike incisors, tusklike canines, and flat-crowned molars, such as characterize mammals, does not occur in reptiles. Instead, the entire tooth row usually consists of long conical teeth. Venomous snakes have one or several hollow or grooved fangs, but they have the same shape as most snake teeth. The principal differences between species lie in the number, length, and position of the teeth. Crocodilians among the living forms and dinosaurs among the extinct forms have but a single upper and a single lower tooth row. Snakes and many extinct reptilian groups have teeth on the palatal bones (vomer, palatine, pterygoid) and on the bones of the upper jaw (premaxilla, maxilla); only one row of teeth is present on the lower jaw.

Lizards have conical or bladelike bicuspid or tricuspid teeth. Some species have conical teeth at the front of the jaws and cuspid teeth toward the rear, but the latter are not comparable to the molars of mammals in either form (they are not flat-crowned) or function (they do not grind food). Turtles, except for the earliest extinct species, lack teeth, having instead upper and lower horny plates that serve to bite off chunks of food.

The teeth of reptiles are also less specialized in function than are mammalian teeth. The larger carnivorous reptiles (*e.g.*, crocodilians and certain dinosaurs) are equipped only to tear off or bite off large pieces of their prey and to bolt them without chewing. Insectivorous lizards (the majority of lizards) usually crack the exoskeleton of their insect prey, and then swallow the prey without grinding it up. Snakes simply swallow their prey whole without any mechanical reduction.

Skull and joint structures. Many reptiles developed joints (in addition to the hinge for the lower jaw) within the skull, permitting at least slight movement of one part relative to others. The capacity for such movement with-

Kinesis

in the skull, called kinesis, enables an animal to increase the gape of the mouth and thus is an adaptation for swallowing large objects. Apparently some of the large carnivorous theropod dinosaurs (*e.g., Allosaurus*) had a joint between the frontal and parietal bones in the roof of the skull. All reptiles of the subclass Lepidosauria (lizards, snakes, rhynchocephalians, and the extinct eosuchians) have had kinetic skulls, but they differ from the dinosaurs in having the joint on the floor of the skull at the juncture of basisphenoid and pterygoid bones.

The skulls of the lepidosaurians became increasingly kinetic as new groups evolved. The Rhynchocephalia (which include the living tuatara) and their antecedents, the Eosuchia, had only the basisphenoidal–pterygoidal joint. The lizards lost the lower temporal bar, thereby freeing the quadrate bone and allowing greater movement to the lower jaw, which is hinged to the quadrate. Finally, in the snakes, this trend culminates in the most kinetic skull among the vertebrates—a skull having the ancestral basisphenoidal–pterygoidal joint, a highly mobile quadrate (which gives even greater mobility to the lower jaw), upper jaws capable of rotating on their longitudinal axes and of moving forward and backward, and often a hinge on the roof of the skull between the nasal and frontal bones that allows the snout to be raised slightly. In short, the only part of a snake's skull incapable of movement is the braincase.

Nervous system. As in all vertebrates, the nervous system of reptiles consists of a brain, a spinal nerve cord, nerves running from the brain or spinal cord, and sense organs. Reptiles have small brains compared with mammals. The most important difference between the brains of these two vertebrate groups lies in the size of the cerebral hemispheres, the principal associative centres of the brain. In mammals these hemispheres make up the bulk of the brain and, when viewed from above, almost hide the rest of the brain. In reptiles the relative and absolute size of the cerebral hemispheres is much smaller. The brain of snakes and alligators forms less than $\frac{1}{1,500}$ of the total body weight, whereas, in mammals such as squirrels and cats, the brain accounts for about $\frac{1}{100}$ of the body weight. A stegosaur (Stegosauria), roughly the size of an elephant, had a braincase no larger than that of a 2.4-metre crocodile, about large enough to contain a brain the size of a large walnut.

Circulatory system. Modern reptiles do not have the capacity for rapid sustained activity found in birds and mammals. It is generally accepted that this lower capacity is related to differences in the circulatory and respiratory systems. Before the origin of lungs, the vertebrate circulatory system had a single circuit: in the fishes, blood flows from heart to gills to body and back to the heart. The heart consists of four chambers arranged in a linear sequence.

