The priest is by definition a cultic officer, and the title designates the second element of the office, the work of sanctification. Certain ambiguities in the Roman Catholic clerical hierarchical system appear clearly in the priesthood. Ordination empowers the priest to administer the sacraments, but he cannot use this power except by receiving "faculties" (proper permission or license) from a bishop. Teaching and preaching are not powers conferred by ordination, but they are subject to the same "faculties." The priest is lowest in the system of government and actually does not govern unless he is a pastor. Governing is not exercised by curates (priests who assist the pastor) or by the large number of priests engaged in specialized works that can hardly be called ministries: administration, teaching, scholarship, journalism, and other activities.

The pastor of the parish is the ideal and the model priest; in spite of the fact that in large parishes the pastor may be primarily an administrator, the Catholic experiences his church directly through his parochial clergy.

The Catholic hears sermons, worships and receives the sacraments, and looks for religious counsel and direction in his parish. Many Catholics, particularly in the U.S., have their children educated in a school run by the parish. The parish is also the centre of activities ranging from merely recreational to adult education and genuinely social works, all under the direction of the clergy. In Roman Catholicism the parochial clergy are authentic pastors; the pastoral office has often been diminished in the bishop and barely visible in the pope. The strength of the Roman Catholic Church historically has been rooted in its priests, especially in its parochial clergy.

Roman Catholicism for centuries has fostered a distinct clerical identity, symbolized by clerical garb, which sets the priest as a class apart not only from non-Catholics but from Catholics. The most striking feature of this caste is celibacy. There is in the modern church considerable dissatisfaction with this clerical separation and a feeling that it interferes with the ministry. Critics point out that neither in the New Testament nor in the pre-Constantinian church was there a clerical caste; the whole church was a people set apart with a mission to the unbelieving world. Together with this dissatisfaction and related to it has been an unprecedented number of departures from the priesthood and an equally alarming fall in the number of candidates.

Religious communities. Religious communities in the Roman Catholic Church are groups of men or women who live a common life and pronounce vows of poverty, chastity, and obedience (the evangelical counsels). Life in these conditions is traditionally regarded as a state aimed at the achieving of Christian perfection (theologically defined as perfect love) and thus a state that is an option only for a minority of the members of the church. Roman Catholic theology has never quite rationalized the elitism implicit in this idea nor escaped the implicit denigration of the lay state; but up to modern times both religious and seculars have overcome the need for rationalization by mutual respect and services. Religious are distinguished from seculars; the clergy is distinguished from the laity. Religious can be laity, and clergy can be secular (priests ordained for the service of a diocese).

Hermits and monks

The origins of the religious life are seen in the anchorites, or hermits, of the 2nd and 3rd centuries, who escaped sin and temptation by flight from the world, mostly in the deserts of Syria, Egypt, and Palestine. Flight from the world became the rule of the cloister, forbidding either free entrance of "externs" into the enclosure or free egress of religious from the enclosure and imposing supervision in all dealings with seculars. The evangelical counsels meant a life of solitude and destitution and an effort to attain union with God by prolonged, almost constant contemplation. Where large numbers of hermits assembled in the same place, cenobitisni (common life) emerged, and the hermits or monks (Greek *monachos,* "solitary") elected one of their members abbot (Aramaic *abba,* "father"). Eastern monasticism produced the rules of Pachomius and Basil in the 4th century, and travellers (most notably John Cassian) introduced monasticism into the Latin Church. Eastern monasticism, principally because of a lack of discipline, dissipated much of its energy and had no further influence on the West. Western monasticism was dominated by the rule of Benedict of Nursia in Italy, who founded his communities in the 5th century (see MONASTICISM).

The Benedictine Rule emphasized less austerity and contemplation and more common life and common work in charity and harmony. It has many offshoots and variations, and it has proved itself sturdy; it is the longest continuous religious community in the Roman Catholic Church, and it has survived many near collapses and reforms. The monk did not join an "order" but a monastery. Benedictine monasteries were almost always located in remote areas, but the labour of the monks transformed these areas into food-producing areas so that they became centres of settlement. The monks who fled the world found that the world sought them out for services, which they gladly rendered. They conducted what charitable works there were and were the only people who did anything to preserve the learning of antiquity. They supported church reform and furnished many reforming popes and bishops. Benedict did not put contemplation into his rule; prayer was fulfilled by the chanting of the divine office (a set form of liturgical prayer), celebrated at specific times during the day.

Mendicant friars and clerks regular

The 13th century saw the rise of the mendicant friars (Franciscans, Dominicans, Carmelites, Augustinians). The friary was like a monastery, with common life and the divine office in choir; but the friars made excursions, sometimes at great length both in time and distance, for apostolic works, mostly preaching. All of the mendicant orders had apostolic work in mind in their foundation, and they desired a mobility that was had neither by the monks nor the diocesan clergy. They were thus at the ready disposal of the pope, and the principle of clerical exemption (exemption from the jurisdiction of the bishop) became much more important than it had been for the monks. Originally, the friars did not need even the approval of the bishop to preach in his diocese, although this freedom has been restricted in modern times. Preaching became almost the specialty of the mendicant friars in the Middle Ages, and they were important in the foundation of the universities of the Middle Ages.

The 16th century saw the third major form of religious life, the clerks regular. These communities were formally and frankly directed to the active ministry. Even the friary, with the divine office in choir and other monastic restrictions, was dropped; they wore no distinctive religious habit. According to Ignatius of Loyola, founder of the Society of Jesus (Jesuits), the best known example of clerks regular, their life imitated the manner of living of devout secular priests. The Jesuits, almost by accident, had no particular ministry and placed themselves at the disposition of the pope. The clerks regular had even greater mobility than the friars and had the resources to undertake specialized works. Since the 16th century the works of religious communities have been education, foreign missions, preaching, and theological scholarship. Orders founded since the 16th century have adopted the manner of life of the clerks regular.

Nuns and brothers

Religious communities of women until the 17th century were entirely contemplative and subject to rigid cloister, although from the 16th century they had begun to admit girls into the convent not as novices (those admitted to probationary membership in the community) but for the education of a gentlewoman. The modern communities of women all stem from the type of community instituted in France in the mid-17th century by Vincent de Paul under the name of the Daughters of Charity. At first these women were not religious and deliberately so; Vincent did not wish cloister. The group was founded to help the poor and sick and to educate their children in the rudiments and in their religion. These have remained the major works of the communities of women.

Religious communities are orders if the members (or some of them) pronounce solemn vows; they are congregations if the members pronounce simple vows. Solemn vows are perpetual; simple vows may be perpetual or temporary. The difference is subtle; solemn vows were meant to be a more permanent and durable consecration, but they are dispensable. Men who make religious profession but who do not receive the sacrament of holy orders are "brothers."

Secular institutes have arisen since World War II. They are not religious (and therefore do not pronounce the three vows), have little or no common life in a common residence, have no superior but rather a manager of the few common affairs, and intend to bear Christian witness in the world in any type of secular employment.

The laity. The laity as a class do not appear in the New Testament; there could only be a laity when there had become a clergy. When the laity appear, they are the passive element of the church. If the office of the clergy is conceived as teaching, sanctifying, and governing, then the laity are the taught, the sanctified, and the governed. Misleading identification of the church with the clergy (and, within the clergy, with the hierarchy) results.

The modern term Catholic Action (especially under

Pius X and Pius XI) meant in general the assistance of the laity in the mission of the church. Yet, as it was more closely defined, the mission of the church was still entirely clerical, and lay action was accessory to the mission proper. The laity was merely the arm of the hierarchy. Furthermore, lay action lay under close direction and supervision of the hierarchy and clergy. It is not surprising that an action so vaguely defined, so patronized, and so uninspiring aroused relatively little response.

Anti-clericalism and clericalism

Much of the 19th and 20th centuries saw the Roman Catholic Church engaged with anticlericalism in the "Catholic" countries of Europe; this seems to be a peculiarly Roman Catholic phenomenon. Actually, anticlericalism is a rejection of the medieval belief in the power of the clergy to direct all the decisions of the laymen that they thought themselves entitled to direct. Reaction in an exaggerated form nearly excluded the clergy from any activity except public worship in some countries.

The second Vatican Council definitely rejected clericalism. It called "secular" all non-ecclesiastical activity and declared that the secular is the proper area of the layman. This means that the layman is the judge of how to realize his Christian destiny in the secular life. Proper does not mean exclusive, but the statement implies that the clergy can offer only principles and general directions, not concrete decisions. The Roman Catholic Church intended to make the laity the channel of its relevance in the world.

The council also took steps against the passive role of the layman in ecclesiastical life. It recommended the establishment of lay councils in each diocese and in each parish. This has moved slowly, because Roman Catholics are not accustomed to the idea and are uncertain about how it should be implemented. As the secular is the proper but not the exclusive area of the layman, so the ecclesiastical is the proper but not the exclusive area of the hierarchy and the clergy.

CANON LAW

The earliest individual church law was called a canon (Greek *kanōn*, "rule, measure, standard"); the canons were finally called Canon Law. Church laws appear almost as soon as church authority, and some passages of the New Testament reflect early rules; whether they should be called law at this primitive stage is doubtful. Laws of dioceses or of regions appear even before Constantine; they were formed by diocesan synods or regional councils. Laws for the whole church appear with the earliest ecumenical councils. Canon Law remained scattered pieces of papal, conciliar, and diocesan legislation until the 12th century. The first collection and synthesis of Canon Law was made by Gratian in 1142, the *Decretum* Gratiani. To this collection in the next 400 years were added the decretals (papal decrees on points of law) produced in the reigns of Gregory IX (1234), Boniface VIII (1298), and John XXII (1317) and two collections known as Extravagantes (1500). These formed the Corpus *Juris* Canonici ("Body of Canon Law"); no further collection was made of laws later than the Corpus. Effectively, although not formally, Canon Law included the opinions of canonists interpreting the Corpus.

This unsatisfactory and cumbersome collection led to calls for codification. No doubt the desire was influenced by the production of the Code Napoléon, which became the basic law of most of the nations of western Europe. The codification was begun by a document of Pius X (1904) and was completed, directed by Cardinal Pietro Gasparri throughout, under Benedict XV (1917); it became law in 1918. This code has remained the basic law of the Roman Catholic Church, although, following the second Vatican Council, several different attempts were being made to revise it.

The history and structure of church law are treated more fully under CANON LAW.

IV. Beliefs

FAITH

Notions of faith. The idea of faith shared by all Christian churches is rooted in the New Testament. But the New Testament idea of faith is not simple, and it permits a breadth of meaning that has led to variations even within a single Christian communion. Most modem interpreters of the New Testament would agree to a description of New Testament faith as a total commitment of the self to God revealing himself in Christ. Yet, it is doubtful whether the post-Reformation theology of any Christian church has presented faith simply in these terms.

Faith as an intellectual assent

Even before the Reformation, faith in Roman Catholicism had developed an emphasis that is not rooted in the New Testament but can be traced back to the Alexandrian school of theology and Augustine. Faith appeared primarily as acceptance of revelation, and revelation appeared as a revelation of doctrine rather than as revelation of a person. This emphasis ultimately was formulated in the 13th century by Thomas Aquinas in a definition of faith—canonized by the Council of Trent and the first Vatican Council—as an intellectual assent given to revealed truth by the command of the will inspired by grace and motivated by the authority of God revealing.

The Reformers, with Martin Luther as the leader, rejected this idea of faith as nonbiblical and exclusively doctrinal; it seemed to place the teaching authority of the Roman Catholic Church between man and God not as a means of communication but as a replacement of God. Luther saw faith as confidence in the saving power of grace. This, Luther believed, was a return to the New Testament faith. Roman Catholicism rejected this as a mere sentiment; and these positions were crystallized up to the 20th century. At the risk of oversimplification, it is possible to say that both represented exaggerations of the New Testament. New Testament faith is more than either trust in the saving power and will of God or assent to revealed truth, although neither element can be entirely excluded. Controversy was wasted in trying to prove the adversaries wrong rather than in trying to understand the New Testament. The documents of the second Vatican Council reflect a shift in Roman Catholic theology from emphasis solely on faith as intellectual assent to recognition of faith as a loyal adherence to a personal God.

Roman Catholic theology, having chosen the option of faith as assent, was faced with the problems of showing that it was a rational assent rather than an irrational assent and of maintaining that faith was a deliberate and free meritorious act under the inspiration of grace. At first glance the two problems seem to cancel each other out; one can maintain one affirmation only by denying the other.

Preambles and motivation of faith. The study of the problems connected with faith involves the investigation of what are called the preambles of faith and also of the motivation of faith. The preambles of faith include those processes by which the believer reaches the conclusion that it is reasonable to believe—*e.g.*, the proof of the existence of God by the use of one's own reason. The freedom of faith is respected by affirming that this conclusion is as far as the preambles can take one. This process as proposed is a theoretical construction that actually occurs in no one, but the analysis can be of value in uncovering the psychological processes that occur without reflection. The preambles include the study of the scientific and historical difficulties raised against the Christian fact (*i.e.*, the incarnation, Resurrection, Ascension, and glorification of Jesus Christ) itself or against the Roman Catholic interpretation and proclamation of the Christian fact or against the Roman Catholic claim to be the exclusive custodian of revealed doctrine and the means of salvation. These studies were efforts to show what cannot be shown by scientific and critical methods, but in the exaggerated claims of their defenders they showed that faith was a necessary conclusion of a valid rational process. Such a faith could be neither free nor the result of grace.

The evidence for the act of faith

The study of the motivation of faith attempted to meet this difficulty. Some earlier analyses candidly presented faith as resting on evidence and clumsily postulated a movement of grace necessary to assent to this particular evidence. Normally, one "wills" to believe something because the evidence is not compelling; thus, one chooses to believe that the candidate of his choice has the qualities desired for the office, although the evidence is less than overwhelming. The Roman Catholic thinks this is an assent to the probably rather than the certainly true and yet insists that the certainty of faith is the highest of all certainties. Ultimately, the Roman Catholic analysis must say that the evidence that belief is reasonable can never be so clear and convincing that it compels the radical deviation from worldly patterns that assent implies. At this point, the will inspired by grace chooses to accept revelation for other reasons than the evidence.

The motive of faith that has been presented by Catholic theologians is "the authority of God revealing." It is held that the preambles of faith show beyond reasonable doubt that God exists and that he has revealed himself. This evidence and an acceptance of the notion that, if God reveals himself, he does so authoritatively motivate a person to make the act of faith. The problem with such an analysis has been how the authority of the revealer is manifest to the believer. It seems that the authority of God revealing must be an object of faith rather than a motive, because the conjunction of this authority with the fact of revelation cannot be the object of historical experience. In the mid-20th century, this dilemma caused an increasing number of Catholic theologians to move closer to a view that emphasized faith as a personal commitment to God rather than as an assent to revealed truth.

Heresy. Heresy is the denial by a professed, baptized Christian of a revealed truth or that which the Roman Catholic Church has proposed as a revealed truth. The unbaptized person is incapable of heresy, and the baptized person is not guilty of "formal" but only of "material" heresy if he does not know that he denies a revealed truth. The seriousness with which Roman Catholicism regarded heresy is shown by the ancient penalty of excommunication. Civil penalties, including the supreme penalty, did not appear until the Constantinian age. Lesser civil disabilities continued in force, although the law was often ignored, into the 20th century. Protestant governments often borrowed some of this severity from Roman Catholic governments.

Roman Catholic theologians often deal with heresy, paradoxically, as a necessary step in the development of dogma. In order to save themselves from an extremely crass and even cruel rationalization, they point out that the questions raised by heresy were legitimate but that heretics too quickly assumed a one-sided and exclusive view of doctrine that they wished to impose on the entire church. Modern studies have sometimes been less kind to such champions of orthodoxy as Athanasius and Cyril of Alexandria, who were not themselves free of one-sided views and who showed themselves unwilling to listen to their adversaries with sympathy and understanding. In recent times most of the theses of Modernism (a movement to change the Catholic Church by means of radical renovation), which were condemned vigorously by Pius X in 1907, have found their way into Catholic theology. This may have something to do with the absence of the words heresy and heretics from the acts of the second Vatican Council. Like the use of the word church for Protestant churches, this indicates a substantial change of attitude toward a genuinely ecumenical position.

REVELATION

Notion of revelation. Although other religions have an idea of revelation, none of these ideas bears a close resemblance to the idea of revelation found in the Old and New Testaments and in Christianity. Roman Catholic theologians distinguish between revelation in a broad sense, which means knowledge about God deduced from nature and man (and therefore actually philosophy), and revelation in the strict formal sense, by which they mean the utterance of God. This latter idea, of course, can only be conceived by analogy with the utterance of man, and its precise definition involves difficulties.

The earliest idea of revelation is the idea found in the Old Testament in which the speech of God is addressed to Moses and the prophets. They in turn are described as quoting the words of God rather than interpreting them. Jesus, the fulfillment of the prophets, does not speak the word of God; he is the word of God. This phrase, which occurs only in the opening verse of both the Gospel and the First Letter of John, has become a technical term in theology; Jesus is the Incarnate Word. As such he is both the revealer and the revealed. He reveals the Father both by what he says and by what he is. Thus, the earliest Gospel (literally "good news") is the account of the life, death, and Resurrection of Jesus. The Gospel as the recital of his words appears in a later phase of development.

Jesus as revealer and revealed

It has been noted that the Roman Catholic Church has regarded revelation primarily as the revelation of propositions rather than the revelation of a person. Thus, it has thought even of Jesus more as a spokesman who tells of God than as a reality who himself in his being and actions manifests God. Though this latter aspect is found to some extent in the documents of the second Vatican Council, it has normally been considered only in the miracles of Jesus, which have been regarded in Roman Catholic apologetics as works of divine power that assure the credibility of the words of Jesus. These words, which were spoken in a particular historical context, have been preserved in a twofold way. They are written in the Gospels, which together with the Old Testament form a book of revelation that is distinct from the spoken words; but, because the Bible itself is written under divine inspiration, it has the same authority of revelation as the spoken words of Jesus. The Roman Catholic Church also preserves the words of Jesus, independently of the Bible, in its traditional teaching; but it does not utter the very words spoken by Jesus, and thus its words have a lower formal quality of revelation than the words of the Bible, although they are of equal authority. The idea of a book of revelation was taken by the early Christian Church from Judaism when it accepted the sacred books of the Jews as its own, just as it accepted the God of Judaism as the Father whom Jesus claimed for his own.

Mystery and the supernatural

The content of revelation. The proper content of revelation is designated in Roman Catholic teaching as mystery; this theme was important in the documents of the first Vatican Council. The development of the theme of mystery responded to those intellectual movements of the 18th and 19th centuries that are called by such titles as the Enlightenment, Rationalism, scientism, and historicism. To the Roman Catholic Church these movements were threats to the idea of a sacred revelation; they appeared to claim that human reason had no frontiers or that human reason had demonstrated that revelation was historically false or unfounded or that the content of revelation was irrational. The affirmation of mystery meant that the reality of God was unattainable to unaided human reason; theologians had long used the word incomprehensible, which says more than modern theologians wished to say. Mystery refers both to the divine reality and to the divine operations of the world. These operations can be observed only in their effects; the operation itself is not seen, nor is its motivation seen. The plan of God, which is realized in history, is mysterious. The first Vatican Council insisted that the existence of God and of a moral order is attainable to reason, and some of the fathers of the council wished to state that these truths were imposed upon reason by the evidence, a step that the council did not choose to take. Mystery does not mean the incomprehensible or the unintelligible; it means, in popular language, that man cannot know who God is or what God is doing or why God is doing it unless God tells him. Mystery also means that, even when the revelation is made, the reality of God and his works escapes human comprehension.

The term supernatural has been used in Roman Catholic theology since the 17th century to designate not only revelation but other aspects of the divine work in the world. The term has an inescapable ambiguity that has led many modern theologians to avoid its use. The "natural" that the supernatural presupposes is the world of human experience; the quality of this experience is not altered by technological and social changes as long as these are fulfillments of the potentialities of nature. Indeed, it is the spectacular growth in the knowledge of these potentialities in modern times that leads to doubt as to whether there can be a supernatural at all. The supernatural reality is identified with God in his reality and in his operations. This is a reality that man cannot create or control. The supernatural in cognition is this reality as it is perceptible to man; it is, for man, simply unknown as far as unaided reason can move. The first Vatican Council affirmed that without revelation human reason historically has not reached anything but a distorted idea of the divine and an imperfect idea of the moral order. This means also that man is unaware of his destiny, either individually or collectively, without revelation and that he is unable to achieve it without the entrance of the supernatural into the world of history and experience.

Contemporary theologians of revelation are aware of the problems raised by historical and literary criticism that render it impossible to cherish the primitive idea of revelation as the direct utterance of God to man. Roman Catholic theologians have not found a satisfactory way of describing revelation, but they do not see that the destruction of a naïve idea of revelation destroys the whole idea. Theologians also recognize that the older idea of revelation of propositions as a collection of timeless and changeless verities, almost like a string of pearls, is no longer tenable. Every utterance that is called revelation was formed in a definite time and place and bears the marks of its history. There is no revealed proposition that cannot be restated in another cultural situation. Contemporary theologians are aware that these propositions must be restated if the Roman Catholic Church is to speak meaningfully in the modern world. Roman Catholicism does not accept the possibility of a new revelation; it believes that reason can never completely penetrate the "mystery" and that it must continue the exploration of the mystery that has already been revealed.

TRADITION AND SCRIPTURE

Tradition as channel and content

In Roman Catholic theology tradition is understood both as channel and as content. As channel it is identical with the living teaching authority of the Catholic Church. As content it is "the deposit of faith," revealed truth concerning faith and morals. In Roman Catholic belief, revelation ends with the death of the Apostles; the deposit was transmitted to the college of bishops, which succeeds the Apostles.

The Reformers contended that the Roman Catholic Church had imposed teachings that were not contained in the Scriptures, and this Protestant objection has been maintained in modern times. The objection was raised more intensely when the Immaculate Conception of Mary, the mother of Jesus (Pius IX, 1854), and her Assumption (Pius XII, 1950) were defined as dogmas. For neither of these is there any biblical evidence; more significantly, there is no evidence in tradition for either before the 6th century.

The Roman Catholic Church recognizes that the Bible is the word of God and that tradition is the word of the church. In one sense, therefore, tradition yields to the Scriptures in dignity and authority. But against the Protestant slogan of *sola* Scriptura ("Scripture alone"), itself subject to misinterpretation, the Roman Catholic Church recognized that the church existed before the New Testament. In fact, the church both produced and authenticated the New Testament as the word of God. For this belief, at least, tradition is the exclusive source; and this furnished a warrant for the Catholic affirmation of the body of truth transmitted to the church through the college of bishops preserved by oral tradition (meaning that it was not written in the Scriptures). The Roman Church therefore affirmed its right to find out what it believed by consulting its own beliefs as well as the Scriptures. The Council of Trent affirmed that the deposit of faith was preserved in the Scriptures and in unwritten (not in the Bible) traditions and that the Catholic Church accepts these two with equal devotion and reverence. The council studiously avoided the statement that they meant these "two" as two sources of the deposit, but most Catholic theologians after the council understood the statement as meaning two sources. Protestants thought it meant the Roman Catholic Church had written a second Bible.

The question of the two sources of revelation

Only in contemporary Catholic theology has the question been raised again, and a number of theologians believe that Scripture and tradition must be viewed as one source. They are, however, faced with the problem of nonbiblical articles of faith. To this problem several remarks are pertinent. The first is that no Protestant church preaches "pure" gospel; they have all developed dogmatic traditions, concerning which they have differed vigorously. It is true, on the other hand, that they do not treat these dogmatic traditions "with equal devotion and reverence" with the Bible. The second is that the early Christian Church through the first eight ecumenical councils (before the Eastern Schism in 1054) arrived at nonbiblical formulas to profess its faith. Protestants respond that this is at least a matter of degree and that the consubstantiality of the Son (*i.e.*, that he is of the same substance as the Father), defined by the Council of Nicaea, is more faithful to the Scriptures than the Assumption of Mary.

Roman Catholics and Protestants should be able to reach some consensus, not yet formulated, that tradition and Scripture mean the reading of the Bible in the church. Protestants never claimed that a man and his Bible made a self-sufficient Christian church. The New Testament itself demands that the word be proclaimed and heard in a church, and the community is formed on a common understanding of the word proclaimed. This suggests a way to a Christian consensus on the necessity and function of tradition. No church pretends to treat its own history of belief as nonexistent or unimportant. By reading the Scriptures in the light of its own beliefs it is able to address itself to new problems of faith and morals that did not exist in earlier times or to which the church for some reason did not attend.

Development of dogma

Catholic theologians of the 19th century dealt with the problem under the heading of development of dogma. To a certain extent the question can be reduced to epistemology (*i.e.*, theory of knowledge) : is a new understanding of an ancient truth a "new" truth? The problem does not arise out of faith; Sir Isaac Newton's observations of falling bodies saw nothing that men had not seen for thousands of years. Yet the effects of Newton's insights and calculations altered man's understanding of the universe and his actions within the universe. The problem is important in theology because of the necessity of basing belief on the historical event of the revelation of God in Christ. Unless the link is maintained, the church is teaching philosophy and science, not dogma. Hence, the Roman Catholic theological teaching has tended to say that dogma develops through new understanding, not through new discoveries.

THE TEACHING AUTHORITY OF THE CHURCH (THE MAGISTERIUM)

Notion of teaching authority. The Roman Catholic Church claims for itself a teaching authority that is unparalleled in the christian community. The Reformation was primarily a rebellion against the teaching authority, and the Reformers did not claim for their own churches the authority they rejected in the Roman Church.

To teach with authority means that the teacher is able to impose his doctrine upon the listener under a religious and moral obligation. This moral obligation does not flow from the nature of teaching, which of itself imposes no obligation upon the learner; the learner is morally obliged only to assent to manifest truth. The Roman Church derives its teaching authority from the commission given by Jesus to the Apostles as contained in the New Testament ("He who hears you hears me"). The response of the hearers of the Apostles was faith; the response of the Roman Catholic is expected to go beyond faith. The Apostles were presumed to speak to those who had not yet believed; the Roman Catholic Church imposes its teaching authority only upon its members. The definition of the teaching authority must show that these modifications do not exceed the limits of legitimate doctrinal development.

The hierarchy

Organs of teaching authority. The teaching authority is not vested in the whole church but in certain well-defined organs. These organs are the hierarchy—the pope and the bishops. The Roman Catholic Church traditionally has divided the church into "the teaching church" and "the listening church." Clergy below the hierarchical level are included in "the listening church," even though they are the assistants of the bishops in the teaching office. The hierarchy alone teaches what the Roman Catholic Church calls "authentic" doctrine. There is an unresolved antithesis between this idea and the traditional belief that "the consent of the faithful" is a source of authentic doctrine; the conventional resolution that defines the consent as formed under the direction of the pastors of the faithful resolves the problem by depriving the consent of the faithful of any meaning.

The Roman pontiff is vested with the entire teaching authority of the Roman Catholic Church; this was solemnly declared in the first Vatican Council. This means that he is the only spokesman for the entire Roman Church; the papacy carries in itself the power to act as supreme pastor. It is expected that he will assure himself that he expresses the existing consensus of the church, but in fact the documents of the first Vatican Council are open to the understanding that the pope may form the consensus by his utterance. The second Vatican Council clarified this ambiguity in the idea of the spokesman of the church by its emphasis on the collegial character of the primacy of the pope. The pope, however, does not always speak as the supreme pastor and head of the Roman Church, and he is expected to make this clear in his utterance.

The bishops are authentic teachers within their dioceses. Thus, the same implicit conflict exists in regard to teaching as was noted in connection with governing. The conflict is resolved by collegiality; that the authentic teacher teaches orthodox doctrine is recognized by comparing his doctrine with that of his episcopal colleagues. In this way, doctrinal disputes were resolved in the pre-Constantinian church, and a regional council was called if necessary. Since the Reformation, the Roman see has never admitted publicly that a bishop has fallen into doctrinal error; the united front of authentic doctrine is preserved, and the matter is dealt with by subtle means. What is taught by all the bishops is authentic doctrine; it is understood that they teach in communion with the Roman pontiff, and a conflict of doctrine on this level is simply not regarded as a possibility. This consensus of the bishops is known as "the ordinary teaching." "The extraordinary teaching" signifies the solemn declaration of an ecumenical council, which is the assembly of the bishops, or the most solemn type of papal declaration, known as a definition of doctrine ***ex cathedra*** ("from the throne"), a term that signifies that the declaration exhibits the marks of the teaching of the supreme pastor addressed to the universal church.

Object and response. The object of authentic teaching is defined as "faith and morals." Faith means revealed truth. Morals theoretically means revealed moral principles, but it has long been understood as moral judgment in any area of human conduct; thus, the Roman Catholic Church not only prohibits contraception for its members, but by declaring it contrary to "the natural law" the church declares contraception to be universally wrong. Thus, morals includes the declaration and interpretation of the natural law. The limits of faith and morals have never been declared by the Roman Catholic Church, and one cannot take the exercise of the teaching authority as a reliable guide. The teaching authority condemned the heliocentric theory of Galileo as contrary to the Bible. The teaching authority has always understood that revealed truth involves other propositions that are not themselves revealed but that must be affirmed or denied, at least in the present context of knowledge, because of revealed doctrine.

Dogma is the name given to a proposition that is proclaimed with all possible solemnity either by the Roman pontiff or by an ecumenical council. A dogma is a revealed truth that the Roman Catholic Church solemnly declares to be true and to be revealed; it is most properly the object of faith.

Infallibility

The first Vatican Council declared that the pope, when he teaches solemnly and in the area of faith and morals as the supreme universal pastor, teaches infallibly with that infallibility that the church has. The infallibility of the church has never been defined, and its extent is understood by theologians in the sense of pontifical infallibility as limited to faith and morals. These terms are ambiguous, as noted above. Infallibility is actually hedged in with many reservations; nevertheless, pontifical documents often have an aggressive tone that may mislead the incautious reader. The real problem is how a teaching authority that can and does make errors in doctrinal teaching can be called infallible, even with numerous and serious reservations. In the early 1970s some Catholic theologians (*e.g.*, Hans Kiing) suggested that the church should be understood as indefectible (*i.e.*, not able to fail or he totally led astray) rather than infallible.

The proper response of the Roman Catholic to authoritative teaching that is "ordinary" and does not clearly deal with "faith or morals" is religious assent. This is extremely difficult to define; it admits dissent under poorly defined conditions. But the theory of religious assent does in fact permit the somewhat massive dissent from the authoritative teaching of Paul VI in 1968 against contraception. Religious assent is particularly relevant to the pontifical document called the encvclical, a type of document that first appeared in the 18th century and became the normal mode of pontifical communication in the 19th century. The encyclical letter is a channel of ordinary teaching, not solemn and definitive and somewhat provisional by definition. Religious assent may be withheld, in popular language, by anyone who in good conscience thinks he knows better. The traditional discipline has made Roman Catholics slow to say this; in modern times they say it more quickly. At the same time, the documents of the second Vatican Council indicate that the authoritative teaching body will be slower to assert itself in the future.

MAJOR DOGMAS AND DOCTRINES

The Roman Catholic Church in its formula of Baptism still asks the candidate to recite the Apostles' Creed as a sign that he believes what he must believe. The early Church Fathers made the creed the basis of the baptismal homilies given to catechumens, those preparing for the rite. The homilies, like modern Roman Catholic doctrine, went considerably beyond the bare articles of the creed.

Grace

Roman Catholic faith incorporates into its structure the books of the Old Testament. From these books it derives its belief in original sin, conceived as a hereditary and universal moral defect that makes man incapable of achieving his destiny and even of achieving basic human decency. The importance of this doctrine lies in its ex. planation of the human condition as caused by the failure of man and not by the failure of God (nor, in modem Roman Catholic theology, by diabolical influence). Man can be delivered from the human condition only by a saving act of God. This act is accomplished by God in the death and Resurrection of Jesus. In Jesus, God is revealed as the Father who sends the Son on his saving mission, and through the Son the Spirit comes to dwell in the redeemed. Thus, the Trinity of Persons is revealed, and the destiny of man is to share the divine life of the three Persons. The saving act of Jesus introduces into the world grace, a theological idea that has been much and hotly disputed. Grace signifies in Roman Catholic belief both the love of God and the effect produced in man by this love. The response of man to the presence of grace is the three theological virtues of faith, hope, and charity; these enable him to live the Christian life. Man is introduced to grace and initiated into the church by Baptism, which must be preceded by repentance and faith. The life of grace is sustained in the church by the sacraments.

The life of grace reaches its fulfillment in eschatology; in this area of belief about the end of the world and "the last things," there is some uncertainty in modern theology. Most theologians recognize the mythological character of most of the imagery of heaven, hell, and purgatory. The peculiarly Roman Catholic belief in purgatory was an effort to state that most men at death are neither good enough for heaven nor bad enough for hell. The theology of the last things is still unable to cope with the implications of this statement. Belief in a resurrection to eternal life has never been easy, and modern times have produced more difficulties than solutions. Christianity, in fact, shows oscillation between a transcendental direction and an immanent direction; in modern times the emphasis is on immanence—that is, on the meaning of religion in the world. The second Vatican Council reflected this in its statements on the "secular" and the response of the church to the secular.

This summary can state no more than the basic elements of the Christian fact. The complex Roman Catholic dogmatic structure has been mentioned several times, and probably no two statements of "major dogmas and doctrines" would be the same.

V. Worship

THE LITURGY

Cultic worship is so universal in religion that some historians of religion define religion as cult. Cultic worship is social, and this means more than a group worshipping the same deity in the same place at the same time. Cult is structured with a division of sacred personnel (priests) who lead and perform the cultic ceremonies for the people, who are in a more distant relation with the deity. The sacred personnel are designated by the choice and acceptance both of the deity and of the worshipping group. The words and actions of the cultic performance are divided into roles assigned to the leaders and to the worshippers. It is the tendency of cultic worship to replace spontaneity, which it once had, with set and even rigid forms of words and acts. These are preserved by tradition, and they generally have a sacredness that is based on the belief that the directions for cultic worship came ultimately from the deity.

Central act of liturgy

The eucharistic assembly or mass. Roman Catholic liturgy has its roots in Judaism and the New Testament. The central act of liturgy from earliest times was the eucharistic assembly, the commemorative celebration of the Last Supper of Jesus. This was set in a structure of liturgical prayer. The first six centuries of the Christian Church saw the development of a rich variety of liturgical systems, many of which have survived in the Oriental churches. In the West the Latin liturgy appeared fully developed in Rome in the 6th and 7th centuries. From the 8th century the Roman liturgy was adopted throughout western Europe. In this same period, however, liturgy developed in Frankish territories; and the Roman rite that emerged as dominant in the 10th century was a Roman–Frankish creation. The Roman rite was reformed by the Council of Trent by the removal of some corruptions and the imposition of uniformity; after Trent the Roman see was the supreme authority over liturgical practice in the entire Roman Catholic Church.

By the 11th century, Roman liturgy had acquired the classic form that it retained up to the second Vatican Council. The fullness of the liturgy could be witnessed only in some cathedrals, collegiate churches, and monastic churches. The full liturgy included the daily celebration of the solemn high mass and recitation of the divine office in choir. The solemn high mass was performed by at least three major officers (celebrant, deacon, and subdeacon), assisted by many acolytes and ministers. Except during the penitential seasons of Advent and Lent, the altar was decorated, and numerous candles (in the Middle Ages for light rather than ornamentation) and incense were employed. The singing and chanting were accompanied by the organ and in modern times even by orchestral music; Mozart once complained that the Archbishop of Salzburg compelled him to compose a mass without the resources of a full symphonic orchestra.

The divine office. The divine office was a legacy to the clergy from the monks. From the beginnings, monks assembled several times daily for prayer in common. This developed into set common prayer at stated times each day (Matins, midnight; Lauds, first daylight; Prime, sunrise; Terce, midmorning; Sext, noon; None, midafternoon; Vespers, sunset; Compline, before retiring). The divine office consisted basically of the chanting of the Psalms (in a weekly cycle), the recital of prayers, and the reading of the Scriptures (to which were later added selections from the writings of the Church Fathers, probably instead of a homily given by one of those present). Together with the mass, the office has been the only "official" prayer of the Roman Catholic Church; all other prayer forms are "private," even if several hundred people recite them together. For this reason, clerics in major orders for centuries since the Middle Ages have been obliged to recite the divine office, or "breviary," privately if they are not bound to attend the office in choir. It was long recognized that there is an inconsistency in the private silent reading of a prayer structure that is intended for choral chanting, and the second Vatican Council recommended a reform that was not yet implemented in the early 1970s. Many priests, however, had abandoned the breviary.

Official prayer of the church

The cycle and the language of the liturgy. The liturgy has long been arranged in an annual cycle that is a re-enactment of the saving events of the life, death, Resurrection, and glorification of Jesus Christ. Even many Catholics do not realize that the cycle has an eschatological outlook; the events are re-enacted as an assurance that the saving act will reach its eschatological fullness, and the liturgy is an expression and a support of the Christian hope. The cult of the saints is an intrusion into the liturgical cycle, and it has been much reduced in the contemporary liturgical reforms.

Latin did not become the language of the Roman rite until the 6th century; the language of imperial Rome was Greek. As a sacred language Latin really has no parallel. Jews have always made a genuine effort to learn some Hebrew, and other sacred languages are archaic forms of the vernacular; the English of the Authorized Version of the Bible became the language of prayer in many Protestant churches. The effect of Latin was to make the liturgy the preserve of the clergy, and the laity became purely passive. This was countered by the efforts to use sound and spectacle in the performance of the solemn liturgy. The Canon of the mass, the central eucharistic formula, for centuries was recited by the celebrant inaudibly; this was a kind of verbal "sanctuary" that the laity were not even supposed to hear. The abandonment of Latin as a result of the second Vatican Council excited deep antagonisms; one sees in the Latin liturgy an image, cherished by many, of the timeless and changeless Roman Catholic Church. Yet, the restoration of the vernacular should restore to the liturgy two functions that it had in the early centuries: to instruct converts and to confirm members in their faith.

THE SACRAMENTS

The sacraments in general. In Roman Catholic theology a sacrament is an outward sign, instituted by Jesus Christ, that is productive of inner grace. The number is seven (defined by the Council of Trent against the Reformers, who reduced the number). The number seven does not appear in Roman Catholic teaching before the 11th century, and it is an example of truth for which the Roman Catholic Church relies on its own tradition.

The sacrament as an encounter with mystery

The sacrament in modern theology is frequently described as an encounter with mystery, the mystery being the saving act of God in Christ. Theological studies have been directed to the exploration of the idea of sign and significance. The traditional Roman Catholic statement of the effectiveness of the sacraments (defined by the Council of Trent) is described by the untranslatable ex *opere operato,* which is best explained briefly by saying that the faith and virtue of the minister neither add to the sacrament by their presence nor detract from it by their absence. The minister is merely the agent of the church, and the effectiveness of the sacrament is based on the saving act of God in Christ, which is signified by the rite and applied to the recipient of the sacrament.

Protestant theologians formerly charged the Roman Catholic Church with a belief in magic; this controversial angle has generally been abandoned, but the theological explanation of the sign that effects by signifying is still difficult. Roman Catholic theologians remark that the mystery of God's saving act is not capable of complete rational explanation. There are analogies, however, in common experience, and there is no society that does not employ effective signs. These signs are not merely for display. The inauguration of the president of the United States makes the man president; the sign is effective because it signifies the reality of the election that this individual won. The sign of the coronation of a monarch is equally effective, but it is more difficult to define the reality signified. Such effective symbols are a part of human society.

The Roman Catholic Church adheres strictly to the external sign. Traditionally, the church attributes the institution of the sign to Jesus Christ (although this has been the subject of discussion among modern theologians), and this removes the right of anyone to tamper with it. The Roman Catholic Church believes that, if God gave a sign, the alteration of the sign so that the significance is lost might render the sign ineffective. Hence, the use of the proper material and the retention of the traditional formula are treated as sacred. The Roman Catholic Church maintains its own exclusive competence to supervise matter and form "in detail," a competence not precisely defined. Since Thomas Aquinas the material used is called matter, and the words are called form; the terms are borrowed from the Aristotelian theory of the constitution of matter. The material becomes sacred and salutary only by its conjunction with the proper words. The effect produced has been called for centuries grace, but it is difficult to assert a single effect and still explain why there are seven symbols.

Sacramentals

The term sacramental is used to designate verbal formulas (such as blessings) or objects (such as holy water or medals) to which a religious significance has been attached. These are symbols of personal prayer and dedication, and their effectiveness is measured by the particular dispositions of the person who uses them. Although superstition has arisen in connection with sacramentals, the Roman Catholic with elementary instruction knows the difference between these things and sacraments.

Baptism. Baptism is the sacrament of regeneration and initiation into the church. According to a theme of St. Paul, probably influenced by Jewish belief in the circumcision of adult proselytes, Baptism is death to a former life and the emergence of a new person, signified by the conferring of a new name; it is the total annulment of the sins of one's past and the emergence of a totally innocent person. One becomes a member of the church and is incorporated into the body of Christ, thus becoming empowered to lead the life of Christ. Nothing but pure natural water may be used, and Baptism must be conferred in the name of the Father, the Son, and the Holy Spirit. Baptism is normally conferred by a priest, but the Roman Catholic Church accepts the Baptism conferred by anyone having the use of reason "with the intention of doing what the church does." As the sacrament of rebirth it cannot be repeated. The Roman Catholic Church baptizes conditionally in case of doubt of the fact of Baptism or the use of the proper rite.

Points of controversy

Two points of controversy still exist in modern times. One is Baptism by pouring rather than immersion, although immersion was probably the biblical and early Christian rite. The change was almost certainly the result of the spread of Christianity into Europe north of the Alps and the occurrence of the baptismal feasts, Easter and Pentecost, often in early spring. The Roman Catholic Church simply asserts that the symbolism of the bath is preserved by a ritual infusion of water.

The second is the Baptism of infants. There is no certain evidence of this earlier than the 3rd century, and the ancient baptismal liturgies are all intended for adults. The liturgy and the instructions clearly understand the acceptance of Baptism as an independent adult decision; without this decision the sacrament cannot be received. The Roman Catholic Church accepts this principle by introducing adults (sponsors, godparents), who make the decision for the infant at the commission of the parents. In Roman law as in modem law, adults are empowered to make decisions for minors. It is expected that the child will accept the decision made for him and will thus supply the adult decision that was presumed.

Until the recent liturgical renewal, Baptism did not have the religious and ceremonial importance that it had in the early church; the ceremonies were intended to make the adult aware that he had made the most important decision of his life, and the whole church witnessed the ceremony, performed only twice a year on a group of catechumens. Doubtless the Baptism of infants contributed to this loss of ceremonialism and to a corresponding lower esteem of Baptism.

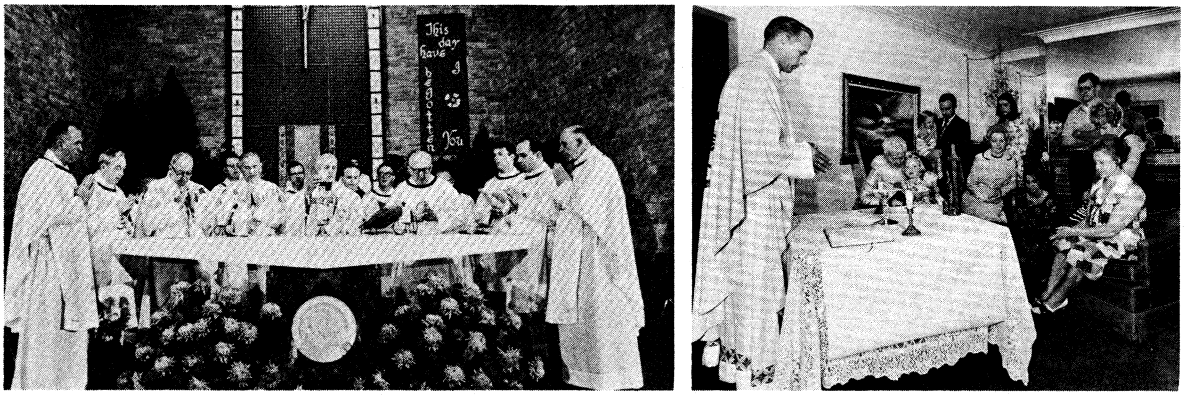
Confirmation. Confirmation since the 11th century has been conferred by the bishop through the anointing with oil and the imposition of hands; the words are a declaration that the Holy Spirit is conferred. This is an echo of the accounts in the Acts of the Apostles (chapters 8 and 19) in which a distinction is made between Baptism and the conferring of the Spirit. In Acts, however, the reception of the Spirit meant the reception and the manifestation of charismatic gifts (*e.g.*, prophecy, speaking with tongues, ecstasy); something else is now meant. Confirmation is normally conferred at or near the beginning of adolescence. The modern liturgical renewal has empowered pastors of parishes to confer confirmation.

Neglect of the theology of confirmation has left some ambiguities. The Oriental churches confer it on infants as a part of the initiation rites of Baptism. The postponement of confirmation has led many Roman Catholic theologians to interpret it as a rite of passage from childhood, like the Jewish Bar Mitzwa ceremony; such rites of passage are common in tribal cultures. Early Christian Baptism, however, was conferred on adults; the catechumenate was the period of "immaturity." It seems that there should be a return to the theology of the Spirit and a consideration of confirmation as the sacrament that empowers the Christian to take an active part in the church. The traditional Roman Catholic view of the laity as passive has contributed to the neglect of the theology of confirmation; it left no room for a charismatic laity.

The Eucharist. The Eucharist (the Lord's Supper, Holy Communion) is with Baptism one of the two sacraments most clearly found in the New Testament; most Christian churches have it in some form. The Roman Catholic Church distinguishes the Eucharist as sacrifice (mass) and sacrament (Communion).

The formula of institution of the Eucharist and the command to repeat it are found in the three Synoptic Gospels (Matthew, Mark, Luke) and in Paul. Originally, the Eucharist was a repetition of the common meal of the local group of disciples with the addition of the bread and the cup symbolizing the presence of Jesus. Even in the 2nd century the meal became vestigial and was finally abandoned. The Eucharist was originally celebrated every Sunday; by the 4th century it was celebrated daily. The eucharistic formula was set in a framework of biblical readings, psalms, hymns, and prayers that depended in form somewhat on the synagogue service. This remained one basis of the various liturgies that arose, including the Roman rite.

The sacrificial character of the Eucharist was determined by its relation to the death of Jesus. This is not seen as sacrificial everywhere in the New Testament, but the theme is so clearly elaborated in the Letter to the Hebrews that it is universally accepted as Christian belief. The Protestant churches denied the sacrificial character of the Eucharist and rejected the mass. Roman Catholic theology has never reached a universally accepted theory explaining the connection between the death of Jesus and the mass, but it has firmly insisted that the mass repeats the rite that Jesus told his disciples to repeat and that the rite is an effective symbolic commemoration of his death. The mass is the only act of worship that the Roman Catholic Church imposes upon its members. Historically,



Two innovations now in practice in the Roman Catholic mass. (Left)The concelebrated mass; (right)mass in a private home.
(Left) Religious News Service, (right) Algimantas Kezys, S.J.

the Roman Church has attached great importance to the mass, conceding almost anything to secure its celebration.

Roman Catholicism believes in the "Real Presence," and this has dominated Catholic–Protestant controversies about Holy Communion. Protestant belief can generally be called dynamic as contrasted with Catholic realism. The celebrated term transubstantiation is defined as the change of the substance of bread and wine into the substance of the body and blood of Jesus Christ. Protestants believe that Jesus is experienced as present. The Roman Catholic theory is difficult to explain in terms other than antiquated Aristotelian physics, and recent theories, not yet successful, have attempted to explore sacramental symbolism in other ways. The realism of belief in the presence is associated with the Roman Catholic practice of distributing only the bread to the laity, a serious modification in the sacramental sign. Not yet universally restored, Communion under both species has become much more common since the second Vatican Council.

Sacrament of unity

Neither in Roman Catholic nor in Protestant eucharistic practice does the sacrament retain much of the symbolism of Christian unity, which it clearly has in the New Testament. Originally, the symbolism was that of a community meal, an accepted social symbol of community throughout the whole of human culture. Roman Catholic efforts to restore this have included the use of the vernacular and the active participation of the laity. Furthermore, the ancient rite of concelebration—*i.e.*, several priests or bishops jointly celebrating a single eucharistic liturgy—was restored by the second Vatican Council as a means of symbolizing unity; and the practice of celebrating the Eucharist in an informal setting—*i.e.*, in private homes or classrooms—was instituted in some places as a way of drawing the laity more intimately into the rite. But a great obstacle to the symbolism of unity remains the liturgical isolation of the celebrant and the passive silence that suited the atmosphere of mystery and the presence of God.

Church law obliges the Roman Catholic to receive Communion once a year (during the Lent–Easter season). Practice of frequency has varied over the centuries; the present law reflects the infrequency that was common in the Middle Ages. The symbolism of the sacrament as nutrition becomes rather feeble with such infrequency; it was rationalized both by the theology of the power of the sacrament and by considerations of the general unworthiness of Christians to receive it.

Penance. The name of the fourth sacrament, penance, reflects the earliest discipline of the penitential rite. Those who sinned seriously were excluded from Communion until they showed repentance by undergoing a period of public penance that included such things as fasting, public humiliation, the wearing of sackcloth, and other austerities. At the end of the period they were publicly reconciled to the church. There were some sins, called capital (murder, adultery, apostasy), for which certain local churches at certain times did not perform the rite; this did not mean that God did not forgive but that good standing in the church was permanently lost. Elsewhere, it was believed that the rite of penance could be performed only once; relapsed sinners lost good standing permanently. Rigorist sects that denied the power to forgive certain sins were regarded as heretical. The penitential rite did not endure beyond the early Middle Ages, and there can be no doubt that it was too rigorous for most Christians. It may also be noticed that the penitential discipline did not reflect the forgiveness of Jesus in the Gospels with all fidelity.

Confessing of sins

It is impossible to assign an exact date for "auricular confession"—the confessing of faults by an individual penitent to a priest—but it must have arisen in the early Middle Ages with the disappearance of the penitential system. This is the penitential rite that has endured into modern times. It was rejected by most of the Reformers on the ground that God alone can forgive sins. The Roman Catholic Church claims that the absolution of the priest is an act of forgiveness; to receive it the penitent must confess all serious (mortal) sins and manifest genuine "contrition," sorrow for sins, and a reasonably firm purpose of amendment. No quality or quantity of sin is too great for sacramental absolution. Roman Catholic theologians have not arrived at an explanation of the process of absolution. They do not admit that absolution is merely a recognition by the priest of dispositions on the part of the penitent that merit forgiveness nor that it is merely a process whereby the penitent is reconciled with the church. There seems to be an unspoken belief that it is a rare person who is really sorry for his sins and that the sacrament is a manifestation of the graciousness of God to human weakness.

Indulgences, which caused such a stir at the beginning of the Reformation, are neither instant forgiveness to the unrepentant nor licenses of sin to the habitual sinner. They are declarations that the church accepts certain prayers and good works, listed in an official publication, as the equivalent of the rigorous penances of the ancient discipline.

The anointing of the sick. This sacrament was long known in English as "extreme unction," literally rendered from its Latin title, *unctio extrema.* This non-English designation concealed the meaning of the Latin, "last anointing." It is conferred by anointing the sense organs (eyes, ears, nostrils, lips, hands, and formerly the feet and the loins) with blessed oil and the pronunciation of a formula. It may be conferred only on those who are seriously ill; seriousness is measured by the danger of death, but a danger, however certain, from external causes (such as the execution of the death sentence) does not render one apt for the sacrament. It may be administered only once during the same illness; recovery renders one apt again. Its effects are described as strengthening both of soul and body; it is an ancient rite that continues Jesus' ministry of healing. The sacrament is directed against "the remains of sin," an ill-defined phrase; but it was long ago recognized that illness saps one's spiritual resources as well as one's physical strength, and one is not able to meet the crisis of mortal danger with all of one's powers. In popular belief anointing is most valuable as a complement to confession or, in case of unconsciousness, as a substitute for it.

The anointing is not the sacrament of the dying; it is the sacrament of the sick. The New Testament passage (James 5:14–15) to which the Roman Catholic Church appeals for this rite does not envisage one who is beyond recovery. Postponement until the patient is critically ill in modern medical terms means that the sacrament is often administered to an unconscious or heavily sedated patient. Under such circumstances, the rite can no longer be effective as a sacrament of the sick, and to the uninformed a magical rite of forgiveness is suggested.

The claim of jurisdiction over marriages

Marriage. The inclusion of marriage among the sacraments gives the Roman Catholic Church jurisdiction over an institution that is of concern to the state and to other persons and groups within society. The Roman Church claims complete jurisdiction over the marriages of its members, even though it is unable to urge this jurisdiction in modern secular states. The sacrament in Roman Catholic teaching is administered by the spouses through the exchange of consent; the priest, whose presence is required, ıs an authorized official witness; in addition, the church requires two other witnesses. Marriage is safeguarded by a number of impediments that render the marriage null and void whether they are known or not, and the freedom of the spouses must be assured. This means that the Roman Catholic Church demands an unusually rigorous examination before the marriage, and this in turn means that it is practically impossible to marry on impulse in the Catholic Church. All of this is for the purpose of assuring that the marriage so contracted will not be declared null in the future because of some defect.

The rigid Roman Catholic rejection of divorce has been a major point of hostility in the modern world. Absolute indissolubility is declared only of the marriage of two baptized persons (Protestants as well as Catholics). The same indissolubility is not declared of marriages of the unbaptized, but the Roman Church recognizes no religious or civil authority except itself that is empowered to dissolve such marriages; this claim is extremely limited and is not used unless a Roman Catholic is involved. Because of its rigorous conditions for contracting marriage, the Roman Catholic Church finds grounds for nullity that do not exist in civil law, and it is willing to make a more searching examination. Declarations of nullity, however, should not be confused with divorce nor be thought a substitute for divorce. Some Roman theologians have suggested that Roman Catholic rigour is based on a misunderstanding of the Gospel texts that reject divorce; but a position maintained for centuries is not easily modified.

The onerous conditions that Roman Catholicism formerly imposed upon non-Catholic partners in mixed marriages have been notably relaxed since the second Vatican Council, particularly as regards written promises that the children would receive religious education in the Roman Catholic faith. The former coldness of the Roman Church toward such marriages is also relaxed; they may be celebrated in church during the mass, and a Protestant minister or a Jewish rabbi may share the witness function with the priest.

Power to administer the sacraments

Holy orders. This sacrament confers upon candidates the power over the sacred, which means the power to administer the sacraments. There are four minor orders (porter, reader, exorcist, acolyte) and four major orders (subdeacon, deacon, priest, bishop), but theologians regard only the last three as sacramental orders. In spite of this hierarchy of orders, the Roman Catholic Church maintains that holy orders is only one sacrament. The minor orders are anachronisms. They represent church services that are still rendered (except for exorcism, the casting out of evil spirits) but not by ordained persons. Ordination is conferred only by the bishop; the rite includes the imposition of hands, anointing, and the delivery of the symbols of the order. The power of the sacred peculiar to the bishop is shown only in the sacraments of confirmation and orders. Ordination can neither be repeated nor annulled. Priests who are suspended from priestly powers or laicized (permanently authorized to live as a layman) retain their sacred power but are forbidden to exercise it except in emergency. The priest is always ordained to a "title," meaning that he is accepted in some ecclesiastical jurisdiction.

Theological developments following the second Vatican Council concerned the ordination of women, against which no solid theological objection has been shown; the restoration of the permanent diaconate (with the powers to baptize, preach, and administer the Eucharist), to which both married and single men are admitted; and the idea of ordination for a fixed period of service. Except for the diaconate, these are radical suggestions in Roman Catholicism.

PARA-LITURGICAL DEVOTIONS

In the Roman Catholic Church, liturgy in the proper sense is the liturgy of the mass, the divine office, and the sacraments. The Latin language, the clerical character of the liturgy, and the search for novelty for hundreds of years have combined to produce forms of worship that are para-liturgical—by which is meant that they lie outside the liturgy and in some cases in opposition to it. These acts are also known as devotions or devotional practices, by which is meant that they are accepted voluntarily and not from obligation.

Benediction and "exposition"

Eucharistic devotions. A number of eucharistic devotional practices arose in the Middle Ages, when Catholics rarely received the Eucharist more than once a year. These were cultic forms that were directed to the Real Presence of Jesus in the Eucharist rather than to sacrifice and Communion. Such were Benediction of the Blessed Sacrament and "exposition." Benediction was a blessing conferred by a priest holding a consecrated Host in a vessel of display called the monstrance; the priest's hands were covered to signify that it was the blessing of Jesus and not his own. This blessing was accompanied by hymns and the use of the organ and incense. Exposition was the public and solemn display of the eucharistic bread, again with the accompaniment of hymns, the organ, incense, and processions. The reservation of the Eucharist in churches was a way in which Catholics could address themselves in personal prayer to Jesus really present. These have often functioned as substitutes for mass and Communion, and since the modern renewal of liturgy they occur much less frequently.

Cult of the saints. Other devotions revolve about the cult of the saints, a practice repudiated by the Reformers as a denial of the total mediation of Christ. This objection oversimplified Catholic practice, but the devotions did sometimes approach superstition. Catholic theologians distinguish (by Greek technical terms) the worship paid to God (latria, "adoration") from the veneration addressed to Mary (hyperdulia, "super-service") and the saints (dulia, "service"). Protestants do not disagree with the principle of admitting the saints as examples of genuine Christianity, but they reject the intercession of the saints as utterly superfluous and ineffective. The Roman Catholic understanding of the intercession of the saints is an extension of the belief in the communion of saints. Although such veneration does tend to multiply mediators, it has often fostered a simple and not unpleasing familiarity with the world of the supernatural. The excesses of the cult of Mary have stirred up controversy, and the tendency to superstition and the deification of Mary have sometimes been painfully present. Mary represents the feminine principle in Roman Catholicism; often in other religions this principle has been personified as a goddess. Mary is given the feminine traits of sympathy and tenderness that are not improper to the deity but are somewhat improper to the father figure and the king figure. The multitude of apparitions of Mary (*e.g.*, at Lourdes, France and Fatima, Portugal) come from the need of a local and national symbol of presence, which enables the Roman Catholics of a nation or region to identify with Mary. Because Mary as a historical person is almost totally unknown, Catholics have been able to find in her all the traits of the ideal person that they needed to find.

Roman Catholicism has always insisted on its right to official supervision of devotional cults, and only approved forms of devotions may be used in the churches or under clerical auspices. Approval does not imply the historical reality of the vision or apparition involved; no Roman Catholic is obliged to believe that Mary appeared to anyone at Lourdes or Fatima, that the rosary (prayer beads) was delivered by a private revelation, or that Jesus manifested himself as the Sacred Heart. Nor is any Catholic obliged to practice any of these devotions. Generally, they serve the purpose of emphasizing some element of Christian faith that is obscured in the preaching and the liturgy at a particular time and place. Devotion to the Sacred Heart, for example, turned the attention of Catholics to the humanity of Jesus and to Christian love in the somewhat arid spirituality of the 17th and 18th centuries. It may be urged that more authentic biblical proclamation would have brought out these things; Roman Catholicism has often manifested itself through devotions when authentic biblical preaching was not available. In approving devotions the Roman Catholic church simply declares that they are not in conflict with Roman Catholic faith and morals. It does not deny that they may be entirely products of the imagination.

Direct experience of God

Mysticism. The search for God through mysticism has never been received cordially by the official Roman Catholic Church. In general terms, the mystical experience can he described as a direct experience of the reality of the divine. A sufficient number of mystics have been proved fraudulent to justify caution but not to justify a blanket antecedent disapproval. Every saint who has been recognized as a mystic had some trouble with church authority. Indeed, one may see in the mystical experience of God something that the official church can neither furnish nor control. In addition, mystics have often had a prophetic character that expressed itself in criticism of abuses in the official church. Whatever the explanation, mystical phenomena have become extremely rare in the modern Roman Catholic Church.

VI. Practices

MISSIONS, EDUCATION, AND ELEEMOSYNARY ACTIVITIES

Missions. From its beginnings Christianity alone among the great religions has regarded itself as a true world religion that appeals to all men without distinction of race, nation, or culture. Roman Catholicism believes that it has preserved this missionary thrust more faithfully than any of the non-Roman churches. From the 4th to the 10th century the Roman Church devoted itself to the evangelization of the barbarians. The barbarians wished to become "Roman," and they accepted the church as a component of Roman civilization. The spread of Islām was met with crusades and not with missionaries, and the Roman Catholic Church has never mounted more than a feeble missionary effort toward Muslims. Thus, the missionary movement languished from the 10th to the 16th century; but the ages of the expansion of Europe, in which the Catholic countries were the early leaders, spread Roman Catholicism to the Americas, Asia, Oceania, and Africa.

Centralized control by the Roman see

This missionary effort differed from both the New Testament missions and the missions to the European barbarians in its very close, centralized control by the Roman see. Missionary churches have begun to achieve that independence proper to the diocesan structure only in the 20th century. It has been difficult for the Roman Catholic missions to divorce themselves from colonialism, and many missionaries did not want the divorce. Again until recent times most of the clergy and all the hierarchy in mission countries were European or American, as were the heads of educational and benevolent operations. Even the peoples of the mission countries, including their clergy and religious personnel, generally wished to give their church a European identity rather than an Asian or African identity. The Roman see, which had suppressed efforts to admit Chinese rites in the 18th century, was unsympathetic to what appeared to be "non-Roman" practices. The second Vatican Council officially ended the colonial phase of missions; in practice, however, the end will take longer. Where possible—meaning where the personnel are available—the operation of the mission churches has been given to native hierarchy and clergy.

Education. Between the barbarian invasions and the Protestant Reformation, education in Europe, except for the Arabic and Jewish centres of learning, was conducted by Roman Catholicism. Learning during the early Middle Ages was preserved by the monasteries; and, although the monks did little more than copy the manuscripts of Greek and Latin pagan writers and the Church Fathers, they educated the few people who had any learning. The foundation of the European universities after 1200 was also the work of Roman Catholicism; these institutions were stimulated by the learning of Arab scholars, through whom Europeans learned the philosophy of Aristotle and produced the learning of Scholastic philosophy and theology. The cultivation of literature and the arts in the 15th century flourished under the patronage of the papacy and Catholic princes and prelates.

The birth of modern science was coincidental with the Reformation and the age of the expansion of Europe. The Roman Catholic response to the new science, accompanied by new philosophical systems, was hostile; and the world of European learning after 1600 was dissociated from the Roman Catholic Church, which patronized only defensive learning. At the same time, movements of general education among the poor began in this period under Roman Catholic auspices. The invention of printing had diffused education far beyond earlier possibilities, and the churches were all interested in reaching the minds of the young. This interest was matched after the French Revolution by the modern states, which in the 19th century moved toward the exclusion of church influence from education. But the Roman Catholic Church, through its religious communities, was a pioneer in the elementary education of the children of the poor.

Critical problems for Catholic schools

In the 20th century the Roman Catholic educational endeavour in many European and American countries, particularly in the United States, had become a vast enterprise. In the second half of the 20th century, mounting costs and diminished religious personnel created critical problems for Catholic schools, and even their survival was at stake in many regions. The problems were not lightened by the realization that Roman Catholic education, even where it was strongest, reached only a minority of Catholic students; and the Roman Church had to face its established reputation as an adversary of the intellectual freedom that the modern academic world cherishes.

Eleemosynary activities. Institutional benevolence to the poor, the sick, orphans, widows, and other helpless has been characteristic of the Christian Church from its beginning. It involved organized assistance, supported by the contributions of the entire community and rendered by dedicated persons. The church in this way fulfilled the duty of "the seven corporal works of mercy" mentioned in the Gospel According to Matthew (chapter 25) and carried on the healing mission of Jesus. Protestant churches continued the works of institutional benevolence after their separation from the Roman Church, and the history of Christian benevolence is a noble portion of church history. Institutional assistance to the helpless is a legacy from the church to modern governments.

This work, which would seem to be above criticism, was beset with troubles in the latter half of the 20th century. Costs for these works, like the costs for education, soared beyond the possibilities of individual contributions. The assumption of benevolence as a government responsibility both rendered the necessity of church works doubtful and narrowed the base of contributions. Church organizations as they existed were not well equipped to deal either with modern urban poverty or with the problem of international poverty.

SOCIOPOLITICAL VIEWS AND PRACTICES

Church and state relations. The most important modification in Roman Catholic theory and practice of church–state relations was the declaration of the second

Recognition of the pluralistic state

Vatican Council in which the Roman Catholic Church recognized the modern, secular, pluralistic nation as a valid political society. Union of church and state had dominated the history of the Roman Catholic Church since the era of Constantine, and all pontifical declarations of the 19th century rejected separation of church and state as pernicious teaching. This position was steadfastly maintained in spite of the fact that the union of church and state had been accepted by the Protestant countries of Europe; it reflects a long history of domination of the church by the state and of the church's involvement in political power struggles. The second Vatican Council declared that the Roman Catholic Church is not a political agent and will not ask political support for ecclesiastical ends. A significant change in the Roman attitude towards the state is the council's express declaration of freedom of religion. (For further treatment see CHURCH AND STATE.)

Economic views **and** practice. In the centuries when the Roman Catholic Church was Christendom, there was a place for every member that corresponded to his place in the social structure. In modern times the hierarchy became identified with the landed aristocracy; this dangerous identification led the Revolutionaries of 18th-century France to attempt to destroy the Roman Catholic Church with other components of the old order. The Roman Catholic Church entered the 19th century with a firm official bias against revolutionary movements, and the brief liberalism of Pius IX was ended with his experiences in the Italian revolution of 1848. The Roman Catholic Church was inflexibly opposed to all forms of Socialism, and its opposition to Marxist Communism was implacable. Thus, the Roman Catholic hierarchy was identified with the new capitalist classes of the industrial society. In many European countries this meant that it lost membership among the working classes. Leo XIII in *Rerum Novarum* (1891; "Of New Things") was the first pope to speak against the abuses of capitalism. Social teaching was further elaborated by Pius XI in *Quadragesimo Anno* (1931; "In the 40th year"), John XXIII in *Mater et Magistra* (1961; "Mother and Teacher") and *Pacem* in *Terris* (1963; "Peace on Earth"), and Paul VI in *Populorum Progressio* (1967; "The Progress of Peoples"). Catholic opposition to Socialism has gradually been diminished, although Catholic teaching tends in the direction of the diffusion of capital and not in its nationalization. In some features, however, such as the recommendation of labour unions, Catholic teaching has reached points that Pius IX would have regarded as Socialism.

In its own practices the Roman Catholic Church has accepted the ownership of property and of productive investments. It has admitted no responsibility to the laity for its funds, which are managed by the hierarchy; hence, the wealth of the Catholic Church has long been a mystery, often attractive to greedy anticlerical governments. Their raids as well as some public disclosures indicate that popular belief exaggerates the wealth of the Catholic Church. Following the second Vatican Council, there was a strong movement in Catholicism for public financial reports.

Stability of the family

The family. Roman Catholic teaching on the family is conservative and attributes to the family a social and moral centrality that many people think it no longer has. The teaching has grown up around a number of factors, not all of which come from the New Testament. The medieval family (whether nobles or commoners) is seen in the guiding principle of Roman Catholic teaching, the stability of the family. The stability of the family forbids divorce. It is preserved by a strong authority structure in which the father is the head; this reflects not only the Old Testament but Roman law. The family is child-centred; traditional Catholic teaching makes the primary end of marriage the procreation and rearing of children. Only recently have Catholic theologians begun to speak of mutual love as an end "equally primary." In earlier cultures, marriages were of concern to the two families involved; and, if they agreed, the social purpose of the marriage was as well fulfilled without love as with it. Rigid monogamy was not unrelated to the common and widely tolerated practice of adultery, which the Roman Catholic Church regarded as more tolerable than divorce. The stability of the family also presupposed a certain tribal view of the family; one's chief security was not in the law and the courts but in one's kinsmen. Such a view of stability is not well adapted to the mobility of the modern family. Nor is it well adapted to the independence possible to the person who wishes it badly enough. In the early 1970s the Roman Catholic Church was faced with the problem of preserving for its members the unquestioned values of mutual love and responsibility without imposing an antiquated authoritarian structure. But the major problem was certainly the practice of birth control. The moral arguments for the Catholic position had suffered general erosion, and many Catholics regarded the declaration of Paul VI in 1968, reiterating the traditional prohibition of birth control, as a simple exercise of authority.

VII. Roman Catholicism following the second Vatican Council

The Roman Catholic Church has been experiencing a renewal that reached its official peak in the second Vatican Council. Renewal has brought benefits, but it has also brought internal disturbances greater than any the church has known since the Protestant Reformation. There has been a clear polarization between liberal and conservative wings of the type that tends to leave no room for moderates. Such disunity is a real threat of schism, but there have been no group departures except in a few instances. The number of individual departures has been large enough to cause concern, but their number is unknown; discontented Catholics in modern times leave quietly.

The Roman Catholic Church has officially abandoned its "one true church" position. It has entered ecumenical conversations with the Protestant churches that could lead to Christian union; the Catholic Church has expressed a readiness to make doctrinal and disciplinary concessions, but how far these may go is not yet clear. The church has even made gestures of friendliness to Islām and Jewry and does not speak of the great Oriental religions as simple paganism. The openness of the Catholic Church toward social movements has been mentioned; this has taken a surprising form in some unexpected places such as Spain and Latin America. The edge of Catholic opposition to Marxism has been taken off, and the Roman see has been engaged in unobtrusive diplomatic conversations with some Communist governments.

Problems within the church

Problems are, however, more in evidence than progress. The long, latent conflict between hierarchy and lower clergy has become open. Priests are resistant to the traditional total obedience in style of life and ministry. This conflict has come to a focus in clerical celibacy; without sure statistics it is a reasonable assumption that at least half of the Catholic clergy wish celibacy to become an option. The discontent with life and ministry has led to a large number of losses in the priesthood and in religious communities, some of which face the possibility of extinction. Much of this discontent revolves around ministry as much as around life style; many religious workers feel that the conventional ministries are not reaching enough people and are not touching their most urgent needs. The desire to work "in the world," while hardly alien to the New Testament ministry, is not adaptable to traditional clerical and religious rules. What might appear to be a minor point in some places has become major; priests and religious (women religious in particular, who have had more of a problem) no longer wish to wear the identifying garb; they believe that it immediately places an obstacle to personal relations. Actually, there is a widespread but not explicit, perhaps not even recognized, rejection of the traditional use of authority and obedience in Roman Catholic clergy and religious communities.

Roman Catholic liturgy has been profoundly changed. The results have not been altogether satisfactory, and some observers say that the effects of the new liturgy cannot be assessed until a new generation has grown up that knows no other liturgy. On this point minor local schisms have occurred, led by reactionary Catholics. Others find the new liturgy stodgy; but the degree to which liturgy ought to be exciting has never been known.

The place of the laity, like the place of the clergy, in church decisions remains uncertain. Bishops, clergy, and laity generally are timid in undertaking a modification in church government for which nothing in their previous church experience has prepared them. They seem to hesitate to employ their experience in government and business, where shared responsibility is the rule rather than the exception. Many Roman Catholics find it difficult to examine the role of their hierarchical officers without also questioning their credibility. Yet the direction of the movements where the problems lie is toward greater responsibility of each member of the Catholic Church—hierarchy, clergy, and laity, each in its own way.

BIBLIOGRAPHY. The best and most recent reference works are the *New Catholic Encyclopedia,* 15 vol. (1967), which treats all phases of Roman Catholicism and topics related to the study of Roman Catholicism; and *Sacramenturn Mundi: An Encyclopedia of Theology,* ed. by KARL RAHNER *et al.* (1968), which deals with Catholic doctrine and theological thought. An excellent brief compendium of doctrine is *De Nieuwe katechismus* (1966; Eng. trans. by KEVIN SMYTH, *A New Catechism: Catholic Faith for Adults,* 1967), the celebrated and controversial Dutch catechism. Roman Catholic theology of the church is discussed by HANS KUNG in *Die Kirche* (1967; Eng. trans., *The Church,* 1967). The contemporary Roman Catholic Church is surveyed by JOHN L. MCKENZIE in *The Roman Catholic Church* (1969).

(J.L.McK.)

Roman Catholicism, History of

Historians generally agree that, in the first half of the 11th century, a new epoch began in the church of the West. Though no modem scholar would hold that Western Christendom suddenly became Roman Catholic or that the Roman Church preached a new creed at that time, it was certainly then that the papacy reorganized itself and proclaimed a doctrine of authority—traditional indeed in its elements but new in its logical and comprehensive dynamism—and, by asserting rights half-forgotten or ill-defined, gathered under its direct and complete control the framework of the Western Church. The main characteristic of that church, from the 11th to the 20th century, is that of a body of Christians claiming to be the only church body with a right to the title of the authentic, apostolic church of Christ and basing this claim and this unity on a recognition of the bishop of Rome, or pope, as the successor of St. Peter and head of the church, with jurisdiction over all its members. Though epochs, eras, and periods are artificial divisions of the continuous stream of history and each so-called revolution is foreshadowed in its causes and imperfect in its effects, some moments of change nevertheless are decisive, and in the 11th century the structure of the institutional church, the ideas of its leaders, and the monuments and records of their thoughts and actions all have a character markedly different from what had gone before. The present article is concerned with the history of this church, which in fact, between 1000 and 1517, contained within its obedience all the professed Christians of Europe, west and north of the domain of the Orthodox Church in Russia, the Balkans, and Greece, save for a few numerically minute groups of Christian "heretics," and (for a time) Bohemia in the 15th century.

This article is divided into the following sections:

I. The Latin Church of the West (1000–1517)

THE CHARACTER OF LATIN CHRISTIANITY IN THE 11TH CENTURY

The church and the social order. At the beginning of the 11th century, Latin Christendom was a rather poorly organized body. Though a large part of Italy was within the papal sphere of control, the degraded papacy—after over a century of occupancy by several weak or immoral popes—remained inactive, and its jurisdiction was overlaid, partly by powerful lay rulers at home and partly by the kings or emperors of Germany, who controlled many ecclesiastical activities within their own territories. France was fragmented into many feudal domains, but this allowed the ecclesiastical hierarchy there a certain independence and cohesion, while the growth of the French reform-oriented monastery at Cluny laid the country open to the message of reform when it finally came. In England there was a unique intermingling of ecclesiastical and royal administration that, in fact, left the church entirely free. On the fringes of Christendom—Scandinavia, Scotland, Ireland, and northern Spain—there was little hierarchical development.

The condition of the papacy

Although the papacy had virtually no practical significance for the Christian population and its priests, Rome was everywhere recognized by the bishops and other leaders as the ultimate source of doctrine and discipline; her permission was traditionally recognized as necessary for the creation or transference of a see, and archbishops sought from Rome the pallium (a mantle that symbolized their office and jurisdiction). Moreover, popes, even of the most decadent period, possessed the archives of the Roman see and issued on request grants of immunity and confirmation of property. The city of Rome also remained a goal of pilgrimage for all the western European peoples. In short, papal jurisdiction, though largely dormant, was not challenged save when, in German lands, the king or emperor claimed or tacitly exercised superior powers. The liturgy, administration of the sacraments, and general canonical (church law) principles were basically identical everywhere, though modified in places by local peculiarities or customary law or (as with clerical celibacy) inveterate contrary practice.

In the year 1000 the church in continental Europe—northern Italy, the German lands, France, and northern Spain—lay under a regime of feudal organization and lay ownership. This last had gradually replaced the ecclesiastical ownership of the late Roman Empire. Whereas Roman law recognized a church as a legal *persona*, the customary law of the invaders (such as the Germanic tribes) assumed that all upon the land belonged to its lord. Churches were treated as private real property, and the priest, appointed by the lord, received a part only of the revenues. Simultaneously, the feudal system, now accepted almost everywhere save in Germany, regarded bishoprics and abbeys as fiefs (feudal estates) or benefices (ecclesiastical estates), bestowed by the ruler in return for loyal service or—as in part of Germany—the private possession of lay proprietors. At the highest level of all, the papacy, which for a century had been the pawn of Roman political factions, was regarded by the newly founded German Empire (the Holy Roman Empire, founded by Charlemagne in 800) as an endowment over which it had rights.

The Ottonian Empire. German kingship had entered upon a new epoch in the 10th century, and, under Otto I, the Great, the bishops and greater abbots were drawn into royal service and enriched with estates and counties, for which they did feudal homage. Otto conquered northern Italy and extracted from the pope an imperial coronation (962). Both he and his grandson Otto III regarded the papal territory as part of their realm; they appointed and removed popes and presided at synods.

Otto III, an enlightened ruler, appointed as pope his old tutor, Gerbert of Aurillac—who took the name Sylvester

11—whose brief reign (999–1003) was a shaft of light between two periods in which Roman factions dominated the papacy.

Otto's successors continued to keep control over both the church and the degraded papacy. Emperor Henry III was a capable reformer who appointed energetic bishops in his dominions, but a new age began when the Emperor appointed his relative—the non-Italian Bruno, known as the reforming bishop of Toul—as Pope Leo IX (1002–54) in 1049.

Forces of reform

Meanwhile, the forces of reform had been building up in Italy, beginning with the monks from Cluny and Greeks from southern Italy and developing into the austere reform orders at Camaldoli and Vallombrosa (Italy). The reform found active expression among a group of monks who were related by their zeal to purify the church, including the Italian hermit–monk and cardinal, St. Peter Damian; the Lotharingian cardinal, Humbert of Moyenmoutier; and Hildebrand, archdeacon of the Roman Church and later Pope Gregory VII. This great reform movement began as a moral campaign; the two enemies were nicolaism (marriage and incontinence of clergy) and simony (the purchase of ecclesiastical office). The remedies proposed were a monastic discipline and piety and the code of the ancient canon law revived; the instruments were to be a reformed and powerful papacy and a hierarchy freely elected.

Popular Christianity. By 1050 the population of Europe west of the German marches and the hinterland of Scandinavia was Christian, though pockets of paganism and many heathen practices remained. Of this Christendom, the greater part had been divided into bishops' dioceses and individual parishes, though in the northern and western regions the proliferation of small private churches had not yet been wholly absorbed, and the existence of proprietary and exempt enclaves continued to the Reformation and beyond. The priest, in rural districts usually a villein of the lord (subject to the lord but not to others), cultivated his acres of glebe (revenue lands of the parish church), celebrated mass on Sundays and feasts, recited some of the hours (liturgical or devotional services for use at certain hours of the day, according to the monastic daily schedule), and saw that his flock was baptized, anointed, and buried. Lay people normally received communion four times a year—Christmas, Easter, Pentecost, and Assumption (August 15). Auricular (privately heard) confession was widespread but not universal.

Education in 1000 was at a very low ebb outside the monasteries. Cathedral schools were few, and rural priests who could read Latin easily were rare. Almost all literary work came from the monasteries and, in Celtic lands (mainly Ireland), from the half-monastic Culdees (religious recluses). The larger monasteries, such as Cluny or St. Gall (Switzerland), were towns in miniature with social services; they were also the only reservoirs of learning and artistic skill. On the land, pious practices and beliefs often merged into superstition or "white" magic; and marriage customs, together with the complicated degrees of prohibited relationships, provided endless problems in an epoch when the presence of a priest was not necessary for a valid union. In an age of protective lordship, heavenly patrons were highly valued, and the body or relics of a reputed saint made him the *persona,* a quasi-living protective presence, of a church or abbey. This aspect of belief explains the popularity of pilgrimages to shrines such as that of the apostles at Rome, St. James of Compostela (Spain), the Magi at Cologne (Germany), and countless others. Monastic piety, in addition to the liturgy, was expressed in "little offices" (liturgical or devotional services) of the Blessed Virgin, of the cross, of all saints, and of the dead; and the primary reason for a monastery's existence was intercessory prayer—hence the numerous monastic foundations by royal and noble families.

THE INVESTITURE CONTROVERSY (1049–1122)

The first reformers: Leo IX and Nicholas II. Leo IX was the first pope to impress his authority upon the church in general; he achieved this policy by a tactic of lengthy tours beyond the Alps, punctuated by synods, in which decrees both dogmatic and disciplinary were passed. He also began the practice of appointing non-Romans to curial (papal administrative) posts and sending legates (papal representatives) to carry out his decrees. A man of great energy and spiritual purpose, he must nevertheless bear the responsibility for a disastrous war that ended in capitulation to the Normans and for choosing the rigid and violent Humbert for the mission to Constantinople in 1054, the year from which the Schism between the churches of the East and West is dated. In the confused years that followed, the papal election decree of Nicholas II in 1059 stands out: it gave the right and duty of papal election to the cardinals, tacitly eliminating the king of Germany. The same pope shortly afterward renewed earlier decrees on simony and clerical celibacy but avoided the issue of pope and empire.

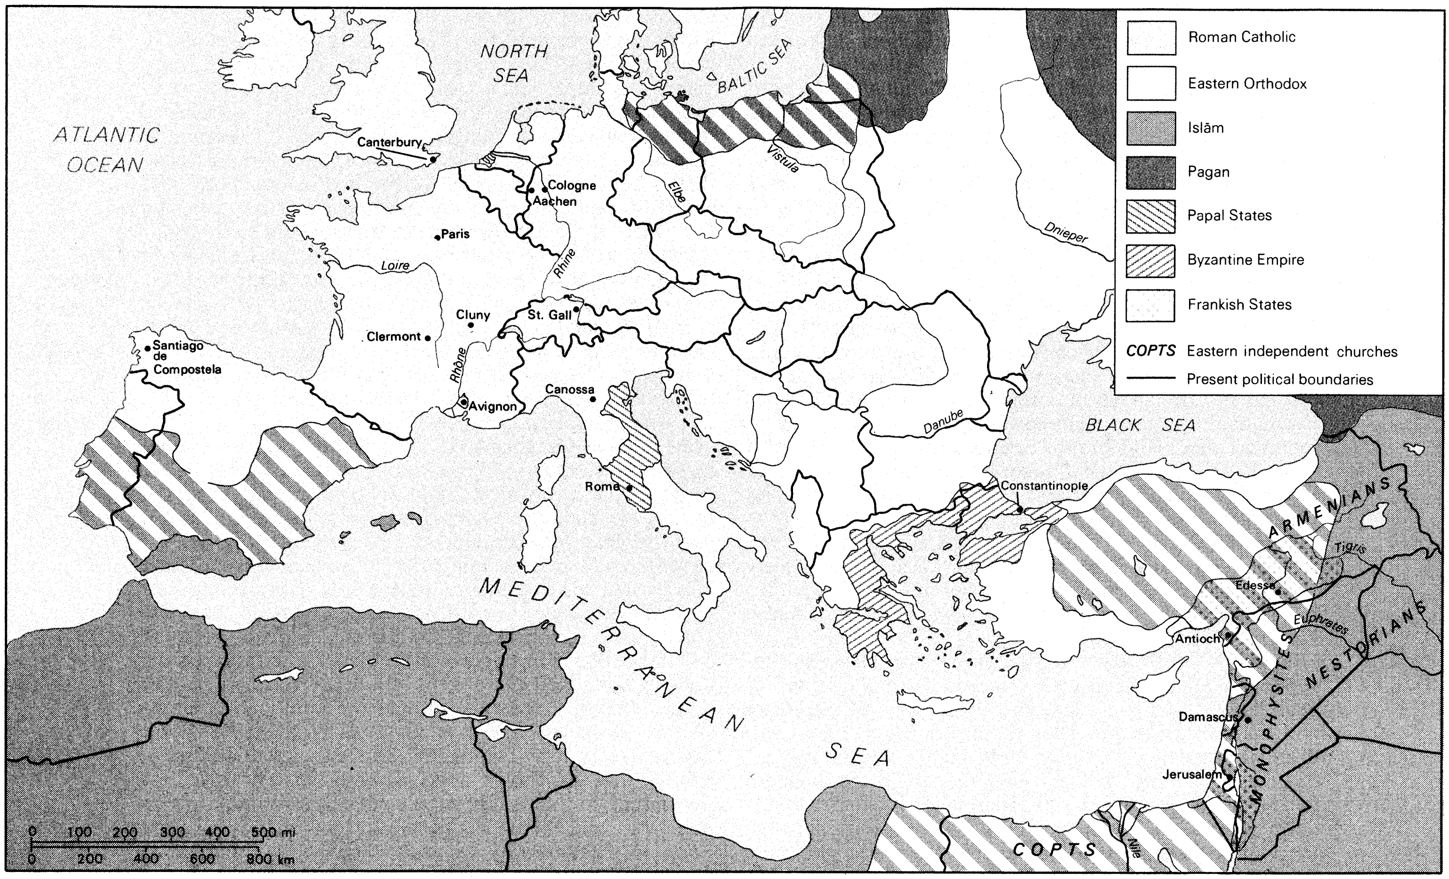
The Schism between the Eastern and Western churches

The reign of Gregory VII. Hildebrand, who succeeded in 1073 as Gregory VII, proved to be one of the greatest of his line and had more influence than any other person of his time upon the external fabric of the church. In his long struggle with the German king, Henry IV, he suspended and excommunicated his opponent, pardoned him as penitent at Canossa, Italy (1077), excommunicated him again (and was himself twice deposed), and was finally driven from Rome by Henry to die in exile at Salerno (1085). In opposition to Henry's claim to be the divinely appointed vice regent of Christ over the activities of the church, Gregory presented the unlimited commission of Christ to Peter over all souls (Matt. 16:18–19). Beneath these lofty claims lay the resistance of the ruler, who did not want to be deprived of his ancestral right of appointing to office his most influential subjects (who often also held the richest fiefs), and the insistence of the Pope on the authority of ancient canon law and papal decrees. If the King's claims were inconsistent with the current conception of a free church, the Pope's claim and actions were without precedent within the memory or records of his age.

Gregory was defeated by force of arms, but his principles had-been established: Even more directly influential was Gregory's centralization of the church. Plenipotentiary legates (representatives with full power to negotiate); the immediate control of diocesan bishops, canonical elections, and Roman and local synods; the publication of canonical collections and polemical manifestos—all combined to fashion a web in which every thread led to Rome. The scattered priests and the distant bishops were gradually becoming a class, the clergy, distinct from others and with a law and a loyalty of their own. Gregory died a lonely exile, yet his principles of reform had found reception all over Europe, and the new generation of bishops was Gregorian in sympathy and obedient in practice to papal commands, in a way unknown to their predecessors.

The Investiture Conflict (1085–1122). The efforts of the reformers to make the church independent of lay control inevitably centred upon the appointment of bishops by the ruler of the country or region. In ancient canon law, election of bishops had been by clergy and people; entrance upon office followed lawful consecration. Feudalism and royal claims had transformed election into royal appointment, and admission to office was by means of the bestowal, or investiture, by the lord of ring and staff (symbols of the episcopal office), preceded by an act of homage. This savoured of simony, both because a layman bestowed a spiritual benefice and because money was often offered or demanded. The conservatives appealed to immemorial practice, accepted and even enjoined by the papacy.

Gregory VII, though asserting the principle of freedom, was in fact tolerant of royal appointments free from simony. Pope Urban II (reigned 1088–99) was equally ambivalent, though in other ways he was a reformer. Pope Paschal I1 (reigned 1099–1118) at once condemned lay investiture, thus precipitating the crisis in England between Anselm, archbishop of Canterbury, and King Henry I. This and a similar crisis in France were settled



The extent of Christianity during the period of the Crusades.
From F.W. Putzger, *Historischer Weltatlas*

by a compromise. Election (by the cathedral chapter) was to be free; investiture was waived, but homage before the bestowal of the fief was allowed. Meanwhile Paschal, at issue with the German king Henry V, who was demanding imperial coronation, suddenly offered to renounce all church property held by the king if investiture were also abandoned. Henry accepted, but the bishops refused the terms; thereupon the Emperor seized the Pope who, under duress, allowed investiture. By this time, however, a large majority of the bishops were Gregorians, and the Pope was persuaded to retract. Eleven years later, Pope Gelasius II provisionally accepted the Concordat of Worms (1122). According to this agreement, free election by ecclesiastics was to be followed by investiture (without staff and ring) and homage to the king.

The Concordat of Worms

This ended a strife of 50 years, in which pamphleteers on both sides had revived every kind of claim to supremacy and God-given authority. Nominally a compromise, the concordat was in effect a victory for the monarch, for he could in fact usually control the election. Nevertheless, the war of ideologies had exposed the weakness of the emperor who, in the medieval context, had in the last resort to admit the spiritual authority of the pope, and the struggle left intact the claim of the church to moderate the whole of society.

The Crusades. The authority of the papacy and the relative decline of the empire also became clear in the unforeseen emergence of the Eastern Crusades as a major preoccupation of Europe. The idea of a holy war, blessed by the pope, had encouraged volunteers in the reconquest of Spain and had been exploited by William the Conqueror in his invasion of England (1066). Moreover, the papacy had been stirred more than once by the disasters that befell Eastern Christians, such as their defeats by the Seljuq Turks at Manzikert (1071) and Antioch (1085) in Asia Minor. The Byzantine emperor Alexius I had appealed for help to Pope Urban II, and this may have been the decisive motive, though the advantages of diverting the Normans of Sicily and other turbulent warriors away from Europe to wage a sacred war were obvious. Urban's celebrated call to the Crusade at Clermont (France) in 1095 was unpredictably effective, placing the Pope at the head of a large army of volunteers. The capture of Jerusalem (1099) and the erection of a Latin kingdom in Palestine were balanced by disasters and quarrels, but the papacy had gained greatly in prestige. Though Germany as a whole remained aloof, a pope had for the first time stood out as the leader of European endeavour. The Crusades, with their combination of idealism, ambition, heroism, cruelty, and folly are essentially medieval and, as such, are outside modern man's experience, but they were part of the religious background for two centuries and were to add greatly to the anxieties, both spiritual and financial, of the papacy.

THE 12TH CENTURY

The Proto-Renaissance. The 12th century, or, more correctly, the century 1050–1150, has been called the first Renaissance. A more accurate title would be the adolescence of Europe, in which higher education, the techniques of thought and speech, and a fresh attack upon the old problems of philosophy and theology appeared for the first time in postclassical Europe. All these activities were exercised by clerics and controlled by churchmen. The focus was the cathedral school, and the new agency was the semiprofessional, unattached teacher, such as the French philosopher–theologians Berengarius, Roscelin, and Abelard, though monks still had a share, such as Lanfranc, Anselm of Canterbury, and Hugh and Richard of the Monastery of St. Victor, Paris.

Significance of churchmen in the first Renaissance

Philosophy was revived with logic and dialectic, which were applied to doctrines of the faith, either as formal exercises, Augustinian speculation, or critical reformulation. From 1100 onward theology, in the modem sense of the word (first used by Abelard), emerged. The teaching of Scripture and of the early Church Fathers on the various doctrines were consolidated and organized in works called Sentences. Then masters gave judgments and opinions, and the first handbook of theology was composed by Abelard. Finally, Peter Lombard (bishop *c.* 1159) published his Books of Sentences, which summarized the Christian faith, using the Sic et *non* (Yes and No) dialectic popularized by Abelard and the canon lawyers, and himself pronounced on vexed questions. His classic manual may be said, in modern terms, to have created the syllabus of theological study for the age that followed. Together with the expansion of logic—brought about by the arrival (through Muslim sources) of what was called the new logic of Aristotle—and the emergence of the university, the Sentences ended the era of literary, humanistic, and monastic culture and opened that of the formal, impersonal, Scholastic age.

Proliferation of monasteries

Reformed monasticism. The most distinctive feature of the century 1050–1150, according to some scholars, was the appearance and diffusion of reformed monasticism. Beginning with a few relatively small quasi-hermit orders in Italy, such as the Camaldolese and the Vallombrosans, it spread to France with the extreme eremitical Grandmontines (founded in 1077) and the eremitical Carthusians (founded in 1084), and became as wide as Christendom with the multiplication of the daughter monasteries of Citeaux (founded in 1098). The keynote of the Cistercians (based at Citeaux) was exact observance of the Rule of St. Benedict, with emphasis on simplicity, poverty, and manual work. The addition of lay brothers tapped a large reservoir in an age of economic and demographic expansion, and the organization of the order—with annual visitations and a general chapter—ensured good discipline and enabled the order to accommodate itself to the strain of a vast family of houses, scattered throughout the Latin Church. The success of Citeaux owed much to the genius of St. Bernard, abbot of Clairvaux from 1115 to 1153, who was for 30 years the untitled religious leader of Europe. Owing to his influence, other new orders, such as the Premonstratensians, the English Gilbertines, and the military Knights Templars, accepted or imitated Cistercian practices. All these and others had a popularity that in any other age would have seemed miraculous, since they practiced austerity. By the end of the 12th century the saturation point for monasticism had been reached all over Europe, save in a few peripheral regions, and the golden age of monasticism had passed.

The papacy. Popes, often elected as elderly men, normally had a brief span of power, and the 12th century saw few of individual significance. In its early decades the papacy was neo-Gregorian in character; that is, papal policy continued that of Gregory VII, but with an emphasis on the political and legal side. There was a great increase in bulls (papal documents) confirming the possessions and privileges of churches and abbeys and a gradual increase of appeals to Rome that led to the use of local judges who were delegated as fact finders and who presided over courts of first instance (first trials). Legates were sent out to visit and to hold synods, and every effort was made to ensure free elections of bishops, while the papal control of regional churches increased. At the same time the pressure against a married clergy continued with some success and the private ownership of churches by laymen decreased, through gifts to bishops and monasteries and through the foundation of religious communities in churches with large incomes.

In the second half of the century the spread of canon law increased rapidly, despite resistance from the newly organized royal administrations. There were few distinguished popes between Paschal II and Innocent III (reigned 1198–1216). Three, however, stand out: Eugenius III (reigned 1145–53), a disciple of St. Bernard, the holiest of the group; Adrian IV (reigned 1154–59), the Englishman, whose promising rule was cut short; and Alexander III (reigned 1159–81), whose pontificate was the longest and most influential. The first of the former university canonist popes, Alexander III settled many disputed points of discipline and sacramental practice. A succession of short-lived pontiffs followed him, who were unable to cope with the difficulties of their time.

The age of faith

Popular Christianity. The 12th century, perhaps more than any other, was an age of faith in the sense that all men, good or bad, pious or worldly, were fundamentally believers, and religious causes and interests (crusades, monastic foundations, building churches, and assisting education and charities) made up much of the life of the literate and administrative classes. Lay religion was, as never before or since, permeated with monastic ideals. Prodigious numbers of the populace became monks, knights (members of military-religious orders), labourers (lay brothers), and lay people who followed monastic rules, and the favourite lay devotions were short versions of monastic offices. Almost every church—whether cathedral, monastic, parochial, or private—was built or rebuilt between 1050 and 1200. Almost all baronial families founded a monastery, and townspeople not only paid for their cathedrals but often supplied materials and labour.

Heresy. Heresy on a large scale was unknown in the West before the middle of the 12th century. The early dissenters were often radical reformers such as the Italian canon, Arnold of Brescia (d. 1155), an outspoken critic of clerical wealth and corruption. Then there appeared in north ltaly and southern France the sect, Eastern and Manichaean in origin, later known as the Cathari (the "pure," from the ascetic lives of their leaders). This sect had an organization and liturgical life that imitated Christianity but that overtly denied many key doctrines, such as the incarnation of Christ, and was dualistic in that it regarded matter and the human body as evil and the spirit as good. Its emphasis on poverty and its genuine solidarity of mutual assistance appealed to many by contrast with the luxury and wealth of the Catholic hierarchy. A little later, another type of dissent appeared with the Waldenses (founded by a French reformer named Peter Valdes) of the Rhône Valley and Piedmont. These groups, basically and professedly orthodox, together with the reform-minded Humiliati of Lombardy (Italy), practiced poverty, scripture reading, and preaching. The Cathari were proscribed as heretics by the papacy, attacked by a crusade and later by the Inquisition, and gradually disappeared. The Humiliati remained orthodox as a quasi-religious order. The Waldenses, largely through mismanagement by the bishops, drifted away from the church and remained throughout the Middle Ages and beyond as a non-Catholic body. These heretical movements, together with numerous legal disputes between monks and bishops, and bishops and metropolitans (ecclesiastical provincial leaders), imparted a sense of decline and peril to the last decades of the 12th century, which were notably barren of saints and great men. The church was too rich and too set in its hierarchical ways to meet the demands of larger populations and economic stresses, especially in urban conditions. Reformers demanded a spirit of poverty and a fresh wind of spirituality.

THE 13TH CENTURY (1198–1303)

The significance of Innocent III

The papacy. Elected at the age of 37 and youngest of the cardinals, Innocent III (reigned 1198–1216) was one of the greatest of the popes, capable of realizing and satisfying the needs of his age. His program was the reform of Christendom, lay and clerical, and he attempted to influence, in Christian terms, its political life by papal action, direct and indirect. A legislator and reformer rather than a theologian and evangelist, lacking the charisma of sanctity yet a leader of genius and integrity, Innocent III came nearer than any medieval pope to being the acknowledged arbiter of Europe in all matters affecting men as Christians. He made mistakes: he condoned too readily the rape of Constantinople by the Crusaders (1204); he turned too lightly to force after failing to convert the Cathari; he misunderstood English affairs. But on the credit side must stand the great Lateran Council of 1215; the acceptance of the mendicant (begging) religious orders of St. Francis and St. Dominic; and a long series of wise judgments and decretals. His pontificate ended and began an epoch; it was in many ways a summit between them.

There followed a series of great administrators and lawyers: Gregory IX (reigned 1227–41), Innocent IV (reigned 1243–54), and Alexander IV (reigned 1254–

61), who practiced as popes what they had learned or taught in the schools. They exalted the powers of the papacy and curia in a centralized church and used spiritual sanctions to enforce conformity and later to obtain from their unwilling subjects the funds necessary for a government that was not only a great administration but also the political and diplomatic centre of Europe. By the midcentury, many were beginning to feel and to say that the papacy, which under Innocent III had guided the church wisely, was now, under Alexander IV, beginning to fleece rather than feed the sheep. The canon lawyers continued to exalt the powers of the pope as universal ordinary (jurisdictional leader), with a real if ill-defined right of control in political life. Boniface VIII (reigned 1294–1303), personally ambitious and intemperate, pressed his extreme claims against the first "secular" monarch, Philip IV (1268–1314) of France, and was overcome by force.

The mendicant orders: the friars. Below the level of the papacy, a spiritual revival took place. The pontificate of Innocent 111 saw the appearance of a totally new form of religious life, that of the penniless or mendicant friar. Francis of Assisi (1181/82–1226), a personality of magnetic originality who believed that he was called by Christ to preach poverty, bad no thought of founding an order; but his message and his genius exactly suited his age, and the vast concourse of his followers gradually changed from a homeless, penniless band of preachers and missionaries in Italy into an international body, governed by a single general and devoted to the service of the papacy. Dominic of Spain (c. 1170–1221,) on the other hand, with a vocation to preach doctrine to heretics and with followers keeping a canonical rule, changed his existing institute into one of friars. Gradually, through mutual influence and pressure of circumstances, the two groups became similar: international, articulated groups of men, bound to an order but not to a community. They took the customary monastic vows of poverty, chastity, and obedience but dropped the vow of *stobilitas,* stability, in favour of mobility, and were governed by elected superiors under a supreme chapter and general. Unpredictably, first the Dominicans and then the Franciscans entered and soon dominated the theological schools of Paris and Oxford. Two similar bodies joined them, the Carmelites and Austin Friars, and for almost a century the friars were the theologians, the preachers, and the confessors of the Christian people.