Evolution of the reptile heart

With the evolution of lungs in amphibians, a new and apparently more efficient circulatory system evolved. Two chambers of the heart, the atrium (or auricle) and ventricle, became increasingly important, and the beginnings of a double circulation appeared. An early stage in this evolution can be seen in amphibians today, where one of the main arteries from the heart (the pulmonary artery) goes directly to the lungs, whereas the others (the systemic arteries) carry blood to the general body. The blood is aerated in the lungs and carried back to the atrium of the heart. From the left side of the atrium, which is at least partially divided for the first time, the aerated blood is pumped into the ventricle and there mixes with the nonaerated blood from the body that was returned to the heart via the right half of the atrium. Then the cycle begins again. One of the features of the amphibian system is that the blood leaving the heart for the body is only partially aerated; part of it is the deoxygenated blood returned from the body.

All groups of modern reptiles have a completely divided atrium; it is safe to assume, therefore, that this was true of most, if not all, extinct reptiles. In reptiles, the ventricle for the first time becomes at least partially divided in the four major living groups.

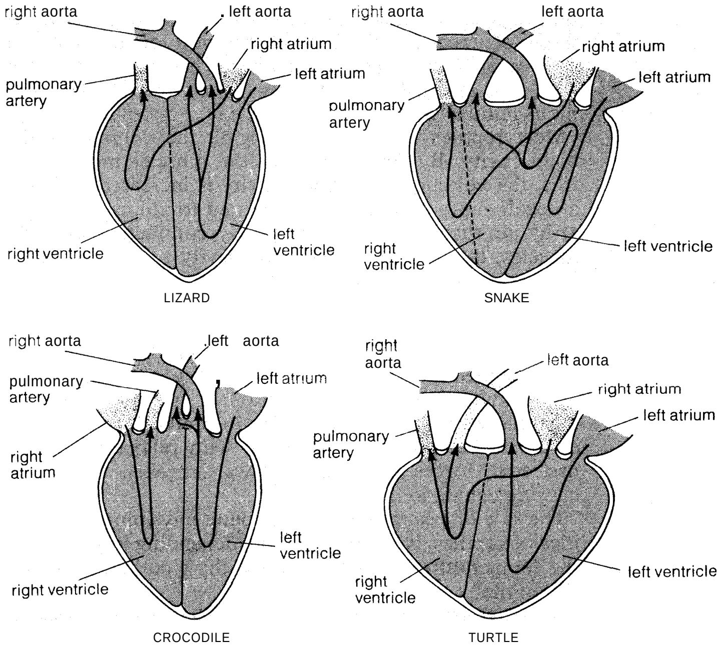

Figure 3: Types of reptilian hearts.

When the two atria of a lizard's heart contract, the two streams of blood (aerated blood from the lungs in the left atrium and nonaerated blood from the body in the right atrium) flow into the left chamber of the ventricle. As pressure builds up in that chamber, the nonaerated blood is forced through the gap in the partition into the right chamber of the ventricle. Then, when the ventricle contracts, nonaerated blood is pumped into the pulmonary artery and thence to the lungs, while aerated blood is pumped into the systemic arteries (the aortas) and so to the body.

In snakes all three arterial trunks come out of the chamber of the ventricle that receives the nonaerated blood of the right atrium. During ventricular contraction, a muscular ridge forms a partition that guides the nonaerated blood into the pulmonary artery, while the aerated blood received by the other chamber of the ventricle is forced through the opening in the ventricular septum and out through the aortas.

In crocodiles the ventricular septum is complete, but the two aortas come out of different ventricular chambers. A semilunar valve at the entrance to the left aorta prevents nonaerated blood in the right ventricle from flowing into the aorta. Instead, part of the aerated blood from the left ventricular chamber pumped into the right aorta flows into the left by way of an opening.

The ventricle of the turtle is not perfectly divided, and some slight mixing of aerated and nonaerated blood takes place.