The golden age of Scholasticism. The 13th century was an age of fresh endeavour and splendid maturity in the realms of thought, theology, and art. Philosophy, hitherto almost exclusively devoted to logic and dialectic, had stagnated in the later 12th century. It was revived by the gradual arrival from Spain and Sicily of translations of the whole corpus of Aristotle's writings, often accompanied by Arab and Jewish commentaries and treatises. Aristotle, especially in his *Metaphysics* and Ethics, opened the whole field of philosophy to the schools. After a short period of hesitation they were used by theologians, at first eclectically, and then systematically. The great German philosopher and theologian Albert of Cologne (known as Albertus Magnus) and his more famous pupil Thomas Aquinas rethought the system of Aristotle in Christian idiom, pouring into it a fair dose of Neoplatonism from St. Augustine. Aquinas, in some 25 years of work, set theology firmly on a philosophical foundation. The Italian theologian Bonaventure (1217–74), in an even shorter career, renewed the traditional approach of Augustine and the Victorine monks, regarding theology as the guide of the soul to the vision of God. At the same time, masters in the arts school of Paris used Aristotelian thought to present a naturalistic system that clashed with orthodox teaching. The condemnations that ensued in 1272 and 1277, coinciding with the deaths of Bonaventure and Aquinas (1274), included some Thomist theses. This apparent victory of conservatism ended the long era in which Greek thought was regarded as right reason and foreshadowed the age of individual systems and the divorce of philosophy from theology.

Revival of philosophy

Ecclesiastical life. The coming of the friars and the legislation of the fourth Lateran Council in Rome (1215) —including requirements of annual confession and communion and a reduction in number of the impediments to marriage—saved for the church the lower classes of the population and silenced many of the critics of the establishment. Well-trained mentally and socially and extremely mobile, the friars were able to reach and hold sections that the static monks and clergy had failed to move. The 13th century in Europe as a whole was a time of pastoral endeavour in which bishops and university-trained clergy perfected the diocesan and parish organization and reformed many abuses. It was an age of active and spiritual bishops, many of them masters in theology and themselves friars. There also were controversies. The early friars served and were welcomed by the bishops and parish clergy, but clashes soon occurred; the papacy gave the friars exemptions and privileges so wide that the basic rights of the secular clergy were threatened. An academic war of pamphlets led to an attack on the vocation and work of the friars. A compromise was finally arranged by Boniface VIII (*c.* 1235–1303) that was just and workable, and under a revised form it lasted for two centuries. The bishop could refuse friars entry into his diocese, but once they had been admitted the friars were free from his control.

Troubles of the church. The last quarter of the 13th century was a time of growing bitterness and harshness. The golden age of Scholastic theology had come to an abrupt end. The troubles of the Franciscans—divided into those who stood for the absolute poverty prescribed by the rule and testament of Francis (the Spirituals) and those who accepted papal relaxation and exemptions, (the Conventuals)—were a running sore for 60 years, vexing the papacy and infecting the whole church. The Inquisition (the ecclesiastical tribunal instituted in 1229 to deal with heretics) and the papal court incurred odium for their inhumane and inequitable treatment of those suspected of heresy. Beneath the beauty of the Italian poet Dante's great poem, *The Divine Comedy* (begun in 1300), one can see a whole world of hatred and cruelty in the city-states of Italy. The papacy—held after about 1260 by a succession of popes of mediocre talent—was surrounded by a small group of feuding cardinals. The debacle of Boniface VIII at Anagni (Italy) in 1303, when he was made a prisoner by his enemies, was only the climax of extravagant claims—such as the bull Unam *Sanctam* (1302), which asserted papal supremacy—arousing equally violent resistance.

Persecution of the Jews

Another instance of hardening sentiment is seen in the treatment of the Jews. Between 800 and 1200 the Jews had multiplied in Lombardy, Provence, and the towns of the river valleys of the Rhône, the Rhine, and the Dan-

~ b eThey entered England only after the Norman Conquest (1066.) Everywhere they became wealthy and were used by governments that were in need of funds. Apart from heretics such as the Cathari, they were the only "foreign body" in Western Christendom, and as such served as an irritant to the ignorant and brutal. There were shocking massacres of Jews when the crusades were preached, especially in the Rhineland, and after various instances of panic on the part of Christians, Jews were accused of sacrilege and child murder. These, however, were all mob movements, resisted by kings and bishops. Later, the Jews suffered from suspicions that were aroused by the Cathari. The fourth Lateran Council gave the Jews a distinguishing badge and forbade their employment by governments. This established once and for all the ghetto system in large towns but did not at first impair Jewish prosperity. Later on, the growing class of Christian merchants became jealous and hostile, and in 1290 and 1306 the Jews were expelled from England and France. This swelled their numbers in Germany, thenceforward called "the classic land of Jewish martyrdom." Groups remained in Italy, and the Roman colony was never disturbed. In Spain, toleration gave way to widespread persecution and conversion under duress that left a heritage of sorrow for the future.

THE 14TH CENTURY (1303–78)

The intellectual enterprise. In the early decades of the 14th century, the Aristotelian abstraction of the essence from the thing perceived, which had been the philosophical method of the previous century, was challenged and the emphasis shifted to the individual, either as a "thisness" known by the mind (as taught by Duns Scotus) or as an object of intuition (as taught by William of Ockham). William of Ockham regarded all general terms, such as man or animal, as mere names (thus the term Nominalism) given by man's mind to his experience. He thus eliminated all natural theology—which claimed that man could know God through reason—and left no bridge between experience and divine revelation. The existence of God, he claimed, could not be proved. Causality and value were words only; the good was simply what God commanded. Ockham cut the Aristotelian link between philosophical statement and scientific observation and eliminated speculative theology, but his emphasis on the individual "thing" led to a gradual interest in scientific method and in nature.

Removal of the papacy from Rome

The Avignon papacy (1309–1377). After the death of Boniface VIII (1303) the papacy, through a series of accidental circumstances, settled at Avignon, a papal enclave in French territory, where it remained for 75 years. This, the Babylonian Captivity (named for the 70 years of the Jewish exile in Babylon in the 6th century BC), was bitterly denounced at the time and, until recent times, historians have concurred in this judgment. Viewed in the perspective of history, however, the popes of Avignon are now generally seen as personally devout and even reformist, with a sense of universal responsibility. They created a government machine of great complexity and efficiency, comprising a judicial system, chancery, and financial system that raised papal income to a higher level than ever before, and the monastic reforming decrees of Benedict XII (reigned 1334–42) endured until the Council of Trent (1545–63). Nevertheless, it was considered disgraceful that the bishop of Rome should live permanently in French territory, in a wealthy papal city surrounded by a small body of rich cardinals jealously divided along national lines; the Avignon residence of the popes was held largely responsible for the disasters that followed.

Attacks on the papacy. The disputes of the Franciscans, crystallizing finally upon the teaching of the Spiritual Franciscans that their absolute poverty was that of Christ, were harshly settled (1322) by the irascible octogenarian John XXII (reigned 1316–34), but a group of them, led by Michael of Cesena, general of the order, and William of Ockham, became bitter and formidable critics of the papacy. With them for a time was the Italian political philosopher, Marsilius of Padua, a Paris master who, in his *Defensor pacis* (1324), outlined a secular state in which the church was a government department, the papacy and episcopate human institutions, and the spiritual sanctions of religion relegated to a position of honourable nonentity. Between them, Ockham and Marsilius used almost all the arguments that have ever been devised against the papacy. Condemned more than once, Marsilius had little immediate effect or influence, but during the Great Schism of the papacy (1378–1417) and later, in the 16th century, he and Ockham had their turn.

Advocacy of a secular state

The apptoaching storm. With the papacy "in captivity" and Nominalism capturing the universities, Europe and the church entered upon an epoch of disasters, of which the Hundred Years' War between England and France (began 1337) and the Black Death (1348–49) were the most clearly seen by contemporaries. When the papal states in Italy had been recovered, Urban V (reigned 1362–70) returned to Rome, but only for a short time (1367–70). Gregory XI (reigned 1370–78) made the final move in 1377, but then an even greater disaster occurred immediately: the papal schism, in which there were usually two, but sometimes three, popes.

Christian life. For all this, Christian life in the first half of the 14th century changed little. Many of the largest parish churches of Europe date from this time, as do many popular devotions, prayers, hymns, and carols; also, many hospitals and almshouses were founded. Though the relations between the friars and the secular clergy had been canonically settled, friction still continued. The friars came under wider criticism for worldliness and immorality, but they still remained popular. Though heresy and antisacerdotal (anticlerical) sentiment became almost endemic in the cities of Belgium and the Netherlands, the 14th century was a period that produced some of the greatest mystical writers of the church's history: Johann Tauler and Jan van Ruysbroeck in the north, Catherine of Siena in Italy, the author of *The Cloud of Unknowing,* and Walter Hilton in England.

The spread of the faith. The missionary enterprise during the period 1000–1350 involved three principal fields of work: Spain, central Europe, and Asia. In Spain the absorption of the Mozarabic Church (the Arabic term for Spanish Christians under Moorish rule) and the reestablishment of Catholic practices was accomplished by Spaniards who followed the crusade ideal and by volunteers, partly monastic, from beyond the Pyrenees. In central Europe, Pope Sylvester II (reigned 999–1003) had founded the ecclesiastical hierarchies of Hungary and Poland. The space between these countries and Germany was gradually conquered and Christianized by neighbouring bishops and German missionaries. The Baltic lands were won by a mixture of preaching and the swords of the Teutonic Knights (a military monastic order) between 1100 and 1400. Purer in motive and magnificent in design were the efforts of the Franciscans and Dominicans in the Near and Far East. Both orders preached to the Muslims, and early in the 13th century the Franciscans were in Georgia (now in the U.S.S.R.) and Persia and the Dominicans in Syria. In midcentury the Franciscans penetrated Mongolia and established a church in China with an archbishop and ten suffragan bishops, and under John XXII there was a hierarchy in Persia. All this might well have endured, had not the last of the great invasions (1383), under the Turkic conqueror Timur, or Tamerlane, broken all links between Europe and the East. (M.D.K.)

THE LATE 14TH TO EARLY 16TH CENTURIES (1378–1517)

The Great Schism and conciliarism. The desire of Christendom for the return of the pope from Avignon to Rome was at last fulfilled by Urban VI (reigned 1378–89), unfortunately an extreme believer in the principle of papal power. Because the Romans had exerted pressure on the conclave in which Urban was elected, and because the French cardinals opposed both the return to Rome and the extremely impetuous reform demands of the new Pope, the election was declared invalid. Within the same year Clement VII (reigned 1378–94), a relative of the French king, was elevated as antipope; he returned

The origin of the Western Schism

to Avignon and there formed a second Curia. The Western Schism had begun.

The German kings had long since made Christendom familiar with the ominous figure of an antipope; Ockham had, indeed, put forward the thesis that there could certainly be several popes simultaneously—this would, however, have signified the destruction of the unity of the church. But never before had the split been so deep as now, for each pope had a successor upon his death, and Christendom divided itself into two allegiances of approximately equal size, one Roman, one Avignonese. The adherence of the Western countries to the one or the other was decided for the most part on purely political grounds —for example, England belonged to the Roman allegiance, France and Scotland to the Avignonese. The consequence was that antipathy to the papacy grew, and ecclesiastical punishments against sovereigns lost all power, since the two popes excommunicated and interdicted each other. The whole church was thus under excommunication and appeared to be disintegrating. A merely human institution would fail in trying to revive itself by its own force. The church (interpreted as a divine–human institution), however, was able to do so. It regained its unity—for unity is the very life of the church—although it was a lengthy and tiresome process. In the many writings that ensued (particularly the ones produced at the University of Paris), those that dealt with the possibility of "root and branch" reform—an idea familiar from the Defensor pacis—were more and more emphasized, especially those that held that a general council, as the supreme authority of the church, would be the means of re-establishing unity. After mutual stubbornness had brought to naught all negotiations between the Popes, the two parties of cardinals finally united, after 31 years of schism, in calling a general council at Pisa (1409). Here both of the reigning popes, Gregory XII in Rome, Benedict XIII in Avignon, were deposed and Alexander V (reigned 1409–10) was elected. This was an unheard of action, *i.e.*, for the council to sit in judgment on the popes.

But the problem was too deeply rooted; neither would yield. Instead of two popes, there were now three (Alexander V resided at Bologna). Alexander was followed by a very unworthy successor (John XXIII, who reigned 1410–15 and is not considered a legitimate pope), and the demand for a new council became stronger. The German king proved once again to be the supreme protector of the church. King Sigismund (1368–1437) was able to compel the summoning of a general council at a German city, Constance. When John XXIII tried, by shameful flight, to break up the council, the King kept it together.

The Council of Constance

Conciliarism. The Council of Constance (1414–18) was one of the truly great church assemblies; in it the Christian West once again presented itself as a single whole. The problem of unity was solved: two popes, John XXIII and Benedict XIII, were deposed; the third, Gregory XII, withdrew. Martin V (reigned 1417–31), a member of the Colonna family of Rome, was newly elected and generally acknowledged. (Ironically, after his election, he worked, first and foremost, against the Constance theory of the superior authority of the council over that of the pope.) But the second task of this council, that of reform, remained unfulfilled. And for precisely this reason the oppositional movements in the church, which were calling for reform, remained alive; at the same time, the conflict with the Bohemian reformer Jan Hus (c. 1370–1415) and his followers finally broke out openly. Constance was thus both the symbol of unity and the beginning of the great convulsions that grew from the culpable failure to satisfy the church's demands for reform. At Constance it was decided that a general council should assemble every ten years. These councils, however, which were indeed summoned (at Pavia in 1423 and Basel in 1431), remained unfruitful because they were burdened with national controversies and the attempts of various democratic elements to limit the papacy. In the structure of the church as it was instituted, there must be room for primacy (papal authority) and for collegiality (collective authority). In the antagonism between these two poles of the church, the council at Basel actually became schismatic; instead of thoroughgoing reforms, the actions of that council culminated in the formation of another—the last—antipapacy (Felix V, reigned 1439–49).

Eugenius IV (reigned 1431–47), with whom the Renaissance became established in Rome, tried to achieve unity with the Greek Church. In order to secure the help of the West against the encroaching Turks, the Greek Emperor and the Greek Patriarch at Constantinople signed an agreement, but Eastern churchmen would have none of it; after the fall of Constantinople (1453) to the Turks, it became only a scrap of paper. The winners in the schism of the Western Church were the sovereigns of Europe; the influence upon the churches of their countries that they acquired in this period paved the way for the politically-based religious decisions made in the Reformation. The great loser was church reform.

Heretical movements. Because a genuine religious reform within the church, bearing the stamp of sacrifice and deepened faith, thus failed to come about, there developed a new kind of reform that became a most severe attack upon the church—the Reformation.

Reform movements led by Wycliffe

In England. Prologues to the Reformation were the movements headed by John Wycliffe (*c.* 1330–84) in England and Jan Hus in Bohemia. Besides the biblical basis of their theology, the power of these movements was characterized by a national coloration, which was particularly prominent in that of Hus. The resistance that England had shown to Rome ever since Innocent III's interference in English affairs (*e.g.*, his prohibition of the Magna Carta of 1215) grew with the increasing national consciousness and was nourished during the Hundred Years' War by mistrust of the French pope resident in Avignon. In 1366 the English Parliament refused the pope feudal tribute. The preacher and professor John Wycliffe provided a theological basis for this anticlerical and anti-Roman resistance. He taught that the church had no right to worldly power and wealth but was subordinate to the state. In an extreme emphasis on the Augustinian doctrine of predestination (*i.e.*, that men are foreordained to salvation or damnation,) Wycliffe finally opposed monasticism, indulgences, and sacraments. There was, he claimed, no need of a professional priesthood; the papacy was unnecessary, indeed, it stemmed from the antichrist. Wycliffe found adherents in all strata of the population. There was a Roman condemnation and later—after the uprising of the Lollards (poor farmers and the unemployed of the towns)—an English condemnation as well, but he himself was not molested. In 1417, however, when the connection between Wycliffe's doctrine and that of Hus had been recognized, his bones were dug up and burned.

In Bohemia. John Hus (c. 1370–1415), a professor of the University of Prague, protested in 1403 against the condemnation of Wycliffe by the German majority at the university; he was the Czech leader in the university struggles between Bohemians and Germans, which temporarily ended in 1409 with the exodus of the Germans from Prague. As a relentless preacher of reform (against the wealth and unspiritual conduct of the mostly German prelates), Hus drew upon himself the wrath of his archbishop, who brought his case before the Pisan pope Alexander V. Against Alexander's order for him to recant, Hus appealed to the new pope, John XXIII; the excommunication that the latter pronounced against him Hus answered by passionate sermons against papal politics and simony. The German king Sigismund (1368–1437), who wanted to be king of Bohemia as well, attempted to suppress the growing unrest; executions were already taking place. At the king's summons Hus came to Constance to "bear witness for Christ and his law." After three days of public hearings he was condemned as a heretic and, in violation of the royal safe-conduct given him, was burned at the stake.

Assessment of the Council of Constance

The proceedings of the council could be defended from a formal juristic standpoint, but the execution of Hus has been regarded as a frightful, unchristian, and historically dangerous act. Hus adopted much from Wycliffe, but, contrary to Wycliffe, he retained the Catholic concept of the sacraments, which indeed acquired substantial importance in his movement. The fate of their leader embittered the Bohemians; a whole people then rose against the rest of Western Christendom, whose sense of unity, already seriously weakened by the Great Schism, was now shaken again most severely. (Other forerunners, some of them from much earlier times were: Joachim of Fiore and his followers; some mystics; and, in an ambivalent way, nominalism.)

Problems and accomplishments of the medieval church. Alongside the far-reaching phenomena of decav, there were-in the 14th and 15th centuries a large number of significant beginnings of deeper religious life within the church. In almost all the monastic orders, reform efforts were seen: the Franciscan Observants, the observers of the old Rule; the alliance of Benedictine monasteries with reform congregations in Germany; the reform-minded Cardinal Ximénez in Spain. Important preachers of repentance also came to the fore, and the evangelistic movement took hold in France and Italy. A fruitful intensification of evangelical, biblical, and sacramental devotion found expression in many new foundations, such as that of the congregation of the Brethren (later also Sisters) of the Common Life founded by the Dutch preacher Gerhard Groote. Independent of clerical leadership, a new piety developed, called the *devotio rnoderna* (modern devotion), which was nourished by a personal imitation of Christ and which anchored church life in the continuity of faith and the sacraments. From this movement came Thomas à Kempis (*c.* 1380-1471) who wrote the *Imitatio Christi* ("Imitation of Christ"), the last universally accepted book of Christendom before it was split. This book of biblical and eucharistic prayer was, within a few years after its appearance, translated into many European languages; next to the Bible, it was the most widely read book in European literature. Strongly influenced by the *devotio rnoderna* were such diverse men, important for modern times, as the philosopher and cardinal Nicholas of Cusa, the Nominalist philosopher Gabriel Biel, Pope Adrian VI (reigned 1522–23), the Humanist Erasmus, and the reformer Martin Luther. In addition to the monastic reform congregations and the *devotio rnoderna,* there arose numerous brotherhoods devoted to charitable works and the religious education of the people. In view of these facts the total picture was not entirely negative, for the crucified Lord remained the centre of faith. At the same time, however, the interrelation of spiritual and material aspects had very unfortunate consequences.

The coming of a new spirit in Western Christendom

A great longing for ecclesiastical and worldly renewal existed in a large part of the population of the West. This led, initially in Italy, to retrospection toward the past. The ground appeared ready for a new culture. Since, however, disintegration had made such headway in the church, the new spirit did not fulfill itself primarily within the church but instead went more and more against it. The new elements, together with the medieval heritage, were undergoing a reordering that was at once decay and reformation; from it modern times were born. The most important transition of society, learning, and the church from the Middle Ages into modern times heralded itself intellectually (though not ecclesiastically or politically) in what became known as Humanism, the Renaissance attitude emphasizing man and his affairs.

II. Roman Catholicism in Europe in modern times

CATHOLIC REFORMATION AND COUNTER–REFORMATION

The condition of religious life on the eve of the Reformation. *Papal power and lack of spiritual care.* The great schismatic-papacy movement within the late medieval church, which found its most significant expression in the idea of conciliarism, had collapsed. The influence of the sovereigns upon the churches of their respective countries had grown extraordinarily, but the papacy had also increased in power. To be sure, its gains in power were primarily political, economic, and cultural, and not religious. The church's surrender to the culture of the Renaissance deepened still further the gulf between the religious view of Peter's office and its actualization. The Curia's excessive claim to power called forth opposition of the canonists in various countries and of their sovereigns. They demanded the limitation of the papal *plenitudo potestatis* ("fullness of power"); this division between national concerns and papal concerns likewise weakened the church.

The overall result of late medieval developments was, thus, the obscuring of the concept upon which the papacy had risen to prominence and influence. The concept of an institution founded by Jesus Christ—unique, unassailable in religious terms, its catholicity firmly based upon the Bible and standing above all one-sidedness—had been dangerously weakened. This widespread theological confusion was one of the factors that made the Reformation possible. Fateful also was the financial conduct of the Curia, which exploited Christendom, and the privileges of nobility attached to the lucrative ecclesiastical hierarchical positions, which were seldom regarded as spiritual offices for the cure of souls, but for the most part were used as sources of income for a life of pleasure.

Since a genuine development of spirituality was lacking, the growing masses in the cities found not even an approximately adequate spiritual care—in spite of enormously increasing numbers in religious professions (up to 10 percent of the city populations consisted of parish clergy, monks, and nuns); in the countryside, the economic misery of the parish priests and priests consecrated only for reading the mass made any constructive work impossible. In spite of some important exceptions, the lower clergy in general were without a "calling," without formal knowledge or dignity, despised by the people, and ridiculed by the Humanists. The abuses outweighed the still-existing islands of deeper piety. The proliferation of religious activities, including those of the pious foundations, brotherhoods, and the like, reflected an excessive preoccupation with the idea of gaining merit by good works and an unhealthy increase in the number of ecclesiastical pardons granted.

Deterioration of religious life

Inner. decay. Hand in hand with the multiplication of religious activities went an inner decay; the dogmatic doctrines of baptism, the mass, the church, and salvation became shallow. The catchword associated with piety was "being saved," in an outward sense, rather than primarily that of being justified through the crucified Jesus in repentance. Nevertheless, the doctrinal teaching of the redeeming life of Christ spoke to the people from innumerable pictorial representations and was thus a reality to them; the sublime liturgy of the Holy Mass continued to bear witness to the people the doctrine that all things happen "through Christ our Lord." Thus, in spite of all the disintegration and confusion, the negative side of medieval church life was not the whole picture, and the church's practices should not be characterized simply as the authentic product of the church's doctrines, as many of the propagators of the Reformation so declared.

A striking proof of the dislocation of the religious life of this period is supplied by the increased prevalence of heretical and sectarianizing tendencies (as in the teachings of Wycliffe and Hus and also in penitential movements) that drew their religious strength from the Bible. The New Testament praises poverty (see the Sermon on the Mount, Matt. 5–7; Parable of the Rich Man, Matt. 19:23–24), but the ecclesiastical hierarchy had devoted itself to riches. The disinherited confronted the hierarchy with the word poverty; there developed a Christian socialism (peasant uprisings in southern Germany and by the Lollards in England). While this movement took hold of the lower classes and brought them into confrontation with the hierarchy, the Renaissance and Humanism led the educated classes—who until then had been exclusively in the service of the church—to new secularized (but by no means exclusively non-Christian) conceptions of the world and human culture.

In the pious—but not entirely well-balanced—Dominican monk Girolamo Savonarola (burned at the stake in 1498, after having tried to reform the Italian city of Florence through his moral preaching and the passing of strict laws for conduct), the conflict of all these forces was expressed as if concentrated into one symbol. Savonarola was a striking embodiment of the rousing but, in its effect, vague repentance preaching of the time and also a revelation of its sharp contradictions. His personality and his fall from power and public support penetratingly illuminate the confusion of the period, particularly within the church, which had elected the notorious Alexander VI (Rodrigo Borgia) in 1492.

The Catholic Reformation. Doctrinal issues. Since the Reformation, according to many of the Protestant Reformers, was concerned with doctrinal issues primarily and with moral and practical issues secondarily, an understanding of the Reformation should necessarily begin with doctrinal matters. Martin Luther (c. 1483–1546), the founder of the Protestant Reformation, understood correctly that the gospel hinged upon but few major points, indeed, upon only a single one: the justifying faith that is the gift of God. His doctrinal approach could thus be strikingly simple. Together with the uncompromisingness and the impressive oratorical power with which he set forth his views, this simplicity made his preaching an uncommon attraction; it seemed to produce effective phrases of its own accord: "the Word," the "pure doctrine," the "freedom of the Christian man," "the gospel" (as opposed to the Law).

The Catholic "and" and the Protestant "alone"

Luther seized upon a central point of the Christian message—that of trusting faith in God the Father through the crucified Christ—and pronounced it to be the whole. Accordingly, the relationship of Reformation to Catholic doctrine may be correctly expressed in the statement: the Catholic "and," which illustrates its inclusive quality, stands opposed to the Protestant "alone," which is concerned with the centrality of a particular doctrine. (The Protestant Reformation battle cries were "Scriptures Alone," "Faith Alone," and "Grace Alone.") But this Catholic formulation is more "evangelical" than has long been thought by some church historians, theologians, and sectarian polemicists. The exclusive formulations of Protestantism place especially strong emphasis on what is the central point, yet, correctly understood, this central point is also Catholic. The Catholic "and" does not denote an addition but rather a dynamic-functional relationship and development. Scripture and tradition do not stand opposed as things foreign to each other; on the contrary, tradition in the church is viewed as the whole living heritage, transmitted primarily through inspired scripture. The functional meaning of the Catholic "and" leads to a concept of the church that affirms the sacramental priesthood (the office of those who by the power of their ordination as priests can officiate at the mass and perform other sacramental acts), the teaching office of the church, and the general priesthood of all believers, who have access to God through prayers and other such acts, thus pointing to the final decisive difference between Reformation-oriented and Catholic. It is a different concept of the church that is involved. Catholic doctrine tries to realize fully the biblical command: to be "hearer" of the word preached by the Apostles and their successors the bishops; *i.e.*, to take into account all the texts and books of the Bible according to the teaching of tradition and magisterium. The undermining or rejection of the magisterium in favour of "Scriptures alone" brought along increasing insecurity and separations within Protestantism. Contrary to Luther's intention—*i.e.*, the restoration of the pure gospel in one church—he became in a certain sense the father of modern liberalism.

Beginnings of Catholic reform. The history of the Reformation can only have a depressing effect upon Roman Catholics. One Catholic defeat, ecclesiastical and political, followed another, and Catholic failures were to blame for many of them. Catholic strength appeared to be exhausted. But this was only apparently so. For there was also—besides the Protestant Reformation—a Catholic Reformation of the 16th century that grew out of independent roots within the church and was a positive Catholic achievement, not merely a reaction to the Protestant assault. Important beginnings of the Catholic Reformation dated, in fact, from before the Reformation; others occurred later, independently of it (particularly in Spain, as in the work of lgnatius of Loyola, the founder of the Jesuits, and the mystical writer Teresa of Avila). The results, too, were not merely negatively defensive, but were in large part extensions based on Catholicism's own central foundations; *e.g.*, a new birth of Catholic piety.

At the same time, of course, the impact of the Reformation itself aroused many Catholic forces and induced and accelerated Catholic reform. Destruction threatened the church as it had been viewed for centuries, but the Catholic will to live responded. This reciprocal effect may be seen most clearly in the Council of Trent (1545–63). This will to live expressed itself in holiness, which is the very root of the entire Catholic reform of the 16th century, as at other turning points in church history. The church found the strength to renew itself. From the beginning the reformers, to a great extent, did not criticize others but themselves. They did not begin to alter the institution of the church, but rather their representatives.

The role of the papacy in the Protestant Reformation

Reform of the priesthood—which had become secularized—became the motto of the Catholic renewal. In spite of all the reservations and detailed criticisms that can be made, the work of reform was unexpectedly successful, although certainly far from uniform in the different countries. South of the Alps, secularization had gone much further than in Germany, yet it turned out that in that northern country, where the ecclesiastical organization—centred in a foreign city, Rome—was much more severely shattered, the Catholic religious renewal advanced at a significantly slower pace. It was quite otherwise in the south—in spite of the fact that, into the middle of the 16th century, the papacy displayed alarmingly little understanding of the dangers with which the church was threatened by the Reformation. By its altogether politically motivated actions, the papacy repeatedly compelled the Holy Roman emperor to put aside the struggle against the Protestants, so that the papacy inadvertantly became the very saviour of the Protestant Reformation. With the exception of Pope Adrian VI (reigned 1522–23), the papacy had no part in the early stages of the Catholic reform.

Forces of religious *renewal.* Not until the devastation of Renaissance Rome during the sack of Rome in 1527, by the unpaid German and Spanish mercenaries of the emperor Charles V (1500–58), was the negative prerequisite created for the papacy's collaboration with reform-minded groups. Just as in the Middle Ages, the forces of religious renewal did not emanate directly from the papacy and even less so from the bishops. They rather came from the strength of the faith of the religious community or of certain leading groups. Again, as in the Middle Ages, the forces of reform first reached their full strength through union with the papacy.

For a historical understanding of the Catholic Reformation it is important to note how the Catholic renewal was able to succeed even against very strong obstacles within the church itself and with numerous setbacks. The centre of resistance was, above all, the families and international politics of the popes, as well as curial resistance to the council for which reformers were calling. The reforms expected from such a council were extraordinarily feared by the curial officeholders. The effect of this state of mind was that, in Rome, the danger of incipient Protestant reforms to the Catholic Church was at first simply not seen. Thus, resistance was offered to the reforming zeal of Pope Adrian VI, and, as late as 1534, a man like Paul III (reigned 1534–49), entirely a product of the acutely secularized Renaissance, was elected pope. Even Paul IV (reigned 1555–59), zealous for reform, lapsed into a disgraceful nepotism. The same impression of ineradicable corruption is given by the style of living of the clergy who were members of the high nobility in France, Germany, and Poland right up to the end of the 16th century. With such a worldly, immoral attitude, such members of the hierarchy acted as if the Reformation had never occurred, as if the church were not fighting for its life.

Intrachurch reform. Hence, the intrachurch reconstruction of the 16th and 17th centuries was a complex process. The intrachurch reform was, in the first instance, the fulfillment of the manifold reform stirrings of the late Middle Ages. The basically nonclerical groups of the devotio *moderna*, which practiced a lay piety that was humanistic in form, were the forerunners of those religious associations from whose spirit new churchliness and Catholic piety arose in Italy. An important role in the reform was played by the Oratory of Divine Love, an ordinary religious order founded by laymen to aid in the moral and spiritual improvement of its members. The number of priests it admitted was limited. As early as 1497, a brotherhood founded at Genoa bore this name, which was adopted also by similar brotherhoods in other Italian cities. Supporters of the Catholic reform in Italy, such as Gaetano da Thiene (1480–1547) and Gian Pietro Carafa, later Paul IV (1476–1559), emerged from this oratory. The pious practices it prescribed for its members (*e.g.*, attendance at mass, communion, fasts, prayer, care of the sick) were the model for many associations subsequently founded. Similar reform groups were formed in Venice, led by Paolo (formerly called Tommaso) Giustiniani (1476–1528), Vincenzo Quirini (1479–1514), and Gasparo Contarini (1483–1542); the latter was a liaison man for the Italian reform forces. The specific goal of the Catholic reconstruction was the restoration of that which was most lacking in the church—the cure of souls. This was also the goal of the Theatine Order, founded by Gaetano da Thiene and Gian Pietro Carafa. Among the many abuses in the church, the two most ruinous had been clearly recognized as interconnected: the irreligious clergy and excessive wealth. Hence this new order (the Theatines) was expected to be, in complete poverty, a living example of irreproachable churchly spirituality, and an example that would encourage reform of the clergy from the ground up.

The Theatine Order

All these foundations were not bellicose in outlook; they wished to render positive services to church renewal. In many cases their connection with Humanism was determined already by the identity of their leading members. The piety that these groups practiced was not infrequently misunderstood and deprecated as protestantizing. Indeed, an often too-amorphous "evangelism" made itself felt—but in spite of some crises (such as the conversion to Protestantism of the Franciscan Bernardino Ochino), loyalty to the church remained unbioken. The positive role that Humanism played through its revivification of the Holy Scriptures was very evident. The spirit of this reform bore fruit in the regulations established at Trent regarding the education and life of the clergy.

Long before, Adrian VI had wanted to introduce reform. The last non-Italian Pope, he combined German intensity and Spanish churchliness. He was a great but tragic figure. He had the courage to publicly acknowledge (at the Diet of Niirnberg of 1523) the responsibility of the clergy—and in particular of the Roman Curia—for the religious-ecclesiastic revolt; but the time—or more correctly, the church—was not yet ready for his reforms. He was given no appropriate response, and his early death was a setback for reform. His successor, Clement VII (reigned 1523–34) was an entirely political figure, who vehemently rejected the council that persons all over Europe were demanding.

The Council *of* Trent. Only under Paul III (reigned 1534–49) did a slow change begin. Personally still living in the spirit of the Renaissance, yet thinking and acting with the political outlook of a modern monarch, he encouraged the newly formed orders (Theatines, Capuchins, Ursulines, and later the Jesuits). He revitalized the Sacred College of Cardinals by appointing the most important religious figures of the time (Gasparo Contarini, Giovanni Morone, Reginald Pole, and others) and finally—after much dangerous delay—convened the Council of Trent.

The council came too late for the re-establishment of church unity, but it undoubtedly gave Catholics new strength and reinforced the will to reform. To be sure, it achieved a transformation in Catholic self-confidence but only with difficulty and over a long period of time. The 'council continued through three periods of sessions: 1545–47/48, 1551–52, 1562–63. The core of its membership--which particularly in the first period was numerically very small—always consisted of Spaniards (Diego Lainez, the successor of Ignatius as general of the Jesuits, Domingo de Soto, Alfonso Salmerón, and Melchor Cano); the theological achievements of the general of the Augustinians, Seripando (1492–1563), were probably of the greatest value. Voting rights were no longer extended to the theologians, as at the Councils of Constance and Basel, but were held only by prelates having their own jurisdictions. The influence of political considerations was evident in the transfer of the council from German-controlled Trent to the Italian city of Bologna (1547), precisely at the moment when the Emperor, triumphant in Germany, had secured the participation of the Protestants in the council. With this transfer the Emperor's attempt to mediate a reconciliation of the Protestants with the church decisively failed, since the Protestants refused to go to a city that was controlled by the papacy. At the second session, again in Trent, representatives of the German Protestants appeared, but without success. This time the German princes conspiring against Charles V compelled the breaking off of the consultations. The third period of sittings brought the council to its conclusion and a profusion of reform decrees,

From the beginning, questions of reform and of faith were treated concurrently. Of especial importance was the decree of justification, in which this question, which was at the centre of Reformation doctrine, was finally clarified in Roman Catholic theology. The council declared that, in accord with scriptural doctrine, God and his mercy alone are decisive, but God works mysteriously to enable man to accept faith so that nothing in justification is other than God's work, and the very merit is a gift of God. The questions of reform were dealt with primarily in the third period of the council; a general cleanup of abuses was at least in principle agreed upon. Regulations regarding multiple benefices (having more than one revenue-producing ecclesiastical office), commerce in benefices, and, above all, the cure of souls, were reformed; through the issuance of the decree on the establishment of seminaries, the creation of a new clergy was begun.

Significance of the Council of Trent

The execution of the Trent decrees—that is, the actual achievement of the Catholic reform—required decades and, in some countries, centuries. The deepest meaning of the Council of Trent lay in that it contributed decisively to the clarification of the Catholic concept of the church; it was a victorious conclusion—in favour of the papacy—of the conflict that had begun in the 13th century.

The Counter-Reformation. Unfortunately, the expression Counter-Reformation is often used inexactly. Here it will be used literally to mean the totality of Catholic efforts directed against the Protestant movements. They were, of course, connected with the concept of power that since the Middle Ages had been central to the thought of the leading elements of the church and particularly of the popes. But these efforts can by no means be described as simply the expression of egotistic and nonreligious tendencies. The totality of the Catholic action directed against the Protestant Reformation was governed not only by the instinct of self-preservation but also by the church's comprehensive missionary mandate.

Intellectual achievements. Accordingly, it brought to light an amazing religious strength among Catholics. In the defense against the Protestant theological attack, there came forward in the first instance scholars who remained loyal to the Catholic Church. In first place among these was the highly learned Johann Eck (1486–1543), who was the first to recognize in Luther's theses the sign of a revolutionary attack. Others prominent in the first years after Luther's public fame were: the polemicizing chaplain of Duke George of Saxony, Hieronymus Emser; the satirical preacher and folk writer Thomas Murner; the Franciscan Kaspar Schatzgeyer; and the schoolmaster Johannes Cochlaeus. In Italy there was Cardinal Cajetan (who had been involved in a discussion with Luther in Augsburg in 1518) and the previously mentioned Contarini and Seripando, who were notable for their deep appreciation of the problems that the Reformation leaders had newly raised on the basis of the Bible. In England there was Bishop John Fisher of Rochester (1469–1535), and, initially, King Henry VIII (1491–1547).

Many noteworthy theological works, springing from devoted loyalty toward the church, could be cited; but none even approached the power of creative genius of Luther or Calvin. There was too little positive contribution issuing from the very centre of Catholic life and instead too much polemic. A large part of the struggle against Protestantism took place in the political sector. The outstanding figure, Luther's only opponent of equal genius, was Charles V, in whom deep Christian faith was combined with the concept of a Western Empire. In taking the side of the Catholic faith, Charles realistically took setbacks and detours in his stride, including the insufficient support accorded him by the popes of his time. When, as a result of the Peace of Augsburg of 1555, the continued existence of the Lutheran confession—and therewith the Schism—was recognized in imperial law, Charles abdicated. His son Philip II (reigned 1556–98) successfully fought for Catholicism in Spain (using the notorious Inquisition). In the German Empire Charles's brother Ferdinand I made concessions to Evangelical (Protestant) princes on the "heathen" principle ***cujus regio ejus religio*** (*i.e.*, the religion of the prince is the religion of the land). At this, the Counter-Reformation definitely began to take hold. Because its rulers remained Catholic, Bavaria remained with the Catholic Church. Their intervention also kept the Rhine area as ecclesiastical territories for Catholicism. Later the Austrian lands were recatholicized.

Importance of the Jesuits

In alliance with the princes, the Jesuit Order in particular became religiously effective. Founded in 1534 by Ignatius of Loyola (1491–1556), this order united many inspired and inspiring pioneers of the Catholic renewal on the basis of stern discipline of the will and unconditional self-sacrifice. The Jesuits worked as pioneer detachments in contested centres; through their schools and colleges, through preaching and the cure of souls, they ecclesiastically and religiously consolidated the ground won.

In England and France. In England there was only a short period during which the Counter-Reformation and Catholic Reform could operate: in the reign of Henry VIII's Catholic daughter Mary, from 1553 to 1558. She at once sought, with the help of her cousin, the influential Cardinal Pole, to restore and build up what remained of Catholicism. Here, too, from February 1555, violent methods were adopted, which claimed 273 victims. A symbol of the tragic character of Mary's effort is the double appellation with which she is recorded in history; one side called her Mary the Catholic, the other, Bloody Mary.

After her early death, her sister and successor, Elizabeth I (reigned 1558–1603), slowly and cautiously but effectively again eliminated all Catholic activity; only as underground groups and in emigration did Catholic remnants persist. A papal bull of anathema against Elizabeth in 1570, which seemed to sanction even the murder of the Queen, contributed greatly to making the lot of the Catholics in England yet worse. Furthermore, after the execution of their pretender to the throne, Mary Stuart, in 1587, Catholics no longer had political representation.

In France the question of creed submerged in that of politics. The royal house at first took severe measures against Calvinism, but at the same time Henry II (reigned 1547–59)—out of political considerations—supported the German Protestant princes in their struggle against the Catholic emperor. The Pope was threatened by Gallicanist (French antipapal) manoeuvres, with a national (French) council, and even with schism. In the cruel Huguenot Wars (French religious wars of the 16th century), the question of creed eventually became unimportant.

Papal activities of the Counter-Reformation. The collaboration of the popes with reform elements in the Counter-Reformation began with the establishment of the Roman Inquisition, instituted in 1542 to destroy heresy. Its creator was Cardinal Carafa, who as Paul IV (reigned 1555–59) put it to work, and most frightfully. He was a genuine reformer who eliminated many abuses but finally, through his cruel excess of zeal, did more harm than good. In contrast to him, the personal focus of Pius IV (reigned 1559–65) was worldly. By wise management, however, he saw the Council of Trent to its conclusion. Under him there also began, properly speaking, the ecclesiastical Counter-Reformation, in that he installed important men in the right places; *e.g.*, the Jesuit Peter Canisius in Germany and Cardinal Hosius in Poland. Even his practice of nepotism worked out well for the church. His nephew, whom he made a cardinal at the age of 14, was Charles Borromeo (1538–84), a saint who was to be of immense importance for the spiritual renewal of the church. Above all, to Charles Borromeo must go the credit for the election of Pius V (reigned 1566–72), the first pope of modern times to have been considered saintly. With him occurred the definitive reversal of the papal policies that had originated in the Middle Ages and had been secularized in the Renaissance, that is, there was a turning away from political goals. Pius V enforced the Tridentine decrees (those of Trent) in Rome and concerned himself with ending the serious abuses in the Curia. His reign was the first high point of Catholic reform and the Counter-Reformation.

Missions in Asia and Latin America

Pius V's successors, Gregory XIII (reigned 1572–85) and Sixtus V (reigned 1585–90), were no saints, but they continued his work. In Rome, seminaries were founded for the training of the European clergy (Germanicum, English College, Collegium Romanum); these were all headed by Jesuits. The extra-European missions (India, Latin America, China), again led principally by Jesuits, achieved extraordinary results at first, as in the work of Francis Xavier. But now there arose the problem still familiar to modem missions—the propagation of Christianity, which had Western characteristics, among peoples with entirely different traditions. In Asia, an attempt was made to solve the problem by extensive adaptation to existing customs. This magnificent experiment, entirely in the tradition of the Christianizing work of the early church, was later forbidden by Rome; thereafter the decline of Asiatic Christianity was assured. In Latin America, where Christianization was coupled with brutal suppression of the native population, including forced baptism, the bishops (such as Bartolomé de Las Casas) were the only defenders of the Indians, and Christianity was only very slowly able to take root. Through the founding of the Congregation for the Propagation of the Faith (Congregatio de Propaganda Fide; 1622), the papacy sought to unify and organize its missionary work.

Europe, however, remained the centre of the church's activity. The church had reconsolidated itself, and a whole band of saints (including Philip Neri, Francis de Sales, Frances de Chantal, Vincent de Paul, and many others) had revived its strength. The popes of the first half of the 17th century were mostly of lesser importance, and a certain reduction in the energy of the Curia was evident. An ill omen for the future relationship of the church to the fast-developing modern world was the rejection of the new natural science by theology in the trial of the astronomer Galileo (1633).

The Thirty Years' War

European religious and political antagonisms. In Bohemia, the heartland of Europe, the difficulties caused by the religious schism, which had increasingly turned into political antagonisms, led to a partly religious, partly dynastic conflict involving the destruction of Protestant churches in Catholic territories, the deposition in 1619 of the Catholic Habsburg ruler, Ferdinand II, and the calling of Frederick V, the "Winter King," to the throne of Bohemia. In the course of the following 30 years, nearly all of Europe was drawn into a terrible war, in which all fronts finally became entangled. Only England remained uninvolved, because of its own difficulties. In the struggle against the German Emperor—who claimed to be fighting for the cause of the church and who proposed an Edict of Restitution in 1629 to compel the return of the stolen church properties—the lead was eventually taken by France, whose all-powerful prime minister was Cardinal de Richelieu. Acting out of purely political motives and unhindered by creed, Richelieu personified the force that was to be largely decisive in the development of the church during the next century and a half, the age that would be characterized by the state church. This period, known as the Baroque era, produced, in the Catholic countries, splendid achievements in religious education, art, intellectual and literary production, and spirituality. Yet it must be acknowledged that Catholic thinkers and scholars lagged behind the forefront of European leadership, and that even many theological disciplines stagnated.

The Thirty Years' War in Germany, precipitated by religious reasons, was at last ended by the Peace of Münster and Osnaburg (1648)—known as the Peace of Westphalia—which finally acknowledged the equal rights of Catholics, Lutherans, and Calvinists in the Holy Roman Empire. The automatic assumption, however, was still that there was a universal validity of the Christian confession. There was no question of general tolerance in the modern sense of the 20th century. (J.L.)

ROMAN CATHOLICISM IN THE 17TH AND 18TH CENTURIES (1648–1789)

Emphasis on "Roman" Catholicism

Changing conditions. The signing of the peace in 1648 may have meant that the era of the Reformation had ended, but, for those who remained loyal to the see of Rome it meant that what had been thought of as a temporary flurry would now be a permanent condition—in a word, that henceforth Catholicism would have to be seen as "Roman" Catholicism. The church still claimed to be the only true church of Jesus Christ on earth, but, in the affairs of men and of nations, it had to live with the fact of its being one church among several. The Roman Catholic Church was also obliged to deal with the nations and national states of the modern era one by one. To understand the history of modern Roman Catholicism, therefore, it is necessary to identify trends that went beyond geographical boundaries and to consider particular states or regions—such as France, Germany, the New World, or the mission field--only as illustrations of tendencies that permeated the entire life of the church. Most of the development of Roman Catholicism since 1648 makes sense only in the light of this changed situation.

The papacy of the 17th and 18th centuries manifested the results of the change. On June 6, 1622, Gregory XV (1621–23) created the Congregation for the Propagation of the Faith (Congregatio de Propaganda Fide, hence "propaganda"). Its responsibility was, and still is, the organization and direction of the missions of the church to the non-Christian world, as well as the administration of the affairs of the church in areas that do not have an ordinary ecclesiastical government (for example, the United States as late as 1908). It has therefore played an important role in the efforts to restore Roman Catholicism in Protestant and, to some degree, in Eastern Orthodox territories.

The incumbent of the papal throne at the time of the Peace of Westphalia, Innocent X (1644–55), formally protested the provisions of the Peace of Westphalia as a violation of church law, but without avail. Under several of the popes of the 17th century, notably Alexander VII (1655–67), the artistic embellishment of the city of Rome, begun in the Renaissance but interrupted by the Reformation, was resumed and advanced. Under Alexander VII, Queen Christina of Sweden was converted from Lutheranism to Roman Catholicism. The internal reform of the life and law of the church was a continuing issue. Clement XI (1700–21), who is perhaps best remembered for his role in the Jansenist controversy (see below *Jansenism*), also engaged in conflicts with the rulers of Prussia, the Holy Roman Empire, Savoy, and Spain. That the process of electing Benedict XIV (1740–58) began February 17, 1740, and took six months, with (according to contemporary accounts) 255 votes before the deadlock was broken, was symptomatic both of the party spirit within the church and of its precarious relation to the cultural and political forces around it.

Developments in France. ***The Gallican problem.*** In many ways, however, it was this relation to political powers that determined the course of church history more than did the leadership of the popes. Not only the shrinking authority of the church as a consequence of the Reformation but also the expanding ambition of the state as a consequence of the growth of nationalism put ecclesiastical and secular government on a collision course throughout Europe. France, "the first daughter of the church," was the national state whose development during the 17th and 18th centuries most strikingly dramatized the collision, so much so that Gallicanism, as the nationalistic ecclesiastical movement was called in France, is still the label put on the efforts of any national church to achieve autonomy.

Nationalistic ecclesiastical movements

Usually, the autonomy from Rome implied subjection to the French crown, particularly during the reign of Louis XIV, who sought to extend still further the so-called prerogatives of France when Rome resisted. A conclave of bishops and deputies met on March 19, 1682, in Paris and adopted the Four Gallican Articles, which had been drafted by Jacques-Bénigne Bossuet, a French bishop and historian. These asserted that: (1) In temporal matters rulers are independent of the authority of the church. (2) In spiritual matters the authority of the pope is subject to the authority of a general council, as had been declared at the Council of Constance. (3) The historic rights and usages of the French church cannot be countermanded even by Rome. (4) In matters of faith the judgment of the pope is not irreformable but must be ratified by a general council. The next move was up to the papacy: Innocent XI and Alexander VIII rejected Louis' candidates for bishoprics in France, and only in 1693, when Innocent XII was pope, was this all but schismatic conflict resolved. Though Gallicanism was in part an expression of the distinctive traditions of French Catholicism and in part a result of the personal power of Louis XIV, the Sun King, it was, perhaps even more fundamentally, a systematic statement of the inevitable opposition between the papacy and a series of rulers from Henry VIII (1491–1547) of England to Joseph II (1741–90) of Austria, who, though remaining basically Catholic in their piety and belief, wanted no papal interference in their royal business but insisted on the right of royal interference in the business of the church.

Jansenism. The church in France was the scene of controversies other than these administrative and political ones. In 1640 there was published, posthumously, a book by a Dutch theologian Cornelius Jansen, entitled ***Augustinus,*** a defense of the theology of Augustine against the dominant theological trends of the time within Roman Catholicism. Its special target was the teachings and practices associated with the Jesuits. Jansen and his followers claimed that the doctrine of grace defined by the theologians of the Counter-Reformation in their opposition to Luther and Calvin had erred, in their view, in the other direction; *i.e.*, emphasizing human responsibility at the expense of the divine initiative and thus relapsing into the Pelagian heresy, against which Augustine had fought in the early 5th century. Over against this emphasis, Jansenism asserted the Augustinian doctrine of original sin, including the teaching that man cannot keep the commandments of God without a special gift of grace and that the converting grace of God is irresistible. Consistent with this anthropology was the rigoristic view on moral issues taken by Jansenism in its condemnation of the tendency, which it claimed to discern in Jesuit ethics, to find loopholes for evading the uncompromising demands of the divine law. When it was espoused in the ***Lettres Provinciales*** ("Provincial Letters") of Blaise Pascal, a French philosopher, this campaign against Jesuit theology became a cause célèbre. The papacy struck out against Jansenism in 1653, when Innocent X issued his bull, *Cum Occasione* ("With Occasion"), and again in 1713, when Clement XI promulgated his constitution, *Unigenitus* ("Only-Begotten").

Theologically, Jansenism represented the lingering conviction, even of those who refused to follow the Reformers, that the official teaching of the Roman Catholic Church was Augustinian in form but not in content; morally, it bespoke the ineluctable suspicion of many devout Roman Catholics that the serious call of the Gospel to a devout and holy life was being compromised in the moral theology and penitential practice of the church. Though Jansenism was thus condemned, it did not remain without effect, and, in the 19th and 20th centuries, it contributed to an evangelical reawakening, not only in France but throughout the church.

Quietism. Quietism, another movement within French Roman Catholicism, was far less strident in its polemics and far less ostentatious in its erudition but no less threatening in its ecclesiastical and theological implications. Quietism was, in many ways, yet another form of the Augustinian opposition to any recrudescence of the "Pelagian" idea that man's religious activity can make God propitious to him. In Quietism this belief was associated with the development of a technique of prayer in which passive contemplation became the highest form of religious activity. Christian mysticism had always combined, in an uneasy alliance, the techniques of an aggressive prayer that stormed the gates of heaven and a resigned receptivity that awaited the way and will of God, whatever it might be. In the theology of François de Fénelon, a French archbishop and mystical writer, Quietism was combined with a scrupulous orthodoxy of doctrine to articulate the distinction between authentic Catholic mysticism and false spiritualism. Nevertheless, as scholars of medieval mystical movements have suggested, Quietism showed the great gulf fixed between the Roman Catholicism that came out of the Counter-Reformation and the spirituality of the preceding centuries, both Greek and Latin. A devotion such as that of St. Gregory of Nyssa and Evagrius of Pontus, Greek theologians of the 4th century, was completely ruled out by the legalistic theology that condemned Quietism.

Adaptation to non-Western religious traditions

Controversies involving the Jesuits. ***The Chinese rites controversy.*** An analogous judgment would have to be voiced concerning the Chinese rites controversy, centring on Matteo Ricci, an Italian Jesuit missionary in China. Decades of scholarly research into Buddhist and Confucian thought had prepared Ricci for a campaign that sought to attach the Roman Catholic understanding of the Christian faith to the deepest spiritual apprehensions of the Chinese religious tradition; the veneration of Confucius, the great Chinese religious and philosophical leader of the 6th century BC, and the religious honours paid to ancestors were to be seen not as elements of paganism to be rejected out of hand, nor yet as pagan anticipations of Christianity, but as rituals of Chinese society that could be adapted to Christian purposes. Ricci's apostolic labours won him many converts in China, but they also won the suspicion of many in the West that the distinctiveness of Christianity was being compromised in syncretistic fashion. The suspicion did not assert itself officially until long after Ricci's death; but, when it did, the outcome was a condemnation of the Chinese rites by Pope Clement XI in 1704 and again in 1715 and by Pope Benedict XIV in 1742. Ancestor worship and Confucian devotion were said to be an inseparable element of traditional Chinese religion and hence incompatible with Christian worship and doctrine. Here again, the embattled situation of the Roman Catholic Church in the 17th and 18th centuries helps to account for an action that seems, in historical perspective, to have been excessively defensive and rigoristic.

Suppression of the Jesuits. Among the repercussions of the controversy over Chinese rites was an intensification of the resentment directed against the Society of Jesus, to which some of the other movements mentioned above also contributed. The widespread support enjoyed by Jansenism was due in part to its attack on the moral theology associated with the Jesuits. Pascal's ***Lettres Provinciales,*** although placed on the Index in 1657, voiced an opposition to Jesuit thought and practice that continued to be read throughout the century that followed. The political role played by members of the Society most probably evoked the campaign to suppress it. The Portuguese crown expelled the Jesuits in 1759, France made them illegal in 1764, and in 1767 Spain and the Kingdom of the Two Sicilies also took repressive action against them. But the opponents of the Society achieved their greatest success when they took their case to Rome. Pope Clement XIII is said to have replied that the Jesuits "should be as they are or not be at all" and refused to act against them. But his successor, Clement XIV (1769–74), whose election was urged by the anti-Jesuit forces, finally did take action. On July 21, 1773, he issued a brief, ***Dominus*** ac ***Redemptor*** ("Lord and Redeemer"), suppressing the Society for the good of the church. Frederick II of Prussia and Empress Catherine II of Russia—one of them Protestant and the other Eastern Orthodox—were the only monarchs who refused to promulgate the order to suppress the Jesuits when it was issued. In these lands and in others, the Society of Jesus maintained a shadow existence until, on August 7, 1814, Pope Pius VII restored it to full legal validity. Meanwhile, however, the suppression of the Jesuits had done serious damage to the missions and the educational program of the church, and this at a time when both enterprises were under great pressure.

Religious life. Yet, it would be a mistake to allow the narrative of these controversies to monopolize one's attention. Less dramatic but no less important was the continuing life of the Roman Catholic Church during these centuries as "mother and teacher." Bossuet was not only the formulator of Gallican ideology; he was also one of the finest preachers of Christian history, addressing king and commoner alike and asserting the will of God with eloquence, if sometimes with undue precision. Together with Jean Mabillon, a Benedictine monk and scholar, Bossuet helped to lay the foundations of modern Roman Catholic historiography. During the 18th century their work was continued and expanded, especially by Mabillon's confreres, the Maurists, a Benedictine group that edited the works of the Greek and Latin fathers. Both Jansenism and Quietism must be seen not only as parties in a controversy but also as symptoms of religious vitality. Engaging as they did considerable segments of the Roman Catholic laity, they expressed "the practice of the presence of God" with a new vigour. The Roman Catholic Church of this period exercised a profound influence on culture and the arts. Indeed, the spirit of Baroque is inseparable from the Counter-Reformation, as is visible, for example, in the Gesù Church in Rome and in the sculpture and architecture of Gian Lorenzo Bernini. Among the literary figures of the time, Pascal and Cervantes are notable examples of Roman Catholic thought and piety expressed through writing. The most fateful of the church's conflicts with modern culture in this period took place in the natural sciences. The condemnation of Galileo in 1616 and again in 1633 as "vehemently suspected of heresy" was more important symbolically than intrinsically, as a sign of the alienation between science and theology. From this period came the establishment or further development of several major religious orders, including the Daughters of Charity, founded by Vincent de Paul in 1633, and the Trappists, who take their name from the Cistercian abbey of La Trappe, which in 1664 was transformed into a community of the Strict Observance.

Scholarly and literary activities

ROMAN CATHOLICISM IN THE REVOLUTIONARY ERA

The church in France (1789–1801). The period of the Reformation and the Counter-Reformation was a time of convulsion for the Roman Catholic Church, but the era of revolution that followed it was, if anything, even more traumatic. This was partly because, despite the polemical rancour of Reformation theology, both sides in the controversies of the 16th and 17th centuries still shared much of the Catholic tradition. Politically, too, the assumption on all sides was that rulers, even when they opposed one another or the church, stood in the Catholic tradition. In the 18th century, however, there arose a political system and a philosophical outlook that no longer took Christianity for granted, that in fact explicitly opposed it, compelling the church to redefine its position more radically than it had done since the conversion of the Roman emperor Constantine in the 4th century.

What made the relation of the Roman Catholic Church to the ***ancien régime,*** the political and social system before the French Revolution in 1789, so problematical at the time of the revolution was a subtle but fundamental difference. Although the rhetoric of the revolution spoke as though the church and the old order had been one, no one could study the history of the church under (or over against) Louis XIV and accept so simplistic an interpre-

Underlying causes of anti-ecclesiastical sentiments

tation. Conflict there had been, bitter and uncompromising conflict—and yet conflict within the context of given presuppositions. It is significant, for example, that the French aristocracy, soon to become the hated object of revolutionary zeal, constituted the source of almost all the bishops of the church in the *ancien régime.* This also meant that positions of authority in the church were largely foreclosed to the lower clergy because of their class. The theological and ecclesiastical parties identified with opposition to Rome were frequently those that drew the support of the laity; Jansenism, for example, was identified as the position of the lay lawyers who spoke for the French courts of justice over against the hierarchy. In spite of the hostility between church and state, therefore, the old regime appeared to its critics to be a monolith. Thus, when the French philosopher Voltaire said, "Écrasez l'infâme" ("Crush the infamous one"), he may have meant superstition, ignorance, and tyranny, but what it added up to concretely in the minds of the revolutionaries was the supposed alliance of the monarchy with the Roman Catholic Church. This identification was only confirmed when the defenders of the established order, both lay and clerical, spoke out against the threat of revolution with a greater awareness of its dangers than of its justification.

Complicating the predicament of the church in the old regime was the corrosive influence of the Enlightenment on the religious beliefs of much of the lay intelligentsia. Enlightenment rationalism took hold among many defenders of the political status quo, as well as among clerical scholars, helping to produce the beginnings of critical biblical scholarship and of religious toleration. It would be an oversimplification, therefore, to put the Enlightenment unequivocally on the side of the critics and revolutionaries. Perhaps no one embodied the spirit of the Enlightenment more completely than Frederick II the Great of Prussia. But the confidence in reason and the hostility to "superstition" cultivated by the Enlightenment inevitably clashed with the Christian reliance on historical revelation and with the belief in supernatural grace as communicated by the sacraments. The political and social prerogatives of the church were threatened by the Enlightenment, especially when it was allied with the expanding claims of an autocratic "enlightened despotism." The brotherhood taught by such groups as the Freemasons, members of secret fraternal societies, and the Illuminati, a rationalistic secret society, provided a rival to the Catholic sense of community as found in the church. In the *Magic Flute,* the Austrian composer Wolfgang Amadeus Mozart (who wrote his *Requiem Mass* in the same year) celebrated the Masonic alternative to the mass of the church. When the church condemned Galileo, it confirmed the suspicion of many that traditional theology was inseparably wedded to an obsolete world view and that science had to be freed from its tyranny if it was to progress.

Although leaders of the state were often more hospitable to the ideas of the Enlightenment than were leaders of the church, the latter proved to have been more accurate in their estimate of the revolutionary implications of these ideas. The "heavenly city of the 18th century philosophers" may originally have been intended as a substitute for the City of God, but it also provided much of the ideological rationale for the attack upon the *ancien régime.* In the familiar epigram of the Swiss writer, Jacques Mallet du Pan, after the French Revolution, "philosophy may boast her reign over the country she has devastated." The action of the French Revolution against the church took many forms, but the most significant was the "Civil Constitution of the Clergy" of 1790. In it, a Gallicanism originally enunciated in the name of the absolute French monarchy attempted to subject the church to the National Assembly. The entire church in France was reorganized, with the authority of the pope restricted to doctrinal matters. Later in that year, a constitutional oath was required of all the French clergy, most of whom refused. Pope Pius VI (1775–99) denounced the "Civil Constitution" in 1791, and Catholic France was divided between the adherents of the papal system and the proponents of the new order. The closing decade of the 18th century was dominated by this conflict, and no resolution was provided by either church or state. The ultimate humiliation of the church came when Pius VI was driven out of Rome by the French armies in 1798 and in the following year was taken captive by them and dragged back to France, where he died. Not since the Great Schism and the Babylonian Captivity had the prestige of the papacy sunk so low.

The Concordat of 1801

Napoleon I—exportation of the Revolution. As it was obvious that the French Revolution itself had to be carried to some more permanent settlement, so it was recognized on all sides that a more stable arrangement of church–state relations was essential. This was achieved by Napoleon Bonaparte in a concordat concluded with Pope Pius VII on July 15/16, 1801. It recognized that Roman Catholicism was the faith of most Frenchmen and granted it freedom of worship. All incumbents of bishoprics were to resign and were to be replaced by bishops whom Napoleon, as first consul, would nominate. The properties of the church that had been secularized during the Revolution were to remain so, but the clergy were to be provided with proper support by the government. Many historians maintain that the Concordat of 1801 has been as decisive for modern church history as the conversion of Constantine had been for ancient church history. As Constantine first recognized and then established Christianity in the Roman Empire, so a series of concordats and other less formal agreements have created the modus vivendi between the church and modern secular culture. What this meant for the papacy was the realization that most of the temporal holdings of the church in Europe would have to be surrendered. The eventual outcome of this realization was to be the creation of Vatican City as a distinct political entity, but only after a long conflict over the States of the Church during the unification of Italy in 1869–70. First, however, came the period after the fall of Napoleon, when those who had emerged victorious at the Battle of Waterloo (1815) attempted to restore the previous condition. The Society of Jesus was revived in 1814, and the Congress of Vienna in 1814–15 helped to establish a basis for the recovery of the church during the 19th century. Temporary though these supposed settlements were, they made it clear to those living in the following period that the church would continue to be a force to be reckoned with in the affairs of Europe and America.

THE 19TH CENTURY

Much of the history of Roman Catholicism in the 19th century is identified with the pontificates of two men: Pius IX, who was pope for a third of a century (1846–78), and Leo XIII, who was pope for a quarter of a century (1878–1903).

Promulgation of the dogma of papal infallibility

The reign of Pius IX (1846–78). Few popes of modern times have presided over so momentous a series of decisions and actions as Pius IX. During his reign the development of the modern papacy reached a kind of climax with the promulgation of the dogma of papal infallibility. It had long been taught that the church, as "the pillar and bulwark of the truth," could not fall away from the truth of divine revelation and therefore was "indefectible" or even "infallible." Inerrancy had likewise been claimed for the Bible by both Roman Catholic and Protestant theologians. As the visible head of that church and as the authorized custodian of the Bible, the pope had also been thought to possess a special gift of the Holy Spirit, enabling him to speak definitively on faith and morals. But this gift had not itself been identified in a definitive way. The outward conflicts of the church with modern thought and the inner development of its theology converged in the doctrinal constitution *Pastor Aeternus* ("Eternal Shepherd"), promulgated by the first Vatican Council on July 18, 1870. It asserted that "the Roman Pontiff, when he speaks *ex cathedra,* that is, when in discharge of the office of pastor and teacher of all Christians, by virtue of his supreme apostolic authority he defines a doctrine regarding faith or morals to be held by the universal Church, by the divine assistance promised to him in blessed Peter, is possessed of that infallibility with which the divine Redeemer willed that his Church should be endowed." The decree was, of course, retroactive, even though there were historical incidents that appeared to contradict the retroactivity, such as the condemnation of Pope Honorius I by the third Council of Constantinople in 680, which were cited by opponents of the decree. This opposition was, however, ineffective, and the dogma of infallibility became the public doctrine of the church. Those who continued to disagree withdrew to form the Old Catholic Church, which was centred in The Netherlands, Germany, and Switzerland.

Even before the promulgation of this dogma, Pope Pius had exercised the authority that it conferred on him. In 1854, acting on his own prerogative and without any council, he defined as official teaching the doctrine of the immaculate conception of the Virgin Mary, "that the Most Blessed Virgin Mary, at the first instant of her conception, was preserved immaculate from all stain of original sin, by the singular grace and privilege of the Omnipotent God, in virtue of the merits of Jesus Christ." This put the church unequivocally on one side of a debate over the doctrine of Mary that had been going on since the Middle Ages. Ten years later, Pius issued a document that was in some ways even more controversial, the ***Syllabus of Errors*** (December 8, 1864). In it he condemned various "errors" characteristic of modem times, including pantheism, Socialism, civil marriage, secular education, and religious indifferentism. By thus appearing to put the church on the side of reaction against the forces of liberalism, science, democracy, and tolerance, the ***Syllabus*** seemed to be part of the retreat of Roman Catholicism from the modem world. At the same time, it did seek to clarify the identity of Roman Catholic teaching at a time when it was being threatened on all sides.

This combination of reactions to modern thought and society came to a head in the conflict over "Americanism," which was condemned by Leo XIII in 1899, and even more vigorously in the ***Kulturkampf*** (*i.e.*, struggle in Germany with Catholicism). Prince Otto von Bismarck, both because he was a Prussian and because he was a Protestant, resisted the basic trend of the developments just traced. In the Roman Catholic parties of the centre in the German states, he saw an obstacle to the form of German reunion to which he was dedicated, viz., a predominantly Protestant Germany without Roman Catholic Austria. The ***Syllabus of Errors*** and the dogma of infallibility represented the hostility of Roman Catholicism to the very sort of state he was trying to establish. Much of the theological opposition to papal infallibility came from German thinkers, notably Ignaz von Döllinger, to whose defense Bismarck sprang. The conflict between church and state came in several principal areas. The ***Kulturkarnpf*** began with the exclusion of the Roman Catholic Bureau from the Ministry of Culture and Cultus in the Prussian state. Bismarck asserted the authority of the state over all education in Prussia and had the Society of Jesus expelled. Then, in direct defiance of the ***Syllabus of Errors,*** he required civil marriage of all, regardless of whether or not they had also exchanged their vows before a clergyman. Laws were passed compelling candidates for the Roman Catholic priesthood to attend a German university for at least three years. Bismarck summarized his defiance of the Pope in an allusion to the conflict between Pope Gregory VII and Emperor Henry IV in the 11th century: "We are not going to Canossa!" When Pius IX died in 1878, the conflict was still unresolved.

Rise of the Modernist movement

The reign of Leo XIII (1878–1903). Although Leo XIII was no less conservative in his theological inclinations than his predecessor, his positive appreciation of the church's opportunities in modem society gave his pontificate a significantly different cast from that of Pius. On issues of church doctrine and discipline, his administration was a strict one. It was during his reign that the Modernist movement, which advocated the use of biblical and historical criticism and freedom of conscience, arose within Roman Catholicism; and, although the formal condemnation of its tendencies did not come until 1907, four years after his death, he had made his opposition to this trend clear by the establishment of the Pontifical Biblical Commission as a monitor over the work of scriptural scholars. The positive side of his theology came to voice in the encyclical ***Aeterni Patris*** ("Eternal Father") of August 4, 1879, which, more than any other single document, provided a charter for the revival of Thomism (the medieval theological system based on the thought of Thomas Aquinas) as the official philosophical and theological system of the Roman Catholic Church. It was to be normative not only in the training of priests at the seminaries of the church but also in the education of the laity at universities. To this end Leo also sponsored the launching of a definitive critical edition of the works of Thomas Aquinas. In 1895 Pope Leo appointed a commission to decide the long-mooted question whether, despite the separation from Rome in the 16th century, the priestly ordination of the Anglican communion was valid, as, for instance, that of the separated Eastern churches was; in 1896 he issued ***Apostolicae Curae*** ("Apostolic Concerns"), which denied the validity of Anglican orders and was a setback for ecumenical hopes on both sides.

The "pope of peace"

Nevertheless, Leo XIII is best remembered for his social and political thought, which earned him the sobriquet the "pope of peace." He managed to mollify the church's position toward the policies of Bismarck, and the Chancellor in turn moved toward a compromise. Diplomatic relations between Germany and the Vatican were restored in 1882, and gradually the restrictive laws were lifted. But the greatest achievements of Leo's work in the relation between the church and modern culture were his social and political encyclicals. Without repudiating the theological presuppositions of the ***Syllabus of Errors,*** these encyclicals articulated a positive social philosophy, not merely a defensive one. In ***Libertas*** ("Liberty"), an encyclical issued on June 20, 1888, he sought to affirm what was good about political liberalism, democracy, and freedom of conscience. Above all, the encyclical ***Rerum*** *Novarum* ("Of New Things") of 1891 put the church on the side of the modern struggle for social justice. Though rejecting the program of 19th-century Socialism, the Pope was also severe in his condemnation of an exploitative laissez-faire capitalism and in his insistence upon the duty of the state to strive for the welfare of all its citizens. The social thought of Leo XIII helped to stimulate concrete social action among Roman Catholics in various lands, such as the Christian Social Movement. When he died, soon after the close of the 19th century, the church seemed in many ways to be entering a new era of respect and influence, but the turmoil of war, depression, and revolution in the 20th century intervened.

THE 20TH CENTURY

Two historical forces, one external and the other internal, have dominated the development of Roman Catholicism during the 20th century: the world wars of 1914–18 and 1939–45, with the accompanying upheavals of politics, economics, and society; and the second Vatican Council of 1962–65, with upheavals no less momentous in the life and teaching of the church.

The period of the world wars. Pope Pius X (1903–14) symbolized the transition from the 19th century to World War I. In his encyclical, ***Pascendi Dominici Gregis*** ("Feeding the Lord's Flock"), of September 8, 1907, he formally condemned Modernism as "the résumé of all the heresies," and, in 1910, he prescribed that clergy and seminary professors take an oath abjuring Modernism and affirming the correctness of the church's teachings about revelation, authority, and faith. He sponsored the revision and clarification of the code of canon law. More perhaps than any of his immediate predecessors or successors, Pius X gave attention to the reform of the church's liturgy, especially to the Gregorian chant and advocated early and frequent reception of communion. Yet hanging like a cloud over his pontificate was the growing threat of the world war, which neither diplomacy nor piety was able to forestall. The last major document issued by Pius X was a lament over the outbreak of war, dated August 2, 1914; less than three weeks later he was dead.

World War I, often called the real end of the 19th century, was also a major turning point in modern Roman Catholic history. Ever since ancient times, the church had been accustomed to order its relations to human society by negotiations with kings and emperors, preferably members of its own fellowship. The war and the revolutions attending it meant the end of the Hohenzollern (Germany), Habsburg (Austria-Hungary), and Romanov (Russia) dynasties, obliging the church to come to terms with the new realities of democratic, Communist, and Fascist regimes.

The Lateran Treaty

Of special significance was a series of pacts with the Fascist Italy of Benito Mussolini. In 1929 the church and the Italian government signed the Lateran Treaty, which finally regularized relations between them and gave Vatican City independent status. In 1933 the church went on to conclude a concordat with Nazi Germany, hoping to protect its own interests and those of minorities; but this hope proved to be ill founded, and the church's relation with Hitler and his regime deteriorated. Although Pius XI (1922–39) and Pius XII (1939–58) both spoke out several times against the excesses of the regime, they did little to restrain it. The papacy spoke out much more often, for example, during the Spanish Civil War (1936–39), against the dangers of Communism, the eventual dominance of which over Poland, Hungary, and other strongly Roman Catholic lands was a major setback to the church of the 20th century. As a diplomat and former papal secretary of state, Pope Pius XII was obliged, under the pressures of World War II, to clarify and redefine the church's teachings on war and peace, as well as to work out a strategy of survival. In 1950 he became the first pope since the first Vatican Council to exercise the right of defining doctrine, proclaiming the bodily assumption of the Virgin Mary to be a dogma binding on all members of the church. Earlier in that same year, in the encyclical ***Humani Generis*** ("Of the Human Race"), he had given a reproof to various theological trends that appeared to be reviving the ideas and methods of Modernism.

Vatican II. From these two papal promulgations of 1950 many observers were ready to conclude that, in the second half of the 20th century, Roman Catholicism would assume an essentially defensive posture in relation to the modern world. Those who had come to that conclusion were compelled to revise it by the pontificate of John XXIII (1958–63) and by the second Vatican Council (1962–65). During his brief reign, Pope John issued several important encyclicals. Of special interest was ***Mater et Magistra*** ("Mother and Teacher"), published in 1961, which explicitly attached itself to the ***Rerum Novarum*** of Leo XIII in calling for justice and the common good as the norms of social conduct. Two years later, in ***Pacem in Terris*** ("Peace on Earth"), the Pope addressed himself not only to members of the church but to "all men of good will." In this encyclical he formulated, more completely than any previous pope had done, a social philosophy for peace among men and between nations. This spirit of reform and concern came to expression in the council, which Pope John convoked but which he did not live to see to its conclusion. The council brought about drastic changes in the life and worship of the church, encouraging the use of the vernacular in the liturgy and greater lay participation everywhere. Perhaps even more historic were its actions toward those outside the borders of the Roman Catholic Church. To Eastern Orthodox and Protestant Christians, it extended the hand of fraternal understanding instead of denouncing them as heretics. To the Jewish community, it addressed words of reconciliation and regret for the anti-Semitism of the Christian past. To the world religions, it spoke of the church's admiration for the spiritual values that had been preserved in those traditions that did not know the name of Christ. And to all men, believers and unbelievers, it expressed its respect for the integrity and freedom of man and its repudiation of coercion as a means for bringing men to faith. In its importance for the development of the church, the second Vatican Council will probably rank with the councils of Nicaea (325), Chalcedon (451), and Trent (1545–63). **(J.J.Pe.)**

III. Roman Catholicism outside Europe in modem times

THE NEW WORLD: THE SPANISH AND PORTUGUESE EMPIRES

Colonial period. The Western Hemisphere was discovered by Europeans immediately before the Protestant Reformation began in Europe. The fact of that discovery at that moment in history and the original development of the New World by Roman Catholic empires (*e.g.*, Spain) is of major significance in the religious history of the hemisphere. The only part of it that was to be non-Catholic in its general cultural outlook was the area of those colonies that was to become the United States. Spain and Portugal were in their prime as sea powers in the late 15th and early 16th centuries, and they were most responsible for exploring, colonizing, and establishing the Christian faith in the southern two-thirds of the American half of the world.

Relations between missionaries, colonists, traders, and indigenous peoples

The chief institutions for Catholicizing were the Franciscans, Dominicans, Augustinians, Jesuits, and other religious orders. Well-trained and self-sacrificing representatives of the orders were able to go wherever Spanish and Portuguese ships went. Sometimes they could be accused of serving as religious supporters of anything the Crown desired. Because the missionaries were in quest of souls, however, even though the imperial powers often wanted merely to exploit the bodies and material resources of New World natives, there were also clashes between Catholic churchmen and colonizers or traders.

The establishment of Catholicism in Central and South America, then, did not always mean that there was a moderation of the empires' exploitations of the natives, who came to be called Indians. There were, however, some missionary efforts and successes among these natives. At times Catholicism was able to temper the inhumanity of the conquerors. Best known among the humane spokesmen for Indians was the Dominican Bartolomé de Las Casas (1474–1566), "the Apostle of the Indies."

In the course of the 16th through the 19th centuries, European colonists and immigrants from nations other than Spain and Portugal came to Latin America. Even when these movements were made up of Protestant minorities or when they included Protestant missionaries, however, they did little to disrupt the generally or nominally Catholic cultures.

Modern secular forces also served to jostle the Catholic settlements. The case of Mexico is illustrative; time and again its ruling powers have proscribed Catholic education and embodied anticlerical interests. Still, the Mexican people remained largely Catholic and blended some of their inherited native religious values and practices with distinctively Catholic forms. In Mexico as elsewhere, then, it is difficult to know just who is Catholic and who is non-Catholic. Estimates of the number of nominal Catholics in Latin America run as high as 200,000,000.

After independence. The inevitable reaction by Catholic and non-Catholic alike arose against the colonial powers. This took the form of movements of independence, anticlerical revolts that were directed against European powers. Some institutions, particularly those devoted to education, were opposed to the practices of Catholicism. Because so many of the clergy came from Europe, anti-European sentiment assured that the American fields were not attractive, and chronic clerical shortages prevailed. As was the case in Europe, the various revolutions were often concurrent with or encouraging to the various versions of Enlightenment thought, and this meant that they were expectably uncongenial to the truth claims of Christianity.

Effects of anti-clericalism and revolutionary Catholicism

By the middle of the 20th century, wherever Latin American Catholicism remained strong, it still tended to identify itself with increasingly reactionary national regimes and was then dismissed by much of the rest of the world as appearing to be uncongenial to the legitimate aspirations of majorities. Because of the cosmopolitan influences of the second Vatican Council (1962–65), however, the self-generated renewal of the church, and the presence of a new socially responsible leadership, there appeared during the 1960s a more radical Catholicism. Dom Helder Câmara of Recife, Brazil, exemplified the impulse toward drastic social reform. Camillo Torres, killed in the role of a Colombian guerilla, typified the association of a Catholic minority with violent revolutionary programs.

Spanish and French missions in North America. Though at the time of its settlement the United States under British and continental Protestant influences became a largely Protestant outpost, Spanish Catholics did establish missions in Florida and elsewhere. Franciscans began work in California in 1514 and in New Mexico in 1581; this work reached its greatest success when the Spanish missionary Fra Junipero Serra founded stations all along the California coast after 1769. Similarly, to the north, French explorers, traders, and conquerors settled much of eastern Canada and brought with them a Catholic Church that has remained dominant there until the present. French missionaries also penetrated the Great Lakes region and the Mississippi Valley, but their efforts left few traces when the North American interior came to be settled by English-speaking people late in the 18th century.

ROMAN CATHOLICISM IN THE UNITED STATES AND CANADA

United States. As far as the 13 colonies of the emerging United States were concerned, only Maryland, which had been settled in 1634 and established in 1649, included an appreciable number of Catholics before American indeyendence. Catholics were often unwelcome in and even excluded from many colonies, where Congregational or Episcopal churches were supported by law. According to some estimates, there were at most 25,000 Catholics in a colonial population of almost 4,500,000 at the time of independence after 1776.

Relationship of Catholics to Protestants

From the first, however, Catholic leadership enjoyed its place in the free society of the new United States. Bishop John Carroll, a representative of a notable colonial Catholic family, pioneered in exploring positive relations between Catholic religionists and their fellow citizens. Beginning in the 1830s and 1840s, the assurances of religious freedom were added attractions for millions of Catholic immigrants who had to make their way to the United States for economic reasons. Coming as most of them did from Ireland or the European continent to a nation of largely British and almost exclusively Protestant provenance, they awakened suspicion and hostility and were met by what has since been called a nativist Protestant Crusade.

Catholicism endured, however, and built impressive institutions including parochial schools. These elementary and secondary schools were formed late in the 19th century because Catholic leaders feared Protestant influences in the public schools. Through these Catholic agencies, Catholic leaders were able to help their people sustain religious loyalties to Rome and civil loyalties to America. The church was plagued by several issues: "trusteeism," a debate over lay versus clerical control of ecclesiastical institutions; "Americanism," the charge that American Catholics were innovating in doctrine and practice; immigration; and the rescue of souls. The Church prospered through all these adversities.

After World War I, anti-Catholicism declined. By 1960 a Roman Catholic, John F. Kennedy, had become president —an office previously thought to be out of range for Catholics. Tensions over church–state issues remained, but these were minimized or at least they grew more confused because neither Catholics nor their old opponents continued to present a united front. The ecumenical age also brought about better relations between the various faiths.

Canada. Farther north, in Canada, England came to dominance in 1713, but the Quebec Act of 1774 guaranteed Catholic rights. The period of new nationalisms after World War II found French Catholics in Quebec nervous about the assimilation and even possible disappearance of their culture. They took steps to assure the perpetuation of the faith, language, and outlook of the French-speaking Catholic millions in an otherwise largely Protestant nation. Some militant movements even asked for separation and the formation of a new nation in Quebec.

ROMAN CATHOLICISM IN AFRICA AND ASIA

Though Catholicism had shaped Latin American and eastern Canadian culture and though it came to be at home in the United States, it also found itself to be a worldwide presence for the first time in the 19th century. This expansion was the result both of Western nations' imperial intrusions into Africa and Asia and of the rebirth of a missionary spirit in Christendom.

Catholicism as a worldwide presence

Some of the expansive efforts may have been built upon the traces of 16th-century missionary activities, such as those of St. Francis Xavier, a Jesuit missionary to Asia; usually, however, they had to develop on the basis of original methods and in new territories.

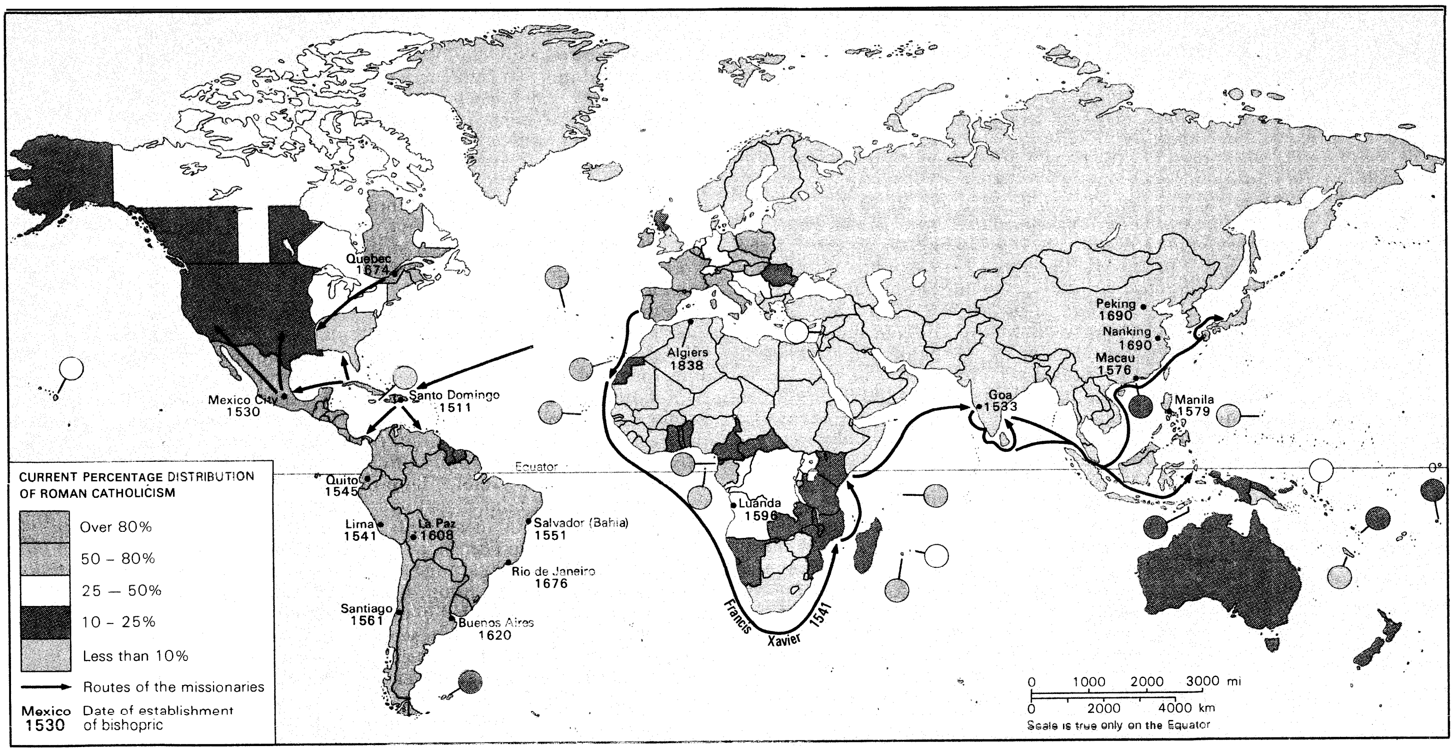
Early missions. ***Africa.*** In Africa almost nothing remained of the strong early Christian presence in the north. Through the centuries North Africa had become largely Muslim. The Muslim presence there offered more resistance than did native African religionists who lived on in the rest of the continent. Christians were not welcomed and were often persecuted. Even in partly Christian Abyssinia (Ethiopia), where the Coptic Church was prominent, Catholics were largely excluded except between 1702 and 1839. An archbishopric was established in Algiers, and in 1868 Archbishop Charles Lavigerie founded the White Fathers who were energetic but largely unsuccessful missionaries from that base.

West Africa presented obvious and persistent problems for all Christians, because it was from there that European nations had carried on most of the slave trade. Portuguese colonialists did help the Catholic Church establish itself in parts of West Africa, but progress was slow. Catholicism fared better in East Africa, particularly in Madagascar and around Lake Victoria. Uganda, Kenya, and Tanganyika (now Tanzania), for example, have thriving churches. The record was less triumphant farther south, in no small measure because of Dutch and British Protestant power. Yet there, as elsewhere, independent missionary societies worked desyite considerable hardshiy.

Asia. In Asia, Catholicism was able to profit from Portuguese and Spanish adventures from the 16th century on. In that part of the world, however, different styles of clashes occurred. Asians had not had contact, as Muslims had, with biblical views of history and destiny. Buddhists, Taoists, followers of Confucianism, and Hindus were devoted to world views uncongenial to Western attitudes toward God, time, and history. In the encounter, Catholicism was itself torn over debates concerning the permissible degrees of accommodation to Eastern ways and views of life, rituals, and terms.

Problems of accommodation

In India there were traces of missionary extensions from premodern centuries (*e.g.*, the Malabar Syrian Christians), and Catholicism here and there found new bases. But the suppression of the Jesuits in 1773 for reasons of European politics removed the most assertive group from



Routes of missionaries, dates of establishment of dioceses, and current distribution of Roman Catholicism,

the scene at the most inopportune moment. Catholics flourished under persecution in Indochina, in what is now called Vietnam. The major drama occurred, however, in China and Japan, which were opened to Westerners after centuries of relative isolation. In the 19th century, Catholic institutions became familiar sights on the Chinese landscape. Churches, hospitals, and schools were established. The Boxer Rebellion in 1900 symbolized the growing resistance of the Chinese to Western presences in their country.

In Japan little was left of the 16th-century missions except for an isolated sect of Catholics on an island near Nagasaki. In both China and Japan only a small percentage of the people ever became Catholic. The triumph of Communists in China in 1949 brought the end of Catholic missionary activity and proscriptions against native Catholic practices. Postwar Japan saw Catholicism engulfed by resurgent religions and a new secular spirit.

The Roman Catholic Church in Asia and Africa in the 20th century. *The development of indigenous clergy and native institutions.* Foreseeing some of the 20th-century difficulties, thoughtful Catholics began during the 19th century to argue that Western religions were not able to be appropriated directly and may not long be permitted in many places. Therefore, they began to advocate the development of indigenous clergy. The resultant native institutions often blended some elements of local cultures, but seldom were fusions of distinctive elements of Asian or African religion with Christian doctrine consciously permitted.

Conflicts and relations with national governments. If the recent centuries represented much promise for Catholicism's self-definition as a universal church, they also meant setbacks. Christians of the West had often exploited the developing nations, looted their resources, enslaved or demeaned their populations, and extirpated their religions and cultures. As colonial yokes were thrown off, new nations in quest of their own identities encouraged the renewal of the non-Christian religions that had long been part of their cultures. The Western Catholic could serve as a bogey. Overt anti-Christianity of most Marxist or Communist parties in these countries meant a rolling back of Catholicism.

The new world consciousness of Roman Catholicism. The second Vatican Council also saw the definition of more positive views of non-Catholic high religions, a fact that served somewhat to diminish the impulse to convert the whole world to explicit faith in Christ and obedience to Rome. Catholicism engaged in internal reforms that suggested a new responsiveness to revolutionary social situations. At least minor new local adaptations in Asian and African churches were permitted, and Western imperial pride was specifically condemned by modern popes. Although the dominating and conversionist impulses do not seem to have wholly died, nevertheless, in the majority of the world's nations Catholics have shown themselves more ready than ever before to be brothers to adherents of other religions and to have a new regard for secular human development. (M.E.M.)

Effectsof the second Vatican Council

BIBLIOGRAPHY

The Latin Church in the West (1000–1517): The only large-scale work covering the whole period (except for the century 1274–1378) is AUGUSTIN FLICHE and VICTOR MARTIN (eds.), *Histoire de l'Église depuis les origines jusqu'à nos jours*, vol. 8–10, 12–14 (1946–64). An earlier classic is ALBERT HAUCK, *Kirchengeschichte Deutschlands* (1887–1920), which covers most of continental Europe. Neither of these has been translated into English. There are useful chapters in *The Cambridge Medieval History*, vol. 5–7 (1929–32). HORACE K. MANN, *The Lives of the Popes in the Early Middle Ages*, 18 vol. (1902–32), is narrow in scope. The only history of medium size is DAVID KNOWLES, *The Christian Centuries*, vol. 2, *The Middle Ages* (1969), with bibliography. For a perceptive introduction, see RICHARD W. SOUTHERN, *The Making of the Middle Ages* (1953). GEOFFREY BARRACLOUGH, *Mediaeval Germany*, 911–1250, 2 vol. (1961), is the only adequate work in English. See also R.W. and A.J. CARLYLE, *A History of Mediaeval Political Theory in the West*, 3rd ed., vol. 3–5 (1938–50). ETIENNE GILSON, *History of Christian Philosophy in the Middle Ages* (1955), is a masterly summary with full bibliography to date; DAVID KNOWLES, *The Monastic Order in England*, 2nd ed. (1963), also covers part of Europe. Other recommended studies include: HENRY C. LEA, *The Inquisition of the Middle Ages*, a partial edition with introduction by WALTER ULLMANN (1963); GUILLAUME MOLLAT, *Les Papes d'Avignon, 1305–1378*, 9th ed. (1949; Eng. trans., *The Popes at Avignon*, 1305–1378, 1963); WALTER ULLMANN, *The Growth of Papal Government in the Middle Ages*, 3rd ed. (1970), indispensable, but in parts controversial; and SCHAFER WILLIAMS (ed.), *The Greporian Epoch* (1964), a useful collection of reprinted studies by early and recent authorities.

The late Middle Ages: WILLY ANDREAS, *Deutschland vor*

der Reformation, 6th ed. (1959), a presentation of history and culture at the end of the Middle Ages; GEORGE CLARK (ed.), *The Oxford History of England:* vol. 5, MAY MCKISACK, *The Fourteetzth Century,* 1307–1399 (1959); and vol. 6, E.F. JACOB, *The Fifteenth Century, 1399–1485* (1961); FLICHE-MARTIN, *Histoire de l'Église:* vol. 15, ROGER AUBENAS and ROBERT RICARD, *L'Église et la Renaissance, 1449–1517* (1951); vol. 16, E. DE MOREAU, PIERRE JOURDA, and PIERRE JANELLE, *La Crise religieuse du XVI^e siècle* (1950); and vol. 17, L. CRISTIANI, *L'Église à l'époque du concile de Trente* (1948); GEORGES DE LAGARDE, *La Naissartce de l'esprit laïque, au déclin du Moyen Age,* 3rd ed., vol. 1–5 (1956–63), a study of the lay movement in the Middle Ages; JOSEPH LORTZ, *Geschichte der Kirche in ideengeschichtlicher Betrachtung,* 22nd–23rd ed., 2 vol. (1965; Eng. trans. of 5th–6th ed., *History of the Church,* 1939), the history of the church from the history of ideas point of view; and "Zur Problematik der kirchlichen Missstande im Spat-Mittelalter," in *Trierer Theologische Zeitschrift* (1949), a presentation of the situation of the church in the late Middle Ages; HEIKO AUGUSTINUS OBERMAN, *The Harvest of Medieval Theology: Gabriel Biel and Late Medieval Nominalism,* rev. ed. (1967), a study of the theology of the late Middle Ages in its entirety, with special emphasis on Nominalism; WILLIAM A. PANTIN, *The English Church iiz the Fourteenth Century* (1955); REGNERUS RICHARDUS POST, *The Modern Devotion: Confrontation with Reformatioiz and Humanism* (1968), a history of the Brothers of the Common Life and their confrontation with Humanism and the Reformation; BRIAN TIERNEY, *Foundations of the Conciliar Theory: The Contributions of the Medieval Canonists from Gratian to the Great Schism* (1955), on the conciliar theories.

Roman Catholicism in Europe irt modern times: CONRAD BERGENDOFF, *The Church of the Lutheran Reformation* (1967), a study of Reformation history from its beginnings to the 20th century; INTERNATIONAL COMMITTEE OF HISTORICAL SCIENCES, *Bibliographie de la Réforme,* 1450–1648, vol. 1–7 (1958–70), a reference work for the investigation of the history of the Reformation; *The New Cambridge Modern History:* vol. 1, G.R. POTTER (ed.), *The Renaissance, 1493–*1520 (1957); and vol. 2, GEOFFREY R. ELTON (ed.), *The Reformation,* 1520–1559 (1958), a reference work; ARTHUR G. DICKENS, *Reformation and Society in Sixteenth-Century Europe* (1966), an account of the sociological relationships in the 16th century; GEOFFREY R ELTON, *Refortnation Europe, 1517–1559* (1963); HAROLD JOHN GRIMM, *The Reformation Era,* 1500–1650 (1964; with rev. bibliography, 1965), a study of the Reformation and the Counter-Reformation; HUBERT JEDIN (ed.), *Handbuch der Kirclzengeschichte:* vol. 3, pt. 1, *Die mittelalterliche Kirche* (1966); vol. 3, pt. 2, *Voin kirchlichen Hochmittelalter bis zum Vorabend der Reforznation* (1968); and vol. 4, *Reformation, katholische Reform und Gegenreforrnation* (1967); PHILIP HUGHES, *The Reformation in England,* 3 vol. (1950–54); JOSEPH LORTZ, *Wie Kam es zur Reformation?,* 3rd ed. (1955; Eng. trans., *How the Reformation Came,* 1964), on the causes of the Reformation in England; *Die Reformation als religiöses Anliegen heute* (1948; Eng. trans., *The Reformation:* A *Problem for Today,* 1964), thesis for ecumenical discussions; and *Die Refortization in Deutschland,* 5th ed., 2 vol. (1965; Eng. trans., *The Reformation in Germany,* 2 vol., 1968), standard work on the history of the Reformation; JAROSLAV PELIKAN, *Obedient Rebels: Catholic Substance and Protestant Principle in Luther's Reformation* (1964), an investigation of Luther's thought; SIR MAURICE POWICKE, *The Reformation in England* (1958); GOLO MANN and AUGUST NITSCHKE (eds.), *Propylaen Weltgeschichte,* vol. 7, *Von der Reformation zur Revolution* (1964); KARL SCHOTTENLOHER, *Bibliographie zur deutscken Geschichte im Zeitalter der Glaubensspaltung,* 1571–1585, 2nd ed., 7 vol. (1956–58, 1966), a reference work; HERBERT MAYNARD SMITH, *Henry VIII and tlze Reformation* (1962); GEORGES HUNTSTON WILLIAMS, *The Radical Reformation* (1962), a synoptic presentation of efforts for reform on the part of the "left wing" from the beginning until the end of the 16th century; JOHN D. MACKIE, *The Earlier Tudors, 1485–1558* (1952), textbook for the study of the history of the English Reformation; ERNST WALTER ZEEDEN, *Die Entstehung der Konfessionen* (1965), on the problems of the formation of the confessions of faith at the time of the development of different denominations; and *Das Zeitalter der Gegenreformation* (1967) covers the battle for the reorganization of the Roman Church.

Roman Catholicism outside Europe in modern times: The standard work on church history is KARL BIHLMEYER and HERMANN TUCHLE, *Kirchengeschichte,* 17th ed., 3 vol. (1951–62; Eng. trans., *Church History,* 3 vol., 1958–66). The documents of Roman Catholicism are conveniently assembled in HEINRICH J. DENZINGER, *Enchiridion symbolorum,* 33rd ed. (1965). ROLAND H. BAINTON, *The Horizort History of Christianity* (1964), is a well-written, beautifully illustrated, comprehensive introduction to Western Christianity through the centuries and includes references to modern worldwide Catholicism. Much more extensive and valuable, especially because of the excellent bibliographical clues it provides, is KENNETH SCOTT LATOURETTE, *Christianity in a Revolutiortary Age: A History of Christianity in the Nineteenth and Twentieth Centuries,* 5 vol. (1958–62). Volumes 1, 3, and 5 concentrate on Roman Catholic themes. The author was an advocate of the worldwide missionary activities of the church, and a bias in favour of Christian expansion colours his work. AUGUST FRANZEN and JOHN P. DOLAN, *Kleine Kirchengeschichte,* 2nd ed. (1968; Eng. trans., *A History of the Church,* 1969), is a convenient brief introduction that includes some modern materials. E.E.Y. HALES, *The Catholic Chrrrch in the Modern World* (1958), concentrates on the European and American settings. A number of works dealing with Catholicism outside that orbit fall into the category of histories of colonialism or missions. First to be noted are two works by STEPHEN C. NEILL: *Colonialism and Christian Missions* (1966) and *A History of Christian Missions* (1964). Though Neill is non-Catholic, he provides brief and generally fair comments on Catholic ventures. A much more conservative Protestant bias is measurable in the standard work by ROBERT HALL GLOVER, *The Progress of World-Wide Missions,* rev. ed. (1960). ROBERT L. DELAVIGNETTE, *Christianisme et colonialisme* (1960; Eng. trans., *Christianity and Colonialism,* 1964), is written by a Catholic and concentrates on Catholic experience, but in too brief a scope. Two works that make aspects of the American Catholic experience readily available to readers are JOHN TRACY ELLIS, *American Catholicism,* 2nd ed. rev. (1969); and the somewhat less adequate THEODORE MAYNARD, *The Story of American Catholicism,* 2 vol. (1960).

Romance (Literature)

The subject of this article is medieval romance as it was developed in western Europe from the 12th century onward. It contains a brief history of romance as a literary form, of its extension and influence throughout western Europe up to and after the Renaissance, and of its re-emergence in the 18th century.

The Old French word *romanz* originally meant "the speech of the people," or "the vulgar tongue," in contrast with the written form of literary Latin. Its meaning then shifted from the language in which the work was written to the work itself. Thus, an adaptation of Geoffrey of Monmouth's *Historia regum Britanniae* (*c.* 1137), made by Wace of Jersey in 1155, was known as *Li Romanz de Brut,* while an anonymous adaptation (of slightly later date) of Virgil's *Aeneid* was known as Li *Romanz d'Enéas;* it is difficult to tell whether in such cases *li romanz* still meant "the French version" or had already come to mean "the story." It soon specialized in the latter sense, however, and was applied to narrative compositions similar in character to those imitated from Latin sources but totally different in origin; and, as the nature of these compositions changed, the word itself acquired an increasingly wide spectrum of meanings. In modern French a *roman* is just a novel, whatever its content and structure; while in modern English the word "romance" (derived from Old French *romanz)* can mean either a medieval narrative composition or a love affair, or, again, a story about a love affair, generally one of a rather idyllic or idealized type, sometimes marked by strange or unexpected incidents and developments; and "to romance" has come to mean "to make up a story that has no connection with reality."

For a proper understanding of these changes it is essential to know something of the history of the literary form to which, since the Middle Ages, the term has been applied. The account that follows is intended to elucidate historically some of the ways in which the word is used in English and in other European languages.

THE COMPONENT ELEMENTS

The romances of love, chivalry, and adventure produced in 12th-century France have analogues elsewhere, notably in what are sometimes known as the Greek romances — narrative works in prose by Greek writers from the 1st century BC to the 3rd century AD. The first known, the

Greek romances

fragmentary Ninus romance, in telling the story of the love of Ninus, mythical founder of Nineveh, anticipates the medieval *roman d'antiquite'*. A number of works by writers of the 2nd and 3rd centuries AD—Chariton, Xenophon of Ephesus, Heliodorus, Achilles Tatius, and Longus—introduce a theme that was to reappear in the *roman d'aventure:* that of faithful lovers parted by accident or design and reunited only after numerous adventures. Direct connection, however, can be proved only in the case of the tale of *Apollonius of Tyre*, presumably deriving from a lost Greek original but known through a 3rd- or 4th-century Latin version. This too is a story of separation, adventure, and reunion, and, like the others (except for Longus' pastoral *Daphnis and Chloë*), it has a quasi-historical setting. It became one of the most popular and widespread stories in European literature during the Middle Ages and later and provided Shakespeare with the theme of *Pericles.*

Romance style and subject matter. But the real debt of 12th-century romance to classical antiquity was incurred in a sphere outside that of subject matter. During the present century, scholars have laid ever-increasing emphasis on the impact of late classical antiquity upon the culture of medieval Europe, especially on that of medieval France. In particular, it is necessary to note the place that rhetoric (the systematic study of oratory) had assumed in the educational system of the late Roman Empire. Originally conceived as part of the training for public speaking, essential for the lawyer and politician, it had by this time become a literary exercise, the art of adorning or expanding a set theme: combined with grammar and enshrined in the educational system inherited by the Christian Church, rhetoric became an important factor in the birth of romance. Twelfth-century romance was, at the outset, the creation of "clerks"—professional writers who had been trained in grammar (that is to say, the study of the Latin language and the interpretation of Latin authors) and in rhetoric in the cathedral schools. They were skilled in the art of exposition, by which a subject matter was not only developed systematically but also given such meaning as the author thought appropriate. The "romance style" was, apparently, first used by the authors of three *romans d'antiquité*, all composed in the period 1150–65: *Roman de Thebes*, an adaptation of the epic *Thebaïs* by the late Latin poet Statius; *Roman d' Enéas,* adapted from Virgil's *Aeneid;* and *Roman de Troie,* a retelling by Benoît de Sainte-Maure of the tale of Troy, based not on Homer (who was not known in western Europe, where Greek was not normally read) but on 4th- and 5th-century Latin versions. In all three, style and subject matter are closely interconnected; elaborate set descriptions, in which the various features of what is described are gone through, item by item, and eulogized, result in the action's taking place in lavish surroundings, resplendent with gold, silver, marble, fine textiles, and precious stones. To these embellishments are added astonishing works of architecture and quaint technological marvels, that recall the Seven Wonders of the World and the reputed glories of Byzantium. *Troie* and *Enéas* have, moreover, a strong love interest, inspired by the Roman poet Ovid's conception of love as a restless malady. This concept produced the first portrayal in Western literature of the doubts, hesitations, and self-torment of young lovers, as exemplified in the Achilles–Polyxena story in *Troie* and in the Aeneas–Lavinia story in *Enéas.* Yet even more important is the way in which this new theme is introduced: the rhetorical devices appropriate to expounding an argument are here employed to allow a character in love to explore his own feelings, to describe his attitude to the loved one, and to explain whatever action he is about to take.

Earliest works in the "romance style"

Developing psychological awareness. As W.P. Ker, a pioneer in the study of medieval epic and romance, observed in his *Epic and Romance* (1897), the advent of romance is "something as momentous and as far-reaching as that to which the name Renaissance is generally applied." The Old French poets who composed the chansons de geste (as the Old French epics are called) had been content to tell a story; they were concerned with statement, not with motivation, and their characters could act without explicitly justifying their actions. Thus, in what is one of the earliest and certainly the finest of the chansons de geste, the *Chanson de Roland* (c. 1100), the hero's decision to fight on against odds—to let the rear guard of Charlemagne's army be destroyed by the Saracen hordes in the hopeless and heroic Battle of Roncesvalles rather than sound his horn to call back Charlemagne—is not treated as a matter for discussion and analysis: the anonymous poet seems to take it for granted that the reader is not primarily concerned with the reason why things happened as they did. The new techniques of elucidating and elaborating material, developed by romance writers in the 12th century, produced a method whereby actions, motives, states of mind, were scrutinized and debated. The story of how Troilus fell in love with Briseïs and how, when taken to the Grecian camp, she deserted him for Diomedes (as related, and presumably invented, by Benoît de Sainte-Maure in his *Roman de Troie)* is not one of marvellous adventures in some exotic fairyland setting: it is clearly a theme of considerable psychological interest, and it was for this reason that it attracted three of the greatest writers of all time: Boccaccio in his *Filostrato* (*c.* 1338), Chaucer in his *Troilus and Criseyde* (before 1385), and Shakespeare in his *Troilus and Cressida* (*c.* 1601–02). With the 12th-century pioneers of what came to be called romance, the beginnings of the analytical method found in the modern novel can easily be recognized.

The development of more sophisticated techniques

Sources and parallels. Where exactly medieval romance writers found their material when they were not simply copying classical or pseudo-classical models is still a highly controversial issue. Parallels to certain famous stories, such as that of Tristan and Iseult, have been found in regions as wide apart as Persia and Ireland: in the mid-11th-century Persian epic of *Wis and Ramin* and in the Old Irish *Diarmaid and Grainne;* but while in the latter case it is possible to argue in favour of a genetic link between the two traditions, the former is more likely to be a case of parallel development due, on the one hand, to the inner logic of the theme and, on the other, to certain similarities in the ideological and social background of the two works. Failure to maintain the essential distinction between source and parallel has greatly hindered the understanding of the true nature of medieval romance and has led to the production of a vast critical literature the relevance of which to the study of the genre is at best questionable.

The marvellous as a romance element. The marvellous is by no means an essential ingredient of "romance" in the sense in which it has been defined. Yet to most English readers the term romance does carry implications of the wonderful, the miraculous, the exaggerated, and the wholly ideal. Ker regarded much of the literature of the Middle Ages as "romantic" in this sense—the only types of narrative free from such "romanticizing" tendencies being the historical and family narrative, or Icelanders' sagas developed in classical Icelandic literature at the end of the 12th and in the early 13th century. The *Chanson de Roland* indulges freely *in* the fantastic and the unreal: hence Charlemagne's patriarchal age and preternatural strength (he is more than 200 years old when he conquers Spain); or the colossal numbers of those slain by the French; or, again, the monstrous races of men following the Saracen banners. Pious legends, saints' lives, and stories of such apocryphal adventures as those of the Irish St. Brendan (*c.* 486–578) who, as hero of a legend first written down in the 9th-century, *Navigatio Brendani,* and later widely translated and adapted, wanders among strange islands on his way to the earthly paradise—these likewise favour the marvellous. The great 12th-century *Roman d'Alexandre*, a *roman d'antiquite'* based on and developing the early Greek romance of Alexander the Great (the Alexander romance), was begun in the first years of the century by Alberic de Briançon and later continued by other poets. It introduces fantastic elements, more especially technological wonders and the marvels of India: the springs of rejuvenation, the flower-maidens growing in a forest, the cynocephali (dog-headed men), the bathyscaphe that takes Alexander to the bottom of the ocean, and the car in which he is drawn through the air by griffins on his celestial journey.

The setting. The fact that so many medieval romances are set in distant times and remote places is not an essential feature of romance but rather a reflection of its origins. As has been seen, the Old French word ***romanz*** early came to mean "historical work in the vernacular." All the ***romans d'antiquité*** have a historical or pseudohistorical theme, whether they evoke Greece, Troy or the legendary world of Alexander; but while making some attempt to give antiquity an exotic aspect by means of marvels or technological wonders, medieval writers were quite unable to create a convincing historical setting; and thus in all important matters of social life and organization they projected the western European world of the 12th century back into the past. Similarly, historical and contemporary geography were not kept separate. The result is often a confused jumble, as, for example, in the Anglo-Norman Hue de Rotelande's ***Protesilaus,*** in which the characters have Greek names; the action takes place in Burgundy, Crete, Calabria, and Apulia; and Theseus is described as "king of Denmark." This lavish use of exotic personal and geographical names and a certain irresponsibility about settings was still to be found in some of Shakespeare's romantic comedies: the "seacoast of Bohemia" in ***The Winter's Tale*** is thoroughly medieval in its antecedents. For in the medieval period, myth and folktale and straightforward fact were on an equal footing. Not that any marvel or preternatural happening taking place in secular (as opposed to biblical) history was necessarily to be believed: it was simply that the remote times and regions were convenient locations for picturesque and marvellous incidents. It is, indeed, at precisely this point that the transition begins from the concept of romance as "past history in the vernacular" to that of "a wholly fictitious story."

Errors of history and geography in early romance

THE MEDIEVAL VERSE ROMANCES

Arthurian romance. ***The matter of Britain.*** In his ***Historia regum Britanniae,*** Geoffrey of Monmouth "invented history" by drawing on classical authors, the Bible, and Celtic tradition to create the story of a British kingdom, to some extent paralleling that of Israel. He described the rise of the British people to glory in the reigns of Uther Pendragon and Arthur, then the decline and final destruction of the kingdom, with the exile of the British survivors and their last king, Cadwalader. Romances that have Arthur or some of his knights as main characters were classified as ***matikre de Bretagrte*** by Jehan Bodel (flourished 1200) in a well-known poem. There is in this "matter of Britain" a certain amount of material ultimately based on the belief, probably Celtic in origin, in an otherworld into which humans can penetrate, where they can challenge those who inhabit it, or enjoy the love of fairy women. Such themes appear in a highly rationalized form in the lays (*lais*) of the late 12th-century Marie de France, although she mentions Arthur and his queen only in one, the lay of ***Lanval.***

Chre'tien de Troyes. But it was Chrktien de Troyes (flourished 1165–80) who in five romances ***(Erec; Cligès; Lancelot, ou Le Chevalier de la charrette; Yvain ou Le Chevalier au lion;*** and ***Perceval ou li Conte du Graal)*** fashioned a new type of narrative based on the matter of Britain. The internal debate and self-analysis of the ***roman d'antiquite'*** is here used with great artistry. At times, what seems to matter most to the poet is not the plot but the thematic pattern he imposes upon it and the significance he succeeds in conveying, either in individual scenes in which the action is interpreted by the characters in long monologues or through the work as a whole. In addition to this, he attempts what he himself calls a ***conjointure—that*** is, the organization into a coherent whole of a series of episodes. The adventures begin and end at the court of King Arthur; but the marvels that bring together material from a number of sources are not always meant to be believed, especially as they are somehow dovetailed into the normal incidents of life at a feudal court. Whatever Chrétien's intentions may have been, he inaugurated what may be called a Latin tradition of romance—clear, hard, bright, adorned with rhetoric, in which neither the courtly sentiment nor the enchantments are seriously meant. Chrktien had only one faithful follower, the trouvère Raoul de Houdenc (flourished 1200–30), author of ***Méraugis de Portlesguez.*** He shared Chrétien's taste for love casuistry, rhetorical adornment, and fantastic adventure. For both of these authors elements of rhetoric and self-analysis remain important, although the dose of rhetoric varies from one romance to another. Even in Chrktien's ***Perceval ou Li Conte du Graal*** ("Perceval, or the Romance of the Grail")—the work in which the Grail appears for the first time in European literature—the stress is on narrative incident interspersed with predictions of future happenings and retrospective explanations. Arthurian romances of the period 1170–1250 are ***romans d'aventure,*** exploiting the element of the strange, the supernatural, and the magical in the Arthurian tradition. A number (for example, La ***Mule sans frein*** ["The Mule Without a Bridle"], ***c.*** 1200; ***L'Âtre périlleux*** ["The Perilous Churchyard"], ***c.*** 1250) have as their hero Arthur's nephew Gawain, who, in the earlier Arthurian verse romances, is a type of the ideal knight.

Introduction of the Grail theme into European literature

Love as a major theme in romance. The treatment of love varies greatly from one romance to another. It is helpful to distinguish sharply here between two kinds of theme: the one, whether borrowed from classical antiquity (such as the story of Hero and Leander, or that of Pyramus and Thisbe, taken from Ovid's ***Metamorphoses)*** or of much more recent origin, ending tragically; the other ending with marriage, reconciliation, or the reunion of separated lovers. It is noteworthy that "romance," as applied to a love affair in real life, has in modern English the connotation of a happy ending. This is also true of most Old French love romances in verse: the tragic ending is rare and is usually linked with the theme of the lover who, finding his or her partner dead, joins the beloved in death, either by suicide or from grief.

The Tristan story. The greatest tragic love story found as a romance theme is that of Tristan and Iseult. It was given the form in which it has become known to succeeding generations in about 1150–60 by an otherwise unknown Old French poet whose work, although lost, can be reconstructed in its essentials from surviving early versions based upon it. Probably closest in spirit to the original is the fragmentary version of c. 1170–90 by the Norman poet Béroul. From this it can be inferred that the archetypal poem told the story of an all-absorbing passion caused by a magic potion, a passion stronger than death, yet unable to triumph over the feudal order to which the heroes belong. The story ended with Iseult's death in the embrace of her dying lover and with the symbol of two trees growing from the graves of the lovers and intertwining their branches so closely that they could never be separated. Most later versions, including a courtly version by an Anglo-Norman poet known only as Thomas, attempt to resolve the tragic conflict in favour of the sovereignty of passion and to turn the magic potion into a mere symbol. Gottfried von Strassburg's German version, ***Tristan und Isolde (c. 1210),*** based on Thomas, is one of the great courtly romances of the Middle Ages; but although love is set up as the supreme value and as the object of the lovers' worship, the mellifluous and limpid verse translates the story into the idyllic mode. Another tragic and somewhat unreal story is that told in the anonymous ***Chastelaine de Vergi (c. 1250),*** one of the gems of medieval poetry, in which the heroine dies of grief because, under pressure, her lover has revealed their secret and adulterous love to the duke of Burgundy. The latter tells it to his own wife, who allows the heroine to think that her lover has betrayed her. The theme of the dead lover's heart served up by the jealous husband to the lady—tragic, sophisticated, and far-fetched—appears in the anonymous ***Chastelain de Couci (c. 1280),*** and again in ***Daz Herzmaere*** by the late 13th-century German poet Konrad von Wiirzburg. The theme of the outwitting of the jealous husband, common in the fabliaux (short verse tales containing realistic, even coarse detail, and written to amuse), is frequently found in 13th-century romance

Later versions of the Tristan and Iseult theme and in lighter lyric verse. It occurs both in the *Chastelain de Couci* and in the Provencal romance. *Flamenca (c.* 1234), in which it is treated comically.

The theme of separation anti reunion. But the theme that has left the deepest impress on romance is that of a happy resolution, after many trials and manifold dangers, of lovers' difficulties. As has been seen, this theme was derived from late classical Greek romance by way of *Apollonius of Tyre* and its numerous translations and variants. A somewhat similar theme, used for pious edification, is that of the legendary St. Eustace, reputedly a high officer under the Roman emperor Trajan, who lost his position, propel-ty, and family only to regain them after many tribulations, trials, and dangers. The St. Eustace theme appears in *Guillaume d'Angleterre*, a pious tale rather than a romance proper, which some have attributed to Chrétien de Troyes.

The Floire and Blanche-flor romance

A variant on the theme of separation and reunion is found in the romance of *Floire et Blancheflor* (*c.* 1170), in which Floire, son of the Saracen "king" of Spain, is parted by his parents from Blancheflor. daughter of a Christian slave of noble birth, who is sold to foreign slave dealers. He traces her to a tower where maidens destined for the sultan's harem are kept, and the two are reunited when he gains access to her there by hiding in a basket of flowers. This romance was translated into Middle High German, Middle Dutch, Norse, and Middle English (as *Floris and Blancheflur*, *c.* 1250) and in the early 13th century was imitated in *Aucassin et Nicolette*, which is a *chantefable* (a story told in alternating sections of sung verse and recited prose) thought by some critics to share a common source with *Floire et Blancheflor*. In it, the roles and nationality, or religion, of the main characters are reversed; Nicolette, a Saracen slave converted to Christianity, who proves to be daughter of the king of Carthage, disguises herself as a minstrel in order to return to Aucassin, son of Count Gavin of Beaucaire. Jean Renart's *L'Escoufle* (c. 1200–02) uses the theme of lovers who, accidentally separated while fleeing together from the emperor's court, are eventually reunited; and the highly esteemed and influential *Guillaume de Palerne* (*c.* 1200) combines the theme of escaping lovers with that of the "grateful animal" (here a werewolf, which later resumes human shape as a king's son) assisting the lovers in their successful flight. The popular *Partenopeus de Blois* (*c.* 1180), of which ten French manuscripts and many translated versions are known, resembles the Cupid and Psyche story told in the Roman writer Apuleius' *Golden Ass* (2nd century AD), although there is probably no direct connection. In the early 13th-century *Galeran de Bretagne*, Galeran loves Fresne, a foundling brought up in a convent; the correspondence between the two is discovered, and Fresue is sent away but appears in Galeran's land just in time to prevent him from marrying her twin sister, Fleurie.

The theme of a knight who undertakes adventures to prove to his lady that he is worthy of her love is represented by a variety of romances including the *Ipomedon* (1174–90) of Hue de Rotelande and the anonymous mid-13th-century Anglo-Norman *Gui de Warewic*. Finally, there are many examples of the "persecuted heroine" theme; in one variety a person having knowledge of some "corporal sign"—a birthmark or mole—on a lady wagers with her husband that he will seduce her and offer proof that he has done so (this is sometimes called the "Imogen theme" from its use in Shakespeare's *Cymbeline*). The deceit is finally exposed and the lady's honour vindicated. In the early 13th-century *Guillaume de Dôle by* Jean Renart, the birthmark is a rose; and in the *Roman de Violette*, written after 1225 by Gerbert de Montreuil. it is a violet. Philippe de Beaumanoir's *La Manekine* (*c.* 1270), Jean Maillart's *La Contesse d'Anjou* (1361), and Chaucer's *Man of Law's Tale* (after 1387) all treat the theme of the tribulations of a wife falsely accused and banished but, after many adventures, reunited with her husband.

The "Imogen theme"

THE MEDIEVAL PROSE ROMANCES

Arthurian themes. The Arthurian prose romances arose out of the attempt, made first by Robert de Borron in the verse romances *Joseph d'Arimathie, ou le Roman de l'estoire dou Graal* and *Merlin* (c. 1190–1200), to combine the fictional history of the Holy Grail with the chronicle of the reign of King Arthur. Robert gave his story an allegorical meaning, related to the person and work of Christ. A severe condemnation of secular chivalry and courtly love characterize the Grail branch of the prose Lancelot-Grail, or Vulgate, cycle as well as some parts of the post-Vulgate "romance of the Grail" (after 1225); in the one case, Lancelot (here representing fallen human nature) and, in the other, Balain (who strikes the Dolor.. ous Stroke) are contrasted with Galahad, a type of the Redeemer. The conflict between earthly chivalry and the demands of religion is absent from the *Perlesvaus* (after 1230?), in which the hero Perlesvaus (that is, Perceval) has Christological overtones and in which the task of knighthood is to uphold and advance Christianity. A 13th-century prose *Tristan* (*Tristan de Léonois*), fundamentally an adaptation of the Tristan story to an Arthurian setting, complicates the love theme of the original with the theme of a love rivalry between Tristan and the converted Saracen Palamède and represents the action as a conflict between the treacherous villain King Mark and the "good" knight Tristan.

The ideals of chivalry

In the 14th century, when chivalry enjoyed a new vogue as a social ideal and the great orders of secular chivalry were founded, the romance writers, to judge from what is known of the voluminous *Perceforest* (written *c.* 1330 and still unpublished in its entirety), evolved an acceptable compromise between the knight's duty to his king, to his lady, and to God. Chivalry as an exalted ideal of conduct finds its highest expression in the anonymous Middle English *Sir Gawayne and the Grene Knight* (*c.* 1370), whose fantastic beheading scene (presumably taken from a lost French prose romance source) is made to illustrate the fidelity to the pledged word, the trust in God, and the unshakable courage that should characterize the knight.

The special structure of the Lancelot-Grail romance

Structure of the prose romances. The Vulgate *Lancelot-Grail* cycle displays a peculiar technique of interweaving that enables the author (or authors) to bring together a large number of originally independent themes. The story of Lancelot. of Arthur's kingdom, and the coming of Galahad (Lancelot's son) are all interconnected by the device of episodes that diverge, subdivide, join, and separate again, so that the work is a kind of interlocking whole, devoid of unity in the modern sense but forming as impregnable a structure as any revolving around a single centre. One of its most important features is its capacity for absorbing contrasting themes, such as the story of Lancelot's love for Guinevere. Arthur's queen, and the Quest of the Grail; another feature is its ability to grow through continuations or elaborations of earlier themes insufficiently developed. The great proliferation of prose romances at the end of the Middle Ages would have been impossible without this peculiarity of structure. Unlike any work that is wholly true to the Aristotelian principle of indivisibility and isolation (or organic unity), the prose romances satisfy the first condition, but not the second: internal cohesion goes with a tendency to seek connections with other similar compositions and to absorb an increasingly vast number of new themes. Thus the prose *Tristan* brings together the stories of Tristan and Iseult, the rise and fall of Arthur's kingdom, and the Grail Quest. It early gave rise to an offshoot, the romance of *Palamède* (before 1240), which deals with the older generation of Arthur's knights. A similar example of "extension backward" is the *Perceforest*, which associates the beginnings of knighthood in Britain with both Brutus the Trojan (reputedly Aeneas' grandson and the legendary founder of Britain) and Alexander the Great and makes its hero, Perceforest, live long before the Christian era.

LATER DEVELOPMENTS

The Arthurian prose romances were influential in both Italy and Spain; and this favoured the development in these countries of works best described as *romans d'aventure*, with their constantly growing interest in tournaments, enchantments, single combat between knights, love intrigues, and rambling adventures. In Italy, early prose compilations of Old French epic material from the Charlemagne cycle were subsequently assimilated to the other great bodies of medieval French narrative fiction and infused with the spirit of Arthurian prose romance. The great Italian heroic and romantic epics, Matteo Boiardo's *Orlando innamorato* (1483) and Ludovico Ariosto's *Orlando furioso* (1516), are based on this fusion. The serious themes of the Holy Grail and death of Arthur left no mark in Italy. The romantic idealism of Boiardo and Ariosto exploits instead the worldly adventures and the love sentiment of Arthurian prose romance, recounted lightly and with a sophisticated humour.

The Spanish romance

In Spain the significant development is the appearance, as early as the 14th, or even the 13th, century, of a native prose romance, the *Amadís de Gaula.* Arthurian in spirit but not in setting and with a freely invented episodic content, this work, in the form given to it by Garci Rodriguez de Montalvo in its first known edition of 1508, captured the imagination of the polite society of western Europe by its blend of heroic and incredible feats of arms and tender sentiment and by its exaltation of an idealized and refined concept of chivalry. Quickly translated and adapted into French, Italian, Dutch, and English and followed by numerous sequels and imitations in Spanish and Portuguese, it remained influential for more than four centuries, greatly affecting the outlook and sensibility of western society. Cervantes parodied the fashion inspired by *Amadís* in *Don Quixote* (1605); but his admiration for the work itself caused him to introduce many of its features into his own masterpiece, so that the spirit and the character of chivalric romance may be said to have entered into the first great modern novel.

Parallels with sculpture and painting

More important still for the development of the novel form was the use made by romance writers of the technique of multiple thematic structure and "interweaving" earlier mentioned. Like the great examples of Romanesque ornamental art, both sculptural and pictorial, the cyclic romances of the late Middle Ages, while showing a strong sense of cohesion, bear no trace whatever of the classical concept of subordination to a single theme: an excellent proof, if proof were needed, of the limited relevance of this concept in literary aesthetics. Even those romances which, like the *Amadís* and its ancestor, the French prose *Lancelot*, had one great figure as the centre of action, cannot be said to have progressed in any way toward the notion of the unity of theme.

The spread and popularity of romance literature. This is as true of medieval romances as of their descendants, including the French and the English 18th-century novel and the pastoral romance, which, at the time of the Renaissance, revived the classical traditions of pastoral poetry and led to the appearance, in 1504, of the *Arcadiu* by the Italian poet Jacopo Sannazzaro and, in about 1559, of the *Diana* by the Spanish poet and novelist Jorge de Montemayor. Both works were widely influential in translation, and each has claims to be regarded as the first pastoral romance, but in spirit *Diana* is the true inheritor of the romance tradition, giving it, in alliance with the pastoral, a new impetus and direction.

The social milieu

Medieval romance began in the 12th century when clerks, working for aristocratic patrons, often ladies of royal birth such as Eleanor of Aquitaine and her daughters, Marie de Champagne and Matilda, wife of Henry the Lion, duke of Saxony, began to write for a leisured and refined society. Like the courtly lyric, romance was a vehicle of a new aristocratic culture which, based in France, spread to other parts of western Europe. Translations and adaptations of French romances appear early in German: the *Roman d'Enéas*, in a version written by Heinrich von Veldeke before 1186, and the archetypal Tristan romance in Eilhart von Oberge's *Tristant* of *c.* 1170–80. In England many French romances were adapted, sometimes very freely, into English verse and prose from the late 13th to the 15th century; but by far the most important English contribution to the development and popularization of romance was the adaptation of a number of French Arthurian romances completed by Sir Thomas Malory in 1469–70 and published in 1485 by William Caxton under the title of *Le Morte Darthur*. In the Scandinavian countries the connection with the Angevin rulers of England led to importation of French romances in the reign (1217–63) of Haakon of Norway.

The decline of romance. As has been seen, in the later Middle Ages the prose romances were influential in France, Italy, and Spain, as well as in England; and the advent of the printed book made them available to a still wider audience. But although they continued in vogue into the 16th century, with the spread of the ideals of the New Learning, the greater range and depth of vernacular literature, and the rise of the neoclassical critics, the essentially medieval image of the perfect knight was bound to change into that of the scholar-courtier, who, as presented by the Italian Baldassare Castiglione in his *Il Cortegiano* (published 1528), embodies the highest moral ideals of the Renaissance. The new Spanish romances continued to enjoy international popularity until well into the 17th century and in France gave rise to compendious sentimental romances with an adventurous, pastoral, or pseudo-historical colouring popular with Parisian *salon* society until *c.* 1660. But the French intellectual climate, especially after the beginning of the so-called classical period in the 1660s, was unfavourable to the success of romance as a "noble" genre. Before disappearing, however, the romances lent the French form of their name to such *romans* as Antoine Furetière's *Le Roman bourgeois* (1666) and Paul Scarron's *Le Romant comique* (1651–57). These preserved something of the outward form of romance but little of its spirit; and while they transmitted the name to the kind of narrative fiction that succeeded them, they were in no sense intermediaries between its old and its new connotations. The great critical issue dominating the thought of western Europe from about 1660 onward was that of "truth" in literature; and romance, as being "unnatural" and unreasonable, was condemned. Only in England and Germany did it find a home with poets and novelists. Thus, while Robert Boyle, the natural philosopher, in his *Occasional Discourses* (1666) was inveighing against gentlemen whose libraries contained nothing more substantial than "romances," Milton, in *Paradise Lost,* could still invoke "what resounds/In fable or romance of Uther's son . . ."

The search for "truth" in literature

The 18th-century romantic revival. The 18th century in both England and Germany saw a strong reaction against the rationalistic canons of French classicism—a reaction that found its positive conterpart in such romantic material as had survived from medieval times. The Gothic romances, of which Horace Walpole's *Castle of Otrunto* (1764; dated 1765) is the most famous, are perhaps of less importance than the ideas underlying the defense of romance by Richard Hurd in his *Letters on Chivalry and Romance* (1762). To Hurd, romance is not truth but a delightful and necessary holiday from common sense. This definition of romance (to which both Ariosto and Chrétien de Troyes would no doubt have subscribed) inspired on the one hand the romantic epic *Oberon* (1780) and on the other the historical romances of Sir Walter Scott. But influential though Scott's romantic novels may have been in every corner of Europe (including the Latin countries), it was the German and English Romantics who, with a richer theory of the imagination than Hurd's, were able to recapture something of the spirit and the structure of romance—the German Romantics by turning to their own medieval past; the English, by turning to the tradition perpetuated by Edmund Spenser and Shakespeare.

BIBLIOGRAPHY. Among older works the most notable are RICHARD HURD, *Letters on Chivalry and Romance* (1764); GEORGE ELLIS, *Specimens of Early English Metrical Romances,* 3 vol. (1805); and SIR WALTER SCOTT, "Essay on Romance" in the Supplement to the 1815–24 edition of the *Encyclopædia Britannica.* The academic study of romance as a form of imaginative narrative may be said to have begun in 1897 with the publication of W.P. KER, *Epic and Romance* (2nd ed. 1908, reprinted 1957), and of GEORGE SAINTSBURY, *The Flourishing of Romance and the Rise of Allegory.* It was soon continued in innumerable monographs and editions of texts, a full list of which would fill a volume. Most of the

critical works on romance fall into one of two major categories: studies of origins and sources and works on the nature and development of the genre. The former group includes such works as EDMOND FARAL, *Recherches sur les sources latines des contes et romans courtois du moyen âge* (1913); JESSIE L. WESTON, *From Ritual to Romance* (1920, reprinted 1957); ROGER S. LOOMIS, *Arthurian Tradition and Chrétien de Troyes* (1949); and JEAN MARX, *La Légende arthurienne et le Graal* (1952); the study of the genre, in addition to monographs on individual works and authors such as Chrétien de Troyes, Guillaume de Lorris, *Sir Gawain and the Green Knight,* and Sir Thomas Malory, is represented in recent years by FANNI BOGDANOW, *The Romance of the Grail* (1966); EUGENE VINAVER, *The Rise of Romance* (1971); by chapters on romance in ERICH AUERBACH, *Mimesis* (1946; 2nd ed., 1959; Eng. trans., 1953); and ROSEMOND TUVE, *Allegorical Imagery* (1966). J.D. BRUCE, *The Evolution of Arthurian Romance,* 2nd ed., *2* vol. (1928), at one time the standard work in this field, has now been largely superseded by R.S. LOOMIS (ed.), *Arthurian Literature in the Middle Ages: A Collaborative History* (1959). Since 1949 the International Arthurian Society has been publishing an annual *Bibliographical Bulletin* covering the whole range of Arthurian literature in all languages.

(E.Vi./F.Wh.)

Romance Languages

The Roman origins of Romance

The Romance languages, all derived from Latin within historical times, form a subgroup of the Italic branch of the Indo-European language family (see also ITALIC LANGUAGES). The major languages of the family include French, Italian, Spanish, Portuguese, and Romanian; among the Romance languages that now have less political or literary significance or both are the Occitan and Rhaetian dialects, Catalan, Sardinian, and Dalmatian (extinct), among others. Of all the so-called families of languages, the Romance group is perhaps the simplest to identify and the easiest to account for historically. Not only do Romance languages share a good proportion of basic vocabulary—still recognizably the same in spite of some phonological changes—and a number of similar grammatical forms, but they can be traced back, with but few breaks in continuity, to the language of the Roman Empire. So close is the similarity of each of the Romance languages to Latin as currently known from a rich literature and continuous religious and scholarly tradition that virtually no one doubts the relationship. For the layman, the testimony of history is even more convincing than the linguistic evidence; Roman occupation of Italy, the Iberian Peninsula, Gaul, and the Balkans accounts for the "Roman" character of the major Romance languages. Later colonial and commercial contacts with parts of the Americas, of Africa, and of Asia readily explain the French, Spanish, and Portuguese still spoken in those regions.

The name Romance indeed suggests the ultimate connection of these languages with Rome: the English word is derived from a French form of Latin Romanicus, used in the Middle Ages to designate a vernacular type of Latin speech (as distinct from the more learned form used by clerics) as well as literature written in the vernacular. The fact that the Romance languages share features not found in contemporary Latin textbooks suggests, however, that the version of Latin they continue is not identical with that of Classical Latin as known from literature. Nonetheless, although it is sometimes claimed that the other Italic languages (the Indo-European language group to which Latin belonged, spoken in Italy) did contribute features to Romance, it is fairly certain that it is specifically Latin itself, perhaps in a popular form, that is the precursor of the Romance languages.

Distribution of the Romance languages

Nearly 400,000,000 people today claim a Romance language as their mother tongue. To this number may be added the not-inconsiderable number of Romance creole speakers (a creole is a simplified or pidgin form of a language that has become the native language of a community) scattered around the world. French creoles are spoken in the West Indies (with perhaps 5,000,000 speakers), in North America (*e.g.,* Louisiana), and islands of the Indian Ocean (*e.g.,* Mauritius, Réunion, the Seychelles); Portuguese creoles in Africa, India, and Malaysia (perhaps 500,000 speakers); and Spanish creoles in the West Indies (about 200,000 speak Papiamento) and the Philippines. Many speakers use creole for informal purposes and the standard language for formal occasions. Romance languages are also used formally in some countries where one or more non-Romance languages are used by most speakers for everyday purposes. French, *e.g.,* is used alongside Arabic in Tunisia, Morocco, and Algeria; it is the official language of some 20 countries in West and Equatorial Africa and of the Malagasy Republic (Madagascar). Portuguese is the official language of Angola, Mozambique, and Portuguese Guinea; Italian, alongside English, is an official language in Somalia.

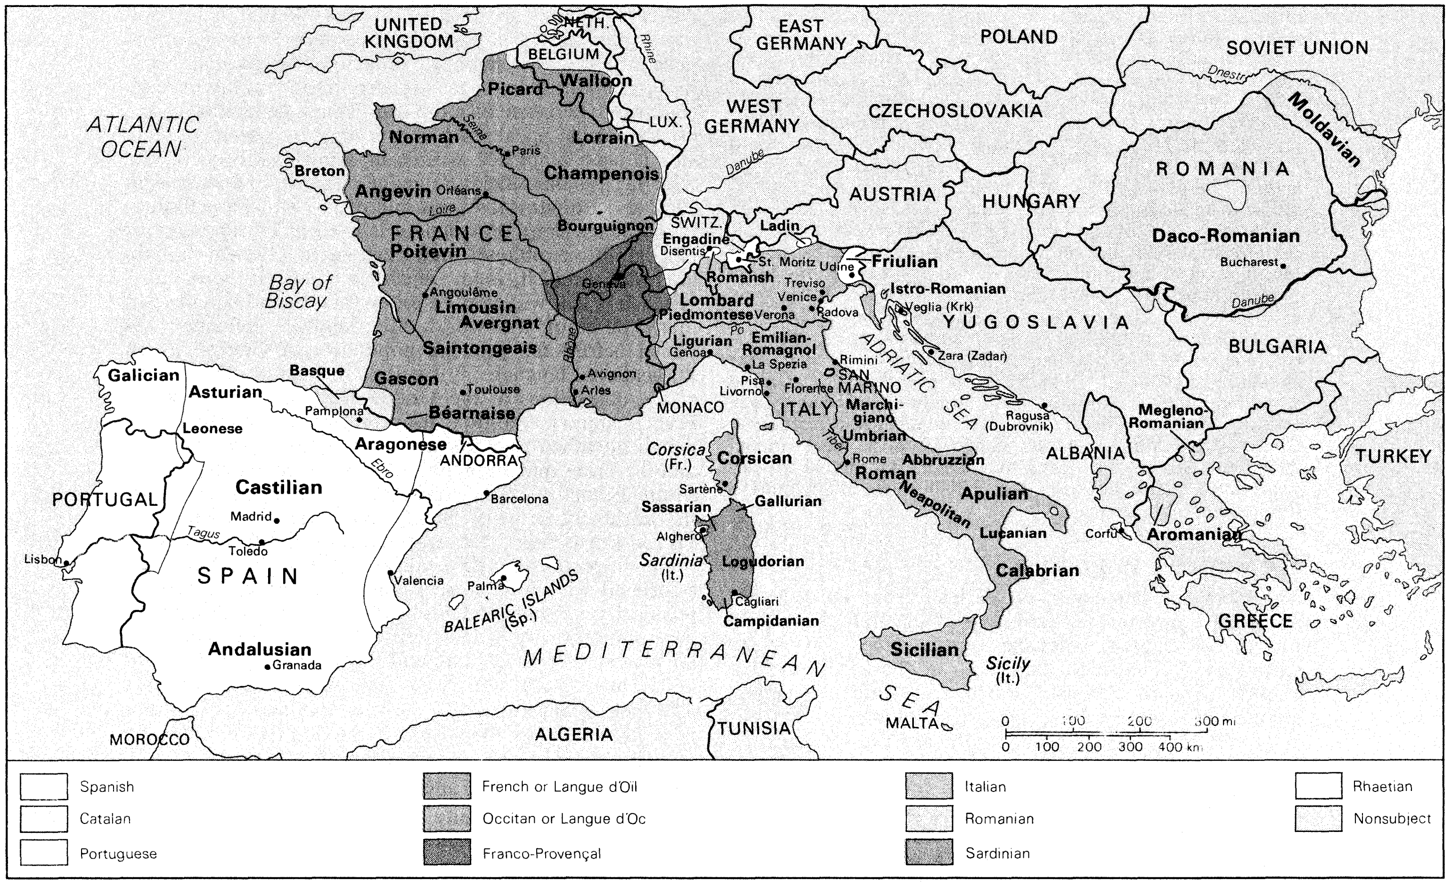
French is still widely used today as a second language in many parts of the world. Although its influence has waned before the growing popularity of English as an international language, it is still used by more than a third of the delegations at the United Nations; the wealth of French literary tradition, its precisely formulated grammar bequeathed by 17th- and 18th-century grammarians, and the pride that Frenchmen feel in their language may ensure French a lasting importance among languages of the world. By virtue of the vast territories in which Spanish and Portuguese hold sway, they will continue to be of prime importance. The beauty of the Italian language, associated with Italy's great cultural heritage, assures its popularity among students, even though territorially it has comparatively little extension. Some lesser Romance languages, such as Catalan and Romanian, retain their vitality, but others, with very few monolingual speakers left, such as Sardinian and the Rhaetian and Occitan dialects, are surely doomed to the extinction that has already overtaken a number of Romance tongues.

This article is divided into the following sections:

I. Languages of the family

Distinguishing languages and dialects

What constitutes a language, as distinct from a dialect, is a vexing question, and opinion varies on just how many Romance languages are spoken today: estimates range between five and 11. The political definition of a language—one that is accepted as standard by a nation or people—is the least ambiguous one; according to this definition, French, Spanish, Portuguese, Italian, and Romanian are certainly languages and possibly also Romansh (a national language of Switzerland since 1938 but probably related to other Rhaetian dialects spoken in



Distribution of Romance languages in Europe.

Italy) and Catalan (the official language of Andorra but also widely used in parts of Spain and France). On linguistic grounds Sardinian (not the language of an independent nation since the 14th century) and Occitan (the medieval Provençal) are usually regarded as languages rather than dialects, though in modern times Occitan has grown so near to French as to be intelligible to French speakers with comparative ease. The Rhaetian dialects of Italy (Ladin in the Dolomites and Friulian around Udine) are usually regarded as non-Italian. Sicilian is different enough from northern and central Italian dialects to be given separate status often, but in Italy all neighbouring dialects are mutually intelligible, with differences becoming more marked with geographical distance. Franco-Provençal (the name given to a group of dialects spoken around the Alpine region of France and Italy) is often also assumed to be a different language from both French and Occitan, though some think it is merely a transitional dialect. Only a few persons know it in France today, though it still survives in the Italian Valle d'Aosta (where French, rather than Italian, remains the language of culture).

Judeo-Spanish

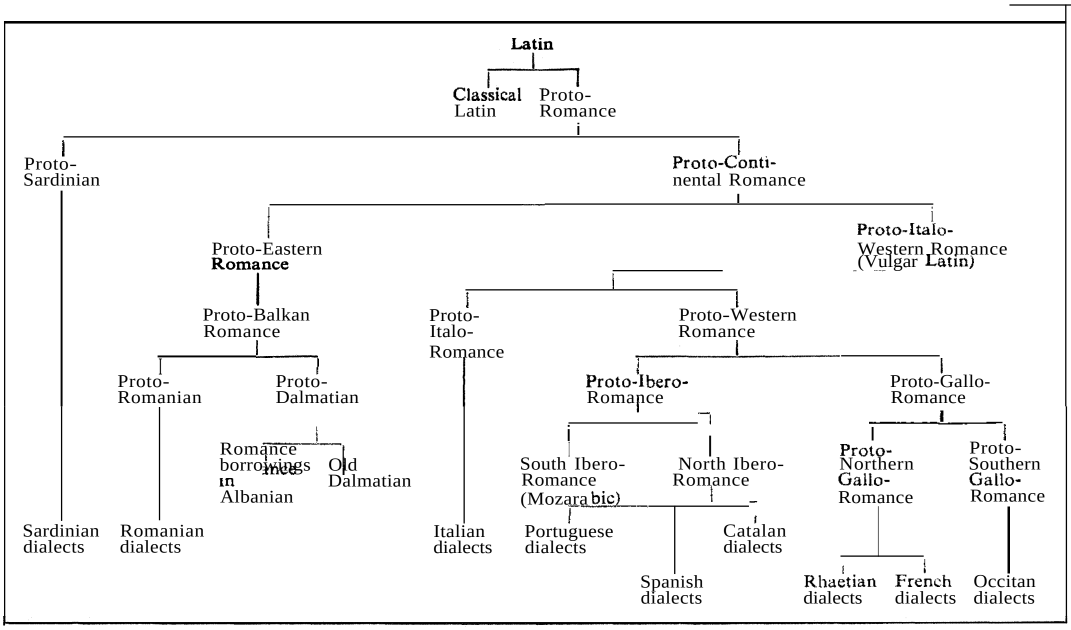
Judeo-Spanish is normally regarded not as an independent language but as an archaic form of Spanish preserving many features of the Castilian of the 15th century, when the Jews were expelled from Spain. There are possibly about 200,000 speakers, mostly originating in the Balkans and Asia Minor but, since World War II, scattered around the world; about 20,000 speakers now reside in Israel, and a significant number live in New York City and Buenos Aires.

Some linguists believe that creoles are often different languages from their metropolitan counterparts; Haitian, for instance, is said to be mutually unintelligible with French. Intelligibility varies so much with the speaker and the hearer, however, that it is difficult to formulate firm criteria on this basis.

The Dalmatian dialect

Many Romance dialects have virtually ceased to be spoken in the last century. Of these, Dalmatian is the most striking, its last known speaker, one Antonio Udina, having been blown up by a land mine in 1898. He was the main source of knowledge for his parents' dialect (that of the island of Veglia, or Krk), though he was hardly an ideal informant; Vegliot Dalmatian was not his native language, and he had learned it only from listening to his parents' private conversations. Moreover, he had not spoken the language for 20 years at the time he acted as an informant, and he was deaf and toothless as well. Most of the other evidence for Dalmatian derives from documents from Zara (modern Zadar) and Ragusa (modern Dubrovnik) dating from the 13th to 16th centuries. It is possible that, apart from isolated pockets, the language was then replaced by Croatian and, to a lesser extent, by Venetian (a dialect of Italian). It is certain, even from scanty evidence, that Dalmatian was a language in its own right, noticeably different from other Romance languages and presenting difficulties of classification.

On the Istrian Peninsula of the Yugoslav mainland close to the island of Veglia, another Romance language precariously survives (5,000 speakers); known as Istriot, it may be related to Vegliot, though some scholars dispute this and connect it with Rhaetian Friulan dialects or with Venetian dialects of Italian; others maintain that it is an independent language. There are no texts except those collected by linguists. A little further north in the same peninsula, another Romance dialect, Istrio-Romanian, is threatened with extinction (2,000 speakers). Usually classified as a Romanian dialect, it may have been carried to the Istrian Peninsula by Romanians taking refuge from the Turks in the 16th and 17th centuries and has undergone strong Croatian influence. There is evidence for its existence from a short list of words in a 1698 historical wofk, but it is otherwise unwritten. Another isolated Romanian dialect that may be nearing extinction is Megleno-Romanian, from a mountainous region of Macedonia, just west of the Vardar River, on the border between Yugoslavia and Greece. In 1914 there were 13,000 speakers, but many have emigrated to Asia Minor, Yugoslavia, and Romania, where small pockets survive. The only texts are those transcribed from oral traditions.



From R.A. Hall Jr., *Introductory Linguistics*; originally published by Chilton Books, now distributed by Rand McNally & Co.

Other Romance tongues earlier ceased to be spoken; there is evidence, for instance, of a form of Spanish spoken in Arab-occupied Spain until shortly after its liberation by the Spanish, accomplished at the end of the 15th century. Usually known as Mozarabic, from the Arabic word for an "Arabized person," or as *ʿajamī* "barbarian language," it was originally the spoken language of the urban bourgeoisie, who remained Christian while the peasantry generally converted to Islām, but it appears that many Arabs also came to use it, even though Arabic remained the only written language. Because most of the evidence, apart from a 15th-century glossary from Granada, is written in Arabic script (which uses no vowel signs), it is difficult to reconstruct the phonology of the language, but it appears to be a very conservative Spanish dialect. Much of modern information about Mozarabic comes from medical and botanical works that give Mozarabic terms alongside the Arabic. To this was added recently the discovery of Romance refrains (*kharjahs*) inserted in Arabic love ballads (*muwashshaḥs*) of the 11th and 12th centuries; study of these began only in 1946. For much of the Muslim period (beginning in 711), Christians were treated tolerantly and became culturally Arabized. Even after persecution by fanatical Muslim newcomers in the 12th century, the Mozarabs were often in conflict with Westernized "liberators" from the north. Their language died out soon after the Arabs were driven out of Spain at the end of the 15th century, though it is sometimes claimed that Mozarabic has left its mark on the dialects of southern Spain and Portugal.

Mozarabic

Other Romance languages may have developed in peripheral regions of the Roman Empire only to die out under pressure from neighbouring non-Italic languages. Often these extinct Romance dialects are known from words borrowed into surviving languages; Berber, for instance, bears witness to the long and brilliant Roman period in North Africa that was to end in the 7th century AD with Arab invasions, and British Celtic (especially Welsh) retains many traces of what appears to have been a conservative Romance dialect, completely eliminated by Anglo-Saxon in about the 5th century. Albanian has so many Romance words that some style it "semi-Romance," and farther north, in what was formerly the Roman province of Pannonia (modern northwestern Yugoslavia and western Hungary), Romance speech was probably not dead at the time of the Magyar invasion at the end of the 10th century. Thus, there is reason to believe that Romance dialects may have been spoken at one time over much of southeastern Europe. It is also evident that Romance languages have been retreating south before German for some time, and it is probable that Romance tongues were used in the whole of Switzerland and parts of Bavaria and Austria until about the 9th century. Some scholars maintain that the modern Rhaetian dialects of Switzerland and northern Italy are remnants of an earlier Germano-Romance speech form.

CLASSIFICATION METHODS AND PROBLEMS

Though it is quite clear which languages can be classified as Romance, on the basis primarily of lexical (vocabulary) and morphological (structural) similarities, the subgrouping of the languages within the family is less straightforward. Most classifications are, overtly or covertly, historico-geographical—so that Spanish, Portuguese, and Catalan are Ibero-Romance, French, Occitan, and Franco-Provençal are Gallo-Romance, and so on. Shared features in each subgroup that are not seen in other such groups are assumed to be ultimately traceable to languages spoken before Romanization. The first subdivision of the Romance area is usually into West and East Romance, with a dividing line drawn across Italy between La Spezia and Rimini. On the basis of a few heterogeneous phonetic features, one theory maintains that separation into dialects began early, with the Eastern dialect areas (including central and south Italy) developing popular features and the school-influenced Western speech areas maintaining more literary standards. Beyond this, the substrata (indigenous languages eventually displaced by Latin) and superstrata (languages later superimposed on Latin by conquerors) are held to have occasioned further subdivisions. Within such a schema there remain problem cases. (1) Is Catalan, for instance, Ibero-Romance or Gallo-Romance, given that its medieval literary language was close to Provençal? (2) Do the Rhaetian dialects group together, even though the dialects found in Italy are closer to Italian and the Swiss ones closer to French? Sardinian is generally regarded as linguistically separate, its isolation from the rest of the Roman Empire by incorporation into the Vandal kingdom in about 455 providing historical support for the thesis. The exact position of Dalmatian in any classification is open to dispute.

Systems for classifying the Romance languages

A family-tree classification is a commonly used method of classifying the Romance languages. If, however, historical treatment of one phonetic feature is taken as a classificatory criterion for construction of a tree, results differ. Classified according to the historical development of stressed vowels, French would be grouped with North Italian and Dalmatian but not with Occitan, while Central Italian would be isolated. Classifications that are not based on family trees usually involve ranking languages according to degree of differentiation rather than grouping them; thus, if the Romance languages are compared with Latin, it is seen that by most measures Sardinian and Italian are least differentiated and French most (though in vocabulary Romanian has changed most). By most nonhistorical measures, standard Italian is a "central" language (*i.e.*, it is quite close and often readily intelligible to all other Romance languages), whereas French and Romanian are peripheral (they lack similarity to other Romance languages) and require more effort if other Romance speakers are to understand them. Spanish and Portuguese are even today so close in most respects that they can be regarded from a linguistic point of view as dialects of the same language, even though structural criteria would assign them to different broad classes.

Extent of mutual intelligibility

In general, it is possible to maintain that all of the standard Romance languages are to some extent mutually intelligible (especially in their Latin-based written forms) and that they have become more so during the course of history, because of much borrowing from one another and remodelling on Latin, the religious language of most speakers. In 19th-century Romania, for instance, national pride prompted a turning toward other Romance cultures, especially the French, in order more clearly to differentiate Romania from neighbouring Slavic countries, with the consequence that Romanian has become "more Romance" in vocabulary if nowhere else. Local dialects in all the countries are less affected by such converging movements, but even here encroachment on the local dialect by the standard form of the language leads to the ironing out of dialect peculiarities, often ending with the loss of the local dialect, replaced by a regional variety of the standard dialect; this process is particularly evident in southern France, much less so in Italy.

MINOR LANGUAGES

Occitan. Occitan is the modern name given by linguists to the group of dialects spoken by some 12,000,000–14,000,000 people in the south of France (or about one-fourth of the whole French population). All Occitan speakers now use French as their official and cultural language, but their local dialects remain lively and, across most of the area, remarkably homogeneous. The name Occitan derives from the name of the area Occitanie (formed on the model of Aquitania). The medieval language is often called langue d'oc (from the word for "yes," compared with langue d'oïl, Northern French, and with the *si* languages, Spanish and Italian). In the area itself, the names Lemosi (Limousin) and Proensal (Provençal) were formerly used, but today these are often considered too localized to designate the whole range of dialects. Members of a vigorous literary movement in the Provence region, however, still prefer to call their language Provençal.

Occitan was rich in poetic literature in the Middle Ages until the north crushed political power in the south (1208–29). The standard language was, however, well established and did not really succumb before French until the 16th century, while only after the French Revolution did the French language penetrate into popular use in place of Occitan. In the mid-19th century, a literary Renaissance led by the Félibres (from an old word meaning "wisemen"), based on the dialect of the Arles–Avignon region, lent new lustre to Occitan, and a modern standard dialect was established. The most famous figure of this movement was a Nobel Prize-winning poet, Frédéric Mistral. Almost contemporaneously, a similar movement, based in Toulouse, arose and concentrated on problems of linguistic and orthographic standardization to provide a wider base for literary endeavour.

The Occitan dialects have changed comparatively little since the Middle Ages, though now French is influencing them more and more. Perhaps this influence has helped them to remain more or less mutually intelligible. The main dialect areas are Limousin, in the northwest comer of the Occitan area; Auvergnat, in the north central region of this area; northeastern Alpine-Provençal; and Languedocian and Provençal, on the west and east of the Mediterranean seacoast, respectively.

Gascon and Franco-Provençal

Gascon, in the southwest of France, is usually classified as an Occitan dialect, though to most other southerners it is today less readily comprehensible than Catalan. Some scholars claim that it has always been distinct from Occitan, because of the influence of a non-Celtic Aquitanian pre-Roman population. The Roman name of the region, Vasconia (from which the name Gascony derives), suggests the relationship of its original population with the non-Indo-European Basques. Although poets from this region used the Occitan literary language during the Middle Ages, there is evidence that their spoken language was noticeably different (the 14th century *Leys **d'amor*** calls it *lengatge estranh* "strange language"). Some of the region remained politically independent for a long period (the Kingdom of Béarn, which used its own standardized dialect as an official language, was not incorporated into France until 1620), and popular use of French is evident only from about 1700. Documents in the dialect are few, however; they date from about the 12th century.

Northeast of the Occitan region, along the French, Swiss, and Italian frontiers, is located a group of dialects that historically have shared most vowel developments with languages to the south and many consonant changes with those to the north. For the last 100 years claims have been made for the linguistic autonomy of these dialects, usually called Franco-Provençal; today it is estimated that somewhat fewer than 2,000,000 speakers use them (urban speakers are hard to find, and even in the countryside young speakers are few). Dialects are extremely diversified and heavily influenced by French, which has been used extensively in the area since the 13th century. Even during the Middle Ages there was no standard form of Franco-Provençal, though some 12th–13th-century documents exist. The dialect of Geneva (now extinct except in some rural communes) was the official language of the Swiss republic for some time, but otherwise none of the dialects has had official status. Some claim that a section of a manuscript, the so-called Alexander fragment, dating from the 1lth–12th century and apparently part of a lost poem, is Franco-Provençal in character, but others maintain that it, like other literary texts from the region, is mainly Provençal with some French features. Since the 16th century, there has been local dialect literature, notably in Savoy, Fribourg, and Geneva.

Catalan. Currently spoken by about 4,800,000 people in Spain and 200,000 in France (in Roussillon), as well as by 10,000 in Andorra and 12,000 in Alghero (Sardinia), Catalan has lost little of its former lustre, even though it is no longer an important national language (as it was between 1137 and 1749, as the official language of Aragon). Although in the Middle Ages there is no evidence of dialectalization, perhaps because of the standardizing influence of its official use in the Kingdom of Aragon, since the 16th century the dialects of Valencia and the Balearic Isles, especially, have tended to differentiate from the Central (Barcelona) dialect. Nevertheless, some degree of uniformity is preserved in the literary language, which continues to flourish in spite of the little encouragement received from Madrid since the Spanish Civil War. Although there were no publications of any sort in Catalan between 1939 and 1941, and only 12 titles were published in 1946, in 1968 the number of titles published had reached 520.

Historic use of Catalan

The earliest surviving written materials in Catalan date from the 12th century (a charter and six sermons), with poetry flourishing from the 13th century, before which time Catalan poets wrote in Provençal. The first true Catalan poet was Ramon Llull (1235–1315), and the language remained vigorous (its greatest poet was Ausiàs March, 1397–1459, a Valencian) until the union of the Aragonese and Castilian crowns in 1474 marked the beginning of its decline. After that, although mainly grammatical works appeared, the language was to wait for its renaissance until the late 19th century. In 1906 the first Catalan Language Congress attracted 3,000 participants, and in 1907 the Institut d'Estudis Catalans was founded. Yet not until 1944 was there a course in Catalan philology at the University of Barcelona; a chair of Catalan language and literature was not founded there until 1961.

It is much disputed whether Catalan is more closely related to Occitan or to the Hispanic languages. Medieval Catalan was so close to Lemosi, the literary dialect of Occitan in southern France, that it is thought by some to have been imported from beyond the Pyrenees in the resettlement of refugees from the Moors. In more modern times, Catalan has, however, grown closer to Aragonese and Castilian, so that its family-tree classification becomes less relevant. It mas occasionally called Llemosi by 19th-century Catalan revivalists, however, who wished to emphasize its independence from other Iberian tongues by stressing its relation to Occitan. Certainly, by most standards, Catalan merits the distinction of being deemed a language in its own right, and it shows little sign of decline.

Historical extent of Sardinian

Sardinian. Sardinian is currently spoken by more than 1,000,000 people, but it has many dialect differences, and there is virtually no literature, nor even a newspaper in the language (although satirical journals do appear from time to time). In earlier times the language was probably spoken in Corsica, where a Genoese dialect of Italian is now used (although French has been Corsica's official language for two centuries). Since the early 18th century Sardinia's destiny has been linked with that of the Italian mainland, and Italian is now the official language. From the 14th century till the 17th century, Catalan (at that time the official language of Aragon, which ruled Sardinia) was used extensively, especially for official purposes; a Catalan dialect is still spoken in Alghero. Castilian began to be used in official documents in 1600 but did not supplant Catalan in the south of the island until later in the 17th century. Sardinia was more or less independent from 1016, when Arab occupation was ended, until the arrival of the Aragonese in 1322, though much influenced by the Genoese and Pisans. The first documents in Sardinian are legal contracts dating from about 1080; in the north of the island Sardinian was used for such documents until the 17th century. The main dialect groupings are Logudorian (Logudorese), the central, most conservative dialect, which appears to have been used throughout the island in earlier times and which (in a northern form) provides the basis for a *sardo illustre* (a conventionalized literary language used mainly for folk-based verse); Campidanian (Campidanese), centred around Cagliari in the south, heavily influenced by Catalan and Italian; Sassarian (Sassarese) in the northwest; and Gallurian (Gallurese) in the northeast. It is sometimes said that these last two are not Sardinian dialects but rather Corsican. Gallurian in particular is related to the dialect of Sartène in Corsica, and it may have been imported into the Gallura region in the 17th and 18th centuries by refugees from vendetta feuds.

Sardinian is unintelligible to most Italians and, with its harsh consonants and hammered accent, gives an acoustic impression more similar to Spanish than Italian. It is clearly and energetically articulated but has always been regarded as barbarous by the soft-speaking Italians; Dante, for instance, said that Sardinians were like monkeys imitating men. It retains its vitality as a "home language," but dialect diversification is such that it has little chance of development to greater prominence. Perhaps the development of the island as a tourist centre, with better communications with the mainland, will lead to the eventual decline of the language.

Rhaetian. The Rhaetian, or Rhaeto-Romanic, dialects derive their conventional name from the ancient Raetics of the Adige area, who, according to classical authors, spoke an Etruscan dialect. In fact, there is nothing to connect Raetic with Rhaetian except geographical location, and some scholars would deny that the different Rhaetian dialects have much in common, though others claim that they are remnants of a once-widespread Germano-Romance tongue. Three isolated regions still use Rhaetian.

Romansh and other Swiss dialects of Rhaetian

In Switzerland, where in 1960 some 49,800 speakers (about 1 percent of the population) spoke one or another Rhaetian dialect, Romansh (Rumantsch), the standard dialect of Grisons canton, has been a "national" language, used for cantonal but not federal purposes, since 1938. The proportion of Rhaetian speakers in Grisons fell from 39.8 percent in 1880 to 26 percent in 1960, with a corresponding increase in the Italian-speaking population, but interest in Romansh remains keen, and there are five Romansh newspapers. The main Romansh dialects are usually known as Sursilvan (or Surselvan) and Sutsilvan (or Subsilvan), spoken on the western and eastern banks of the Rhine, respectively. Another important Swiss Rhaetian dialect, Engadine, is spoken in the Protestant Inn Valley, east of which there is now a German-speaking area that has encroached on former Romance territory since the 16th century. The dialects from the extreme east and west of the Swiss Rhaetian area are mutually intelligible only with difficulty, though each dialect is intelligible to its neighbour. Sursilvan (spoken around the town of Disentis) has one text dating from the beginning of the 12th century but then nothing else until the work of Gian Travers (1483–1563), a Protestant writer. The Upper Engadine dialect (spoken around Samedan and Sankt Moritz) is attested from the 16th century, notably with the Swiss Lutheran Jacob Bifrun's translation of the New Testament. Both dialects have had a flourishing local literature since the 19th century. In many ways the Swiss Rhaetian dialects resemble French, and speakers seem to feel more at home with French than with Italian.

Ladin and Friulian

In the Alto-Adige and Dolomites area of Italy, between 12,000 and 20,000 persons speak a language they call Ladin. Some Italian scholars have claimed that it is really an Italian (Veneto-Lombard) dialect. German is the other main language spoken in this now semi-autonomous region, much of which was Austrian until 1919. Though it is sometimes said that Ladin is threatened with extinction, it appears to retain its vitality among the mountain peasantry, as distinct from German-speaking hotel owners. Ladin newspapers are on sale in village shops, and speakers welcome visitors (there mainly to ski or climb) who show interest in their language, which is comprehensible without too much difficulty to a student of Romance languages. As it appears that these remote valleys were very sparsely populated until recently, it may even be that the number of speakers there has in fact grown. Since World War II, Ladin has been taught in primary schools in the Gardena and Badia valleys, in different conventionalized dialect forms. Although a Ladin document of the 14th century (from Val Venosta, to the west of the modern Ladin region) is known from references, the earliest written materials in Ladin currently possessed dates from the 18th century, a word list of the Badia dialect. In more recent times there have been a few literary and religious texts.

In Italy, north of Venice, stretching to the Yugoslav border on the east and to the Austrian border on the north, its western boundary almost reaching the River Piave, is the Friulian (Friulan, Frioulian) dialect area, centred around Udine, with 500,000 speakers. This dialect is much closer to Italian than Ladin or Romansh, and it is often claimed to be a Venetian dialect. Venetian proper has gained ground at the expense of Friulian both to the east and west since the 1800s. Friulian retains its vitality today in the well-populated, industrialized region, however, and supports a vigorous local literature; its most notable poet was Pieri Zorut (1792–1867). The first text in Friulian (apart from a doubtful 12th-century inscription) is a short one dating from about 1300, followed by numerous documents in prose, as well as some poems, up to the end of the 16th century, when a rich poetic tradition began.

Creoles. The French, Spanish, and Portuguese creoles, together with their metropolitan equivalents, share many things in common. Indeed, some scholars regard them as in some sense related, either in sharing an African grammatical base, with a superimposed Romance lexicon, or in historical derivation from a Portuguese pidgin lingua franca used by colonizers and slavers. with later addition of vocabulary from metropolitan languages, such as French and Spanish, with which they came into contact. Other scholars maintain that the creoles are continuators of French, Spanish, and Portuguese in the same way as these are themselves continuators of Latin but that, under the conditions that attended the slave trade, linguistic change was exceptionally rapid, so that the origins of the creoles are often hardly recognizable.

Origin of the term creole

"Creole" is a word first found in Spanish (*criollo;* 1590), meaning a Spaniard born in the colonies or his black household servant. It most probably originated in Portuguese, in which it is related to such words as *criança* "child" and criada "maid-servant," generally indicating a household dependent, although the word *crioulo* is not known until 1632. Today, "creole" has come to indicate a pidgin or trade language that has become the mother tongue of a population, often black; the conditions under which this has happened have included forcible transplantation and intermingling of people with mutually unintelligible native languages and imposition of the master's language, during the slave-trade era.

Of Romance creoles used today, French creoles are most widespread. In Haiti, for instance, there are 3,000,000–4,000,000 creole speakers, of whom only about 10 percent know French; the island of Santo Domingo (Hispaniola), of which the eastern half forms the Haitian Republic, was settled in 1665. The Lesser Antilles (Martinique, Guadeloupe, Dominica, St. Lucia, St. Kitts, etc.) were colonized in 1635, and many still use French creoles, even when change of ownership led to the imposition of English as the official language. French creoles are also used in Cayenne (French Guiana) and, though dying out, in Louisiana. In all, probably 5,000,000 speakers use French creoles in the Americas. On islands of the Indian Ocean, too, French creoles are spoken; in Mauritius (population 160,000), owned by France from 1715 to 1810, the creole retains its hold as a lingua franca even though English is the official language and though the majority of the population use Indian dialects as home languages. In the Seychelles (population 40,000), owned by France from 1768 until 1814, when they became British, and in Réunion (originally L'Île Bourbon; population 300,000), where French is still the official language, French creoles are still in use. Some French-creole speakers claim that creoles from other far-off regions are easily intelligible to them. Others contest this, however, pointing out that the creole used by educated speakers is often heavily larded with standard French on all but very informal occasions. Certainly, the linguist can easily discern similarities, especially in grammatical structure, that make the various French creoles seem more like each other than like standard French.

Portuguese creoles were purportedly once widely used in Asia, though probably more frequently as trade languages than as mother tongues. They survive today in Macau and Hong Kong and to some extent in Malaysia and Goa. In Africa a Portuguese creole is used by about 200,000 people in Portuguese Guinea, Senegal, the Cape Verde Islands, and some Gulf of Guinea islands (Annobón and Principe, where it is losing ground to Spanish, and São Tomé, a previously uninhabited island settled in 1485, where, of the 64,000 inhabitants, just over 28,000 speak creoles). In South America a Brazilian creole is still used in the interior, although at one time this language was more widespread in the country (spreading even to Surinam, where Portuguese Jews and their slaves fled from Brazil in the 17th century).

Papiamento

Papiamento, spoken by 200,000 people in the Dutch Caribbean islands of Aruba, Curaçao, and Bonaire, is today classed as a Spanish creole, though some claim that it was once a Portuguese creole that later acquired many new words from Spanish. A Spanish creole also survives precariously in the Philippines among descendants of mixed Spanish–Filipino stock.

On the whole, creoles are rarely used for literature, except satirical and comic pieces. Most speakers regard them as "bad" versions of the standard language and in formal situations try to improve their usage on the model of the standard, though they admit to feeling more relaxed speaking natural creole. Sometimes "purer" creole speech can be heard among speakers not as much exposed to the standard form of the language, as in West Indian islands where English is the official language, while a French creole is the home language.

MAJOR LANGUAGES

French. Probably the most internationally important of the Romance languages, French is used as the official language in 21 countries and as a co-official language in several more (including Algeria, Belgium, Canada, Luxembourg, Switzerland, Jersey). In France and Corsica about 47,000,000 use it as their first language; in Canada, 5,000,000; in Belgium, 4,000,000; in Switzerland (cantons of Neuchâtel, Vaud, Genève, Valais, Fribourg), more than 1,000,000; in Monaco, 20,500; in the Italian Valle d'Aosta, 100,000; and, in the United States (especially Maine and Louisiana), nearly 1,500,000. Moreover, about 5,000,000 Africans and 4,000,000 Indo-Chinese use it as their principal international language; many creole French speakers, too, use standard French in formal situations.

Standard French is based on the dialect of Paris (in the so-called Île de France with its Francien dialect), which assumed importance in about the second half of the 12th century; it was basically a north central dialect with some northern features. Before that, other dialects, especially Norman (which developed in Britain as Anglo-Norman, widely used until about the 14th century), and northern dialects, such as Picard, had more prestige, especially in the literary sphere. The Edict of Villers-Cotterêts (1539), however, established Francien as the only official language, as against both Latin and other dialects. From then on, standard French began to smother local dialects, which were officially discouraged until recent times, though the standard language did not spread to popular usage in all regions until well into the 19th century. Dialectal features, still admired and cherished by 16th-century writers, were ridiculed in the 17th and 18th centuries, when the grammar and vocabulary of the modern language were standardized and polished to an unprecedented degree.

Linguistic change in French

Linguistic change was more rapid and more drastic in northern France than it was in other European Romance regions, and influence from Latin was comparatively slight (though borrowing of Latin vocabulary has been great since the 14th century). The influence of the Germanic Frankish invaders is often held to account for exotic features in Old French, such as strong stress accent and abundant use of diphthongs and nasal vowels; but the change in about the 15th century to a more sober (even monotonous) intonation and loss of a stress accent on each word can hardly be attributed to influences from neighbouring languages. The popularity of French as a first foreign language, in spite of numerous pronunciation difficulties for nearly all foreigners, is perhaps as much the result of the precise codification of its grammar, effectuated especially in the 18th century, as of the brilliance of its literature at all periods. Thus. though Italian would be an easier language for them to master, most foreign speakers of Romance languages become acquainted with French at school and often retain an affection and admiration for the language.

The first document apparently written in French purports to date from 842; known as the Strasbourg Oaths, it is a Romance version of an oath sworn by two of Charlemagne's grandsons. Some claim that the text is thinly disguised Latin constructed after the event to look authentic, for political propaganda purposes; others suppose that its Latinizing tendencies reveal the struggle of the scribe with the problems of spelling French as it was spoken at the time. If the language of the Strasbourg Oaths is Northern French, it is difficult to decide what dialect it represents—some say that of Picard, others Franco-Provençal, and so on. The second existing text in Old French is a short sequence of the writings of St. Eulalia, precisely dated (AD 880–882) and localized (Valenciennes); it is definitely Picard in character. Two 10th-century texts (the Passion du Christ and the ***Vie*** de *St.* Ltger) seem to mingle Northern and Southern dialect features, while another (the "Jonas fragment") is obviously from the far north. After that the Norman dialect seems to dominate literature, though here it is probable that the language is better described as a standard language with elimination of gross dialect features. Two manuscript traditions---one from the far north and one from the west—seem to have developed, and it is possible that the intersection of the two produced the Francien dialect that was eventually to reign supreme.

Modern dialects of French

Modern dialects are classified mainly on a geographical basis, and most survive only in the peasant speech. Walloon, a dialect spoken mainly in Belgium, is something of an exception in that it has had a flourishing dialect literature since about 1600. Other dialects are grouped as follows:

Central: Francien, Orléanais, Bourbonnais, Champenois
Northern: Picard, Northern Norman
Eastern: Lorrain, Bourguignon (Burgundian), Franc-Comtois
Western: Norman, Gallo (around the Celtic Breton area), Angevin, Maine
Southwestern: Poitevin, Saintongeais, Angoumois.

Outside France, apart from the creoles, the French of Canada, originally probably of Northwestern dialect type, has developed the most individual features. Although in the 18th century Canadian French was regarded as exceptionally "pure" by metropolitan commentators, it began to diverge from Parisian French as English influences took over from the French after 1760. It is less clearly articulated, with less lip movement and with a more monotonous intonation than standard French; some change in consonantal sounds occurs (t, d shift to *ts, dz*, respectively, and *k* or *g* followed by *i* or *e* become palatalized [pronounced with the tongue touching the hard palate, or roof of the mouth]); nasal vowels tend to lose the nasal element; vocabulary and syntax are heavily anglicized. Though intellectuals turn toward France for cultural inspiration (some university-educated French Canadians may not even know English), the pronunciation and usage of standard French is sometimes derided by French Canadians; this may be because their English compatriots are taught Parisian at school. The French-speaking population of Canada is growing at a relatively fast rate, and at present 82 percent of the population of Quebec Province use French as their normal language. Even today, however, French is not as socially prestigious as English; the activities of the separatist movement are evidence of the feeling of grievance that many French Canadians still have.

Spanish. Spanish, the Romance language spoken as a first language by the most people in the world, is the official language of 18 American countries as well as that of Spain, and, though many South and Central Americans use native Indian languages as their first language, Spanish is spreading and achieving continuing educational progress. Estimated numbers of speakers are as follows (in order of numerical importance): Mexico, 35,000,000; Spain, 23,000,000; Argentina, 16,000,000; Colombia, 13,000,000; Dominican Republic and El Salvador, 3,000,000 each; the United States, Puerto Rico, and Uruguay, 2,500,000 each; Honduras and Bolivia, 2,000,000 each; Nicaragua and Guatemala, 1,500,000 each; Panama, Paraguay, Costa Rica, 1,000,000 each; the Philippines, 500,000. There are also a few hundred thousand Judeo-Spanish speakers and about 100,000 Spanish speakers in Africa.

The dialect spoken by nearly all these speakers is basically Castilian, and indeed Castellano is still the name used for the language in several American countries. In the norrh of Spain two other Spanish dialect groups (Asturo-Leonese and Aragonese) survive but seem doomed to extinction. The dialect of the Northwest (Galician, or Gallego) is properly a Portuguese dialect, and, on the east,,Catalan can be held to be a different language, as noted above. The now-unchallenged ascendancy of Castilian among Spanish dialects is the result of the particular circumstances of the Reconquista (the conquest of Moorish Spain by the Spanish, completed in 1492), with which the language went south. Having established itself in Spain, the Castilian dialect, possibly in its southern, or Andalusian, form, was then exported to the New World during the 16th century.

Standard Castilian is no longer the language of Old Castile, which was already regarded as rustic and archaic in the 15th century, but a modified form developed in Toledo in the 16th and 17th centuries and, more recently, in Madrid. American countries have developed their own standards, differing mainly in phonology (in which they often agree with the southern Spanish dialects) and in vocabulary (in which loanwords from English are more frequent), but differentiation is comparatively slight, and some Americans still regard true Castilian as their model, On the whole, American forms of Spanish are more musical and suave than the harsh Castilian of Madrid, but it is remarkable how little deformation, or creolization, of the language has occurred, even in the mouths of uneducated Indian speakers.

The standard Spanish dialect, Castilian

The first texts in Spanish consist of scattered words glossing two Latin texts of the 10th century, one from Rioja and the other from Castile; the language in the two documents shows few dialect differences. Another document, dating from about 980, seems to be Leonese in character. The Mozarabic verse forms known as *kharjahs* are the next-oldest surviving texts, but by the middle of the 12th century the famous epic poem El *cantar de mio Cid* ("The Song of the Cid") appeared in a language that is basically Castilian. Literary works in Leonese appear till the 14th century and in a conventionalized Aragonese till the 15th century, but Castilian was destined from the first to gain the upper hand, even making an impact on Portuguese, especially in the 15th and early 16th centuries.

Judeo-Spanish (Jewish-Spanish, Sefardi, Ladino) is the continuation of an archaic form of Castilian, reflecting the state of the language before 16th-century standardization. The expulsion of the Jews from the Iberian Peninsula in 1492 affected mainly the humbler classes, with the rich preferring "conversion," but the latter often later chose voluntary exile to settle in England and Holland, where their Sefardic tongue precariously survives as a religious language in a few communities. Earlier refugees fled to the Middle East and, once settled, continued to produce learned works in a literary archaic form of their language, Ladino, written in an adapted Hebrew script. The spoken dialects have differentiated considerably from Ladino, mainly by borrowing from Hebrew and local languages, and, after further dispersion during and after the World War II, these dialects are now threatened with extinction, though Ladino survives with a mainly religious function.

Portuguese. Portuguese owes its importance largely to its position as the language of Brazil, where between 60,000,000 and 70,000,000 people speak it. In Portugal itself there are about 10,000,000 speakers. The Galician (Gallego, Galego) dialect of northwestern Spain is historically a Portuguese dialect, though now much influenced by the standard Castilian Spanish; about 2,000,000 speakers use Galician as their home language. It is estimated that there are also about 1,500,000 Portuguese speakers in Africa (some of whom also use creole) and about 250,000 each in the United States and Goa, with a few thousand in other Portuguese possessions, such as Macau.

Portuguese dialect groups

There are four main Portuguese dialect groups, all mutually intelligible: (1) Northern, or Galician; (2) Central (Beira); (3) Southern (Estremenho, including Lisbon, Alemtejo, and Algarve); and (4) Insular, including the dialects of Madeira and Brazil. Standard Portuguese was developed in the 16th century, basically from the dialects spoken between Lisbon and Coimbra, to the north. Brazilian (Brasileiro) differs in several respects, in syntax as well as phonology and vocabulary, but many writers still use an academic metropolitan standard. A creolized form, once widespread in Brazil, seems now to be dying out. A Jewish Portuguese is attested in 18th-century Amsterdam (Holland) and Livorno (or Leghorn, in Italy), but virtually no trace of this remains today.

Portuguese speakers have little difficulty in understanding and speaking Spanish, in spite of considerable acoustic and grammatical differences between the two languages. In Portugal, however, they often show considerable resentment at being addressed in Spanish, and there are signs of social resistance to this neighbouring tongue, perhaps because Portugal has so frequently had to play a subordinate role to Spain in the course of its history. In the region of northwestern Spain that adjoins Portugal, the Galician dialects lack uniformity and are closer to Spanish. Even in Castile, where standard Spanish (Castilian) originated, Galician was the conventional language of the courtly lyric until about 1400, but it lost ground in the 15th century, and Castilian replaced Galician as the official language of Galicia in 1500. Dialect poetry in Galician has flourished from the 18th century, with an upsurge in the 19th century.

Before the reconquest of Moorish Spain, largely completed in the 13th century, Galician and Portuguese were indistinguishable. The first evidence for the language consists of scattered words in 9th–12th-century Latin texts; continuous documents date from about 1192, the date assigned to an extant property agreement between the children of a well-to-do family from the Minho Valley. Literature began to flourish especially during the 13th and 14th centuries, when the soft Gallego-Portuguese tongue was preferred by courtly lyric poets all over the Iberian peninsula except in the Catalan area. In the 16th century, Portugal's Golden Age, Galician and Portuguese grew further apart, with the consolidation of the standard Portuguese language.

Italian. Italian is currently spoken by over 50,000,000 people, of whom the vast majority live in peninsular Italy (including the Republic of San Marino), with about 5,000,000 more in Sicily and 1,500,000 Italian speakers in Sardinia. France, including Corsica, has about 1,000,000 Italian speakers and Switzerland about 500,000; there are, in addition, about 300,000 in Yugoslavia. For a large, if decreasing, proportion of these speakers, standard Italian is not the language of the home, where dialectal forms are used. Overseas (*e.g.,* in the United States, where it is estimated that there are 3,500,000 Italian speakers; in Argentina, with 1,500,000; and in Brazil, with 500,000), speakers sometimes do not know the standard language and use only dialect forms. A speaker of an Italian dialect, even one as superficially different as Sicilian, can with effort understand standard Italian, however, and can even teach it to himself by such means as listening to radio programs. For most Italians their first contact with the standard language comes in primary school, in which until recently it was the only dialect used; standard Italian is virtually the only dialect of culture in modern Italy, and with immigration from the south to the industrial north it is becoming more and more the language of intercommunication. Standard Italian is used as a cultural language in Malta and as a co-official language (with English) in Somalia. In Libya and Ethiopia it is now dying out of use.

Distribution of Italian speakers

Standard Italian began to be developed in the 13th and 14th centuries as a literary dialect. At first basically a Florentine dialect, stripped of local peculiarities, it has since acquired some characteristics of the dialect of Rome in particular and has always been heavily influenced by Latin. It overlies a wide variety of dialects, sometimes considered to represent a fundamental differentiation between northern and southern Italy that dates from Roman times. Today, however, these variant dialects form a continuum of intelligibility, although geographically distant dialects may be radically different. The northern dialects include what are often called the Gallo-Italian dialects (Piedmontese, Lombard, Ligurian, Emilian-Romagnol), in which some linguists discern the influence of a Celtic (Gaulish) substratum (*i.e.,* the traces of a language previously spoken in the region). The other northern group of dialects, spoken in northeastern Italy, is called Venetan (including Venetian, Veronese, Trevisan, and Paduan dialects, etc.). Istriot, a language spoken in Yugoslavia, is sometimes considered yet another northern Italian dialect, rather than an independent language. The Tuscan dialects (including those of Corsica) are often held to form a linguistic group of their own, while in the south and east three broad dialect areas are grouped loosely together: (1) the dialects of the Marche (Marchigiano), Umbria, and Rome; (2) Abruzzian, Apulian, Neapolitan, Campanian, and Lucanian; and (3) Calabrian, Otrantan, and Sicilian, believed by some to be influenced by the Greek once spoken there (which still survives in isolated pockets on the toe and heel of the peninsula).

Italian dialect regions

Outside Italy, Italian dialects are heavily influenced by contact with other languages (English in New York; Spanish in Buenos Aires). A pidgin Italian can still be heard in Addis Ababa but has little extension. Relics of a Jewish Italian survive within Italy; a colony of 6,000 Jews, who used a Venetan dialect as a home language in Corfu, was exterminated during World War II.

Early texts from Italy are written in dialect, because there was not yet, of course, any standard dialect. Possibly the very first text is a riddle from Verona, dating from perhaps the 8th century, but its interpretation is obscure and its language Latinized. More surely Italian are some 10th-century documents from Montecassino, after which there are three Central Italian texts of the 11th century. The first literary work of any length is the Tuscan Ritmo *Laurenziano* ("Laurentian Rhythm") from the end of the 12th century, followed soon by other compositions from the Marches and Montecassino. In the 13th century, lyric poetry was first written in a conventionalized Sicilian dialect that influenced later developments in central Italy.

In modem Italy, although dialects are still the primary spoken idiom, standard Italian is virtually the only written language and, with the spread of literary regional varieties of the standard language, may eventually replace the dialects. Neorealism, especially in the cinema, has introduced a limited use of dialect into cultural media, but the relevance of such a development is hotly debated.

Romanian. There are about 20,000,000 speakers of Romanian (or Rumanian), of whom about 16,000,000 live in the Socialist Republic of Romania, 2,500,000 in the U.S.S.R., and about 1,000,000 in Yugoslavia, Bulgaria, Greece, and Albania. There are about 75,000 Romanian speakers in the United States.

Standard Romanian

The standard language of Romania is based on a Walachian variety of so-called Daco-Romanian, the majority group of dialects; it was developed in the 17th century mainly by religious writers of the Orthodox Church and includes features from a number of dialects, though Bucharest usage now provides the model. Daco-Romanian is fairly homogeneous but shows greater dialectal diversity in the Transylvanian Alps, from which region the language may have spread to the plains. Moldavian, the variety of Romanian spoken in the U.S.S.R., is still written in a form of Cyrillic script, and some claim that it is a language in its own right, though most Western linguists see it definitely as a variant of Daco-Romanian. Other dialects of Romanian are barely mutually intelligible with the standard, and some can be counted as separate languages; these include Megleno-Romanian (Vlaši) and Istrio-Romanian, both already mentioned as nearly extinct. More vigorous is the Aromanian group of dialects scattered throughout Greece (150,000 speakers in 1932), Yugoslavia (100,000), Albania (65,000), and Bulgaria (40,000). Numbers have probably decreased considerably, but certainly before the war Aromanians were often prominent businessmen in their localities. The first known inscription in Aromanian, dated 1731, was found only in 1952 at Ardenita, in Albania; texts date from the end of the 18th century, and literary texts have been published in the 19th and 20th centuries (mostly in Bucharest).

The first known Daco-Romanian text is a letter dated 1521, though some manuscript translations of religious texts show Transylvanian dialect features and may be earlier. The vast majority of early texts are written in Cyrillic script, the Roman (Latin) alphabet having been adopted in 1859 at the time of the union of Walachia and Moldavia. Literature in Romanian began to flourish in the 19th century, when the emerging nation turned toward other Romance countries, especially France, for cultural inspiration. Today, in spite of efforts at industrialization, peasant life continues almost unchanged in many regions, and the linguistic standards of the capital have little impact; an autonomous Magyar-speaking (Hungarian) region in the middle of Romania adds further complication to the linguistic situation.

II. Historical survey of the Romance languages

LATIN AND THE PROTOLANGUAGE

Latin and the Italic languages

Latin is traditionally grouped with Faliscan among the Italic languages, of which the other main member is the Osco-Umbrian group. Oscan was the name given by the Romans to a group of dialects spoken by Samnite tribes to the south of Rome. It is well attested in inscriptions and texts for about five centuries before Christ and was used in official documents until c. 90–89 BC. The absence of great dialectal variations in the texts suggest that they are written in a standardized form. In early times, Umbrian was sooken northeast of Rome. to the east of the Etruscan region, possibly as far west as the Adriatic Sea at one period. It is attested mainly in one series of texts, the Tabulae Iguvinae, dated from 400 to 90 BC, and it is similar to Oscan. Probably Latin and Osco-Umbrian were not mutually intelligible; some claim they are not closely related genetically but that their common features arose from convergence as a result of contact.

The Roman dialect was originally one of a number of Latinian dialects, of which the most important was Faliscan, the language of Falerii, 32 miles (51 kilometres) north of Rome. The Faliscans were probably a Sabine tribe that early fell under Etruscan domination. The dialect is known mainly from short inscriptions dating from the 3rd and 2nd centuries BC and probably survived until well after the conquest of Falerii by the Romans in 241 BC. It shares one phonetic feature with Osco-Umbrian (medial f from Indo-European **bh* [the asterisk marks a hypothetical reconstructed form] when Latin has *b*—*e.g.*, Faliscan carefo = Latin carebo), but others are like Latin (*e.g.*, Faliscan cuando = Latin quando = Umbrian pan(*n*)*u*). Some Latin diphthongs, however, appear as simple vowels in Faliscan (*e.g.*, Latin ae = Faliscan *e*), and Latin final consonants are often absent (*e.g.*, Faliscan *cra* = Latin *cras*).

The earliest Latinian text is an inscription on a cloak pin (fibula) of the 6th century BC, from Palestrina (Praeneste); the inscription is definitely dialectal and seems to have Oscan features (*e.g.*, a reduplicated syllable in the perfect form — fhefaked = Latin fecit "he did, made"). Other Latinian inscriptions show marked differences from Roman Latin, for which there is, however, little evidence before the end of the 3rd century BC. What is certain is that the language changed so rapidly between the 5th century (the date of a mutilated inscription said to mark the tomb of Romulus and of the Twelve Tables, the contents of which are known from later evidence) and the 3rd century BC that older texts were no longer intelligible.

During this period the Romans subjugated their Latin neighbours (by 335 BC), and their language began to establish itself as a standard form, absorbing features from other dialects. The first author of any note was the comedian Plautus (254–184 BC), whosk language is thought to reflect a spoken idiom, some features of which appear to have survived into Romance.

Literary development in Latin

By 265 Rome had conquered Magna Graecia, in the south of the Italian peninsula, and had begun to absorb some of its Greek literary and cultural ideals. Poetic language was especially influenced by Greek until Latin poetry reached its zenith with Virgil. In the 1st century BC a literary prose was to be developed, with emphasis placed on rejection of vulgarity and rusticity and pride of place accorded to elegance and clarity. Grammatical rules were codified and tightened and vocabulary pruned, and the cult of the harmonious, balanced period held sway in rhetorical circles. With Cicero, Golden Age prose style attained its highest point; for the linguist, the distinction Cicero makes between the style of his letters and that of his speeches is especially interesting in that it provides evidence that even educated speech differed from written language. When Cicero uses the *sermo plebeius* ("plebeian speech"), his language is more elliptical, with shorter, less complex sentences and more colourful vocabulary (including plentiful diminutives). It seems obvious that truly popular language differed even more from the elaborate, sophisticated, classical literary idiom; there is evidence that archaic features, banned from literary style, survived in vulgar speech right through to the Romance stage of the language. It is sometimes claimed that the language of Roman historian and politician Sallust (86–35 BC) approximated popular usage, but it is more probable that his archaizing style derives more from conscious imitation of old Roman poetry. The Roman "judge of elegance" Petronius Arbiter (died AD 65/66), too, is often thought to imitate vulgar speech, but many of the odd features found in his "Cena Trimalchionis" ("Trimalchio's Dinner") may represent the broken Latin spoken by Greeks and such.

SOME CHARACTERISTICS OF CLASSICAL LATIN

Pronunciation. Evidence for pronunciation of the Latin of the classical era is often difficult to interpret. Orthography is conventionalized, and grammarians' comments lack clarity, so that to a considerable extent it is necessary to extrapolate from later developments in Romance in order to describe it. On the whole, linguists think that Latin probably sounded something like Italian, though areas of uncertainty exist.

Among these uncertainties, the most important concerns Latin intonation and accentuation. The way vowels developed in prehistoric Latin suggests that there was a heavy stress accent on the first syllable of each word, but in later times the accent fell on the penultimate syllable or, when this had "light" quantity, on the antepenultimate (much as in modern Italian). The nature of this accent is hotly disputed: contemporary grammarians seem to suggest it was a musical, tonal accent and not a stress accent. If this were so, the acoustic effect of Latin would be quite different from Romance and similar, perhaps, to modern West African languages or even Chinese. Some scholars claim, however, that Latin grammarians were merely slavishly imitating their Greek counterparts and that the fact that in Latin accent is linked with syllable vowel length makes it unlikely that such an accent was tonal. Probably it was a light stress accent that was normally accompanied by a rise in pitch; in later Latin evidence suggests that the stress became heavier.

The system of syllable quantity, connected with that of vowel length, must have given Classical Latin distinctive acoustic character. Broadly speaking, a "light" syllable ended in a short vowel and a "heavy" syllable in a long vowel (or diphthong) or a consonant. The distinction must have been reflected to some extent in late Latin or early Romance, for, even after the system of vowel length was lost, light, or "open," syllables often developed in a different way from heavy, or "closed," syllables.

Vowel length

Because the system of vowel length was lost after the classical period, it is not known with any certainty how vowels were pronounced at that period; but, because of later developments in Romance, the assumption is that the vowel-length distinctions were also associated with qualitative differences, in that short vowels were more open, or lax, than long vowels. Standard orthography did not distinguish between long and short vowels, although in early times various devices were tried to remedy this. At the end of the Roman Republic an "apex" (one form was like this: ') often was used to mark the long vowel, but this was replaced in imperial times by an acute accent (′). In Classical Latin the length system was an essential feature of verse, even popular verse, and mistakes in vowel length were regarded as barbarous. In later times, however, many poets were obviously unable to conform to the demands of classical prosody and were criticized for allowing accent to override length distinctions.

Besides the vowels *ā, ē,* i, *ō, ū* (long vowels) and *ă, ĕ, ĭ, ŏ, ŭ* (short vowels), educated speech at the classical period used a sound taken from Greek upsilon and pronounced rather like French *u* (the symbol [y] in the International Phonetic Alphabet — IPA) in words borrowed from Greek; in popular speech this was probably pronounced like Latin *ŭ*, though in later times *ī* sometimes substituted for it. A neutral vowel was probably used in some unaccented syllables and was written *u* or i (*optumus,* optimus "best"), but the latter rendering became standard. A long *ē*, from earlier ***ei***, had probably completely merged with i by the classical period. Classical pronunciation also used some diphthongs pronounced by educated Romans much as they are spelled, especially ae (earlier ai), pronounced perhaps as an open long e in rustic speech, au (rustic open long *ō*), and oe (earlier oi, late Latin *ē*).

The consonant system

The Classical Latin consonant system probably included a series of labial sounds (produced with the lips), p, b, *m*, *f*, and probably *w*; a dental or alveolar series (produced with the tongue against the front teeth or the alveolar ridge behind the upper front teeth), t, d, *n*, *s*, *l*, and possibly ɫ; a velar series (produced with the tongue approaching or contacting the velum or soft palate), *k*, *g*, and perhaps *ng;* and a labiovelar series pronounced with the lips rounded, k^w and g^w. The *k* sound was written c, and the k^w and g^w were written *qu* and *gu*, respectively.

Of these, k^w and *g''* were probably single labialized velar consonants, not clusters, as they do not make for a heavy syllable; g^w occurs only after *n*, so only guesses can be made about its single consonant status. The sound *ng* (as in English "sing"; represented in the International Phonetic Alphabet by [ŋ]]), written *ng* or *gn*, may not have had phonemic status (in spite of the pair *annus/agnus* "year"/"lamb," in which [ŋ] may be regarded as a positional variant of g). The Latin letter f probably represented by classical times a labiodental sound pronounced with the lower lip touching the upper front teeth like its English equivalent) but earlier it may have been a bilabial (pronounced with the two lips touching or approaching one another). The so-called consonantal i and *u* were probably not true consonants but frictionless semivowels; Romance evidence suggests that they later became a palatal fricative, [j] (pronounced with the tongue touching or approaching the hard palate and with incomplete closure) and a bilabial fricative, [β] (pronounced with vibration of the lips and incomplete closure), but there is no suggestion of this at the classical period. Some Romance scholars suggest that Latin *s* had a pronunciation like that of modern Castilian (with the tip, rather than the blade, raised behind the teeth, giving a lisping impression): in early Latin it was often weakened in final position, a feature that also characterizes eastern Romance languages. R was probably a tongue trill at the classical period, but there is earlier evidence that in some positions it may have been a fricative or a flap.

The nasal consonants were probably weakly articulated in some positions, especially medially before *s* and in final position; here probably there was mere nasalization of the preceding vowel.

In addition to the consonants shown, educated Roman speakers probably used a series of voiceless aspirated stops, written *ph, th, ch,* originally borrowed from Greek words but also occurring in native words (pulcher "beautiful," *lachrima* "tears," *triumphus* "triumph," etc.) from the end of the 2nd century BC.

Another nonvocalic sound, *h,* was pronounced only by educated speakers even in the classical period, and references to its loss in vulgar speech are frequent.

Doubled consonant sounds

Consonants written double in the classical period were probably so pronounced (a distinction was made, for instance, between anus "old woman" and *annus* "year"). When consonantal i appeared intervocalically, it was always doubled in speech. Earlier than the 2nd century BC consonant gemination (doubling of sounds) was not shown in orthography but was probably current in speech. Among the Romance languages, the eastern ones on the whole retained Latin double consonants, whereas in the west they were often simplified.

Morphology and **syntax.** Latin reduced the number of Indo-European noun cases from eight to six by incorporating the sociative-instrumental (indicating means or agency) and, apart from isolated forms, the locative (indicating place or place where) into the ablative case (originally indicating the relations of separation and source). The dual number was lost, and a fifth noun declension was developed from a heterogeneous collection of nouns (principally verbal abstracts in *-ie*). Of the other declensions, the Indo-European *ā*- and *ŏ* classes remained, with the introduction of new genitive singular forms in -ce and *-i*, while consonantal and *-i* stem nouns were amalgamated into a "third" declension, which also took in adjectives formerly of the *ū*-class (a "fourth" declension). Probably before the Romance period the number of cases was further reduced (there were two in Old French—nominative, used for the subject of a verb, and oblique, used for all other functions—and Romanian today has two, nominative–accusative, used for the subject and the direct object of a verb, and genitive–dative, used to indicate possession and the indirect object of a verb), and words of the fourth and fifth declension were absorbed into the other three or lost.

Among verb forms, the Indo-European aorist (indicating simple occurrence of an action without reference to duration or completion) and perfect (indicating an action or state completed at the time of utterance or at a time spoken of) combined, and the conjunctive (expressing ideas contrary to fact) and optative (expressing a wish or hope) merged to form the subjunctive mood. New tense forms that developed were the future in *-bō* and the imperfect in *-bam;* a passive in *-r*, also found in Celtic and Tocbarian, was also developed. New compound passive tenses were formed with the perfect participle and *esse* "to be" (*e.g.*, esf *oneratus* "he, she, it was burdened°)—such compound tenses were to develop further in Romance. In general, the morphology of the classical period was codified and fluctuating forms rigidly fixed. In syntax, too, earlier freedom was restricted; thus, the use of the accusative and infinitive in *oratio obliqua* ("indirect discourse") became obligatory, and fine discrimination in the use of the subjunctive was insisted on. When earlier writers might have used prepositional phrases, classical authors preferred bare nominal-case forms as terser and more exact. Complex sentences with subtle use of distinctive conjunctions were a feature of the classical language, and effective play was made with the possibilities offered by flexible word order.

New tense forms

In the postclassical era, Ciceronian style came to be regarded as laboured and boring, and an epigrammatic, compressed style was preferred by such writers as Seneca and Tacitus. Contemporaneously and a little later, florid, exuberant writing—often called African—came into fashion, exemplified especially by Apuleius (2nd century AD). Imitation of classical and postclassical models continued even into the 6th century, and there seems to have been continuity of literary tradition for some time after the fall of the Western Roman Empire.

The growth of the empire spread Roman culture over much of Europe and North Africa. In all areas, even the outposts, it was not only the rough language of the legions that penetrated but also, it seems, the fine subleties of Virgilian verse and Ciceronian prose. Recent research suggests that in Britain, for instance, Romanization was wider spread and more profound than hitherto suspected and that well-to-do Britons in the colonized region were thoroughly imbued with Roman values. How far these trickled down to the lower classes is difficult to tell; because Latin died out in Britain, it is often thought that it had been used only by the higher classes of the population, but some suggest that it was a result of wholesale slaughter of the Roman British. It is, however, more likely that the pattern of Anglo-Saxon settlements was not in conflict with the Romano-Celtic and that the latter were gradually absorbed into the new society.

Develop-mentof Romance from Latin

In the lands in which Romance is still spoken, it is of course certain that, sooner or later, Latin in some form was the normal language of most strata. Whether, however, the Romance languages continue rough peasant dialects of Latin (or even slave creoles) or the usage of more cultured urban communities is open to question. There are those who maintain that tbe Latin used in each area differentiated as soon as local populations adopted the conqueror's language for any purpose. According to this belief, dialects of Latin result from "interference" from indigenous languages (substrata), even though clear evidence for dialectal diversification cannot be found in extant texts. It is obvious that Latin usage must have differed over a wide area, but it can be questioned whether the differences were merely phonetic and lexical variations—regional accents and usage—not affecting mutual intelligibility or whether they were profound enough to form the basis of further differentiation when administrative unity was lost. The latter hypothesis would suggest a long period of bilingualism (up to about 500 years), as experience shows that linguistic interference between languages in contact rarely outlives the bilingual stage. Virtually nothing is known about the status of the indigenous languages during the imperial period, and only vague contemporary references can be found to linguistic differences within the empire. It seems odd that no one among the numerous Latin grammarians should have referred to well-known linguistic facts, but the absence of evidence is not sufficient to justify the assertion that there was no real diversification during the imperial era. Historical parallels are lacking—the British Empire did export English to widely different lands, but it lasted a comparatively short time, and its linguistic contribution was backed by modern communications media, besides being to some extent negated by nationalist feeling.

Latin and Romance coexisting

What is certain is that, even if popular usage within the empire showed great diversification, it was overlaid by a standard written language that preserved a good degree of uniformity until well after the administrative collapse of the empire. As far as the speakers were concerned, they apparently thought they were using Latin, though they were often conscious that their language was, through sheer ignorance, not quite as it should be. Not until about the 8th or 9th century—later in some parts—did it strike them that Classical Latin was perceptibly a different language, rather than merely a more polished, cultured version of their own.

Later Latin (3rd century AD onward) is often called Vulgar Latin—a confusing term in that it can designate the popular Latin of all periods and is sometimes also used for so-called Proto-Romance (roman commun), a theoretical construct based on consistent similarities among all or most Romance languages. All three Vulgar Latins in fact share common features but, given their different theoretical status, can hardly be called identical or even comparable. Written Vulgar Latin attained wide diffusion as the language of the Christian Church, officially adopted by the empire from the 4th century on. Its "vulgarisms" often called forth apologies from Christian authors, whose false humility seems akin to pride in that they did not succumb to the frivolities of pagan literary style.

Aside from the numerous inscriptions from all over the empire, there is no shortage of texts in Vulgar Latin. One of the first is the so-called Appendix Probi (3rd–4th centuries AD; "Appendix of Probus"), which lists correct and incorrect forms of 227 words, probably as an orthographical aid to scribes, but as a result illustrates some phonological changes that may have already occurred in the spoken language (*e.g.*, loss of unstressed penultimate syllables and loss of final m). The Vulgate, St. Jerome's translation of the Bible (AD 385–404), and the works of St. Augustine (AD 354–430) are among Christian works in Vulgar Latin. Particularly amusing and linguistically instructive also is the so-called Peregrinatio Etheriae ("Journey of Etheria"), written probably in the 4th century by a nun, describing her visit to the Holy Land. Medical and grammatical works also abound from the 4th to the 7th centuries (among the writers were the provincials Cosentius, from Gaul; Virgilius Maro, from southern Gaul; and St. Isidore of Seville, from Spain).