Oxygen capacity of reptile blood

Despite the peculiar and complex circulation, a double system has been achieved by lizards, snakes, and crocodilians. Tests of the blood in the various chambers and arteries have shown that the oxygen content in both systemic aortas is as high as that of the blood just received by the left atrium from the lungs and is much higher than that of the blood in the pulmonary artery. Except for the turtles, limitation of activity in reptiles cannot be explained on the basis of imperfect heart circulation.

An explanation may lie in the chemistry of the blood. Apparently, the blood of reptiles has less hemoglobin and thus can carry less oxygen that that of mammals.

Respiratory system. The form of the lungs and the methods of irrigating them may also influence activity by affecting the efficiency of respiration. In snakes the lungs are simple saclike structures having small pockets, or alveoli, in the walls. In the lungs of many lizards and turtles and of all crocodilians the surface area is increased by the development of partitions that, in turn, have alveoli. Because exchange of respiratory gases takes place across surfaces, an increase of the ratio of surface area to volume leads to an increase in respiratory efficiency. In this regard, the lungs of snakes are not so effective as those of crocodilians. The elaboration of the internal surface of lungs in reptiles is simple, however, compared with that reached by mammalian lungs with their enormous number of very fine alveoli.

Most reptiles breathe by changing the volume of the body cavity. By contractions of the muscles moving the ribs, the volume of the body cavity is increased, creating a negative pressure, which is restored to atmospheric level by air rushing into the lungs. By contraction of body muscles, the volume of the body cavity is reduced, forcing air out of the lungs.

This system applies to all modern reptiles except turtles, which, because of the fusion of the ribs with the rigid shell, are unable to breathe by this means; they do use the same mechanical principle of changing pressure in the body cavity, however. Contraction of two flank muscles enlarges the body cavity, causing inspiration. Contraction of two other muscles, coincident with relaxation of the first two, forces the viscera upward against the lungs, causing exhalation.

The rate of respiration, like so many physiological activities of reptiles, is highly variable, depending in part upon the temperature and in part upon the emotional state of the animal.

Digestive and urogenital systems. The digestive system of modern reptiles is similar in general plan to that of all higher vertebrates. It includes the mouth and its salivary glands, esophagus, stomach, and intestine, ending in a cloaca. Of the few specializations of the reptilian digestive system, the evolution of one pair of salivary glands into poison glands in the venomous snakes is the most remarkable.

During development the embryos of higher vertebrates (reptiles, birds, and mammals) use three separate sets of kidneys consecutively; these are arranged in longitudinal sequence in the body cavity. The first set, the pronephroi, are vestigial organs left over from the evolutionary past that soon degenerate and disappear without having had any function. The second set, the mesonephroi, are the functional kidneys of adult amphibians, but their only contribution to the lives of reptiles is in providing the duct (the wolffian duct) that forms a connection between the testis and the cloaca. The operational kidneys of reptiles, birds, and mammals are the last set, the metanephroi, which have separate ducts to the cloaca. The principal function of the kidney is the removal of nitrogenous wastes resulting from the oxidation of proteins. Vertebrates eliminate three kinds of nitrogenous wastes: ammonia, urea, and uric acid. Ammonia and urea are highly soluble in water; uric acid is not. Ammonia is highly poisonous, urea slightly so, and uric acid not at all. Among reptiles the form taken by the nitrogenous wastes is closely related to the habits and habitat of the animal. Aquatic reptiles tend to excrete a large proportion of these wastes as ammonia in solution. This method, involving a great loss of body water, is no problem for an alligator, which eliminates between 40 and 75 percent of its nitrogenous wastes as ammonia. Terrestrial reptiles, such as most snakes and lizards, which must conserve body water, convert their nitrogenous wastes to insoluble, harmless uric acid, which forms a more or less solid mass in the cloaca. In snakes and lizards these wastes are eliminated from the cloaca together with wastes from the digestive system.

Discharge routes for eggs and sperm

Prior to the evolution of the metanephric kidney, the products of the male gonad, the testis, travelled through the same duct with the nitrogenous wastes from the kidney. But with the appearance of the metanephros, the two systems became separated. The female reproductive system never shared a common tube with the kidney. Oviducts in all female vertebrates arise as separate tubes with openings usually near, but not connected to, the ovaries. The oviducts, like the wolffian ducts of the testes, open to the cloaca. Both ovaries and testes lie in the body cavity near the kidneys.