New vocabulary

Some of the characteristics of Vulgar Latin recall popular features of classical and preclassical times and foreshadow Romance developments. In vocabulary, especially, many of the sober classical words are rejected in favour of more colourful popular terms, especially derivatives and diminutives: thus, *portare* "to carry" (French porter, Italian *portare,* etc.) is preferred to ferre; *cantare* "to sing again and again" (French chanter, Spanish and Portuguese *cantar,* etc.) to *canere*; *vetulus* "little old man" (Romanian vechi, Italian vecchio, French *vieux,* etc.) to *vetus.* In grammar, classical synthetic constructions are often replaced by analytic; thus, the use of prepositions often makes case endings superfluous. *Ad regem* for regi "to the king," for instance, or anomalous morphological forms are simplified and rationalized (*e.g.,* plus *sanus* for *sanior* "healthier"). Shorter, less complex sentences are preferred, and word order tends to become less flexible.

The most copious evidence for Vulgar Latin is in the realm of phonology, though interpretation of the evidence is often open to dispute, consisting as it does of the confused descriptions of grammarians and the misspellings of bewildered scribes. Much of the evidence points to a strengthening of stress accent during the late period, leading to the shortening and swallowing of unaccented syllables: thus, viridem "green" becomes virdem (verde in several Romance languages); vinea "vine" becomes vinia (French vigne, Spanish *viña* ["vineyard"], etc.). It is often thought that Classical Latin had a tonal, not a stress, accent; though this is uncertain, any stress on accented syllables was probably light and less acoustically perceptible than an accompanying rise in pitch. There is some scant evidence that a stress accent was used in popular and dialectal preclassical speech (*e.g.,* vinia in a 3rd-century-BC epitaph, Oscan minstreis for Latin *minister* "attendant"), but the first undisputed testimony is to be found in 3rd-century-AD texts.

Among other phonological features of Vulgar Latin, probably the most striking is the loss of the system of long and short vowels. On the whole, long vowels became tense and short vowels lax, resulting in a wholesale change in the rhythm of the language. In the texts there is evidence of the confusion of *ĭ* and *ē* and of *ŭ* and *ō* that has occurred in the western Romance languages. A similar collapse of *ō* and *ŭ* seems to have occurred in Oscan, but it is unlikely that this is connected with later developments. It is to be remembered that even popular Latin verse used measures of vowel length, and there is no evidence to suggest that vowel-length distinctions were lost in vulgar preclassical speech.

An archaic feature that does recur in Vulgar Latin is the loss of word-final -m, of which virtually no trace remains in Romance. It is possible, however, that the written letter of Classical Latin was no more than an orthographical convention for a nasal twang: in scanning Latin verse, the *-m* is always run in (elided) before a vocalic initial. Reduction of the diphthongs ae (to e) and au (to o) seems also to be a popular and dialectal feature reflected in Vulgar Latin texts; in the latter case, however, the Romance languages do not support the hypothesis that the diphthong was reduced early, for it remains in Old Provençal and in Romanian and, probably, in early Old French.

Borrowing from Latin into non-Romance languages

The prestige of Rome was such that Latin borrowings are to be found in virtually all European languages, as well as in the Berber languages of North Africa, which preserve a number of words, mainly agricultural terms, lost elsewhere. Basque has borrowed a good number of words, mainly from administrative, commercial, and military spheres, though it is difficult in some cases to determine whether the terms were later borrowings from Spanish, rather than from Latin. This is not a problem in the case of the 800 Latin words found in three British Celtic languages (Welsh, Cornish, and Breton)—words drawn from a wide sphere of activities. In the Germanic languages, borrowed Latin words principally involve trade and often reflect archaic forms. The very large number of Latin words in Albanian form part of the basic vocabulary of the language (including kinship terms) and cover such spheres as religion, although there is doubt about whether some of them were later borrowings from Romanian. In other cases Latin words in Albanian have survived in no other part of the former Roman Empire. Greek and Slavic languages have comparatively few Latin words, many of them administrative or commercial in character.

Latin has had a continuous influence on the Romance languages and their neighbours in its capacity as a language of religion and culture. With Christianity, Latin penetrated to new lands, and it was perhaps the cultivation of Latin in a "pure" form in Ireland, whence it was exported to England, that paved the way for an 8th-century reform of the language by Charlemagne. Conscious that current Latin usage was falling short of classical standards, Charlemagne invited Alcuin of York, a scholar and grammarian, to his court at Aix-la-Chapelle (Aachen), where he remained from 782 to 796, inspiring and guiding an intellectual renaissance. It was perhaps as a result of the revival of so-called purer Latin that vernacular texts began to appear, for it now became obvious that the vernacular and Latin were not the same language. Thus, in 813, just before Charlemagne's death, the Council of Tours decreed that sermons should be delivered in *rusticam Romanam* linguam ("in the rustic Roman language") to make them intelligible to the congregation.

Latin as the language of religion and education

Latin has remained the official language of the Roman Catholic Church and as such has been in constant use by most Romance speakers; it is only very recently that church services have begun to be conducted in vernacular. As the language of science and scholarship, Latin held sway until the 16th century, when, under the influence of the Reformation, nascent nationalism, and the invention of the printing press, it began to be replaced by modern languages. Nevertheless, in the west, along with Greek, the Latin language has remained a mark of the educated man throughout the centuries, although since World War II the popularity of classical languages in schools has declined, and a generation of scholars who know no Latin, except for the numerous terms borrowed by all European languages, will soon be seen.

THE EMERGENCE AND DEVELOPMENT OF THE ROMANCE LANGUAGES

Earliest period. The question of when Latin ended and Romance began, which has occupied scholars in the past, is largely a problem created by terminology. In some senses, today's Romance languages are regional varieties of one uniform set of speech patterns that resembles the Vulgar Latin of attested texts fairly closely—indeed, the analyses of generative phonologists make the modem "underlying forms" (as distinct from their phonetic representation in speech) look almost identical with the reconstructed ancestor of the Romance languages, Proto-Romance. On the other hand, sveakers are conscious that today they are speaking a "different language" from their neighbours, even though they may understand a good deal of their neighbours' discourse. Perhaps the speaker's consciousness is the best measure of divergence; when, one may ask, did Romance speakers realize that they were not using Latin in their everyday speech? Some scholars suggest that the realization must have dated from about the 5th century, when barbarians were streaming into the Roman Empire and, supposedly, hindering communication. Others prefer to rely on positive textual evidence, indicative of efforts to make up a written form of Romance distinct from Latin. Such evidence begins to appear only in the 9th century, first in northern France and then in Spain and Italy. The reforms of Charlemagne, re-establishing more classical standards in written Latin, may have been at once cause and result of the development of conventional written forms for vernacular Romance. Perhaps it was also the emergence of a new type of social organization, feudalism, that had linguistic effects as a result of the splitting of the open society of Roman tradition into small closed territorial units.

Romance glosses to Latin texts

From the 7th century onward, consciousness of linguistic change was strong enough to prompt scribes to gloss little-known words in earlier Latin texts with more familiar terms. Though the glosses often reflect Romance forms, however, they are usually given in a Latinate form, and one gains the impression of a few superficial adjustments to archaic but fundamentally comprehensible texts. The best known set of glosses—to the Vulgate Bible of St. Jerome—formerly belonged to the abbey of Reichenau, on an island in Lake Constance, Germany, and probably dates from the 8th century. The vocabulary of the Reichenau glosses appears to be French in flavour (*e.g., arenam* "sand" glossed by sabulo, French sable; vespertiliones "bats," by calvas *sorices*, French *chauve-souris*), and some words of Frankish origin appear (*e.g.*, scabrones "beetles" is glossed by wapces "wasps," *respectant* "they look about" by rewardant). The glosses provide some evidence of morphological simplification (*e.g.*, saniore "healthier" is glossed by plus sano "more healthy" and cecinit "he sang" by cantavit), but for the most part only lexical items are regarded as meriting comment. Another well-known glossary, known as the Kassel (or Cassel) glosses, probably dates from the very early 9th century. It gives Latin equivalents of German (Bavarian) words and phrases and provides evidence of lexical and phonetic differentiation within Latin that permits scholars to localize the work as probably French or Rhaetian (*e.g., mantun* "chin," as compared with modern French *menton*). Although orthographically eccentric, however, the text is obviously meant to represent Latin, not a Romance tongue; when phrases rather than isolated words are glossed, the Latin is often very close to classical models.

Beginnings of Romance literature

Later in the 9th century (with the Strasbourg Oaths, possibly, and more clearly in the Eulalia poem), deliberate attempts were made to write vernacular Romance, though the resources of the Latin alphabet were not wholly adequate to the task. That northern French texts were the first to appear is not surprising, for in that region Latin had changed more radically than elsewhere. By the 10th century the need to couch legal documents in more readily comprehensible vernacular, rather than Latin, was felt in other regions. Vernacular literature did not really get under way, however, until around the 12th century, when the arts flourished throughout western Europe. Raeto-Romance and Romanian, however, had to wait for the Reformation period to take on literary form.

Late-medieval period to the Renaissance. There was a good deal of cross-fertilization between Romance literary languages during the period of development of medieval poetry; the example of the Provençal lyric especially left its mark on all vernacular literatures, and borrowing of lexical items from one language to another was abundant. The 13th century saw some shift of linguistic influence from southern to northern France and from Sicily to Tuscany, toward the politically and economically more powerful regions. Portuguese and Catalan developed flourishing literatures somewhat later, taking over some of the traditions of the badly battered southern French region and dominating the literary scene of the Iberian Peninsula. French was fast losing its hold in England, which, a century earlier, had boasted a rich Anglo-Norman literature, and within France the central Parisian dialect began to dominate. In Italy, the Florentine dialect was showing signs of rising to prominence and providing the base for a literary standard.

Influence of Classical Latin on Romance

The rediscovery of classical literature and art, first in Italy and then in other Romance regions, had some considerable effect on the languages in the shape of extensive borrowing from Latin and Greek and, often, conscious attempts to model grammatical constructions in the vernacular on Classical Latin. The Italian standard language, in particular, owes much to the influence of Latin, which it resembles more closely than do the spoken dialects. French, except in the 16th century, was influenced grammatically less by Latin, but from the 14th century onward the habit of preferring words with a quasi-Latin shape to inherited forms became well established, so that much of the French vocabulary has a "learned" appearance. The trickle of Latinisms into Spanish became a flood in the 15th century, and, though Spanish has been more reluctant than French to reject old words, they today form a considerable proportion of the lexicon.

Standardization of the Romance languages in the 17th and 18th centuries. It was in Italy first that the "question of the language" became a matter of hot dispute. Dante himself made an important contribution to the debate on what should constitute a *volgare illustre* (an "illustrious popular speech") capable of rivalling Latin for literary and scholarly purposes. Controversy did not reach its peak, however, until the 16th century. In the Spain of 1492 the completion of the reconquest of Spain from the Arabs and the discovery of America were matched linguistically by the appearance of Antonio de Nebrija's

Gramática Castellana ("Grammar of the Castilian Language"), which argues the need for an ennobled language fit for imperial exportation. In France during the 16th century, with the Renaissance backed by the Reformation and the advent of printing, French really took over the remaining functions of Latin—scholarly, scientific, and religious—and efforts were made to put together a worthy national language from dialect and Latin sources. The choice of standard was not made definitively, however, until the late 17th century, when, with political power and social influence centred exclusively at the royal court, the only acceptable usage became that of the court. It would seem that social acceptance and advancement were inextricably bound up with correct behaviour, especially linguistic behaviour, so that the well-to-do bourgeoisie set out to ape the speech habits of their "betters"—hence the popularity of works describing *le bon* usage "good usage." The influence of French, resplendent with the achievements of French dramatic poet Racine and of Louis XIV, was destined to remain dominant within the Romance languages; the Golden Age of Spain and Portugal had already passed, and Italy was going through a period of comparative stagnation.

"Correct" language

The French grammarians of the 18th century had lasting effect on all the Romance standards, concerned as they were with maintaining "purity," eliminating "vulgarity," and strictly codifying usage, often more in accord with logical than linguistic considerations. The belief that correct language is not a birthright but a tool to be carefully fashioned and skillfully handled, that conscious effort was required to allow it to mirror thought with the minimum of distortion, is one that has persisted in Romance and that still has important effects on educational practice. To many English speakers it seems ludicrous that the criterion of competence in a language should be strict adherence to grammar-book rules rather than native-like performance, but in Romance countries a foreigner is often frowned upon if he permits himself the "negligence" of native usage, rather than the more stilted correct expression. Educated Romance speakers often speak very formally, with flowing, complex sentences and precise vocabulary, in contrast with the casual, slangy expression of the less educated (who openly envy the speech habits of their "betters"). The passionate interest shown in subtleties of language usage (including regular articles in the better class newspapers) is something that characterizes all Romance speakers, though perhaps only the French take it to excess.

Modern developments. The Romantics of the early 19th century were eager to break the stranglehold of intellectual, aristocratic language, but their attempts to introduce more colourful expressions did not bring them nearer to popular usage, for their efforts were mainly directed toward enriching the vocabulary while leaving grammar intact. Sentimental idealization of peasant existence aroused interest in dialectal usage, and egalitarian sentiments provoked some groups of speakers to proclaim the worthiness of their own mother tongues to rival more politically important languages. Occitan, Catalan, Rhaeto-Romance, and, indeed, Romanian were to develop literatures under the impact of such ideas, which took political form in the demands of regional separatists.

Popular usage in literature

The introduction into literature of conventionalized popular usage is mainly a 20th-century trend, but in the Romance languages it remains more limited than, for example, in English. Other, more literary attempts to break out of the straitjacket of standard usage are connected with such artistic movements as Symbolism and Surrealism, in which syntax, as well as vocabulary, suffers onslaught, and sentence construction tends to cut loose from logical ties. Yet, even within these movements, fine, elegant style continues to be appreciated by many, and it is the traditional forms that have wider appeal. The use of a weighty bureaucratic style in nonliterary writings is also evident, often characterized by an excessive use of Latinism and by the use of verbal nouns, but educational systems continue to place emphasis on plain, classic style. It is difficult to imagine that the long-continuing tradition of interest in "correctness" in language will die out in the Romance countries; recent educational reforms of France and Italy seem rather to emphasize the value of such a tradition, and organizations and individuals, no matter how revolutionary in political outlook, rarely work to counteract the cultural values so long regarded as paramount in their homelands.

III. Characteristics of the Romance languages

As a group, the Romance languages share many characteristics besides that which defines the family (*i.e.*, the presence of a significant proportion of lexical cognates). In comparison with Germanic languages, for instance, they seem musical and mellifluous—probably because of the relatively greater importance of vowels than consonants. On the whole, the vowels are clear and bell-like and articulation energetic and precise, though Portuguese and Romanian convey a more muted acoustic impression. Foreigners often think that Romance speech is particularly rapid and voluble, no doubt because individual words receive only light stress (or, in French, no stress), and elision, the running of words into each other within stress groups, is common. Romanian is something of an exception in that speech tempo is comparatively slow. Intonation patterns, surface manifestations of nonlexical meaning, such as interrogation, exclamation, scorn, surprise, and so forth, seem to some to denote excitability and emotional expressiveness in the speakers. Northern French is comparatively sober, with typically about a one-octave range in intonation, but Italian seems to be sung, with sinuous pitch movement over two octaves, and Castilian jumps jerkily and up and down over about an octave and a third.

Retention of the synthetic character of Latin

Grammatically, the modern languages have retained to a greater or lesser extent some of the synthetic character of Latin, principally in the verb, but in Romanian also in the noun. French, since about the 14th century, has undergone most radical changes in grammatical typology, so that much greater reliance is placed on word order and intonation to convey sentence meaning than on morphological form. Other languages allow a little more flexibility of word order but far less than in Classical Latin.

Dominant purist grammarians have always opposed influence from foreign languages and reproved their fellows for sullying their language with lavish borrowing (at present primarily from English), but they have never been able to stem the flood of neologisms. French vocabulary, particularly, has always been receptive to change and has been as quick to lose old words as to adopt new. Codification of grammar, on the other hand, has had a permanent effect on the stability of the standard languages, even feeding back into spoken usage via the education system. Acceptance of the most minor changes follows long debate and deliberation and requires governmental edicts that decree what can be marked as correct in all-important examinations. Curiously enough, this rigidity and consequent self-confidence have resulted in greater teachability, so that standards of correctness of, for instance, French among Africans or Spanish among American Indians are remarkably high. The moves toward codification were, indeed, originally linked to a desire to give the languages international importance, and language teaching is, in the Romance ethos, indissolubly linked to the diffusion of cultural and moral values.

LINGUISTIC TYPOLOGY OF THE ROMANCE LANGUAGES

As stated previously, the most "central" Romance language is standard Italian, which has retained and even re-adopted many Latin characteristics. In some ways its morphology lacks the elegance and efficiency of Castilian, which has most ruthlessly eliminated anomalies during the modem period; there are signs in Italian of historical inertia, a harking back to a glorious past, that has hindered popular development. Romanian remains closest in grammatical type to Latin, though its noun-declenison system, based on the definite article placed after the noun, and its frequent use of the subjunctive mood may owe much to its Balkan neighbours (or to an earlier linguistic substratum). Its vocabulary has incorporated so many Slavic and Turkish words, however, that it often

Causes of the divergences in French

appears less Romance than the rest. French, by any standard, has diverged most—radical phonetic changes that transformed the outward appearance of the language must have preceded the earliest surviving (9th-century) texts. Such changes are usually ascribed to Celtic and Frankish influence. Another wave of change, with loss of word accent and of many morphological markers, probably dates from around the 15th century, but it is difficult to find external motivation for these phenomena. Occitan and Catalan are conservative in character; the long persistence of Roman schools in South Gaul is often seen as the cause of stability there. Spanish and Portuguese are close enough to lead some scholars to assign their shared characteristics to Iberian substratum and Moorish superstratum influence. Castilian's forceful character and receptivity to grammatical innovation contrast sharply with Portuguese softness and its inertia in retaining morphological oddities, however. One might conceivably see the differences as connected with climatic and geographical conditions, though just how would be difficult to discern. Rhaeto-Romance and Dalmatian peculiarities can most easily be connected with the impact of other languages (mainly German, Italian, and Serbo-Croatian), while Sardinian is often regarded as an extremely conservative, peasant language, some dialects of which have been penetrated by features from Italian and Spanish.

PHONOLOGY

Some important phonological developments, such as the loss of the system of contrasting vowel lengths and the strengthening of the stress accent, must have occurred during the Vulgar Latin period, while some degree of unity still existed among the various Romance dialects. Certain other changes shared by the Western Romance languages, especially the collapse of *ē* and i, might have postdated the linguistic separation of Sardinia and parts of southern Italy from the other areas, while the distinct development of 6 and *ŭ* in Romanian and Vegliot suggests a split between Eastern and Western Romance at a later date.

Unaccented vowels

Vowels. Everywhere, unaccented vowels have had a different history from accented, and in some languages they have so weakened as to disappear altogether in certain positions. At the end of a word, for instance, even -a, the most sonorous of the vowels, has weakened to a neutral vowel in Romanian, Portuguese, and some Catalan and Rhaetian dialects—in some French dialects it is still pronounced as a neutral vowel sound (such as the second vowel in English "alphabet"), but it has been lost completely in the standard language. Final *-o*, from Latin *-o* or *ŭ*, was lost very early in French, Occitan, Catalan, and Rhaetian and remains only before an article following the word in Romanian; in Portuguese it is closed to a *u* sound (such as the *u* in English "lunar"). Final *-e* is even more evanescent, regularly remaining as a full vowel only in parts of central and southern Italy and Sardinia.

Under the main stress accent of the word, Latin vowels have often become diphthongs in Romance, perhaps as a result of lengthening under heavy stress or as a consequence of the raising influence of following high vowels (a process known as breaking, similar in action to German umlaut). The vowels most affected are the "open" *e* sound (as in "met"), from Latin *ĕ*, and to a lesser extent the "open" o sound (similar to the aw sound in "law" in many American English dialects and to the o in British English "ingot"), from Latin 6, while high close vowels i and *u* are virtually untouched. Transformation of short *e* to a diphthong (usually a ye sound, as in "yet") is so common that some believe it occurred during the Vulgar Latin period. The conditions of this process (and similar ones) vary, however; in some languages (notably French and Italian) it happens only in open syllables (*i.e.*, those ending in a vowel in Vulgar Latin), whereas Romanian, Vegliot, Spanish, and perhaps Rhaetian show similar developments in all accented syllables. Portuguese possibly did not join in the diphthong-forming process at all, though, as in Occitan, Catalan, Sardinian, and some Italian dialects the short e- and *o*- sounds may at one time have developed into diphthongs under the influence of a following high vowel (i or u), later to be reduced once more to a single vowel. Table 1 illustrates treatment of stressed Latin *ĕ* and 6 in different languages.

Table 1: Occurrence of Diphthongs Replacing Stressed Short Vowels in Romance Languages

	pĕde "foot"	*hhrba* "grass, herb"	*mŏrit* "he dies"	*mŏrtem* "death"
Sardinian	*pe*	*erva*	*móridi*	*morte*
Portuguese	*pe*	*herva*	*morre*	*morte*
Catalan	*peu*	*herba*	*mor*	*mort*
Occitan	*pe*	*erba*	*mor*	*mort*
French	*pied*	*herba*	*meurt* (Old French *muert*)	*mort*
Italian	*piede*	*erba*	*muore*	*morte*
Romanian	—	*iarbă*	*moare*	*moarte*
Spanish	*pié*	*hierba*	*muere*	*muerte*
Rhaetian (Sursilvan)	*pei*	*jarva*	*miere*	*mort*
Rhaetian (Friulian)	*pid*	—	—	*muart*
Vegliot	*pi*	*járba*	—	*muart*

Reflexes of Latin *ō* (and *ŭ*) and *ē* (i) became diphthongs ou and ei in Northern French at an early period (after the 5th but before the 9th century); the 12th-century phonetic results *eu* and oi provided the present-day spellings, though the sounds thus represented have changed considerably since (compare *fleur* "flower," from flour, from Pore). The greater extension of spontaneous diphthong formation in French than in other Romance languages (including perhaps also reflexes of a--compare mer "sea," from **maer* [?], from Latin mare) is often attributed to the effects of the heavy stress presumably used by the Frankish superstratum.

Effects of nasal consonants on vowels

In nearly all Romance languages a following nasal consonant has caused peculiar development in a preceding vowel. In most cases the effect is limited to a raising or closing influence, but in two major languages, French and Portuguese, phonological nasalization has taken place (*i.e.*, a series of vowels distinguished by the presence of nasal resonance has developed). Here, as well as in some other dialects (especially Chilean, Caribbean, and Andalusian Spanish, in the Romanian spoken in Albania, and in northern Occitan), nasal vowels are distinct from their oral counterparts and not mere variants (*i.e.*, they are phonemic). Thus, they serve to differentiate one meaningful form from another: *e.g.*, French pin "pine," pronounced *pɛ̃* (ɛ stands for a short *e* sound, and ˜ marks nasalization) versus *paix* "peace," pronounced *pɛ*; Portuguese *lã* "wool" versus la "there"; Andalusian *cantã* "they sing" versus *canta* "he sings." Occasionally, nasalization of a vowel is caused by a preceding consonant (*e.g.*, Portuguese *mãe* "mother," from *matre*), but this is comparatively rare.

Nasalization in both French and Portuguese was probably noticeable by the 10th century, though it may not have become phonemic until much later. Some claim that even today nasal vowel resonance is merely a surface manifestation of a latent underlying nasal consonant. It would appear that in both languages nasal vowels were more frequent in the Middle Ages than today; in about the 16th century in France, denasalization took place when the nasal consonant was intervocalic, and the n sound was retained—in, for example, French bon "good [masculine]" (pronounced *bõ*) and bonne "good [feminine]" (pronounced bon or [bon]). In Portuguese the consonant did not always reappear after denasalization (compare boa "good [feminine]," from *bõa*, from bona), though between i and a or o the palatal nasal consonant (close to ny in "canyon") is inserted (vinho "wine," from vio, from vinu).

Nasalization has sometimes, though without much conviction, been attributed to Celtic substratum influence. A better case can be made for the effect of such influence in the French *u* sound, [y], pronounced like German *ü* or Greek upsilon, though ignorance of Gaulish and certain chronological and geographical discrepancies make it difficult to argue in detail. The French *u* sound is also found in most Occitan dialects (in which it may be a recent introduction from French), in Rhaetian, and in parts of Portugal and Italy; elsewhere it is sometimes a characteristic of affected speech.

French uvular *r*

Consonants. Another French pronunciation that is often imitated by socially pretentious speakers is that of the Parisian uvular *r* (produced by vibration of the uvula, an appendage at the back of the mouth), which was not accepted in standard French until after the Revolution, though probably used by the Parisian bourgeoisie from the 17th century. It probably developed from the Latin double *-rr-*, differentiated from single *-r-*, which in Middle French tended to be pronounced with local friction, almost as a ***th*** or *z* sound (compare ***chaise*** "chair" and ***chaire*** "chair—throne, pulpit"). In most dialects of Provence today the distinction between the two *r* sounds is still made (though Occitanian dialects in general are adopting the French pronunciation). Brazilian Portuguese uses a similar contrasting pair of ***r*** sounds, with the usual trilled *r* represented in orthography by "*r*" and a velar, or "rough," *r* represented by "rr": Brazilian *caro* "dear" and ***carro*** "cart." Elsewhere only Puerto Rican Spanish and a few North Italian and Romanian dialects use the velar ***r*** regularly, though it is heard sporadically nearly everywhere.

One phonological development that is thought by many to be indicative of a very early split between the Eastern and Western Romance areas concerns the treatment of consonants between vowels. To the north and west of a line drawn between La Spezia and Rimini, in Italy, most dialects voiced Latin voiceless consonants between vowels and simplified geminates (doubled consonants); southern and eastern dialects to a greater extent retain the Latin voiced–voiceless–geminate system. The dividing line appears also to run through Sardinia, so that northern dialects are "Western" and southern ones "Eastern." Table 2 shows the treatment of intervocalic ***p*** and ***t***.

Table 2: Development of Latin Intervocalic p and t in Romance Languages

	ripa "bank"	***rota*** "wheet"
Vegliot	*raıpa*	—
Romanian	*rîpă*	***roata***
Italian	***ripa***	***ruota***
Logudorian	***rrba***	***roda***
Occitan	*riba*	***roda***
Catalan	***riba***	***roda***
Spanish	***riba***	***rueda***
Portuguese	***rrba***	***roda***
French	***rive***	***roue*** (Modern French) ***ruede*** (Old French)
Rhaetian	***riva***	***roda, ruede***

Some believe that the voicing of voiceless sounds is connected with a similar, though not identical, process known as lenition in Celtic. Lengthening and subsequent development into diphthongs of accented vowels may be linked to the reduction of Latin doubled consonants to single consonants, as some recent theories suggest.

One noticeable difference between Latin and all the Romance languages is that the consonantal systems of the latter include a number of palatal and palato-alveolar consonants, which did not exist in Latin. (Palatal consonants are formed with the tongue touching the hard palate; palato-alveolar sounds are made with the tongue touching the region of the alveolar ridge or the palate.) One consequence of the strengthening of the stress accent in the later Latin period was that unstressed *ĭ* and *ĕ* following consonants became shortened to a nonsyllabic palatal y sound (called ***jod***). The effects of this new sound on preceding consonants are varied, but in many cases these have been pronounced with the tongue raised more toward or against the roof of the mouth, or palate (a process classified under the general heading assimilation), sometimes ending up eventually as a dental fricative (such as ***z*** or ***th***) or affricate (such as ***ch***) and perhaps modifying the preceding vowel. That this process began early is suggested by the not-infrequent confusion of *-tĭ-* and *-cĭ-* in orthography, sometimes represented even as ***tz*** in inscriptions. This palatal shift in pronunciation led to developments such as French ***rouge***, Portuguese *ruivo*, Catalan ***roig***, and Italian *rosso* from Latin *rubeum* "red" and French *feuille*, Portuguese *folha*, Italian *foglia*, and Sardinian ***fodza*** from Latin ***folia*** "leaf."

Shifts involving palatal consonants

Another source of palatal consonants in Romance has been back (velar) consonants when immediately followed by a front sound: the velar consonant has often moved forward in the mouth, sometimes eventually to dental or alveolar position but often settling on a palatal or palato-alveolar position. This process, too, probably began early, first affecting velar consonants *k* and *g* preceding front vowels ***e*** and ***i***. That it had not occurred at the classical period is shown by its absence in early loanwords into other languages (Berber, Basque, Celtic, Germanic, Albanian, and Greek). As central Sardinian dialects retain velar pronunciation in the environment of front vowels, it may be assumed that palatalization postdated the separation of the island from the rest of the empire. Vegliot evidence is difficult to interpret, as *ē* does not seem to have provoked palatalization, whereas *ĕ*, *ĭ*, and ***u*** did so. It was this sound change that resulted in the pronunciation of "soft" ***c*** before ***e*** and ***i*** (in most Romance languages this is an ***s*** or ***ts*** sound; in Italian and Rhaetian it is a ***ch*** sound). Before ***a***, ***o***, and ***u*** the ***c*** retained its "hard" pronunciation (that is, a ***k*** sound). In Classical Latin, before the sound change occurred, all ***c*** sounds were "hard." Hence, Latin ***centum*** ("kentum") gave rise to Italian ***cento*** ("chento"), Portuguese ***cento*** ("sento"), and Spanish ***ciento*** ("siento" or, in Castilian, "thiento").

In north central France, Latin ***a*** must have advanced to a front position, with the result that it, too, palatalized preceding ***k*** and ***g*** sounds. The results give the palato-alveolar sounds of ***sh*** and *zh* (written in the International Phonetic Alphabet as [ʃ] and [ʒ], respectively), via [tʃ], the ***ch*** sound in "church," and [dʒ], the *j* sound in "jam"; *e.g.*, French ***chanter*** "to sing" developed from Latin *cantare*, ***joie*** "joy" from *gaudia*. West Rhaetian dialects show a similar development (compare Sursilvan *tgaun*, Engadine ***chaun***, French *chien*, from Latin *canem* "dog"), as do Franco-Provençal and Northern Occitan dialects, but Picard and some Norman dialects do not (Picard ***canter***, with an unpalatalized ***c***, from Latin *cantare*; ***kier*** "dear," from *carum*). The change is assumed to have taken place at a later period than the palatalization of k when followed by ***e*** or i, which did not affect Frankish words. These, on the other hand, succumbed to the type of palatalization in which k changed to ***ch*** [tʃ] and then to ***sh*** [ʃ] (**skina* > *échine* "backbone").

Romanian consonant developments

In Romanian, velar consonants were moved forward under the influence of a following i and ***e***, and dental consonants were moved back to a palatal position under the same influence; *e.g.*, *ţară* from *terram* "earth"; ***şi*** "and" from ***sic*** "thus." Labial consonants are also affected in some dialects: ***k'ept*** from ***piept*** from ***pectum*** "chest"; *jin* from *vin* from *vinum* "wine." Romanian also has, in final position, a series of "soft" consonants, reminiscent of the Slavic sounds. These are transparently derived from earlier "hard" consonants followed by *i*, performing certain important morphological functions: *lupi* [lup'] "wolves" / *lup* [lup] "wolf"; *cînţi* [kints'] "thou singest" / *cînt* [kint] "I sing."

Palatalization of consonants in Romance was effected not only by following front vowels but also by juxtaposed front consonants, especially when a velar (such as Latin ***c*** or ***g***) was next to a dental (such as ***t***, ***s***, ***n***) or a lateral (***1*** sound) in medial position, sometimes as a consequence of the loss of an unaccented vowel during the Vulgar Latin period. Results of this process vary from language to language. Table **3** gives examples of these changes.

It will be noted that in Romanian a labial consonant has been substituted for the velar in the Latin clusters *-ct-*, *-x-* [ks], and *-gn-*. Perhaps there was first assimilation of the velar to the dental—as in Italian *-tt-* from Latin *-ct-* and

Table 3: Results of Palatalization of Consonant Clusters

	noctem "night"	*coxam* "hip"	*piscem* "fish"	*pugnum* "fist"	*oc'lum* "eye"
Venliot	*nwaf*	—	*pask*	—	*vaklu*
Romanian	*noapte*	*coapsă*	*peşte*	*pumn*	*ochi*
Sardinian	*notte*	*koša*	*piske*	*pundzu*	*okru*
Italian	*notte*	*coscia*	*pesce*	*pugno*	*occhio*
Occitan	*nôit, nuech*	*cuoissa*	*peis*	*ponh*	*uelh*
Catalan	*nit*	*cuixa*	*peix*	*puny*	*ull*
Spanish	*noche*	*cojo*	*pez*	*puño*	*ojo*
Portuguese	*noite*	*coxa*	*peix*	*punho*	*olho*
Rhaetian					
Sursilvan	*notg*	*queissa*	*pesch*	*pugn*	*egl*
Engadine	*not*	—	—	*puoñ*	—
Friulian	*ñot*	—	*pes*	—	—
French	*nuit*	*cuisse*	*(poisson)*	*poing*	*oeil*

Sardinian *-nn-* from Latin *-gn-* (***linna*** from ***Iigna*** "line")—followed by differentiation of the first element of the geminate. It is notable that Latin *1* regularly becomes *jod* after another consonant in Italian (*piacere* from *placere* "to please"; *fiore* from ***flore*** "flower"; ***chiave*** from ***clave*** "key"; ***ghianda*** from *glanda* "acorn") and after velars in Romanian (*plăcea, floare,* but **cheie** [kjej], *ghindă* [gjinda]). In Spanish and Portuguese a following *l* in Latin often palatalizes labial consonants ***(p, f)*** as well as velars, in initial as well as medial position; *e.g.*, Latin ***planum*** becomes Spanish ***llano*** "plain," Portuguese *chão;* Latin *afflare* becomes Spanish *hallar* "to find," Portuguese ***achar.***

GRAMMAR

Item for item, the Romance languages all appear grammatically close to Latin and to each other: superficial resemblances in individual expressions may, however, mask differences of content and construction that are difficult to describe. The most obvious difference between Latin and Romance is in the comparative autonomy of morphemic units, especially words. In Romance, Latin inflectional endings have been much reduced, and more reliance is placed on syntactic construction to convey sentence meaning; that is, Romance languages are more "analytic" than the predominantly "synthetic" Latin. A corollary of this is that word order is less flexible in Romance, as it has become the principal means of showing relationship between words in the sentence.

Reduction of inflectional endings

Forms of nouns and adjectives. The inflectional endings have been lost most in nouns and adjectives. The Classical Latin five-case declensional system has everywhere been replaced (with a couple of doubtful exceptions) by a two-gender system, in which normally masculine gender is marked by survivors of the second ***(-us)*** declension endings of Latin (Italian ***cavallo,*** Portuguese ***cavalu,*** Romanian *calul,* Sardinian ***kaddu,*** Rhaetian ***cavagl,*** from Latin *caballus* "horse"), and feminine is marked by first ***(-a)*** declension endings (Italian ***capra,*** Spanish ***cabra,*** Rhaetian ***caura,*** Romanian *capră,* from Latin ***capra*** "goat"). Cognates of third-declension Latin noun forms are incorporated into the same system, but their gender is marked by changes in the article or accompanying adjective (agreement or accord) rather than by overt markers in the word itself (for example, masculine Italian ***il monte,*** Catalan ***es mumt,*** from Latin ***mons, montem*** "mountain"; feminine Italian ***la notte,*** Catalan ***sa nit,*** from Latin ***nox, noctem*** "night"). In modern French, although gender is marked in the written language, however inconsistently, by the presence or absence of final ***-e,*** any overt morphological markers the spoken language may have are more complex in character, and more reliance is placed on syntactic agreement; thus, ***chatte*** "she-cat" is distinguished from ***chat*** "cat" by the presence or absence of the final consonant sound *-t* in pronunciation, but ***(le) tour*** "tour, trick" and ***(la) tour*** "tower" have identical phonetic shapes though they belong to different gender classes.

All the Romance languages continue to mark plurality in nouns and adjectives morphologically, though in modern spoken French this is not done consistently. In Western Romance the sign of the plural is usually *-s,* derived from the Latin accusative plural flection: Spanish ***caballos, cabras, montes;*** Occitan ***cavals, cabras,*** *mons;* Catalan ***cavalls, cabres,*** *muntes;* Sardinian ***kaddos, krabas, montes;*** Old French ***chevals, chkvres, monts.*** In Italian and Romanian, however, plurality is shown by a final ***-i*** (which in Romanian "softens" the preceding consonant) or, in the case of some feminine nouns, by a final ***-e:*** Romanian ***cai, capre, munţi, nopţi;*** Italian ***cavalli, capre, monti, notti.*** These endings may derive from Latin nominative plural first- and second-declension endings ***-ae*** and -**i**, or they may represent a somewhat irregular development of the *-s,* favoured elsewhere.

The Latin nominal case system has disappeared in all modern languages except Romanian, in which the inflected article distinguishes the nominative and accusative from the genitive and dative (see Table 4). Thus, when other Romance languages would use a preposition to indicate a certain relationship between words, Romanian resembles Latin in using an inflected form (*e.g.*, Latin ***matris*** "the mother's: Romanian ***mamei,*** French ***de la mkre,*** Italian *della madre*).

Loss of case system

Table 4: Declensional System of Romanian

	singular	plural
Masculine "son"		
Nominative–accusative	*un fiu, fiul*	*fii, fiii*
Genitive–dative	*unui fiu, fiului*	*unor fii, fiilor*
Feminine "mother"		
Nominative–accusative	*o mamă, mama*	*mame, mamele*
Genitive–dative	*unei mame, mamei*	*unor mame, mamelor*

In Old French and Old Provençal some remnants of a case system remained, in that the masculine nominative (subject of the verb) was distinguished from the other cases (collectively called oblique). Today such grammatical information is conveyed by word order in most Romance languages, as in English, with the subject normally preceding the verb: French ***Pierre appelle Paul*** "Peter calls Paul"; Portuguese ***Pedro chama Paulo;*** Italian ***Piero*** *chiama* ***Paulo.*** Some Romance languages pick out the object of the verb, if it is a person, by an additional particle: Spanish ***Pedro llama a Pablo;*** Romanian ***Petru cheamii pe Pavel.*** Several Italian dialects, as well as Sardinian and occasionally Engadine and Portuguese dialects, have similar constructions: Calabrian ***Chiamu a Petru*** "I call Peter"; Elba *Ò visto* ***a*** *ttuo* ***babbo*** "I saw your grandpa"; Engadine ***Amk a vos inimihs*** "Love your enemies." It is notable that the Italian-based lingua franca used by Mediterranean sailors since the 16th century also picks out the personal object (*e.g.,* ***Mi mirato per ti*** "*I* saw you").

The definite and indefinite articles were unknown in Latin but developed everywhere in Romance, usually from the Latin demonstrative *ille* "that" (though in a few parts from reflexive ***ipse*** "himself") and the numeral *unus* "one." The articles seem to have played some part, during the older stages of the languages, in distinguishing subject from object; the article is more often used where a Latin nominative would have occurred than in other cases, perhaps to give prominence to the topic of the sentence. Today the use of the article has so extended that such distinction is no longer possible; in French, for instance, a common noun is always accompanied by a determiner such as an article, demonstrative, or possessive, so forms remaining from the earlier stage, such as ***avoir faim*** "to be hungry," are often regarded as idiomatic and inexplicable in terms of modern structure.

The system of verbs. In the passage from Latin to Romance, verbal inflection has survived much more than noun declension. Although the four regular Latin conjugations have been virtually reduced to two, with only the ***-a-*** class remaining truly productive, other features of the verb seem almost unchanged. In most languages, for instance, the person markers are directly traceable to Latin origins (*i.e.,* to Latin ***-6, -s, -t, -mus, -tis, -nt***). Modern spoken French is the only major language in which the personal endings no longer serve the same function as Latin. Today, person is marked in French principally by pronouns derived mainly from the Latin emphatic nominative forms of the personal pronoun: *J'aime* [ʒɛm] "I love," *tu aimes* [tyɛm] "you love" from *(ego) amo, (tu) amas*. The creoles have taken this process even further, in that their verb forms are usually invariable but are prefixed by elements indicating person, tense, aspect, etc., as in many West African languages: Louisiana French [motegt] "I was having" from *mon* [mo] *étais* [te] *gagner* [gẽ]; and similarly [ilagt] "he will have."

Verb conjugations

In the metropolitan languages, verbal modalities are shown, as in Latin, by inflection. Some Latin verb endings, such as that of the *-r* passive or of the future, have disappeared; others, such as the pluperfect indicative and subjunctive, have survived in a few languages with modified function. But most languages today have reflexes of the present, perfect, and imperfect indicatives and of one or more subjunctive tenses. The imperfect indicative, a Latin innovation, survives almost intact, though the evolution of its form, not to mention its function, presents problems. The -ī- stem form in Latin *-iēba-* is thought to have coalesced early with the *-P-* stem *-ēba-* form, but a few languages (notably Italian, Friulian, and some Spanish and Portuguese dialects) today have reflexes of an *-ība-* form that might have survived from popular Latin. The Latin *-āba-* form survives almost everywhere, though in most French dialects its older reflexes, *-eve* and *-oue*, have been replaced in modern times by forms derived from Latin *-ēba-*. These latter are thought to be widespread but are puzzling phonologically as they have very often irregularly lost their *-b-* (Spanish, Portuguese, etc., *-ía*, French *-ais*).

The Latin perfect of the type *amdvit* "he has loved" is known by all the literary languages but is rare in speech in French, Italian, and Romanian, in which it has been replaced by a new compound past made up of the verb for "to have" and a past participle. The latter structure is known to some extent in all Romance languages, often being used to express a more recent past than the preterite *amāvit* form, which also indicates action in the past (without reference to duration or repetition): Romanian *au cîntat*, Italian *ho cantato*, French *j'ai chantk,* Spanish *he cantado*, Old Portuguese *hei cantado*, Engadine *ha chantd, hè chantò*, Sardinian *kantau appo,* from Latin *habeo cantatum "I* have sung." In Modern Portuguese the preferred auxiliary is *ter* "to have, to hold" rather than *haver,* producing forms such as *tenho cantado*, while modem Catalan more commonly uses the verb for "to go" plus the infinitive, giving *vaig cantar* rather than the pan-Romance type *he' cantat*.

Representation of the future tense

The disappearance of the Latin future has been remedied in most Romance languages by the development of new forms of periphrastic origin. Many of these forms use some reflex of *habēre* "to have" joined to an infinitive. From Latin *cantāre habēo* "'I will sing" are derived Italian *canter&,* Spanish, Catalan *cantare'*, Portuguese *cantarei*, French *je chanterai*, Rhaetian *c(h)antero, c(h)antera*, Occitan *cantarai; habēo cantāre* gives southern Italian *aggio cantd* (similar forms are seen in earlier Spanish, Portuguese, and northern Italian). Latin *habēo ad cantāre* produces Sardinian *ap a kantare*, and *habēo de cantare* gives Portuguese *hei-de cantar* (more popular than *cantarei)*.

A periphrastic future of the type known in English "I'm going to sing" enjoys popularity in Romance, mainly to indicate a less distant future event than the more formal future tense (*e.g.*, French *je vais chanter,* Spanish *voy a cantar*). Other periphrases used in Romance are "I will (wish to) sing," as in Romanian *voi cinta;* "I must sing," as in Sardinian *deppo kantare;* "I'm coming to sing," Sursilvan *jeu vegnel a cantar;* and *"I* have that I should sing," as in popular Romanian *am sa cînt*. Notably, Dalmatian does not seem to know periphrastic Romance futures but uses a form *kantuora* (perhaps from Latin *cantāverō*) as both future and conditional.

The Romance conditional, or "future in the past," a form not found in Latin, is in many languages related to the new future. In the Western languages it is composed of the future stem (or infinitive) plus a past-tense marker related to reflexes of *habēre*. In some cases an imperfect form is used, in others a perfect form; examples are French *je chanterais* "I would sing," Spanish, Portuguese, Occitan, and Catalan *cantaria,* and Italian *canterei, -ebbe*, etc. In Romanian the conditional marker can either precede or follow the infinitive and may be derived from the imperfect of *vrea* "to wish": for example, *aşi cinta, ar cînta*, etc., or (more literary) *cîntare-aş, cîntare-ar*, etc.

Word order

Word order is the means most used by modern Romance languages to show the grammatical relationship between words; statistically the most frequent order in statements is subject–verb–noun object. In many of the Romance languages, interrogation can be shown by inversion of the subject and verb, placing the verb, as the element on which the interrogation falls, at the beginning of the sentence (Spanish *¿Vino el hombre?,* Italian *È venuto l'uomo?* "Has the man come?"). In such examples, however, it is the intonation (represented in writing by the question mark) rather than the word order alone that marks the question. Inversion, without interrogative intonation, is not infrequent in emphatic assertions. Unambiguous question markers—such as the Latin particles *-ne, nonne*, and *num*—are lacking in most Romance standards; popular speech, though relying everywhere principally upon intonation, often has developed new particles to reinforce interrogation. Romanian has *oare, şi (Oare a venit?* "Has he come?" *Si te ai culcat?* "Have you been to bed?"); Italian uses dialectal *ce, che,* or *o* (Vulgar Tuscan *Che è venuto?* "Has he come?"; *O come si chiame?* "What is he called?"); Sardinian has *a (A mosse kkŭstu kăne?* "Does this dog bite?'); and French and Limousine have ti (generalized from such forms as *a-t-il?;* French *Je suis-ti bête?* Limousine *Sieu-ti nesci?* "Am *I* stupid?"). In modern standard French great use is made of *est-ce que* as an interrogative particle: *Est-ce qu'il est venu?* "Has he come?" *Comment est-ce qu'il s'appelle?* "What is his name?"

Negation in Latin was expressed by a range of special items *(non, nemo, nihil, nullus, nunquam,* etc.). Although some of the others survive in Romance, continuators of *non* have taken over the main burden of negative expression and are regularly prefixed to the verb. Nuances within negation are usually expressed by the adjunction of other items. In France, both north and south, and in northern Italy and some of the Swiss Rhaetian areas, the *non* particle has been so weakened phonetically that it no longer can express unambiguously the important distinction between negative and positive; hence, formerly positive adjuncts have acquired its negative meaning.

French *personne / une personne* signifies "no one / a person"; *pas / un pas* means "not / a step"; and *plus* can mean "more / no more." In popular speech the *non* particle is frequently omitted altogether in areas that use these additional forms (*e.g.*, French *Je (ne) le vois pas;* Occitan *Lou vese pas* for *Noun lou vese* "I don't see it").

Reduction of the subjunctive

Morphologically, the verb system survived comparatively intact from Latin to Romance; if the schoolbooks, heavily influenced by Latin grammar, are right, the ways in which the verb forms are used are not so very different from Latin either. The most obvious change has been the reduction of uses as well as of forms of the subjunctive, with, at the extreme, modern French treating them as automatically determined variants to be used obligatorily after certain phrases and conjunctions and virtually eliminating tense differences within the subjunctive mood. When the subjunctive retains a function in Romance—that is, in contexts in which it can contrast with the indicative—it has developed emotive overtones, especially suggesting doubt, unreality, or some sort of hypothetical futurity. It is used especially in subordinate clauses dependent on verbal expressions of command and exhortation, emotion, or doubt: Romanian *voi sa vină* "I want him to come"; Engadine *Mieu bap voul ch'eau lavura* "My father wants me to work"; French *Je doute qu'il vienne* "I doubt that he's coming"; Portuguese *Duvido que seja feliz* "I doubt that he is happy"; Italian *Temo che sia tarde* "I'm afraid it's late"; Spanish *Temo que él lo diga* "I'm afraid he'll say it." The subjunctive also regularly follows subordinating conjunctions that project action forward into the future, such as “until,” “before,” "in order that": French *avant que vous soyez venu* "before you came"; Spanish *hasta que sea feliz* "until he is happy"; Italian *perch2 potessi fare in tempo* "so that I might do it in time"; Portuguese *antes que eu o veja* "before I see it"; Catalan *abans que vingui* "before he comes."

On the whole, however, the Romance languages use the subjunctive less than Latin, with recession particularly, when no doubt is implied, in indirect speech and in temporal and concessive clauses (in French, use of the subjunctive after concessive conjunctions such as *bien que* and *quoique* "although" was imposed by 18th-century grammarians). The infinitive is often used in subordinate constructions when Latin would have used a subjunctive; *e.g.*, French *dites-lui de s'en aller*, for *dites-lui qu'il s'en aille* "tell him to go away." Romanian, on the other hand, has even extended the use of the subjunctive in such constructions, perhaps reflecting a substratum influence that is felt, too, in other Balkan languages. Greek influence is sometimes credited with similar constructions (usually using the indicative rather than the subjunctive) found in northeast Sicily, northern Calabria, and the Salentine Peninsula.

Conditional clauses

One area of syntax in which the Romance languages vary widely in the extent to which they retain and in the manner in which they replace the Latin subjunctive is that of past-tense hypothetical conditional clauses. The Latin formula *si habuissem dedissem* "if I had had it, I would have given it," though challenged by a type using the indicative tense since Ciceronian times, has sporadically survived into Romance, especially in the older stages of the languages and in scattered parts of southern Italy *(Se potessi, facessi* "If I could, I would do it"), Rhaetian (Sursilvan *Jeu vegness, sche jeu vess peda* "I'd come, if I had time") and Romanian *('dacă agi avea destui bani, agi cumpăra-o* "If I had enough money, I'd buy it").

In most languages, however, a new conditional form replaces the subjunctive in "if" clauses. Thus, in Spanish, Portuguese, and most Italian dialects, sentences of this type are seen: Spanish *si* yo *tuviese bastante dinero, lo compraria;* Italian *se avesse abbastanza danaro, lo comprerei;* Portuguese *se tivesse bastante dinheiro compraríao* (“if I had enough money, I'd buy it"). Spoken Catalan usually prefers a similar construction *(si estudiessis ho sabries* "if you studied, you would know it"). Another construction that replaces the subjunctive by the imperfect indicative in the "if" clause is, however, considered more correct in Catalan and is normal in French as well as in Corsica and Sardinia: Catalan *si estudiaves ho sabries* ("if you studied, you would know"); French *si j'avais assez d'argent, je l'achèterais* ("if I had enough money, I'd buy it"); Logudorian *si denia abba deo dia buffare* ("if I had water, I'd drink”). Other constructions using the imperfect indicative or the conditional in both clauses are found mainly in substandard styles—both types are common in French, the former in Tuscany, southeastern Italy, and Spain and the latter in much of southern Italy.

Forming new words

Word formation. Romance methods of forming new words from native sources are in part inherited from Latin (the morphological device of adding a suffix and that of prefixing an element that modifies the original meaning) and in part later developments (mainly that of combining two or more free forms to make compound words and of changing or extending the syntactic distribution of an already existing word).

Derivation by means of suffixes is the most popular and widespread device; verbs in particular must be morphologically marked as members of a conjugation, of which those corresponding to Latin *-āre* form by far the most frequent and indeed in modern times virtually the only productive class (thus Latin *plantāre* "to plant," Italian *plantare,* Engadine *plaunter*, French *planter,* Catalan *plantar,* from *planta* "plant"). Infixes, inserted between the verbal root and the conjugation marker, are common. Sometimes they continue Latin infixes, such as the frequentative (compare *jactāre* for *jacere* "to throw," Italian *gettare*, French *jeter*, Catalan *getar*, etc.); sometimes they add semantically to the root meaning (compare pejorative Italian *lavoracchiare* “to slack off” from *lavorare* "to work," French *criailler* "to bawl" from *crier* “to cry"). The Greek verbal infix *-iz* (as in English “ize”) is particularly popular in Romance today *(e.g., latinisare, automatiser)*.

Among noun suffixes, diminutives are frequent and, except perhaps in French, still productive. Romanian uses *-aş (degetaş* "little finger", but the other languages prefer derivatives of Latin *-ittus* (especially in Spanish: *arbolito* "little tree," *señorita* “Miss, young lady," etc.; but also French *sachet* "little sack," Italian *foglietta* “little leaf," etc.) or of Latin *-īnus* (preferred in Italian: *tavolina* "little table, desk," *signorina* "young lady"; and Portuguese: *copinho* "little drinking glass," *senhorinha* "young lady"). The Latin *-ōne* suffix has, conversely, acquired augmentative meaning in several languages (Romanian *căloiu*, Italian *cavallone,* Spanish *caballón* "large horse").

Other frequent suffixes sometimes have a "learned" modern form alongside the older "popular" one; *e.g.*, Latin *-atione:* Italian *-agione / -azione*, French *-aison / -ation*, Spanish *-azón / ación*, Portuguese *-azão / ação;* also Romanian *-ăciune*, and Occitan *azó*.

Suffixes that remain extremely productive include the Latin verbal adjectival *-bilis* (not found in Romanian): Italian *bastevole* "enough," French *admirable,* Spanish *ainable* "pleasing"; and verbal nominal *-mentum:* French *abonnement* "subscription," Spanish *cobijamiento* "lodging," Italian *abboccamento* "interview, parley," Romanian *acoperămînt* "cover."

Prefixing of modifying elements remains frequent in all languages (Italian *autostrada* “highway,” Spanish *contraveneno* "antidote," French *photocopie* "photocopy"), although some older prefixes may hardly be recognized as such today. The "repetitive" verbal prefix *re-* remains particularly active (Romanian *răsări* "rebound," Italian *ricattare* "to recover," French *racheter* "to buy back." etc.).

Compound words, though less frequent than in the Germanic languages, are not uncommon (*e.g.*, French *cheflieu* "principal town," Italian *primavera* "spring," Spanish *lavamanos* "wash basin").

Adverb formation

Originally a compounding process, the most common method of forming adverbs from adjectives (suffixing of Latin *mente* "mind") has become in most languages a morphological process, although Spanish and Portuguese retain traces of the earlier stage in phrases such as *severa e* (y) *cruelmente* "severely and cruelly."

Among the syntactic means that most Romance languages use to extend vocabulary is the potent device, unavailable to Latin, of juxtaposing to any part of speech an article or other determiner and using it as a noun (*e.g.*, Italian *il perch2* "the reason," Spanish *lo útil* "utility, something useful," French *un je ne sais quoi* "an I-don't-know-what"). In French and Spanish, verbal infinitives are frequently so treated (*le devoir* "duty," *el poder* “power,” etc.); Romanian also uses infinitives as verbal nouns, but they are differentiated formally by retaining the full form (*e.g.*, *cintare* "singing"), compared with the shortened verbal form *(cinta)*. In earlier stages of most Romance languages the verbal root (most often as it appears in the 3rd-person singular present indicative) could be used as a noun, a process known as back-formation (compare Romanian *laudă* "praise," Italian *domanda* "question," French *approche* "approach," *désir* "desire," Spanish *baila* "dance," Portuguese *muda* "change").

Just as former adjectival forms are frequently used as substantives, so are nouns used with adjectival function; there seem to be few restrictions on this use, though practice varies as to whether agreement should be made (French *les frères ennemis* "enemy brothers," with agreement; *une femme médecin* "a woman doctor," without agreement). Past-participial forms normally act as adjectives, as in English.

Romance makes use of gender classification to extend and modify its vocabulary, especially by relating the gender markers to sex differences (*e.g.*, Romanian *nepot, nepoată;* Occitan *nebut, nebudo,* Spanish *nieto, nieta,* Portuguese *neto, neta*, Catalan net, *neta* “nephew, niece," with Italian invariable *nipote*, and French lexically differentiated *neveu, nièce*). Modern French makes particularly fruitful use of gender differences (originally via ellipse); thus, *le* (vin de) *champagne* (the drink) / la *Champagne;* La Nor*mandie* (the province) / *le Normandie* (the ship).

VOCABULARY

Importance of Latin in vocabulary formation

The basic vocabularies (the most frequently used lexical items) of all the Romance languages are in the main directly inherited from Latin. This applies equally to "function" words, such as *de* "of, from" (Romanian de, Italian di, Rhaetian *da*, French de, Spanish *de*, Portuguese *de*), as to common lexical items, such as *facere* "to do" or aqua "water" (Romanian face, *apă*, Italian fare, *acqua,* Logudorian *fágere,* abba, Engadine fer, ova, French *faire,* eau, Catalan *fer,* aygua, Spanish *hacer*, agua, Portuguese fazer, *água*). In some cases different Romance languages inherit words perhaps from different strata of Roman society. Thus, for "lamb," forms derived from Latin *agnus* remain in southern Italy and Galician (*año*), but forms derived from diminutive *agnellus* prevail in Romanian (*miel*), Italian (*agnello*), French (*ag*ncau), Rhaetian (Engadine *agné*, Friulian *añel*), Occitan (*anhel*), and Catalan (anyell), with Sardinian and some Calabrian dialects using another form derived from Latin agnone (Logudorian *andzone*). Spanish and Portuguese, however, prefer a derivative of a different word, *chorda* (cordero, *cordeiro*), referring perhaps to the birth process; this word is also found in Occitan and Catalan.

Some words shared by the majority of the Romance languages are not of Latin origin but were probably borrowed from other languages before Latin unity was disrupted. These include especially words of Celtic origin, such as Latin *carrum* "cart," Romanian car, Italian carro, Logudorian karru, Rhaetian k'ar, French *char*, Occitan and Catalan cur, Spanish and Portuguese carro.

In Christian Latin a great many Greek ecclesiastical terms were borrowed, which survived in most Romance languages. For example, the Greek word *episkopos* (literally, "overseer") was borrowed into Latin as *episcopus* "bishop," which gave rise to Vegliot *pasku*, Logudorian *pískamu*, Italian vescovo, Engadine *ovaisch*, Friulian *veskul*, French *evêque*, Occitan avesque, Catalan bisbe, Spanish obispo, and Portuguese bispo.

Germanic words did not penetrate into Latin very frequently before the separation of the various Romance languages from Latin, so that few of them have more than limited extension. Only one Germanic word is known for certain to be found in both Eastern and Western Romance—*sapōne* "soap," recorded in Pliny and occurring as Romanian *săpun*, Vegliot *sapaun*, Italian *sapone*, Logudorian *sabone*, Engadine *savum*, French *savon,* Occitan and Catalan *sabó,* Spanish *jabón*, and Portuguese *sabão.*

"Learned" words

Many Latin words are widespread throughout the Romance languages even though they do not date back directly to the imperial period; these are the “learned” words that have freely entered the languages at virtually every period, borrowed from Latin used as a scholarly language. Because of this later borrowing, such words as capital, *natura*, *adulterium*, and discipulus appear in Romance virtually unchanged from Latin, as they do in other European languages; Romance Latinisms, however, are quite normally used in contexts in which similar words would sound stilted and pedantic in English (*e.g.*, French *supprimer* "suppress" but often used to mean "to do away with").

However similar the Romance vocabularies are to each other, considerable differences nevertheless exist. Some of these may be traced back to imperial times, when provinces may have developed their own vocabulary preferences. For instance, for "oak" Eastern Romance seems to have preferred Latin quercus (Logudorian kerb ~sọuthern Italian *quercia,* etc.), whereas the West preferred the alternative *robur* (Italian *rovere*, Occitan and Catalan *roure*, Spanish and Portuguese roble, Old French louvre—modern French *chêne* is of Celtic origin, while Romanian *stejar* is perhaps of Balkan origin). In some cases the conservative peripheral areas have retained a word that was displaced in more central regions; thus, for "beautiful," *formosus* is preferred in Romanian (*frumos*), Spanish (*hermoso*), and Portuguese (*formoso*), whereas *bellus* is more popular in Vegliot (bial), Italian (*bello*), Rhaetian (*bal*, *biel*), French (beau), Occitan (bel), and Catalan (bell).

Borrowing from substratum and super-stratum languages

When Romance borrowed vocabulary from the substratum, differentiation must have taken place early (certainly before the indigenous languages died out). Thus, Spanish *vega*, Portuguese *veiga* "wooded ground by a river" (probably from a non-Indo-European Iberian language, compare Basque ibaiko “riverbank”), French *charrue* "plow," borne "boundary stone" from Celtic, and Romanian *barză* "stork" (perhaps from Dacian, compare Albanian bar) probably were used during Roman times in some form. The debt of Romance vocabulary to substrata languages is probably great but difficult to estimate with any certainty. When there is no known source form or cognate for a word, scholars often suggest an Iberian, Dacian, Ligurian, or Gaulish origin, but, as little is known of these languages, some such theories are mere speculation.

After the influx of barbarian invaders, Romance vocabularies differentiated further as each borrowed from its own superstratum (language superimposed upon Romance). French, for instance, is estimated to have taken some 700 words from Frankish (a Germanic language), not all of which have survived but some of which have passed via French into other Romance languages. Many of these were concerned with agriculture (*jardin* "garden," *houe* “hoe,” ble' "wheat," *gerbe* "sheaf," etc.) or with war (*guerre* "war," *héaume* "helmet") or social organization (*sénéchal* "seneschal," chambellan "chamberlain," *maréchal* "marshal," *baron* "baron"). The occupation of much of north Italy by speakers of Langobardic (also a Germanic language) left less of a mark on Italian vocabulary, though dialects retain more words (estimated at about 300) than the standard language. Standard Italian borrowed little in the way of administrative or military terms but accepted a number of words from rural life (*melma* "mud," *zecca* "sheep tick," *stamberga* "hut," etc.). The Visigoths, who occupied Iberia, were more Romanized than the other Germanic invaders and indeed had abandoned their Germanic tongue by the 7th century AD. Thus, borrowings from Visigothic into Spanish and Portuguese are less frequent, though still not inconsiderable; some (such as estaca "stake," brotar "to bud") are common to all the Iberian Peninsular languages.

Slavic infiltration into the Balkans led Romanian to adopt a very large number of Slavic words, some in the basic part of the vocabulary. At exactly what stage in history they were borrowed is uncertain, for the earliest Romanian texts: of the 16th century AD, are saturated with Slavic terms from different dialectal sources, though South Slavic predominates. Possibly the borrowings occurred in the 9th century, when the Hunnish Bulgarians, who had adopted Slavic speech, established a powerful state and embraced Christianity, and Slavic pressures were already very strong. Among common Romanian words of Slavic origin one may mention a *trăi* "to live," *hrană* "food," *ceas* “hour,” *bogat* "rich," *prieten* "friend," *munci* “to work." The Magyars (modern Hungarians) also lent a smaller number of words to their Romanian neighbours (*e.g.*, *oraş* "town").

Words borrowed from Arabic

Islāmic invaders into Europe from the 8th century had considerable effect on the vocabulary of the Western Romance languages, even though occupation was confined to southern regions. With its superior cultural and agricultural skills, the Arab world had much to teach Europe of the Dark Ages. Words entered via two routes: Sicily and Spain, and usually their form gives clues about their provenance—if the Arabic definite article (al) has coalesced with the root, the word is from Moorish Spain (thus Spanish *algodón* "cotton," Portuguese *algodão,* Old French *auqueton* via Spain, but Italian *cotone*, French *coton* via Sicily). The Arabs introduced into Europe many exotic plants and fruits and with them their names, such as oranges (Spanish *naranja*), lemons (Spanish *limón*), and artichokes (Spanish alcachofa, Italian *carciofo*). In some cases the Iberian Peninsula has adopted the Arabic word for such plants, while other languages prefer words of other origin—“rice” is arroz in Spanish and Portuguese, *arròs* in Catalan, but Italian and French prefer a Greek word (riso, *riz*), as do Vegliot (rize), Rhaetian (Friulian *ris*), and Romanian (orez). Apart from the numerous Arabic words known throughout Romance (especially "arithmetic," "algebra," and the like), many are peculiar to the Hispanic languages, such as administrative terms such as Spanish alcalde "mayor" or *alguacil* "senior police officer," commercial terms such as *almacén* "warehouse, department store," as well as everyday words such as ahorrar "to save," alboroto "noise."

Many of the words individual languages borrowed from other sources or fashioned themselves from native sources did not remain private property for long. Interchange among the Western languages has been common since the earliest times and especially from the 16th century. Perhaps French has been the greatest supplier of words throughout the ages, often displacing native words. But French, too, has borrowed heavily from the other languages, especially when they have been purveyors of new objects (such as *patate*, *banane*, tabac, introduced into Europe by Spanish and Portuguese explorations) or of special cultural values (Italian musical and architectural terms, as well as words to do with banking). Borrowing into minor languages from prestigious neighbours has, naturally, been prolific. Passage of words in the other direction is rare and usually employed for comic or other emotive effect (though Occitan in its heyday supplied a good many words of all sorts—even, it is said, amour "love" to French).

Anglicisms

Borrowings from non-Romance languages are less frequent and often frowned on by purists, but far from negligible. Any contact in specialized spheres has produced a crop of loanwords, especially since the 17th century, when French in particular began to borrow a fair number from its Germanic neighbours. In recent times, the influx of anglicisms has become a flood, resisted to the death by some purists. Many are, however, ephemeral or specialized, and none affects the basic vocabulary in which Latin-inherited words continue to predominate.

ORTHOGRAPHY

Today the Romance languages are all written in the Latin alphabet, with certain modifications, though until the mid-19th century Romanian was normally written in Cyrillic (still used in Moldavia), and, in the Middle Ages, Arabic script was used for some Spanish dialects.

As soon as scribes first made attempts to write in vernacular Romance, they found the resources of the Latin alphabet inadequate to represent the non-Latin sounds of their spoken language. One device used to overcome these difficulties was to add the letter *h* to another, to indicate a deviant pronunciation: thus, *ch* might represent the ch sound in Spanish (*e.g.*, *muchacho* "boy") or the *sh* (earlier ch) sound in French (*e.g.*, chef "chief"). *C* would normally be used for the k sound (before a, o, *u*) or an *s* or th sound (before *i, e*). In Italian, conversely, *ch* serves to distinguish the k sound, followed by e, from the ch sound (compare *che* [key] “that, who" with *c'è* [chey] "there is"). H was also sometimes added to *n* and *l* to indicate a palatal pronunciation (similar to the ny in English "canyon" and *li* in "scallion"), as today in Portuguese *vinho* "wine" and *filho* "son." Another device frequently used to stretch the capacity of the Latin alphabet was to distinguish the letters i and *j*, u and v, which were originally each single letters i (with variant form j) and v (with variant form *u*, and in Latin pronounced u or w). In Romance, v and *j* came to represent consonants, while u and i retained their vowel values.

The palatal consonants *n* and 1 are also often depicted by doubled letters or other combinations of letters: the palatal n as *nn* (or its scribal variant A), *gn,* nj, or *in;* palatal l as *ll, gl, lj,* il, or *yl*, as well as the combinations nh and *lh*, already mentioned. The Latin letter *x*, an abbreviation for *ks*, was also put to other uses in Romance; in Portuguese, Catalan, Sicilian, and Old Spanish it represents an sh sound, in modem Spanish a strong h sound, more commonly spelled with a *j*, and in northern Italian dialects the *z* sound. Other letters pressed into use for new consonantal sounds were *z* (used in Italy for *ts* and *dz* sounds, Germanic k and w, and the Visigothic *ç* for ts and sometimes *s*, as today in French and Portuguese).

Vowels were less of a problem for early Romance scribes-diphthongs were simply shown as vowel combinations such as ie, uo. Later, the diaeresis (¨) was sometimes introduced to distinguish diphthongs from adjoining vowels that were to be pronounced separately. Non-Latin vowels are rarely clearly distinguished: French *u* (pronounced like German *ü*), for instance, was written *u* and not consistently distinguished from Latin u (pronounced as in "lunar" and, in modern French, written *ou*). Nasal vowels in French are marked by a following n or m; in Portuguese a tilde (~) is often used for final nasal vowels and diphthongs (*ã, ãi*). Use of diacritics was not consistent until modern times; thus, so-called long and short *e*, still not always distinguished in Italian, are shown as *é* and *è* or *ê* (e.g., *élève* "student") in French (since the 18th century) and as e and *é* in Portuguese (since about 1930). Romanian established the use of *î* and *ă* only in the 20th century.

Diacritical Markings

In most of the languages with a long history of writing, the original attempts by scribes at phonological transcription were followed by an "etymological" period in which Latinized spelling gained ground. Castilian was least subject to this fashion, and, because its phonology has changed comparatively little since the Middle Ages (when its spellings became more or less fixed), it has few orthographical problems today. Standard Italian retains a fairly etymological orthography that covers up various minor regional differences of pronunciation; small reforms have been made through the centuries (in the 17th century, for instance, the use of h--except in *ho,* ha, hanno—was discontinued; in the 20th century, *î* and *j* for *ii*, as in studii, have virtually disappeared), but chaos still reigns in the use of accents. Romanian suffered from etymologizing orthography in the 19th century, but successive edicts of the Romanian Academy, of which the most important was dated 1932, have established a more or less phonetic spelling (the notable exception being the depiction of final "soft" consonants by a following i). Modern Catalan, like other “minor” languages, has had the aid of expert linguists in the establishment of its orthography. A standard was proposed by Antonio Maria Alcover Sureda, a Catalan priest, philologist, and writer from Majorca, in 1913, which is accepted, with small variations, by most writers.

Only two of the Romance languages, French and Portuguese, have had major orthographical problems, mainly resulting from the radical transformations that have affected their phonology since the Latin period. Portuguese has attempted to overcome its difficulties by a series of governmental reforms during the 20th century, but, in spite of official agreements between Portugal and Brazil in 1931 and 1945, there is still little consistency in usage, with Brazilian writers, especially, remaining more conservative (*i.e.*, etymological). In France, in spite of vociferous demands for reform since the 16th century, only minor changes have been accepted (usually originally from unofficial sources, such as printers), so that French orthography today reflects 12th-century phonology, overlaid by the etymologizing of Middle French legal scribes. Battles still rage between the reformers, who deplore the absurdly large proportion of school time devoted to teaching spelling, and the defenders of tradition, who point out that the phonological character of French, with no consistent phonetic markers for the word, make it unsuitable for phonetic transcription and that written French has its own structure, not identical with that of the spoken language.

BIBLIOGRAPHY. I. IORDAN and J. ORR, ***An*** *Zntroduction to* Romance *Linguistics*, revised reprint of the 1937 edition, with an additional essay, "Thirty Years On" by REBECCA **POSNER** (1970), describes the work done in Romance during the 19th

and 20th centuries and provides an extensive bibliography of all works written both on the family as a whole, and on individual languages. On the Romance languages in general, two books written in English will prove useful: the more philologically oriented The Romance Languages by W.D. ELCOCK (1960); and the more popular, linguistically oriented The Romance Languages: *A* Linguistic Introduction by REBECCA POSNER (1966). Outstanding is Y. MALKIEL, *Essays* on Linguistic Themes (1968), which includes several articles on the Romance languages and Romance linguistics. On the individual languages, among works in English particularly to be recommended, are L.R. PALMER, The Latin Language (1954); BRUNO MIGLIORINI, with T. GWYNFOR GRIFFITH, *Storia della* lingua *italiana* (1960, Eng. trans., The Italian Language, 1966); A.E. EWERT, The French Language, 2nd ed. (1961); and WILLIAM ENTWISTLE, The Spanish Language (1936).

(Re.P.)

Romania

Romania, a country of southeastern Europe (formally the Socialist Republic of Romania), derives much of its ethnic and cultural character from its position astride major continental migration routes. But emphasis should also be placed on three distinct elements basic to the physical geography. The vast arc of the Carpathian Mountains and their extension, the Transylvanian Alps, crosses the country from north to south, encircling the Transylvanian Plateau to create a huge natural amphitheatre. In terms of drainage, the country is indisputably Danubian, for the lower course of this great river runs eastward across the lowlands of the southern portion of the country, emptying into the Black Sea by way of a delta that is one of the finest natural endowments of the continent. Finally, a small eastern portion of the country, because of its Black Sea littoral, exhibits maritime characteristics.

Since the late 19th century, Romania has undergone an economic and social transformation marked by accelerating urbanism and a drop in the traditional predominance of agriculture. Romania's population of more than 21,-000,000 in 1975 made it nearly as populous as Canada, ninth in population among European countries, and sixth among the 14 nations of the Commuhist bloc. At 91,699 square miles (237,500 square kilometres), its area is comparable to that of Laos or Uganda. Its boundaries total 1,959 miles (3,153 kilometres), with the Soviet Union on the east and north, Hungary on the west, Yugoslavia on the southwest, Bulgaria on the south, and the Black Sea on the east. The national capital is Bucharest (Bucureşti), with a population exceeding 1,700,000 by 1976.

This article is concerned with the contemporary nation. For information on related subjects, see BALKANS, HISTORY OF THE; BLACK SEA; BUCHAREST; CARPATHIAN MOUNTAINS; and DANUBE RIVER.

THE LAND

There is a certain symmetry in the physical structure of Romania. The country forms a complex geographical unit centred on the Transylvanian Plateau, around which the peaks of the Carpathians and their associated subranges and structural platforms form a series of crescents. Beyond this zone, the extensive plains of the south and east of the country, their potential increased by the Danube and its tributaries, form a fertile outer crescent extending to the frontiers. There is great diversity in the topography, geology, climate, hydrology, flora, and fauna. For millennia this natural environment has borne the imprint of a human population, ever renewed by migratory movements but nevertheless having roots deep in the country's past.

Relief divisions. The *Carpathians.* The relief of Romania is dominated by the Carpathian Mountains, which can be divided into three major sections: the Eastern Carpathians (Carpafii Orientali), the Southern Carpathians (also known as the Transylvanian Alps and called in Romanian the Carpaţii Meridionali), and the Western Carpathians (Carpaţii Occidentali).

The Eastern Carpathians extend from the Soviet frontier to the Prahova River Valley and reach their maximum height in the Rodna Mountains (Munfii Rodnei), with Pietrosul rising to 7,556 feet (2,303 metres). They are made up of a series of parallel crests that are oriented in a more or less north–south direction. Within these mountains is a central core made up of hard, crystalline rocks and with a bold and rugged relief. Rivers have cut narrow gorges here (known locally as *chei*)—in, for example, Cheile Bistrifei and Bicazului—and these offer some magnificent scenery. This portion of the Carpathians is bounded on the eastern side by a zone of softer flysch. For some 250 miles on the western fringe the volcanic ranges Oag (Munfii Oagului) and Harghita, with a concentration of volcanic necks and cones, some with craters still preserved, lend character to the landscape. St. Ana Lake—the only crater lake in Romania—is also found here. The volcanic crescent provides rich mineral resources (notably copper, lead, and zinc) as well as the mineral-water springs on which are founded such health resorts as Vatra Dornei, Borsec, Tugnad, and Malnaş. The Carpathian range proper is made up in large part of easily weathered limestones and conglomerates, which again provide some striking scenery. The Maramureş, Giurgiu, Ciuc, and Birsei depressions further break up the mountainous relief.

Volcanic scenery

The Southern Carpathians, or Transylvanian Alps, lie between the Prahova River Valley on the east and the structurally formed Timiş and Cerna river valleys to the west. They are mainly composed of hard crystalline and volcanic rocks, which give the region the massive character that differentiates it from the other divisions of the Carpathians. The highest points in Romania are reached in the peaks of Moldoveanu (8,346 feet- [2,544 metres]) and Negoiu (8,317 feet [2,535 metres]), both in the Făgăraş Massif (Munfii Făgărasului), which, together with the Bucegi, Paring, and Retezat–Godeanu massifs, forms the major subdivision of the region. The last named contains a national park of more than 49,000 acres (20,000 hectares), which, besides offering spectacular mountain scenery, provides an important refuge for the chamois (Rupicapra rupicapra) and other animals. Ancient erosion platforms, another distinguishing feature of the area, have been utilized as pastures since the dawn of European history. At the highest levels, beautiful glacial lakes testify to the last Ice Age. The southern slopes of this region offer special interest: the waters of the Bistrifa, Cerna, and other rivers have carved deep valleys in the soft limestone rock, and the region also contains the Polovragi Cave and the Muierii Grotto. Communication is possible through the high passes of Bran, Novaci-Şugag, and Vîlcan, at altitudes of up to 7,400 feet, but the scenic Olt, Jiu, and Danube river valleys carry the main roads and railways through the mountains. At the Porţile de Fier (Iron Gate) on the Danube, a joint Romanian–Yugoslavian navigation and power project has harnessed the fast-flowing waters of the gorge; its power station has a capacity exceeding 2,000,000 kilowatts, and navigation facilities have been greatly improved. Finally, as in the Eastern Carpathians, there are important lowland depressions within the mountains (notably Brezoi, Haţeg, and Petrogani), and agriculture and industry are concentrated in them.

The Western Carpathians extend for about 220 miles (350 kilometres) between the Danube and Someş rivers. Unlike the other divisions of the Carpathians, these do not form a continuous range but a cluster of massifs around a north–south axis. Separating the massifs is a series of deeply penetrating structural depressions. Historically, these have functioned as easily defended "gates," as is reflected in their names: the Iron Gate of Transylvania (at Bistra); the Eastern Gate, or Poarta Orientaliă (at Timiş-Cerna); and, most famous, the Iron Gate on the Danube.

Historic "gates"

Among the massifs themselves, the Banat and Poiana Ruscă mountains contain a rich variety of mineral resources and are the site of two of the country's three largest metallurgical complexes, at Regifa and Hunedoara. The marble of Ruschiţa is well known. To the north lie the Apuseni Mountains, centred on the Bihor Massif, from which emerge fingerlike protrusions of lower relief. On the east, the Bihor Mountains merge into the limestone tableland of Cetăţile Ponorului, where the erosive action of water along joints in the rocks has created a fine example of the rugged karst type of scenery. To the west lie the parallel mountain ranges of Zărand, Codru-Moma (also called Munţii Codrului), and Pădurea Craiului; on the south, along the Mureş River, the Metaliferi and Trască mountains contain a great variety of metallic and other ores, with traces of ancient Roman mine workings still visible.

The Western Carpathians generally are less forested than other parts of the range, and human settlement reaches to the highest altitudes. The population maintains many traditional features in architecture, costumes, and social mores, and the old market centres, or *nedei,* are still important. The Tîrgul de Fete (Maidens' Fair) is still held every year in late July on Găina Mountain and is attended by peasants from the Arieş and Crişul Alb valleys. Mining, livestock raising, and agriculture are the main economic activities, the last named being characterized by terrace cultivation on the mountain slopes, a survival from Roman times.

The Subcarpathians. The great arc of the Carpathians is accompanied by an outer fringe of rolling terrain known as the Subcarpathians and extending from the Moldova River in the north to the Motru River in the southwest. It is from two to 19 miles wide and reaches heights ranging between 1,300 and 3,300 feet (400 and 1,000 metres). The topography and the milder climate of this region favour vegetation (including such Mediterranean elements as the edible chestnut) and aid agriculture; the region specializes in cereals and fruits, and its wines—notably those of Odobegti and the Călugărească Valley—have a European reputation. The area is densely populated, and there are serious problems of economic development in remoter areas where there is little scope for further agricultural expansion.

Carpathian "double towns"

The tablelands. Tablelands are another important element in the physical geography of Romania. The largest is in Transylvania, with large deposits of methane gas and salt, first exploited for a chemical industry in the 1930s. The salt lakes have given rise to the health resorts of Ocna Sibiului and Sovata. The region as a whole is well populated, with a good transport system. A belt of towns has grown up on the margins, and these often parallel another outer fringe of towns commanding the main trans-Carpathian passes. Examples of such "double towns" are Suceava and Bistrifa; Făgăraş and Cîmpulung; Sibiu and Rîmnicu Vîlcea; Alba Iulia and Arad; and Cluj and Oradea.

In the east, between the outer fringe of the Subcarpathians and the Prut River, lies the Moldavian Plateau (Podigul Moldovei), with an average height of 1,600 to 2.000 feet. In contrast to Transylvania, which experienced considerable urban development during the Dacian and Roman periods, Moldavia did not begin to develop towns till the Middle Ages, when the old Moldavian capitals of Iagi and Suceava had close commercial connections with the towns of Transylvania and derived benefit from trade passing between the Baltic and Black Sea ports. Finally, the Dobruja tableland, an ancient, eroded, rock mass in the southeast, has an average altitude of 820 feet and reaches a maximum of 1,532 feet (467 metres) in the Pricopan Hills (Dealul Pricopanului).

The plains. Plains cover a third of Romania, reaching their fullest development in the south and west. Their economic importance has increased very greatly since the early 19th century. In the southern part of Romania is the lower Danube Plain, which can be divided into the Romanian Plain (Cimpia Romînă), to the east of the Olt River, and the Oltenian Plateau (Podişul Olteniei), to the west. The whole region is covered by deposits of loess, on which rich, black chernozem soils have developed, providing a strong base for agriculture. The Danube floodplain is important economically, and along the entire stretch of the river, from Calafat in the west to Galafi in the east, former marshlands have been diked and drained to increase food production. Willow and poplar woods border the river, which is important for fishing but much more so for commerce. Ten river port towns (including Drobeta–Turnu Severin, Turnu Măgurele, Giurgiu, Brăila, and Galafi) complement the rural settlements. There are good rail connections with the main lines, including the two that cross the Danube, at Cernavodă (linking Bucharest with the Black Sea port of Constanfa) and Giurgiu (connecting Romania with Bulgaria).

Economic importance of the Danube Delta

The Danube Delta. On the northern edge of the Dobruja region, adjoining the Soviet Union, the great, swampy triangle of the Danube Delta is a unique physiographic region covering some 1,950 square miles, of which 1,750 square miles (4,530 square kilometres) are in Romania. The delta occupies the site of an ancient bay, which in prehistoric times became wholly or partially isolated from the sea by the Letea sandbanks. The delta contributes about half of Romania's fish production from home waters, fishing off the Danube mouth contributing 90 percent of the sturgeon catch (and subsequent caviar production) as well as 80 percent of Danube herring catch. The plant and animal life of the delta region is unique in Europe, with many rare species. The area is also a stopping place for migratory birds. A great number of birds, including pelicans, swans, wild geese, ibis, and flamingos, as well as wild pig and lynx, are protected by law, and a large part of the region has been declared a nature reserve, with hunting and fishing prohibited. The whole delta is of great interest to scientists, conservationists, and a growing number of tourists from other countries. Two dozen or more settlements are scattered over the region, but many are exposed to serious flood risks and only two (the ports of Sulina and Tulcea) have attained urban status.

The Black Sea coast. The Black Sea coastal strip has its own special environment, including a temperate climate with continental aspects and good sand beaches. Lakes—among which Taşaul, Siutghiol, Agigea, Techirghiol, and Mangalia are the most significant—further enhance the attractions of the region. Several of them contain deposits of mud and sulfurous hot springs believed to have therapeutic properties. The development of recreational facilities dates back to the turn of the century, and a series of new health and tourist centres has sprung up in recent decades. The towns of Năvodari, Mamaia, and Eforia are entirely new creations, while the older settlements of Mangalia and Techirghiol have undergone extensive redevelopment. It seems likely that the whole 34-mile stretch between Năvodari and Mangalia will become within a few years a single resort area.

Climate. Romania's geographic situation in the southeastern portion of the European continent gives it a climate that is transitional between temperate regions and the harsher extremes of the continental interior. In the centre and west, humid Atlantic climatic characteristics prevail; in the southeast the continental influences of the Russian Plain make themselves felt; and in the extreme southeast there are even milder sub-Mediterranean influences. This overall pattern, however, is substantially modified by relief, and there are many examples of climatic zones induced by altitudinal changes.

The effect of relief on climate

The average annual temperature is 52° F (11° C) in the south and 45° F (7" C) in the north, although, as noted, there is much variation according to altitude and related factors. Extreme temperatures range from 111° F (44" C) in the Bărăgan region to —36" F (—38" C) in the Braşov Depression. Average annual rainfall amounts to 26 inches (660 millimetres), but in the Carpathians it reaches about 55 inches (1,400 millimetres) and in the Dobruja region it is only about 16 inches (400 millimetres). Humid winds from the northwest are commonest, but often the drier winds from the northeast are'strongest. A hot southwesterly wind, the *austru,* blows over western Romania, particularly in summer. In winter, cold and dense air masses encircle the eastern portions of the nation, with the cold northeasterly known as the *crivăţ* blowing in from the Russian Plain, while oceanic air masses from the Azores, in the west, bring rain and mitigate the severity of the cold.

Drainage. The rivers of Romania are virtually all tributary to the Danube, which forms the southern frontier from Moldova Nouă to Călăraşi. Nearly 40 percent of the total Danubian discharge into the Black Sea is, in fact, provided by Romanian rivers. The final discharge takes place through three arms—the Chilia (67 percent of the flow), Sulina (9 percent), and Sfintu Gheorghe (24 percent)—that add to the scenic attractions of the delta region. The most significant of the Romanian tributary rivers are the Prut, Mureş, Olt, Siret, Ialomifa, and Someş. The rivers have considerable hydroelectric potential, although there are great seasonal fluctuations in the discharge and few natural lakes to regulate the flow. The total surface-water potential of the tributary rivers exceeds 1,400,000,000,000 cubic feet (40,000,000,000 cubic metres) annually, although this figure is dwarfed by the volume discharged at the Danube mouth, which is more than five times as large. Subsoil waters have been estimated at an annual volume of some 250,000,000,000 cubic feet (7,000,000,000 cubic metres). These overall figures, like those for many aspects of the Romanian environment, mask the fact that water resources are not uniformly distributed over the country and may vary not only from year to year but within the same year.

Hydro-electricity

The total theoretical hydroelectric potential of Romania —given optimum technological conditions—hasbeen calculated at some 70,000,000,000 kilowatt-hours in an average year. About half this amount might well be harnessed, given the present state of technology, but for economic reasons a figure of 24,000,000,000 kilowatt-hours represents a more feasible goal. Geographically, the hydroelectric reserves of Romania are concentrated along the Danube and in the valleys of rivers emerging from the mountain core of the country. Other hydrographic resources include the more than 2,500 lakes, ranging from the glacial lakes of the mountains to those of the plains and the marshes of the Danube Delta region. The main effort since the 1940s, however, has been on the Argeg, Bistrifa, Lotru, Olt, and Someş as well as on the Danube at the Iron Gate.

Plant and animal life. Forests, which cover almost 27 percent of Romania, are an important component of the vegetation cover, particularly in the mountains. Up to about 2,600 feet (800 metres) oaks predominate, followed by beeches between 2,600 and 4,600 feet and conifers between 4,600 and 5,900 feet (1,400 and 1,800 metres). At the highest levels, alpine and subalpine pastures are found. In the tableland and plains regions, the natural vegetation has to a large degree been obliterated by centuries of human settlement and agriculture.

The rich and varied Romanian animal life includes some rare species, notably the chamois, which is found on the alpine heights of the Carpathians. Forest animals include brown bear, red deer, wolf, fox, wild pig, lynx, marten, and various songbirds. The lower course of the Danube, and particularly the delta, is rich in animal, bird, and fish life. Among the last named the most valuable is undoubtedly the sturgeon, yielding caviar.

THE PEOPLE

Settlement patterns. The natural environment of Romania has offered favourable conditions for human settlement. The accessibility of the region to the movements of peoples across the Eurasian landmass has also meant that the region has absorbed cultural influences from many nations and peoples, and this, too, is reflected in the contemporary patterns of Romanian life.

The population is fairly uniformly distributed from the shores of the Black Sea, across the plains, and up to the mountain foothills. The mountain areas themselves are inhabited by peoples whose origins are found in very early European history and who have, in many respects, been little changed by contemporary events. The villages scattered among the mountains up to altitudes of more than 5,000 feet, the sheepfolds, the newer holiday resorts, and the large number of roads all combine to give the human geography of the Carpathian Mountains a distinctive character. Pastures on the ancient erosional platforms among the mountain peaks can be found up to the highest levels, and cultivation is possible up to 3,900 to 4,300 feet. Further, the ancient commercial trade between the old market towns on either side of the Carpathians lends support to the view that the mountains have served as much as a link as a barrier in the country's development. In the many lowland areas scattered among the mountains there has been a long continuity of settlement, as may be seen in very old place-names and distinct regional consciousness.

The Carpathian heritage

Ethnic origins. *Ancient times.* Historical and archaeological evidence and linguistic survivals seem to confirm that the present territory of Romania had a fully developed population, with a high degree of economic, cultural, and even political development, long before the Roman armies crossed the Danube into what became known as the province of Dacia. Roman influence was profound, creating a civilization that managed to maintain its identity during the great folk migrations that followed the collapse of the empire. The Dacian–Roman population of the region led a life in which farming and particularly transhumance played an important part. They lived in small settlements, sometimes retiring to places providing better shelter in the troubled centuries. Life was not entirely transhumant, however, and a primitive agriculture was practiced on the upland terraces and in the more secluded river valleys. Thus the ethnic core of contemporary Romania developed in the remoter regions, although settlement did take place on the more exposed plains. The Romanian language—the morher tongue of almost 90 percent of the people, one of the Romance languages, with Latin grammatical structure—was formed between the 7th and 10th centuries. The first mention of Walachs (Volokhs, Vlachs), the name given to the Romanian people by their neighbours, appears in the 9th century.

Origin of the language

The feudal period. As more settled conditions gradually came to prevail on the continent, more complex economic activities—embracing agriculture, fruit growing, viticulture, and livestock raising—developed in both the mountains and plains. The densest settlement was in the Subcarpathians, where the population could exchange products with persons living on both sides of the mountain range. Population density increased as the feudal economy developed. In the 13th century, the existing largely Romanian population was augmented by colonists brought to Transylvania, particularly into the Carpathians, and including Saxons, Szeklers, and Teutonic Knights. The proliferation of mining also brought in foreign elements. The Hungarian monarchy wished to consolidate the defenses of eastern Transylvania against raiders from the steppes, but during the same period, with the mountain crests marking a political frontier, there appeared two independent Romanian feudal states: Walaehia (called in Romania Ţara Românească, literally "Romanian Land") and Moldavia (Romanian Moldova), both on the southern and eastern slcpes of the Carpathians. Initially, the core areas of these states were centred in the foothills of the Carpathians, at Curtea de Argeş, Cimpulung, and Baia; only later, as the Romanian lands on the plains were gradually consoiidated, were the major settlements transferred from the mountains, first to Tîrgovişte and Suceava and later to Bucharest and Iaşi. This marked an important stage in the development of the human geography of Romania.

The modern period. The 19th century saw important political advances, notably the unification of the two Romanian principalities (1859) and the attainment of independence under a Hohenzollern monarch (1878). The monarchy survived until 1947, when the Soviet Union, whose forces were maintaining the first Russian occupation (1944–58) in the country's independent history, demanded a complete Communist takeover. Although the Romanian Communist Party seeks credit for recent economic achievements, it should not be overlooked that for the first 70 years of independence the monarchy presided over the modernization of the country, including the expansion of education and the building of administrative and transport systems to sustain industrialization.

The country increased in size, first by the annexation of southern Dobruja in 1913 and second by the acquisition of Bessarabia, Bukovina, and Transylvania in 1918–19. As a consequence of World War II, southern Dobruja was lost to Bulgaria, and Bessarabia and northern Bu-

kovina to the Soviet Union. A large Romanian population remains in Bessarabia and northern Bukovina, and as long as they remain under Soviet control (Moldavian and Ukrainian Soviet Socialist republics) Romania's national unity cannot be considered complete.

Demographic trends. Within the present frontiers, a growth of population can be traced from 8,600,000 in 1859 to 14,250,000 in 1930, 17,500,000 in 1956, and an estimated 21,245,000 in 1975. By the mid-1970s, more than one-quarter of the population was under 15 years of age, a reduction in the proportion shown in the years of high birth rate immediately following World War II. The bulk of the population—just over 60 percent—was of adult working age (15 to 59 years old), and there was a slight preponderance of females over males. Substantial changes in the social composition of the population have taken place as a result of increasing industrialization, reflected in the rise of the working class population. Similarly, the collectivization of agriculture transformed the rural population, the proportion of peasants with individual households falling from more than half to something less than 5 percent during 1945–70.

Age distribution of population

In education and geographical distribution of the labour force there have been substantial changes since World War II. By the end of the 1960s, for example, official census figures showed a sharp rise in the proportion (some 16 percent) that had achieved some kind of higher education. Geographically, the picture is more complex. Differing rates of economic development in different parts of Romania have produced a movement toward towns and cities, largely for daily and seasonal work. Government planners seek to reduce migration across county boundaries by trying to ensure that each area has its share of development, and the benefits of modernization are consciously spread out over both favoured and unfavoured areas of the country.

This ideal equalization has not yet been attained, however, and the heavy reliance placed on the most advanced regions maintains a modest flow of migrants, and a more substantial flow of temporary workers, coming especially from those backward areas that have relatively high birth rates.

The population density of the country as a whole was by 1970 virtually double that of 1900 although, in contrast to other central European states, there was still considerable room for further growth. The overall density figures, however, conceal considerable regional variation. Population densities are naturally highest in the towns. But in the plains (up to altitudes of some 700 feet) even the rural population has a density of about 250 per square mile (100 per square kilometre), a figure that may rise to as high as 350 (135) in areas with intensive agriculture or a traditionally high birth rate (*e.g.*, northern Moldavia and the "contact" zone with the Subcarpathians). At altitudes of 700 to 2,000 feet the mineral resources, along with the orchards, vineyards, and pastures, support densities of some 75 per square mile (29 per square kilometre).

Variations in density

Settlement types. In 1975 some 57 percent of the population still lived in rural areas. Following administrative reforms of 1968, these areas were regrouped into some 2,700 communes, of which about 150 were classified as suburban. The average population per commune is about 4,500.

The average population for a village is just under 1,000, but an average figure has little relevance because of the sharp regional contrasts in settlement. A dispersed type of rural settlement is generally found in the foothill, ta-

bleland, and upland regions. The scattered village proper is found at the highest levels and reflects the rugged terrain and the pastoral economic life. Small plots and dwellings are carved out of the forests and on the upland pastures wherever physical conditions permit. Where the relief is less difficult, the villages are slightly more concentrated, although individual dwellings still tend to be scattered among agricultural plots.

The Subcarpathian region, with hills and valleys covered by plowed fields, vineyards, orchards, and pastures and dotted with dwelling places, typically has this type of settlement. The more familiar concentrated villages, marked by uniform clustering of buildings, are to be found in the plains, particularly those given over to cereal cultivation.

Urban settlements

The first urban settlements were situated at points of commercial or strategic significance, and the great majority of present-day towns are either on or in the immediate neighbourhood of the ruins of ancient settlements, whether of fortress or market town. The oldest towns were founded on the Black Sea shores, and urban development only later spread to the plains and then to the mountains. The turbulent history of the country favoured some of these early settlements, which grew into modern towns and cities, while other, once important towns have regressed to become villages or have simply vanished. In the mid-1970s there were 236 towns, of which 47 had the special status of municipality. Many of the towns are small (208 have fewer than 50,000 inhabitants, and 152 have fewer than 20,000), but 15 towns have more than 100,000 inhabitants and apart from the capital (1,706,-818) five exceed 200,000: Cluj–Napoca, Iaşi, Brasov, Galafi, and Timişoara.

THE ECONOMY

Overall development. A program of economic development has transformed the nation since independence. A formerly backward and largely agricultural economy has been transformed into a modern economy, with a strong emphasis on industry.

A very radical land reform was carried out in 1921 (and completed in 1948), although the independence of the peasantry has since been compromised. The restructuring of the economy since the Communist takeover included compulsory collectivization of agriculture, carried out between 1949 and 1962. The means of production were nationalized, including the banks and the main branches of industry, and a system of medium-term central planning was introduced. The result has been an acceleration of economic growth but along lines that had been clearly established by World War II.

Economic growth

The industrial base of the economy has been developed by expanding both those industrial branches that have a raw material base within the country—notably the chemical, power, building materials, and food industries—and those that depend on imported raw materials; the metallurgical industry is probably most important in this respect. Parallel with this process, an attempt has been made to achieve a rational distribution of industrial centres. The growth of new plants has accelerated since the late 1960s (some 1,500 new industrial units were commissioned in the last half of that decade), and this process has been facilitated by the purchase of licenses and patents from firms all over the world.

Economic growth, and in particular the expansion of industry, has required a major program of capital investment. The proportion of national income so allocated rose to about 20 percent in 1960 and to 30 percent in 1970, at which level it is projected to remain for some years. This high rate is thought by many experts to be the only feasible method by which intensive development can take place and reduce the gap that still separates Romania from other industrialized nations. The intensification of industrial activity, however, has caused some problems of air and water pollution, particularly in the case of old industries sited in narrow valleys or low-lying areas. Strict environmental controls have been introduced, although the problem is major only in certain restricted areas.

The role of industry. By the mid-1970s, about 65 percent of the national income was being produced by industry, in marked contrast to the pre-World War II situation, when the percentage was only 30. The main emphasis has been on the development of heavy industry (see Table 2), and the metallurgical, machine-building, metal-processing, and chemical industries have shown the strongest rate of growth.

Coal. The largest reserves are those of bituminous coal; half of Romania's bulk coal production comes from the Petroşani Depression alone. Reserves of poorer quality lignite are being tapped more and more to meet energy requirements. Except for the Baraolt-Vîrghiş Basin, which lies within the Carpathians, most deposits are found along the fringe of the mountain areas. A large lignite field in the Motru Valley (Gorj) supplies some of

the largest power stations in the country, Rovinari and Turceni.

Oil. Oil deposits are found in the flysch formations that run in a band along the outer rim of the Carpathians and through the Subcarpathians. Deposits in the plains, notably Videle, have been tapped since World War II. Bacău and Prahova districts have long been famous for their oil-refining industry, and they have been joined in recent years by production from Argeg (Pitegti). Natural gases—mainly methane—are produced in the centre of the Transylvanian Plateau, and gases produced as by-products of the oil industry are becoming of increasing importance. Finally it is worth mentioning that oil shales are to be mined at Anina, in the Caraş-Severin district, to supply a new power station to be built at Oravifa.

Hydro-
electric
projects

Electric power. One of the greatest problems facing Romania after World War II, when the Soviet Union demanded the delivery of Romanian petroleum as war reparations, was the very limited development of power stations based on other fuels. Under a plan spanning the years 1951–60 and supplemented by later plans, a remarkable rise in power output took place. The latter totalled 1,100,000,000 kilowatt-hours in 1938, 2,100,000,000 in 1950, and almost 54,000,000,000 by 1975. The foundation for this increase was a series of large power projects, each having 200,000 to 1,000,000 kilowatts' capacity. The most important projects have been the hydroelectric projects of the Argeg, Bistriţa, Danube, and Olt and Lotru rivers and the thermal stations based on Motru lignite. Nuclear power is envisaged, but the time and cost involved in developing a largely independent program have brought delays and completion of a nuclear power station cannot be expected before the 1980s.

The metallurgical industry. Romanian iron industry has particularly strong connections with Galafi as well as with Hunedoara and Reşiţa, where iron was smelted in classical times. Small units exist at Brăila, Cîmpia Turzii (near Turda), Iaşi, Roman, and Tîrgovişte, and a complex is projected for Călăraşi. The nonferrous metallurgical industry, which also dates from the Dacian–Roman period, is largely concentrated in the southwest and west, with copper, gold, and silver production still very active. Aluminum production is a recent development; alumina factories at Oradea and Tulcea supply the aluminum reduction complex at Slatina in the Olt district. Small quantities of lead, mercury, and zinc are also produced.

The machine-building and metal-processing industry is the main branch of the industrial economy, accounting for (by the mid-1970s) nearly a third of bulk industrial production. It provides a good index of the changing priorities in the Romanian economy; before World War II it accounted for only 10 percent of the total, being exceeded in importance by food processing (32 percent) and even the textile and ready-made clothing industry (13 percent). Contemporary centres of production are Bucharest, Bragov, Ploieşti, Cluj, Craiova, Arad, Reşiţa, and many others, with a considerable degree of regional specialization. There has been a strong tendency to concentrate on such modern branches as the electronics industry, as well as to widen and diversify the range of production.

Timber
industry

Other industries. In contrast to metallurgy (which relies on imports of ore and coke to supplement the modest domestic resources), the timber industry can rely on domestic raw materials. In recent decades the emphasis, in what is a traditional industry, has switched from production of sawn timber to finished products. A chain of modern wood industrialization combines turns out a range of products, including furniture and chipboard, which have done well in foreign markets. The building materials industry also utilizes a wide range of resources across the country; cement manufacture represents the most important sub-branch. The main centres are at Turda, Medgidia, Bicaz, Fieni, and Tîrgu Jiu. The long-established textile industry has also undergone a steady development since its radical overhaul in the 1930s. The closely connected ready-made clothing industry has undergone considerable expansion, with a heavy investment in new plant. Finally, the food industry—formerly the foundation of the economy—has been all but eclipsed by the rapid development of other branches. It has, nevertheless, continued to grow in absolute terms, and centres are distributed throughout the country.