With the evolution of the reptilian egg, internal fertilization became necessary. The males of all modern reptiles, with the exception of the tuatara, have copulatory organs. The structures vary from group to group, but all include erectile tissue as an important element of the operating mechanism, and all are protruded through the male's cloaca into that of the female during copulation. Unlike the penis of turtles and crocodilians, the copulatory organ of lizards and snakes is paired, each unit being called a hemipenis. The hemipenes of lizards and snakes are elongated tubular structures lying in the tail. The penis of a crocodile or turtle is protruded through the cloacal opening wholly by means of a filling of blood spaces (sinuses) in the penis; protrusion of a lizard's or snake's hemipenis, however, is begun by a pair of propulsor muscles. Completion of the erection is brought about by blood filling the sinuses in the erectile tissue. Only one hemipenis is inserted into a female, but which one is a matter of chance. Unlike the penis of mammals, the copulatory organs of reptiles do not transport sperm through a tube. The ducts from the testes, as already mentioned, empty into the cloaca, and the sperm flow along a groove on the surface of the penis or hemipenis.

Sense **organs.** *Sight.* In general construction the eyes of reptiles are like those of other vertebrates. Accommodation for near vision in all living reptiles except snakes is accomplished by pressure being exerted on the lens by the surrounding muscular ring (ciliary body), which thus makes the lens more spherical. In snakes the same end is achieved by the lens being brought forward under pressure built up on the vitreous humour by contractions of muscles at the base of the iris. The pupil shape varies remarkably among living reptiles, from the round opening characteristic of all turtles and many diurnal lizards and snakes to the vertical slit of crocodilians and nocturnal snakes and the horizontal slits of a few tree snakes. Undoubtedly the most bizarre pupil shape is that of some geckos, in which the pupil contracts to form a series of pinholes, one above the other. The lower eyelid has the greater range of movement in most reptiles. In crocodilians the upper lid is more mobile. Snakes have no movable eyelids, their eyes being covered by a fixed transparent scale. The tuatara and all crocodilians have a third eyelid, the nictitating membrane, a transparent sheet that moves sideways across the eye from the inner corner, cleansing and moistening the cornea without shutting out the light.

Visual acuity

Visual acuity varies greatly among living reptiles, being poorest in the burrowing lizards and snakes (which often have very small eyes) and greatest in active diurnal species (which usually have large eyes). Judging by the size of the skull opening in which the eye is situated, similar variation existed among the extinct reptiles. Those that hunted active prey (*e.g.*, the ichthyosaurs) had large eyes and presumably excellent vision; many herbivorous types (*e.g.*, the horned dinosaur Triceratops) had relatively small eyes and weak vision. Colour vision has been demonstrated in few living reptiles.

Hearing. The power of hearing is variously developed among living reptiles. Crocodilians and most lizards hear reasonably well, but snakes are not sensitive to airborne waves; the hearing capability of turtles is not known. The auditory apparatus in reptiles typically consists of a tympanum, a thin membrane located at the rear of the head; a small bone, the stapes, running between the tympanum and the skull in the tympanic cavity (the middle ear); the inner ear; and a eustachian tube connecting the middle ear with the mouth cavity. In reptiles that can hear, the tympanum vibrates in response to sound waves and transmits the vibrations to the stapes. The inner end of the stapes abuts against a small opening (the foramen ovale) to the cavity in the skull containing the inner ear. The inner ear consists of a series of hollow interconnected parts: the semicircular canals; the ovoidal or spheroidal chambers called the utriculus and sacculus; and the lagena, a small outgrowth of the sacculus. The tubes of the inner ear, suspended in a fluid called perilymph, contain another fluid, the endolymph. When the stapes is set in motion by the tympanum, it develops vibrations in the fluid of the inner ear; these vibrations activate cells in the lagena, the seat of the sense of hearing. The semicircular canals are concerned with equilibrium.