Developments in agriculture and fisheries. The natural conditions within Romania make possible a great diversity of agriculture. The resources of the plains, hills, and mountains tend to be complementary, and, despite a strong subsistence element in peasant agriculture, exchanges of staple products are traditional.

Field crops. The climate and relief of the extensive Romanian plains are most favourable to the development of cereal crops, although these are also found in the Subcarpathians and in the Transylvanian Plateau, where they occupy a high proportion of the total arable land. Wheat and corn (maize) are most important, followed by barley, rye, and oats. Two-row barley is cultivated in the Braşov, Cluj, and Mureş areas, where it is used for brewing. The tendency is for the acreage of cereals to fall as yields increase and industrial crops require more land. In 1975, for example, cereals, dominated by wheat and maize, were planted on 64.1 percent of the total area of arable land; in 1938, by contrast, they occupied almost 85 percent.

Vegetables. Vegetables—peas, beans, and lentils—are planted on a relatively small area. Peas are the predominant crop; being capable of early harvest, they allow a second crop, usually fodder plants, to be grown on the same ground. Vegetable cultivation is particularly marked around the city of Bucharest, with specialization in the production of early potatoes, tomatoes, onions, cabbages, and green peppers. Similar gardening areas are found around Timigoara, Arad, Craiova, Galafi, Brăila, and other cities. The most important potato-growing areas are Bragov, Sibiu, Harghita, and Mureş districts. Other related crops include sugar beets; sunflower seed, mostly on the Danube, Tisa, and Jijia plains; and hemp, flax, rape, soybeans, and tobacco.

Wines

Viticulture. With some 730,000 acres (295,000 hectares) under cultivation by the mid-1970s, Romania can be counted among the main wine-producing countries of Europe. It specializes in the production of high-quality wines, using modern methods; with the growth of the tourist trade, its wines are becoming known to, and appreciated by, a larger international public. Large quantities are exported annually. The major vineyards are at Odobeşti, Panciu, and Nicoregti, with a half-dozen or more other major centres. Both white and red wines have won various international awards.

Orchards. At an altitude of between 1,000 and 1,600 feet (300 and 500 metres), orchards are found on almost all the hillslopes on the fringe of the Carpathians. There is increasing specialization in fruits with a high economic yield, and there are plans to extend the orchards, particularly those of apples and pears, into higher altitudes. Orchards have solved problems of soil erosion on many unstable hillsides.

Livestock. Livestock raising has a very long history in Romania. Sheep can be raised wherever grass is available, whether in the alpine pastures or the Danube plain and valley. Though there are only around 6,000,000 cattle, about half of these are beef and important to exports. Bees are also raised throughout the country, and silkworm production retains a modest importance despite the introduction of man-made fibres. Silk, the weaving of which was long the occupation of peasant women in the south and southwest, has lent much to the beauty of local folk costumes, especially the richly embroidered blouses and headscarves.

Fishing. The rivers of Romania, its lakes—especially the group around Razelm—and its Black Sea coastal region support a well-developed fishing industry. The largest quantity of fish is obtained from the Danube and its delta, and about 80 percent of the annual catch is consumed fresh. The canneries that process the remainder, especially the marine species, are located at Tulcea, Constanţa, and Galafi. Ocean fishing in foreign waters is developing rapidly to supplement the production from home waters and allow more meat to be exported.

Transportation. Railways provide the main method of transportation for both freight and passengers in Romania. Since World War II, diesel and electric motors have been placed in service, and the major lines have been electrified. Romania also has a system of national roads, the majority of which have been brought up to modern standards. The main lines of communication tend to focus on Bucharest and include many scenic routes. The country has maritime connections with many countries, and the port of Constanfa, undergoing major expansion, plays a major role in the national economy. Finally, the Danube River continues to be a major transportation route, which eventually will be connected with Constanfa by the Danube–Black Sea Canal.

Bucharest is the main centre for air transportation. In addition to local routes, its international traffic—again aided by the growing tourist trade—has been growing in significance. The great majority of flights by the national airline (Tarom, derived from Transporturile Aeriene Române) are to Europe, North Africa, and the Middle East, but there are also services to the U.S. and China.

Role in Comecon

Foreign trade and tourism. The modernization of the Romanian economy has resulted in a considerable upsurge in its foreign trade and commercial contacts, which by the mid-1970s involved more than 100 countries. The nation has also taken part in international fairs and exhibitions. Romania is an active participant in Comecon, the Communist bloc international trade group, under the Romanian policy of "Socialist internationalism." Great attention has also been paid to broadening trade with the developing countries. Total foreign trade in fact increased by more than two and a half times during the 1960s and doubled in the first five years of the 1970s, and there have been radical changes in exports, notably toward emphasis on machinery, industrial equipment, and other durable goods.

Tourism has become of special significance to Romania, with more than 3,800,000 persons a year visiting the country in the mid-1970s. Tourist attractions range from winter sports in the mountains to summer seaside activities in the resort belt fringing the Black Sea, with health spas receiving special emphasis. The Danube Delta, too, has become increasingly popular because of the growing worldwide interest in ecology and conservation. Special features of interest to tourists include the mountain lakes and underground cave systems that are features of the Carpathians and the fine churches and monasteries, with frescoes dating from the 14th to the 16th century, that are found in northern Moldavia. More generally, the folk costumes and the ancient folklore of Romanians, notably in the Carpathian Mountains, provide a reminder of the country's long traditions. Foreign tourists have been encouraged by much-improved hotels and by favourable tourist rates of exchange. Compulsory currency exchange regulations and a prohibition on the use of private accommodation, however, prove frustrating to the individual tourist.

The financial system. The basic financial vehicle for Romanian economic policy is the state budget presented annually to the National Assembly. By the mid-1970s, 19 percent of the budget income was derived from the profits of state enterprises, the remainder coming from taxation and insurance. Some 66 percent of annual budget expenditure goes toward financing economic development, some 22 percent for state services and cultural activity, about 5 percent for national defense, and less than 2 percent for administration. The National Bank of Romania, founded in 1880, is the heart of the banking system, managing budgetary cash resources and issuing currency. It also establishes foreign exchange rates and engages in foreign exchange operations. It is supported by an investment bank, which finances the investment projects of all state and cooperative organizations; an agricultural bank; and a foreign trade and loan bank, which also handles the money incomes--deposited as current and savings accounts—of individual citizens.

Prices

Lnterest rates do not: reflect scarcity of money or the element of risk; they are used by the government as one of the economic levers intended to motivate enterprises toward greater efficiency; penalties are built into the system to allow discrimination against enterprises that are poorly managed. Prices, too, are set arbitrarily. They have tended to assure high profits for many enterprises and provide resources from which unprofitable enterprises can be subsidized. Prices of agricultural commodities and other raw materials have usually been set low. In this way the price system has served to transfer resources from agriculture to industry and keep consumption low for the benefit of investment. This strategy, however, gives industrial enterprises little incentive to cut costs, and the government's drive for economic efficiency is thereby compromised.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional and political framework. The constitutional framework derives from the state constitution adopted in 1965, which characterized Romania as a Socialist republic. The constitution gives equal rights to all citizens, without regard to nationality, sex, or religion, and state power is said to rest on an alliance of peasants, workers, and intellectuals. The National Assembly is the supreme organ of state power, but in the intervals between its sessions the State Council, composed of a president, four vice presidents, and 22 members, exercises supreme power.

The administration of state affairs is in the hands of the Council of Ministers, which, on the authority of the National Assembly, acts as the national executive. Local people's councils are elected at the district level. Judicial functions are headed by the Supreme Court—elected by the National Assembly—which supervises the activities of all district courts, lawcourts, and military tribunals.

The Communist Party

The most fundamental fact of the political system, however, is the constitutional status of the Communist Party of Romania (Partidul Comunist Romhn) as the leading force of society and of every organized group within it. The CPR was founded in 1921 and pursued an underground existence from 1924 to 1944. In 1948 the Communist Party merged with the Social Democratic Party to form the Romanian Workers Party (Partidul Muncitoresc Romhn), which in 1965 reverted to its original name. Other political parties, including the Liberal and Peasant parties that previously dominated the political life of the country, have been suppressed, although exiles continue to propagate their philosophies. Left-wing parties survived but lost their independent existence through amalgamation into a large grouping dominated by the Communists.

Education. With the exception of certain university courses, education is free and universal in Romania, and its development has been a key to the economic transformation of the country in modern times and to the gradual elimination of illiteracy. One in five of the country's inhabitants is a pupil or student, whether at the obligatory general school; the middle schools (general or specialized, four or five years); or the wide range of professional and technical schools and institutes of higher education. Associated with this educational system is an extensive national library network.

The major institution of academic research is the Academia Republicii Socialiste Romhnia (Academy of the Socialist Republic of Romania), which traces its origins to the Societatea Literară Română founded in 1866. Its publishing house, Editura Academiei, produces research papers and more than 75 journals. The academy's library contains almost 7,500,000 volumes and is the national depository for all Romanian and United Nations publications. The Central State Library, founded in 1955, is the copyright depository, with more than 6,800,000 volumes and periodicals.

Of the institutions of higher learning, the University of Bucharest was founded in 1864. Other important schools are Babes–Bolyai University in Cluj and the Gheorghe Gheorghiu–Dej Technical Institute in Bucharest.

Health services. As in other Communist countries, medical care is provided free by the state. The quality of service has improved with the training of more doctors and the construction of new hospitals in the main towns and administrative centres and with the new drugs that have become available from the country's growing pharmaceutical industry. The antibiotics factory built at Iaşi in 1955 is a particularly important postwar achievement. Facilities have also been improved in rural areas; before World War II, doctors were available only in the main villages, but now every commune has its clinic and dispensary. Moreover, to reduce the formerly high rate of infant mortality, all babies are delivered in hospitals. Several new hospitals in the mountains serve tuberculosis patients. Overall there has been a considerable increase in life expectancy. The standard of living, however, is still relatively poor by European and North American standards, and many kinds of sophisticated medical treatment are not widely available.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. The authorities have emphasized the need to bring the broad mass of the populace in contact with the nation's contemporary culture and with its heritage. This includes emphasis on open public expression of varying viewpoints on cultural life, as well as access to the works of culture. Sadly, this policy has been gravely compromised in the Communist period by party control of all cultural activity and the consequent necessity for all contributors to the national culture to support party prescriptions. This control is exercised through the Council on Socialist Culture and Education, a government ministry, and the professional unions to which all practicing artists must belong.

Emphasis on mass cultural activity

Cultural institutions and the folk heritage. There are more than 150 institutions of mass cultural education putting on performances, often in remote regions and sometimes in the languages of minority ethnic groups (Hungarian, German, Ukrainian, etc.). They include theatres and puppet shows, operas, music hall shows, song and dance ensemble productions, and musical performances ranging from folk music to symphony concerts. The institutions in which these performances take place are village clubs, houses of culture, and clubs run by trade unions and other mass organizations. The "people's universities" in both towns and villages also emphasize mass cultural life.

The number of museums has undergone a dramatic increase, a third of the 1979 total of more than 300 having been set up during the 1966–70 Five-Year Plan alone and nearly 70 more added during 1971–75. The film industry, present in Romania since 1912, is controlled by the state. Two motion-picture studios in the Bucharest area produce documentaries and some feature-length films. There are more than 6,000 cinemas in the country; a special feature is the village film festival of the winter months.

In spite of these modern developments, Romania still offers a variety of customs, traditions, and forms of folk art. Wood carvings, brightly ornamented costumes, skillfully woven carpets, pottery, and other elements of traditional Romanian culture remain popular and, with the onset of tourism, have become known internationally. Folk art is characterized by abstract or geometric designs and stylized representations of plants and animals. In embroidery and textiles, designs and colour schemes can be associated with particular regions of the country. Special folk arts of Romania are the decoration of highly ornamental Easter eggs and painting on glass, which, however, is becoming a lost skill. Folk music includes dance music, laments and ballads, and pastoral music. Major instruments are the violin, the *cobza* (a stringed instrument resembling a lute), the *ţambal* (a dulcimer played with small hammers), and the flute. Folk melodies are preserved in the music of modern Romanian composers such as Georges Enesco.

The Romanian language, although developing over the centuries in difficult historical conditions, is as Latin as any other Romance language and, like the culture as a whole, continues to exhibit a remarkable vitality. The fact is perhaps paralleled by some of the Modernist tendencies in the Romanian fine arts; the sculptor Constantin Brancusi, a promoter of absolute Modernism coupled with a firm sense of classical Mediterranean values, had great international influence early in the 20th century. Romanian poets and writers, too, have operated in a cultural tradition somewhat different from that in neighbouring countries; in architecture, the elegant new Bucharest television centre is but one example of another Modernist trend.

THEOUTLOOK

Romanian prospects for the 1980s, although obviously subject to international conditions, rest basically on the long-term economic plans worked out for the country. These call for continued expansion of foreign trade, introduction of newer and better techniques throughout the economy, and concentration on consumer products to supplement the continued emphasis on industrialization. The emphasis on technical efficiency will be reflected throughout the economy. Culturally the prospects are less promising, with the "détente" envisaged under the Helsinki agreement (1975) being frustrated by growing ideological activity and very strict controls on the issue of passports.

Roman Law

The term Roman law denotes first of all the law of the city of Rome and of the Roman Empire: in the West, the law in force at any period from the foundation of the city (traditional date 753 BC) until the fall of the Western Empire in the 5th century AD, and the fall'ofthe Eastern Empire in 1453.

The range of influence of Roman law

The term Roman law today, however, often refers not merely to the law of those political societies to which the name Roman may in some sense be applied; for the legal institutions evolved by the Romans have had influence on the law of other peoples in times long after the disappearance of the Roman Empire as a political entity, and even in countries that were never subject to Roman rule. To take the most striking example, in a large part of Germany, until the adoption of a common code for the whole empire in 1900, the Roman law was in force as "subsidiary law"; that is, it was applied unless excluded by contrary local provisions. This law, however, which was in force in parts of Europe long after the fall of the Roman Empire, was not the Roman law in its original form. Its basis was indeed always the *Corpus Juris Civilis*—the codifying legislation of the emperor Justinian I (see below The law of Justinian)—but from the 11th century this legislation was interpreted, developed, and adapted to later conditions by generations of jurists and received additions from non-Roman sources. All of the forms it assumed in different countries and at different epochs can be included under Roman law.

Roman law is important not only as the system once in force in many places but also as an influence on the development of law in general. Even today, the legal systems of Western civilization (with some exceptions, especially the Scandinavian) fall into two groups, in one of which the main elements are of Roman origin; the other is the English common law, which itself is not without Roman influences. To the English group belong England, nearly all of the United States of America, and most British territories; to the Roman group belong the rest. Nearly all of the nations of continental Europe have legal codes that are Roman in structure, fundamental categories, and general method of thought. Within the British territories, Scotland has a system largely derived from the Roman; Quebec and most countries of Latin America have systems of French law built largely with Roman materials; and South Africa has a system known as "Roman–Dutch," based on Roman law as developed by Dutch jurists.

This article deals with Roman law as it developed in Rome up to the age of the emperor Justinian (reigned 527–565). (Subsequent developments in the Eastern Empire were mainly modifications of Justinian's codes.)

SOURCES OF ROMAN LAW

Development of the jus civile and jus gentium. In the great span of time during which the Roman Republic and Empire existed, there were naturally many phases of development. During the period of the Republic (753–31 BC), there first developed the *jus civile* (civil law), which was based on custom or legislation and which applied exclusively to Roman citizens. By the mid-3rd century BC, however, there had developed another type of law, *jus gentium*, which the Romans applied both to themselves and to foreigners. *Jus gentium* was not the result of legislation but rather was developed by the magistrates and governors who were responsible for administering justice in cases in which a foreigner was involved. The *jus gentium* became, to a large extent, part of the massive body of magisterial or praetorian law that was developed by the magistrates for citizens as well as for foreigners as a flexible alternative to *jus civile.*

Roman law, like other ancient systems, adopted originally the principle of personality—that is, that the law of the state applied only to its citizens. The foreigner was strictly rightless and, unless protected by some treaty between his state and Rome, could be seized like an ownerless piece of property by any Roman. But from early times there were treaties with foreign states guaranteeing mutual protection. Even in cases in which there was no treaty, the increasing commercial interests of Rome forced it to protect, by some form of justice, the foreigners who came within its borders. A magistrate could not simply apply Roman law because that was the privilege of citizens; even had there not been this difficulty, foreigners, especially those coming from Greek cities and used to a more developed and freer system, would probably have objected to the cumbrous formalism that characterized the early *jus civile.*

The law that the magistrates applied probably consisted of three elements: (1) an already existing mercantile law used by the Mediterranean traders; (2) those institutions of the Roman law that, after being purged of their formalistic elements, could be applied universally to any litigant in a Roman court, whether Roman or foreigner; (3) in the last resort, a magistrate's own sense of what was fair and just. This system of *jus gentium* was also adopted when Rome began to have provinces and provincial governors administered justice to the *peregrini* (foreigners). This word came to mean not so much persons living under another government (of which, with the expansion of Roman power, there came to be fewer and fewer) as Roman subjects who were not citizens. In general, disputes between members of the same subject state were settled by that state's own courts according to its own law, whereas disputes between provincials of different states or between provincials and Romans were resolved by the governor's court applying *jus gentium*. By the 3rd century AD, when citizenship was extended throughout the empire, the practical differences between *jus civile* and *jus gentium* ceased to exist. Even before this, when a Roman lawyer said that the contract of sale was *juris gentium*, he meant that it was formed in the same way and had the same legal results whether the parties to it were citizens or not. This became the practical sense of *jus gentium*. Because of the universality of its application, the idea was also linked with a theoretical sense, that of a law common to all peoples and dictated by nature—an idea that the Romans took from Greek philosophy.

Written and unwritten law. The Romans themselves divided their law into *jus scriptum* (written law) and *jus non scriptum* (unwritten law). By "unwritten law" they meant custom; by "written law" they meant not only that derived from legislation but, literally, that which was based on any source in writing.

Types of written law

There were various types of written law, the first of which consisted of leges (singular lex), enactments of one of the assemblies of the whole Roman people. The wealthier classes, or patricians, dominated these assemblies; and the common people, or plebeians, therefore had their own council, wherein they enacted resolutions called *plebiscita*. Only after the passage of the Lex Hortensia in 287 BC did *plebiscita* become binding on all classes of citizens; thereafter, *plebiscita* were generally termed leges along with other enactments. In general, legislation was a source of law only during the republic. When Augustus established the empire in 31 BC, the assemblies did not at once cease to function, but their assent to any proposal was a mere formal ratification of the emperor's wishes. The last known lex was passed under the emperor Nerva (AD 96–98).

It should be mentioned that the earliest and most important legislation or body of leges was the Twelve Tables, enacted in 451–450 BC during the struggle of the plebeians for political equality. It represents the desire to obtain a written and public code that patrician magistrates could not alter at will against plebeian litigants. Little is known of the actual content of the Twelve Tables; the text of the code has not survived, and only a few fragments are extant, collected from allusions and quotations in the works of such authors as Cicero. From the fragments it is apparent that numerous matters were discussed, among them family law, delict (tort, or offense against the law), and legal procedure.

A second type of written law consisted of the *edicta* (edicts), proclamations issued by a superior magistrate (praetor) on judicial matters. The office of praetor was created in 367 BC to take over the expanding legal work involving citizens; later, a separate praetor was created to deal with foreigners. Upon entering office, a praetor issued an edict that was, in effect, his program of his year in office. In addition, the curule aediles, who were the magistrates responsible for the care and supervision of the markets, also issued edicts. By the later part of the republic, these praetorian and magisterial edicts had become an instrument of legal reform, and leges ceased to be a major source of private law.

The Roman system of procedure gave the magistrate great power over the provision or refusal of judicial remedies, as well as over the form that such remedies were to take. The result was a new body of rules that existed alongside, and often superseded, the civil law. The *edicta* remained a source of law until about AD 131, when the emperor Hadrian commissioned their reorganization and consolidation and declared the result to be unalterable except by the emperor himself.

A third type of written law was the *senatus consulta,* resolutions of the Roman senate that had no legislative force during the Republic but were instead suggestions to various magistrates that could be given force by the magistrates' edicts. In the early empire, as the assemblies declined and the position of the emperor increased, *senatus consulta* became resolutions endorsing the proposals of the emperor. The approval of the senate became increasingly automatic, for the emperor's proposals were the true instrument of power. Consequently, the emperors ceased referring proposals to the senate and, not long after the early imperial period, ended the practice of legislating through the senate.

A fourth type of law consisted of the constitutiones *principum*, which were, in effect, expressions of the legislative power of the emperor. By the middle of the 2nd century AD, the emperor was, essentially, the sole creator of the law. The chief forms of imperial legislation were edicts or proclamations; instructions to subordinates, especially provincial governors; written answers to officials or others who consulted the emperor; and decisions of the emperor sitting as a judge.

The last type of written law was the *responsa prudentium*, answers on legal questions given by learned lawyers to those who consulted them. Although law, written and unwritten, was originally a rather secretive monopoly of the pontiffs, a college of priests, there had developed by the early 3rd century BC a recognizable class of legal advisors, *juris consulti* or *prudentes*, who were not professionals as such but men of rank who sought popularity and advancement in a public career by giving free legal advice. They interpreted statutes and points of law, especially unwritten law, and advised the praetor on the content of his edict and assisted parties and judges in litigation. Augustus empowered certain jurists to give *responsa* with the emperor's authority, and this increased their prestige, although this practice lapsed as early as AD 200.

During the early empire, numerous commentaries were written by the great jurists on individual leges, on the civil law, on the edict, and on law as a whole. In the 5th century, a law was passed stipulating that only the works of certain jurists could be cited. Postclassical law produced little in comparison to the classical world.

The law of Justinian. When the emperor Justinian I assumed rule in AD 527, he found the law of the Roman Empire in a state of great confusion. It consisted of two masses that were usually distinguished as old law and new law.

Old law and new law under Justinian

The old law comprised (1) all of the statutes passed under the republic and early empire that had not become obsolete; (2) the decrees of the senate passed at the end of the republic and during the first two centuries of the empire; (3) the writings of the jurists and, more particularly, of those jurists to whom the emperor had given the right of declaring the law with authority; these jurists, in their commentaries, had practically incorporated all that was of importance. All of these records and writings, however, were very numerous; many had become exceedingly scarce or had been altogether lost, and some were of doubtful authenticity. They were so costly that even the public libraries did not contain complete collections. Moreover, these writings contained many inconsistencies.

The new law, which consisted of the ordinances of the emperors promulgated during the middle and later empires, was in a condition not much better. These ordinances or constitutions were extremely numerous and conflicting. No complete collection existed, for the earlier codices did not include all of them; others had to be obtained separately, and many of them were probably inaccessible to a private person. It was thus necessary to collect into a reasonable corpus so much of the law, both new and old, as was regarded as binding and to purge away its contradictions and inconsistencies.

Immediately after his accession, Justinian appointed a commission to deal with the imperial constitutions. The commissioners, ten in number, went through all of the constitutions of which copies existed, selected such as were of practical value, cut these down by retrenching all unnecessary matter, got rid of contradictions by omitting one or the other of the conflicting passages, and adapted all the provisions to the circumstances of Justinian's own time. The resulting Codex Constitutionum was formally promulgated in 529, all imperial ordinances not included in it being repealed. This Codex has been lost, but a revised edition of 534 exists as part of the so-called Corpus Juris Civilis.

The success of this first experiment encouraged the Emperor to attempt the more difficult enterprise of simplifying and digesting the writings of the jurists. Thus, beginning in 530, a new commission of 16 eminent lawyers set about this task of compiling, clarifying, simplifying, and ordering; and the results were published in 533 in 50 books that became known as the Digest (*Digesta*) or Pandects. In enacting the Digest as a lawbook, Justinian repealed all of the other law contained in the treatises of the jurists and directed that those treatises should never be cited in the future even by way of illustration; at the same time, he abrogated all of the older statutes that had formed a part of the old law.

About the same time, there was published an outline of the elements of Roman law called the Institutes of Justinian (or simply *Institutiones*). In addition, between 534 and his death in 565, Justinian himself issued a great number of ordinances, dealing with all sorts of subjects and seriously altering the law on many points. These ordinances are called, by way of distinction, new constitutions (Novellae constitutiones) and in English are called the Novels.

Corpus Juris Civilis: the civil law code of Justinian

All of these books—the revised Codex Constitutionum, the *Digesta*, the *Institutiones*, and the Novellae—are collectively known as the Corpus Juris Civilis. This Corpus Juris of Justinian, with a few additions from the ordinances of succeeding emperors, continued to be the chief lawbook of the Roman world. In the 9th century a new system that is known as the Basilica was prepared by the emperor Leo VI the Wise. It is written in Greek and consists of parts of the Codex and of the Digest, joined and often altered in expression, together with some matter from the Novels and imperial ordinances posterior to Justinian. In the western provinces, the law as settled by Justinian held its ground.

CATEGORIES OF ROMAN LAW

The law of persons. Slavery. "The main distinction in the law of persons," said the 2nd-century jurist Gaius, "is that all men are either free or slaves." The slave was, in principle, a human chattel who could be owned and dealt with like any other piece of property. As such, he was not only at the mercy of his owner but rightless and (apart from criminal law) dutiless. But if the slave was in law a thing, he was in fact a man, and this modified the principle. A slave could not be a party to a contract nor own property, but he could be given a de facto patrimony, which could be retained if he were freed; if he made a "commitment," it could ultimately be enforced against his master. A slave could be manumitted and became, in most instances, not only free but a citizen.

Citizenship. The definition of citizenship was important for the purposes of private law because certain parts of private law applied only to citizens (jus *civile*). Noncitizens could be either Latini, inhabitants of Roman settlements that had the rights of members of the original Latin League, or peregrini, who were members of foreign communities or of those territories governed but not absorbed by Rome. The great extension of the citizenship by the emperor Caracalla in AD 212 reduced the importance of this part of the law.

Patria potestas: the power of the paternal head of the Roman family

Family. The chief characteristic of the Roman family is the *patria* potestas (paternal power in the form of absolute authority), which the elder father exercised over his children and over his more remote descendants in the male line, whatever their age might be, as well as over those brought into the family by adoption—a common practice at Rome. This meant originally not only that he had control over the persons of his children, amounting even to a right to inflict capital punishment, but that he alone had any rights in private law. Thus, any acquisitions made by a child under potestas became the property of the father. The father might indeed allow a child (as he might a slave) certain property to treat as his own, but in the eye of the law it continued to belong to the father.

By the 1st century AD there were already modifications of the system: the father's power of life and death had shrunk to that of light chastisement, and the son could bind his father by contract with a third party within the same strict limits that applied to slaves and their masters.

Sons too could keep as their own what they earned as soldiers and even make wills of it. In Justinian's day, the position as regards property had changed considerably; what the father gave to the son still remained in law the father's property, but the rules concerning the son's own earnings had been extended to many sorts of professional earnings; and in other acquisitions (such as property inherited from the mother), the father's rights were reduced to a life interest (usufruct). At all times, *patria potestas* ceased normally only with the death of the father; but the father might voluntarily free the child by emancipation, and a daughter ceased to be under her father's *potestas* if she came under the *manus* of her husband.

Marriage with and without *manus,* or husbandly authority

There were two types of marriage known to the law, one with *manus* and one without, but the *manus* type was rare already in the late republic and had disappeared long before Justinian's day. *Manus* was the autocratic power of the husband over the wife, corresponding to *patria potestas* over the sons.

Marriage without *manus* was by far the more common in all properly attested periods. It was formed (provided the parties were above the age of puberty and, if under *potestas,* had their father's consent) simply by the beginning of conjugal life with the intention of being married, and this was normally evidenced by the bringing of the bride to the bridegroom's house. The wife remained under her father's *potestas* if he were still alive; if he were dead, she continued (so long as guardianship of women continued) to have the same guardian as before marriage. Both spouses had to be citizens, or if one was not, he or she must have *conubium* (the right, sometimes given to non-Romans, of contracting a Roman marriage). In marriage without *manus,* the property of the spouses remained distinct, and even gifts between husband and wife were invalid.

Divorce was always possible at the instance of the husband in cases of marriage with *manus*; in marriage without *manus,* either party was free to put an end to the relationship at will. A formal letter was usual, but any manifestation of intention to end the relationship—an intention made clear to the other party and accompanied by actual parting—was all that was legally necessary. The Christian emperors imposed penalties on those who divorced without good reason, but the power of the parties to end the marriage by their own act was not taken away.

Concubinage was recognized in the empire as a "marriage" without a dowry, with a lower status for the woman, and with provisions that the children were not legally the father's heirs. **A** man could not have both a wife and a concubine. The emperor Constantine in the 4th century first enacted that the children of such unions might be legitimated by the subsequent marriage of their parents, a rule that the medieval civil law extended to all illegitimate children.

Guardianship

Persons under the age of puberty (14 for males, 12 for females) needed *tutores* if they were not under *patria potestas.* Such tutors could be appointed under the will of the father or male head of the household; failing such appointment, the guardianship went to certain prescribed relatives; if there were no qualified relations, the magistrates made an appointment. Originally, children were considered adult at the age of puberty; but, by a long development, it became usual for those above puberty and under 25 to have guardians who were always magisterially appointed. Originally, all women not under *patria potestas* or *manus* similarly needed *tutores,* appointed in the same way as those for children. By the early empire, this provision was little more than a burdensome technicality, and it disappeared from Justinian's law.

Corporations. The Romans did not develop a generalized concept of juristic personality in the sense of an entity that had rights and duties. They had no terms for a corporation or a legal person. But they did endow certain aggregations of persons with particular powers and capacities, and the underlying legal notion hovers between corporate powers, as understood in modern law, and powers enjoyed collectively by a group of individuals. The source of such powers, however' was always an act of state,

Four types of corporation may be distinguished:

1. *Municipia* (the citizen body, originally of the conquered cities and later of other local communities) possessed a corporateness that was recognized in such matters as the power to acquire things and to contract. In imperial times, they were accorded the power to manumit slaves, take legacies, and finally—though this became general only in postclassical law—to be instituted heir.

2. The *populus Romanus,* or the "people of Rome," collectively could acquire property, make contracts, and be appointed heir. Such property included property of the treasury.

3. *Collegia—private* associations with specialized functions, such as craft or trade guilds, burial societies, and societies dedicated to special religious worship—seem to have carried on their affairs and to have held property corporately in republican times and were apparently numerous. The emperors, viewing the *collegia* with some suspicion, enacted from the beginning that no *collegium* might be founded without state authority, and such rights as the manumission of slaves and the taking of legacies were closely regulated.

4. Charitable funds became a concern of postclassical law. Property might be donated or willed—normally, but not necessarily, to a church—for some charitable use, and the church would then (or so it appears from the evidence) have the duty to supervise the fund. Imperial legislation controlled the disposition of such funds so that their alienation in excess of powers was void. Ownership is thought in such cases to have been vested in the administrators for the time being.

The Roman concept of absolute ownership

The law of property and possession. In Roman law (today as well as in Roman times), both land and movable property could be owned absolutely by individuals, This conception of absolute ownership (*dominium*) is characteristically Roman, as opposed to the relative idea of ownership as the better right to possession, which underlies the Germanic systems, including English law.

Methods of acquisition by the jus civile. *Mancipatio* (or formal transfer of property) involved a ceremonial conveyance needing for its accomplishment the presence of the transferor and transferee, five witnesses (Roman citizens of full age), a pair of scales, a man to hold them, and an ingot of copper. The transferee grasped the object being transferred and said, "I assert that this thing is mine by Quiritarian [Roman] law; and be it bought to me with this piece of copper and these copper scales." He then struck the scales with the ingot, which he handed to the transferor "by way of price." Clearly, this was a symbolical sale and the relic of a real sale.

In jure cessio was a conveyance in the form of a lawsuit. The transferee claimed before the magistrate that the thing was his, and the transferor, who was the defendant, admitted the claim. The magistrate then adjudged the thing to the transferee. (The sham-lawsuit theory, however, is not acceptable to all modern scholars, principally because the judgment of ownership was valid against any possible private claimant, not merely against the defendant, as in a true lawsuit.)

Usucapio referred to ownership acquired by length of possession. In early Roman law, two years' continuous possession gave title in the case of land, one year in the case of movables. In the developed law, possession must have begun justifiably in good faith, and the thing must not have been stolen (even though the possessor himself may have been quite innocent of the theft) or occupied by violence.

Methods of acquisition by the jus gentium. In terms of *occupatio,* ownerless things, provided that they were susceptible to private ownership (excluding such things as temples), became the property of the first person to take possession of them. This applied to things such as wild animals and islands arising in the sea. In some views, it also applied to abandoned articles.

Accessio worked in this manner: if an accessory thing belonging to A was joined to a principal one belonging to B, the ownership in the whole went to B. For example, if A's purple were used to dye B's cloth, the dyed cloth belonged wholly to B. By far the most important application of this rule asserted that whatever is built on land becomes part of the land and cannot be separately owned.

Specificatio was somewhat different. If A made a thing out of material belonging to B, one school of thought held that ownership went to A, and another held that it remained in B. Justinian adopted a "middle opinion," according to which B retained ownership if reconversion to the original condition was possible (a bronze vase can be melted down); A obtained ownership if it was not (wine cannot be reconverted into grapes).

According to *thesauri inventio* or treasure trove, the final rule was that if something was found by a man on his own land, it went to him; if it was found on that of another, half went to the finder, half to the landowner.

Traditio was simple delivery of possession with the intention of passing ownership and was the method of conveyance of the *jus gentium.* If A sold and merely delivered a slave to B, *A* under the *jus civile* remained owner of the slave until a specified length of time had elapsed. The praetors, however, devised procedural methods of protecting B's possession in such a way that A's title became valueless, and B was said to have the thing *in bonis.* This was a remarkable triumph for informality in the granting of title. From the phrase *in bonis,* later writers coined the expression "bonitary ownership." Justinian abolished the theoretical distinction between civil and bonitary ownership.

Forms of property in land other than ownership. The ordinary leaseholder had no protection beyond a contractual right against his landlord, and he could not assign his tenancy. But there were certain kinds of tenure that did provide the tenant protection and that were assignable: there were agricultural and building leases granted for a long term or in perpetuity, whereby the leaseholders often enjoyed rights hardly distinguishable from ownership.

Servitudes: rights to specific, limited use or enjoyment of another's property

There were also servitudes, in which one person enjoys certain rights in property owned by another. *Ususfructus* was the right to use and take the fruits (such as crops) of a thing and corresponded to the modem notion of life interest. *Usus* was a more restricted right, likewise not extending beyond the life of the holder but merely to the use of a thing; thus, a person could live in a house himself but could not let it, as that would be equivalent to taking the fruits.

Since ownership was absolute, it was sharply distinguished from possession, which the civil law did not protect as such. Any owner wishing to interfere with an existing possessor, however, must bring an action and prove his title. If he interfered on his own authority, the praetor would see that the original state of affairs was restored before adjudication upon the title.

Obligations. Obligations were classified by the classical jurists into two main categories, according to whether they arose from delict or contract. Justinian's law recognized two further classes of obligation termed quasi-delict and quasi-contract.

Delict. As early as the 6th and 5th centuries BC, Roman law was experiencing a transition from a system of private vengeance to one in which the state insisted that the person wronged accept compensation instead of vengeance. Thus, in the case of assault *(injuria),* if one man broke another's limb, *talio* was still permitted (that is, the person wronged could inflict the same injury as he had received); but in other cases, there were fixed money penalties. Theft involved a penalty of twice the value of the thing stolen, unless the thief was caught in the act, in which case he was flogged and "adjudged" to the person wronged.

By the early empire, reforms had substituted a fourfold penalty in the case of thieves caught in the act, and the court assessed all penalties for *injuria* (which now included defamation and insulting behaviour). The law of damage to property was regulated by statute, which in turn was much extended by interpretation. Additionally, there were situations in which a person might be held liable for damages even though he was not personally responsible.

Contract. In the early republic, a law of contract hardly existed. There was, however, an institution called *nexum,* of which little can be said with certainty except that it was a kind of loan so oppressive in character that it might result in the debtor's complete subjection to the creditor. It was obsolete long before imperial times. The contracts of classical law were divided into four classes: literal, verbal, real, and consensual. The literal contract was a type of fictitious loan formed by an entry in the creditor's account book; it was comparatively unimportant and was obsolete in Justinian's day. The verbal contract or *stipulatio* was of great importance, for it provided a form in which any agreement (provided it was lawful and possible) might be made binding by the simple method of reducing it to question and answer: "Do you promise to pay me 10,000 sesterces?" "I promise." Originally, it was absolutely necessary that the words be spoken, but it may be said that by Justinian's day a written memorandum of such a contract would be binding, even though in fact there had been no speaking at all.

If an agreement was not clothed in the form of a stipulation, it must, to be valid, fall under one of the types of real or consensual contracts. A real contract was one requiring that something should be transferred from one party to the other and that the obligation arising should be for the return of that thing. Real contracts included such items as loans of money or loans of a horse. Consensual contracts needed nothing except verbal or written agreement between the parties, and though there were only four such known to the law, these were the most important in ordinary life—those dealing with sale, hire, partnership, and mandate (acting upon instructions). In Justinian's day there was a further principle that in any case of reciprocal agreement—such as an agreement for exchange (but not sale)—if one party had performed, he could bring an action to enforce performance by the other. In addition to the foregoing contracts, a few other specific agreements were recognized as enforceable, but the general recognition of all serious agreements as binding was never achieved by the Romans.

Quasi-delict: This covered four types of harm, bracketed together on no clearly ascertainable principle. They included the action against an occupier for harm done by things thrown or poured from his house on to a public place; and the action against a shipowner, innkeeper, or stablekeeper for loss caused to customers on the premises through theft or damage by persons in his service.

Quasi-contract: This miscellaneous category embraced obligations that had no common feature save that they did not properly fall under contract, there being no agreement, nor under delict, there being no wrongful act. The most noticeable instances were, first, *negotiorum gestio,* which enabled one who intervened without authority in another's affairs for the latter's benefit to claim reimbursement and indemnity; second, the group of cases in which an action *(condictio)* is allowed for the recovery by A from B of what would otherwise be an unjustified enrichment of B at A's expense, as when A, mistaking the facts, paid B something that was not due *(condictio indebiti).* This notion of unjust enrichment as a source of legal obligation was one of the most pregnant contributions made by Roman law to legal thought.

The law of succession. The first requirement of any Roman will of historical times was the appointment of one or more heirs. An heir, in the Roman sense of the term, is a universal successor; that is, he takes over the rights and duties of the deceased (insofar as they are transmissible at all) as a whole. On acceptance, the heir becomes owner if the deceased was owner, creditor if he was creditor, and debtor if he was debtor, even though the assets be insufficient to pay the debts. It was thus possible for an inheritance to involve the heir in loss. Until Justinian's day this consequence could be avoided only by not accepting the inheritance, but Justinian made one of his most famous reforms by providing that an heir who made an inventory of the deceased's assets need not pay out more than he had received. Freedom of testation, furthermore, was not complete; a man was obliged to leave a certain proportion of his property to his children and in some cases to ascendants and brothers and sisters.

With regard to intestate succession, or succession without a will, those first entitled in early times were the deceased's own heirs—that is, those who were in his *potestas* or *manus* when he died and became free from that power at his death. Failing these, the nearest agnatic relations (relations in the male line of descent) succeeded, and, if there were no agnates, the members of the gens, or clan, of the deceased succeeded. Later reforms placed children emancipated from *potestas* on an equality with those under *potestas* and gradually gave the surviving spouse (in marriage without *manus*) greater and greater rights of succession. By Justinian's day the system had evolved as follows: descendants had the first claim, and failing these, a composite class consisting of ascendants, brothers and sisters of full blood, and children of deceased brothers and sisters. Next came brothers and sisters of the half blood and, finally, the nearest cognates (relations in the female line). Husband and wife were not mentioned, but their old rights were kept alive in the absence of any of the preceding categories. Justinian also gave to the poor widow a right to one-quarter of her husband's estate unless there were more than three children, in which case she shared equally with them. If, however, the heirs were her own children by the deceased, she only received the *ususfructus* (life interest) in what she took.

The law of procedure. In the earliest forms of procedure there were two stages: a preliminary one before the jurisdictional magistrate, in which the issue was developed; then the actual trial before the *judex,* or judge. The system required that set forms of words be spoken by the parties and, sometimes at least, by the magistrate. The parties making an assertion of ownership, for instance, would grasp the thing in dispute and lay a wand on it, after which the magistrate would intervene and say, "Let go, both of you." So formal was the procedure that a plaintiff who made the slightest mistake lost his case. Under the system it was also the responsibility of the plaintiff to produce the defendant physically in court and often to carry out the sentence of the court.

Instructions to the judge

Under new procedures developed in the 2nd and 1st centuries BC, the issue at the magisterial stage was formulated in written instructions to the *judex,* couched in the form of an alternative: "If it appears that the defendant owes the plaintiff 10,000 sesterces, the *judex* is to condemn the defendant to pay the plaintiff 10,000 sesterces; if it does not so appear, he is to absolve him." A draft of these written instructions was probably prepared for the plaintiff before he came into court, but there could be no trial until it was accepted by the defendant, for there was always a contractual element about a lawsuit under both the new and the older system. Pressure, however, could be exercised by the magistrate on a defendant who refused to accept instructions of which the magistrate approved, just as a plaintiff could be forced to alter instructions of which the magistrate disapproved, by the magistrate's refusal otherwise to give his order to the *judex* to decide the case.

In late republican times, still another system developed, first in the provinces, then in Rome. Under the new system, the magistrate used his administrative powers, always large, for the purpose of settling disputes. He could command, and thus if one man brought a complaint against another before him, he could investigate the matter and give the order he thought fit. As imperially appointed officers superseded republican magistrates, this administrative process became more common. The result was that the old contractual element in procedure disappeared as well as the old division into two stages. Justice was now imposed from above by the state—not, as originally, left to a kind of voluntary arbitration supervised by the state. (H.F.J./R.Po./M.A.M.)

Roman Religion

This article deals with the beliefs and practices of the inhabitants of the Italian peninsula from ancient times until the ascendancy of Christianity, 4th century AD.

NATURE AND SIGNIFICANCE

The Romans, according to the 1st-century-BC Roman orator and politician Cicero, excelled all other people in the unique wisdom that made them realize that everything is subordinate to the rule and direction of the gods. Yet Roman religion was not based on divine grace but instead on mutual trust (*fides*) between god and man. The object of Roman religion was to secure the cooperation, benevolence, and "peace" of the gods (*pax deorunz*). The Romans believed that this divine help would make it possible for them to master the unknown forces around them that inspired awe and anxiety *(religio),* and thus they would be able to live successfully. Consequently, there arose a body of rules, the *jus divinum* (divine law), ordaining what had to be done or avoided.

Object of Roman religion

These precepts for many centuries contained scarcely any moral element; they consisted of directions for the correct performance of ritual. Roman religion laid almost exclusive emphasis on cult acts, endowing them with all the sanctity of patriotic tradition. Roman ceremonial was so obsessively meticulous and conservative that, if the various partisan accretions that grew upon it throughout the years can be eliminated, remnants of very early thought can be detected near the surface.

This demonstrates one of the many differences between Roman religion and Greek religion, in which such remnants tend to be deeply concealed. The Greeks, when they first began to document themselves, had already gone quite a long way toward sophisticated, abstract, and sometimes daring conceptions of divinity and its relation to man. But the orderly, legalistic, and relatively inarticulate Romans never quite gave up their old practices. Moreover, until the vivid pictorial imagination of the Greeks began to influence them, they lacked the Greek taste for seeing their deities in personalized human form and endowing them with mythology. In a sense, there is no Roman mythology, or scarcely any. Although recent discoveries, notably at Caere (Cerveteri), confirm that Italians were not entirely unmythological, their mythology is sparse. What is found at Rome is chiefly only a pseudomythology (which, in due course, clothed their own nationalistic or family legends in mythical dress borrowed from the Greeks). Nor did Roman religion have a creed; provided that a Roman performed the right religious actions, he was free to think what he liked about the gods. And, having no creed, he usually deprecated emotion as out of place in acts of worship.

In spite, however, of the antique features not far from the surface, it is difficult to reconstruct the history and evolution of Roman religion. The principal literary sources, antiquarians such as the 1st-century-BC Roman scholars Varro and Verrius Flaccus, and the poets who were their contemporaries (under the late Republic and Augustus), wrote 700 and 800 years after the beginnings of Rome. They wrote at a time when the introduction of Greek methods and myths had made erroneous interpretations of the distant Roman past unavoidable. In order to supplement such conjectures or facts as they may provide, scholars rely on surviving copies of the religious calendar and on other inscriptions. There is also a rich, though frequently cryptic, treasure-house of material in coins and medallions and in works of art.

HISTORY

Early Roman religion. For the earliest times, there are the various finds and findings of archaeology. But they are not sufficient to enable scholars to reconstruct archaic Roman religion. They do, however, suggest that early in the 1st millennium BC, though not necessarily at the time of the traditional date for the founding of Rome (753 BC), Latin and Sabine shepherds and farmers with light plows came from the Alban Mount and the Sabine Hills, and that they proceeded to establish villages at Rome, the Laiins on the Palatine Hill and the Sabines (though this is uncertain) on the Quirinal and Esquiline hills. About 620 the communities merged, and *c.* 575 the Forum Romanum between them became the town's market.

Deification of functions. From such evidence it appears that the early Romans, like many other Italians, sometimes saw divine force, or divinity, operating in pure function and act, such as in human activities like opening doors or giving birth to children, and in nonhuman phenomena such as the movements of the sun and seasons of the soil. They directed this feeling of veneration both toward happenings that affected human beings regularly and, sometimes, toward single, unique manifestations, such as a mysterious voice that once spoke and saved them in a crisis (Aius Locutius). They multiplied functional deities of this kind to an extraordinary degree of "religious atomism," in which countless powers or forces were identified with one phase of life or another. Their functions were sharply defined; and in approaching them it was important to use their right names and titles. If one knew the name, one could secure a hearing. Failing that, it was often best to cover every contingency by admitting that the divinity was "unknown" or adding the precautionary phrase "or whatever name you want to be called" or "if it be a god or goddess."

Veneration of objects. The same sort of anxious awe was extended not only to functions and acts but also to certain objects that inspired a similar belief that they were in some way more than natural. This feeling was aroused, for example, by springs and woods, objects of gratitude in the torrid summer, or by stones that were often believed to be meteorites—*i.e.*, had apparently reached the earth in an uncanny fashion. To these were added products of human action, such as burial places and boundary stones, and inexplicable things, such as Neolithic implements (probably the mysterious meteorites were often these) or bronze shields (artifacts that had strayed in from more advanced cultures).

High gods

To describe the powers in these objects and functions that inspired the horror, or sacred thrill, the Romans eventually employed the word *numen*, suggestive of a god's nod, *nutus*; though so far there is no evidence that this usage was earlier than the 2nd century BC. The application of the word spirit to *numen* is anachronistic in regard to early epochs because it presupposes a society capable of greater abstraction. Nor must the term mana, used by Melanesians to describe their own concept of superhuman forces, be introduced too readily. The two societies are not necessarily analogous and, besides, the deduction from such comparisons that the Romans experienced an impersonal, pre-deistic, primordial stage of religion that neatly preceded the personal stage cannot be regarded as correct. On the contrary, from the very earliest times, the supernatural forces that they envisaged included a number of deities in analogous human forms; among them were certain "high gods." Foremost among these was a divinity of the sky, Jupiter, akin to the sky gods of other early Indo-European-speaking peoples, the Sanskrit Dyaus and Greek Zeus. Not yet, probably, a Supreme Being, though superior in some sense to other divine powers, this god of the heavens was easily linked with the forces of function and object, with lightning and weather, or with the uncanny stone that came from on high and was called Jupiter Lapis.

Purpose of sacrifice and magic. These gods and sacred functions and objects seemed charged with power because they were mysterious and alarming. In order to secure his food supply, physical protection, and increase, the early Roman believed that such forces had to be propitiated and made allies. Sacrifice was necessary. The product sacrificed would revitalize the divinity, which was seen as a power of action and therefore likely to run down unless so revitalized. By this nourishment he or it would become able and ready to fulfill requests. And so the sacrifice was accompanied by the phrase *macte* esto! ("be you increased!").

Prayer was a normal accompaniment of sacrifice, and as a conception of the divine powers gradually developed, it contained varying ingredients of flattery, cajolery, and attempted justification; but it also was compounded by magic—the attempt not to persuade nature, but to coerce it. Though the authorities (*e.g.*, c. 451–450 BC, Twelve Tables) sought to limit its noxious aspects, magic continued to abound throughout the ancient world. Even official rites remained full of its survivals, notably the annual festival of the Lupercalia and the ritual dances of the Salii in honour of Mars. Romans in historical times regarded magic as an oriental intrusion, but Italian tribes, such as the Marsi and Paeligni, were famous for such practices. Among them curses figured prominently, and curse inscriptions from c. 500 BC onward have been found in large numbers. There were also numerous survivals of taboo, a negative branch of magic: have no dealings with strangers, corpses, newborn children, spots struck by lightning, etc., lest harm befall you.

Religion in the Etruscan period. The amalgamation of the Latin and Sabine (?) villages of Rome coincided with, or more probably was soon followed by, a period in which Rome was under the control of at least one dynasty (the Tarquins) from Etruria, north of the Tiber (c. 575–510 BC, though some scholars would extend this domination to c. 450).

Importance of ritual. The Etruscans felt profound religious anxieties and were more devoted to ritual than any other people of the ancient Western world. Though sources are, again, late and unsatisfactory, it appears that they possessed a comprehensive collection of rules regulating these rites. Etruscan culture was heavily based on influences from Greece in its orientalizing period, supplemented by direct contacts with Phoenicia and other eastern lands. But the religion of Etruria proclaims a very un-Greek view of the abasement and nonentity of man before the gods and their will.

Divination and views of the afterlife

To the Etruscans the whole fanatical effort of life was directed toward forcing their deities, led by Tinia or Tin (Jupiter), to yield up their secrets by divination. They saw an intimate link existing between heaven and earth, which seemed to echo one another within a unitary system, and they were more ambitious than either Greeks or Romans in their claims to foretell the future. They also formed an exceptionally complex, rich, and imaginative picture of the afterlife. The living were perpetually obsessed by their care for the dead, expressed in elaborate, magnificently equipped and decorated tombs and lavish sacrifices. For, in spite of beliefs in an underworld, or Hades, there was also a conviction that the individuality of the dead somehow continued in their mortal remains; and it was therefore imperative that they should take pleasure in their graves or tombs and not return to haunt the living. From the 4th century BC onward, after the Etruscans had lost their political power to Rome, their art depicts horrors indicating an increasing fear of what death might bring.

Influence *on Roman* religion. The Roman religion continued to display certain obvious debts to the period when the city had been under Etruscan control: It is true that the Roman shades (Di Manes) were much less substantial than the fantastic Etruscan conceptions and. although Etruscan divination by the liver and entrails survived and later became increasingly fashionable in Rome, Roman diviners in general, products of a more realistic and prosaic society, never aspired to such precise information about the future as the Etruscans had hoped to gain. Yet, it was the Etruscans who first gave a vigorous definition to Italian religious forms. Indeed, many of the religious features that patriotic historians preferred to ascribe to the mythical King Numa Pompilius (who was supposed to have been Romulus' Sabine successor in the 8th century BC—the man of peace following the man of war) date, in fact, from the period of Etruscan domination two centuries later. Nevertheless, Romans acknowledged a debt to Etruria that included much ceremony and ritual, and the plan, appearance, and decoration of a number of temples, notably the great shrine of the Capitoline Triad, Jupiter, Juno, and Minerva. The Romans also were indebted to the Etruscans for their first statues of gods, including the cult image of Jupiter commissioned from an Etruscan for the Capitoline temple. Such statuary, showing the gods in human shape, encouraged the Romans to think of their gods in this way, with the consequent possibility of investing them with myths, which thereafter gradually accumulated around them in the form of Hellenic stories often infused with a native patriotic eiement.

The calendar

Above all, Rome owed to its Etruscan kings its religious calendar. In addition to poetical works discussing the calendar in antiquarian fashion, such as the Fasti of Ovid, there are extant fragments of about 40 copies of the calendar itself, in a revised shape established by Julius Caesar. Besides the Julian revision, there is an incomplete pre-Caesarian, Republican calendar, the Fasti Antiatos, discovered at Antium (Anzio); it dates from after 100 BC. It is possible to detect in these calendars much that is very ancient, including a pre-Etruscan ten-month solar year. However, the basis of the calendars, in their surviving form, is later, since it consists of an attempt to reconcile the solar and lunar year, in accordance with Babylonian calculations. This endeavour belongs to the period of Etruscan domination of Rome—for example, the names of the months April and June (in their Roman form) come from Etruria. Moreover, the presence or absence of certain festivals permits a dating approximating to the time of Etruscan domination in the later 6th century BC. Additional modifications were introduced in the following century and again when the calendar was subsequently published (30 BC).

The festivals it records, of which the earliest are indicated in large letters, reflect a period of transition between country and town life. Though local cult continued to remain active, many forms of worship hitherto maintained by families and farms had now been taken over by the comparatively mature Roman state. The state management blocked any tendency toward spiritualization and removed the need for any vigorous individual participation; however, by ensuring that the gods were conciliated by a schedule corresponding to the regular process of nature, it made the individual citizens feel for centuries that relations with the supernatural were being maintained safely.

Influence of Greek religion

Religion in the early Republic. Even if, as tradition records, a coup d'etat dislodged the Etruscan kings before 500 BC, the first half of the 5th century saw no weakening of trade relations with Etruria. Its southern cities, such as Caere (Cerveteri) and Veii close to Rome, had long used the Greek city of Cumae in Campania as a commercial outlet, converting it into an important grain supplier. And now Rome, faced with a shortage of grain, arranged for it to be imported from Cumae. The same city also influenced the foundation of Roman temples in the Greek style. Rome, which had already become accustomed to Greek religious customs in the Etruscan epoch, now showed a willingness to absorb them. This forms a strange contrast to its deeply ingrained religious conservatism. Moreover, at some quite early stage (though there is no positive evidence of the practice until the 3rd century), Romans borrowed from elsewhere in Italy a special ritual (evocatio) for inviting the patron deities of captured towns to abandon their homes and migrate to Rome.

In an emergency in 399 BC, during a difficult siege of Veii, Rome carried Hellenization further by importing a Greek rite in which, as an appeal to emotional feeling, images of pairs of gods were exhibited on couches before tables spread with food and drink; this rite (*lectisterni*urn) was designed to make them Rome's welcome guests. From the same century onward, if not earlier, pestilences were averted by another ritual (supplicatio), in which the whole people went around the temples and prostrated themselves in Greek fashion. Later the custom was extended to the celebration of victories.

Importation of mystery religions and astrology

Religion in the later Republic: crises and new trends. The *lectisternium* was repeated, with increased elaboration and pomp, in 217 BC during a period in which emotional religion was running rampant because of Hannibal's invasion of Italy in the Second Punic War. Faced with a flood of fears and anxieties and reports of many alarming and extraordinary events, Rome took precautions to secure the favour of all manner of gods. Among them, as a desperate attempt at novelty when appeals to the usual deities seemed stale, was the introduction of the Great Mother of Asia Minor, Cybele (204). Eighteen years later, the equally orgiastic worship of Dionysus (Bacchus) was coming in so rapidly and violently, by way of southern Italy, that the Senate, scenting subversion, repressed its practitioners. But these and other mystery religions, promising initiation, afterlife, and an excitement that Roman national cults could not provide, had come to stay and, although there were long periods of official disapproval before acclimatization was completed, they gradually played an immense part upon the religious scene. Eastern astrology, too, became extremely popular. It was based on the conviction that, since there is cosmic sympathy between the earth and other heavenly bodies, and since, therefore, the emanations of these bodies influence the earth, men must learn how to foresee their dictates—and outwit them.

Influence of Stoicism

Astrological practices received encouragement from Stoic philosophy, which was introduced to Rome in the 2nd and early 1st centuries BC, notably by Panaetius and Poseidonius. The Stoics saw this pseudoscience as proof of the Platonic unity of the universe. Stoicism affected Roman religious thinking in at least three other ways. First, it had a deterministic effect, encouraging a widespread belief in Fate and also, somewhat illogically, in Fortune, both of which were revered in other parts of the Mediterranean and Near Eastern world. Second, Stoicism infused a new spirituality into religious thinking by its insistence that the human soul is part of the universal spirit and shares its divinity. Third, the moral implication of this, as the Stoics pointed out, was that all men are brothers and must treat each other accordingly. This demonstration struck a chord in the psychology of the Romans, who possessed strongly ethical inclinations and now, at last, saw this trend supported and justified by a philosophical sanction that their formalistic religion had not provided. In changing times of imperialism, materialism, and widespread heart-searching, the state religion had failed to fill the vacuum, and philosophy stepped in instead. At the same time the negative approach of Roman religion to the afterlife was counteracted by an influx of speculations that blended theology, mysticism, and magic and claimed the legendary Orpheus and Pythagoras as prophets.

While their national poet Ennius *(239–169* BC) helped to diffuse such beliefs, he and the comic dramatist Plautus ridiculed the traditional Roman gods on the stage. The upper class attitude of the times was expressed by the historian Polybius, the priestly lawyer Scaevola, the scholarly Varro, and the orator and philosopher Cicero, who maintained that the importance of religion was political, residing in its power to keep the multitude under control, to prevent social chaos, and to promote patriotic feeling.

The imperial epoch: the final forms of Roman paganism. After the prolonged horrors of civil war had ended *(30* BC), the victorious Octavian, the adoptive son of the dictator Caesar and founder of the imperial regime or principate, decided, correctly, that the ancient religion was far from dead and that the restoration of all its forms would respond to a strong popular, instinctive belief that the disasters of the past generations had been due to the neglect of religious duties.

Deification of Caesar and Augustus

The imperial cult. Octavian himself took the name Augustus, a term indicating a contrast to *humanus.* This did not make him a god in his lifetime, but, combined with the insertion of his *numen* and his *genius* (originally the procreative power that enables a family to be carried on) into certain cults, it prepared the way for his posthumous deification, just as Caesar had been deified before him. Both were deified by the state because they seemed to have given Rome gifts worthy of a god. From earliest times in Greece there had been an idea that if someone saved you, you should pay him the honours you would offer to a god. Alexander the Great and his successors had demanded reverence as divine saviours, and Ptolemy II Philadelphus of Egypt *(285–246* BC) introduced a cult of his own living person. The Stoic belief that the human soul was part of the world soul was a corollary of the view that great men possessed a larger share of this divine element. Moreover, the philosopher Euhemerus *(c.300* BC) had elaborated a theory that the gods themselves had once been human; this idea was readily adapted to the supposed careers of Hercules and of Castor and Pollux; and the Romans applied it to their own gods Saturn and Quirinus, the latter identified with the national founder, Romulus, risen to heaven. And so it became customary, if emperors (and empresses) were approved of in their lives, to raise them to divinity after their deaths. They were called *divi,* not *dei* like the Olympian gods; the latter were prayed to, but the former were regarded with veneration and gratitude.

As the empire proceeded and the old religion seemed more and more irrelevant to people's personal preoccupations and successive national emergencies, the cult of the *divi,* subsequently grouped together in a single Hall of Fame, remained foremost among the patriotic cults that were increasingly encouraged as unifying forces. Concentrating on the protectors of the emperor and the nation, they included the worship of Rome herself, and of the *genius* of the Roman people; for the army a number of special military celebrations are recorded on the Calendar of Doura-Europus in Mesopotamia (Feriale Duranum, *c.* AD *225–27).* As for the ruling emperors, they were more and more frequently treated as divine, with varying degrees of formality, and officially they often were compared with gods. As monotheistic tendencies grew, however, this custom led not so much to their identification with the gods as to the doctrine that they were the elect of the divine powers, who were defined as their companions *(comites).* In pursuance of this way of thinking, as official paganism approached its last days, the emperors Diocletian (AD *284–305)* and Maximian took the names Jovius and Herculius respectively, after their Companions and Patrons Jupiter and Hercules.

Anderson— Alinari

Introduction of *Christianity and Mithraism.* By now, however, the humanistic idea that men could *become* gods had ceased to have any plausibility. Plotinus and his Neoplatonism, the dominant philosophy of the pagan world from the mid-3rd century AD, had given powerful, mystical shape to the Platonic and Stoic conception that the universe is governed by a single force. On the other hand, the greatest religious figure of the century, the Iranian Mani, who had started to preach in Mesopotamia *c. 240,* dramatically preached the opposing dualistic idea that the world is the creation not only of a good power but of an evil one as well. Mani's church, which alarmed Diocletian and for a time attracted the great Christian theologian St. Augustine, absorbed many of the innumerable cults of Gnostics who claimed special knowledge (*gnōsis*) by illumination and revelation and taught how man can purge the nonspiritual from within him and escape his earthly prison. More impressively, the cult of the Persian Mithra blended the dualism of Mani with the emotional initiations of the mystery religions (corrected by a much sterner tone of moral endeavour) and became a strong link between the cult of the sun (which appealed to contemporary monotheists) and the fashionable revulsion from the senses that was shortly to lead to Christian monasticism. Like Christianity, Mithraism had its sacraments; but the life of Mithra exercised a less far-reaching appeal than the life of Christ, and Mithra's cult excluded women.

Speculative religious thought

Christianity, unique in its universal charity and unique also in its demand for a noble effort of faith in Jesus' blend of divinity and humanity, was the religion that prevailed in the Roman world. It satisfied the emperor Constantine's impulsive need for divine support, and from AD 312 onward, by a complex and gradual process, it became the official religion of the empire.

The survival of Roman religion. For a time, coins and other monuments continued to link Christian doctrines with the worship of the sun, to which Constantine had been addicted previously. But even when this phase came to an end, Roman paganism continued to exert other, permanent influences, great and small. The emperors passed on to the popes the title of chief priest, *pontifex maximus.* The saints, with their distribution of functions, often seemed to perpetuate the many *numina* of ancient tradition. The ecclesiastical calendar retains numerous remnants of pre-Christian festivals—notably Christmas, which blends elements including both the feast of the Saturnalia and the birthday of Mithra. But, most of all, the mainstream of Western Christianity owed ancient Rome the firm discipline that gave it stability and shape, combining insistence on established forms with the possibility of recognizing that novelties need not be excluded, since thev were implicit from the start;

ROMAN GODS AND GODDESSES

Jupiter, Mars, and Quirinus

The earliest divinities. The early Romans, like other Italians, worshipped not only purely functional and local forces but also certain high gods. Chief among them was the sky god Jupiter, whose cult, at first limited to the communities around the Alban Mount, later gained Rome as an adherent. The Romans gave Jupiter his own priest (*flamen*), and the fact that there were two other senior *flamines,* devoted to Mars and Quirinus, confirms other indications that the cults of these three deities, envisaged perhaps in some sort of association, belonged to a very early stratum (though the theory of their correspondence to the three-class social division of the early Indo-European-speaking peoples is generally unacceptable). Mars, whose name may or may not be Indo-European, was a high god of many Italian peoples, as liturgical bronze tablets found at Gubbio, the Tabulae Iguvinae (c. 200–c. 80 BC), confirm, protecting them in war and defending their agriculture and animals against disease. Later, he was identified with the Greek god of war, Ares, and also was regarded as the father of Romulus. Mars Gradivus presided over the beginning of a war and Mars Quirinus over its end, but earlier Quirinus had apparently, as a separate deity, been the patron of the Quirinal village before its amalgamation with the Palatine; subsequently he was believed to have been the god that Romulus became when he ascended into heaven.

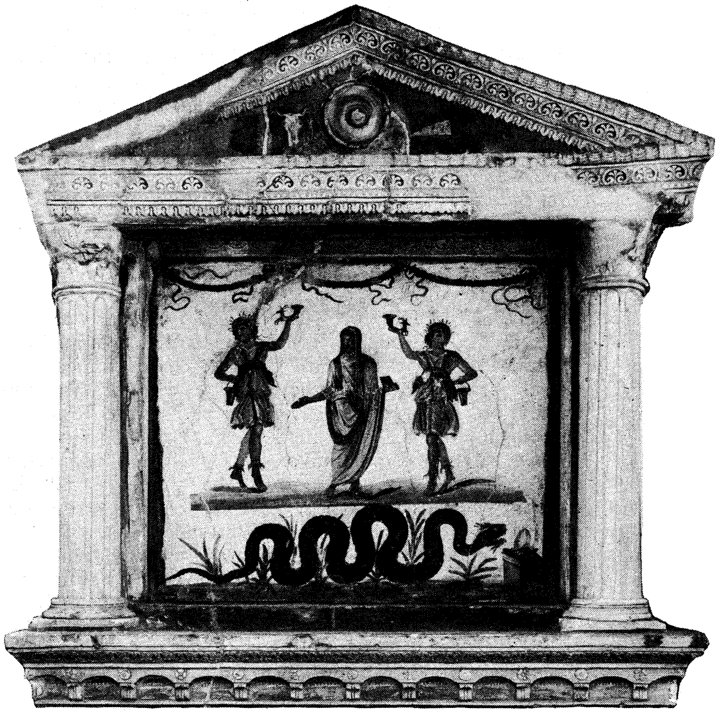
Janus and Vesta

Two other forces that belong to an early phase were Janus and Vesta, the powers of the door and hearth, respectively. Janus, who had no Greek equivalent, was worshipped beside the Forum in a small shrine with double doors at either end, and originated either from a divine power that regulated the passage over running water or rather, perhaps, from sacred doorways like those found on the art of Bronze Age Mycenae. Janus originally stood for the magic of the door of a private house or hut and later became a part of the state religion. The gates of his temple were formally closed when the state was at peace, a custom going back to the primitive war magic that required armies to march out to battle by this properly sanctified route, Vesta, too, passed from the home to the state, always retaining a circular temple reminiscent of the primitive huts whose form can be reconstructed from traces left in the earth and from surviving funerary urns. Vesta's shrine contained the eternal fire, but the absence of a statue indicates that it preceded the anthropomorphic period; its correspondence with the Indian *garhapatya,* "house-father's fire," suggest an origin prior to the time of the differentiation of the Indo-European-speaking peoples. The cultic site just outside the area of the primitive Palatine settlement indicates that there had been a form of fire worship even earlier than Vesta's (dedicated to the deity Caca) on the Palatine itself. The cult of Vesta, tended by her Virgins, continued to flourish until the end of antiquity, endowed with an important role in the sacred protectorship of Rome.

Manes, Indigetes, Lares, and Penates

The Di Manes, collective powers (later "spirits") of the dead, may mean "the good people," an anxious euphemism like the Greek name of "the kindly ones" for the Furies; an alternative connection with the Phrygian god Men seems less probable. As a member of the family or clan, however, the dead man or woman would, more specifically, be one of the Di Parentes; reverence for ancestors was the core of Roman religious and social life. Di Indigetes was a name given collectively to these forebears, as well as to other deified powers or spirits who likewise controlled the destiny of Rome. For example, the name Indiges is applied to Aeneas, whose mythical immigration from Troy led to the eventual foundation of the city. According to an inscription of the 4th century BC (found at Tor Tignosa, 15 miles south of Rome), Aeneas is also called Lar, which indicates that the Lares, too, were originally regarded as divine ancestors and not as deities who presided over the farmland. The Lares were worshipped wherever properties adjoined, and inside every home their statuettes were placed in the domestic shrine (*lararium*). Under state control they moved from boundaries of properties to crossroads (where Augustus eventually associated his own *genius* with the cult) and were worshipped as the guardian spirits of the whole community (Lares Praestites). The cult of the Di Penates likewise moved from house to state. From very early times the Penates, the powers that ensured that there was enough to eat, were worshipped in every home. They also came to be regarded as national protectors, the Penates Publici. Originally they were synonymous with the Dioscuri (Castor and Pollux). The legend that they had been brought to Italy by Aeneas was imported from Lavinium (Pratica di Mare) when the early Romans incorporated that town into their own state.

Brogi—Alinari



Altar of the Lares, depicting two Lares on either side of the Genius, AD 69–72. In the House of the Vettii, Pompei.

Diana and Fors Fortuna

The divinities of the later Regal period. Two other deities whose Roman cults tradition attributed to the period of the kings were Diana and Fors Fortuna. Diana, an Italian wood goddess worshipped at Aricia in Latium and prayed to by women who wanted children, was in due course identified with the Greek Artemis. Her temple on the Aventine Hill (*c.* 540 BC) with its statue, an imitation of a Greek model from Massilia (Marseille), was based on the Temple of Artemis of Ephesus. By establishing such a sanctuary, the Roman monarch Servius Tullius hoped to emulate the Pan-Ionian League among the Latin peoples. Fors Fortuna, whose temple across the Tiber was one of the few that slaves could attend, was similar to the oracular shrines of Fortuna at Antium (Anzio) and Praeneste (Palestrina). Originally a farming deity, 'she eventually represented luck. She came to be identified with Tyche, the patroness of cities and goddess of Fortune among the Hellenistic Greeks.

In Roman tradition, Servius Tullius reigned between two

Etruscan kings, Tarquinius Priscus and Tarquinius Superbus. The Etruscan kings began and perhaps finished the most important Roman temple, devoted to the cult of the Capitoline Triad, Jupiter, Juno, and Minerva (the dedication was believed to have taken place in 509 or 507 BC after the expulsion of the Etruscans). Such triads, housed in temples with three chambers (cellae), were an Etruscan institution. But the grouping of these three Roman deities seems to be owed to Greek anthropomorphic ideas, since Hera and Athena, with whom Juno and Minerva were identified, were respectively the wife and daughter of Zeus (Jupiter). In Italy, Juno (Uni in Etruscan) was sometimes the warlike high goddess of a town (*e.g.*, Lanuvium in Latium), but her chief function was to supervise the life of women, and particularly their sexual life. The functions of Minerva concerned craftsmen and reflected the growing industrial life of Rome. Two gods with Etruscan names, both worshipped at open altars before they had temples in Rome, were Vulcan and Saturn, the former a fire god identified with the Greek blacksmiths' deity Hephaestus, and the latter an agricultural god identified with Cronus, the father of Zeus. Saturn was worshipped in Greek fashion, with head uncovered.

Juno, Minerva, Vulcan, and Saturn

The focal point of the cult of Hercules was the Great Altar (Ara Maxima) in the cattle market, just inside the boundaries of the primitive Palatine settlement. The altar may be traced to a shrine of Melkart established by traders from Phoenicia in the 7th ccntury BC. The name of the god, however, was derived from the Greek Heracles, whose worship spread upward from southern Italy, brought by traders who venerated his journeys, his labours, and his power to avert evil. In a market frequented by strangers, a widely recognized divinity of this type was needed to keep the peace. The Greek cult, at first private, perhaps dates from the 5th century BC.

The divinities of the Republic. An important series of temples was founded early in the 5th century BC. The completion of the temple of the Etruscan Saturn was attributed to this time (497). A shrine honouring the twin horsemen, the Dioscuri (Castor and Pollux), was also built in this period. An inscription from Lavinium describing them by the Greek term ***kouroi*** indicates a Greek origin (from southern Italy) without Etruscan mediation. In legend, the Dioscuri had helped Rome to victory in a battle against the Latins at Lake Regillus, and in historic times, on anniversaries of that engagement, they continued to preside over the annual parade of knights (equites). From southern Italy, too, came the cult of Ceres, whose temple traditionally was vowed in 496 and dedicated in 493. Ceres was an old Italian deity who presided over the generative powers of nature and came to be identified with Demeter, the Greek goddess of grain. She owed her installation in Rome to the influence of the Greek colony of Cyme (Cumae), from which the Romans imported grain during a threatened famine. The association of Ceres at this temple with two other deities, Liber (a fertility god identified with Dionysus) and Libera (his female counterpart), was based on the triad at Eleusis in Greece. The Roman temple, built in the Etruscan style but with Greek ornamentation, stood beside a Greek trading centre on the Aventine Hill and became a rallying ground for the plebeians, the humbler section of the community who were hard hit by the grain shortage and who, at this time, were pressing for their rights against the patricians.

Ceres, Apollo, and Venus

Cumae also played a part in the introduction of Apollo. The Sibylline oracles housed in Apollo's shrine at Cumae allegedly were brought to Rome by the last Etruscan kings. The importation of the cult (431 BC) was prescribed by the Sibylline Books at a time when Rome, as on earlier occasions, had requested Cumae for help with grain. The Cumaean Apollo, however, was primarily prophetic, whereas the Roman cult, introduced at a time of epidemic, was concerned principally with his gifts as a healer. This role may possibly have been derived from the Etruscans, whose Apollo is known from a superb statue of *c.* 500 BC from Veii, Etruria's nearest city to Rome. In 82 BC the Sibylline Books were destroyed and replaced by a collection assembled from various sources. Later, Augustus elevated Apollo as the patron of himself and his regime, intending thereby to convert the brilliant Hellenic god of peace and civilization to the glory of Rome.

Unlike Apollo, Aphrodite did not keep her name when she became identified with an Italian deity. Instead, she took on the name Venus, derived, without complete certainty, from the idea of *venus*, "blooming nature" (the derivation from ***venia***, "grace," seems less likely). She gained greatly in significance because of the legend that she was the mother of Aeneas, the ancestor of Rome, whom statuettes of the 5th century BC from Veii show escaping from Troy with his father and son. From the time of the Punic Wars 200 years later the Trojan legend grew, for long before the 1st-century-BC dictators Sulla and Caesar claimed Venus as their ancestors, the story was interpreted as the preface to the Carthaginian struggle.

A number of gods were spoken of as possessing accompaniments, often in the feminine gender; *e.g.*, Lua Saturni, Moles Martis. These attachments, sometimes spoken of as cult partners, were not the wives of the male divinities but rather expressed a special aspect of their power or will. A similar origin could be ascribed to the worship of divine powers representing "qualities." Fides (Faith, Loyalty), for example, may at first have been an attribute or aspect of a Latin-Sabine god of oaths, Semo Sanctus Dius Fidius; and in the same way Victoria may come from Jupiter Victor. Some of these concepts were worshipped very early, such as Ops (Plenty, later associated with Saturn, and equated with Hebe), and Juventas (who watched over the men of military age). The first of these qualities to receive a temple, as far as is known, is Concordia (367), in celebration of the end of civil strife. Salus (health or well-being) followed in c. 302, Victoria in c. 300, Pietas (dutifulness to family and gods, later exalted by Virgil as the whole basis of Roman religion) in 191. The Greeks, too, from the earliest days, had clothed such qualities in words; *e.g.*, Shame, Peace, Justice, Fortune. In the Hellenic world they had a wide variety of signification, ranging from full-fledged divinity to nothing more than abstractions. But in early Rome and Italy they were in no sense abstractions or allegories and were likewise not thought of as possessing-the anthropomorphic shape that the term personification might imply. They were things, objects of worship, like many other functions that were venerated. They were external divine forces working upon men and affecting them with the qualities that their names described. Later on, under philosophical (particularly Stoic) influences that flooded into ethically minded Rome, they duly took their place as moral concepts, the Virtues and Blessings which abounded for centuries and were depicted in human form on Roman coinage as part of the imperial propaganda.

Divine qualities

The sun and stars. Little or no contribution to cosmology was made in the Roman world, and the demonstration of Aristarchus of Samos (*c.* 270 BC) that the earth revolves around the sun received virtually no support. The complicated geocentric interpretation that held sway in Rome was summed up in Cicero's ***Dream*** of *Scipio*. It formed the basis for the concept of the solar system on which the popular pseudoscience of astrology was founded, the sun being regarded as the centre of the concentric planetary spheres encircling the earth—not the centre of the cosmos in the sense of Aristarchus but its heart. From the 5th century BC onward this solar god was identified with Apollo in his role as the supreme dispenser of agricultural wealth. Possessor of a sacred grove at Lavinium, Sol Indiges was regarded as one of the divine ancestors of Rome. During the last centuries before the Christian era, worship of the sun spread throughout the Mediterranean world and formed the principal rallying point of paganism's last years. Closely associated with the sun cult was that of Mithra, the sun's ally and agent who was elevated to partake of communion and the love feast as the god's companion. Sun worship was popular in the army, and particularly on the Danube. Aurelian, one of the great military emperors produced by that area in the 3rd century, built a magnificent temple of

Sol

Sol Invictus (the Unconquered Sun) at Rome (274). Constantine the Great declared the sun his Comrade on empire-wide coinages and devoted himself to the cult until he adopted Christianity in its stead.

WORSHIP, PRACTICES, AND INSTITUTIONS

The ***rex sacrorum, flamines,*** and colleges of priests

Priests. Precedence among Roman priests belonged to the ***rex sacrorum*** ("king of the sacred rites"), who, after the expulsion of the kings, took over the residue of their religious powers and duties that had not been assumed by the Republican officers of state. Nevertheless, the hold exercised by the *rex sacrorum* and his colleagues was weakened by the Code of the Twelve Tables (*c.* 451–450 BC), which displayed the secular arm exercising some control over sacral law. As late as *c.* 275 BC the religious calendar was still dated by the ***rex sacrorum,*** but by this time he was already fading into the background.

Very early origins can also be attributed to some of the ***flamines,*** the priests of certain specific cults, and particularly to the three major ***flamines*** of Jupiter, Mars, and Quirinus. Jupiter's priest, the *flamen dialis*, was encompassed by an extraordinary series of taboos, some dating back to the Bronze Age, which made it difficult to fill the office in historic times.

Except for the ***rex sacrorum*** and *flamen dialis*, whose duties were unusually professional and technical, almost all Roman priesthoods were held by men prominent in public life. The social distinction and political prestige carried by these part-time posts caused them to be keenly fought for.

There were four chief colleges, or boards, of priests: the ***pontifices, augures, quindecimviri sacris faciundis,*** and ***epulones.*** Originally three, and finally 16 in number, the ***pontifices*** (whose name may recall antique tasks and magic rites in connection with bridges) had assumed control of the religious system by the 3rd century BC. The chief priest, the *pontifex maximus* (the head of the state clergy), was an elected official and not chosen from the existing *pontifices.* The ***augures,*** whose name may have been derived from the practice of magic in fertility rites and perhaps meant "increasers," had the task of discovering if the gods did or did not disapprove of an action. This they performed mainly by interpreting divine signs in the movements of birds ***(auspicia).*** Such divination was elevated, perhaps under Etruscan influence, into an indispensable preliminary to state acts, though the responsibility for the decision rested not with the priests but with the presiding state officials, who were said to "possess the auspices." In private life too, even as late as Cicero and Horace in the 1st century BC, important courses of action were often preceded by consultation of the heavens. The Etruscan method of divining from the liver and entrails of animals ***(haruspicina)*** became popular in the Second Punic War, though its practitioners (who numbered 60 under the empire) never attained an official priesthood.

Of the other two major colleges, the ***quindecimviri*** (Board of Fifteen, earlier Ten) ***sacris faciundis*** looked after foreign rites, and the members of the other body, the *epulones*, supervised religious feasts. There were also ***fetiales,*** priestly officials who were concerned with various aspects of international relationships, such as treaties and declarations of war. Also six Vestal Virgins, chosen as young girls from the old patrician families, tended the shrine and fire of Vesta and lived in the House of Vestals nearby, amid a formidable array of prehistoric taboos.

Annual festivals

Shrines and temples. The Roman calendar, as introduced or modified in the period of the Etruscan kings, contained 58 regular festivals. These included 45 Feriae Publicae, celebrated on the same fixed day every year, as well as the Ides of each month, which were sacred to Jupiter, and the Kalends of March, which belonged to Mars. Famous examples of Feriae Publicae were the Lupercalia (February 15) and Saturnalia (December 17, later extended). There were also the Feriae Conceptivae, the dates of which were fixed each year by the proper authority, and which included the Feriae Latinae (Latin Festival) celebrated on the Alban Mount, usually at the end of April.

Templum is a term derived from Etruscan divination. First of all, it meant an area of the sky defined by the priest for his collection and interpretation of the omens. Later, by a projection of this area onto the earth, it came to signify a piece of ground set aside and consecrated to the gods. At first such areas did not contain sacred buildings, but there often were altars on such sites, and later shrines. In Rome, temples have been identified from *c.* 575 BC onward, including not only the round shrine of Vesta but also a group in a sacred area (S. Omobono), close to the river Tiber beside the cattle market (Forum Boarium). The great Etruscan temples, made of wood with terra-cotta ornaments, were constructed later and culminated in the temple of the Capitoline Triad. Subsequently, more solid materials, such as tufa, travertine, marble, cement, and brick, gradually came into use. Temple archives, now vanished, play a large part in the historical tradition, and the anniversaries of the vows to build the temples and their dedication were scrupulously remembered and celebrated on numerous coins.

Sacrifice and burial rites. The characteristic offering of the Romans was a sacrifice accompanied by a prayer or vow. (The Triumph, associated with Jupiter, was regarded as a thanksgiving in discharge of a vow.) Sacrifices did not have to be animals, but they were regarded as more effective than anything else, the pig being the commonest victim, with sheep and ox added on important occasions. Considered best of all were the basic elements of life: heart, liver, and kidneys. Human sacrifice, on the whole, was extraneous to Roman custom, though its practice among the Etruscans may have contributed to the institution of gladiatorial funeral games in both Etruria and Rome, and it was resorted to in major crises, notably during the Second Punic War (216). Earlier in the century, and perhaps once before, a member of the family of the Decii had given up his life by human self-sacrifice ***(devotio)*** in a critical battle.

Cremation and inhumation

Although ancestors were meticulously revered, there was nothing resembling the comprehensive Etruscan attention to the dead. In spite of elaborate philosophizing by Cicero and Virgil about the possibility of some sort of survival of the soul (especially for the deserving), most Romans' ideas of the afterlife, unless they believed in the promises of the mystery religions, were vague. Such ideas often amounted to a cautious hope or fear that the spirit in some sense lived on, and this was sometimes combined with an anxiety that the ghosts of the dead, especially the young dead who bore the living a grudge, might return and cause harm. Graves and tombs were inviolable, protected by supernatural powers and by taboos. In the earliest days of Rome both cremation and inhumation were practiced simultaneously, but by the 2nd century BC the former had prevailed. Some 300 years later, however, there was a massive reversion to inhumation, probably due to an inarticulate revival of the feeling that the future welfare of the soul depended on comfortable repose of the body—a feeling that, as sarcophagi show, was fully shared by the adherents of the mystery cults, though, on the rational level, it contradicted their assurance of an afterlife in some spiritual sphere. The designs on these tombs reflect the soul's survival as a personal entity that has won its right to paradise.

Religious art. A vast gallery of architecture, sculpture, numismatics, painting, and mosaics illustrates Roman religion and helps to fill the gaps left by the fragmentary, though extensive, literary and epigraphic record. Starting with primitive statuettes and terra-cotta temple decorations, this array eventually included masterpieces such as the Apollo of Veii. Other works of art, over 400 years later, include paintings illustrating Dionysiac mysteries at Boscoreale near Pompeii, and the reliefs of Augustus' Ara Pacis at Rome; and with the Christian emblems of Constantinian sarcophagi and coinage a thousand years of ancient Roman religious art comes to an end.

CONCLUSION

Though Roman religion never produced a comprehensive code of conduct, its early rituals of house and farm engendered a feeling of duty and unity. Its idea of reciprocal understanding between man and god not only imparted the sense of security that Romans needed in order to achieve their successes but stimulated, by analogy, the concept of mutual obligations and binding agreements between one man and another. Except for rare aberrations, such as human sacrifice, Roman religion was unspoiled by orgiastic rites and savage practices. Moreover—unlike ancient philosophy—it was neither sectarian nor exclusive. It was a tolerant religion, and it would be difficult to think of any other whose adherents committed fewer crimes and atrocities in its name.

Rome

A capital of kingdoms and of republics and of an empire the armies and polity of which defined the Western world in antiquity and left seemingly indelible imprints thereafter, a city called eternal, as the spiritual and physical centre of the Roman Catholic Church, and a name that evokes major pinnacles of man's artistic and intellectual achievement, Rome, in the late decades of the 20th century, retains all of these attributes: the capital of Italy, a font of religious authority, a memorial to the creative imagination of the past. Probably more than any other city in the West, possibly more than any other in the world, it is a city whose history continues to shape nearly every aspect of its being but, at the same time, whose contemporary consciousness of that history projects it into the very core of modem life.

Location and historical character of the city

Rome is located in central Italy on the Tiber (Tevere) River, 15 miles (24 kilometres) inland from the Tyrrhenian Sea. The Roman countryside, the Campagna, was one of the last areas of central Italy to be settled in antiquity. The city was built on a defensible hill dominating the last downstream, high-banked river crossing where traverse was facilitated by a midstream island.

For well over a millennium, Rome controlled the destiny of all civilization known to European man, then fell into dissolution and disrepair. Physically mutilated, economically paralyzed, politically senile, and militarily impotent by the late Middle Ages, Rome nevertheless remained a world power—as an idea. The force of Rome the lawgiver, teacher, and builder continued to radiate throughout Europe. Although the situation of the popes from the 6th century to the 15th was often precarious—at times tragic, ridiculous, or shameful—Rome knew glory as the fountainhead of Christianity and eventually won back its power and wealth and re-established itself as a place of beauty, a source of learning, and a capital of the arts.

This article focusses entirely on the city of Rome, covering features of the Roman Republic and Roman Empire only as they affected the life or structure of the city. It is divided into the following sections:

For information on related topics, see the articles ITALY; ITALY AND SICILY, HISTORY OF; and ROME, ANCIENT. Aspects of Rome's contributions to Western culture will be found in such articles as RENAISSANCE; VISUAL ARTS, WESTERN; and PAPACY. See also ROMAN RELIGION.

(B.E.)

I. The history of the city

ROME OF ANTIQUITY

Founding and the kingdom. Although the site of Rome was occupied as early as the Bronze Age (c. 1500 BC) and perhaps earlier, continuous settlement did not take place until the beginning of the 1st millennium BC. By the 8th century, separate villages of various iron-using Indo-European peoples appeared, first on the Palatine and the Aventine hills and soon thereafter on the Esquiline and Quirinal ridges. The artifacts and especially the funerary customs of these communities indicate that, from the beginning, diverse culture groups—including Latins, Sabines, and perhaps others—played important roles in the formation of the future city.

Early peoples and cultures

With the settlement of the valleys between the Palatine, Esquiline, and Caelian hills in the 7th century, the independent villages began to merge. Before the end of this century, the Forum valley, originally used as a cemetery, was partially drained and occupied by wattle-and-daub huts. The mixed agricultural and pastoral economies of the earliest settlements were slowly exposed to commercial contacts with both Etruscan and Greek traders. The formation of a politically unified city probably occurred in the early 6th century BC under the influence of the Etruscan city-states to the north. Under the rule of its kings, traditionally seven in number (the last three probably Etruscans), Rome became a powerful force in central Italy.

During the regal period, social and economic differences began to shape the two classes, patrician and plebeian, whose struggles for political power dominated the early republic. The tribal organization of the populace was replaced by one based on military units, whose composition in the late regal period depended on property qualifications.

The early Roman Republic. The overthrow of the last Roman king and the establishment of the republic, either in 509 BC or a generation or two later, coincided with the decline of Etruscan power in central Italy. The new government under the leadership of two patrician consuls was at first a mixed blessing. Although Etruscan techniques and symbols survived in republican Rome, commercial ties with the Etruscans and with the Greek colonies in southern Italy gradually withered. During the ensuing economic crisis, grain shortages occurred, a problem that was to plague the city intermittently for a millennium and more; the government was forced to make purchases from as far away as Sicily.

Political upheaval followed economic depression. The first major confrontation between the patricians and plebeians in the mid-5th century led to the writing down of the customary laws in the Law of the Twelve Tables (451–450) and to the formation of a plebeian political

Paolo Koch—Rapho Guillumette

organization whose leaders, the tribunes, acted to protect the plebeians from arbitrary patrician actions. In the last half of the 5th century, Rome began again to expand its control over neighbouring territories and peoples, a process that culminated in the conquest of the Etruscan city of Veii in 396.

In 390 Rome suffered a disastrous check when a Gallic army laid siege to the city. After seven months, during which only the Capitoline remained in Roman hands, the Gauls were bought off but left Rome in ruins. The Romans set about reconstructing their city almost immediately, surrounding it with a continuous wall of huge tufa blocks. Later writers attributed Rome's haphazard appearance to the rapid rebuilding during this period; Livy described Rome as looking more like a squatters' community than a planned community. For eight centuries, however, no foreign invader was to breach Rome's walls.

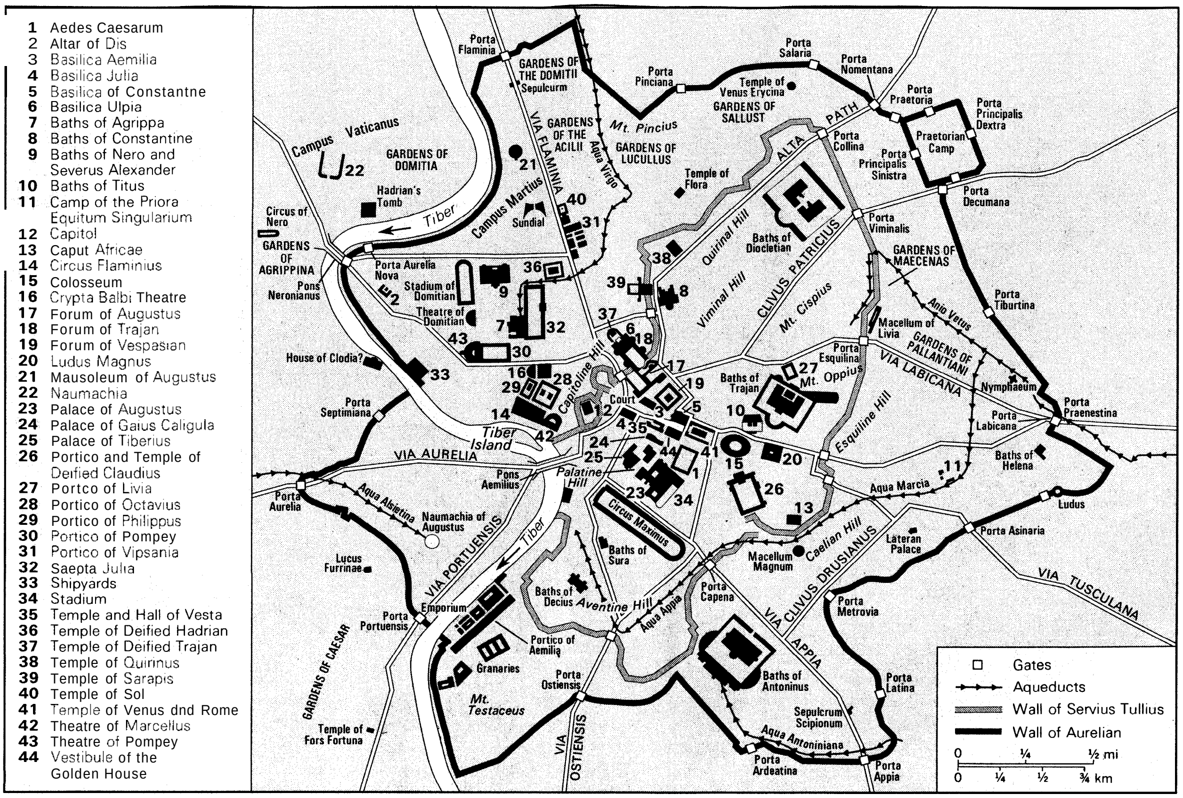
Origins of the haphazard municipal plan

The economic dislocation caused by the Gallic attack helped renew the conflict between the patricians and the plebeians; but, before the end of the 4th century, through a series of judicious compromises, the plebeians had won access to all of the offices of the state, and the actions of the plebeian assembly (plebicites) had been made legally binding on all Romans. Economic legislation dealing with debt and land distribution was directed toward relieving the distress of the lower classes.

The city of world power. The remarkable though largely unplanned territorial expansion of Rome between 375 and 275 brought lasting economic gains. With control of all of peninsular Italy, Rome established colonies on some of the conquered territories and elsewhere assigned lands to individual Roman citizens. The nearly 60,000 holdings distributed before the middle of the 3rd century helped to solve the pressure of Rome's land-hungry population; nevertheless, by c. 250 the city's population had grown to almost 100,000. The booty from conquests also helped to defray the costs of such public works as the building of temples and roads and the improvement of the city's water supply. By the early 3rd century, two aqueducts carried fresh water into the city.

In 264 Rome was drawn into a war with Carthage, the great Phoenician emporium in North Africa. After more than a century of conflict, Rome emerged as the strongest power in the Mediterranean; but the acquisition of an empire, which, for the most part, had not been the conscious desire of the Roman people, brought new social and economic problems to the city itself. The Second Punic War (218–201) saw the devastation of large areas of the peninsula by invading troops from Carthage, led by the famous general Hannibal; much land was abandoned and many peasants sought refuge in Rome. The growing requirements of a standing army depopulated the countryside and concentrated veterans in the city. The Roman nobility, prohibited by law and by custom from investing in commerce or industry, profited from the economic distress of the peasantry by buying up large tracts of land in central and southern Italy. Slaves, whom Rome's wars in the Mediterranean made available in large numbers, were introduced into Italy as farm labourers and herdsmen, causing further dislocation among the free peasantry. In general, the Roman economy lagged well behind the political development of both city and empire.

The late republic. During the 2nd century, the rapid growth of the urban population and the extension of Roman citizenship led to the effective disenfranchisement of the urban vote. The Senate, now the chief policy-making body of the Roman state, was preoccupied with the problems of the empire and too often ignored the needs of the city. With no separate municipal government, public works and the management of food and water supplies were left to private initiative or to amateur pub-



Rome during the imperial period.

lic officials. Nevertheless, some progress did occur. Some of the main streets were paved; drains were covered; and several large basilicas and a new row of shops were built in the Forum. The first stone bridge across the Tiber was completed in 142, and the first high-level aqueduct was erected in 144, allowing settlement on the higher ground of the city's eastern ridges. From the early 2nd century, the river port at the base of the Aventine acquired new warehouses and docking facilities.

These and other projects, however, were inadequate to deal with the growing urban proletariat increasingly swollen with slaves and freedmen. Crowded into jerry-built apartment houses (*insulae*) and with only minimum employment opportunities in what was an essentially non-industrial city, the lower classes were surviving on the sporadic public-works projects of the state and the largess of the rich before the end of the 2nd century. Rome had, moreover, neither police nor fire protection.

Impact of the Gracchi on municipal squalor

The Gracchi—Tiberius and later Gaius—attempted to deal with the problems of urban unemployment and rising food prices, first by advocating the re-establishment of a small farmer class in Italy, then through the subsidization of the grain supply for the poor. Gaius Gracchus also encouraged public expenditure on roads and buildings. Coupled with currency reforms and heavy government spending, these measures partially restored prosperity to Rome in the late 2nd century, but the basic structural faults in the city's economy and political life remained.

During the civil strife that occupied most of the first half of the 1st century BC, both population and problems multiplied in Rome. The creation of private armies attached to the Roman nobility offered employment to some of the urban lower classes but contributed greatly to the political violence that eventually spelled the end of the republic. Securing an adequate supply of cheap grain offered possibilities for the political manipulation of the urban masses. By the middle of the century, perhaps as many as 500,000 persons were receiving free grain. The upper classes became more interested in luxurious living and their tastes were matched in the public sphere by the building programs of Sulla and Pompey. Public buildings and theatres paid for with tribute and booty enhanced Rome's beauty but did not make a more livable city. In addition, heavy migration to Rome, especially from the Hellenistic east, added to the burdens of the already overcrowded city.

Municipal reforms of Augustus. Julius Caesar, the first to try to deal with the problems of Rome in a systematic way, did not live long enough to carry out his plans, which included canalizing the Tiber and building up the Campus Martius. His adopted son and successor, Augustus, attempted to transform Rome into a worthy capital for the new empire. Although his claim that he found the city brick and left it marble is exaggerated, Augustus and his colleagues did provide it with many fine public buildings, baths, theatres, temples, and warehouses. Such construction projects, together with the restoration of old buildings, provided employment for the urban masses; but the lack of any overall city planning left them to live in the unsafe and unsanitary tenements amid the narrow, winding streets and alleys of old Rome. Agrippa, a friend and supporter of Augustus, used his own immense wealth to further enhance the city's beauty and improve its water supply.

Advent of a professional city management

Augustus' reorganization of the administration of the city and his institution of certain public services were a significant break with the republican past. In 7 BC he divided Rome into 14 *regiones* ("wards") and these into *vici* ("precincts"), each with officials who performed both administrative and religious functions. The office of urban prefect, which Augustus revived in *c.* 26 BC, did not become permanent until later, but in the late empire the post became the most important in Rome.

In response to an obvious need, Augustus organized a fire brigade in 21 BC, placing a number of public slaves under the command of aediles, officials in charge of streets and markets; after a bad fire in AD 6, he established a corps of professional firemen *(vigiles),* comprising seven squads, or cohorts, of 1,000 freedmen apiece. The *vigiles* also had minor police duties, especially at night. He sought to impose order in the often violent streets by creating three cohorts under the command of the urban prefect; their main duty was to keep order in the city, and they could call on the Praetorian Guard for help if necessary. Altogether, Augustus saw to it that the amateur system of Roman municipal administration was replaced by a more professional and permanent set of institutions

—a work that probably contributed more to making Rome a great city than all of his marble monuments.

Contributions of later emperors. For the most part, the successors to Augustus continued his administrative policies and building program, though with less innovation and more ostentation. Claudius began a great port near Ostia, at the mouth of the Tiber, to facilitate grain shipments directly to Rome. Commerce remained largely in private hands, with public officials acting to ensure a regular supply and to prevent speculation.

Nero can be credited with introducing the most up-to-date ideas on town planning, though at a terrible price. The great fire of AD 64 destroyed large sections of the city. In the devastated areas Nero built new streets and colonnades as well as his fabulous Golden House, and he encouraged private citizens to build more spacious and more fireproof houses and apartment buildings with better access to the public water supply. Although Nero made Rome a more pleasant city in which to live, his measures did not prevent other devastating fires such as the one in 191 that gave Septimius Severus the opportunity to rebuild the city.

Other emperors in the late 1st and early 2nd centuries added to the glory of the imperial house and the amenities of Roman life—grandiose imperial forums, temples, arches, baths, and stadiums. Trajan's Forum, with its complex of buildings and courtyards, and his market, with its tiers of shops and its great market hall, represent, in the judgment of many historians, the supreme achievement of city planning in Rome. Trajan's Column, which narrates his victories beyond the Danube, was recognized as without peer even in the Christian Middle Ages. Hadrian left two enduring structures in Rome: the great domed Pantheon and his mausoleum, which in AD 590 was renamed Castel Sant'Angelo.

Populace and economy at the height of the empire

In the late 1st and early 2nd centuries Rome was at the peak of its grandeur and population, which has been estimated at over 1,000,000 persons but was probably less. It was kept at a high level by a steady stream of immigrants, both slave and free, from the provinces and beyond—although life expectancy in the city was probably lower than elsewhere in the empire. Rome's famous paved streets, water supply, and sewage system, however, should not be overestimated; even after the reforms of Nero, large numbers of the urban inhabitants continued to live in expensive, poorly built, overcrowded, and unheated slums without water or cooking facilities. The arena and the public bath relieved some pressures of high density and physical squalor, but Rome's refined technology was applied haphazardly to the problems of urban social organization. Garbage was usually dumped into the Tiber or pits on the city's outskirts.

Rome was a city of consumers, both rich and poor, and never a great industrial or commercial centre. The small shop was the basic unit of production and distribution through the imperial period, and the numerous trade associations served social and religious functions until they were enveloped in the economic regimentation of the late empire. Although Rome far surpassed any other ancient city in size and monumental splendour, its minimal economic and social achievement augured ill for the future.

Slow decline of the late empire. Rome's population probably began to decline in the late 2nd century. At the height of an outbreak of the plague in the reign of Marcus Aurelius, 2,000 persons a day are thought to have died. The economic and political disasters of the 3rd century did little good for Rome. In the 270s the walls built by Aurelian were more a symbol of the danger of barbarian attack than a restoration of Rome's grandeur.

By the time Diocletian (ruled 284–305) reformed the imperial government and ushered in the period of relative prosperity symbolized in his great baths, Rome was no longer the administrative capital of the empire. The founding of Constantinople merely confirmed Rome's loss of political primacy. Constantine, however, did much to restore the buildings and monuments of imperial Rome. In addition, his patronage of Rome's small Christian community laid the foundations of Christian and papal Rome of the medieval and modern periods.

Rome in the 4th century remained, nonetheless, a distinctly conservative and pagan city dominated by proud senatorial families. When the Visigothic army of Alaric first threatened the city in 408, the Senate and the prefect proposed pagan sacrifices to ward off the enemy, and even the pope would have allowed them to be performed in secret. In 410 Alaric seized Rome and allowed his troops to pillage the city for three days; much booty was taken, and many Romans fled.

It is unlikely, however, that the monuments of Rome suffered extensive damage. Its churches, for the most part, were spared. Even the longer, 14-day sack of Rome by the Vandals in 455 did less damage than the Romans themselves. In the 4th and 5th centuries, the emperors repeatedly legislated against those who were stripping buildings and monuments for their materials, especially the marble. By the middle of the 5th century, the population had dropped well below 250,000.

THE CITY OF THE POPES

Decay of imperial authority. Within a decade of Theodoric's death in 526, Justinian began his attempt to restore Roman imperial rule in the West. His ultimate success was disastrous for Italy and for Rome. Three times Rome was under siege; its aqueducts were cut, and once it was abandoned by its inhabitants. By the end of the century, with the urban population under 50,000, civil authority and the responsibility for protecting the city were in the hands of the church. Pope Gregory I tried to provide an adequate urban administration, and for nearly two centuries his successors played a similar role.

Bases of the papacy's temporal power

In the middle of the 8th century, when the Byzantines were no longer able or willing to supply Rome with adequate military aid, the papacy turned to the Franks. The "Donation" of Pepin—who owed his new title as king of the Franks in part to the Pope—and that of his son Charlemagne were the theoretical foundations of the temporal power of the papacy. In 774 Charlemagne conquered the Lombard kingdom, and in 800 he was crowned emperor by Pope Leo III and acclaimed by the people of Rome. The period of the late 8th and early 9th centuries was one of vigorous building and restoration of churches in Rome.

Factional struggles: papacy ad nobility. The decline of Carolingian authority in Italy led to the renewal of family and factional struggles. After the Muslims plundered St. Peter's and the outlying areas of Rome in 846, Pope Leo IV built a wall around the area of the Vatican, thus enclosing the suburb that came to be known as the Leonine City. From the late 9th through the middle of the 11th century, Rome and the papacy were controlled by various families from Rome's landed nobility, with brief interludes of intervention from the German emperors.

After decades of dispute between the Roman nobility and the papacy, the latter was able to establish an uneasy peace in Rome by the end of the 11th century. Much rebuilding was necessary after the Norman sack of 1084. Generally, the reformed papacy, begun under Leo IX (1049–54), was supported and financed by new Roman families such as the Frangipane and the Pierleone, whose wealth came from commerce and banking rather than landholdings. By the late 11th century the seat of the church had begun to draw many pilgrims and prelates to Rome, and their gifts and expenditures on food and housing stimulated a considerable flow of money. Although Rome had a population of fewer than 30,000 (occupying less than one-quarter of the lands within the old walls), it was becoming once again a city of consumers dependent on the presence of a governmental bureaucracy.

Emergence of the Roman commune. The Roman revolution in 1143 had fundamentally the same goals as other contemporaneous communal movements in northern Italy: freedom from episcopal (in Rome's case, papal) authority and control of the surrounding countryside. The revival of the Roman Senate and other echoes of the Classical past perhaps owed something to the preaching of Arnold of Brescia, a priest and monk, who said strong things against ecclesiastical property and church interference in temporal affairs. Rome's new republican constitution survived both papal and imperial attack alike, and in 1188 Pope Clement III recognized the communal government. In theory, the senators were to become papal vassals, but, in fact, the Pope had to make large cash payments to the senators and other communal officials. In the 1190s a single senator was able to exercise wide authority in the territories surrounding Rome.

Papal and communal authority in conflict

Pope Innocent III made it his first order of business to secure a firm papal position in Rome and in the Vatican. Only moderately successful, he found it expedient to support the Roman commune's expansionist policies. Territorial rivalry between Innocent's family and the Orsini led to rioting and finally open warfare in the streets of Rome in 1204, during which siege machines destroyed many ancient buildings. After a settlement, Innocent's many charitable projects won him Roman support. Gregory IX and the Roman commune clashed over Rome's expansionist policies and its claims to the right to tax the clergy and church property. Bitter struggles with the Hohenstaufen emperor Frederick II as well as the varied interests of Rome's leading families — the Orsini, the Savelli, the Annibaldi, and, above all, the Colonna—complicated the situation. After Frederick's death, an anti-papal regime promoted a rising middle class and a resurgence of the commune.

Period of the Avignon papacy. Few popes in the second half of the 13th century were able to reside in Rome. In the 1280s and 1290s, Rome was torn by the bitter rivalries among the Colonna, the Orsini, and the Annibaldi families, a discord encouraged by Pope Boniface VIII. In 1309 Clement V moved the papal residence to Avignon in France; Rome was left to its factional strife and its economic impoverishment.

In spite of sharp rivalries, Roman and papal interests had often coincided throughout the 13th century. Since Rome was never an important industrial or commercial city, its citizens, from the small shopkeepers and innkeepers to the great banking families, had depended economically on the presence of the papal Curia and the large numbers of pilgrims, prelates, and litigants it brought to Rome. The many brick campaniles of its Romanesque churches and the fortress towers on the palaces of its leading families symbolized Rome's ecclesiastical character; but, with a population of never more than 30,000 in the 13th century, it retained a village air for all its urbanity and classical aspirations. Most of the populace was concentrated around St. Peter's and in the low-lying areas of the Campus Martius and Trastevere; large sections of the city within the old Aurelian walls were pastures, gardens, and vineyards and wastelands.

Ambience of the city in the late Middle Ages

The popes in Avignon were able to maintain a tenuous rule over the city, especially under Benedict XII (1334–42). The brief popular revolution (1347) of Cola di Rienzo — who, styling himself tribune of Rome, combined apocalyptic visions with ideas of a renewal of Rome's ancient glories — had more dramatic than political impact. The terrible mortality of the Black Death reduced Rome's population to less than 20,000, and the city staggered through the last half of the 14th century still racked by factional strife. The return of the papacy from Avignon in 1377 did not help. Around 1400, Rome was described as a city filled with huts, thieves, and vermin, and in the neighbourhood of St. Peter's wolves could be seen at night.

The city of the Renaissance. The entry of Pope Martin V (a member of the Colonna family) into Rome in 1420 marked the beginning of the Renaissance city and of the absolute papal rule that lasted until 1870. Although Martin was neither a builder nor a patron of the arts, he laid the foundations of government that made Rome the capital of a Renaissance state. From this period, the apostolic vice chamberlain, as governor of Rome, controlled municipal offices, communal finances, and the statutes of the city. The Roman commune was transformed into a unit of authoritarian papal rule, and the papal states increasingly came under the firm control of papal officials.

From the pontificates of Nicholas V (1447–55) and, especially, Sixtus IV (1471–84), the squalid narrow streets of medieval Rome were widened and paved, and new Renaissance buildings replaced crumbling structures. At the same time, the monuments of ancient Rome suffered further damage as they were torn apart for their building materials, and their marble went too often into the lime kilns rather than into new structures. The popes attracted scholars and artists from across Italy, and, by the end of the 15th century, Rome was the principal centre of Renaissance culture. The high point was reached under Leo X (1513–21), with his plans for a new St. Peter's and his patronage of such artists as Michelangelo and Raphael. Rome flourished economically under the Renaissances popes. Banking and the exploitation of alum deposits near Civitavecchia by the popes (with the help of the Medici family of Florence) stimulated a flow of capital into the city. Although Rome once again had become a great consumer of imported luxuries, it still had little large-scale industry or commerce.

Destruction of ancient buildings

EVOLUTION OF THE MODERN CITY

Rebuilding and repopulation. The sack of Rome in 1527 by the armies of Emperor Charles V ended the city's pre-eminence as a Renaissance centre. In eight days, thousands of churches, palaces, and houses were pillaged and destroyed. But, even under the repressive rule of the Counter-Reformation papacy, Rome recovered; a new era of construction was begun, culminating in a vast program of city planning by Sixtus V (1585–90) and his architect Domenico Fontana. New streets and squares were laid out, obelisks raised, the Lateran and Vatican palaces rebuilt, and aqueducts repaired. Fortunately, his project to convert the Colosseum into a wool factory to provide employment for Rome's prostitutes came to nothing.

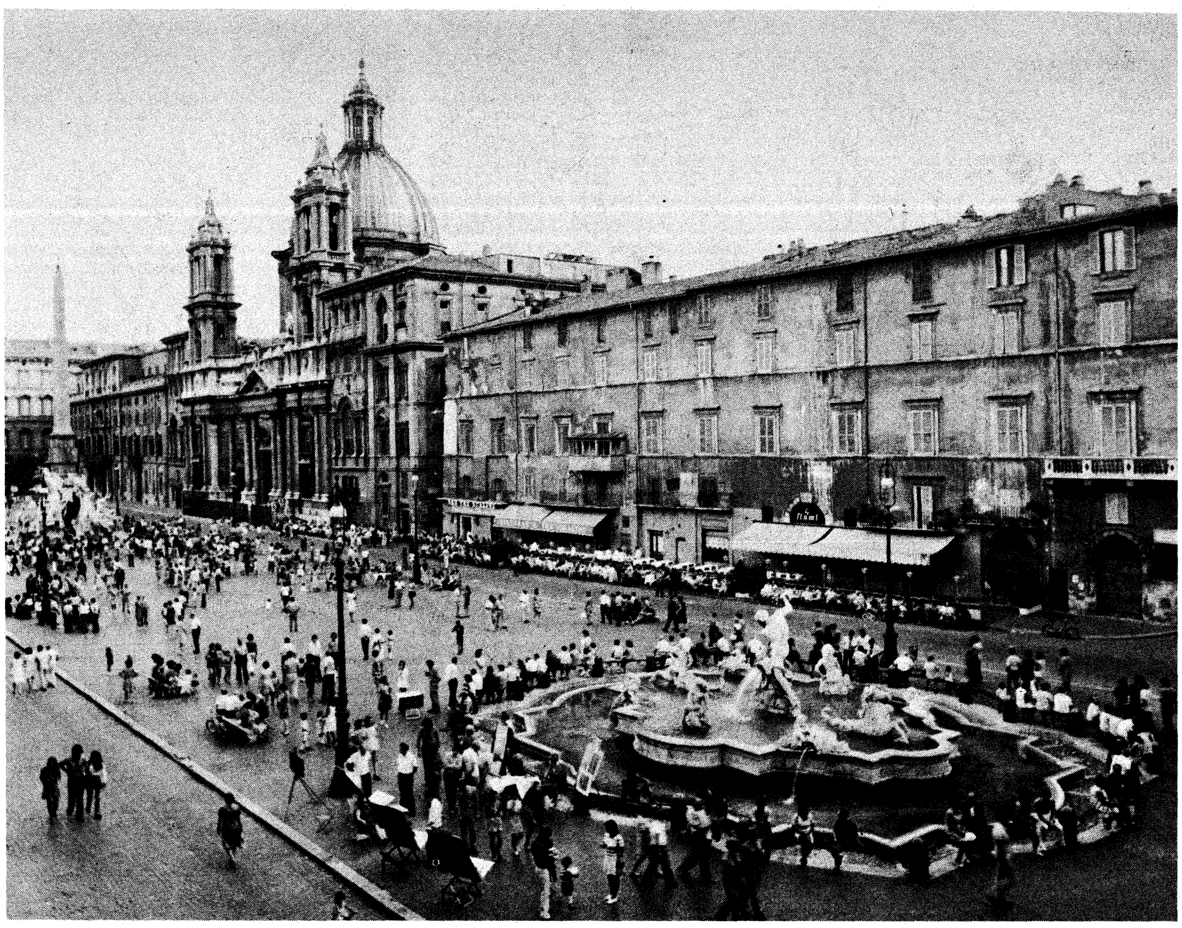
By 1600, Rome was again a prosperous cosmopolitan city. A great influx of new inhabitants attracted by employment opportunities in the papal bureaucracy and related service industries increased Rome's population to over 100,000. Much of the big business of the city remained in the hands of foreigners, however, for the wealth and power of the Roman nobility was based on land and ecclesiastical officeholding.

Decline and fall of the papal empire. In the 17th and 18th centuries Rome's noble families built fine palaces and patronized the arts while manoeuvring to win high positions in the church hierarchy. The highest prize of all, the papal crown, brought wealth and status to the wearer's family. But as corruption and bribery within these circles became a way of life, the influence of the papacy and of Rome declined throughout Europe and even throughout the Papal States. Although Sixtus V had created one of the best-planned cities in Europe, by the 18th century Rome was still a backward town, with poorly paved streets on which there were no road signs nor public lighting and little sanitation. To foreign observers, the Romans, from the most aristocratic families to the poorest classes, seemed to lead lives of provincial vacuity unconcerned with anything outside Rome. The population reached 165,000 by 1790, but as many as one-quarter of the inhabitants were employed in the petty bureaucracy that overran the city.

Continued backwardness and provinciality

The armies of Napoleon occupied Rome for the first time in 1798, and a republic was declared; but in 1809 Rome and the Papal States were annexed into the French Empire. The return of the pope to Rome in 1814 led to a long period of repression and reaction, though popes Leo XII and Gregory XVI promoted educational improvements and new public baths and hospitals. With the liberal attitude that characterized the early part of his reign, Pope Pius IX (1846–78) granted Rome a constitution in 1848; but, after the Revolution of 1848–49, he became an archconservative, attempting with French support to save the temporal power of the papacy and to stave off the modem world.

Capital of a united Italy. Most of the Papal States were included in the Kingdom of Italy, proclaimed in 1861, but Rome was excluded. Attempts by Garibaldi to



The Piazza Navona with the Church of S. Agnese designed by Borromini and, facing it, Bernini's "Fountain of the Four Rivers"; at right is Bernini's "Fountain of the Moor."
Garofalo—Grimoldi

capture the city in 1862 and 1867 were unsuccessful, but the withdrawal of the French garrison supporting Pius allowed Italian troops to enter Rome on September 20, 1870. After a plebiscite in October, Rome became the capital of a united Italy. Pius refused to accept the government's offer of settlement, choosing to style himself a prisoner in the Vatican. The situation was not resolved until 1929, when the Lateran Treaty between Pius XI and Mussolini recognized the pope's sovereignty within Vatican City.

Rome's population grew rapidly after 1870, passing the 500,000 mark before World War I and reaching more than 1,000,000 by 1930. Its area of settlement also expanded for the first time well beyond the old walls of the ancient city. During the Fascist regime of Benito Mussolini in the 1920s and 1930s, Rome was transformed into a modern capital, with grandiose new avenues and pompous buildings. Mussolini's encouragement of archaeological excavation contributed to the revelation and preservation of many of the monuments of classical Rome. Throughout the 20th century, Rome has been a great administrative and tourist centre, though it still lacks the large-scale commerce or industry characteristic of most modern urban development. (R.R.R.)

Mussolini's transformations

II. The contemporary city

The city of the seven hills, the city of treasures and tourists, the honey-coloured city of fountains and cupolas lies mostly within the old city walls. The so-called Servian Wall, built almost certainly 12 years after the Gauls' destruction of Rome in 390 BC, enclosed most of the Esquiline and Caelian hills and all the other five. It was built into ramparts that dated from the early republic or even the late kingdom. Although Rome grew beyond the Servian defenses, no new wall was constructed until Aurelian began building in brick-faced concrete in AD 270. Almost 12 miles long and girdling about four square miles, this is the wall that Italian troops had to assault and breach to claim their capital in 1870, and it is still largely intact.

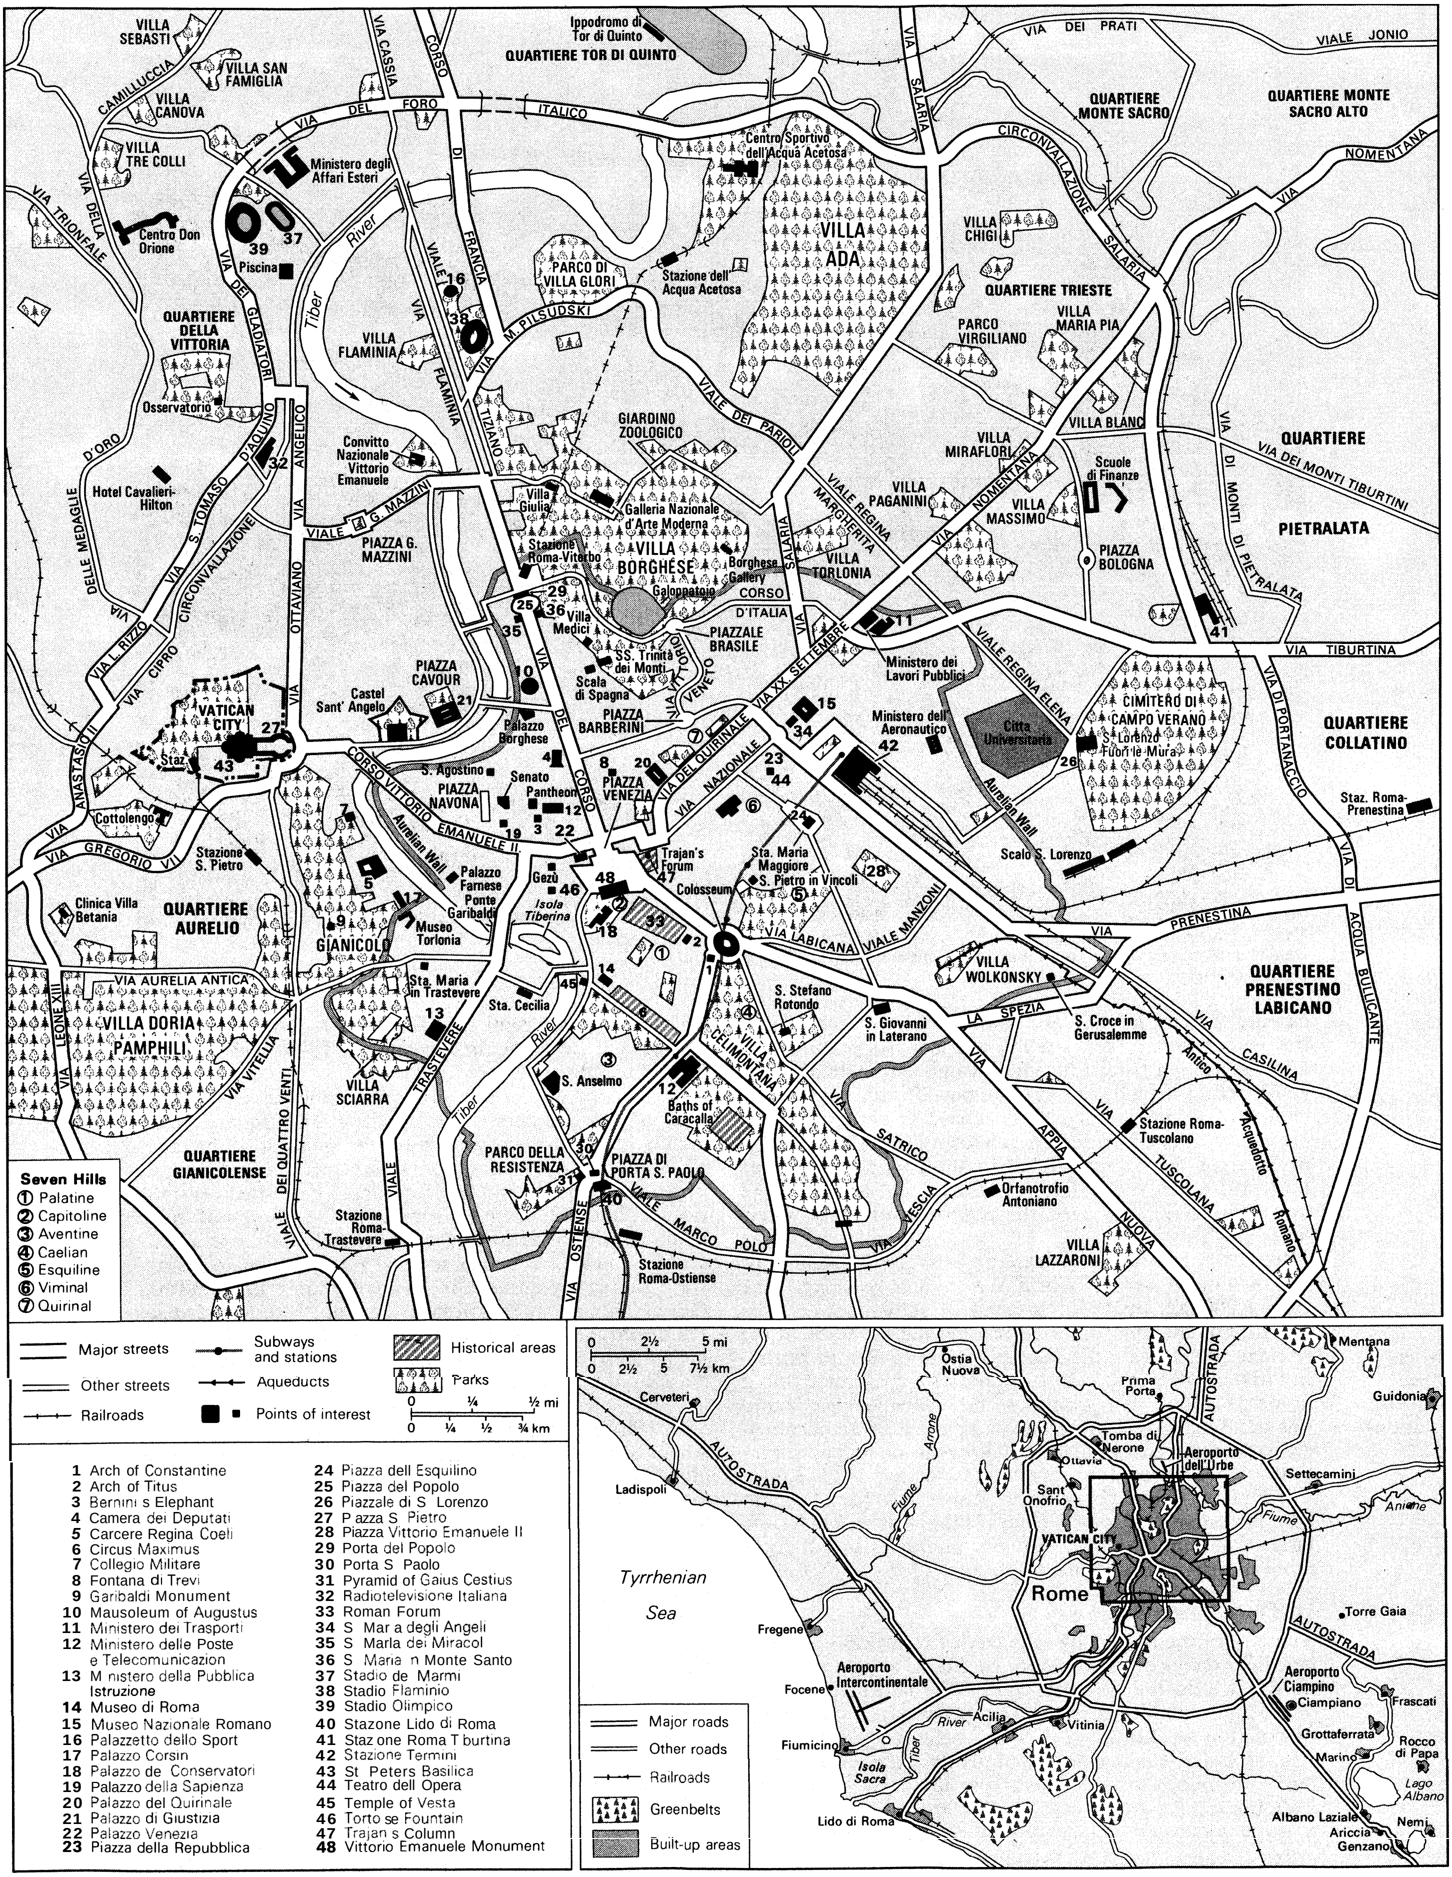
Extent of modern Rome

The ancient walled city of Rome embraces only 4 percent of the modern municipality's 582 square miles (1,508 square kilometres) and is the smallest of the city's 12 administrative zones, containing less than 10 percent of the more than 2,780,000 Romans. The walled centre is divided into 22 *rioni* ("districts"), the names of most dating from Classical times, while surrounding it are 32 *quartieri urbani* ("urban sectors") that began to be absorbed officially into the municipality after 1911. Within the city limits on the western and northwestern fringes are six large *suburbi* ("suburbs"), while beyond the municipal boundaries the commune of Rome about doubles the area of the city itself.

THE AMBIENCE OF ROME

About six miles out from the centre of Rome, a belt highway describes a huge circle around the capital, tying together the antique roads that led from everywhere to Rome, the Via Flaminia, Via Aurelia, Via Appia. Melancholy masses of modern apartment buildings rise in the districts outside the centre, in which the small amount of contemporary construction is inconspicuous. Street frontages and show windows are often rebuilt to keep pace with the times, and the Romans succeed in harmonizing the new, the simply old, and the antique with a talent that they have demonstrated since the first extensions of the republican Forum were made under the emperors.

Small as it is, the old city contains 300 hotels, 300 *pensioni,* more than 200 palaces, 20 churches, eight of the city's major parks, the residence of the Italian president, the houses of Parliament, offices of city and national government, and the great historical monuments, in addition to thousands of offices, workshops, restaurants, and bars,



Central Rome and (inset) its metropolitan area.

It is there that the millions of tourists seem to descend annually, to supplement and, in large measure, support the local populace.

Administrative mazes. Rome is one of the most beautiful and exciting capitals in the Western world. According to local authorities, it is also the filthiest, noisiest, and most heavily indebted city in Italy.

The city that introduced the public sewer lacks an adequate sewage system. Four treatment plants planned to end the flow of raw outfall into the Tiber remained unbuilt in the early 1970s because the $160,000,000 was not available to pay for them. The municipal debt in 1971 was $2,400,000,000; and interest on this debt amounted to $144,000,000 of the $200,000,000 annual municipal revenue in 1971.

Housing shortage

The city that invented both concrete and the apartment house (insulaj suffers a perennial housing shortage. At Christmas 1970 Pope Paul VI appealed to the municipality to house the 70,000–100,000 inhabitants of shantytowns on Rome's outskirts. The housing shortage persists because of the incessant arrival of job-seeking migrants from all over Italy but mostly from the impoverished south. Rome is not industrial, but it does have government and tourism to provide employment, and its growth continues unabated. By 1968 all the plans, powers, agencies, and even state building funds were in hand, but three things impeded construction: first, land cannot be built upon until the municipality supplies public services and schools (the city is so short of school space that schools operate classes in three successive shifts for 12 straight hours a day); second, Roman politics are more Byzantine — more labyrinthine and convoluted — than a 5th-century mosaic; third, the notorious glacier-slow Roman bureaucracy can, by paper shuffling alone, delay an approved project up to five years. Life in Rome remains an endless paper chase through the obscure corridors of petty authority.

Traffic becomes a typical Roman dilemma because much of the municipal revenue is derived from the 900,000 automobiles and 100,000 motor scooters that help render city life difficult. The average noise during waking hours is at or above the level that gradually induces deafness, whereas speed of motor traffic, in spite of the audacity and acuity of the drivers, is four miles per hour. A traffic analysis in 1971 projected that in six years Rome would have enough motor vehicles to cover every foot of its road surface.

In 45 BC Julius Caesar forbade any wagon to be led or driven during the daytime within the continuous built-up area of Rome. Unfortunately, the police force required for enforcement was seriously under strength so that generally during the daytime almost no traffic police were on duty. "Where can you find lodgings that give you a chance of sleep?" a celebrated writer demanded. "The roar of the wheeled traffic in the City's narrow, winding streets and the shouts of abuse . . . ," thus wrote Juvenal, who lived in Rome in the late 1st and early 2nd centuries AD. In 1970 and 1971 municipal authorities introduced stringent rules to keep some of the traffic out of the centre, and in 1972 the city experimented inconclusively with free buses to determine whether vehicular traffic could be reduced.

Deterioration of the city's monuments was being accelerated by traffic fumes and vibration, yet the monuments themselves impeded the one undertaking that could reduce road traffic: construction of a subway. Mussolini decreed the building of a subway from the central railway station, and by 1955 it was in operation. In 1959 a comprehensive metropolitan subway system was approved. After five years of tunnelling through the bureaucracy, the first line began tunnelling a route some 14 miles long under the streets. It was diverted to protect monuments, halted when it unearthed archaeological remains, and, at long last, resumed again, with completion expected in the mid-1970s. Two future lines will go three times deeper, to 60 feet, to avoid disturbing any more buried heritage.

The people and their pace of life. The knowledge that Rome is eternal, that nothing lasts but nothing changes, gives rise to the local watchword, pazienza ("patience"). In this overcrowded, understaffed city, pazienza is demonstrated everywhere, every day. Except for brief, lowering, summer-lightning flashes of an underlying volatility, the Roman is apt to be cheery and courteous, a little less operatic in his reactions than many other Italians.

Family life

In Rome, as in the rest of Italy, all children are godsends and are demonstrably, publicly loved, patted, petted, cuddled, and kissed. Unmonied families make sacrifices to provide the biggest possible dolls and the flashiest possible tricycles. This continues far into life, with the man playing the role of adored but respectful princeling to his queen mother and imperious but indulgent king to his wife and children. In society outside the family the important thing is bella *figura*, or keeping face. Thus the *dottore* (the only degree the university of Rome gives is the doctorate) salutes the street sweeper as capo ("chief"), a gesture of respect called for by the uniform.

For 1,000 years, to be a citizen of Rome was to hold the keys to the world, to live in safety, pride, and relative comfort. Today there is still considerable pride in being a Romano di *Roma*, a Roman Roman. Among such are the "black nobility," families with papal titles who form a society within high society, shunning publicity and not given to great intimacy with the "white nobility," whose titles were conferred by mere temporal rulers. They avoid the "jet set," the loose group of affluent international itinerants for whom Rome is a major and frequent stopover in their worldwide wanderings.

In the 1970s the cinematic wing of the jet set continued to congregate at the café tables ranged on the plane-tree-shaded sidewalks of the Via Vittorio Veneto, a street of grand hotels, airline offices, and government buildings. Laid out in 1887 from the Villa Borghese gardens to the Piazza Barberini, it runs downhill in a dogleg, Italians preferring the right-hand side, foreigners coagulating on the other. During the 15 or so years of peak prosperity in Italian film making, about 1950–65, international film celebrities abounded and clouds of beautiful career hopefuls drifted among the tables, making the Via Veneto one of the most intriguing — in both senses of the word — streets in the world. In the 1970s cinema production was depressed; but hope was thicker than the exhaust fumes and dreams as bright as the neon signs, and the street remained gaily and expensively animated until long after midnight.

At the same hour, less glittering Romans can be found in the Piazza Navona, on the flat plain in the bend of the Tiber that was the Campus Martius of classical times. The piazza retains the shape and some of the remains of Domitian's circus (AD 81–89), which remained intact until at least 1450. This is far more typical of central Rome than the Via Veneto, a mere centenarian and therefore a new street. Mussolini's regime cut some new routes through the city, mainly to render historic sites more accessible, but 20th-century streets are rare in the historic centre.

The most nobly Roman of the Romans

The inhabitants who consider themselves the most nobly Roman of them all are the people of Trastevere (Across the Tiber). They have been in their neighbourhood for a very long time, although they are of neither pure nor primordial stock. Trastevere was the quarter for sailors and foreigners, whereas the founding fathers eastward across the river were soldiers and farmers. In the Middle Ages a number of palaces were the homes of powerful families, and palaces continued to be built during the Renaissance (Palazzo Farnesina) and even in the 18th century (the Palazzo Corsini). Some authorities — not all from Trastevere — claim Sta. Maria in Trastevere as the oldest church in Rome, pointing out that under the empire the district was the home of Orientals with alien religions, among them a goodly number of Jews proselytized by SS. Peter and Paul. It is said that Alexander Severus (reigned 222–235) permitted Christians to foregather at this site under the leadership of Pope St. Calixtus I, and it is recorded that Pope St. Julius I either raised or rebuilt a church there in 341–352. Today's church is largely 12th-century Romanesque, with a beguiling mosaic facade.

Sidewalk cafe along the Via Vittorio Veneto.

Paolo Koch—Rapho Guillumette

Over the millennia the area has lost little of its vigour. The people have maintained the earthiest of Roman accents, their taverns have remained generally faithful to simple fare, robust wine, and the unison bawling of irreverent songs. One of Rome's few secular statues—a top-hatted marble effigy of Giuseppe Gioacchino Belli, a 19th-century satirical dialect poet—stands near the Ponte ("bridge") Garibaldi.

Most of the streets are still narrow and without sidewalks, appearing only on the most detailed maps and baffling taxi drivers who do not live there. Every 100 paces or so the haphazard cobbled lanes open upon some surprising, small plaza with a church, a palace, a cloister, or a group of cafés. In recent years rents have been rising, and the occasional commercially folkloric restaurant has appeared because artists, actors, and their friends have been moving to Trastevere in response to the unaffected village ambience and the warm humanity of the local folk —who are taking their profits and moving away to modern flats.

MAIN STREETS AND THEIR MONUMENTS

The Via del Corso

The main street in central Rome is the Via del Corso, an important thoroughfare since classical times, when it was the Via Flaminia, the road to the Adriatic. Its present name comes from the horseraces (corse) that were part of the Rome carnival celebrations. From the foot of the Capitoline Hill, the Corso runs to the Piazza del Popolo and through a gate in the city wall, the Porta del Popolo, there to resume its ancient name. It begins spectacularly with the Vittoriano, the monument to Victor Emmanuel II, first king of united Italy. The nation's unknown soldier was interred there after World War I. A Neo-Baroque marble mountain, it is the whitest, biggest, tallest, newest (1911), and possibly the most pompous of Rome's major monuments. Useful as well as ornamental, it contains a museum of the 19th-century cultural revival, a police station, and rare Roman public restrooms.

Along the street among the smart shops are five churches, eight palaces (and one palazzetto), and the column of Marcus Aurelius. The first church is S. Marco, the first of Rome's parish churches to be built (c. AD 336) on the plan of a classical basilica. The present church, third on the site, dates from the 9th century and was restored in the 15th by the Venetian Pope Paul II, who built the Palazzo and the Palazzetto Venezia around the church in 1445, when he was cardinal, enlarging the residence when he became pope. Thereafter, the basilica's priest was always a Venetian cardinal, sharing the palace with the Venetian embassy. Mussolini had his headquarters there and harangued the crowds from the balcony from which Paul II had cheered the carnival races and given his papal benediction. The palace is now a Renaissance art museum and the Biblioteca dell'Istituto Nazionale d'Archeologia e Storia dell'Arte (Library of the National Institute of Archaeology and Art History).

While her son Napoleon languished on St. Helena, Madame Laetitia languished in the Palazzo Bonaparte, now Palazzo Misciatelli. Across the way is the Palazzo Salviati, built by the Duc de Nevers in the 17th century, owned in the 19th by Louis Bonaparte. The Palazzo Doria is a late-15th-century building behind a 1734 facade. Four mornings a week the family admits the public—through a side door—to its state rooms and its art gallery, in which are many Titians, Bruegels, Caravaggios, a Bronzino, a Memling, and a Velázquez portrait and Bernini bust of the family pope, Innocent X. Behind S. Marcello, the Baroque reworking of a church founded in the 4th century, is the mid-17th-century Palazzo Ballestra, in which Bonnie Prince Charlie of Scotland was born in 1720 and to which he returned in 1788 to die.

The column of Marcus Aurelius, with reliefs showing his victory over Danubian tribes, was preserved from the assorted Christian looters of Rome because it was the property of a religious order. In the square around the column are the Palazzo Chigi (1562), for many years the Ministry of Foreign Affairs and now the offices of the Italian Cabinet, and the Palazzo Wedekind. Although built in the 19th century, the Wedekind, which now houses a daily newspaper, is not without its plundered antique columns.

The Piazza del Popolo

The Corso emerges onto the splendid oval Piazza del Popolo, which is monumental without being intimidating, a sort of toy theatre stage set magically magnified. Over a period of 300 years, it was constructed as the ceremonial entryway to Rome, and, although its elements are diverse in style and in age (13th century BC–19th century AD), a remarkable harmony prevails. In 1561 the Porta del Popolo, the medieval gate in the city wall, was rebuilt. Ninety-four years later its inner face was redone by Bernini for the grand entrance of Queen Christina, who had abandoned the Protestant throne of Sweden for the Catholic hospitality of Rome. In 1589 Pope Sixtus V punctuated the plaza centre with an obelisk (13th century BC) brought by Augustus from Heliopolis to the Circus Maximus.

The church next to the gate, Sta. Maria del Popolo, which stood for centuries before the piazza existed and gives its name to the area, was founded in 1227 to replace a 1099 chapel built over what was presumed to be Nero's tomb. It was replaced in 1472–77 by today's church, further disguised on the piazza frontage by a Neoclassical facade. The interioı is fraught with the works of great Renaissance and Baroque artists. The main chapel has tombs by Andrea Sansovino and frescoes by Pinturicchio. In the Cerasi Chapel are Caravaggio's "Conversion of St. Paul" and his "Crucifixion of St. Peter." The Chigi Chapel, unique for the early 16th century in being a miniature church, was designed by Raphael. Bernini sculpted two of the four prophets in the corners.

At the opposite end of the piazza stand "twin" churches (1662) framing the entrance to three streets. The streets were there first, so the churches were ingeniously squeezed into awkward, different-sized plots between them. Sta. Maria di Montesanto, on the narrower plot toward the Tiber on the west, has an oval plan and dome, while Sta. Maria dei Miracoli, on the east, has a round dome. Carlo Rainaldi, the architect, turned both facades slightly inward to frame the welcoming parades that would proceed up the Corso between the two churches. One of the streets, the Via del Babuino, was one of many built by Sixtus V (1585–90) to try to repopulate parts of Rome deserted after the Gothic wars.

Since lack of water had driven residents off the high ground, he restored the aqueduct of Alexander Severus, the Aqua Alexandrina, and gave it his own first name, Aqua Felice. He laid out new roads, the basis for the modern street plan of Rome. He also built the Vatican Library, saw to the completion of St. Peter's dome, rebuilt the papal palaces of the Vatican, the Quirinal, and S. Giovanni in Laterano (St. John Lateran), refurbishing the squares in front of the last two, and built a new square at Sta. Maria Maggiore. He re-erected four obelisks found among the ruins and restored a great number of fountains, dearly beloved of the Romans.

The Piazza di Spagna

An obelisk in the Piazza di Spagna is not his work but was discovered in the Piazza in Campo Marzio in 1778 and erected in 1857 to commemorate the 1854 promulgation of the dogma of the Immaculate Conception. The fountain is fed by the Aqua Vergine, Agrippa's aqueduct of 19 BC, which escaped Gothic destruction because it was mainly underground and which was repaired in 1447. When the fountain was planned in the early 1600s by Bernini (whether by father or son has not been established), there was insufficient water pressure for spouting jets, so the Barcaccia (Scow) was conceived, an ancient marble boat foundering endearingly in its marble bath.

The most striking architectural element in the piazza—indeed, one of the most striking in all Rome—is the renowned Scala di Spagna (Spanish Steps, or Stairs) which transmutes an irksome climb into a sensuous pleasure. The staircase is a rare case of the failure of French cultural propaganda, for while they are called the Spanish Steps—the Spanish Embassy moved onto the square in the 17th century—they are unequivocally French. First suggested by the French about the time the Spanish Embassy was being installed, the idea was approved by papal authorities 100 years later and paid for with a legacy from a French diplomat. The stairs ascend to the French-built church and convent of Trinità dei Monti, begun in 1495 with a gift from the visiting French king Charles VIII and restored by Louis XVIII.

Charles Dickens described the steps as thronged with unengaged "artist's models" in regional costume. They are still crowded with loiterers in distinctive dress, students from all over the world. Artists were among the first to move into the area, and some few who have not been shouldered out by galleries and ultra-modish shops retain their studios among the walled gardens of the Via Margutta. Since the end of the 16th century, the Piazza di Spagna, with its innkeepers who followed the artists, has been a stopping place for tourists. Young lords on the Grand Tour of Europe left their heavy touring coaches for refitting in a side street still called Via delle Carozze (Carriage Street). The room on the piazza in which John Keats died in 1821 has been made into a museum. The surrounding streets at both the top and the bottom of the steps are among the smartest shopping streets in Rome.

III. Monuments of the Roman past

The historic scourges of Rome

Many of the treasures of Rome no longer can be seen where they were placed originally, many can be seen only in other cities of the world, while many others still in Rome represent the spoils of conquest brought to the city from around the ancient world or the cannibalizing of one age or of one faith upon the creations of an earlier one. Rome was sacked first by the Gauls in 390 BC and subsequently by the Visigoths in AD 410, the Vandals in 445, the Normans in 1084, and Spanish troops in 1527. Muslims laid it under siege in 846. The Great Fire of Rome—Nero's fire—occurred in AD 64, and fires and earthquakes ravaged individual buildings or whole areas fairly often over the millennia. But, of all these scourges, it was the stripping of the structures of antiquity for building materials, especially from the 9th century through the 16th, that destroyed more of Classical Rome than any other force. The heritage of the past that survives in Rome is nevertheless unsurpassed in any city of the West, and it is so ubiquitous that its highlights must be comprehended in terms both of geography and of type.

1HE SEVEN HILLS

The Palatine. The origins of Rome, as of all ancient cities, are wrapped in fable. The Roman fable is of Romulus and Remus, twin sons of Mars, abandoned on the flooding Tiber and deposited by the receding waters at the foot of the Palatine. Suckled by a she-wolf, they were reared by a shepherd and grew up to found Rome, Romulus being obliged to execute Remus for disobeying one of the city's first laws. The Etruscan bronze statue of the maternally ferocious wolf (late 6th or early 5th century BC; Capitoline Museum) is one of the greatest works among the thousands of masterpieces in Rome. The nursing infants were sculpted and placed under the Etruscan statue in 1509.

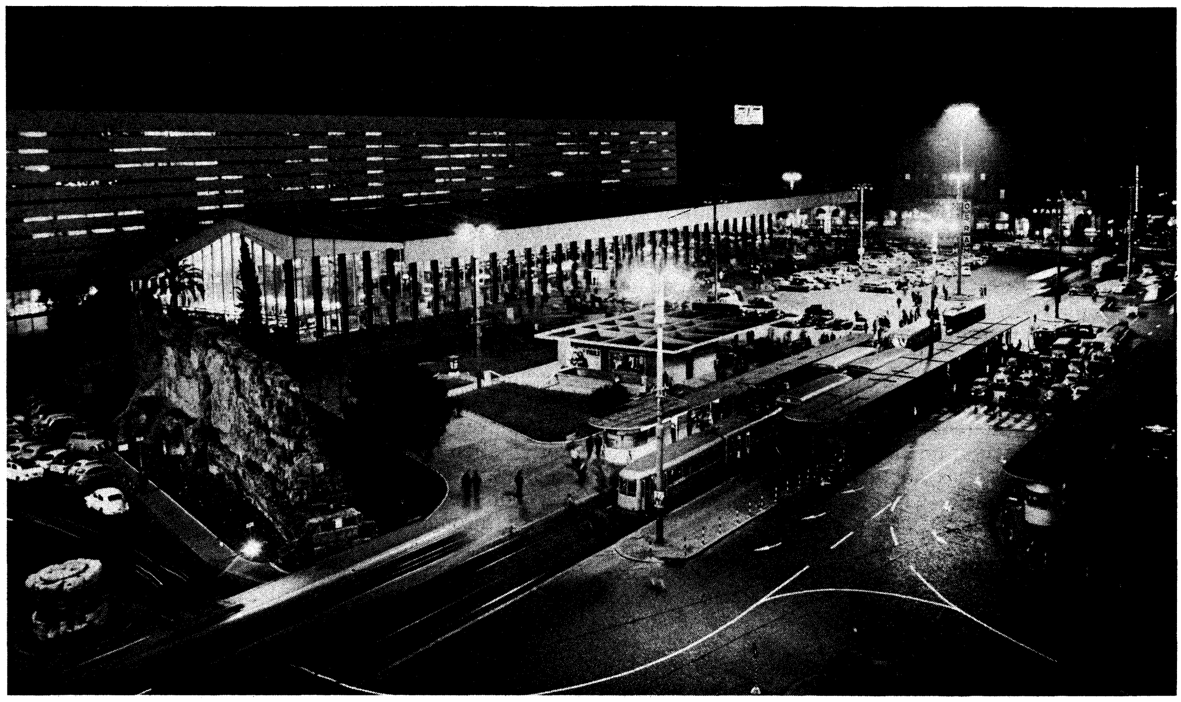
The wolf cave, the Lupercal, was maintained as a shrine at least until the fall of empire but is now lost. On the same side of the Palatine, "Romulus' House," a timber-framed circular hut covered in clay-plastered wickerwork, was kept in constant repair. Modern excavations have revealed the emplacement of just such Iron Age huts from the period (8th–7th century BC) given in the fable for the founding of Rome.

On this hill the columns of lost palaces rise in uncompromised beauty from fields of wildflowers and the dust of history. Ilex and pine and bay frame views of Rome. This is the landscape—classical, with figures—that has stirred romantics since it was first limned by 17th-century etchers and sketchers. Before the emperors departed, virtually the entire hill was one vast palace.

Residences of the 1st century

The Palatine was a superior residential district by the 3rd century BC. Augustus was born there in 63 BC and continued to live there after he became emperor. His private dwelling, built about 50 BC and never seriously modified, still stands. Known as the House of Livia, for his widow, it has small, graceful rooms decorated with paintings of fruit and flowers and mythological scenes. Other private houses, now excavated and visible, were incorporated into the foundations of the spreading imperial structures, which eventually projected down into the Forum on one side and onto the Circus Maximus on the other. The three crests of the hill were flattened in the course of building. The palace was begun by Tiberius, to whose work Nero, Caligula, Trajan, Hadrian, and Septimius Severus made their own additions.

The biggest and richest structure of all was created for Domitian (reigned AD 81–96), whose architect achieved feats of construction engineering not seen before in Rome. Parts of the lavish structure—the richly marbled, centrally heated dining hall of which is among the chambers visible today—were occupied by popes after there were no more emperors, and then the hill was abandoned.



The Stazione Termini in the Piazza dei Cinquecento and the remains of the 4th-century BC Servian Wall (left) that abuts the building.

Garofalo—Grirnoldi

After some six centuries the great Roman families returned to the Palatine, planting 16th-century pleasure gardens and pavilions over past glories. A whole set of rooms from the private wing of Domitian's palace was preserved by incorporation into the Villa Mattei. Atop Tiberius' palace the Farnese family built two aviaries and a garden house and laid out one of Europe's first botanical gardens—some parts of which have escaped archaeological excavation.

The Capitoline. The seat of Roman government, the Capitoline is little changed from Michelangelo's design and represents one of the earliest examples of modern town planning. The centrepiece of this piazza of three palaces is a bronze equestrian statue of Marcus Aurelius, which stood unmolested for ages by the barracks of the imperial guard (later the Lateran Palace) because it was believed to be a statue of Constantine, the first Christian emperor.

The Palazzo Senatorio incorporates remains of the facade of the Tabularium, a state-records office constructed in 78 BC and one of the first buildings to use concrete vaulting and employ the arch with the Classical architectural orders. After a popular uprising in 1143, a palace was built on the site for the revived 56-member Senate, supposedly elected by the people but by 1358 a body of one appointed by the pope; when it was rebuilt to Michelangelo's design, it was called the Palazzo Senatorio (Senate Palace).

The palace of the municipal councillors, the *conservatori*, is on the south side of the square opposite the Palazzo del Museo Capitolino (Capitoline Palace), which, as a papal collection of Classical works offered back to the citizens of Rome by Sixtus IV in 1471, became the first public museum of sculpture in the Western world. Now occupying both the Capitoline Palace and the Palazzo dei Conservatori, as well as a later private palace, the museum contains only objects found in Rome, including the famed Romulus and Remus wolf, the "Capitoline Venus," the "Dying Gaul" and the "Boy with Thorn," as well as the host of portrait busts that can, in imagination, repeople the Forum just below.

The hill was the fortress and asylum of Romulus' Rome. The northern peak was the site of the Temple of Juno Moneta (the word money derives from the temple's function as the early mint) and the citadel emplacements now occupied by the Victor Emmanuel monument and the Church of Sta. Maria d'Aracoeli. The southern crest, sacred to Jupiter, became, in 509 BC, the site of the Temple of Jupiter Optimus Maximus, the largest temple in central Italy. The tufa platform on which it was built, now exposed behind and beneath the Palazzo dei Conservatori, measured 203 by 174 feet (62 by 53 metres), probably with three rows of six columns across each facade and six columns and a pilaster on either flank. The first temple, of stuccoed volcanic stone quarried at the foot of the hill, had a timber roof faced with brightly painted terra-cottas. Three times it burned and was rebuilt, always of richer materials. The temple that Domitian built was marble with gilded roof tiles and gold-plated doors. It was filled with loot by victorious generals who came robed in purple to lay their laurel crowns before Jupiter after riding in triumph through the Forum. The Clivus Capitolinus, the antique pavings of which can be walked today, was lined with 40 elephants bearing torches to light the way for Caesar coming in triumph from Gaul. In this centre of divine guidance, the Roman Senate held its first meeting every year. When Petrarch was crowned with laurel among the ruins of the capitol in 1341, it was a harbinger of the Renaissance.

The church of Sta. Maria d'Aracoeli, built before the 6th century, remade in its present form in the 13th, is lined with columns rifled from Classical buildings. It is the home of "I1 Bambino," a much loved miracle-performing wooden Christ child who is called to save desperately ill children. At Christmas, adorned in jewels given by the grateful, he can be seen in the church's celebrated manger scene, where he is serenaded by shepherd pipers.

The Aventine. Though considerably built over with modem houses and travelled by modern bus lines, the Aventine still bespeaks a Rome of the past, if not the Classical past. The repeated fires that swept the city destroyed all the republican buildings, and the Temple of Diana remains only as a street name. Under the 4th-century Church of Sta. Prisca is one of the best preserved and maintained Mithraic basilicas in the city. The Basilica of Sta. Sabina, little altered since the 5th century, is lined with 24 magnificent matching Corinthian columns rescued out of Christian charity from an abandoned pagan temple or palace. The Parco Savello, a small public park luminous with orange trees, was the walled area of the Savello family fortress, one of 12 that ringed the city in medieval times.

The Knights of Malta

A romantic gem is the Piazza dei Cavalieri di Malta, designed in the late 1700s by Giambattista Piranesi, an engraver with the heart of a poet and the eye of an engineer. To the right of this obelisked and trophied square, set about with cypresses, is the Knight's Priory, residence of the grand master of the Knights of Malta. It is this order, rather than Vatican City, which is the smallest sovereign state in the world, whose extraterritorial rights, recognized by the Italian government, cover this building as well as the seat of the organization. In 1113 the newly founded order, the Knights Hospitaller of St. John of Jerusalem, were in the Holy Land, whence they were driven to Rhodes, which they held until 1522, thence to Malta until 1789, when they repaired to their stronghold in a Roman side street. The sovereign military order has its own flag, issues its own license plates and (rarely) passports, and continues its long history of international medical work.

The Caelian. Almost half parkland, the Caelian includes the public park of Villa Celimontana, once the garden of the Mattei family, who had another on the Palatine, a clutch of palaces in the Campus Martius, and another in Trastevere. The six churches on the hill date from the 4th to the 9th century.

In the medieval confines of the only fortified abbey left in Rome stands SS. Quattro Coronati, today sheltering nuns and their charges, deaf-mute children. The Basilica of SS. Giovanni e Paolo, from the 5th century, stands in a piazza that has few buildings later than the Middle Ages. Alongside the church are the remains of the platform of the Temple of Claudius, partly dismantled by Nero, completely by Vespasian. The round Church of S. Stefano Rotondo (460–483) may have been modelled on the Church of the Holy Sepulchre in Jerusalem.

The Hospital of St. John was founded in the Middle Ages as a dependence of S. Giovanni in Laterano (St. John Lateran), just off the hill, and maintains its Romanesque gateway. The Hospital of St. Thomas, established at the same period, has disappeared save for its mosaic gateway, signed by the original Cosmate of the Cosmati school of carvers and decorators and by his father Jacobus. Nearby stands the Arch of Dolabella (AD 10), and not far away are the ruins of Nero's extension of the Claudian aqueduct. Also on the hill is the extensive Military Hospital of Celia.

Nero's palace

The **Esquiline.** Between the Esquiline and the Caelian, the end of the Forum valley is filled by the Colosseum and the Arch of Constantine, with the Palatine edging down from the north. After the fire of AD 64 had destroyed so much of the city, Nero undertook to rebuild the end of it —200 acres (81 hectares)—as a palace for himself: seawater and sulfur water were piped into its baths; flowers were sprinkled down through its fretted ivory ceilings; and the facade was covered in gold, from which the name Domus Aurea, the Golden House. The expropriation so enraged the citizens that his successors hastened to efface all trace of Nero's incredible palace: the ornamental artificial lake was drained and on its bed the Colosseum was erected for free entertainment; Trajan built magnificent baths—also with free admission—atop the domestic wing of the Golden House; and Domitian converted the portico on the edge of the Forum into Rome's smartest shopping street. The obliterators were aided by the fire of AD 104. In 131 Hadrian erected his Temple of Venus and Rome where the vestibule had stood at this end of the Forum; the church and former convent buildings of Sta. Maria Nova were built on the western comer of the temple platform in the 10th century. Less than 70 years after the Golden House had been started, nothing was left of it but a 150-foot (50-metre) gilded statue of Nero. Popular tradition has it that the face was changed with each succeeding emperor, but it was destroyed by one of the early popes.

The removal was so complete that later Romans could not remember where the Golden House had stood. When the domestic wing was discovered under Trajan's Baths in the 15th century, the rooms painted in the Pompeiian style were thought to be decorated grottoes. Some years later, when Raphael and his friends were let down on ropes to look, the style they imitated in decorating the Vatican loggias was called ***grottesche.***

The Colosseum

The Colosseum that replaced Nero's lake is more correctly called the Flavian Amphitheatre. It was begun by Vespasian and inaugurated by Titus in AD 80. The oval stadium measures one-third of a mile around, with external dimensions of 615 by 415 feet. The 160-foot (49-metre) facade has three superimposed series of 80 arches and an attic story. The attached columns follow the order applied on the Theatre of Marcellus (13 BC): sturdy, unadorned Doric on the ground floor, more elegant Ionic next, and luxuriant Corinthian on top. The attic story bore corbels supporting masts from which royal sailors manipulated awnings to protect the 50,000 seats from the sun during the gladitorial contests, combats with wild animals, sham battles, and, when the arena was flooded, naval displays. The main structural framework and facade are travertine, the secondary walls of volcanic tufa, the inner bowl and the arcade vaults of concrete. Until Pius VIII (reigned 1829–30) began conserving what was left, it had been a convenient quarry for 1,000 years.

The nearby Arch of Constantine was erected hastily in 315 to celebrate a victory two years earlier. Almost all the sculpture on this splendid arch was snatched from earlier monuments: a battle frieze from the Forum of Trajan, a series of Hadrianic roundels, and eight panels from a Marcus Aurelius monument.

Not all the rooms of the Golden House on the Oppio have been excavated. Above them spread the remains of Trajan's Baths, theatrical decorations for the public garden, Parco di Traiano. They served as models for the baths of Caracalla (c. 212–217) and Diocletian (298–305/306), which, in turn, served as a pattern for the Basilica of Maxentius. The bath building that housed the hot, warm, cold, and exercise rooms and the swimming pool was a huge, rectangular concrete structure lined with marble. It was surrounded by a garden enclosed in an outer rectangle of libraries, lecture halls, art galleries, and other facilities of a big community centre.

Caracalla's baths on the river flats behind the Caelian Hill covered more than six acres, part of which area is occupied today by the modern glass-fronted buildings of the United Nations Food and Agriculture Organization and the Ministrv of Posts and Telecommunications. Among the towering remains set in a large park, the caldarium (steamroom) is used today for summer opera performances. Much of the famed Farnese collection of marbles was stripped from these baths.

The Baths of Diocletian are over the brow of the Viminal, and some idea of their size (130,000 square yards, or 110,000 square metres, for the main bath block) can be gained from the fact that the Church of S. Bernardo was built into one of the chambers some 500 feet west of the central hall of the 92-foot- (28-metre-) high *frigidarium* ("cold room"), into which Michelangelo built the cloister church of Sta. Maria degli Angeli in 1561.

The first seven halls of the Museo Nazionale Romano, also called the Museo delle Terme, are rooms of the *frigidarium* block. This matchless collection of antiquities includes wall paintings from villas, mosaics, sarcophagi, and sculptures, including the famous Ludovisi throne (Greek, 5th century BC), the Niobid from the Gardens of Sallust where the Via Veneto wends today, and the bronze "Pugilist" (2nd century BC), discovered in 1884 in a building site on the Quirinal.

The Basilica of Maxentius (also named after Constantine, who completed it after dispatching Maxentius) was started about 311. This massive hall of justice and commerce was an oblong 265 feet (81 metres) long and 120 feet (37 metres) high, covered by three groin vaults with three deeply coffered tunnel-vaulted bays on either side. Probably ruined by the earthquake of 847, it was also mined for its materials. One of the great Corinthian columns stands obelisk-like before Sta. Maria Maggiore on the Esquiline. The head of Constantine's 40-foot- (12-metre-) high statue reposes in the courtyard of the Palazzo dei Conservatori.

The Viminal and Quirinal. Like much of the Esquiline, the Virninal and Quirinal lie in the heart of modem

Rome. Heavily built upon and sclerotic with traffic, the former seems almost flattened under the Ministry of the Interior, the weighty department that directs the state's police forces. The Quirinal, pierced by a modern traffic tunnel, has been a distinguished address since Pomponius Atticus, recipient of Cicero's letters, was a resident. Starting with the Crescentii, who planted the family fortress there in the Middle Ages, powerful Roman families built their homes in this location. The Colonnas still live in theirs at the foot of the hill near the Corso, an art gallery open to the public, and their gardens, climbing the slope to the Piazza Quirinale, contain remnants of Caracalla's Temple of Sarapis. The piazza has been graced since antiquity with two large statues of men with rearing horses, "The Horsetamers" or "Castor and Pollux." Closed on three sides by palaces, the piazza opens on the fourth to a splendid view over the Tiber. The Quirinal Palace, built by Pope Gregory VIII in 1574 as a summer palace away from the heat and malaria of the Vatican, was enlarged and embellished over the next 200 years by a succession of noted architects. The palace, with many extensions and wings, is huge, and its garden is five times as big as the building. From 1550 to 1870, the Quirinal rather than the Vatican was the official papal residence. In 1870 it became the royal palace of the new Kingdom of Italy; and, in 1948, the presidential palace. Both monarchs and presidents, however, have preferred to inhabit the homier palazetto at the far end.

The hill of family strongholds

The handsome buildings opposite are the stables (1730–40), built on the site of the Crescenti 10th-century stronghold. The Palazzo della Consulta (1734) was erected for part of the papal administration. The Palazzo Pallavicini-Rospigliosi, built by a Borghese cardinal in 1603, is still a private house. The Palazzo Barberini farther up the hill, constructed 1629–33 on the site of the old Palazzo Sforza, was occupied by the family until 1949. Part of the collection of the Galleria Nazionale d'Arte Antica is housed here, the rest across the river in the Palazzo Corsini in Trastevere. The 1,700 pictures, most of them works by celebrated masters, were contributed by distinguished families, including the Barberinis. Architecturally, the palace is important, because it marks a departure from the heavy-set four-square town houses of the early and High Renaissance. In the Rome region, only country villas had previously been built on so open a plan, with two wings coming forward from an open, arcaded facade. Further, it pioneered the Baroque style in domestic architecture.

Carlo Maderno, who put the facade on St. Peter's, made the plans, which were carried out after his death by Bernini, assisted by Borromini. Each of these two rivals has a church just around the corner. After 20 years of apprenticeship, Borromini was given his first chance to do his own building. It was an impossibly tiny site at the crossroads of the Quattro Fontane (Four Fountains, one of which is built into a niche in the church wall), but S. Carlo alle Quattro Fontane was a triumph. To his revolutionary solutions of site problems, for which he employed a brilliant variation on the oval, Borromini added a facade in 1667, the year he died, which responded to the waves of motion generated by the spatially complex interior. Walls that flow and sway created a sensation, and the idea was seized upon by Baroque artists, especially from other nations.

Bernini's S. Andrea al Quirinale is also small, but it took 12 years to build (1658–70), late in his career. An oval building with the naves sculpted into the outer wall, it enlarges on concepts advanced by Michelangelo. Bernini's use of coloured marbles and shrewd lighting effects gives the small structure extra dimension.

Other hills. Behind the river plain of Trastevere is the Gianicolo (Janiculum), and behind the Piazza del Popolo across the river is the Pincio. Both are now parkland, with villas, gardens, and churches discreetly disposed. The Janiculum crest was made into a park in 1870 to honour Garibaldi for his heroic but unsuccessful defense of the Roman Republic in 1849. During the Roman Empire the Pincio was covered with villas and gardens, but it was made into a public park only in the 19th century. By day, nannies wheel their charges through the greenery, and toward sunset Romans arrive to carry on the turn-of-the-century tradition of the before-dining Pincio promenade. Down the road toward Trinità dei Monti is the 1554 Villa Medici, bought by Napoleon in 1803 to house the French Academy of Rome, which is still in occupation. This academy, founded in 1666, is the oldest of many national academies established from the 17th to the 19th century to give architects, artists, writers, and musicians the opportunity to study the vast textbook that is the city itself and to use its museums and libraries.

The French Academy of Rome

The Villa Giulia and the Villa Borghese are also on the hill, both housing art collections of world importance. The Villa Giulia was a typical mid-16th-century Roman suburban villa, conceived not as a dwelling but as a place for repose and entertainment during the afternoon and early evening. It has a collection of Etruscan art and artifacts of singular beauty and historical value. The Borghese collection is small but choice, with a roomful of Caravaggios and, in addition, Titian's "Sacred and Profane Love." Canova's Neoclassical nude statue of Pauline Bonaparte, for a time a Borghese princess, as Venus retains its capacity to scandalize. The Italian government bought the grounds, house, and contents in 1902.

THE FORUM

The Forum was the religious, civic, and commercial centre of pastoral, royal, and republican Rome. After Julius Caesar, though it became more imposing, it was only one (albeit the most distinguished) of several complexes serving the same functions. Essentially, it was a small, closed valley ringed by the Seven Hills. There were two meeting places, formal open spaces in the northwest corner, the political Comitium and the social Forum—the name later applied to the entire valley—with shops down both sides. At the other end of the valley was the precinct of the high priest next to the Vestals, the keepers of the sacred flame. Between these two were the temples of the gods. Various emperors opened up the ends of the valley, and there was more building; but the poles of activity did not alter.

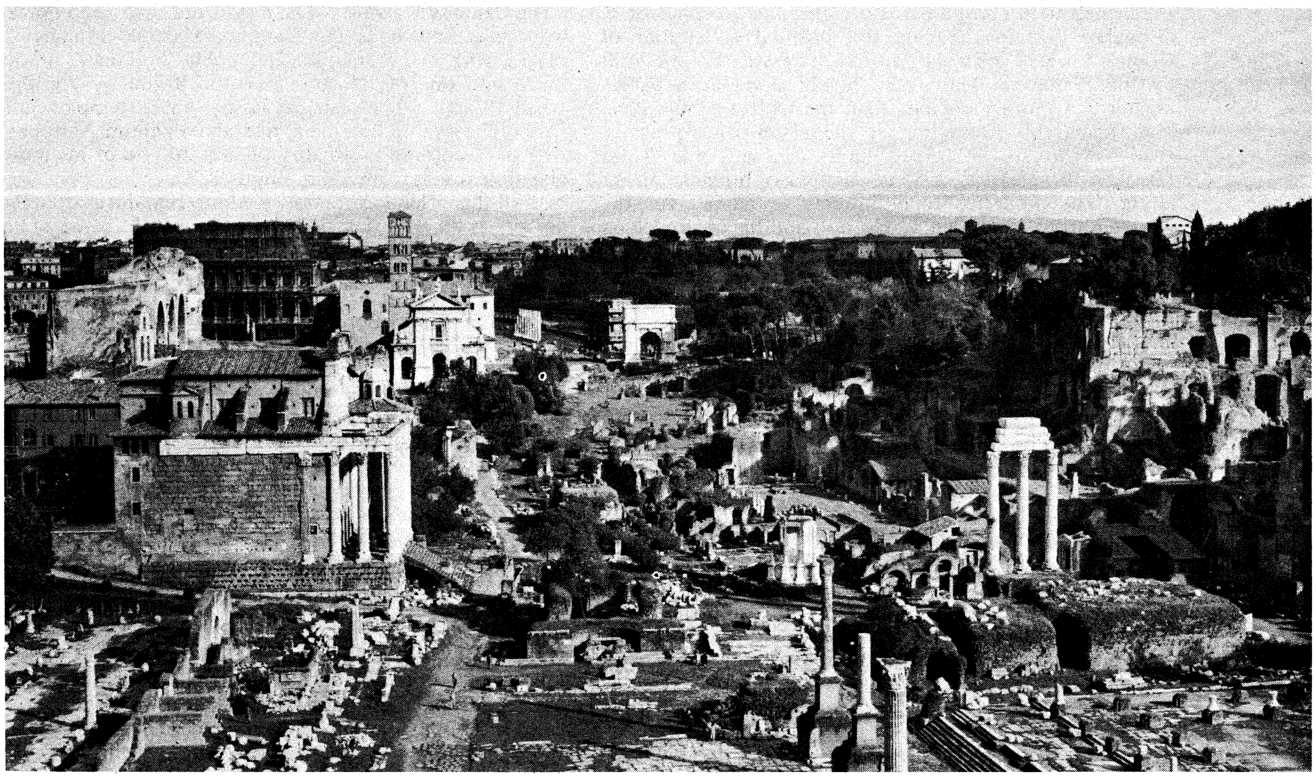
Fires, earthquakes, and invasions repeatedly levelled the buildings, and new ones were erected on their remains until the valley was covered by 50 feet of debris, earth, and ashes. Medieval Romans called it Campo Vaccino (Cow Field) and the abutting Capitoline Hill, Monte Caprino (Goat Hill). Excavation began late in the 19th century, and most of the accumulation has been dug away, down to the level at which Julius Caesar knew it.

The little stream cutting diagonally across the valley floor was, according to tradition, canalized as the Cloaca Maxima in the 6th century. Stratigraphic excavations again support the folktales and date the sewer construction at about 575 BC. Although later buildings perpetuated the name and roughly the position of the first halls and temples, they do not necessarily stand where earlier buildings stood, and many details of the earlier Forum are still the subject of scholarly speculation.

Janus and Saturn, both of whom have temples here, were among the gods of early Rome, and the Temple of Vesta, even in its last marble version (AD 191), retained the circular shape of a primitive clay-and-wattle hut. The forge of Vulcan, the Volcanal, had very early beginnings. The Regia, traditionally described as the residence of Numa Pompilius, the priest-king, became the administrative building for the pontifex *maximus*, who took on the monarchy's priestly duties. The Temple of Castor and Pollux was built at the establishment of the republic.

Building and rebuilding of the Forum

The oldest formally consecrated monument was the open space of the social Forum. A roughly trapezoidal stretch of ground about 125 by 70 feet (38 by 21 metres), it was bare save for three plants essential to Mediterranean agriculture: the grape, the fig, and the olive. Centuries later, when the basilicas were built behind the bordering shops, they served as a protective palisade for the Forum and a covered extension of its open space. At the wide end of the Forum and to one side was the Comitium, in which the Popular Assembly met. Between the



Ruins of the Roman Forum with the Colosseum (left background).

two clearings lay the orators' platform, the Rostra, decorated in 338 BC with the iron rams *(rostra)* taken as trophies from the warships of Antium.

At the other end of the Comitium stood the Curia, where the Senate met. When it was destroyed by fire, along with the Basilica Porcia (184 BC, the first of the basilicas), Julius Caesar built a new and greatly enlarged one that encroached on the open space of the Comitium. For the assembly, he built a meeting hall in the Campus Martius, outside the valley altogether. He built a new and much bigger Rostra, though across the wide end of the Forum. He supplanted the Basilica Sempronia (170 BC) on the western side of the Forum with his own Basilica Julia (54 BC), installing new shops in place of the old Tabernae Veteres. On the other side of the Forum already stood the shop-fronted Basilica Aemilia (179 BC), named for the censor who constructed the Tiber bridge now called the Ponte Rotto.

Caesar also carried his building program onto the flat ground just north of the valley between the Quirinal and Esquiline hills, making his own forum of shops and temple, alongside which Augustus, Trajan, Nerva, and Vespasian later constructed their forums. Pompey's theatre in the bed of the Tiber (55 BC) was followed by the Theatre of Marcellus (13 BC). The great baths, Agrippa's grand concourse in the Campus Martius, the circuses, and the Colosseum all drew the populace away to other centres of activity. The political attraction of the Forum, already vitiated in Caesar's day, continued to decline.

Nevertheless, the halls and temples of the Forum were assiduously rebuilt, ever grander, and more were added. Caesar, after his death, was made a god, and his temple was erected between the Forum proper and the Regia. Eventually, the sacred open space was defiled with honorary columns and an equestrian statue of Domitian. The last thing to be erected in the Forum was a column, raised by Phocas, a Byzantine usurper (608) to honour himself. Septimius Severus placed his arch over the Via Sacra. Other temples were rammed into empty places, and the whole became a forest of towering columns, gleaming walls, and ornate statuary. The dazzling marble mountain of the Palatine flowed down into the Forum as well, and the opposite rim glittered with the splendours of the imperial forums.

Today, the Forum is a confusing boneyard of history. Of the thousands of columns, not many more than 50 stand erect. Amid the ruins are Christian churches, thickets of trees and bushes, and hundreds upon hundreds of free-living cats.

THE RIVERLANDS

Along a 1%-mile stretch of the Tiber, around a big kangaroo-nosed bend, lie all the historic quarters of the river plain. On the left (east) bank are the Campus Martius, Circus Flaminius, Forum Boarium, and Forum Holitorium; on the right, the Castel Sant'Angelo, or Hadrian's Tomb, the entrance to Vatican City, and Trastevere. At the bottom of the bend is Tiber Island.

The palace-citadel-tomb on the Tiber

Castel Sant'Angelo and the bridges. Four of the 11 bridges along this part of the Tiber are of special interest. The Ponte Sant'Angelo, to which Bernini was asked to add angels, is in the main the Pons Aelius built in AD 134. A year later Hadrian began his tomb, just off the end of the bridge. A towering cyclinder 20 metres high on a square base, it was in size and form a typical imperial mausoleum. In 271 it was built into the Aurelian Wall and became a key fortress in the defense of Rome. In 587 Gregory the Great, leading a procession to pray for the end to a plague, allegedly had a vision of the archangel Michael atop the tomb. The epidemic ceased and the tomb-citadel became known as the Castel Sant'Angelo (Castle of the Holy Angel). In time it became a papal castle, with richly furnished and frescoed rooms, loggias for the view, a siege store of 5,800 gallons (22,000 litres) of oil and 770,000 pounds (3,500 quintals) of grain, a centrally heated bathroom, a prison that incarcerated Benvenuto Cellini, among others, and a still intact fortified passage from the Vatican to carry the pope to refuge there. It is now a state museum with an arboured terrace for outdoor drinking and dining.

At Tiber Island are two bridges. The Ponte Cestio, often rebuilt since the 1st century BC, leads to Trastevere, while the Ponte Fabricio (62 BC), the oldest in Rome, runs from the shore below the Capitoline. The island, 1,100 feet (350 metres) long and less than 330 feet (100 metres) wide at its widest, has been a place of healing since the Temple of Aesculapius was erected after the plague of 291 BC; the largest building there today is the

Fatebenefratelli hospital (also called the Hospital of S. Giovanni di Dio). Facing the hospital is another of Rome's towered medieval family fortresses, this one built by the Pierleone. The traffic howls along both banks, noisier and more voracious than the wolves of the Pierleone's anarchic Rome, but on the island peace prevails. Just downstream are the remains of the Ponte Rotto (Broken Bridge) of 179 BC and two bridges farther along. The modern Ponte Sublicio is named for the wooden bridge defended by Horatio and his comrades on this part of the river.

The lower east bank. On the shore by the Ponte Rotto is the site of the earliest cattle market (Forum Boarium) and vegetable market (Forum Holitorium), girt with temples, of which two remain: the elegant, circular Pentellic marble structure of the 1st century BC and a nicely proportioned, rectangular Ionic building, perhaps a few decades older. Their dedications are disputed, save that they are not, as they are popularly called, temples of Vesta and of Fortuna Virilis. In the 6th century the Church of Sta. Maria in Cosmedin was built into the antique grain-commission offices. Some of the Forum Boarium columns can still be seen on the interior of the church, and one of its drain lids, fixed to the outer wall, was carved to represent a face with a gaping mouth. This classical manhole cover became the dread Bocca della Verità, the mouth of truth, which allegedly would crunch down upon the hand of anyone telling a lie.

Nearby is the Theatre of Marcellus, begun by Caesar and completed in AD 13 by Augustus, who named it for a short-lived nephew. It owes its preservation to its conversion into a fortress for one of the quarrelsome clans of the Middle Ages. Converted into a palace for the Orsinis in the 16th century, it remains private property. The classical orders of the facade, adopted for the Collosseum, became the model for Renaissance architects.

From there northward to the tomb of Augustus and as far inland as the Via Flaminia (today's Corso), the river plain was a vast plantation of temples, baths, and sports grounds until the Middle Ages, when the remaining Romans took up residence there. Today, three major imperial monuments survive: the Pantheon, the reconstructed Ara Pacis Augustae (Altar of Augustan Peace), and Hadrian's Column. Here and there among the 40 palaces and 100 churches are remnants of what the emperors built.

The Jewish ghetto

The portion closest to the Tiber Island was once a major republican racing and sports ground, the Circus Flaminius (220 BC), which in the 16th century became the Jewish ghetto. Jews were not persecuted in Rome until Pope Paul IV (1555–59) herded them into a ghetto under curfew. Although Paul was so loathed that the Romans decapitated his statue when he died, other popes carried on his anti-Jewish program. Except for brief respites under Napoleon and the momentary Roman Republic of 1848, Jews until 1870 were debarred from all the professions, government service, and landownership. Until recently the neighbourhood retained a Jewish flavour, with some 3,000 Jews living there in the 1960s, but by 1971 only 300 remained, as the ghetto, like Trastevere, became ripe for conversion to luxurious flats. Nearby, the Largo Argentina, excavated 1926–29, contains four small temples of the 1st and 2nd centuries BC.

The crescent of buildings between the Piazza del Biscione, an open-air junk market, and the Piazza dei Satiri take their curved shape from having been built into and around Pompey's Theatre, the first stone theatre building in Rome. Inspired by the Greek theatre of Mitylene, in which Pompey had been so spectacularly entertained, it had a portico of 100 columns that was equipped to be a community centre almost as much as the baths. The Senate met there on the Ides of March in 44 BC, when Julius Caesar was stabbed 23 times and fell at the foot of Pompey's statue. For almost 400 years a piece of sculpture, unearthed nearby in 1550 and deposited in the Palazzo Spada, was erroneously believed to be the Pompey statue. A part of the threatre was fortified by the Orsinis in the 12th century and later converted into the Palazzo Righetti, or Pio.

The Campus Martius. The rest of the river bend northward was known as the Campus Martius. Marshy in places, with a few temples and public buildings, it was made into one of the grandeurs of Rome by Agrippa (died 12 BC), a landscape of lawns, baths, temples, and parks The swamp became a lake, the Stagnum Agrippae, where—according to Tacitus—Nero led one of his more elaborate orgies from a sumptuous raft.

Of all this splendour almost nothing remained after the fire of AD 80. Hadrian undertook to restore some of it. Among his works was the new Pantheon, one of the West's great buildings, extraordinary as architecture, remarkable as a feat of engineering. This "Temple of All the Gods," imperial property, survived because it became a church, the gift of the Byzantine emperor Phocas to Pope Boniface IV in 608. This protected the building from everyone but the pope: the bronze roof beams of the grandiose pedimental porch of 18 sixty-ton columns of Egyptian granite were stripped by Urban VIII, the Barberini pope, who took them as raw material for the baldachin in St. Peter's, provoking the celebrated anonymous comment, Quod non fecerunt barberi, fecerunt *Barberini*, "What was not done by the barbarians was done by the Barberinis."

The Pantheon

It has been suggested that the temple was designed by Hadrian himself, whose villa at Tivoli is another landmark in the development of architecture. The Pantheon was possibly the first monumental building of antiquity conceived as an interior. Evenly lighted from a single source—the open eye (*oculus*) in the centre of the dome—the enormous interior, circular and richly marbled, is almost unchanged from classical times. Until the 20th century the dome was the largest ever built, 141 feet in diameter, exactly the height of the building. Two things made its construction feasible: the magnificent quality of the mortar used in the concrete and the meticulous selection and grading of the aggregate, which became lighter in weight with increasing height. Roman concrete was essentially a hydraulic cement, deriving its unique strength from the properties of the dark volcanic ash (pozzolana) of the Roman subsoil that was substituted for sand. There is some brick ribbing in the lowest part of the dome and thrust-containing brick outer facing, but, in general, brick was not used by the Romans as a building material in itself. Brick and tile were used to help hold the concrete until it dried, making for a less brutal exterior. The stamped trademarks on the bricks from the big yards behind Vatican Hill and up the Tiber Valley help in determining chronology. The Pantheon, for example, bears the original dedicatory inscription of Agrippa, modestly replaced by Hadrian. The latter's name does not appear, but the stampings on the bricks show that construction does indeed date from Hadrian's reign. The original bronze doors are still in place. Italy's first two kings are buried in the Pantheon, as are many artists, of whom Raphael is the most notable. Nearby are fragments of Agrippa's baths, and the Rome stock exchange gains considerable dignity from the incorporation of some of the Temple of Hadrian.

The shattered drum of Augustus' tomb marks the spot where he was buried AD 14. The mausoleum became a 12th-century Colonna fortress, a 16th-century garden, a ring for Spanish bullfights in the 17th century, and then a concert hall until 1936, when it was scraped down to its impressive but mournful foundations by Mussolini, who may have planned to be buried there himself. Next to the tomb is the delicately beautiful white marble Ara Pacis Augustae (Altar of Augustan Peace, designed 13 BC, dedicated 9 BC). The altar, raised on steps, is enclosed in a sculptured screen. Bits of the friezes were discovered off the Corso in the 15th century, and the altar itself was dug up there in 1938 after 35 years of labour. The pieces unearthed earlier were bought back from museums, and the whole was reassembled to stand four streets away from its original location.

In the Campus Martius Italy's Chamber of Deputies sits in the Bemini-designed Palazzo di Montecitorio, its Senate in Palazzo Madama (17th century), and its Council of State in Palazzo Spada (c. 1540), the picture gallery of which is open to the public. The Museo di Roma, which illustrates the life of the city through the ages, is in Palazzo Braschi (18th century). The Brazilian embassy is in the Palazzo Pamphili, which has a gallery designed by Borromini and painted by Pietro da Cortona. The early-16th-century Palazzo di Firenze was the Florentine embassy until the union of Italy; it is now occupied by the Società Dante Alighieri. The Palazzo Capranica is a cinema, while the Palazzo della Sapienza, near the Senate, is now the National Archives but was from 1431 to 1935 the seat of the University of Rome (founded 1303).

Architecture of the palaces

The palaces. The three architecturally celebrated palaces in this palace-truffled quarter are the Cancelleria, the Farnese, and the Massimo alle Colonne. Because all the pertinent documents were destroyed in the Spanish sack of Rome in 1527, the architect of the Cancelleria remains unknown. Dated 1486–98, it was built by Cardinal Raffaelo Riario out of a night's winnings at the gaming table. Seized by the Medici Pope Leo X (1513–21), it has housed some portion of the Vatican chancellery ever since, except for Napoleonic and revolutionary interruptions. A square building with a rusticated ground floor, its upper stories are plain and rhythmically pilastered, while the columned inner court is noble and deeply harmonious. The city's first High Renaissance building, it could be said to symbolize Rome's displacement of Florence as art capital of the world—its artists drawn from north and south but not from Rome.

The Farnese, the most monumental of Rome's Renaissance palaces, was designed by Antonio da Sangallo the Younger, who was succeeded after his death by Michelangelo, Vignola, and Giacomo della Porta. Sangallo followed the Renaissance precepts regarding the architectural orders on the lower floors, but Michelangelo's top story uses the traditional elements in a willful way, capping it all with an overpowering cornice—a personal expression that foreshadowed Mannerism, a leaching of Renaissance ideals, and the subsequent theatrical self-expression of Baroque. Michelangelo's project to join this palace to the Farnesina by a bridge over the river was actually begun. It can be seen from the surviving arch over the Via Giulia, one of the city's most charming streets.

Mannerist architecture is typified by Baldassare Perruzi's Palazzo Massimo alle Colonne (1535), the name of which comes from a colonnaded palace on the site destroyed in the 1527 sack. It disregards all Renaissance canons, with its brooding entry and heavy cornice below a slightly bowed and airy facade punched with small windows. The Massimo family, who still live in the palace, gave shelter to Konrad Sweynheym and Arnold Pannartz, who produced Rome's first printed book in their house in 1467.

THE CHURCHES

Today, 25 of the original parish churches, or tituli, the first legal churches in Rome, still function. Most had been private houses in which the Christians illegally congregated, and some of these houses, as at SS. Giovanni e Paolo, are still preserved underneath the present church buildings. Since the 4th century the tituli priests have been cardinals who, over the centuries, have rebuilt, enlarged, and embellished their churches.

In the 4th century, basilicas were built to mark the burial places of martyrs. Most had been interred beyond the city walls in underground galleries, the catacombs. When later sieges of Rome laid waste the Campagna, saintly relics were removed to the safety of city churches. During the Middle Ages, when the prevalence of malaria and of tomb robbers—there was a brisk commerce in religious relics—made ventures beyond the walls risky, some of the oratories and basilicas fell almost to ruin and the location of some catacombs was forgotten.

The "great" basilicas. Among the basilicas, seven are designated as great (maggiore) : St. Peter's, S. Paolo Fuori le Mura (St. Paul's Outside the Walls), and S. Giovanni in Laterano, all built by Constantine, and those of S. Lorenzo Fuori le Mura (St. Lawrence Outside the Walls), Sta. Croce in Gerusalemme (Holy Cross in Jerusalem), S. Pietro in Vincoli (St. Peter in Chains), and Sta. Maria Maggiore. Under the 1929 concordat with Vatican City, the Italian government grants them extraterritorial privileges.

The basilicas established the model for Western ecclesiastical architecture for centuries to come. Basilica, a Greek word meaning royal, was used by the pre-Christian Romans to designate a public hall, but no surviving example of Roman basilica anywhere in the empire is the architectural predecessor of the Christian basilica.

Basic design of the basilicas

The basilical church has a nave higher than the aisles, from which it is separated by a colonnade on each side. It has either a cloistered court (atrium) or anteroom (narthex) or both at the west end and a semicircular projection (apse) at the east. The basilicas in Rome that are closest to the early Christian structures are the churches of competing cults, as strikingly exemplified by the Neo-Pythagorean-sect basilica of the Porta Maggiore, unearthed by the railroad viaduct in 1926.

Some early Christian churches were centrally rather than longitudinally organized, a plan dictated by the circular form of the imperial mausoleums into which they were built. A good example is Sta. Costanza (c. AD 320), which also has a superb series of 4th-century vault mosaics in pagan designs. Although churches of this type were few, they had a strong influence on the development of the centrally planned house of worship.

St. Peter's. Protected by the fortified Castel Sant'Angelo, St. Peter's Basilica and the Vatican Palace gained precedence over the cathedral church and Lateran Palace during the papacy's troubled centuries. St. Peter's was built over the traditional burial place of the Apostle from whom all popes claim succession. The spot was marked by a three-niched monument (aedicula) of AD 166–170. Excavations in 1940–49 revealed well-preserved catacombs, with both pagan and Christian graves dating from the period of St. Peter's burial.

Constantine enclosed the aedicula within a shrine and during the last 15 years of his life (died 337) built his basilica around it. The shrine was sheltered by a curved open canopy supported by four serpentine pillars that he brought from the Middle East. The design, enormously magnified, was followed in making the baiacnin (1623–33) over today's papal altar.

In spite of fires, depredations by invaders, and additions by various popes, the original basilica stood for 1,000 years much as it had been built, but in 1506 Julius II ordered it razed and a new St. Peter's built. His architect was Donato Bramante, a Florentine who in 1502 had completed the first great masterpiece of the High Renaissance, the Tempietto in the courtyard of S. Pietro in Montorio, a mile away on the Janiculum Hill. Built to mark the spot where, according to tradition, St. Peter had been crucified, the Tempietto is round, domed, and unadomed. Its outer face is a colonnade of bare Tuscan Doric, the earliest modem use of this order. Because of its proportions, the tiny temple has the majesty of a great monument.

Work of Bramante and Michelangelo on St. Peter's

Bramante's ground plan for St. Peter's was central: a Greek cross, all of the arms of which are equal, around a central dome. Both he and the Pope died before much could be built. Successive architects, including Raphael, drew fresh plans. The last of them, Antonio da Sangallo, died in 1546, and the 71-year-old Michelangelo was solicited to complete Sangallo's projects, which included St. Peter's, the Palazzo Farnese, and the Capitol. He accepted but refused payment for his work on the basilica.

Michelangelo adapted Bramante's original plan, the effect being more emotional and mighty, less classically serene. Of the exterior, only the back of the church, visible from the Vatican Gardens, and the dome are Michelangelo's. After his death Giacomo della Porta and Domenico Fontana, who executed the dome, altered the shape, making it taller and steeper than the original design.

The east end remained unfinished, and it was there that Carlo Maderna was ordered to construct a nave, the clergy having won its century-long battle to have a longitudinal church for liturgical reasons. Thus, St. Peter's orientation reverses the normal. Maderna added a Baroque facade in 1626. Then came Gian Lorenzo Bernini, busy from 1633 to 1677, both inside and outside the building. His pontifical crowd-funnelling colonnade in the shape of a keyhole around the piazza, a fountain for the piazza, the breathtaking baldachin, his several major pieces of sculpture, his interior arrangements for the church, and his dazzling Scala Regia (Royal Stair) to the Vatican exhibit his legendary technical brilliance and his masterful showman's flair. Before the lamentable assault in 1972 which damaged the sculptural masterpiece, one could enter the church and, in the first chapel at the right, see the "Pieta" (1499) of Michelangelo in the original splendour.

All the planning, plotting, labour, and faith of all the popes, priests, artists, and artisans produced a vast, gorgeous ceremonial chamber. Amid the gleam and glitter of gold and bronze and precious stones eddy throngs of awed, dwarfed humanity.

S. Giovanni in Laterano. When Borromini redid the interior of S. Giovanni in Laterano (St. John Lateran) in 1646–50, little of the original Constantinian fabric remained after destruction by the Vandals (5th century), damage by earthquake (9th), two devastating fires (14th), and four consequent rebuildings. The Emperor had built a five-aisled basilica over the remains of the barracks of the imperial guard, the Equites Singulares. The bronze doors come from the Curia (the Senate chamber in the Forum); the silver reliquaries containing the heads of SS. Peter and Paul are copies of the twice-stolen originals.

The octagonal 5th-century baptistery replaced that of the 4th, which had been built into the baths of the House of Fausta, Constantine's second wife. (Later, in another palace, she was strangled in the hot room of the bath, a conventional Roman device for suggesting accidental suffocation of an awkward relative.) Its chapels are decorated with mosaics of the period. The cloisters contain some of the finest examples of early 13th-century carved and inlaid decoration called Cosmatesque after the Cosmati, one of several families of traditional craftsmen. (The cloisters of S. Cosimato, S. Paolo Fuori le Mura, and SS. Quattro Coronati are notable examples of this work, which often was accomplished with porphyries and marbles robbed from classical buildings.)

On the exterior a 1732 facade is topped with 15 giant statues that were visible across the city. The piazza around which the Lateran buildings are grouped is decorated with another obelisk, the oldest and tallest in Rome (15th century BC), one of those erected by Sixtus V late in the 16th century. At the same time, he demolished the old patriarchate, from which the Sancta Sanctorum (the papal chapel) and the Scala Santa (Holy Stairs) were preserved. The Scala had been the principal ceremonial stairway of the palace, but about the 8th or 9th century it began to be identified popularly as having been brought from Jerusalem by St. Helena, Constantine's mother, reportedly as from Pilate's palace and thus the stair climbed by the Saviour. The steps are protected by a wooden cover, and believers mount on their knees. The Scala Santa is not mentioned, however, in ecclesiastic, imperial, or personal writings from the 4th, 5th, or 6th century.

The Holy Stairs

Sta. Croce in Gerusalemme. There is similar lack of record regarding St. Helena's acquisition of the True Cross, which is at Sta. Croce in Gerusalemme. This basilica was built into the palace in which St. Helena lived (317–322). At about this time a hall of the palace was converted into a church and two adjoining small rooms were converted into chapels. The rest of the palace continued to be lived in for centuries. The alleged relics of the cross, found in 1492 walled into a niche, are now in a modern chapel. The facade and narthex of the church are 1743 Rococo, the interior an earlier Baroque with a 12th-century Cosmatesque pavement, some antique columns, a few Renaissance details, and, somewhere within it all, part of a palace built around 180–211.

S. Lorenzo Fuori le Mura. Now in the midst of the Campo Verano cemetery, Rome's Catholic burying ground since 1830, S. Lorenzo Fuori le Mura (St. Lawrence Outside the Walls) dates from the 4th century. The nave is a 13th-century basilica built by Pope Honorius III, and the chancel is another basilica built by Pope Pelagius II in the late 6th century as a replacement for the 4th-century original. On the inner part of the triumphal arch between the two is a 6th-century mosaic, and along the walls are giant Corinthian columns of rare marble taken from a non-Christian building.

S. Paolo Fuori le Mura. A basilica built by Constantine over the Apostle's grave, S. Paolo Fuori le Mura (St. Paul's Outside the Walls), was replaced starting in 386 by a structure mammoth for its time, 328 by 170 feet (100 by 52 metres). It was faithfully restored after a fire in 1823 and thus remains an outstanding example of early basilica1 architecture. It has a single eastern apse, a lofty transept, and five majestic nave aisles. Before the Muslim rampage around the walls in 846, the approach to the basilica was a mile-long colonnade down the Ostian Way from the Porta S. Paolo. Today, after leaving the tomb of Gaius Cestius (died 12 BC), a 120-foot (37-metre) pyramid that has inspired many monument builders since, one-third of the route is fenced by gasworks on one side and warehouses on the other, the rest being given over to waste ground and decaying houses.

Sta. Maria Maggiore. Located on the Esquiline, Sta. Maria Maggiore was founded in 432, just after the Council of Ephesus, which raised the Virgin above all created things; it was thus the first great church of Mary in Rome. Behind its Neoclassic facade (1741–43), the original basilica has resisted change. Most of the mosaics date from the time it was built, lining the walls and bursting with blue and gold around the altar. When a new apse was added in the 13th century, it was also decorated with mosaics. Although the ceiling is Renaissance, the slabs of fine marble and the classical columns are pieces of original plunder from other buildings. The great treasure of the church is the Crib of Christ, five pieces of wood connected by bits of metal. Another pope, St. Liberius (352–366), built another church on the Esquiline in response to a vision of the Virgin, who told him to erect a church where snow fell on the night of August 5. In remembrance, it "snows" white flower petals from the roof of the Pope Paul V chapel in Sta. Maria Maggiore every August 5.

Other major churches. *Gesù.* The mother church of the Jesuit order, Gesù, was built 1568–84. Over the following four centuries, it supplied one of the most pervasively influential designs for church building. Michelangelo offered the new order plans for their first church but died before his plans could be acted upon. Building began under Giacomo Vignola (1507–73), very possibly following Michelangelo's ideas. The Jesuits, shock troops of the Counter-Reformation, proselytizers rather than liturgists, needed a new kind of church for their new approach. Vignola combined the central plan (for preaching) with the longitudinal plan (for ritual) by transforming the aisles into a series of chapels opening into the nave. The facade carried the classical orders upward, though only across the width of the tall nave, and the space above the lower aisles to either side was filled with a scroll. The ideas were not new in the history of architecture, but they were new to Rome and new to the age; and they spread with rapidity.

S. Pietro in Vincoli. Originally the Basilica Eudoxiana, S. Pietro in Vincoli (St. Peter in Chains) was built in 432–440 with money from the empress Eudoxia for the veneration of the chains of St. Peter's Jerusalem imprisonment. Later, his Roman chains were added. The chains became famous after they were mentioned at the Council of Ephesus (431). Michelangelo's thunderous Moses is on the tomb of Julius II. Behind the main altar is a 4th-century sarcophagus with seven compartments, brought to Rome from Antioch during the 6th century in the belief that it contained relics of the seven Maccabees.

Sta. Maria della Vittoria. Built 1605–26, Sta. Maria della Vittoria harbours an unfailing crowd pleaser, Bernini's "Ecstasy of St. Teresa" (1645–52). It is a chapel conceived entirely in theatrical terms, even to having the

Cornaro family (in marble) seated in opera boxes at the sides of the chapel. Their eyes are directed at the central group in a niche framed in columns, exactly like a proscenium arch, the back wall concealed by gilded metal beams of glory, the scene lighted from above and behind by a hidden yellow-paned window. Amid this setting the angel hovers above the swooning saint, who is—and the illusion is nigh to perfect—borne into the air at the moment of her ecstatic mystical union with Christ. Extraordinarily convincing and utterly voluptuous, it has been both praised as a masterwork of consummate spirituality and condemned as an impious, pornographic peepshow.

*S. **Agostino.*** Of the scores of churches in the Campus Martius of historical, architectural, and artistic interest, the S. Agostino (1479–83) is the most Roman, the church to which would-be mothers come and in which they have offered ex-votos when their prayers have been answered. The "Madonna and Child" (1521) by Jacopo Sansovino, obviously derived from a pagan Juno, is covered with gold and jewels given by the gratified. The church was constructed entirely of travertine looted from the Colosseum. Caravaggio painted the "Madonna with Pilgrims"; Raphael did the fresco of Isaiah. This was these artists' favourite church, and some of the more celebrated among them managed to be interred in it.

THE FOUNTAINS

Rome is as much a city of fountains as it is of churches or palaces, antiquities or urban problems. The more than 300 monumental fountains are an essential part of Rome's seductive powers. Part of the everyday, yet part of the daily surprise, they are points of personal, often sentimental attachment to the city. The Roman composer Ottorino Resphigi found in them inspiration for his orchestral tone poem ***Fontane di Rorna*** (1917; ***The Fountains of Rome***). In their ceaseless pouring forth, they also provide a sense of luxury: on her arrival Queen Christina, having watched the fountains in St. Peter's Square, gave her permission for them to be turned off and was impressed to learn that they flowed all the time.

Legends of the waters

Every fountain has its history and many have legends, the best known of which guarantees a return to Rome to those who toss coins into the Trevi Fountain. Restored after 1,000 years of silence by Pope Nicholas V in 1485, the fountain was renewed in the 17th century and then transformed from a handy source of household water into a scenic wonder. The huge fountain bulges into most of a tiny square and takes up the entire end of an abutting palace. Nicolò Salvi won a 1732 competition by designing a late Baroque marble mass of rocks and rills, rush and gush, beards and buttocks, all very allegorical and damp. It took 30 years to complete. Its water, from Acqua Vergine, was considered Rome's softest and best tasting; for centuries, barrels of it were taken every week to the Vatican and carried off by the jugful by expatriate English tea brewers. Declared nonpotable in 1961, the waters are now recycled by electric pumps.

Out of the Bernini–Borromini rivalry that so enriched the Roman cityscape arose a legend, still believed and recounted today. This explains that, on Bernini's allegorical Piazza Navona fountain, the statue of the Nile River, whose source was then unknown, hides its head to avoid seeing the Borromini facade on the church opposite, and that of the Rio de la Plata raises its arm in alarm to prevent the building from falling. The fountain was, in fact, unveiled in 1651, a year before the Church of S. Agnese was begun, two years before Borromini was called in, and 15 years before the facade was completed. The church is owned and maintained by the Doria-Pamphili family.

The oldest of the city's fountains is really a spring, the Lacus Juturnae in the Forum, restored in 1952 to the appearance it had in Augustan times. The newest fountain in the old city is one of the most admired. Inaugurated as simple jets of water in the Piazza Esedra (now the Piazza della Repubblica) by Pius IX just ten days before the troops of united Italy broke into the city, it was probably the last public work dedicated by a pope in his role of temporal magistrate of the city. In 1901 the nymphs frolicking with sea beasts were added.

The least-liked fountain figure in Rome, unpopular since it was installed in 1587, is on the triumphal arch fountain in the Piazza S. Bernardo, commissioned by Sixtus V. The figure is a pallid Moses, apparently in imitation of Michelangelo's, and its sculptor, Prospero Bresciano, is said to have been so hurt by the public's jeers that he died of a broken heart. Rome, Ancient

From humble beginnings in the 8th century BC as a minor people settled on a few hills overlooking the Tiber River, the Romans progressively conquered the Italian peninsula, extended their dominion over the entire Mediterranean basin, and expanded their empire into continental Europe toward the Atlantic. Their conquests allowed them not only to dominate but also to civilize a large number of peoples, on whom they made a lasting impression. Modern historians can still distinguish those regions that were deeply penetrated by the Latin language and Roman law from those that, because of their remoteness, were untouched by it. In attempting to explain the extraordinary and lasting success of Roman culture, it is necessary to seek its sources not only in the vicissitudes of history but also in the psychology of the Roman people. Although the Romans were not gifted in the areas of artistic creativity, scientific research, or philosophic thought, they did possess a steadfast attachment to their native land and a profound sense of political and administrative organization. From a nation of peasants and soldiers, Rome was able to develop an urban civilization, on the pattern of the Greek *polis.* In the domain of art and thought, the Romans were the heirs of the Greeks, and their political genius, common sense, and exemplary piety—which gave them the constant conviction of being sustained and guided by the gods—made it possible for them to create an empire in which the conquered, instead of being kept at a distance, participated in the life and prosperity of the conqueror. No barriers were raised between the nations or races; the emperors themselves often came from outlying regions of the Roman world. The Romans' tenacity, civic feeling, and fundamental liberalism made it possible to establish a lasting peace among men and to confer the benefits of culture and material prosperity on a large number of peoples. Certainly, faults were not absent from a world that could not survive without slavery and that occupied its leisure hours with the unwholesome pleasures of the amphitheatre. The overall balance remains positive, however, and Rome appears to modern eyes as the great teacher of the Western world (see also ROMAN RELIGION; ROMAN LAW).

This article is divided into the following sections:

I. Rome from its origins to 264 BC

EARLY ROME TO THE 6TH CENTURY BC

Greco-Latin historiography

Historiographical problems. For the history of the later republic and the empire there is an abundance of documentary sources, epigraphic texts, and archaeological data that provide the historian with a sound basis for research. But for the founding of Rome and the early years of the republic, there is little evidence. The archaeological remains for this period are rare, and inscriptions, which do not begin to increase in number until the 1st century BC, are scarcer still. There are, however, numerous Greek and Latin writings dating from the end of the republic and the beginning of the empire that recall the birth and early years of the urbs. These later histories have for centuries enriched the literary traditions of the Western world, but their value as history remains problematical. Until recently, critical opinion has been suspicious of the highly colourful accounts of the Roman annalists and has seen in them only fantasy and lies intended to appease the vanity of great families and the patriotism of a proud people. The attitude of many current historians, however, is considerably different, for archaeology has brought indisputable corroboration to tradition. The tale of the founding of Rome by Romulus in the middle of the 8th century BC, for example, has to a certain extent been confirmed by the discovery after World War II of a village of huts on the Palatine effectively dating from about 750 BC. The power and prosperity accorded to the Rome of the Tarquins (Etruscan kings) by the annals are confirmed by discoveries resulting from excavations of ancient Rome. Archaeological and epigraphic discoveries, in fact, continue to demonstrate that the legendary guise of the traditional material actually masks a real foundation of authentic events.

Aeneas and Romulus

The myths of origin and early monarchy. The legend pertaining to the origins of Rome is twofold and distinguishes two events: the colonization of Latium, the territory surrounding Rome, in the 12th century BC by the Trojan Aeneas and the actual founding of the city of Rome 500 years later by the Latin Romulus. The arrival on the Latin plain of Aeneas and his troop of Trojans, who had escaped the destruction of their country, has until recently been viewed as pure legend. Current archaeology, however, has proven that in that remote epoch Italy was visited by Late Bronze Age navigators whose trading activities have been attested as far as southern Tuscany. The legend of Aeneas perhaps expresses the memory of these ancient contacts with the Orient. In any case, the legend of Aeneas can no longer be viewed as the creation of Roman writers of the last centuries of the republic. The figure of Aeneas was familiar to Etruscans from the 6th century BC, and the legend could have made its way to Rome during the period of Etruscan hegemony.

The second aspect of the legend concerns the founding of the town by its eponym Romulus, whose life is depicted in legend as a succession of marvellous and violent episodes. Having miraculously escaped death with his twin brother Remus, he and his brother asked for signs from the gods to designate which of them was to found a new city. Romulus was designated by the divine omens and killed his twin in a murderous quarrel. He then became the first of seven legendary kings who, according to tradition, ruled in Rome from c. 754 BC to the advent of the republic in 509 BC.

The early kings

This account was elaborated gradually and had received its definitive form by the 6th century BC. It rests on a fact now attested by archaeology: the establishment on the Palatine (one of the seven hills of Rome) in the 8th century BC of a primitive village of huts where shepherds of Latin origin had gathered. Much of the legend surrounding the early history of Rome is derived from the account of Livy (59 or 64 BC–AD 17) writing hundreds of years after the events he describes. Livy's first book of Roman history recounts in great detail the activity and achievements of the kings. Mythical, legendary, and strictly historical elements are blended into the text of this narrative, which was based on the annal material. According to Livy, Romulus was a military chief who possessed wide political and military powers. He set out to organize the Roman state and, in order to provide wives for his comrades, planned the rape of the Sabines, a neighbouring people. The war with the Sabines ended in the union of the two peoples, and, after the mysterious death of Romulus in 717, a Sabine, Numa Pompilius, reigned until 673. He was a pious sovereign who dedicated himself to giving Rome, founded by force and arms, its laws and morality. It was he who first gave form to the Roman religion. He was succeeded by a warrior king, Tullus Hostilius (traditional reign 672–641), who framed the military code. The famous episode of the Horatii and Curiatii, the champions of Rome and Alba Longa, respectively, occurred during a war Tullus Hostilius conducted against Alba Longa. The line of pre-Etruscan kings ended with Ancus Martius, a Sabine, who was the

Archaeological accounts

grandson of Numa Pompilius. He supposedly expanded Rome and founded Ostia. Beneath the surface of the traditional account rests the reality of the progressive growth of a town that initially was only a federation of villages perched on the Palatine and neighbouring hills. Recent archaeology has made it possible to trace from early times the course of the growth of Rome, which became a true city only with the arrival of the Etruscans. The Latin population settled on the hills overlooking the Tiber presumably brought with it its language and its scrupulous piety, expressed in a whole series of ancient rituals that were faithfully preserved until classical times.

The reign of Servius Tullius

The Etruscan hegemony over Rome. According to tradition, the end of the 7th century and the 6th century BC were taken up by the reigns of the Etruscan sovereigns Tarquinius Priscus and Tarquinius Superbus, between whom was interposed a man of obscure origin, Servius Tullius. The annalistic account gives many dramatic details of this period, during which Rome obeyed rulers of foreign origin who allegedly made the very name of royalty odious to the Romans. As legend has it, Tarquinius Priscus was a native of Tarquinii, where his father Demaratus, a Corinthian Greek, had taken refuge. This first of the Etruscan kings supposedly ruled from 616 to 579 BC. He was a good administrator and a great builder and gave Rome new lustre. Assassinated by the sons of Ancus Martius, who considered him a usurper, he was succeeded by Servius Tullius, whose name suggests a man of humble origin. Many historians believe that Servius was an interpolation by later annalists, who, for patriotic reasons, refused to ascribe the achievements of this period to the Tarquins. Servius was an enlightened king who was supposed to have established the organization of the city by census results and the distribution of the citizens into classes, in turn divided for military purposes into centuries (groups of 100). Servius is alleged to have divided the town into four territorial tribes and encircled it with a strong, unbroken wall. Assassinated in turn by the sons of Tarquinius Priscus, Servius was succeeded by one of them, Tarquinius Superbus, whom legend depicts as a violent and unjust tyrant. He successfully waged war against neighbouring peoples and continued his father's construction work. The Cloaca Maxima (a remarkable drainage system) and the completion of the temple of Jupiter Capitolinus are attributed to him. According to legend, the excesses of the Tarquins provoked an insurrection among the Roman citizens. Lucretia, an honorable Roman matron, supposedly committed suicide after being violated by one of the King's sons. Lucius Junius Brutus, a freedom-loving Roman, roused the outraged populace and condemned the tyrant and his family to exile. Thus was the Roman Republic born and power transferred to its legitimate custodian, the people themselves.

Etruscan influence on Rome

This fictionalized and patriotic account contains some elements of truth. Rome came under the ascendancy of its powerful neighbour Etruria in the 7th century BC. Somewhat later than tradition would have it, near *550,* it was ruled directly by the Etruscans, who thus obtained an invaluable passageway to Campania, which they controlled. As a result of the Etruscan seizure of power, Rome became a great and prosperous city with a preponderant influence over the rest of Latium. The Etruscan leaders encircled it with a continuous wall and adorned it with stone monuments, the most imposing of which was the Capitoline temple, which was dedicated to Jupiter, Juno, and Minerva. The gods were Roman, but their grouping in a triad reflects the Etruscan predilection for grouping things in threes. Rome was thus genuinely affected by the Etruscan religious and cultural influence. The Etruscans' more significant achievements included passing on to the Romans the alphabet, which they had themselves borrowed from the Greek world, and acquainting them with certain Hellenic religious and art forms.

It should not be concluded, however, that Rome owed a great debt to its 6th-century Etruscan masters. On the contrary, the limits of their influence should be emphasized. Although the Etruscans physically transformed and reorganized Rome, the city on the whole withstood any profound exertion of Etruscan influence. The Latin tongue was little influenced by the Etruscan language, which had a quite different structure. In addition, once the Etruscan occupation had ended, Etruscans and Romans followed widely divergent paths. Rome had changed considerably in outer appearance, hut its people, who, after a century of foreign domination, patiently and stubbornly continued their progress and history, remained the same.

The development of Roman institutions. *Social institutions.* At the very basis of the Roman city were the gentes, groups composed of all those linked by a common ancestor, who gave the gens its name and character. Each gens had its own cults and traditions that stubbornly withstood the ravages of time. In addition to those citizens bound together by the blood of the gentes, the city included a varying number of *clierztes,* men who owed allegiance to patrons in return for aid and assistance. The gens comprised subdivisions, the *familiae,* the more limited but fundamental units of Roman society. They were grouped around the head of the family, the *paterfamilias,* whose authority is often demonstrated in Roman history by striking examples.

As far back as the period of monarchy, a privileged class, the patriciate, gradually began to form, made up of members of the privileged gentes. Opposed to it was the plebs, which was excluded from the gens organization. The plebeians had neither a cult nor common ancestors. They initially formed an unorganized class made up of former clients of vanished gentes and foreigners who had settled along the Tiber as traders or artisans. Lacking civil, political, or religious rights, the plebs initially also had no civic obligations and was liable to neither military service nor taxation. Although the reform attributed to Servius Tullius is full of dating errors, the Etruscan monarchy, following the principle of organizing the city according to census figures, was responsible for re-enlisting the plebs into the army.

The priesthoods

Religious institutions. The intense religious life of ancient Rome had achieved in remote times the essential organization it was to maintain for centuries. Greek and Etrurian influences were assimilated but did not profoundly alter the traditional religious structure. Several priesthoods of varying importance were charged with administering the *jus divinum* ("divine law"), keeping order within the city, and maintaining good relations with the gods. In the period of the monarchy, the king possessed religious authority in addition to his political, judicial, and military roles. Under the republic, this authority was passed on to a priest appointed for life, the *rex sacrorum,* who resided in the Regia in the Roman Forum. But the real religious power lay elsewhere. *Flamines* ("priests"), of which there were three major and 12 minor in the classical epoch, were assigned to the cult of individual deities. The *flamines* of Jupiter, Mars, and Quirinus were of remote origin and guaranteed the benevolent presence of the ancient triad of gods. The augurs were a body of theologians responsible for preserving and applying the rules pertaining to the observation and interpretation of the auspices, divine omens revealed by, among other things, the flight of birds. The pontiffs, particularly the *pontifex maximus,* held wide powers. They were the trustees of sacred knowledge and saw that it was strictly applied. They supervised the venerable college of the Vestals, virgin priestesses appointed for 30 years, who were charged with keeping the sacred fire of the city in the Temple of Vesta. There were also ancient brotherhoods, such as the Arvales and Salii, who assured the survival of ancient magic rituals.

Political and military institutions. The political and military power of the kings was absolute. This power, called the *imperium,* developed out of the right of military command but also had a religious dimension. The ceremony of the king's investiture was, in fact, controlled by a prior examination of the auspices through the offices of the augur. According to annals, each accession to the throne was normally contingent on a popular vote and the Senate's confirmation. What is certain is that the Roman monarchy was not hereditary and that it functioned for at least two and one-half centuries.

Early political divisions

According to legend, the kings, beginning with Romulus, organized the Roman people politically. They supposedly were divided into three tribes and 30 *curiae.* The primitive tribes may have corresponded to various ethnic elements: Latins, Sabines, and Etruscans. Each tribe was divided into ten *curiae,* which resembled the gentes and were local in character. Each *curia* was headed by a *curio* and had common meals and sacrifices. Together they formed the assembly called the Comitia Curiata, which elected the king and possessed a certain number of legislative and judicial rights.

The mos majorurn: the Roman virtues. Such was the general structure that controlled the life of Rome during the early centuries of its existence. Simultaneously stable and flexible, it made possible the progressive development of a town that was self-governing and at the same time open to constructive influences from abroad. The cardinal Roman virtues, which were Rome's most steadfast support and the guarantor of its survival, had already asserted themselves. Rome was characterized by a profound patriotism that consistently subordinated the individual to the group and always resolved the conflicts of duty to the benefit of the state. The deep sense of the permanence of the state assured a continuing respect for ancestral custom, although it did not entail the rejection of innovation. But this continuity could be assured only by the exercise of a high level of morality, which gave first place to the civic virtues of unwavering piety and good faith. *Virtus, pietas, fides:* these guaranteed the survival and growth of Rome.

EARLY CENTURIES OF THE ROMAN REPUBLIC (6TH CENTURY BC–264 BC)

Dedication of the temple of Jupiter Capitolinus

The overthrow of the monarchy. The annals give a coherent and highly colourful account of the fall of the monarchy and the establishment of the republic. According to this account, the tyranny of Tarquinius Superbus became hateful to the Romans, who rose under the leadership of Lucius Junius Brutus after the rape of Lucretia. The Tarquins were banished from Rome; the popular assembly, grouped by centuries, named the first two magistrates in 509, Brutus and Tarquinius Collatinus. The king of Clusium, Lars Porsena, laid siege to Rome in an attempt to restore Tarquinius Superbus to power; but, according to legend, the heroism of Horatius Cocles and Mucius Scaevola forced him to retreat. The dedication of the temple of Jupiter Capitolinus by Marcus Horatius, who replaced Spurius Lucretius, Brutus' successor, as magistrate, also took place in 509 after the exile of Tarquinius Superbus and his family. In the same year was allegedly begun the custom of drawing up the list of eponymous magistrates, the consular *fasti,* the first and foremost document of Roman history.

Analysis of the various elements of the tradition shows that the annalists, for patriotic reasons, more or less consciously telescoped events that occurred over several years into that *annus mirabilis,* 509. The reliable basis for the chronology of the period is the dedication of the Capitoline temple of Jupiter, Juno, and Minerva, which took place in 509 BC. At that time began the annual rite of driving a nail into the wall of Minerva's cella in the Capitoline sanctuary. By counting the number of nails the true date of the dedication was easily obtained. But the Etruscan departure from Rome and the subsequent founding of a republic freed from foreign occupation has to be placed later, even as late as 470 BC. Archaeological data and the persistence of religious ceremonies show that until that time there was no break in Roman life. The Etruscans abandoned Rome and Latium only after they had been defeated by the Greeks in the waters of Cumae (474 BC), when they were already on the decline. The annals placed their departure in 509 BC because patriotism required it. The Capitoline temple, which was to become the symbol and centre of Rome and its empire, could not remain what it had in fact been, a purely Etruscan achievement. Its dedication at least had to be Roman. By arbitrarily placing the expulsion of the Tarquins in 509, the annalists could ascribe the glory of the dedication to Horatius, a true Roman.

Later, the expulsion of the Tarquins was regularly celebrated as the end of a monarchy that stood for the domination of an individual and the servitude of the citizens. In the folklore of later Romans it was at this point that *dominatio* and *servitus* vanished from Roman soil and the state became the property of its legitimate owner, the Roman people, who exercised power. Such was the foundation of Roman liberty (or *libertas),* the prestige of which remained such that even Augnstus, the first emperor, improperly laid claim to it by proclaiming himself *libertatis vindex* ("saviour of liberty").

The chief magistracy and the dictatorship. With the end of the monarchy, a republican constitution gradually began to take form. The Romans' pragmatism led them to create a whole series of powers designed to balance one another while providing the maximum effectiveness to the essential proceedings of the state. Power was divided among the Senate, the popular assemblies, and magistrates of varying degrees of importance. What gradually took shape was an essentially oligarchic republican constitution in which a governing class, the *nobilitas*, consistently held the foremost position.

The king's sovereign executive power appears to have passed initially to a magistrate with the title of *praetor maximus*, who no doubt headed a body of *praetnres,* who had perhaps been the immediate officers of the monarch. It was a *praetor maximus*, Marcus Horatius, who in 509 dedicated the Capitoline temple.

The consuls

The *praetor maximus*, however, soon gave way to a collegiate system in which two elected consuls shared the *imperium* for a single year. The principles of collegiality and of limitation of the term of office were characteristic of the republican constitution and effectively prevented the reappearance of tyrannical and absolute authority. It thus appeared safe to grant royal insignia to the magistrates and to have them preceded by 12 lictors bearing the fasces and the axe, hidden to Rome but visible on the other side of the *pomoerium*, the trench that defined the city limits.

Apparently, the plebeians initially were not excluded from the consulate, but the patriciate quickly closed ranks and made it extremely difficult for anyone not of its order to accede to the chief magistracy. In the middle of the 5th century, pressure from the plebs caused the patricians to create the military tribunate with magistral authority. a kind of promagistracy open to plebeians (see below). The consulate, however, remained open only to patricians until the mid-4th century BC, when a law was passed requiring that one of the two consuls be a plebeian. By that time the ancient distinction between the patriciate and the plebs had become blurred, and a new nobility occupied the forefront of the political scene.

During times of national emergency, the dual consulship was abandoned and a dictator established in their place. The dictator was, in fact, appointed by one of the consuls on the initiative of the Senate, and he was free of the restrictions imposed on the other magistrates. The dictator's *imperium* was unlimited but was entrusted to him for six months only, after which he surrendered his authority, as in the legend of Cincinnatus, who was appointed dictator in the war against the Aequi and afterward returned to his farm. The dictator was backed up by a cavalry commander (or *magister equitum*) of his own choosing, who had to resign at the same time as the dictator. This special form of magistracy was seldom used. It no doubt arose from an early institution of the Latin towns, which reserved special dictatorships for carrying out certain religious rites. The dictator disappeared from Rome after the Second Punic War and reappeared only during the struggle of the 1st century BC among ambitious men who used it to fight their way to personal power.

The praetorship

Other magistracies. Initially, the *imperium* was exercised only by the consuls, but in 366 BC, according to tradition, a praetor was created who also possessed *imperium* but of an order inferior to that of the consuls (*imperium minus).* The praetor was given the responsibility for the administration of justice in the city. Beginning in the second half of the 3rd century, the growth of Rome and its conquests entailed the creation of other praetors who were charged with administering the law in the provinces.

Tradition credits King Servius Tullius with having taken the first census of the citizens and their property. Under the republic, a magistracy, important but *sine imperio,* fulfilled this function. This was the censorship, created, according to tradition, in 433. Two censors were elected every five years, but at the end of 18 months, after they had completed their task, they resigned their posts. They made a census of persons and property and were able to bring disgrace upon a citizen for bad conduct. They thus exercised a true *cura morum,* and this concern for morality made them important and respected figures.

As administration became increasingly complex, more officials were created to aid all of the high magistrates. The quaestors specialized in financial questions and were the custodians of the public coffers. The college of four aediles (two patricians and two plebeians) was charged with maintaining public order in the town and provisioning it, along with the upkeep of public monuments and the organization of games.

Judicial institutions. From remotest times the Romans displayed a concern for legal rules, the religious character of which was striking. According to tradition, a religious brotherhood of 20 members (the *fetiales*) appeared as far back as the 8th century BC, in possession of the laws of warfare. War could not be declared nor treaties concluded without applying strict rules, of which they were the trustees. Rome recognized neither the rule of the strongest nor the right of the conqueror over the vanquished in warfare. The Romans' respect for legal obligations permitted them to conduct only a war that was *pium justumque* ("pious and just"), so that the gods would aid the Roman army to victory. Piety, good faith, and justice were interrelated and, in the mind of the Romans, were needed to guide their struggles and justify their conquests.

Law of the Twelve Tables

In the middle of the 5th century, the law of the Twelve Tables was framed and displayed in the Forum on 12 bronze tablets. It was Rome's first written code and was of extreme importance because it was viewed as the source of all law, public as well as private. The schoolchildren of Cicero's time still learned it by heart. The code survives only in fragments, but enough remains to enable modern historians to grasp its spirit.

The code seems to have been the creation of a special committee. There is an interruption in the consular *fasti* for 451 and 450, when the consuls were replaced by a board of ten men called decemvirs, who ruled with consular authority and who were charged with putting the laws into written form. The first college of decemvirs was appointed for one year and was replaced by a second college that was to complete the task; but the second college tried to retain power illegally. Military defeats and scandals in Roman life brought about its downfall and the consuls' return to power. During their brief rule, however, the decemvirs had sufficient time to fulfill their task of drafting a written code, to which anyone might refer. Until then the law had remained purely oral, and the plebs accused the magistrates of applying it unfairly. According to the ancient writers and from the fragments of extant laws, the code of the Twelve Tables seems to be the heir of a remote past, for many of its provisions present an essentially religious and sacred character. The code, however, also displays the distinguishing feature of judicial law: the assurance to every citizen of the exercise of his rights.

The Senate. In the political life of republican Rome, the Senate constituted a third element, in addition to the popular assemblies and magistracies. Its prestige was great and its influence of continuing importance. The republican Senate was heir to the Senate of the royal epoch, which, according to tradition, was created by Romulus and brought together the most influential of the *patres familiarum.* The royal Senate had been responsible for nominating the king and was, no doubt, his constant adviser, already enjoying an *auctoritas,* an effective power of moral force with religious overtones, which lent value to its acts and gave them unusual weight in the citizens' eyes. After the fall of the monarchy, the Senate was presided over by the acting consul and represented the most stable political authority of the republic.

The Senate was originally composed of heads of the patrician gentes but soon came to include all former magistrates of the city, whose names were entered on the roll and who thus became *conscripti.* This probably explains the name borne by the Senators under the republic —*patres conscripti.* This term denoted two groups of different origin and should be understood as having arisen from the formulation *patres et conscripti.* At first senators were appointed by the consuls, and later by the censors, so that changes in the Senate's composition occurred only every five years, when new censors were elected. Senators were seated for life, and their hierarchy corresponded to that of the magistracies that they had previously held.

The Senate's *auctoritas*

The Senate's *auctoritas* manifested itself in all areas. In the early years of the republic, the Senate approved the laws after they had been voted upon in the assemblies, but from the second half of the 4th century, Senate action no longer followed but, instead, preceded the popular vote. Senatorial assent was succeeded by the right of initiative in proposing laws. The Senate expressed its opinions in the form of a *senatus consultum* (a decree of the Senate), the phrasing of which followed an unvarying scheme. Although it was not obligatory, the magistrates were aware that they should abide by the opinion of the wisest and most respected men of the city. In time, the Senate's opinions gained the force of law.

In the later republic, the Senate also performed the important function of assigning magistrates to govern the provinces. Since the political career of a Roman statesman usually depended upon obtaining a lucrative provincial appointment, this became of great significance in the power struggle of the 1st century BC.

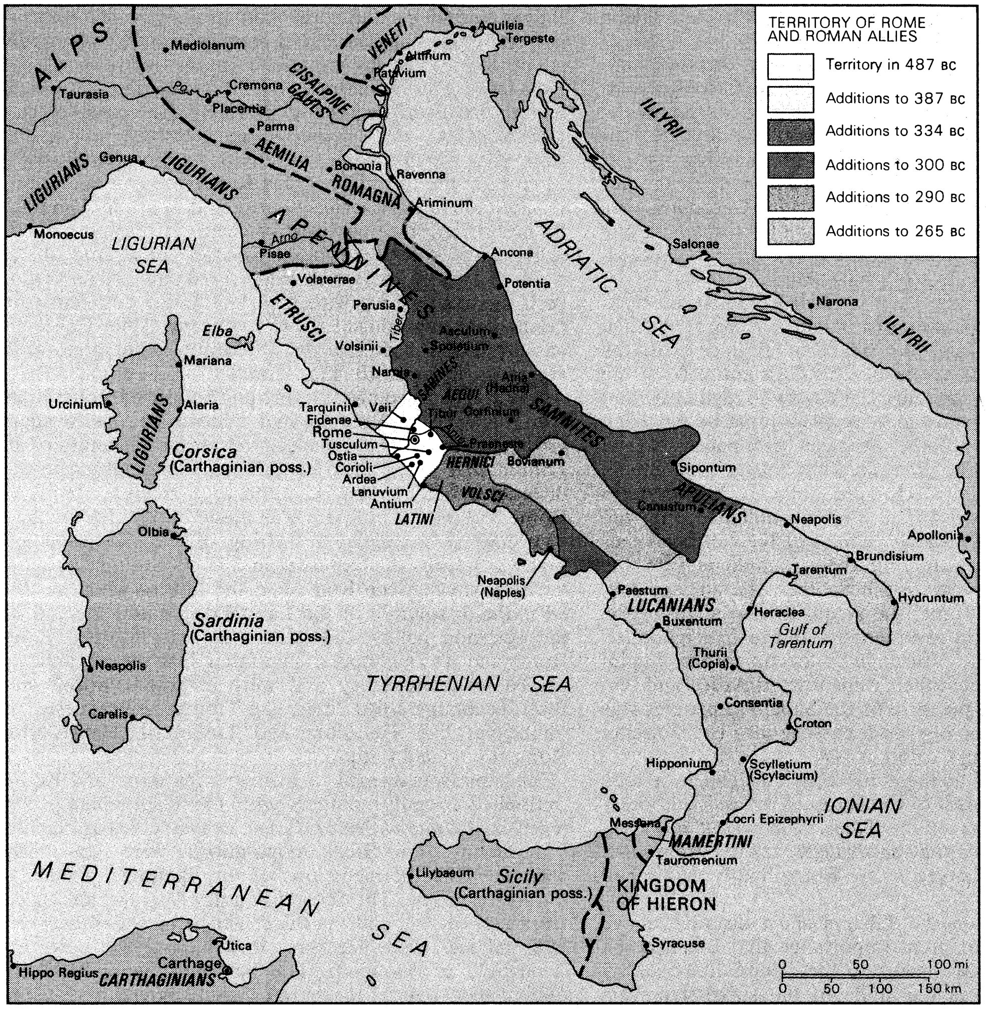
The Senate also had great authority in foreign affairs. The ambassadors of foreign powers presented themselves before it, and it chose the envoys to be sent abroad. With respect to religion, it upheld the ancestral rites and ceremonies, accepting foreign divinities when the need was felt and securing Rome against innovations dangerous to the *mos majorum.* Above all, it had supreme control over public finances since it managed the state treasury (the *aerarium Saturni)* and made final decisions on expenditures and taxation.

In the early centuries of the republic, the Senate thus had supreme influence, due to custom and to the respect in which it was held by the magistrates and popular assemblies. The Roman constitution, which appeared to be based on a combination of forces, was in fact essentially oligarchic and plutocratic. The senators, who were proprietors of great estates, were thrifty, competent administrators. Their real difficulties arose with conquest, which gave them not only a town and a country to govern but a true empire to administer as well.

Plebeian institutions. In a patrician state that wished to exclude all those who had not issued from its ranks, the plebeians, forced into the background, put all of their efforts into forcing recognition of their existence and rights. The first two centuries of the republic were taken up by their unceasingly renewed attempts to gain the political position that they claimed and by the progressive disintegration of the privileges to which the patricians clung tenaciously. The struggle took place on the economic as well as on the civic levels. The plebeians wanted the expanses of the public lands (the *ager publicus),* over which the great proprietors were extending their influence, opened to them. The public domain was expanding continually as a result of the gradual conquests of the Roman armies.

Struggle over public land

The long conflict between patriciate and plebs went through various changes, described by the annalists in accounts that are often unreliable and contain errors of dating. What is certain is that in the first decades of the republic the plebs was able to organize itself and form a state within the state. The unity of the republic was ulti-



Roman expansion in Italy, 487–265 BC.

mately maintained, but not until serious crises had threatened the very foundations of its existence.

Plebeian religious institutions

The process of organization and defense of the plebeians was apparently as follows: around the beginning of the republic, 493–92, according to tradition, the plebs, returning armed from a military campaign, seceded to the Sacred Mount and forced the Senate to grant to it magistrates charged with defending the plebs under all circumstances. The tribunes of the plebs were inviolable and sacrosanct and could bring aid (*jus auxilii*) to plebeians threatened by the possible excesses of the executive power. They also had a right of veto, through which they could prevent the consuls, Senate, or assembly from making a decision, and they could intercede to prevent the carrying out of a decision if they judged it to be unfairly detrimental to the plebs. The tribunes' power, which they exerted only within the city, operated within the sphere of magic and religion. In the face of the regular Roman authorities, it appeared that the plebs could be protected only by figures from its own ranks, who were effectively protected by divine power and who themselves enjoyed a sacred power from the depths of antiquity. Immediately after the tribunates were established, the consul Spurius Cassius dedicated a tripartite temple at the foot of the Aventine, which was constructed on the model of the Capitoline sanctuary but devoted to Ceres, Liber, and Libera. This was to be the appointed sanctuary of the plebs. Ceres was the protectress of agriculture and kept the deadly famine away from the urban population. The couple Liber and Libera presided over the birth and growth of animals and people. Permanently established on the Aventine, this triad of fertility protected the plebs, whose land and herds guaranteed only an uncertain subsistence, and, to some extent, counterbalanced the Capitoline triad, the great protector of the Roman state and its regular authorities, who were patricians. The temple on the Aventine held the plebeian archives and, in the later republic, became the centre for wheat distributions to the plebs. Aediles were created to protect the temple, guard the archives, and keep order in the markets.

Completing the organization of the plebeian class was the assembly of the plebs, the Concilium Plebis, which was organized according to the citizens' domiciles instead of by property qualifications, as in the Comitia Centuriata.

The state was thus apparently divided in half. Rome was wise and fortunate in its ability, through successive measures, to bring the opposing orders to an understanding. A law of 456, which determined the sale of the lands on the Aventine, signalled the first extension of the ***ager publicus.***

THE EXPANSION OF ROME IN ITALY

Rome and its Latin neighbours. Roman historians provide a detailed picture of Rome's foreign policy and its conquests during the early centuries of the republic. There is splendour and grandeur in that account, which often takes on an epic rhythm, in which Rome, engaged with many powerful adversaries, fells them one by one, relying on allies, of course, but bearing the burden of the battles and struggles itself. There are many more or less conscious errors of dating in these highly colourful pages, whose coherence and frequent beauty filled the Romans of the classic era with satisfaction and pride in their ancestors. One important error of perspective makes Rome a capital among the other towns of central Italy as early as the 5th century BC and gives the city a pre-eminence over neighbouring cities that it certainly did not have. Historical research today makes it possible to take a more realistic view of the situation.

The Latin League

The Etruscan departure from Latium to a certain extent weakened Rome, for the Etruscans had fortified Rome as a base for their expeditions to the south of the peninsula. Rome joined the Latin League and had to adopt its policy since it certainly was incapable of imposing its will on it. The entire 5th century and the first part of the 4th was the era of the corzciliurn Latinorum. Decisions were made in common, and in time of war the Romans, along with everyone else, placed themselves under the command of the dictator elected by the league.

These common perils did not prevent Rome from breaking with its Latin neighbours. Rome's victory at Lake Regillus in 499 BC and the treaty of alliance with the Latin towns—known as the Foedus Cassianum from the name of the consul, Spurius Cassius, who signed it, and ascribed by tradition to the year 493—must be put back into the framework of the Etruscan occupation, which had not yet ended. The great conflicts between republican Rome and its Latin rivals for pre-eminence over Latium have to be placed later. The major problem during the 5th century was curbing the peoples of the central Apennines, who were multiplying their incursions into the western plains. These were the Sabines, the ancient enemies of monarchic Rome; the Aequi, whose territory extended from the Anio to Praeneste; and their neighbours, the Hernici and the Volsci, who occupied the Lepini mountains and directed their raids toward Ardea and Antium. Somehow the pressure of the Sahellian peoples was contained, and Rome opened a passage into the Volscian country by occupying Corioli in 444.

Rome found itself at the same time engaged in a long conflict with the nearest of the Etruscan cities, Veii, located on the right bank of the Tiber. Veii was a powerful and formidable rival, and the struggle was to be long and to undergo many changes before Rome finally triumphed over its opponent.

The siege of Veii

Fidenae, situated on the Tiber a short distance above Rome, was a port of great importance that blocked the salt route going from the sea to the mountains, used by the Etruscans. It was the stake in the successive wars between Rome and Veii, which firmly held Fidenae. Rome did not definitely take possession of it until 426 BC. Then, according to tradition, in 405 began the siege of Veii itself, which lasted ten years (like the siege of Troy) and ended in the city's collapse under the blows of the dictator Furius Camillus. Livy paints an epic picture of this siege and its dramatic outcome. The religious notes that sprinkle his narrative certainly derive in part from traditions that are unmistakably Etruscan. Fate and the oracles had announced the impending end of Veii, abandoned by the gods themselves. Camillus, for his part, was fate's moving spirit. He sent an envoy to the Delphic Apollo and promised the tithe of the spoils if he were successful. He was assured of support, but he was loath to attack the town without appealing to Juno, the goddess who protected it. He therefore practiced the ancient rite of evocatio, inviting the deity to leave the besieged town and come to live in Rome, where she would be received with honour. Juno accepted and the town was stormed and captured, after which the statue of the cult left the ruins of Veii and arrived on the Aventine, where it was given a temple suitable to Juno's dignity.

The Gallic invasion and further conquests. The capture of Veii was followed by a catastrophe for Rome that lived on in its history as a disastrous event, the Celtic invasion and the capture of the city by the Gauls. Book V of Livy and the pages dedicated by Polybius to the Celtic world make it possible to portray vividly the vicissitudes of this dramatic period. At the end of the 6th and the beginning of the 5th century, the first bands of invaders began to arrive in northern Italy. In the 4th century the trickle became a flood, and the barbarian hordes penetrated the peninsula in force. According to the annalists, the Gauls allegedly defeated the Etruscan army near Clusium and continued southward toward Rome and crushed the Roman forces on the banks of the River Allia, to the north of the city. About 390 (the traditional date) they succeeded in routing the Roman army, which was dismayed by the appearance and mode of combat of its new adversaries. This day remained in the memory of the Romans a dies *religiosus* (an "accursed day"). Caere, Rome's Etruscan neighbour, received the sacred objects (the sacra) rescued by the Vestals from the pillage and ruin, after which a common religious atmosphere seemed to envelop the two cities. Once Rome was out of danger, its gratitude to the Caerites prompted it to grant them public hospitality, and it soon gave them citizenship without suffrage (civitas sine *suffragio*). After the drama of the occupation of Rome, which engendered an acute feeling of peril revived by Livy with a sort of tragic grandeur, the Gauls were summoned back to the north. Other Celtic invasions followed during the 4th century, but none gave rise to the terror of the first assault.

Since the Latin confederation had abandoned Rome to its own devices, the Romans had confronted the invaders virtually alone. There ensued a period of anarchy in Latium, and Rome took advantage of it to subjugate the disordered Latin towns. A temporary agreement between Rome and the Latin towns was made in 358 BC.

The Samnite Wars

Through a complicated shifting of alliances, Rome's first war against the Samnites in 343 BC brought about a decisive war between Rome and the Latins, which resulted in the dissolution of the Latin League and the end of the common policy undertaken, at least in theory, by Rome and its neighbours. The latter lost the advantages gained by confederacy and were assigned various statuses, becoming allied cities, like Tibur and Praeneste, or municipia, like Tusculum and Lavinium. Henceforth, Rome dominated Latium.

Campania was opened to Roman expansion, and Rome multiplied friendly contacts with the Campanian privileged classes and with such Greek coastal cities as Naples. The Oscan and Greek populations were constantly threatened by the incursions of the Samnites, a martial mountain people. The Second Samnite War, which lasted from 326 to 304, and the third, which extended between 298 and 290, were necessary to subjugate the powerful stronghold of Samnium. The Samnites, who faithfully obeyed their federal magistrates, were moved by a fierce and bellicose spirit. Well-armed and good tacticians, they inflicted heavy losses on the Romans. In 321 they trapped the Roman army in the closed valley of Caudine Forks between Capua and Beneventum; the two consuls, who survived, accepted an agreement that was harsh for Rome, and the entire army surrendered. Rome did not ratify the Pax Caudina, but it had suffered a deep humiliation. Its tenacity enabled it to regain the advantage, and Bovianum, one of the Samnite capitals, was stormed in 306, and the peace signed. At the same time, Rome pressed into central Etruria, which was living out its last years of independence. The Third Samnite War broke out in 298, in which the Etruscans, Gauls, and Samnites united against the increasing threat of the Romans. In 295 the consuls Fabius Rullianus and Decius Mus won a great victory at Sentinum, north of the Umbria, over the Samnito–Gallic coalition, in which Decius, according to legend, heroically sacrificed his own life. The Gallic tide was stemmed, and the Ager Gallicus Romanized. The conquest of Etruria was completed with the fall of the last independent Etruscan town, Volsinii, in 265 BC.

Wars with Pyrrhus

The southward expansion of Rome, which was still on good terms with Carthage, transformed the republic into a Mediterranean power. The Romans came into contact with peoples such as the Lucanians and the Apulians, over whom they extended their influence, which engendered the hostility of the most powerful city of Magna Graecia, Tarentum. When a Roman garrison and ships appeared in areas of Tarentine authority, Tarentum, sensing danger, decided to put a stop to it and appealed to Pyrrhus, the king of Epirus, to bring the insolent Romans to their senses. Pyrrhus thought he could unify the Hellenic cities of southern Italy and the native populations of the interior. Although this ambition miscarried, his expeditionary corps, using formidable combat elephants, defeated the legions on several occasions between 280 and 276 BC. From Carthage, then friendly to Rome, he won back the

Greek cities of Sicily that had fallen under Punic hegemony. But Pyrrhus' victories were short-lived. He returned to Epirus, and Tarentum had to concede defeat in 271. Rome accorded Tarentum the status of an allied city.

The Roman mastery of Italy. Thus, by the beginning of the 3rd century BC, Rome had become mistress of Italy and was rapidly becoming a Mediterranean power. Tarentum had bequeathed to Rome its hegemony in the commerce of the Adriatic. The Greek world for the first time turned its gaze toward this latest arrival on the international chessboard, this city of the west whose dynamism asserted itself through a series of conquests that neither difficulties nor defeats had been able to check. In 306 the agreement with the Carthaginians was renewed once more, the last time before the outbreak of the hostilities that were to lead to great upheavals. This last treaty forbade all Carthaginian intervention in Italy and all Roman intervention in Sicily. Forty years later, however, Rome interfered in Sicilian affairs, and the former allies found themselves in opposition.

The Roman concept of imperialism

In its conquest of Italy, Rome had given proof of a flexible diplomacy, which treated the vanquished honorably and gave them a place, and rights that varied, in a country gradually being unified under Roman law. Roman imperialism sought constantly to justify itself morally, and the demands of Roman good faith (*fides Romana*) were not just empty words, even though such honesty was not always observed. Through deditio, the vanquished relied on the *fides* of Rome, which claimed to use the new power conferred on it for the good of all, in the best way possible. In point of fact, the defeated city usually lost its autonomy and incurred various obligations to Rome, so that after the dissolution of the Latin League, the status of Rome's former allies was diverse. Lanuvium and Tusculum, for example, had citizenship without suffrage (*civitas* sine *suffragio*), while Tibur and Praeneste remained allied cities (civitates foederatae), which did not prevent them from losing part of their territory. Rome also sent new colonists into the conquered regions, and the Roman colonies spread throughout the ever-expanding *ager publicus* were like extensions of the metropolis in a more or less distant land. The population of the Latin colonies was composed largely of proletarians who cleared the conquered soil and brought it under cultivation. Because of this vast extension of Rome's national territory, economic development of the city was rapid. The city soon had need of a currency of its own for its expanding and intensified commercial relations. The war with Pyrrhus gave rise to the first Roman silver coinage.

On the eve of the First Punic War, Rome had become a commercial city participating in the great economic currents of the Hellenistic world. The wars against Carthage forced Rome to become a naval power. Rome could then operate in the east and undertake the expeditions and conquests beyond the seas that ultimately would lead to the extension of its hegemony throughout the Mediterranean world. (R.Bl.)

II. The middle republic (264–133BC)

THE FIRST TWO PUNIC WARS

Roman invasion of Sicily

The First Punic War and the aftermath. The Romans invaded Sicily, in 264 BC, in response to an appeal by the Campanian mercenaries who had seized Messana by treachery in 289 BC. The Romans feared that if they did not act, Carthage, which had saved Messana from King Hieron of Syracuse, would remain in possession of it and stand at the doorstep of Italy. Land fighting broke out in Sicily, in which the Romans had Hieron for an ally after 263; but because Carthage was the first naval power of the western Mediterranean, decisive victory could only be won at sea. So the Romans, who had no naval experience, built a navy and turned their soldiers into sailors and their consuls into admirals. At first, the war went well for the Romans. The consul Marcus Atilius Regulus even invaded Africa in 256, after a naval victory, and the Carthaginians treated for peace; but Regulus was not satisfied. The Carthaginians rallied, however, under the Spartan mercenary captain Xanthippus, and in 255 Regulus was defeated and taken prisoner. After naval disasters in 255 and 253 and a long period of stalemate, the Romans built a new fleet, and with it Gaius Lutatius Catulus won the battle of the Aegates Islands (241) off western Sicily. Carthage could no longer provision its army in Sicily; so peace was made in 241, with the Carthaginians agreeing to pay an indemnity and to abandon Sicily, which, with the exception of Hieron's kingdom, became the first province of the Roman Empire.

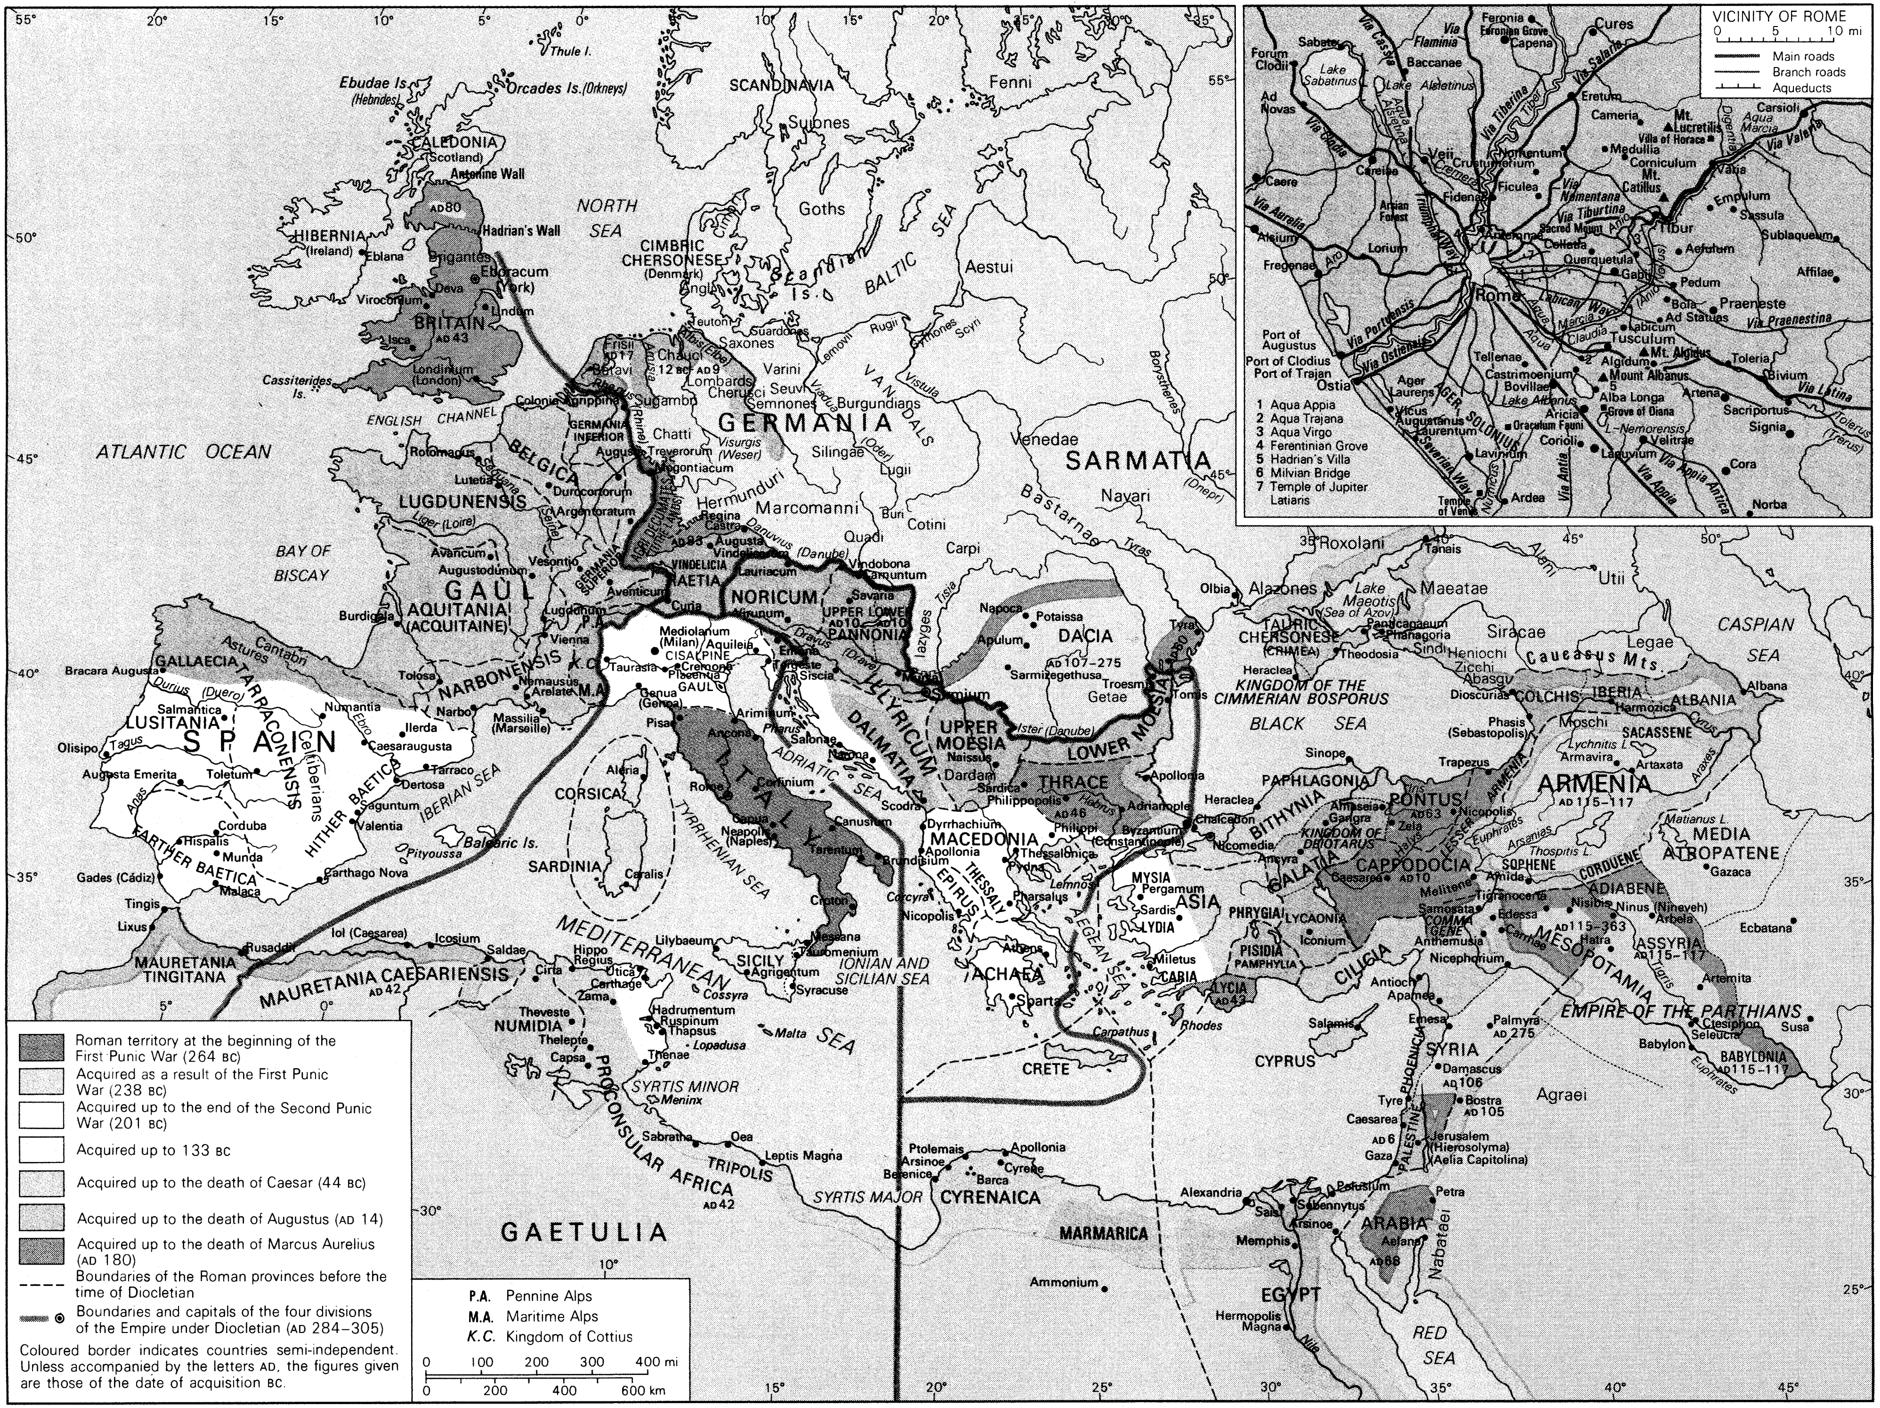
A serious and prolonged mutiny in the Carthaginian army (the "Truceless War"), caused by an attempt to underpay mercenary troops on their discharge, enabled the Romans, with no pretext of justice whatever, but again from fear of the Carthaginians as near neighbours, to take possession of Sardinia and Corsica in 238. This seizure exacerbated the Carthaginians and in particular their general, Hamilcar Barca, who still resented the necessity of capitulation in 241 because his own position at the time, on Mt. Eryx in western Sicily, had been, he thought, unassailable. He, therefore, now turned, with the support of the Carthaginian government, to extending Carthaginian power in Spain, with the intention of using its manpower and resources to mount a war of revenge against Rome. (On his death, in 229, Hamilcar Barca was succeeded as commander in Spain by his son-in-law Hasdrubal; Hamilcar's son Hannibal. who had served under them both, assumed command in Spain on Hasdrubal's murder in 221.) Prompted no doubt by its ally Massilia (Marseille), which was concerned by the growing Carthaginian threat to its own colonies in Spain, Rome protested to Hamilcar in 231 and made an agreement with Hasdrubal in 226, in which he pledged not to push Carthaginian expansion beyond the Ebro. Then, or earlier, Rome made an alliance with Saguntum, a strategically placed city near the coast that lay within the Carthaginian sphere of influence, no doubt with the thought of using it as a bridgehead for operations in Spain if war with Carthage should be resumed.

Even more serious to Rome than the implications of Carthaginian expansion in Spain was the threat of a new Gallic invasion of Italy from the north. There had been an alarm in 236, and in 225 the Boii, Taurini, Insubres, and Gaesati moved southward with more than 50,000 men; after an initial success, these forces were caught between two Roman armies and defeated at Telamon on the west coast, north of Cosa. The Romans followed up their success and in 218 established colonies at Placentia and Cremona, both on the Po. With Hannibal's invasion of Italy that year (for he had rightly counted on Gallic assistance), the work of pacification in the north was undone for the time being.

There was a further diversion east of the Adriatic. Attacks by state-protected Illyrian pirates on Italian shipping and the murder of a Roman ambassador provoked the Romans to declare war on the Illyrian queen Teuta in 229, and a swift victory was won. The Romans then assumed a protectorate over 120 miles of the Illyrian coast, including the ports of Apollonia and Dyrrhachium (modern Durazzo), from Lissos in the north to Corcyra in the south. Greece was delighted to see Illyrian piracy suppressed, and the Aetolian and Achaean leagues, Athens, and Corinth politely received Roman envoys. In 219 the terms of the 229 agreement were violated by the widespread naval depredations of Demetrius of Pharos, an ally of Rome in the first war; and, perhaps with the intention of avoiding the danger of a stab in the back by Illyria if war with Carthage broke out, the Romans went to war again in 219 and again won conclusive success—Pharos was captured and Demetrius fled. That same year Hannibal attacked and took Saguntum; and Rome, with this Illyrian distraction on its hands, did nothing to help its ally.

Hannibal's invasion of Italy

The Second Punic War. The war that the Romans had planned—an invasion of Carthage and a simultaneous landing in Spain to form a Roman bridgehead at Saguntum—never took place. Hannibal assumed the initiative by invading Italy through Gaul and over the Alps, exploiting his superior military genius and experience to defeat a succession of sanguine but inexperienced Roman generals and untrained Roman armies at the Ticinus and



Roman territorial expansion.

Trebia rivers in 218, at Trasimene in 217, and at Cannae in 216. To all appearances, the war was now over; and the greedy Philip V of Macedon broke off his war against the Aetolians, allied himself to Hannibal, and declared war on Rome. Capua joined Hannibal, expecting to become Italy's new capital city; Syracuse seceded from Rome in 215, and Hannibal secured Tarentum in 213. Yet from 215 Hannibal's chances of success dwindled. Historians have questioned his not marching on Rome when it was demoralized after Cannae and wondered if the luxury of Capua, where he wintered, sapped the vigour of his troops.

There are more positive explanations of the turn of the tide. The first is the fact that the Roman Senate never panicked, fortified by the unruffled good sense of Quintus Fabius Maximus, consul in 215 and 214, who by refusing to risk a further pitched battle with Hannibal earned his nickname, "Cunctator." Second is the fact that Rome's Latin allies remained loyal and that Hannibal's army—without reinforcements either from Philip, who with no fleet could not cross the Adriatic, or from Carthage, whose government and navy showed none of Hannibal's enterprise—was a declining and, eventually, a spent force. The army's strength was cavalry; and cavalry cannot besiege cities. Directly after the invasion the Romans decided to keep open a second front in Spain in the hope of preventing reinforcements from reaching Hannibal by land, a plan followed even after a disastrous defeat in 211 and the deaths of two great generals—the elder Publius Cornelius Scipio and his brother.

The Roman recapture of Capua and the fall of Syracuse in 211 were straws in the wind; and the Aetolian League in Greece now allied itself to Rome and relieved Rome of the burden of the war against Philip. Young Publius Cornelius Scipio, who had been sent, at the age of 26, to take over his father's and his uncle's command, failed to prevent reinforcements for Hannibal from leaving Spain under Hasdrubal Barca, Hannibal's brother, in 208. But these forces were disastrously defeated in Italy at the battle of the Metaurus a year later, and Hannibal's last hope was shattered. He remained ineffectively in southern Italy.

The Aetolians, complaining of inadequate support from the Romans, made peace with Philip in 206; and the Romans, concentrating on bigger things, followed suit in 205. Scipio completely defeated the Carthaginian armies in Spain at Ilipa in 207.

With a surge of optimism, the Roman people became determined to take the offensive and end the war by invading Carthage. Scipio was the obvious man to command the invasion; so, though under the legal age, he was elected consul for 205. Despite opposition from Fabius and his supporters, who thought the defeat of Hannibal in Italy should have top priority, Scipio crossed to Africa in 204 with an army of about 25,000. Hannibal was recalled, and Scipio, with the valuable assistance of Masinissa, the Numidian king, defeated Hannibal at Zama in 202 and won for himself the name of "Africanus."

By the peace settlement, Carthage was to pay 10,000 talents in 50 years and to keep no elephants and only ten warships. It was forbidden to wage war outside Africa, or in Africa itself without Rome's consent. Masinissa's power was greatly strengthened on his western border. The Romans assumed direct responsibility for the administration of Spain and established two provinces—Farther and Nearer Spain (see further PUNIC WARS).

THE ESTABLISHMENT OF ROMAN HEGEMONY IN THE HELLENISTIC WORLD

Some scholars believe that Rome made peace with Philip V of Macedonia in 205 in order to concentrate on defeating Carthage but that it intended to settle accounts with him later; others (and this was evidently what Philip himself believed), that Rome intended the settlement to be final. In the latter case, Rome was provoked to declare war against Macedonia (the Second Macedonian War) in 200 by the news brought in 201 by Attalus I of Pergamum (an ally in the first war) and by the Rhodians that Philip had made a secret compact with Antiochus III, king of Syria, to capture and share the external possessions of Egypt, whose new king, Ptolemy V Epiphanes, was a boy.

Provocation for war against Macedonia

Wars against Philip V, Antiochus III, and the Aetolians. Rome's declared object was to force Philip to withdraw Macedonian troops from the three key positions he had garrisoned in Greece—Acrocorinth (since 224), Chalcis in Euboea, and Demetrias on the Gulf of Pagasae. Rome secured the alliance of the Aetolian League; and, with some heart searching because of recent friendly relations with Macedonia, the Achaean League in the Peloponnese; and also of Attalus and Rhodes, whom Philip had provoked in Asia Minor. From the Adriatic, the Romans forced Philip's strongly held position on the Aous River and advanced into Thessaly under Titus Quinctius Flamininus in 198. In 197 they defeated the Macedonian army at the Battle of Cynoscephalae in Thessaly, in which the Roman legion showed its superiority over the Macedonian phalanx.

Peace was made with Philip on generous terms; but the Aetolians, exasperated by being denied the acquisition of towns in Thessaly for which they had hoped, maligned Rome by suggesting that, rather than freeing Greece, the Romans proposed to garrison the country themselves. Flamininus gave the lie to this claim when he proclaimed the liberty of all Greek cities at the Isthmian Games of 196, and the last Roman soldiers left Greece two years later. Rome had kept its word; but some Romans already doubted the wisdom of this move because, with as yet undeclared intentions, Antiochus, who had possessions on the European side of the Hellespont (Lysimacheia, Aenus, and Maroneia) and who had accepted Hannibal as an adviser, was already moving into western Asia Minor.

Negotiations between Antiochus and Rome foundered over the former's refusal to relinquish his possessions in Europe, and the dissatisfied Aetolians solved Antiochus' problem by inviting him, in 192, to save them from the Romans. Antiochus crossed to Greece with inadequate forces and with inadequate supplies to join the Aetolians, who now declared war on Rome. He had no help from Philip, who honoured his peace with Rome. The Achaean League stood by Rome, as did Eumenes 11 (who had succeeded Attalus as king of Pergamum in 197) and the Rhodians, both of whom expected to profit from Antiochus' defeat.

The Romans, under Acilius Glabrio, defeated Antiochus and the Aetolians at Thermopylae in 191. Antiochus retired to Asia; his navy was soundly defeated in two battles by Roman fleets in cooperation with the Rhodians; and in 190 Lucius Scipio (with his brother, the great Africanus, on his staff) crossed the Hellespont and defeated him at Magnesia. Peace was made, Antiochus being compelled to abandon his possessions in Europe and his territory in Asia west of the Taurus range and retaining only a token navy of ten ships. The abandoned Aetolians were forced to capitulate on humiliating terms in 189, becoming subject-allies of Rome. That same year the Romans, under Manlius Vulso, conquered the Galatians in Asia Minor.

Rome's policy in the East was fraught with ambiguity. In the Second Macedonian War, the Romans had crusaded for the "freedom of the Greeks," and, by their own withdrawal from Greece in 194, they had given the appearance of honest crusaders. But although Rome removed Macedonian garrisons from cities in Greece and Asia Minor, Aegina remained the property of Pergamum, having been sold to Attalus in the First Macedonian War, and the Roman peace commission of 197 had even considered giving Eretria in Euboea to Pergamum. After Magnesia, Rome had no compunction about giving a number of Greek cities in Asia Minor to Pergamum and Rhodes.

Establishment of a protectorate over Greece. Considerations of its own interest drove Rome to curtail the aggressive potentiality of Philip, Antiochus, and the Aetolians, with all of whom, after their defeats, Rome was bound by treaty and, so, was justified in acting if terms of these treaties were infringed. Relations with the

Relations with the Achaean League

Achaean League were less clear-cut, and the problem came to a head in 195. The prime object of Achaean policy was to include the entire Peloponnese by the acquisition of Elis, Messene, and in particular Sparta; Sparta's communist regime, established by King Cleomenes III in the previous century, had been revived by Nabis and now evoked envious admiration among the proletariat of the Achaean cities, thus appearing to the governing class in those cities a dangerous contagion that if not stifled might spread. Apprehensive of the slaughter and chaos that might follow an Achaean conquest of Sparta, Flamininus accepted the submission of Sparta in 195 and insisted on its remaining independent; and indeed Rome made a treaty with it.

In 194 Philopoemen, a headstrong Achaean patriot who had separated from Flamininus because of mutual jealousy and antagonism, returned after six years from Crete and controlled the league's policy. In 192 he outwitted Flamininus (now back in Greece with a roving commission) and brought Sparta into the league with the promise of no interference with its government. Then, in 188, he settled the issue once and for all with such acts as eliminating the enemies of the league, pulling down the walls of Sparta, abolishing communism, and enslaving the helots once more and putting them up for sale. In 183 Messene seceded from the league in a short-lived revolt, and Philopoemen, seeking to recover it, was captured and killed.

The year 181 was, in the Greek historian Polybius' view, decisive for the future relationship of Rome and the league. Philopoemen was dead, and the Achaean Callicrates persuaded the Senate at Rome that its interest lay in giving uncritical support in the league to the unequivocal supporters, like himself, of the Roman point of view.

Worsening relations with Macedonia

The Roman government carried a considerable responsibility for the worsening of relations with Macedonia and the eventual outbreak of the Third Macedonian War. Philip's refusal to join Antiochus was of untold value, and he was rewarded by the Romans' return of his younger son Demetrius, a hostage in Rome since 197, and the remission of his outstanding indemnity. But Philip felt himself cheated when he was not allowed to keep the Thessalian cities he had taken from the Aetolians when cooperating with Glabrio in 191. Nor was he allowed to recover Aenus and Maroneia on the Thracian coast, which had once belonged to him and were now given up by Antiochus, even though King Eumenes of Pergamum had been granted Lysimacheia and the Thracian Chersonese, which Antiochus was also forced to abandon. Still worse, Rome made an unprincipled attempt to split the Macedonian royal house. Demetrius had won great popularity in Rome when a hostage and, when he returned to Rome in 184 as Philip's representative to answer a variety of charges against the King, the Romans agreed to accept Philip's defense only because Demetrius was his mouthpiece. Neither Philip nor his elder son Perseus could be blamed for thinking that the Romans wished to upset the natural succession. When it was suspected that Demetrius planned to escape from Macedonia to Rome, and when Macedonian envoys returning from Rome in 181 produced a letter from Flamininus that, whether or not it was forged, suggested that Demetrius was conspiring for power, Philip had him killed. By this time Philip had decided on war with Rome; but he died a year later (179), having by his campaigns in the north in the latter part of his reign greatly increased the resources of his kingdom both in wealth and manpower. The Romans believed these campaigns to be exploratory—the prelude to an attempt to invade Italy from the northeast. Philip's son Perseus turned from the north to a policy of reconciliation with the Greeks and, though he was not a soldier of his father's calibre, roused increasing suspicion at Rome, which Eumenes adroitly fostered. Marriage connections suggested that Perseus might become the nucleus of a formidable anti-Roman combination—his own marriage to the daughter of Seleucus IV of Syria and his sister's marriage to Prusias II of Rithynia.

The Third Macedonian War

The issue was decided when Eumenes, himself a probable sufferer if Macedonia re-emerged as a great power, visited Rome in 172 and persuaded the Senate of Perseus' aggressive plans. The Third Macedonian War was sparked off by a couple of bizarre episodes—an amateurish attempt to kill Eumenes on his way to Delphi while returning from Rome, thought to be instigated by Perseus, and the "evidence" of a prominent citizen of Brundisium that Perseus had invited him to poison eminent Romans who had lodged with him on their way to and from the East. It was a difficult war; the Roman army had to land at Apollonia and cross the mountains into Thessaly. Perseus at the start had the advantage of numbers; indeed he won the first battle, in Thessaly in 171, and after it he offered to treat for peace. The offer was refused; and when, in 170 and 169, the Romans failed to bring Perseus to battle, the belief grew, not only in openly anti-Roman circles, that Perseus might not be defeated after all. The Illyrian chief Genthius joined Perseus. Secret talks were held between Eumenes and Perseus, the full truth of which was never revealed, with the object that, for a suitable price, Eumenes should endeavour to secure a negotiated peace. And the Rhodians, whether or not they had misunderstood Marcius Philippus, the Roman commander in 169, thought that they had been encouraged by him to try their hand at peace negotiations. On June 22, 168 BC, however, the Roman commander Lucius Aemilius Paullus brought Perseus to battle at Pydna and defeated him decisively. Perseus capitulated.

Division of Macedonia and Illyria. Perseus lost his throne and survived in exile for two more years at Alba Fucens, near Rome. Macedonia was divided into four independent republics. Genthius had already been defeated in Illyria and was also condemned to exile in Italy. Illyria, like Macedonia, was given its independence; it was divided into three units, but not before 150,000 of its men had been taken and sold into slavery.

Treatment of Eumenes II and the Achaean League. The effects of the Roman victory over Perseus were momentous. Eumenes, the Achaean League, and Rhodes were all suspect. Although Attalus II, brother of King Eumenes, was received in Rome in 167, Eumenes himself was met by a quaestor at Brundisium and told that the Senate would receive no kings in Rome—a snub that was reinforced by the audience already given to his enemy, King Prusias of Bithynia, who in Rome startled the Senate by doing obeisance to them and addressing them as saviour gods. The Achaeans were required to send 1,000 hostages to Rome; they were relegated to country towns in Italy until 151, when the 300 survivors were allowed to go home. One of the hostages, Polybius, did well, living as a favoured guest of the Scipios and laying the foundations of his great history.

Reduction of Rhodes. Rhodes fared worst of all. Already in 177 it had discovered the ambivalence of Roman policy: having been "given" Lycia and Caria on the mainland by the Romans after Magnesia and having proceeded to their direct administration, it was informed by Rome, in consequence of a Lycian appeal, that it had not been given Lycia and Caria at all but had simply been hound to them in friendship and alliance. Now, in 168, Rhodes's delegates, sent to propose a peaceful settlement of the issue with Perseus, arrived in Rome to learn that the war was over. A Roman praetor in 167 proposed that Rome should declare war on Rhodes, but the censor Cato pointed out that whatever the Rhodians' sympathies in the recent war might have been, they had performed no act of overt hostility. So the Rhodians received and forcibly obeyed Rome's harsh commands—to abandon Caunus and Stratoniceia on the mainland, neither of which had been received from Rome, and to withdraw from Caria and Lycia. Delos was declared a free port, and Rhodes consequently lost about six-sevenths of its income from harbour dues. Then, having reduced Rhodes to a second-class power, Rome consented, in 165, to make a formal alliance with her.

Piracy, based largely on Crete, was always a menace, and Rhodes, with Syria, had been the policeman of the eastern Mediterranean. With the Syrian navy already reduced to a token force and Rhodes now weakened, piracy flourished unchecked; and in the following century the Romans were themselves the victims of their own shortsighted policy.

Establishment of provinces in Africa and the East. Further east, as part of their policy of preserving a balance of power between Syria and Egypt, the Romans in 168 stopped the invasion of Egypt by the Seleucid ruler Antiochus Epiphanes. A Roman legate, Gaius Popillius Laenas, caught up with him and ordered him home, and the King did as he was told. Between 151 and 146 Rome found itself at war with Carthage, Macedonia, and the Achaean League, as a result of which all three powers lost their independence; and the provincial empire of Rome, previously confined to the west, was extended into Africa and into the Balkans.

The *Third* Punic War. In Africa, Carthage studiously respected the peace treaty of 201 despite constant filching of territory by its Numidian neighbours under King Masinissa and by the hostile decisions of successive Roman boundary commissions; but in 151 Carthaginian patience was exhausted and it declared war on Masinissa. The octogenarian Cato—the very man who had scotched the proposal to make war on Rhodes in 167—was fanatically determined that Carthage must be eliminated. Cato was frightened, it seems, by the evidence of Carthage's economic prosperity; for he cannot have thought it strong enough militarily to fight Rome with any prospect of success. In Rome, Scipio Nasica opposed a declaration of war on the grounds that Rome would be in danger of relaxing its military preparedness if Carthage, its historical rival, disappeared. War was declared, however, and both consuls of 149 were sent to conduct it. The Carthaginians were prepared to accept almost any terms—to give up 300 noble hostages, to surrender all their arms—but not Rome's final demand that they leave their city and settle ten miles inland; abandon the sea, which was their livelihood; and turn to farming.

Destruction of Carthage. Carthage was besieged and, despite the surrender of arms, defended with incredible resolution until, in 146, Scipio Aemilianus (son of Aemilius Paullus and adopted by a son of the great Scipio Africanus) captured it and burnt it down. Its site, one of the finest harbours in the Mediterranean, was cursed and abandoned. Carthaginian territory, with its capital at Utica, became the Roman province of Africa.

Subjugation of Macedonia and Greece. Macedonia too, with Illyria and Epirus and with Achaea as an appendage, became a Roman province in 146. The Macedonians had missed their monarchy, and when, in 149, a certain Andriscus claimed that he was the son of Perseus, he found followers and was soon in possession of the whole country. Andriscus was defeated in 148 by Quintus Caecilius Metellus (who won the name "Macedonicus") and was brought to Rome and executed.

Appropriately enough, given past history, the independence of Sparta was the issue that brought an end to the Achaean League. Callicrates had died, and control of league policy passed to fanatical opponents of Rome—Diaeus and Critolaus. Sparta had seceded, and in 147 a Roman commission announced its decision that Corinth and Argos should be detached from the league as well. Negotiation was impossible in the consequent atmosphere of insensate fury. The league was ready for war. The Roman leader Metellus Macedonicus defeated Critolaus north of the isthmus; Lucius Mummius, consul of 146, arrived and defeated Diaeus. Corinth was pillaged, its wealth of artistic treasures plundered and dispatched to Rome. The city was destroyed and abandoned.

The independent kingdom of Pergamum survived until 133, when its last king, Attalus III, died and, having no heir, bequeathed his territory to Rome. With the title of "Asia," it became Rome's seventh province.

Development of an empire

Beginnings of Roman provincial government. The Roman Empire was founded and developed as Rome successively assumed direct responsibility for the government and administration of conquered territories (provinces): of Sicily in 241, of Sardinia and Corsica (always administered as a single province) in 238, of Spain (the two provinces of Nearer and Farther Spain) in 197. It was at the start a western empire. Then, after half a century, came Macedonia (with Illyria and Achaea) and Africa in 146, and finally Pergamum (the province of Asia) in 133. Each province had a separate written constitution (a lex *provinciae*) with detailed regulations made by the conquering general in association with a commission of ten senators (*decem* legati) acting within broad regulations laid down by the Senate. This constitution named the cities within the province that retained their independence, uncontrolled by the governor's jurisdiction (civitates liberae); they were usually cities that had assisted Rome at the time of the conquest and that in some cases were already bound to Rome by treaty (*civitates foederatae*). The constitution also specified the nature of the taxation, whether direct (*stipendium*) or indirect (tithes [*decumae*] on agricultural production, which were the rule in Sicily and Sardinia).

Provincial *administrator*. At the head of the Roman administration were the annually appointed governor and the financial secretary (one of the quaestors of the year). The governor's function was expected to be predominantly administrative (he would constitute the province's high court of justice) and comparable to that of a praetor in Rome. Because the governor was normally a praetor, the number of praetors was, therefore, increased to four in 227 and to six in 197, lots being cast each year to determine the postings. But because the Hannibalic war and the great wars in the East made other demands on praetors (*e.g.*, naval command) it was frequently necessary to extend a governor's provincial command for more than a year. His power (*imperium*) remained the same, but after his magisterial year he was a propraetor or, more properly, a proconsul.

Only when there was a major war in a province, or the prospect of one, was a consul sent out to be its governor. This happened ten times in the case of Nearer Spain and four times in Farther Spain in the period 153–134 BC, and it happened in Sicily after the outbreak of a serious slave revolt in 134 and 133.

Central authority. Consciousness of imperial responsibility, which rested with the Senate, grew slowly and was, perhaps, never fully grasped (except in rare cases, such as by the elder Cato and the elder Tiberius Gracchus) until, under the empire of the Caesars, the responsibility was assumed by the emperor; and only when faced with undeniable evidence of misgovernment and corruption did the Senate take corrective measures. In 149, after a scandalous acquittal in a public trial of Servius Sulpicius Galba, a criminally corrupt governor of Farther Spain, a permanent court (the quaestio repetundarurn) was established in Rome, with senators as jurors, before which provincial subjects—provided that a Roman would act as their patron—could impeach Roman officials for extortionate practices.

The Roman economy was quick to feel the benefits, however unethical, of the great wars and of the new provinces. Apart from the wealth brought back to Rome in official and private loot, there were the indemnities from Carthage, Philip, and Antiochus. The grain paid in taxation in Sicily and Sardinia was sold in Rome at a price with which homegrown grain could not compete, with disastrous effects on large sections of Roman agriculture. Rome also gained wealth from the Spanish mines. In 167 the property tax for Roman citizens in Italy was abolished—evidence of imperialism's dividends.

Apart from brigandage, which had always been endemic in Sardinia, the island provinces, until the great Sicilian revolt of 134, caused little anxiety to the Roman government. Spain, however, was a different matter. Fighting in the mountains was difficult, the policy of resettling communities in cities in the plains was hard to enforce, and the peninsula was never completely conquered and pacified until the time of Augustus. From 154 there was continuous war against both the Lusitani in Farther Spain and against the Celtiberi in Nearer Spain—a war that produced a Spanish resistance leader of genius, Viriathus. After his murder in 139, the war continued until at last Scipio Aemilianus captured the stronghold of Numantia in 133. The war had its repercussions at home. Military service in Spain was exceedingly unpopular, and in both 151 and 138 tribunes imprisoned the consuls, so as to prevent the levies (behaviour that was to point the way to the Gracchi).

Securing the empire. Of the 70 consuls between 200 and 166 BC, 55 were engaged for part of their year of office in campaigning with armies in the north of Italy against the Gauls, particularly against the Ligurians in the northwest and the Boii in the northeast, with the object of clearing the northern Apennines and bringing the peninsula up to the Alps under firm control. Once a district was sufficiently pacified, Latin colonies were founded at strategic points, manned by Latins (and also, sometimes, by Romans) who were attracted by the prospect of free land even in potentially dangerous areas. And great roads were built—always a vital element in Romanization—for communication and, in particular, for the rapid movement of troops.

Establishment of colonial outposts

Particularly in the northeast, fighting was sometimes critical, sometimes a mere matter of triumph hunting (a "Ligurian Triumph" became an expression of mockery), and the serious fighting ended after Marcus Baebius Tamphilus, consul in 181, removed 40,000 Apuani with their families to the neighbourhood of Beneventum in southern Italy. A Latin colony was settled at Luca in 180, and a Roman colony at the port of Luna in 177. In the northeast a Latin colony was sent to Bononia (Bologna) in 189, and another, with unusually large allotments of land, to Aquileia in 181.

The names of the two consuls of 187 are perpetuated in the Via Flaminia from Arretium (Arezzo) to Bononia and in its continuation, the Via Aemilia, from Bononia to Placentia. In 175 Bononia was connected by road with Aquileia, and in 148 a road was driven diagonally across the peninsula from the Mediterranean through the Po Valley to the head of the Adriatic—the Via Postumia, which ran from Genna (Genoa) through Placentia, Cremona, and Verona to Aquileia.

In southern Italy a number of small citizen colonies, each of 300 settlers (coast-guard colonies), were dispatched to vital points on the coast after the Hannibalic war to strengthen coastal defense, particularly in view of fears of a possible invasion of Italy by Antiochus' fleet under the command of Hannibal. These were founded in 194: Puteoli, Salernum, Volturnum, Liternum, Sipontum, Buxentum, Croton, and Tempsa.

ROMAN GOVERNMENT, ECONOMY, AND CULTURE

Polybius, deeply experienced in the political life of the Hellenistic world, completed, during and after the time he was a hostage in Rome, a vast history of the years 264 to 146 BC that shows how Carthage and Macedonia during this period were absorbed into Rome's empire and how the rest of the Hellenistic world fell under the dominating influence of Rome. He tried to determine the secret of Rome's uninterrupted success. He might, as did Philip V (in a letter known from an inscription), have emphasized the liberality with which, in contrast to Greek city-states, Rome increased the number of its citizens through granting citizenship to slaves and aliens, and the manner in which it often resettled, instead of enslaving, conquered peoples. Or he could have stressed the system of clientela (the dependence of the poor and unprivileged on a rich and distinguished patron, which was reflected in public life when they recorded their votes), including foreign clientelae (the protection given to the interests of provincial subjects and foreign kings by particular Roman families of prominence). But he did not. He emphasized the binding force of Roman public religion as inducing in Roman public servants, through the sacrosanctity of oaths, an integrity that had no parallel in contemporary Greece. He was impressed by Roman loyalty to the state and, within the great families, loyalty to their own distinguished traditions. He stressed the unrivalled efficiency of the Roman army as a fighting force.

Elements of government. Above all, Polybius was struck by the manner in which the three elements—of monarchy (the consuls), aristocracy (the Senate), and democracy (the popular assemblies)—struck a balance of power that guaranteed a stable equilibrium; this is not an entirely attractive theory, however, because it greatly exaggerates the independent power and importance of the two annual consuls, whose position was anything but monarchical.

The Roman sovereign body was the Senatus Populusque Romanus (Senate and the Roman People). The Senate's membership depended on the two censors—very senior senators elected normally at five-year intervals. They admitted to the Senate those who had held the quaestorship within the preceding five years (quinquennium), and then they went through the list of existing senators, expelling those who had acquired any public notoriety (*infamia*), as Cato expelled the brother of Titus Quinctius Flamininus in 184 for scandalous behavior when campaigning in northern Italy. The revised list of senators was then published, the first name on the list being that of the princeps *Senatus*, who was invited to speak first in any debate at which he was present. Publius Scipio Africanus was *princeps Senatus* from 199 until his death, in 183; Marcus Aemilius Lepidus, from 179 until his death, in 152.

Qualifications for public service

In the early 2nd century rules were made governing the succession of offices in a public career (*cursus* honorum). The first such rule stated that no one could be elected consul if he had not already been praetor. In 180 minimum ages were established for holding office—for plebeians 36 was the minimum for the curule aedileship, 39 for the praetorship, and 42 for the consulship; patricians, it seems, could hold the magistracies two years earlier. The quaestorship could be held after the ten years' cavalry service done by youths of the upper classes (as against 16 years' infantry service to which others were liable). This service started at age 17; so the quaestorship could be held at age 27, though there are recorded cases when it was held at 25. Whether the quaestorship was an essential part of the *cursus* is uncertain. Tenure in the curule aedileship and the tribunate of the plebs were not compulsory; but the ambitious rarely omitted them because they offered an opportunity to win popularity, which was likely to be reflected in the voting when candidates stood for the praetorship. (The curule aediles were responsible for the public games, and the tribunes of the plebs had the opportunity to champion popular discontents; for instance, during the calling-up for the wars in Spain in 151 and 138, the tribunes stopped the enrollment of soldiers by imprisoning the consuls.) Beginning in 267 there were eight quaestors, whose duties were largely concerned with public finance; there were four aediles (two plebeian, two curule), and ten tribunes. Before 227 there were two praetors (the second, praetor peregrinus, since 242), who were wholly occupied with judicial duties in Rome; after 227 there were four, and after 197 there were six, the additional praetors being required as provincial governors.

The consuls. There were two consuls; therefore, only one in four of those elected to the quaestorship could eventually reach the consulship and so ennoble his family, if it was not noble already (the *nobiles* were families that could number a consul among their ancestors).

If both consuls were in Rome, they held the fasces (badge of authority) and presided in the Senate on alternate months, the consul who had headed the poll presiding in the first month of the year (March until 153 and January after that). In the period of the great wars, however, the consuls generally left Rome early in the year, after they had discharged their necessary formal obligations (for instance, the celebration of the Latin games on Mons Albanus), in order to command armies on campaign; they normally returned at the end of the campaigning season. In the interval, the urban praetor presided over meetings of the Senate.

One of the consuls was made responsible for the holding of the elections, which took place late in the year. If the consul was unable to return to Rome for this purpose, he could nominate a dictator—a man who held office for three nundinae (probably 17 days) and had no other function to perform. If both consuls died before the elections or if the year ended without the elections taking place, there was an interregnum (sovereignty reverting to the patrician members of the Senate, as had happened in early days after the death of a king). An interrex then held the election.

A consul or praetor, on the termination of his magistracy, could retain his imperium with the title of promagistrate (proconsul or propraetor); such extension of *imperium* and use of promagistrates developed quickly during the Second Punic War because the number of necessary military commands exceeded the number of available magistrates. The former consuls Publius Cornelius Scipio and his brother, for instance, commanded in Spain as proconsuls until they were killed in 211. This practice was continued and extended to meet the exigencies of provincial government in the second and first centuries.

Political debates in the Senate

The Senate. Although there were public meetings (*contiones*), it was in the Senate that political debates on the highest issues of state took place. Members were invited to speak in order of seniority, a fact that explains the great weight and importance of the former consuls (the *consulares*) in the Senate. In the middle republic these were members of a limited number of the great families whose influence, exerted through their clientes, assured their election—consuls and praetors were elected by the Comitia Centuriata, in which the rich exercised a predominant influence. The results of the elections show clearly that the presiding magistrate was able to exert great influence in favour of candidates who were related to him or who were his political associates.

In the Senate the consulares did not speak with a single voice; and there was strong infighting, certain families—for example, the Cornelii Scipiones and the Aemilii, and the Claudii and the Fulvii—being closely linked in political friendship (*amicitia*) with one another and in opposition (inimicitiae) to other groups. Such groupings, however, were not rigid, for groups dissolved and re-formed around particular prominent political figures and the policies favoured by those politicians. The Scipios, for example, favoured considerate and friendly relations with the Hellenistic kings and welcomed the genial influence of Greek civilization on Roman life, which Cato opposed. In the years around 170 a new ruthlessness marked Roman foreign policy, and this seems to have been largely due to the influence of the Fulvian group, including Marcius Philippus and Popillius Laenas, who were then in a controlling position in Roman politics.

Some of the personal antagonism of leading members of the great families was shown in the opposition of Fabius Maximus to Scipio Africanus, and it assumed great virulence early in the 2nd century. There was an attempt to deny Acilius Glabrio, consul of 191 (a new man and a protégé of the Scipios), a triumph for his great success in Greece, and soon afterward there came an attack on the integrity of Africanus and his brother Lucius in their dealings with Antiochus. In consequence, both Acilius and Lucius failed to be elected to the censorship, and Africanus spent his last years at Liternum in Campania in a kind of banishment. Similar attacks were launched against Manlius Vulso after his campaign in Asia Minor in 189. This kind of personal hostility could harm Roman interests if a commander in the field was prepared to make peace with an enemy on disadvantageous terms rather than allow his successor the credit of victory, or if a commander tried to overturn a peace so as to continue a war under his own command: in 201 the consul Gnaeus Cornelius Lentulus tried, without success, to overturn the peace with Carthage made after Zama.

Thanks to its cool-headed direction of the Second Punic War, the power of the Senate increased insensibly. In the alarm caused by the exposure of the Bacchanalian conspiracy in 186 (see below Religion), nobody objected to the Senate's behaviour in empowering the consuls to put even citizens to death, though by law a citizen could only be executed after trial and condemnation by the People. Similar behaviour by the Senate in the case of Tiberius Gracchus' supporters in 132 was to be exposed as unconstitutional by Gaius Gracchus nine years later.

The Senate's role in war

The declaration of war and the making of peace were still the formal responsibility of the People, as was shown particularly in the declaration of the First Punic and Second Macedonian wars; but the administrative arrangements that followed peace were in the Senate's hands. If the Senate decided that a conquered land should be made a Roman province, the Senate itself decided the general lines on which the new province should be organized and, as has been seen, sent out ten of its members to collaborate with the victorious general on the spot in giving detailed effect to its general resolution, as well as to issue the charter of the province.

Popular assemblies. The oldest of Rome's effective assemblies, the Comitia Centuriata, was not a democratic body. Of the 193 voting units (after the reform of 241), 70 belonged to the highest of the five property classes and 18 to the aristocratic cavalry (equites equo publico), so that the rich came near to having an absolute majority of votes. A junior century of the top property class (centuria praerogativa) voted first; and its vote, when announced, influenced the voting of the other centuries. The legislative Comitia Tributa, which also elected the quaestors, was more democratic because the voting unit was the tribe; but in the 3rd century BC few members of the 31 country tribes, apart from the rich, could spare the time to come to Rome to vote, so the result was the same. During the 2nd century, however, a big change took place; the population of Rome grew rapidly on account of the drift to the city of the ruined peasantry, who had lost their farms through the spread of large grazing estates (latifundia). These immigrants remained members of their original country tribes, so that by the middle of the 2nd century the Comitia Tributa (and likewise the Concilium Plebis) became representative bodies of the city dwellers of Rome itself.

In the matter of legislation, the Comitia Centuriata and the Comitia Tributa could vote only on measures that had already been approved by the Senate. The Concilium Plebis, on the other hand, under the presidency of the tribunes, had received in 287 the right to legislate for the whole Roman people without consultation of the Senate; and the way seemed open to extreme democracy. This development was arrested by the invasion of Pyrrhus (280) and the succession of great wars. A land bill of Gaius Flaminius in 232, carried against the wishes of the Senate, was a rarity. Normally, if conservative interests were threatened by a revolutionary, or even a reforming, tribune, it was not difficult to persuade one of his nine colleagues, with promises of support in his political future, to veto a proposal. This was the simple means by which Tiberius Gracchus' opponents expected to kill his land bill in 133; and the bill would have failed if Tiberius Gracchus had not been prepared to act in violation of the Roman constitution by persuading the plebs to unseat the dissenting Octavius.

As long as there was an open system of voting, without ballots, the rich and powerful, acting through their agents, were able by intimidation to control the voting of their clients. There was, therefore, strong conservative opposition to the introduction of voting by ballot, with its attendant secrecy, for elections in 139 (Lex Gabinia Tabellaria) and for legislation in 131 (Lex Papiria Tabellaria).

By very early Roman law, constantly re-enacted, no Roman citizen could be executed except after condemnation by the People; and so the People in the Comitia constituted the supreme criminal court of Rome. Impeachment could be by a tribune or an aedile; this popular function was supplemented, and in the end replaced, by the creation of permanent criminal courts, sitting under a praetor, on the model of the quaestio *repetundarum*, the permanent court to handle extortion cases, established by a bill of the tribune Calpurnius Piso in 149.

There was another field in which the People were not altogether voiceless or ineffective. It was at a meeting of the Comitia Tributa under the presidency of tribunes that, despite his youth and inexperience, young Publius Cornelius Scipio was sent to command in Spain in 210; and it was as a result of popular outcry in favour of disregarding legal requirements concerning the minimum age for the consulship that even the Comitia Centuriata in 148 decided that Scipio Aemilianus, a candidate for the aedileship, should instead be elected consul and sent to conduct the war against Carthage. Thus there were 3rd-

and 2nd-century precedents for the extraordinary popular commands of the last decades of the republic.

Economy. By the Lex Claudia of 218, senators and their sons were effectively precluded from trading by being forbidden to own vessels larger than those necessary for shipping produce from their estates to Rome; but it would be a mistake to think of them as utterly distinct from the business and trading class, for they might have relatives who were in business, and even the senators themselves might carry on enterprises in the name of one of their freedmen. Nonetheless, the Senate seemed to show a complete lack of concern with imperial commercial expansion, as evidenced by the closure of the Macedonian mines in 167 and the destruction 21 years later of two of the finest harbours in the Mediterranean—Corinth and Carthage.

Private enterprise

At the same time there were large business interests operated by a class of men that later developed into the equestrian order. As has been seen, during this period many of the great roads of Italy were constructed; and, indeed, the first of the great imperial roads—the Via Egnatia from Dyrrhachium and Apollonia to Thessalonica—was built not long after 146. Tenders for such work were submitted to the censors who, after scrutiny, allotted the contracts. In Spain the state soon abandoned its first attempt to manage the mines and handed the management over to private enterprise, the contractors paying a rent to the state. There were contracts for the arming and equipping of the Roman armies, which must have required particularly large quantities of leather. After Cannae the companies (societates) of contractors agreed to defer payment on condition of being fully insured against losses by storm or war.

The greatest economic change in Italy was the rapid development (in the early 2nd century) of ranching as a major industry, particularly in Campania and south Italy, which had been devastated and depopulated as a result of Hannibal's occupation. Rich men extended their holdings by encroaching on public land (ager publicus), partly by buying up at a low price the small farms of those who, largely through extended periods of military service (particularly in Spain), were no longer able to work their holdings at a profit. Thus, large estates (*saltus*, pascua) came into existence, partly in hill country for summer grazing, partly in the plains for winter grazing. In the south, sheep were raised, farther north, oxen, the hides of which produced the leather that was so badly needed.

These enterprises were assisted by the ready availability of cheap slaves, captives from the wars in the East. The slaves were tough men whose labour was ruthlessly exploited; they were often chained, and they slept in slave prisons (*ergastula*). Large numbers were required—to fight off wild beasts and to prevent cattle rustling.

These great grazing estates, the latifundia that, in the elder Pliny's famous expression, "were the destruction of Italy," had nothing in common with the medium-sized and large arable farms, on the economy and management of which the elder Cato wrote his De agricultura. Cato, indeed, discussing means of making a fortune, dismissed commerce as risky and moneylending as being disreputable in itself and said that more money could be made by ownership of even a poor ranch than by agriculture.

Demographically, the swelling of the population of the big towns, particularly Rome, by immigration of dispossessed small farmers was a striking feature of the first half of the 2nd century and was the movement which Tiberius Gracchus later (133) tried to reverse. In the country towns the immigrants made what money they could as casual labourers, and it is doubtful that there was much unemployment among the expanding population of Rome. Grain production in the vicinity of Rome and the large coastal towns of Italy dropped heavily as a result of the import of tax grain from Sicily and Sardinia; but in the north agriculture flourished in the rich plain of the Po Valley (Gallia Cisalpina).

The rapid growth of luxury imports and also of the number of slaves from the eastern Mediterranean brought Roman and Italian businessmen in large numbers to the East, particularly to Delos (made a free port in 166), where a large Roman and Italian business community came into existence; many thousands of persons a day are said to have passed through the Delos slave market. There were numbers of Roman settlers in the western provinces, too. Wounded Roman soldiers were left behind at Italica in Spain by Scipio Africanus in the Second Punic War. In 171 about 6,000 sons of Roman soldiers who had married Spanish women established the first Latin colony outside Italy, at Carteia, near Gibraltar.

Culture. From the 5th century onward Rome had received mention by Greek historians; after its defeat of Pyrrhus, when Ptolemy II made diplomatic overtures to the city, its formidable potential was evidently recognized in the Hellenistic world, and soon after that Timaeus wrote at length of Italy and Rome in his Sicilian history. By 217 mainland Greece was frighteningly aware of "the cloud in the West"—the victor, whichever it should be, of the Second Punic War. Both of the belligerents were "barbarians" in the technical Greek sense of the word; Rome's very name—"rhōmē"—was a Greek word and meant "brute force."

Hellenizing influences on Rome

In sharp contrast was the impact the Greek world made on the Romans, first in Campania in the 4th century, then in Sicily and Greece. There were magnificent temples, centuries old, permanent stone theatres, public baths (hot baths at that), and luxurious private houses. There were performances of classical and modern tragedy and comedy in the theatres. There were exercises and athletics in the palaestrae of the baths and at public festivals, with young men competing naked—"Greek games," by which Romans were always a little shocked. There was the Greek language, infinitely more delicate and flexible than contemporary Latin; there was the treasure-house of Greek literature, from Homer onward; and there was the deeply embedded Greek interest in philosophy, in argument, in questioning the truth of what, to the Romans, were fundamentals—traditions of religion and government. Rome had to come to terms with this newly discovered dynamic and to determine if it was to enrich Roman life or to serve as a catalyst.

Language. The children of upper class Roman families now learned to speak Greek—often from a Greek slave nurse—at a very early age; and Greek literature was taught, either in school or by a family tutor, a Greek freedman or slave. As a result, the educated Roman of the 2nd century BC was bilingual and was fluent in both languages. It has been suggested that in the family of the younger Scipio, Greek, not Latin, was the language of general conversation.

Literature. Greek literature offered a challenge that was accepted. The Roman poet and dramatist Lucius Livius Andronicus (c. 284–c. 204) published a Latin version of Homer's Odyssey; Gnaeus Naevius (*c.* 270–c. 199) wrote a Latin epic on the First Punic War, set against Rome's early background; and Quintus Ennius (239–169), a Calabrian, wrote an epic history of Rome to 171 BC—the Annales. Roman drama made its debut as an adaptation of Greek, though it sought to be distinctively Roman. Livius Andronicus was the first playwright. Naevius, Marcus Pacuvius (c. 220–*c.* 130), who came from Brundisium, and Pacuvius' uncle Ennius were prolific authors of tragedies. Ennius and Gaius Lucilius (*c.* 180–103/102), respectively, gave a start to the distinctively Roman genres of affable and of hard-biting satire. There were comedies, too—Roman adaptations of Greek Middle Comedy but with a distinctively Roman veneer—in this genre Plautus (born c. 254), an Umbrian, and Terence (c. 186/185–159), who was of Libyan stock, were preeminent (21 comedies of Plautus survive, six of Terence). Plays were acted at Roman festivals on improvised platforms in front of temples, with temporary seats erected for the audience. (There was no permanent stone theatre at Rome until 55 BC.)

Historiography. While, with the exception of Lucilius, Rome's earliest literary figures were men of obscure origins, the first writing of history by Romans was done by politicians (the earliest of them, Quintus Fabius Pictor, flourished at the end of the 3rd century). And so a lasting Roman tradition was established that historical writing was a field for men with experience in public affairs. Based on briefly annotated lists of magistrates preserved by the pontiffs and on the vainglorious traditions of the great families, early Roman history before the invasion of Pyrrhus was largely fictional. The first histories were written in Greek, partly to counter hostile accounts of Rome by contemporary Greeks, including accounts of the Punic Wars written from the Carthaginian standpoint. Cato's history (*Origines*), however, was written in Latin and set the fashion for the future.

Religion. Greek religion both startled and frightened the Romans; unlike Roman religion, it was anthropomorphic, and the Greek world was full of statues—often of the highest art—of Greek gods and goddesses in the image of men and women. At the same time, contemporary Greek skepticism shocked the fundamental piety of the Romans. On the instruction of the Oracle at Delphi, a black stone from Pessinus in Asia Minor was sent to Rome in 205–204 and, worshipped as the Great Mother, became an object of Roman cult, though with Oriental, not Roman, priests. New orgiastic cults seeped in; and in 186 there was panic on the discovery of the existence of a widely diffused cult of Bacchus, which seemingly involved not only unspeakable immorality but also a plot to overthrow the established government. A witch hunt and a spate of executions followed before the cult was transformed to one of closely supervised respectability, not only in Rome but throughout Italy.

Dangers to the traditional life

Philosophical currents. The firm stability of Roman traditional life was endangered, conservatives thought, not only by such orgiastic cults and by the increasing popularity among the wealthy of luxurious homes (with hot baths) but also by the acute logic of Greek philosophers who used reason to destroy belief and by the persuasive arts of Greek rhetoricians. In Rome they shocked the old, but they fascinated the young. Thus, when three distinguished Greek philosophers arrived in Rome in 155 to urge the return of the surviving Achaean hostages and conducted widely attended public discussions, Cato had them bundled out of the city. Greek ideas of social equality were utterly un-Roman—ideas by which, it would be claimed, Tiberius Gracchus was corrupted. On the other hand, Stoic ethics were supremely adapted to suit the best Roman mores.

Two schools of thought existed from the start. Both Scipios were patrons of the new writers—Scipio Aemilianus had such Greeks as Polybius and the Rhodian philosopher and historian Panaetius as his friends; Cato opposed them, himself tutoring his son rather than employing a Greek tutor. But Cato was not a fool; he learned Greek as did everybody else. Yet, morbidly fascinated by the spectre of their own decline, later Romans accepted the commonplace that Eastern conquest had weakened the tough Roman fibre, in particular because it introduced new and extravagant tastes.

Law. Only in law did Greece exercise little influence on Rome. Based on the Twelve Tables that schoolboys had to learn by heart, Roman law was amplified by successive laws and senatorial resolutions (jus civile), by the interpretations of successive praetors (jus *honorarium*), and by the teaching of the jurists—the earliest of them Tiberius Coruncanius, consul of 280 BC and the first plebeian pontifer *maximus* ("chief priest"). (J.P.V.D.B.)

III. The late republic (133–31 BC)

The fall of Carthage and Corinth did not mark even a temporary end to warfare. For a few years the interminable wars in Spain dragged on—against the Lusitanian leader Viriathus (who had rallied that tribe and won some important victories) in the south and against the Celtiberi based on Numantia in the centre of the peninsula. The sorry tale of Roman defeats, treaties concluded and broken, perfidy, and genocide continued to mark these wars as no others in republican history. But Roman methods finally triumphed. Viriathus was assassinated, and resistance in the south soon ended. The Numantines forced a Roman consular army under Gaius Hostilius Mancinus to surrender in order to escape destruction, and Mancinus promised them peace (137 BC)—an act that inevitably was disavowed by the Senate. Finally, in 134 Publius Cornelius Scipio Aemilianus—again elected consul—enrolled an army consisting chiefly of private clients from all over the Roman world (thus avoiding the internal troubles caused by major levies for the unpopular Spanish fiont) and finished the war with the capture and destruction of Numantia, whose inhabitants were killed or enslaved (133). The long wars were over at last, and although the pictuie of peaceful development in Spain must not be exaggerated (five Spanish triumphs are recorded in the 50 years between the time of Scipio and that of Sulla), Spanish wars were no longer a running sore in Roman political life.

End of the wars in Spain

THE AFTERMATH OF THE VICTORIES

War and military glory were an essential part of the Roman aristociatic ethos and, hence, of Roman political life. Apart from major wars still to come, small wars on the frontiers of Roman power—never precisely fixed—continue to provide an essential motive in Roman history: in Spain, Sardinia, Illyria, and Macedonia, barbarians could be defeated and triumphs won. Thus the limits of Roman power were gradually extended, and the territories within them pacified, while men of noble stock rivalled the virtus (courage and qualities of leadership) of their ancestors, and new men staked their own competing claims, winning glory essential to political advancement and sharing the booty with their officers and soldiers. Cicero could still depict it as a major disgrace for Lucius Piso (consul 58 BC) that he had won no triumph in the traditionally "triumphal" province of Macedonia. Nonetheless, the coincidence of the capture of Corinth and Carthage was even in antiquity regarded as a turning point in Roman history: it was the end (for the time being) of warfare against civilized powers, in which the danger was felt to be greater and the glory and the booty were out of proportion to those won against barbarian tribes.

Provincial administration. The first immediate effect was on the administration of the empire. The military basis of provincial administration remained: the governor (as he is called) was in Roman eyes a commander with absolute and unappealable powers (*imperium*) over all except Roman citizens, within the limits (his provincia) assigned to him (normally) by the Senate. He was always prepared—and in some provinces expected—to fight and win. But it had been found that those unlimited powers were often abused and that Senate control could not easily be asserted at increasing distances from Rome. For political and perhaps for moral reasons, excessive abuse without hope of a remedy could not be permitted. Hence, when the decision to annex Carthage and Macedonia had been taken in principle (149 BC), a permanent court (the quaestio repetundarum) was established at Rome to hear complaints against former commanders and, where necessary, to assure repayment of illegal exactions. No penalty for offenders was provided, and there was no derogation from the commander's powers during his tenure; nevertheless, the step was a landmark in the recognition of imperial responsibility, and it was also to have important effects on Roman politics. Another result of the new conquests was a major administrative departure. When Africa and Macedonia became *provinciae* to be regularly assigned to commanders, it was decided to break with precedent by not increasing the number of senior magistrates (praetors). Instead, prorogation—the device of leaving a magistrate in office pro *magistratu* ("in place of a magistrate") after his term had expired, which had hitherto been freely used when emergencies led to shortages of regular commanders—was established as part of the administrative system: thenceforth, every year at least two praetors would have to be retained as promagistrates. This was the beginning of that dissociation between urban magistracy and foreign command that was to become a cardinal principle of the system of Sulla and of the developed Roman Empire.

Social and economic ills. It is not clear to what extent the temporary end of the age of major wars helped to produce the crisis of the Roman Republic. The general view of thinking Romans was that the relaxation of external pressures led to internal disintegration. This has happened in other states and the view is not to be lightly dismissed. Moreover, the end of large-scale booty led to economic recession in Rome, thus intensifying poverty and discontent. But the underlying crisis had been building up over a long period. In view of the inadequacy of the source material and the still limited results of archaeological research, its nature cannot be confidently defined. But some facts are certain. Large tracts of southern Italy had been devastated in the Hannibalic war and, partly for ecological reasons, never recovered. Little successful resettlement took place on the land confiscated there by Rome from rebellious allies after victory, and much of it was turned over to grazing, chiefly by transhumance methods, hence chiefly exploited by wealthy Romans. Nearer Rome, imports of provincial wheat destroyed local wheat growing, with the result that peasants were driven off the land and flocked into the city, while their holdings were bought up by wealthy neighbours and often consolidated into medium-sized mixed farms. It was for this class of men that Cato wrote his book De agricultura. Farther north, causes and effects alike were less catastrophic; but long wars overseas and rigorous conscription led to the decline of peasant holdings and the accumulation of land. A population drift to the cities (both Rome and the country towns) is noticeable by mid-century, with the towns apparently growing and prospering and, no doubt, attracting peasants, who, by selling out and moving there, would cease to be landowners and liable to the draft. Their divorce from the land, however, was not absolute: seasonal work in agriculture always helped to provide a livelihood for former peasants and their families.

Intensified poverty and discontent

Rich landowners probably put tenants in the place of the peasants they had bought out; if progressive, they might change over to Cato's kind of mixed farming, based on slave labour and supplemented by seasonal free labour as required. Rich men owned many medium-sized estates, rounded off by occupation of public land; but there is little evidence of consolidated plantation-type estates such as were found in some provinces and later in Italy as well. Archaeological evidence, even quite near Rome, predominantly shows small- and medium-scale farming. This, however, might well go with the substitution of slaves and tenants (coloni) for free owners and the drift to the towns on the part of the latter.

THE REFORM MOVEMENT OF THE GRACCHI (133–121 BC)

From the state's point of view, the chief effect was a decline in military manpower. The minimum property qualification for service was lowered, the minimum age (17) ignored; resistance became frequent, especially to the distant and unending guerrilla war in Spain.

The program and career of Tiberius Sempronius Gracchus. Tiberius Gracchus, grandson of Scipio Africanus and son of the Gracchus who had conquered the Celtiberi and treated them well, was quaestor in Mancinus' army when it faced annihilation; on the strength of his family name, he personally negotiated the peace that saved it. When the Senate—on the motion of his cousin Scipio Aemilianus, who later finished the war—renounced the peace, Tiberius felt aggrieved and joined a group of senior senators hostile to Aemilianus and with ideas on reform. Elected tribune for 133, in Scipio's absence, Tiberius attempted to find a solution for the social and military crisis, with the political credit to go to himself and his backers. Tiberius had no intention of touching private property; his idea was to enforce the legal but widely ignored limit of about 300 acres (120 hectares) on occupation of public land and to use the land thus retrieved for settling landless citizens, who would both regain a secure living and be liable for service. A slave war in Sicily, lasting several years and threatening to spread to Italy, had underlined both the danger of using large numbers of slaves on the land and the need for a major increase in military citizen manpower.

Plan to settle landless citizens

Tiberius' proposal was bound to meet with opposition in the Senate, which consisted of large landowners. On the advice of his eminent backers, he took his bill—which made various concessions to those asked to obey the law and hand back excess public land—straight to the Assembly of the Plebs, where it found wide support. This was not revolutionary; bills directly concerning the People appear to have been frequently passed in this way. But his opponents persuaded another aristocratic tribune, Marcus Octavius, to veto the bill. Tiberius tried the constitutional riposte: an appeal to the Senate for arbitration. But the Senate was unwilling to help, and Octavius was unwilling to negotiate over his veto—an action apparently unprecedented, though not (strictly speaking) unconstitutional. Tiberius had to improvise a way out of the impasse. He met Octavius' action with a similarly unprecedented retort, and had Octavius deposed by the Assembly. He then passed his bill in a less conciliatory form and had himself, his father-in-law, and his brother appointed commissioners with powers to determine boundaries of public land, confiscate excess acreage, and divide it in inalienable allotments among landless citizens. As it happened, envoys from Pergamum had arrived to inform the Senate that Attalus III had died and made the Roman People his heirs (provided the cities of his kingdom were left free). Tiberius, at whose house the envoys were lodging, anticipated Senate debate and had the inheritance accepted by the People and the money used to finance his agrarian schemes.

Tiberius' opponents now charged him with aiming at tyranny, a charge that many may well have believed: redistribution of land was connected with demagogic tyranny in Hellenistic states, and Tiberius' subsequent actions had been high-handed and beyond the flexible borderline of what was regarded as mos *majorum* (constitutional custom). Fearing prosecution after he left office, he now began to canvass for a second tribunate—another unprecedented act, bound to reinforce fears of tyranny. The elections took place in an atmosphere of violence, with nearly all his tribunician colleagues now opposed to him. When the consul Publius Scaevola, on strict legal grounds, refused to act against him, Publius Scipio Nasica, the chief pontiff, led a number of senators and their clients to the Assembly, and Tiberius was killed in a resulting scuffle. Widespread and bloody repression followed in 132. Thus political murder and political martyrdom were introduced into Roman politics.

Introduction of political murder and martyrdom into Roman politics

The land commission, however, was allowed to continue because it could not easily be stopped. Some evidence of its activities survives. By **129,** perhaps running out of available land held by citizens, it began to apply the Gracchan law to public land held by Italian individuals or communities. This had probably not been envisaged by Tiberius, just as he did not include noncitizens among the beneficiaries of distributions. The Senate, on the motion of Scipio Aemilianus, upheld the Italians' protests, transferring decisions concerning Italian-held land from the commission to a consul. This seriously hampered the commission's activities. Marcus Fulvius Flaccus, chairman of the commission and consul in **125,** tried to solve the problem by offering the Italians the citizenship (or alternatively the right to appeal against Roman executive acts to the Roman People) in return for bringing their holdings of public land under the Gracchan law. This aroused fears of uncontrollable political repercussions. Flaccus was ordered by the Senate to fight a war in southern France (where he gained a triumph) and had to abandon his proposal. There is no sign of widespread Italian interest in it at this time, though the revolt of the Latin colony Fregellae (destroyed **125)** may be connected with its failure.

The program and career of Gaius Sempronius Gracchus. In 123 Gaius Gracchus, a younger brother of Tiberius, became tribune. He had served on Tiberius' land commission and had supported Flaccus' plan. Making the most of his martyred brother's name, Gaius embarked on a scheme of general reform in which, for the first time in Rome, Greek theoretical influences may be traced. Among many reforms—including provision for a stable and cheap wheat price and for the foundation of colonies (one on the site of Carthage), to which Italians were admitted—two major ideas stand out: to increase public revenues (both from the empire and from taxes) and pass the benefit on to the people; and to raise the wealthiest nonsenators (particularly the equites, holders of the "public horse"—who received state financial aid for the purchase and upkeep of their horses—and next to senators in social standing) to a position from which, without actually taking part in the process of government, they could watch over senatorial administration and make it more responsible. The idea was evoked by Tiberius' death. As early as 129 a law compelled senators to surrender the "public horse" (which hitherto they had also held) and possibly in other ways enhanced the class-consciousness and privileges of the equites. Gaius put the *publicani* (public contractors, hitherto chiefly concerned with army and building contracts and with farming minor taxes) in charge of the main tax of Asia—a rich province formed out of Attalus' inheritance, which would henceforth provide Rome with the major part of its public revenues. This was expected both to reduce senatorial corruption and to improve efficiency. Gaius also put eminent nonsenators (probably defined by wealth, but perhaps limited to the equites, or equestrian class) in charge of the *quaestio repetundarum*, whose senatorial members had shown too much leniency to their colleagues, and he imposed severe penalties on senators convicted by that court. Finally, in a second tribunate, he hoped to give citizenship to Latins and Latin rights to other Italians, with the help of Flaccus who, though a distinguished former consul, took the unique step of becoming tribune. But a consul and a tribune of 122 combined to persuade the citizen voters that it was against their interests to share the privileges of citizenship: the bill was defeated, and Gaius failed in his attempt to be re-elected once more. In 121, preparing (as private citizens) to use force to oppose the cancellation of some of their laws, Gaius and Flaccus were killed in a riot, and many of their followers were executed.

During the next decade the measures benefitting the people were largely abolished, though the Gracchan land distributions, converted into private property, did temporarily strengthen the Roman citizen peasantry. The provisions giving power to wealthy nonsenators could not be touched, for political reasons, and they survived as the chief effect of Gaius' tribunates. The court seems to have worked better than before, and, during the next generation, several other standing criminal courts were instituted, as were occasional ad hoc tribunals, always with the same class of jurors. In 106 a law adding senators to the juries was passed, but it remained in force for only a short time.

THE REPUBLIC (C. 121–91 BC)

Struggles of the aristocratic families

War against Jugurtha. Since Roman historians were no more interested in politics than (on the whole) in social or economic developments, the struggles of the aristocratic families must be pieced together from chance information. It would be mere paradox to deny the importance in republican Rome, as in better known aristocratic republics, of family feuds, alliances, and policies, and parts of the picture are known: *e.g.*, the central importance of the family of the Metelli, prominent in politics for a generation after the Gracchi and dominant for part of that time. In foreign affairs the client kingdom of Numidia—loyal ever since its institution by Scipio Africanus—assumed quite unwarranted importance when a succession crisis developed there soon after 120, as a bastard, Jugurtha, relying on superior ability and aristocratic Roman connections, sought to oust his two legitimate brothers from their shares of the divided kingdom. Rome's usual diplomatic methods failed to stop Jugurtha, who disposed of his brothers, but the massacre of Italian settlers at Cirta by his soldiers forced the Senate to declare war (112). The war was waged reluctantly and ineffectively, with the result that charges of bribery were freely bandied about by demagogic tribunes taking advantage of suspicion of aristocratic political behaviour that had smouldered ever since the Gracchan crisis. Significantly, some eminent men, hated from those days, were now convicted of conuption. The Metelli, however, emerged unscathed, and Quintus Metellus, consul in 109, was entrusted with the war in Africa. He waged it with obvious competence but failed to finish it and thus gave Gaius Marius, a senior officer, his chance.

The career of Gaius Marius. Marius, born of an equestrian family at Arpinum, had attracted the attention of Scipio Aemilianus as a young soldier and, by shrewd political opportunism, had risen to the praetorship and married into the patrician family of the Julii Caesares. Though he had deeply offended the Metelli, once his patrons, Marius' military talents were considerable, and Quintus Metellus had taken him to Africa as a *legatus.* Marius intrigued against his commander in order to gain a consulship; he was elected (chiefly with the help of the equites and anti-aristocratic tribunes) for 107 and was given charge of the war by special vote of the People. He did little better than Metellus had, but in 105 his quaestor Lucius Sulla, in delicate and dangerous negotiations, brought about the capture of Jugurtha, opportunely winning the war for Marius and Rome.

Roman sphere of influence in southern France

During the preceding decade a serious threat to Italy had developed in the north. Starting in 125, several Roman commanders (Marcus Flaccus has been noted) had fought against Ligurian and Gallic tribes in southern France and had finally established a Roman sphere of influence there: a road had been built linking Italy with Spain, and some garrison posts probably secured it; finally, a colony was settled at Narbonne, one of the most important road junctions in the region (*c.* 118). But unwilling to extend administrative responsibilities, the Senate had refused to establish a regular *urovincia.* Then some migrating German tribes, chief of them the Cimbri, after defeating a Roman consul, invaded southern France, attracting native sympathy and finding little effective Roman opposition. Two more consular armies suffered defeat, and in October 105 a consul and proconsul with their forces were destroyed at Orange. There was panic in Rome, allayed only by the firm action of the other consul, Publius Rutilius Rufus.

At this moment news of Marius' success in Africa arrived, and he was at once dispensed from legal restrictions and again elected consul for 104. After a brilliant triumph, restoring Roman morale, he took over the army prepared and trained by Rutilius and was reelected consul year after year, while the German tribes delayed attacking Italy. Finally, in 102–101, he annihilated them at Aquae Sextiae (Aix-les-Bains) and, with his colleague Quintus Catulus, on the Campi Raudii (near the Po Delta). Another triumph and a sixth consulship (in 101) were his reward.

In his first consulship, Marius had taken a step of great (and probably unrecognized) importance: aware of the difficulties long endemic in the traditional system of recruitment, he had ignored property qualifications in enrolling his army and, as a result, had recruited ample volunteers from among men who had nothing to lose. This radical solution was thenceforth generally imitated, and conscription became confined to emergencies (like the Social and Civil wars). He also enhanced the importance of the legionary eagle (standard), thus beginning the process that led to each legion's having a continuing corporate identity. At the same time, Rutilius introduced arms drill and reformed the selection of senior officers. Various tactical reforms in due course led to the increasing prominence of the cohort (one tenth of a legion) as a tactical unit and the total reliance on non-Roman auxiliaries for light-armed and cavalry service. The precise development of these reforms cannot be traced, but they culminated in the much more effective armies of Pompey and Caesar.

Marius' African army had been unwilling to engage in another war, and Marius preferred to use newly levied soldiers (no longer difficult to find). But neither he nor the Senate seemed aware of any responsibilities to the veterans. In 103 a tribune, Lucius Saturninus, offered to pass a law providing land in Africa for them in return for Marius' support for some anti-oligarchic activities of his own. Marius agreed, and the large lots distributed to his veterans (both Roman and Italian) turned out to be the beginning of the Romanization of Africa. In 100, with the German wars ended, Saturninus again proved a welcome ally, arranging for the settlement of Marius' veterans in Gaul. An incidental effect was the departure of Marius' old commander and subsequent enemy, Quintus Metellus, who refused to recognize the validity of Saturninus' law and, choosing martyrdom, went into exile. But this time Saturninus exacted a high price. With his ally, the praetor Gaius Glaucia, he introduced laws to gain the favour of plebs and equites and proceeded to provide for the settlement of veterans of wars in Macedonia and Sicily in the same way as for those of Marius' war. He planned to seek re-election for 99, with Glaucia illegally gaining the consulship. Violence and even murder were freely used to accomplish these aims.

Marius' opposition to Saturninus and Glaucia

Marius now had to make a choice. Saturninus and Glaucia might secure him the continuing favour of the plebs and perhaps the equites, though they might also steal it for themselves. But as the saviour of his country, six times consul, he now hoped to become an elder statesman (*princeps*), accepted and honoured by those who had once looked down on him as an upstart. To this end he had long laboured, dealing out favours to aristocrats who might make useful allies. This was the only accepted reward for achievement; Marius never thought of revolution or tyranny. Hence, when called on to save the state from his revolutionary allies, he could not refuse. He imprisoned them and their armed adherents and did not prevent their being lynched. Yet, having saved the oligarchy from revolution, he received little reward; he lost the favour of the plebs, while the oligarchs, in view of both his birth and his earlier unscrupulous ambition, refused to accept him as their equal. Metellus was recalled; this was a bitter blow to Marius' prestige, and he preferred to leave Rome and visit Asia.

Before long a face-saving compromise was found, and Marius returned; but in the 90s he played no major part. Though he held his own when his friends and clients were attacked in the courts, his old aristocratic protégés now found more promising allies. Sulla is typical: closely associated with Marius in his early career, he was by 91 ready to take the lead in attacking Marius and (significantly) found eager support. The oligarchy could not forgive Marius.

WARS AND DICTATORSHIP (C. 91–80 BC)

Events in Asia. In foreign affairs the 90s were dominated by Asia, Rome's chief source of income. Mithradates VI, king of Pontus, had built a large empire around the Black Sea and was probing and intriguing in the Roman sphere of influence. Marius had met him and had given him a firm warning, temporarily effective: Mithradates had proper respect for Roman power. Scheming to annex Cappadocia, he had been thwarted by the Senate's instructing Sulla, as proconsul, to install a pro-Roman king there in 96–95. (It was on this occasion that Sulla received a Parthian embassy—the first contact between the two powers.) But dissatisfaction in the Roman province gave new hope to Mithradates. Ineffectively organized after annexation and corrupt in its cities' internal administration, Asia was soon overrun with Italian businessmen and Roman tax collectors. When the Senate realized the danger, it sent its most distinguished jurist, Quintus Mucius Scaevola (consul in 95 and pontifex *maxi*mus), on an unprecedented mission to reorganize Asia (94). He took Publius Rutilius Rufus—jurist, Stoic philosopher, and former consul—with him as his senior officer, and after Scaevola's return Rutilius remained behind, firmly applying the new principles. This caused an outcry from businessmen, whose profits he had kept within bounds: he was prosecuted for "extortion" in 92 and convicted after a trial in which Roman publicani and businessmen unscrupulously used their power among the class that provided criminal juries. The verdict revealed the breakdown of Gaius Gracchus' system: the class he had raised to watch over the Senate now held irresponsible power, making orderly administration impossible and endangering the empire. Various leading senators were at once vexatiously prosecuted, and political chaos threatened.

Developments in Italy. The 90s also saw dangerous developments in Italy. In the 2nd century BC, Italians as a whole had shown little desire for Roman citizenship and had been remarkably submissive under exploitation and ill-treatment. The most active of their governing class flourished in overseas business, and the more traditionally minded were content to have their oligarchic rule supported by Rome. Their admission to citizenship had been proposed as a by-product of the Gracchan reforms. By 122, it had become clear that the Roman people agreed with the oligarchy in rejecting it. The sacrifices demanded of Italy in the Numidian and German wars probably increased dissatisfaction among Italians with their patent inferiority. Marius gave citizenship to some as a reward for military distinction—illegally, but his standing (*auctoritas*) sufficed to defend his actions. Saturninus admitted Italians to veteran settlements and tried to gain citizenship for some by full admission to Roman colonies. The censors of 97–96, aristocrats connected with Marius, shared his ideas and freely placed eminent Italians on the citizen registers. This might have allayed dissatisfaction, but the consuls of 95 passed a law purging the rolls and providing penalties for those guilty of fraudulent arrogation. The result was insecurity and danger for many leading Italians. By 92 there was talk of violence and conspiracy among desperate men.

Insecurity and danger for leading Italians

It was in these circumstances that the eminent young noble, Marcus Livius Drusus, became tribune for 91 and hoped to solve the menacing accumulation of problems by means of a major scheme of reforms. He attracted the support of the poor by agrarian and colonial legislation and tried to have all Italians admitted to citizenship and to solve the jury problem by a compromise: the courts would be transferred to the Senate, and 300 equites would be admitted to it. (To cope with the increase in business it would need this increase in size.) Some leading senators, frightened at the dangerous situation that had developed, gave weighty support. Had Drusus succeeded, the poor and the Italians might have been satisfied; the equites, deprived of their most ambitious element by promotion, might have acquiesced; and the Senate, always governed by the prestige of the noble principes rather than by votes and divisions, could have returned, little changed by the infusion of new blood, to its leading position in the process of government. But Drusus failed. Some members of each class affected were more conscious of the loss than of the gain; and an active consul, Lucius Philippus, provided leadership for their disparate opposition. After much violence, Drusus' laws were declared invalid. Finally he himself was assassinated. The Italians now rose in revolt (the Social War), and in Rome a special tribunal, manned by the Gracchan jury class, convicted many of Drusus' supporters until the Senate succeeded in suspending its sittings because of the military danger.

The Social War

The first year of the Social War (90) was dangerous: the tribes of central and southern Italy, traditionally among the best soldiers in Rome's wars, organized in a confederacy for the struggle that had been forced upon them. Fortunately all but one of the Latin cities—related to Rome by blood and tradition and specially favoured by Roman law—remained loyal: their governing class had for some time had the privilege of automatically acquiring Roman citizenship by holding local office. Moreover, Rome now showed its old ability to act quickly and wisely in emergencies: the consul Lucius Caesar passed a law giving citizenship to all Italians who wanted it. The measure came in time to head off major revolts in Umbria and Etruria, which accepted at once.

Civil war and the rule of Lucius Sulla. In 89 the war in central Italy was won, and Gnaeus Pompeius Strabo celebrated a triumph. Attention now turned to the East, where Mithradates had taken advantage of Rome's troubles to expel the kings of Cappadocia and Bithynia. A Roman embassy restored them, and he withdrew; but, when the envoys incited Bithynian incursions into his territory, Mithradates launched a major offensive, overrunning the two kingdoms and invading Roman territory, where he attracted the sympathy of the natives by executing thousands of Italians and defeated and captured the Roman commanders in the area.

Sulla's occupation of Rome

Sulla's rise to power. In Rome, various men, including Marius, had hoped for the Eastern command. But it went to Sulla, elected consul for 88 after distinguished service in the Social War. Publius Sulpicius, a tribune in that year and an old friend of Drusus, tried to continue the latter's policy of justice to the Italians by abolishing the gerrymandering that in practice deprived the new citizens of an effective vote. Finding the oligarchy firmly opposed, he gained the support of Marius (who still commanded much loyalty) for his plans by having the Eastern command transferred to him. After much street-fighting, the consuls escaped from Rome, and Sulpicius' bills were passed. Sulla's response was totally unforeseen: appealing to the army he had led in the Social War, still engaged in mopping-up operations in Campania, he persuaded them to march on Rome, which he occupied, executing Sulpicius; Marius and others escaped. Significantly, Sulla's officers left him. It was the first time a private army of citizens had occupied Rome—an effect of Marius' army reform, which had ended by creating a "client army" loyal chiefly to its commander, and of the Social War, which had made the use of force within Italy seem commonplace. The end of the republic was foreshadowed.

Having cowed Rome into acquiescence and passed some legislation, Sulla left for the East. Cinna, one of the consuls of 87, at once called for the overthrow of Sulla's measures. Resisted by his colleague Octavius, he left Rome to collect an army and, with the help of Marius, occupied the city after a siege. Several leading men were killed or condemned to death, Sulla and his supporters were outlawed, and (after Marius' death early in 86) another commander was sent to Asia. The policy now changed to one of reconciliation: the Social War was wound up, and the government gained wide acceptance until Cinna was killed by mutinous soldiers (85).

Dictatorship of Sulla. Sulla meanwhile easily defeated Mithradates' forces in two battles in Boeotia, took Athens, which under a revolutionary regime had declared for Mithradates, and cleared the King's army out of Greece. While negotiating with Cinna's government, Sulla also entered upon negotiations with Mithradates and, when he heard of Cinna's death, quickly made peace and an alliance with Mithradates, driving the government's commander in Asia to suicide. After wintering his troops in the rich cities of Asia, Sulla crossed to Greece and then to Italy, where his veteran army broke all resistance and occupied Rome (82). Sulla was elected dictator and, while Italy and all the provinces except Spain were quickly reduced. began a reign of terror (the "proscriptions"), in which hundreds of his enemies or those of his adherents were killed without trial, while their property went to enrich him and his friends. Wherever he had met resistance in Italy, land was expropriated and given to his soldiers for settlement.

While the terror was going on, Sulla used his powers to put through a comprehensive program of reform (81). Although he had twice taken Rome with a private proletarian army, he had earlier had connections with the inner circles of the oligarchy, and after Cinna's death some eminent men who had refused to collaborate with Cinna joined Sulla. By the time Sulla's success seemed certain, most of those who had collaborated were also on his side, and he was acclaimed as the defender of the nobility who had defeated an illegal revolutionary regime. His reforms aimed chiefly at stabilizing Senate authority by removing alternative centres of power. The tribunate was emasculated; the censors' powers were reduced; provincial governors were subjected to stricter Senate control; and the equites, who had been purged of Sulla's opponents by the proscriptions, were deprived of some symbols of dignity and made leaderless by the inclusion of 300 of Sulla's chief supporters in the Senate. The jury reform of Gaius Gracchus, seen by some leading senators as the prime cause of political disintegration, could now be undone and the criminal courts could once more become a monopoly of senators.

Sulla's attempt to restore stable government

Sulla's measures were by no means merely reactionary. His program was basically that of Marcus Drusus. His overriding aim was the restoration of stable government, and this could only come from the Senate, directed by the *principes* (former consuls and those they chose to consult). He accepted and even extended recent developments where they seemed useful: the Italians retained full citizenship; the system of standing criminal courts was expanded to include six or seven major crimes; the practice of praetors normally spending their year of office in Rome and then going to provinces for a second year was extended to consuls and became an integral part of his system. To prevent long command of armies (which might lead to careers like his own), he increased the number of praetors so that, in principle and in normal circumstances, each province might have a new governor every year. As for the overriding problem of poverty, his contribution to solving it was to settle tens of thousands of his veterans on land confiscated from enemies in Italy; they would be turned into "haves" and would be ready (using their military training) to defend the social order, in which they now had a stake, against "have-riots"--both old and newly created by proscription and confiscation.

The end of Sulla's rule. At the beginning of 80, Sulla laid down his dictatorship and became merely consul, with the senior Metellus (Quintus Metellus Pius), a relative of his wife, as his colleague. The state of emergency was officially ended. At the end of the year, Sulla retired to Campania as a private citizen, after seeing to the election of two reliable consuls, hoping that the restored oligarchy would learn to govern the state he had handed over to them. For 78 Marcus Lepidus, an ambitious patrician whom Sulla disliked and distrusted, was elected consul. Sulla did not intervene. Within a few months, Sulla was dead. Lepidus at once attacked his system, using the grievances of the expropriated as a rallying cry and his province of Gaul as a base. But he was easily defeated by his former colleague Quintus Catulus, assisted by young Gnaeus Pompeius (Pompey).

THE ROMAN STATE IN THE TWO DECADES AFTER SULLA (79–60 BC)

The early career of Pompey. Pompey was the son of Gnaeus Pompeius Strabo, who had triumphed after the Social War but had incurred general hatred because of cold-blooded duplicity during the troubles of 88 and 87. After Strabo's death, young Pompey, who had served under him and inherited his dubiously won wealth, was protected by Cinna's government against his father's enemies. Following in his father's footsteps, he deserted the government after Cinna's death, raised a force among his father's veterans in central Italy, and helped to conquer Italy and, in a lightning campaign, Sicily and the province of Africa for Sulla. Though not old enough to hold any regular magistracy (he was born in 106), he had. from these military bases, blackmailed Sulla into granting him a triumph (81) and had married into the core of the Sullan oligarchy. Out of pique against Sulla, he had supported Lepidus' election for 78, but he had too great a stake in the Sullan system to permit Lepidus to overthrow it.

Revolt of Sertorius

Meanwhile a more serious challenge to the system had arisen in Iberia. Quintus Sertorius, a former praetor of tough Sabine gentry stock, had refused to follow most of his social betters in joining the invader of Italy; he had left for Spain, where he claimed to represent the legitimate government. Although acting throughout as a Roman proconsul, with a "counter-Senate" of eminent Roman citizens, Sertorius won the enthusiastic support of the natives by his fairness, honesty, and charisma, and he soon held most of the lberian Peninsula, defending it successfully even against a large force under Quintus Metellus Pius. The consuls of 77 would have nothing to do with this war, and so Pompey was entrusted by the Senate, through the efforts of his eminent friends and sponsors, with the task of assisting Metellus. The war dragged on for years, with little glory for the Roman commanders. Sertorius had many sympathizers in Italy; but superior numbers and resources finally wore him down, and he was assassinated by a Roman officer. Pompey easily defeated the remnants of his forces in 72.

Meanwhile, the death of Nicomedes IV of Bithynia (74) led to another major war. Like Attalus of Pergamum, Nicomedes left his kingdom to Rome, and this provoked Mithradates, who was in contact with Sertorius and knew of Rome's difficulties, to challenge Rome again. The Eastern command again led to intrigues in Rome, where pressure against the Sullan system had brought a relaxation of the restrictions on the tribunate; amid increasing agitation, the armies in Spain (especially Pompey's) had come to appear as future arbiters of Roman politics. The command finally went to Lucius Lucullus, a relative of Sulla and consul in 74, who hoped to build up a countervailing power in the East.

At the same time, Marcus Antonius, father of the later Triumvir, was given a command against the pirates in the eastern Mediterranean (whom his father had already fought in 102–loo), partly, perhaps, as further re-insurance against Pompey. With Italian manpower heavily committed, a minor slave rising led by Spartacus (73) assumed threatening dimensions, until Marcus Crassus (an old Sullan and profiteer in the proscriptions) volunteered to accept a special command and defeated the slaves. At this point (71), Pornpey arrived back from Spain with his army, crucified the remnants of the slave army, and claimed credit for the victory.

Pompey and Crassus. He and Crassus now confronted each other, each demanding the consulship for 70, though Pompey had held no regular magistracy and was not a senator. Agreeing to join forces, both secured it.

Repeal of the Sullan system. During their consulship, the political, though not the administrative, part of the Sullan settlement was repealed. The tribunes' powers were fully restored, criminal juries were divided between senators and wealthy nonsenators, and, for the first time since Sulla, censors—both supporters of Pompey—were elected, purged the Senate, and in compiling the registers at last fully implemented the Italians' citizenship. The year 70 also saw the prosecution of Verres (son of a "new man" and Sullan profiteer), who had surpassed the very liberal Roman conventions in exploiting his province of Sicily, relying for future impunity on his aristocratic connections (especially the Metelli and their friends), his fortune, and the known corruptibility of the Sullan senatorial juries. But Verres was unlucky. First, he had ill-treated some of Pompey's important Sicilian clients, thus incurring Pompey's displeasure; next, his case coincided with the anti-Sullan reaction of 70; finally, the Sicilians succeeded in persuading Cicero—an ambitious young "new man" from Arpinum, hoping to imitate the success of his fellow citizen Marius by means of his rhetorical ability—to undertake the prosecution. Despite obstruction from Verres' friends, Cicero collected massive evidence against him, presented his case to fit into the political context of the year, and obtained Verres' conviction as an act of expiation for the shortcomings of the Sullan order.

Loss of control by the Sullan establishment

The year 70 thus marks the loss of control by the Sullan establishment. The nobility (families descended from consuls) continued to gain most of the consulships, with the old patriciate (revived by Sulla after a long decline) stronger than for generations; the Senate still supervised administration and took ordinary political decisions; the system continued to rely essentially on *mos majorum* (constitutional custom) and *auctoritas* (prestige)—potent forces in the status society of the Roman Republic. But the solid bases of law and power that Sulla had tried to give it had been surrendered. The demagogue—tribune or consul—could use the legal machinery of the popular assembly (hence such men are called *populares),* while the commander could rely on his army, in the pursuit of private ambition. The situation that Sulla had tried to remedy now returned, made worse by his intervention. His massacres and proscriptions had weeded out the defenders of lawful government, and his rewards had gone to the timeservers and the unscrupulous. The large infusion of equites into the Senate had intensified the effect. While eliminating the serious friction between the two classes, which had made the state ungovernable by 91, it had filled the Senate with men whose tradition was the opposite of that sense of mission and public service that had animated the best of the aristocracy. Few men in the new ruling class saw beyond self-interest and self-indulgence.

One result was that massive bribery and civil disorder in the service of ambition became endemic. Laws were repeatedly passed to stop them, but they remained ineffective because few found it in their interest to enforce them. Exploitation of the provinces did not decrease after Verres: governors (still with unlimited powers) feathered their own nests and were expected to provide for all their friends. Extortion cases became a political ritual, with convictions impossible to obtain. Cicero, thenceforth usually counsel for the defence, presents hair-raising behaviour as commonplace and claims it as acceptable. The Senate's traditional opposition to annexation faded out. Pompey made Syria into a province and added a large part of Pontus to Bithynia (inherited in 74 and occupied in 70); the demagogue Clodius annexed Cyprus—driving its king to suicide—to pay for his massive grain distributions in Rome; Caesar, finally, conquered Gaul by open aggression and genocide and bled it white for the benefit of his friends and his ambitions. Crassus would have done the same with Parthia, had he succeeded. Opposition to all this in the Senate, where it appeared, was based on personal or political antagonism. If the robber barons were attacked on moral grounds, it was because of the use they made of their power in Rome.

Potnpey's extraordinary commands. Politically, the 60s lay under the shadow of Pompey. Refusing to take an ordinary province in 69, he waited for his chance. It came in 67, when his adherent Gabinius, as tribune, secured him, against the opposition of all important men, an extraordinary command, with unprecedented powers, to deal with the pirates. Pompey succeeded within a few months where Antonius and others had failed. The equites and the people were delighted because trade, including Rome's food imports, would now be secure. Meanwhile Lucullus had driven Mithradates out of Asia Minor and into Armenia; but he had offended Roman businessmen by strict control and his own soldiers and officers by strict discipline. Faced with mutinies, he suffered a reverse and became vulnerable to attacks in Rome. In 66 another tribunician law appointed Pompey, fresh from his naval victories, to take over supreme command in the East, which he did at once, studiously insulting his predecessor. He quickly defeated Mithradates and procured his death, then spent some years in a total reorganization of the East, where Asia (the chief source of revenue) was protected by three further provinces and a ring of client states beyond the frontier. The whole of the East now stood in his clientela, and most of it owed him money as well. He returned as by far the wealthiest man in Rome.

Defeat and death of Mithradates VI

Political suspicion and violence. Meanwhile Roman politics had been full of suspicion and violence, much of it stirred up by Crassus who, remembering 71, feared Pompey's return and tried to make his own power impregnable. There was much material for revolution, with poverty (especially in the country, among families dispossessed by Sulla) and debt (among both the poor and the dissolute rich) providing suitable issues for unscrupulous *populares.*

Conspiracy of Catiline. One such man, the patrician Catiline, after twice failing to gain the consulship by traditional bribery and intrigue, put himself at the head of a movement planning a coup d'état in Rome to coincide with an armed rising in Italy (late 63). Cicero, as consul, defeated these efforts and, relying on the doubtful legality of a Senate vote in support, had Catiline's eminent Roman associates executed. Catiline himself fell in a desperate battle.

Isolation of Cicero

For Cicero—the "new man" who had made his way to the top by his own oratorical and political skill, obliging everyone by unstinting service, representing Pompey's interests in Rome while avoiding offense to Pompey's enemies—this was the climax of his life. Like his compatriot Marius, he had saved the state for its rulers: he had taken resolute action when those rulers were weak and vacillating; and, like Marius, he got small thanks for it. Pompey was miffed at having to share his fame with a municipal upstart, and eminent gentlemen could not forgive that upstart for having driven patricians to their death.

Pompey's loss of power. Pompey's return was peaceful. Like Marius, he wanted recognition, not tyranny. He dismissed his army, to the surprise of Crassus and others, and basked in the glory of his triumph and the honours voted to him. But having given up power, he found himself caught in a net of constitutional obstruction woven by his politically experienced enemies and was unable to obtain either of his principal demands: land for his veterans and the ratification of his arrangements in the East. It was at this point that Caesar returned from Spain.

The rise of Caesar. Gaius Julius Caesar, descended (as he insisted) from kings and gods, had shown talent and ambition in his youth: he opposed Sulla, but without inviting punishment; married into the oligarchy, but advocated popular causes; vocally defended Pompey's interests, while aiding Crassus in his intrigues and borrowing a fortune from him; flirted with Catiline, but refused to dabble in revolution, then worked to save those whom Cicero executed. In 63 he won a startling success: defeating two distinguished ***principes,*** he, who had not yet been praetor, was elected ***pontifex*** *maximus* —a post of supreme dignity, power, and patronage. The Roman aristocracy had long ceased to believe in the state religion; but its ceremonial was kept up for popular effect and as a recognized means of political manipulation, so that priesthoods could give more lasting power than magistracies, in addition to the cachet of social success. Young Caesar was now head of the hierarchy. After his praetorship (62), Caesar successfully governed Spain, clearing a surplus sufficient to pay off his debts. On returning to Rome, he naturally hoped for the consulship of 59; but his enemies, by legal chicanery, forced him to choose between standing for office and celebrating a triumph. He gave up the triumph and easily became consul.

THE FINAL COLLAPSE OF THE ROMAN REPUBLIC (59–44 BC)

Alliance of Caesar, Pornpey, and Crassus

Caesar, Pompey, and Crassus. For his consulship Caesar fashioned an improbable alliance: his skill in having won the trust of both Crassus and Pompey enabled him to unite these two enemies in his support. Crassus had the connections, Pompey had the soldiers' vote, and Caesar was consul and ***pontifex*** *maximus.* The combination (often misleadingly called the "first Triumvirate") was invincible, especially since the consul Caesar had no scruples about countering legal obstruction with open force. Pompey got what he wanted, and so did Crassus (whose immediate need was a concession to the Asian tax farmers, in whose companies he probably had much of his capital). In return, Caesar got a special command in Cisalpine Gaul and Illyricum for five years by vote of the People; the Senate itself, on Pompey's motion, extended it to Transalpine Gaul. Marriage alliances sealed the compact, chief of them Pompey's marriage to Caesar's daughter Julia.

Caesar left for Gaul, but Rome was never the same; the shadow of the alliance hung over it, making the old-style politics impossible. In 58 Publius Clodius, another aristocratic demagogue, was tribune and defended Caesar's interests. Cicero had incurred Clodius' enmity and was now sacrificed to him: he was driven into exile as having unlawfully executed citizens in 63. By 57 Caesar's allies had drifted back into rivalry. Pompey secured Cicero's return, and Cicero at once tried to break up the alliance by attracting Pompey to the Senate's side. Just when he seemed about to succeed, the three dynasts secretly met and revived their compact (56). Rome had to bow once more. In 55 Pompey and Crassus were consuls, and the contents of their secret agreement were slowly revealed. Caesar, whom his enemies had made efforts to recall, was prolonged in his command for five years and (it later appeared) had been promised another consulship straight after, to secure him against prosecution and give him a chance of another army command. Pompey was given a special command over all of Spain, which he exercised through deputies while he himself remained just outside Rome to keep an eye on the city. Crassus, who now needed glory and new wealth to equal those of his allies, was to attack Parthia with a large army. Thus the three dynasts would practically monopolize military power for the foreseeable future.

Cicero, among others, had to submit and was thenceforth their loyal spokesman. After his achievement of 63 he had dreamt of leading a coalition of all "right-thinking" men in Italy in defending the traditional oligarchy, but he had found little support among the oligarchy and now used this fact to rationalize his surrender. His brother took service in Gaul under Caesar.

The dynasts' pact did not even bring peace. Clodius, as tribune, had created a private army, and there was no state force to counter it. Pompey could have done it by calling his soldiers in, but the Senate did not trust him enough to request this, and Pompey did not wish to parade himself as an unashamed tyrant. Other men formed private armies in opposition to Clodius, and one Milo at last managed to have him killed after a scuffle (52). By then, however, Roman politics had radically and unexpectedly changed.

End of the pact

Political manoeuvres. Julia died in 54, breaking the ties between Caesar and Pompey. Caesar pressed Pompey to renew them, but Pompey held off, preserving his freedom of action. Crassus' Parthian campaign ended in disaster and in Crassus' death (53). By 52 Pompey and Caesar stood face to face, still nominally friends but with no personal link between them and no common interests. Caesar, by conquering the whole of Gaul, had almost equalled Pompey's prestige and, by his utterly ruthless way of waging war, Pompey's wealth. Unlike Pompey, he used his wealth to dispense patronage and buy useful friends. At this point Pompey cautiously offered the oligarchy his support. It had much to give him that he wanted—control of the administrative machine, respectability, and the seal of public approval. Its leaders (even the intransigent young Cato, who had led opposition to the three individually long before their alliance and to their joint oppression of the state ever since) now recognized that acceptance of Pompey's terms and surrender to his protection was their only chance of survival. Pompey at once turned firmly against Milo, who presented a political threat: if Milo could use the force that had killed Clodius to keep firm control of Rome, he—an ambitious man of known conservative views—might in due course offer an alternative and more trustworthy champion to the oligarchy. But he was not yet ready. Pompey forced them to make their choice at once, and they chose Pompey in preference. He was made sole consul and had Milo convicted by an intimidated court. Meanwhile he had made a marriage alliance with the noblest man in Rome, Quintus Metellus Scipio, who became his colleague in the consulship. The state had captured Pompey (or vice versa), and Caesar stood alone in opposition to both of them. The next two years saw a series of manoeuvres: the Senate leaders, with Pompey's silent support, worked for Caesar's recall, which would have meant his instantly sharing the fate of Milo; while Caesar and his agents in Rome tried to strike some bargain that would ensure his safety and his future in politics. Finally, Pompey declared himself, and, early in 49, the Senate voted to outlaw Caesar. Two tribunes supporting him (one of them Mark Antony) had to flee. By the time they reached him, Caesar had already crossed the Rubicon: he now had a cause.

Civil war. Pompey had exuded confidence over the outcome if it came to war. In fact, however, Caesar's veterans were unbeatable, and both men knew it. To the disgust of his followers, Pompey evacuated Rome, then Italy. His plan was to bottle Caesar up there and starve him out. But Caesar, in a lightning sweep, seized Massilia and Spain from Pompey's commanders, then crossed to Greece, where a short campaign ended in Pompey's decisive defeat at Pharsalus (48). Pompey fled to Egypt, where he was assassinated by a man hoping thus to curry

Caesar's favour. This was by no means the end of the war. Almost at once, Caesar was nearly trapped at Alexandria, where he had intervened in a succession dispute; but he escaped and installed Cleopatra on the throne, for personal as well as political reasons. In Africa the Pompeian forces and their native allies were not defeated until Caesar himself moved against them and annihilated them at Thapsus. Cato, disdaining the victor's pardon, committed suicide at Utica (46). In Spain, where Pompey's name was still powerful, his sons organized a major rising, which Caesar himself again had to defeat at Munda (45) in the bloodiest battle of the war. By the time he returned, he had only a few months to live.

The dictatorship and assassination of Caesar. In Rome the administrative machine had inevitably been disrupted, and Caesar had always remained in control, as consul or as dictator. Those who had feared proscriptions, or hoped for them, were proved wrong. Some of Caesar's enemies had their property confiscated, but it was sold at fair value; most were pardoned and suffered no loss. One of these was Cicero, who, after much soul-searching, had followed his conscience by joining Pompey before Pharsalus. Poverty and indebtedness were alleviated, but there was no wholesale cancellation of debts or redistribution of property, and many of Caesar's adherents were disappointed. Nor was there a general reform of the republic. (Caesar's only major reform was of the calendar: indeed, the Julian calendar proved adequate for centuries.) The number of senators and magistrates was increased, the citizenship was more freely given, the province of Asia was relieved of some of its tax burden. But Caesar had no plan for reforming the system—not even to the extent that Sulla had tried to do, for Sulla had at least planned for his own retirement. For a time, honorable men, such as Cicero, hoped that the "Dictator for settling the Constitution" (as Caesar called himself) would produce a real constitution—some return to free institutions. By late 45 that hope was dead. Caesar was everywhere, doing everything to an almost superhuman degree. He had no solution to the crisis of the republic except to embody it in himself and none at all for the hatred of his peers, which he knew this was causing. He began to accept more and more of the honours that a subservient Senate invidiously offered, until finally he reached a position perilously close to kingship (an accursed term in Rome) and even deification. Whether he passed those hazy boundary lines is much debated and not very important. He had put himself in a position in which no Roman ought to have been and which no Roman aristocrat could tolerate. As a loyal friend of his was later to say: "With all his genius, he saw no way out." To escape the problem or postpone it, he prepared for a Parthian war to avenge Crassus—a project most likely to have ended in similar disaster. Before he could start on it, about 60 men—former friends and old enemies, honorable patriots and men with grievances—struck him down in the Senate on March 15, 44 BC.

Changes
under
Caesar

THE TRIUMVIRATE AND OCTAVIAN'S ACHIEVEMENT OF SOLE POWER

Brutus and Cassius, the organizers of the conspiracy, expected all Romans to rejoice with them in the rebirth of "freedom." But to the Roman people the freedom of the governing class had never meant very much; the armies (especially in the west) were attached to Caesar; and the Senate was full of Caesarians at all levels, cowed but biding their time. Mark Antony, the surviving consul, whom Brutus had been too scrupulous to assassinate with his master, gradually gained control of the city and the official machinery, and the "liberators" withdrew to the East. But a challenger for the position of leader of the Caesarians soon appeared in the person of Octavian, Caesar's son by adoption and now his heir. Though not yet 20, Octavian proved an accomplished politician, attracting loyalty as a Caesarian while cooperating against Antony with the Senate, which, under Cicero's vigorous leadership, now turned against the consul. Cicero hoped to fragment and thus defeat the Caesarian party, with the help of Brutus and Cassius, who were making good progress in seizing control of the eastern provinces and armies. In 43 the two consuls (both old Caesarian officers) and Octavian defeated Antony at Mutina, and success seemed imminent. But the consuls died, and Octavian demanded and, by armed force, obtained the consulship; and the armies of Italy, Spain, and Gaul soon showed that they would not fight against one another. Octavian, Antony, and Lepidus (the senior Caesarian with an army) now had themselves appointed "Triumvirs for settling the Constitution" for five years and secured control of Italy by massive proscriptions and confiscations (Cicero, Antony's chief enemy, was among the first to die). They then defeated and killed Brutus and Cassius at Philippi (42) and divided the Roman world among themselves, with Lepidus, a weak man accidentally thrust into prominence, getting the smallest share. Octavian, who was to control Italy, met armed opposition from Antony's brother and wife, but they got no help from Antony and were defeated at Perusia (41). Octavian and Antony sealed their alliance with a marriage compact: Antony married Octavia, Octavian's sister. Octavian then confronted Pompey's son Sextus Pompeius, who had seized control of the islands off Italy. After much diplomatic manoeuvring (including another meeting with Antony), Octavian attacked and defeated Sextus; when Lepidus tried to reassert himself, Octavian crushed him and stripped him of his office of Triumvir (while with conspicuous piety leaving him the chief pontificate, now powerless). Octavian now controlled the West and Antony the East, still officially as Triumvirs (their term of office had been extended), even though Lepidus had been eliminated in 36.

Formation
of the
Triumvirate

Each of the two leaders embarked on campaigns and reorganization in his half—Octavian in Illyricum, Antony particularly on the Parthian frontier. But Antony now married Cleopatra and tried to make Egypt his military and political base. In a war of propaganda, Octavian gradually convinced the western provinces, Italy, and most of the Roman upper class that Antony was sacrificing Roman interests, and trying to become a Hellenistic king in Alexandria, and planning to rule the Roman world from there with Cleopatra. In 32, though he now held no legal position, Octavian intimidated most of Antony's remaining aristocratic friends into joining him, made the whole West swear allegiance to himself, and in 31, as consul, crossed to Greece to attack Antony. On September 2 he defeated Antony and Cleopatra in a naval battle at Actium. Though in itself not a major victory, it was followed by the disintegration of Antony's forces, and Antony and Cleopatra finally committed suicide in Alexandria (30). (E.Ba.)

IV. The early Roman Empire (31 BC–AD 193)

THE CONSOLIDATION OF THE EMPIRE UNDER THF JULIO-CLAUDIANS

The establishment of the principate under Augustus. Actium left Octavian the master of the Roman world. This supremacy, unremittingly maintained until his death more than 40 years later, made him the first of the Roman emperors. Suicide removed Antony and Cleopatra and their potential menace in 30 BC, and the annexation of Egypt with its Ptolemaic treasure brought financial independence. With these reassurances Octavian could begin the task of reconstruction.

The first
of the
Roman
emperors

Law and order had vanished from the Roman state when its ruling aristocrats refused to curb their individual ambitions and thus transformed a republic based on disciplined liberty into a turbulent cockpit of murderous rivalries. Good government depended on limits being set to unrestrained aspirations, and Octavian was in a position to impose them. But, although his military might in 31 BC could guarantee orderly political processes, it was itself incompatible with them; nor did he relish the role of military despot. The fate of Julius Caesar, **an** eagerness to acquire political respectability, and his own esteem for ancestral custom combined to dissuade Octavian from it. He wished to be, in his own words, "the author of the best civilian government possible." His problem was to regularize his own position so as to make it generally acceptable, without simultaneously reopening the door to violent lawlessness. His pragmatic solution not only ensured stability and continuity, but it also respected republican forms and traditions so far as possible.

Large-scale demobilization allayed men's fears; regular consular elections raised their hopes. In 29–28 BC he carried out, with Agrippa, the first census of the Roman people since 70; and this involved drawing up an electoral roll for the Centuriate Assembly. Elections followed, and Octavian was inevitably chosen consul. Then, on January 13, 27 BC, he offered to lay down his powers. The Roman Senate rejected this proposal, charging him instead to administer (besides Egypt) Spain, Gaul, and Syria for the next 10 years, while it itself supervised the rest of the empire. (It is uncertain whether the Senate named him proconsul for this provincia in 27 or expected him to superintend it by virtue of being consul.) Three days later, among other honours, it bestowed upon him the name by which he has ever since been known, Augustus.

Therewith the Roman state ceased to be the plaything of dictators and triumvirs and became a res publica again. Indeed, the Latin expression for this settlement of 27 is res publica restituta, the usual translation of which, "restoration of the republic," is misleading, because the Latin res publica means a state governed by constitutional methods, whether a republic or not.

Augustus' powers

As most of the troops still under arms were in the regions entrusted to Augustus' charge, the arrangements of 27 BC hardly affected his military strength. Moreover, so long as he was consul (he was re-elected every year until 23 BC) he was civilian head of government as well. In other words, he was still pre-eminent and all-powerful, even if he had, in his own words, placed the res publica at the disposal of the Senate and the Roman People. Augustus particularly wished to conciliate the senatorial class, without whose experienced help civilian government was impossible. But his monopolization of the consulship offended the Senate, so that some different arrangement was clearly necessary. Accordingly, in 23 Augustus made a change; he vacated the consulship and never held it again (except momentarily in 5 BC and again in 2 BC, for a limited, specific purpose). In its place he received the tribunician power (tribunicia potestas). He could not become an actual plebeian tribune, as Julius Caesar's action in making him a patrician had disqualified him for the office. But he could acquire the rights and privileges pertaining to the office; and they were conferred upon him, apparently by the Senate, whose action was then ratified by the popular assembly. He had already been enjoying some of a tribune's privileges since 36; but he now acquired them all and even some extra ones, such as the right to convene the Senate whenever he chose and to enjoy priority in bringing business before it. Through his tribunician power he could also summon the popular assembly and participate fully in its proceedings. Clearly, although no longer consul, he still retained the legal right to authority in civilian affairs.

The arrangement of 23 entailed an additional advantage. The power of the plebeian tribune was traditionally associated with the protection of citizens, and Augustus' acquisition of it was therefore unlikely to rouse resentment. Indeed, Augustus thenceforth shrewdly propagated the notion that, if his position in the state was exceptional (which it clearly was), then this was precisely because of his tribunician power. Although he held it for only one year at a time, it was indefinitely renewable and was pronounced his for life. Thus, it was both annual and perpetual and was a suitable vehicle for numbering the years of his supremacy. His era (and this is true also of later emperors) was counted officially from the year when he acquired the tribunician power.

The year 23 likewise clarified the legal basis for Augustus' control of his provincia (the region under his jurisdiction) and its armed forces. The Senate invested him with an imperium proconsulare (governorship and command of an empire); this had a time limit, but it was automatically renewed whenever it lapsed (usually every ten years). This proconsular imperium, furthermore, was pronounced valid inside Italy, even inside Rome and the *pomerium* (the boundary within which only Roman gods could be worshipped and civil magistrates rule), and superior (majus) to the irnperium of any other proconsul. Thus, Augustus could intervene quite legally in any province, even in one entrusted to someone else.

It is clearly this imperium proconsulare *majus* that made Augustus unassailable; but, because it belonged more to military than to civilian life, he preferred not to draw attention to it. In fact, he de-emphasized it: it is not reflected in either his official titles or his autobiography, the tribunician power being paraded as the expression of his supreme authority.

Augustus' honours

After 23 no fundamental change in Augustus' position occurred. He felt no need to hold offices that in republican times would have conferred exceptional power (*e.g.*, dictatorship, lifetime censorship, or regular consulship), even though these were offered him. Honours, of course, came his way: in 19 BC he received some consular rights and prerogatives, presumably to ensure that his *imperium* was in no particular inferior to a consul's; in 12, when Lepidus died, he became *pontifex maximus* (he had long since been elected into all of the priestly colleges); in 8 BC, the eighth month of the year was named after him; in 2 BC, he was designated pater patriae ("father of his country"), a distinction which he particularly esteemed because it suggested that he was to all Romans what a paterfamilias was to his own household. He also accepted special commissions from time to time: *e.g.*, to superintend the supply of grain and water, the maintenance of public buildings (including temples), the regulation of the Tiber, the police and fire-fighting services, and the upkeep of Italy's roads. Such behaviour advertised his concern for public well-being and also his legal correctness; but it hardly altered the fact that his tribunician power and proconsular *imperium*, as defined in 23, were the real bases of his strength and the twin legal supports upon which his position and authority rested. It was these that made him a charismatic leader of unrivalled prestige (auctoritas), whose merest suggestions were binding; they ensured absolute imperial predominance for the future.

Like an ordinary Roman, he contented himself with three names. His, however, Imperator Caesar Augustus, were absolutely unique, with a magic all their own that caused all later emperors to appropriate them, at first selectively but after AD 69 in their entirety. Thereby they became titles, reserved for the emperor (or, in the case of the name Caesar, for his heir apparent); from them derive the titles emperor, kaiser, and tsar. Yet, as used by Augustus and his first four successors, the words Imperator Caesar Augustus were names, not titles—that is, respectively, praenomen, nomen (in effect), and cognomen. One title that Augustus did have was *princeps* ("prince"); this, however, was unofficial—a mere popular label, meaning Rome's first citizen—and government documents (inscriptions, coins, etc.) do not apply it to Augustus. But because of it the system of government he devised is called the principate.

Augustus' relationship with the Senate

The Roman Senate and the urban magistracies. Augustus regarded the Senate, whose leading member (*princeps senatus*) he had become in 28, as a body with important functions; it heard fewer overseas embassies than formerly, but otherwise its dignity and authority seemed unimpaired; its members filled the highest offices; its decrees, although not formally called laws, were just as binding; it soon became a high court, whose verdicts were unappealable; it supervised the older provinces and nominally the state finances as well, and it also in effect elected the urban magistrates; formally, even the emperor's powers derived from the Senate. Nevertheless, it lacked real power. Its provinces contained few troops (and by AD 40 it had ceased to control even these few). Hence, it could hardly dispute Augustus' wishes. Moreover, it was he, in fact, who superintended state finances. Above all, he controlled its membership, every senator's career depending upon his goodwill. But he valued the Senate as the repository of the true Roman spirit and traditions and as the body representing public opinion. He was considerate toward it, shrewdly anticipated its reactions, and generally avoided contention with it. He regularly kept it informed about his activities; and the imperial council (Concilium Principis), which he consulted on matters of policy, in the manner of a republican magistrate seeking the opinion of his advisory committee, consisted of the consuls, certain other magistrates, and 15 senators—not handpicked by him but chosen by lot every six months.

To rid the Senate of unworthy elements he reduced its numbers by successive reviews to about 600 (from the triumveral 1,000 or more). Sons of senators and men of good repute and substance who had served in the army and the vigintivirate (a minor magistracy) could become members by being elected, at age 25 or over, to the quaestorship. Their subsequent rank in the Senate depended on what other magistracies they managed to win; these were, in ascending order, the aedileship (or plebeian tribunate), the praetorship, and the consulship. No one disliked by Augustus could expect to reach any of them, while anyone whom he nominated or endorsed was sure of election. Despite the Emperor's control, there were enough candidates for keen contests. By AD 5 destinatio seems to have been the practice: that is, a special panel of senators and equites selected the praetors and consuls, and the Centuriate Assembly automatically ratified their choice. In c. AD 5, likewise, the consulship was shortened to six months. This not only gratified senators and increased the number of high-ranking qualified officials but also showed that the consuls' duties were becoming largely ceremonial. This was also true, but to a far lesser degree, of the other unpaid magistrates. A senator really made his mark in between his magistracies, when he served in important salaried posts, military or civilian or both, sometimes far from Rome.

Rise of equites to a privileged status

The equestrian order. Senators, however, were either too proud or too few to fill all the posts. Some posts were considered menial and went to the Emperor's freedmen or slaves. Others were entrusted to equites, and the equestrian order soon developed into one of the great institutions of the empire. Augustus decided that membership in the order should be open to Roman citizens of means and reputation but not necessarily of good birth. Ultimately, there were thousands of equites throughout the empire. Although this was a lower aristocracy, a good career was available to them. After tours of duty as an army officer (the so-called *militiae* equestres), an aspiring eques might serve as the emperor's agent (procurator) in various capacities and eventually become one of the powerful prefects (of the fleet, of the vigiles, or fire brigade, of the grain supply, of Egypt, or of the Praetorian Guard). This kind of an equestrian career became standardized only under Claudius I; but Augustus began the system and, by his use of equites in responsible posts, founded the imperial civil service, which later was staffed chiefly by them. The equites also performed another function: the senatorial order had difficulty in maintaining its numbers from its own ranks and depended on recruitment from below; this meant from the equestrian order, and, as it was not confined to Rome or even to Italy, the Senate gradually acquired a non-Italian element. The western provinces were already supplying senators under Augustus.

Administration of Rome and Italy. Ordinary Roman citizens who were neither senators nor equites were of lesser consequence. Although still used, the old formula Senatus Populusque Romanus had changed its meaning: in effect, its Populusque Romanus portion now meant "the emperor." The "Roman People" had become the "Italian People," and it was embodied in the person of Augustus, himself the native of an Italian town. To reduce the risk of popular demonstrations in Rome, the Emperor provided grain doles, occasional donatives, and various entertainments; but he allowed the populace no real power. After AD 5 the Roman People's participation in public life consisted in the formality of holding occasional assemblies to ratify decisions made elsewhere. Ultimately, this caused the distinction between the Roman citizens of Italy and the provincial inhabitants of the overseas empire to disappear; under Augustus, however, the primacy of Italy was insistently emphasized.

The primacy of Italy

Indeed, Italy and justice for its inhabitants were Augustus' first cares. Arbitrary triumviral legislation was pronounced invalid after 29 BC, and ordinary Roman citizens everywhere had access to Augustus' own court of appeal (his appellate jurisdiction dated from 30 BC and in effect replaced the republican appeal to the People). His praetorian and urban cohorts provided physical security; his officials assured grain supplies; and he himself, with help from such aides as Agrippa, monumentalized Italian towns. The numerous Augustan structures in Italy and Rome (a city of brick before his time and of marble afterward) have mostly perished, but impressive ruins survive (*e.g.*, aqueduct, forum, and mausoleum in Rome; bridge at Narni; arch at Fano; gate at Perugia). Doubtless their construction alleviated unemployment, especially among the proletariat at Rome. But economic considerations did not influence Augustus' policies much (customs tariffs, for instance, were for fiscal, not protective, purposes), nor did he build harbour works at Ostia. Italian commerce and industry nevertheless flourished in the conditions he created. Public finances, mints, and coinage issues, chaotic before him, were placed on a sound basis, partly by the introduction of a sales tax and of a new levy (death duties) on Roman citizens—who hitherto had been subject only to harbour dues and manumission (freeing of slaves) charges—and partly by means of repeated subventions to the public treasury (aerarium *Saturni*) from Augustus' own enormous private resources (*patrimonium* Caesaris). His many highways also contributed to Italy's economic betterment.

Augustus' great achievement in Italy, however, was to restore morale and unify the country. The violence and self-aggrandizement of the 1st century BC had bred apathy and corruption. To reawaken a sense of responsibility, especially in official and administrative circles, Augustus reaffirmed traditional Italian virtues (by outlawing adultery, strengthening family ties, and stimulating the birthrate) and revived ancestral religion (by repairing temples, building new shrines, and reactivating moribund cults and rituals). To infuse fresh blood and energy into disillusioned Roman society, he promoted the assimilation of Italy: the flower of its municipal towns entered the Roman Senate, and Italy became firmly one with Rome. To keep the citizen body pure, he made manumission of slaves difficult, and from those irregularly manumitted he withheld the citizenship.

Two types of provinces

Administration of the provinces. Sharply distinguished from Italy were the provinces of the empire. From 27 BC on they were of two types. The Senate supervised the long-established ones, the so-called public provinces: their governors were chosen by lot, usually served for a year, commanded no troops, and were called proconsuls (although only those superintending Asia and Africa were in fact former consuls, the others being former praetors). The Emperor supervised all other provinces, and collectively they made up his provincia: he appointed their governors, and these served at his pleasure, none with the title of proconsul because in his own *provincia* proconsular *imperium* was wielded by him alone. These imperial provinces might be "unarmed," but many of them were garrisoned, some quite heavily. Those containing more than one legion were entrusted to former consuls and those with a legion or less to former praetors; in both cases their governors were called *legati Augusti* pro praetore ("legates of Augustus with authority of a praetor"). 'There were also some imperial provinces governed not by senators but by equites (usually styled procurators but sometimes prefects); Judaea at the time of Christ's crucifixion was such an equestrian province, Pontius Pilate being its governor. An entirely exceptional imperial province was Egypt, so jealously guarded that no senator could visit it without express permission; its prefect was unique in being an equestrian in command of legions.

Taxation. The provinces paid tribute, which helped to pay for the armed services, the growing civil service, and the public-works programs. Periodical censuses, carefully listing provincial resources, provided the basis for the two direct taxes: *tributum* soli, exacted from occupiers of provincial soil, and *tributum capitis*, paid on other forms of property (it was not a poll tax, except in Egypt and in certain backward areas). In addition, the provinces paid indirect taxes, such as harbour dues. In imperial provinces the direct taxes (tributa) were paid to the Emperor's procurator, an equestrian official largely independent of the governor. In senatorial provinces, quaestors supervised the finances; but, increasingly, imperial procurators also appeared. The indirect taxes (*vectigalia*) were still collected by publicani, but they were now much more rigorously controlled and were being gradually replaced by imperial civil servants.

Autonomous communities

Development of urban life. As under the republic, each province was a collection of autonomous communities (civitates), roughly resembling modern counties, and it was through them that Rome governed its empire; without them provincial administration would have simply broken down. The autonomous communities, apart from a privileged few, all paid taxes to Rome. Most of them were peregrine; that is, their burgesses were not Roman citizens; but these non-Roman communities tended to decrease in number because they gradually adopted Rome's language and ways and thereby became qualified to receive "Latin rights" (*Latium*, or *jus Latii*)—a status that prepared them for the eventual bestowal of full Roman citizenship. Peregrine communities upgraded in this way were called municipia.

Whole communities with Roman citizenship in the provinces were virtually a new development, because there had been hardly any before Julius Caesar's dictatorship. Those called coloniae (see below) ranked highest, being regarded as actual extensions of Rome itself: some of them were even exempted from payment of tribute. There were, however, few coloniae and practically no *municipia* in the East.

In both senatorial and imperial provinces the civitates enjoyed local self-government. The Roman and Latin communities were city-states, resembling the towns of Italy; they regularly had an assembly of adult males and a local council (*ordo*), and their chief officials—collegial, annual, and unpaid—were either duoviri (in coloniae) or *quattuorviri* (in municipia). The peregrine communities might or might not be city-states—many were organized on tribal, not municipal, lines; moreover, the city-states among them showed great variety, some of the Greek-speaking ones having constitutions that were centuries old. Although Rome regularly ensured control by the propertied classes, it rarely imposed Roman-style constitutions. It did perhaps favour urbanized communities, rural areas being subordinated to city-states for administrative purposes until ready for municipal institutions of their own. Naturally, too, peregrine communities tended to imitate nearby Roman towns, so that even some tribally organized civitntes boasted duoviri and an *ordo*.

The provinces were generally better off under the empire. The governing power now felt some responsibility foı the governed and sent out salaried and experienced officials. These were closely supervised. During the first two centuries, provincial communities flourished on the whole; in many, a sense of civic liberty and healthy local patriotism induced wealthy burgesses to build baths, theatres, and the like at their own expense. Above all, there was peace, the Pax Romana.

Emperor worship. For this priceless gift of peace, many individuals and even whole communities, in Italy and elsewhere, expressed their thanks spontaneously by worshipping Augustus and his family. Emperor worship was also encouraged officially, however, as a focus of common loyalty for the polyglot empire. In the provinces, to emphasize the superiority of Italy, the official cult was dedicated to Roma et Augustus; to celebrate it, representatives from provincial communities or groups of communities met in an assembly (Concilium Provinciae), which incidentally might air grievances as well as satisfactions. (This system began in the Greek-speaking provinces, long used to wooing their rulers with divine honours. It penetrated the west only slowly; but from 12 BC an assembly for the three imperial Gallic provinces existed at Lugdunum.) In Italy the official cult was to the Genius Augusti (the life spirit of his family); it was coupled in Rome with the Lares Cornpitales (the spirits of his ancestors). Its principal custodians (seviri *Augus*tales) were normally freedmen. Calculation always entered into emperor worship; it was no act of piety but a political gesture, which could be continued after the emperor's death if the Senate pronounced him worthy of posthumous deification.

Allegiance of the army to the Emperor

The army. It was Augustus' soldiers, however, not his worshippers, that made him all-powerful. Their allegiance, like the name Caesar, was inherited from his "father," the deified Julius. The allegiance was to the Emperor personally, through a military oath taken in his name every January 1; and the soldiers owed it after his death to his son or chosen successor. This preference of theirs for legitimacy could not be ignored, because they were now a standing army, something that the republic had lacked. Demobilization reduced the 60 legions of Actium to 28, a number hardly sufficient but all that Augustus' prudence or economy would countenance. These became permanent formations, each with its own number and name; the soldiers serving in them were called legionaries. Besides the legionaries there were auxiliaries (or supporting troops), approximately as numerous. The two corps together numbered about 300,000 men. To them must be added the garrison of Italy—the praetorian cohorts, or emperor's bodyguard, about 10,000 strong—and the marines of the imperial fleet, which had its main headquarters at Misenum and Ravenna in Italy and subsidiary stations and flotillas on seas and rivers elsewhere (the marines, however, were not reckoned good combat forces). All these troops were long-service professionals—the praetorians serving 16 years; legionaries, 20; auxiliaries, *25;* and marines, 28—with differing pay scales, the praetorians' being highest. In addition to their pay, the men received donatives, shares of booty, and retirement bonuses from a special treasury (*aerarium militare*) established in AD 6 and maintained out of the sales tax and Roman citizens' death duties. Under Augustus the praetorians were normally Italians, but many legionaries and virtually all auxiliaries were provincials, mainly from the imperial provinces in the west, the legionaries coming from municipal towns and the auxiliaries from tribal areas. The tendency to use provincials grew, and by the year 100 the Roman imperial army was overwhelmingly non-Italian. Nevertheless, it helped greatly to Romanize the empire. The legionaires were Roman citizens from the day they enlisted, if not before, and the auxiliaries (after Claudius anyway) from the day they were discharged; and, though serving soldiers could not legally marry, many had mistresses whose children often became Roman citizens. The troops, other than praetorians and marines, passed their years of service in the "armed" imperial provinces—the auxiliaries in forts near the frontier and the legionaires at some distance from it in camps that showed an increasing tendency, especially after AD 69, to become permanent (some of them, indeed, developed into great European cities). There was no central reserve, because, although desirable for emergencies, it might prove dangerous in peacetime.

The officers were naturally Roman citizens. In the legions those of the highest rank (legati and tribuni) were senators or equites; lower officers (*centuriones*) might enter directly from Italian or provincial municipalities or might rise through the ranks, and by the time they retired, if not sooner, many of them were equites. In the auxiliaries the unit commanders (pmefecti) were equites, often of provincial birth. On retirement the soldiers frequently settled in the provinces where they had served, made friends, and perhaps acquired families; imperial policy favoured this practice. Indeed, many emperors founded colonies of veterans in the provinces, establishing the men in Roman communities of regular municipal type with free grants of land. Some of Augustus' *coloniae* were in Italy; but many more were overseas, as those of his successors regularly were. These military coloniae were the most highly regarded type of urban community under the empire, and excellent Romanizing agents.

Territorial expansion under Augustus

Foreign policy. After Actium and on two other occasions, Augustus solemnly closed the gates of the shrine of Janus (a gesture of peace), to show that Rome had peace as well as a princeps. These well-publicized gestures were purely temporary; the gates were swiftly reopened. His proconsular *imperium* made Augustus the arbiter of peace and war, and an ostensible search for defensible frontiers made his a very warlike reign. He sought to repair the omission of the republic that had left the limits of Roman territorial claims rather vague and indefinite; he planned conquests stretching to the boundaries defined by nature (deserts, rivers, and ocean shores), not always, however, with immediate annexation in mind. When annexation did occur, it was followed by the construction of solidly built military roads, paved with thick stone blocks: these also served the official post system (*cursus publicus*) and were provided with rest stages and overnight lodges at regular inververals.

Client kingdoms. Areas where subjugation looked arduous and where Romanization seemed problematic were left to client kings, dependent on the Emperor's support and goodwill and under obligation to render military aid to Rome. Such satellite kingdoms spared Augustus the trouble and expense of maintaining strong defenses everywhere; nevertheless, their ultimate and intended destiny was incorporation as soon as it suited their overlord's convenience. Usually, territory was gained more easily by creating and subsequently incorporating a client kingdom than by launching an expansionist war.

Southern frontier. In the south, Augustus found suitable frontiers quickly. In 25 BC an expedition under Aelius Gallus opened the Red Sea to Roman use and simultaneously revealed the Arabian Desert as an unsurpassed and, indeed, unsurpassable boundary. The same year Gaius Petronius, the prefect of Egypt, tightened Rome's grip as far as the First Cataract and established a broad military zone beyond it. The vast region north of the Sahara and the Atlas Mountains was also secured (c. *25)* after a series of punitive raids against native tribes and the annexation of one client kingdom (Numidia) and the creation of another (Mauretania). Three legions, two in Egypt and one in Africa (a senatorial province), policed the southern shore of the Mediterranean.

Western frontier. In the west, consolidation was extended to the Atlantic. Gaul, Julius Caesar's conquest, was organized as four provinces: senatorial Narbonensis and the imperial three Gauls (Aquitania, Belgica, and Lugdunensis). In Spain, after Agrippa successfully ended in 19 BC the terminal campaign that Augustus had launched in person in 26, three provinces were formed: senatorial Baetica and imperial Lusitania and Tarraconensis. Three legions enforced Roman authority from Gibraltar to the mouth of the Rhine. Augustus ignored the advice of court poets and others to advance still farther and annex Britain.

Difficulties in the east and north

Eastern frontier. In the east, Parthia had demonstrated its power against Crassus and Antony, and Augustus proceeded warily. He retained Antony's ring of buffer client kingdoms, although he incorporated some, including the most celebrated of them, Judaea; he made Judaea a province in AD 6, respecting some of the customs of its Jewish inhabitants in the process. Augustus stationed four legions in Syria and obviously envisaged the Euphrates River and the northern extension of the Arabian Desert as the desirable frontier with Mesopotamia. Farther north, however, no such natural line existed. North of the Black Sea the client kingdom of the Cimmerian Bosporus, under its successive rulers Asander and Polemo, helped to contain southward and westward thrusts by the Scythians, an Iranian people related to the Parthians, and this provided protection in the north for Asia Minor and its provinces (senatorial Asia and Bithynia-Pontus and imperial Cilicia and Galatia, the latter a large new province created in 25 BC out of Amyntas' client kingdom). By a show of force, Augustus' stepson Tiberius in 20 recovered the standards lost at Carrhae and installed Tigranes as client king of Armenia, and Augustan propaganda depicted this as a famous victory; but strategic considerations inevitably obliged the Parthians, once they settled their internal, dynastic dissensions, to dispute Roman control of Armenia, so that Augustus hardly settled the eastern frontier. Missions were sent to the East repeatedly (Agrippa, 17–13 BC; Gaius Caesar, AD 1–4; Germanicus, 18–19), and Armenia remained a problem for Augustus' successors: Tiberius successfully maintained Roman influence there, but Gaius and Claudius failed to do so, leaving Nero with a difficult situation.

Northern frontier. In the north, too, there was difficulty. The Alps and their passes were finally subjugated early in Augustus' reign. This enabled Tiberius and his brother Drusus between 16 and 8 BC to conquer all the way to the great rivers of central Europe. New provinces were created in the Alps and Tyrol (Maritime and Pennine Alps, Raetia, Noricum) and also farther east (Pannonia, Moesia). Stability along the Danube was precariously maintained, under Augustus and later, by means of periodical alliances with Maroboduus and his successors, who ruled Germanic tribes like the Marcomanni and Quadi in Bohemia to the north of the river, and by the existence of a Thracian client kingdom to the south of its lowest course. The push across the Rhine began in 12 BC; it reached the Elbe, but consolidation beyond the Rhine proved elusive. A revolt in Pannonia (AD 6–9) interrupted it, and, in AD 9, German tribes under Arminius annihilated Quinctilius Varus and three legions in the Teutoburg Forest. This disaster reduced the number of legions to 25 (it did not reach 28 again until half a century later), and it disheartened Augustus. Old and weary, he withdrew to the Rhine and decided against all further expansion, a policy he urged upon his successor. For the watch on the Rhine the military districts of Upper and Lower Germany were created, containing eight legions between them. Another seven garrisoned the Danubian provinces. These figures reveal imperial anxiety for the northern frontier.

Effects of peace

Economic life. Although widespread, Augustus' wars chiefly affected the frontier districts. Elsewhere, peace prevailed. Indeed, never before had so large an area been free of war for so long. This state of affairs helped trade. The suppression of piracy and the use of military roads, which the frontier warfare itself brought into being, provided safe arteries of commerce. Stable currency also aided economic growth. Activity directly connected with the soil predominated; but there were also many establishments, usually small, engaged in manufacturing, and such products as textiles, pottery, tiles, and papyrus were turned out in surprising quantities. Advanced techniques were also known: glassblowing, for example, dates from the Augustan age. Most products were consumed locally, but the specialties or monopolies from any region usually exceeded its needs, and the surplus was sold elsewhere, generating a brisk interchange of goods. Some travelled great distances, even beyond the empire: trade with India, for example, reached respectable proportions once the nature of the monsoon was understood and the Red Sea was opened to Roman shipping. Merchants, especially Levantines, travelled everywhere, and fairs were frequent. The Mediterranean world was linked together as never before, and standardization made considerable headway. In Augustus' day Italy was economically the most important part of the empire. It could afford to import on a large scale, thanks partly to provincial tribute but above all to its own large productivity. The eastern provinces, for their part, recovered rapidly from the depredations of the civil wars and were industrially quite advanced. The other provinces were less developed, but they soon ceased being mere suppliers of raw materials; they learned to exploit their natural resources by using new techniques and then began overtaking the more advanced economies of Italy and the Greek-speaking regions. The importance of trade in unifying the empire should not be underestimated.

Augustan art and literature. In 17 BC Rome held Secular Games, a traditional celebration to announce the entry into a new epoch (*saeculum*). New it certainly was, for, although Augustus preserved what he could of republican institutions, he also added much that was his own. His Rome had become very Italian, and this Italian spirit is reflected in the art and literature of his reign. Its greatest writers were native Italians, and, like the ruler whose program they glorified, they used the traditional as the basis for something new. Virgil, Horace, and Livy imitated the writing of classical Greece, but chiefly in outward form, their tone and outlook being un-Hellenic. The glory of Italy and faith in Rome are what inspired Virgil's Georgics and *Aeneid*, Horace's Odes, and the first ten books of Livy's history.

In Augustan art a similar fusion was achieved between the prevailing Attic and Hellenistic models and Italian naturalism. The sculptured portraits on the Ara Pacis Augustae of 9 BC, for all their lifelike quality, are yet in harmony with the classical poise of the figures, and they strike a fresh note: the stately converging processions (Rome's imperial family and magistrates on one side; senators, equites, and citizens on the other) became the prototypes for all later processional reliefs. Augustan painting likewise displays a successful combination of Greek and Roman elements, to judge from the frescoes in the house of Livia on the Palatine. In Augustan architecture Greek features abound, elaborated on basically Italic plans. Unless Agrippa's Pantheon was domed, there is not as yet significant evidence of the soaring vaults and domes that Roman concrete could have already made possible. Building was, however, very active and widespread.

Cultural excellence of the Augustan age

The culture of the age undoubtedly attained a high level of excellence, dominated by the personality of the Emperor and his accomplishments. Imperial art had already reached full development, and this is a matter of no small moment, because Rome's political predominance made the spread of its influence inevitable. The Mediterranean world was soon assuming a Roman aspect, and this is a measure of Augustus' extraordinary achievement. Yet it was an achievement with limitations. His professed aim —to promote stability, peace, security, and prosperity— was irreproachable; but perhaps it was also unexciting. Emphasizing conservatism by precept and his own example, he encouraged the simpler virtues of a less sophisticated age, and his very success made this sedate but rather static outlook fashionable. Men comfortably accepted the routine of his continuing rule, at the cost, however, of some loss of intellectual energy and moral fervour. The great literature, significantly, belongs to the years near Actium, when men's imagination still nursed heady visions of Roman victory and Italian destiny. After the Secular Games the atmosphere became more commonplace and produced the frivolities of Ovid and the pedestrian later books of Livy.

Appraisal of Augustus. Augustus' position as princeps cannot be defined simply. He was neither a Roman king (*rex*) nor a Hellenistic monarch (basileus), nor was he, as the 19th-century German historian Theodor Mommsen thought, a partner with the Senate in a dyarchy. He posed as the first servant of an empire over which the Roman Senate presided, and it would appear that his claim to have accepted no office inconsistent with ancestral custom was literally true. Proconsular *imperium* was a republican institution; and, although tribunician power was not, it contained nothing specifically unrepublican. But, while precedents can be cited for Augustus' various powers, their concentration and tenure were absolutely unparalleled. Under the republic, powers like his would have been distributed among several holders, each serving for a limited period with a colleague. Augustus wielded them all, by himself, simultaneously and without any time limit (in practice, at least). This fact made him an emperor, but it did not necessarily make him a military tyrant.

In discharging both military and civilian functions, Au-.gustus was no different from republican consuls or praetors. Admittedly his military power was overwhelming; but, if he chose not to brandish it, the tone of his reign could remain essentially civilian. Constitutional safeguards were indeed lacking; everything was at the emperor's discretion, and even Augustus passed legislation that made anti-imperial behaviour, real or suspected, treasonable (men were, in fact, executed for conspiracy during his reign). But there had been no constitutional safeguards in the republic, under Sulla, Pompey, the triumvirs, or even Julius Caesar. Augustus' improved police services probably made lower class Romans at least feel safer under him. Augustus had not even deprived the Romans of "liberty," if *libertas* be understood as meaning freedom from arbitrary rule and arbitrary interference.

The principate was in truth something personal. It was what the individual emperor chose to make it, and the relations prevailing between emperor and Senate usually indicated what a reign was like. In Augustus' case they reveal a regime that was outwardly constitutional, generally moderate, and certainly effective. But, as he himself implied at the end of his life, he was a skillful actor in life's comedy. Later emperors might have lacked his sureness of touch.

Augustus' accomplishments

When Augustus died, the Senate unhesitatingly pronounced him divus—the deified one who had restored peace, organized a standing army to defend the frontiers, expanded those frontiers farther than any previous Roman, improved administrative practices everywhere, promoted better standards of public and private behaviour, integrated Rome and Italy, embellished Rome, reconciled the provinces, expedited Romanization, and above all maintained law and order while respecting republican traditions.

Augustus' luck was hardly inferior to his statecraft. Despite indifferent health, he headed the Roman state in one capacity or another for 56 years. This is the longest personal supremacy in European history, and it consolidated the principate so firmly that what might have been an episode became an epoch. At his death there was practically no one left with any personal memory of the republic, and Augustus' wish came true: he had fashioned a lasting as well as a constitutional type of government. The principate endured with only minor changes for something like 200 years.

The other Julio-Claudian emperors

The succession. Augustus' first four successors were all related to him by either birth or marriage; he and they collectively formed the Julio-Claudian dynasty (27 BC–AD 68). There being no constitutional provision for the succession, none of them reached the purple by legal right. The Emperor's position was personal, and, on his death, revival of the republic was in theory possible; in practice, however, it was out of the question-even in Augustus' lifetime, appointment of a senator as city prefect was necessary, to deputize for the Emperor during his absences from Rome. Consequently, Augustus began thinking early about who should follow him. The soldiers' views on legitimacy reinforced his own natural desire to found a dynasty; but he had no son and was therefore obliged to select his successor. Death played havoc with his attempts to do so. His nephew Marcellus, his son-in-law Agrippa, his grandsons Gaius and Lucius (Julia's children by Agrippa), were groomed in turn; but they all predeceased him. Augustus, finally and reluctantly, chose a member of the republican nobility, his stepson Tiberius, a scion of the ultra-aristocratic Claudii. In AD 4 Augustus adopted Tiberius as his son and had tribunician power and probably proconsular imperium as well conferred upon him. This arrangement was confirmed in 13, and when Augustus died the following year, Tiberius automatically became emperor.

Tiberius. Tiberius (ruled 14–37), during whose reign Christ was crucified, was a soldier and administrator of proved capacity but of a reserved and moody temperament that engendered misunderstanding and unpopularity. Slander blamed him for the death in 19 of his nephew and heir apparent, the popular Germanicus; and, when informers (delatores), who functioned at Rome like public prosecutors, charged notables with treason, Tiberius was thought to encourage them. By concentrating the praetorian cohorts in a camp adjoining Rome he increased the soldiers' scope for mischief-making without finding any real security, and in 26 he left Rome permanently for the island of Capreae (Capri), entrusting

Rome to the care of the city prefect. Tiberius heeded the aged Augustus' advice and did not extend the empire. (The annexation of Cappadocia, a client kingdom, represented no departure from Augustan policy.) In general he took his duties seriously; but by administering the empire from Capreae he offended the Senate and was never fully trusted, much less really liked. At his death he was not pronounced *divus.* His great-nephew, Germanicus' son Gaius, succeeded him.

Gaius. Gaius (better known by his nickname, Caligula, meaning Little Boot) ruled from 37 to 41 with the absolutism of an Oriental monarch: his short reign was featured by reckless spending, callous murders, and humiliation of the Senate. Gaius' foreign policy was inept. Projected annexation proved abortive in Britain; it touched off heavy fighting in Mauretania. In Judaea and Alexandria, Gaius' contemptuous disregard of Jewish sentiment provoked near-rebellion. When assassination ended his tyranny, the Senate contemplated restoration of the republic but was obliged by the Praetorian Guard to recognize Claudius, Germanicus' brother and therefore Gaius' uncle, as emperor.

Centralization and expansion under Claudius I

Claudius I. Claudius I (ruled 41–54) went far beyond Augustus and Tiberius in centralizing government administration and, particularly, state finances in the imperial household. His freedmen secretaries consequently acquired great power; they were in effect directors of government bureaus. Claudius himself displayed much interest in the empire overseas; he enlarged it significantly, incorporating client kingdoms (Mauretania in 42; Lycia, 43; Thrace, 46) and, more important, annexing Britain. Conquest of Britain began in 43, Claudius himself participating in the campaign; the southeast was soon overrun, a *colonia* established at Camulodunum (Colchester) and a *municipium* at Verulamium (St. Albans), while Londinium (London) burgeoned into an important entrepôt. Claudius also promoted Romanization, especially in the western provinces, by liberally granting Roman citizenship, by founding *coloniae,* and by inducting provincials directly into the Senate—he became censor in 47 and added the senators he wanted, bestowing appropriate quaestorian or praetorian rank upon them to spare the maturer ones among them the necessity of holding junior magistracies; lest existing senators take offense, he elevated some of them to patrician status (a form of patronage often used by later emperors). Claudius' provincial policies made the primacy of Italy less pronounced, although that was hardly his aim. In fact, he did much for Italy, improving its harbours, roads, and municipal administration and draining its marshy districts. The execution of many senators and equites, the insolence and venality of his freedmen, the excessive influence of his wives, and even his bodily infirmities combined to make him unpopular. Nevertheless, when he died (murdered probably by his fourth wife, Agrippina, Augustus' great-granddaughter, who was impatient for the succession of the 16-year-old Nero, her son by an earlier marriage), he was pronounced *divus.*

Nero. Nero (ruled 54–68) left administration to capable advisers for a few years but then asserted himself as a vicious despot. He murdered successively his stepbrother Britannicus, his mother Agrippina, his wife Octavia, and his tutor Seneca. He also executed many Christians, accusing them of starting the great fire of Rome in 64 (this is the first recorded Christian persecution). In Rome his reliance on Oriental favourites and his general misgovernment led to a conspiracy by Gaius Calpurnius Piso (65), but it was suppressed, leading to yet more executions; the victims included the poet Lucan. The empire was not enlarged under this unwarlike emperor, but it witnessed serious disorders. In Britain in 60–61 the rapacity and brutality of Roman officials provoked a furious uprising under Queen Boudicca; thousands were slaughtered, and Camulodunum, Verulamium, and Londinium were destroyed. In the east, a major military effort under Corbulo, Rome's foremost general, was required (62–65) to re-establish Roman prestige; a compromise settlement was reached, the Romans accepting the Parthian nominee in Armenia and the Parthians recognizing him as Rome's client king. In 66, however, revolt flared in Judaea, fired by Roman cruelty and stupidity, Jewish fanaticism, and communal hatreds; the Prefect of Egypt, Julius Alexander, prevented involvement of the Jews of the Diaspora. A strong army was sent to Judaea under Titus Flavius Vespasianus to restore order; but it had not completed its task when two provincial governors in the west rebelled against Nero—Julius Vindex in Gallia Lugdunensis and Sulpicius Galba in Hispania Tarraconensis. When the praetorians in Rome also renounced their allegiance, Nero lost his nerve and committed suicide. He brought the Julio-Claudian dynasty to an ignominious end by being the first emperor to suffer *damnatio memoriae—his* reign was officially stricken from the record by order of the Senate.

The end of the Julio-Claudian dynasty

GROWTH OF THE EMPIRE UNDER THE FLAVIANS AND ANTONINES

The year of the four emperors. Nero's death ushered in the so-called year of the four emperors. The extinction of the Julio-Claudian imperial house robbed the soldiers of a focus for their allegiance, and civil war between the different armies ensued. The army of Upper Germany, after crushing Vindex, urged its commander, Verginius Rufus, to seize the purple for himself. But he elected to support Galba—scion of a republican patrician family claiming descent from Jupiter and Pasiphae—who was recognized as emperor by the Senate. A treasury emptied by Nero's extravagance entailed economy, and this bred unpopularity for Galba; his age (73) was also against him, and unrest grew. Early in January 69 the Rhineland armies acclaimed Aulus Vitellius, commander in Lower Germany; at Rome the praetorians preferred Marcus Salvius Otho, whom Galba had alienated by choosing a descendant of the old republican aristocracy for his successor. Otho promptly procured Galba's murder and obtained senatorial recognition; this ended the monopoly of the purple that the republican nobility had hitherto enjoyed.

Otho, however, lasted only three months; defeated at Bedriacum, near Cremona in northern Italy, by Vitellius' powerful Rhineland army, he committed suicide (April 69). The Senate thereupon recognized Vitellius; but the soldiers along the Danube and in the east supported Vespasianus, the commander in Judaea. In a second battle near Bedriacum, Vitellius' troops were defeated in their turn, and on his death soon afterward an accommodating Senate pronounced Vespasian emperor.

The Flavian emperors. On December 22, 69, the Senate conferred all the imperial powers upon Vespasian en *bloc* with the famous Lex de Imperio Vespasiani, and the Assembly ratified the Senate's action. This apparently was the first time that such a law was passed; a fragmentary copy of it is preserved on the Capitol in Rome.

Vespasian. Vespasian (ruled 69–79) did not originate from Rome or its aristocracy. His family came from Sabine Reate, and with his elevation the Italian bourgeoisie came into its own. He and his two sons, both of whom in turn succeeded him, constituted the Flavian dynasty (69–96). Vespasian faced the same difficult task as Augustus—the restoration of peace and stability. The disorders of 69 had taken troops away from the Rhine and Danube frontiers. Thereupon, the Danubian lands were raided by Sarmatians, a combination of tribes who had overwhelmed and replaced the Scythians, their distant kinsmen, in eastern Europe. The assailants were repelled without undue difficulty, but, because the region between the Rivers Tisa and Danube was now firmly in the hands of the Sarmatian Iazyges, they were an omen for the future.

Developments in the Rhineland were more immediately serious. There in 69 a certain Civilis incited the Batavians serving as auxiliaries in the Roman army to rebel. Gallic tribes joined the movement, and the insurgents boldly overran all but two of the legionary camps along the Rhine. Vespasian sent his relative Petilius Cerealis to deal with the rebels, who, fortunately for Rome, were not united in their aims; and by 70 Cerealis had restored order. That same year Vespasian's elder son, Titus, brought the bloody war in Judaea to its end by besieging, capturing, and destroying Jerusalem.

Vespasian's policies

To rehabilitate the public finances, Vespasian introduced new imposts, including a poll tax on Jews, and practiced stringent economies. With the Senate he was courteous but firm. He allowed it little initiative but used it as a reservoir from which to obtain capable administrators. To that end he assumed the censorship and added senators on a larger scale than Claudius had done, especially from the municipalities of Italy and the western provinces. Already before 69 an aristocracy of service had been born, and the provincialization of the Roman Senate had begun; thereafter this development made rapid headway. Besides the censorship, Vespasian also often held the consulship, usually with Titus as his colleague. His object presumably was to ensure that his own parvenu Flavian house outrank any other. In this he succeeded; the troops especially were ready to accept the Flavians as the new imperial family. On Vespasian's death in 79, Titus, long groomed for the succession, became emperor and immediately had his father deified.

Titus. Titus (ruled 79–81) had a brief reign, marred by disasters (the volcanic eruption that buried Pompeii and Herculaneum and another great fire in Rome); but his attempts to alleviate the suffering and his general openhandedness won him such popularity that he was unhesitatingly deified after his early death.

Dornitian. Domitian (ruled 81–96), Titus' younger brother, had never been formally indicated for the succession; but the praetorians acclaimed him, and the Senate ratified their choice. Throughout his reign Domitian aimed at administrative efficiency, but his methods were very high-handed. For him the Senate existed merely to supply imperial servants. He also used equites extensively, more than any previous emperor. He held the consulship repeatedly, was *censor perpetuus* from 85 on, and demanded other extravagant honours. On the whole, his efficiency promoted the welfare of the empire. Above all, he retained the allegiance of the troops. Although scornful of the Senate's dignity, he insisted on his own and mercilessly punished any act of disrespect, real or fancied, toward himself. He became even more suspicious and ruthless when Saturninus, commander in Upper Germany, attempted rebellion in 89. He crushed Saturninus; executions and confiscations ensued, and *delatores* flourished. The tyranny was particularly dangerous to senators, and it ended only with Domitian's assassination in 96. The Flavian dynasty, like the Julio-Claudian, ended with an emperor whose memory was officially damned.

Military reforms under the Flavians

Military developments and frontiers. The disorders in 69 were the cause of some military reforms. Under the Flavians, auxiliaries usually served far from their native heaths under officers of different nationality from themselves. At the same time, the tasks assigned to them came increasingly to resemble those performed by the legionaries. The latter grew less mobile, as stone camp buildings came to be the rule; and it became common for detachments from a legion *(vexillationes),* rather than the entire legion, to be used for field operations. This new-type army proved its mettle in Britain, where the advance halted by Boudicca's revolt was now resumed. Between 71 and 84 three able governors—Petilius Cerealis, Julius Frontinus, and Julius Agricola, the latter Tacitus' father-in-law—enlarged the province to include Wales and northern England; Agricola even reached the Scottish highlands before Domitian recalled him.

Along the Rhine, weaknesses revealed by Civilis' revolt were repaired. Vespasian crossed the river in 74 and annexed the Agri Decumates, the triangle of land between the sources of the Rhine and the Danube. To consolidate the position, he and Domitian after him penetrated the Neckar Valley and Taunus Mountains, and fortifications began to take shape to the east of the Rhine, a military boundary complete with strongpoints, watchtowers, and, later, a continuous rampart of earthworks and palisades. Once Saturninus' revolt in 89 had been suppressed, Domitian felt the situation along the Rhine sufficiently stable to warrant conversion of the military districts of Upper and Lower Germany into regular provinces and the transfer of some Rhineland troops to the Danube. To the north of this latter river, the Dacians had been organized into a strong kingdom, ruled by Decebalus and centring on modern Romania; in 85 they raided southward across the Danube, and in the next year they defeated the Roman punitive expedition. Domitian restored the situation in 88, but Saturninus' rebellion prevented him from following up his success. Domitian and Decebalus thereupon came to terms: Decebalus was to protect the lower Danube against Sarmatian attack, and Domitian was to pay him an annual subsidy in recompense. The Danubian frontier, however, remained disturbed, and Domitian wisely strengthened its garrisons; by the end of his reign it contained nine legions, as against the Rhineland's six, and Pannonia was soon to become the military centre of gravity of the empire.

Strengthening of the eastern frontier

The Flavians also took measures to strengthen the eastern frontier. In Asia Minor, Vespasian created a large "armed" province by amalgamating Cappadocia, Lesser Armenia, and Galatia; and the whole area was provided with a network of military roads. South of Asia Minor, Judaea was converted into an "armed" province by getting legionary troops; and two client kingdoms—Commagene and Transjordan—were annexed and added to Syria. Furthermore, the legionary camps seem now to have been established right on the Euphrates at the principal river crossings. This display of military strength kept the empire and Parthia at peace for many years.

The Antonine emperors. Marcus Cocceius Nerva, an elderly senator of some distinction, was the choice of Domitian's assassins for emperor; and the Senate promptly recognized him. The soldiers did so much more reluctantly, however; and, because the year 69 had revealed that emperors no longer needed to be Roman aristocrats and could be chosen elsewhere than at Rome, their attitude imposed caution.

Nerva. Nerva (ruled 96–98) adopted a generally lavish and liberal policy, but it failed to win the soldiers over completely, and he proved unable to save all Domitian's murderers from their vengeance. Unrest subsided only when, overlooking kinsmen of his own, he adopted an outstanding soldier, Marcus Ulpius Trajanus, governor of Upper Germany, as his successo . Nerva himself died a few months later.

Trajan. Trajan (ruled 98–117) was the first and perhaps the only emperor to be adopted by a predecessor totally unrelated to him by either birth or marriage. He was also the first in a series of "good" rulers who succeeded one another by adoption and for most of the 2nd century provided the empire with internal harmony and careful government; they are collectively, if somewhat loosely, called the Antonine emperors. More significantly still, Trajan, a Spaniard, was also the first *princeps* to come from the provinces; with the greater number of provincials now in the Senate, the elevation of one of them, sooner or later, was practically inevitable. Throughout his reign, Trajan generally observed constitutional practices. Mindful of the susceptibilities of the Senate, he regularly consulted and reported to it. Modest in his bearing, he did not claim ostentatious honours such as frequent consulships or numerous imperial salutations, and he mixed easily with senators on terms of cordial friendship. This re-established mutual respect between *princeps* and Senate. Empire and liberty, in Tacitus' words, were reconciled, and the atmosphere of suspicion, intrigue, and terror surrounding the court in Domitian's day disappeared. Trajan endeared himself also to the populace at large with lavish building programs, gladiatorial games, and public distributions of money. Above all, he was popular with the armed forces; he was the soldier-emperor *par excellence.* Understandably, he received the title Optimus (Best), officially from 114 on (and unofficially for many years earlier).

Yet Trajan was a thoroughgoing autocrat who intervened without hesitation or scruple even in the senatorial sphere, whenever it seemed necessary. His aim was efficiency; his desire was to promote public welfare everywhere. He embellished Rome with splendid and substantial structures, and he showed his care for Italy by refurbishing and enlarging the harbours at Ostia, Centumcellae, and Ancona. He sent officials called *curatores* to Italian municipalities in financial difficulties and helped to rehabilitate them. He greatly expanded an ingenious charity scheme, which Nerva had probably begun: money was loaned to farmers on easy terms, and the low interest they paid went into a special fund for supporting indigent children. Nor did Trajan neglect Italy's highway network: he built a new road (Via Traiana) that soon replaced the Via Appia as the main thoroughfare between Beneventum and Brundisium.

Interest in Italy implied no neglect of the provinces. *Curatores* were also sent to them; and to rescue Achaea and Bithynia, senatorial provinces, from threatened bankruptcy, Trajan made them both temporarily imperial, sending special commissioners of his own to them. His correspondence with his appointee in Bithynia, the younger Pliny, has survived and reveals how meticulously the Emperor superintended even the smallest details.

Trajan's sense of responsibility cannot be doubted, and his well-meaning example inspired his immediate successors to imitate his paternalism. Such imperial encroachment, however, helped to create a huge and burdensome bureaucracy and to stifle the local initiative on which municipal autonomy throughout the empire depended.

Expansion of the empire under Trajan

Trajan's efforts were as notable in the military sphere as in the civilian. He decided to strengthen the dangerous Danube frontier by converting Dacia into a salient of Roman territory north of the river in order to dismember the Sarmatian tribes and remove the risk of large, hostile combinations to a safer distance. Accordingly, he mustered a large army, conquered Decebalus in two hard-fought wars (101–102; 105–106), and annexed Dacia and filled it with settlers from neighbouring parts of the empire. On the eastern frontier he planned a similar operation, evidently in the conviction, shared by many eminent Romans both before and after him, that only conquest could solve the Parthian problem. Possibly, too, he wished to contain the menace of the Sarmatian Alani in the Caspian region. In a preliminary move, the Nabataean kingdom of Arabia Petraea was annexed in 105–106. Then in 114 Trajan assembled another large army, incorporated the client kingdom of Armenia, and invaded Parthia.

After spectacular victories in 115 and 116, he created additional provinces (Northern Mesopotamia, Assyria) and reached the Persian Gulf. But he had merely overrun Mesopotamia; he had not consolidated it, and, as his army passed, revolts broke out in its rear. The Jews of the Diaspora and others seized their chance to rebel, and before the end of 116 much of the Middle East besides Parthia was in arms (Cyrene, Egypt, Cyprus, Asia Minor). Trajan proceeded resolutely to restore the situation, but death found him still in the East.

Before his last illness, he had not formally indicated his successor. But high honours and important posts had been accorded his nearest male relative, Publius Aelius Hadrianus, the governor of Syria; and, according to Trajan's widow, Hadrian had actually been adopted by Trajan on his deathbed. Accordingly, both Senate and soldiers recognized him. Trajan's posthumous deification was never in doubt.

Hadrian. Hadrian (ruled 117–138), also a Spaniard, was an emperor of unusual versatility. Unlike Trajan, he was opposed to territorial expansion. Being himself in the East in 117, he renounced Trajan's conquests there immediately and contemplated evacuating Dacia as well. Furthermore, four of the consular generals particularly identified with Trajan's military ventures were arrested and executed "for conspiracy"; Hadrian claimed later that the Senate ordered their deaths against his wishes. His policies made his a peaceful reign. The only heavy fighting occurred in Judaea—or Syria Palaestina, as it was thenceforth called—where Bar Kokhba led a furious, if futile, Jewish revolt (132–135) against Hadrian's conversion of Jerusalem into a Roman colony named Aelia Capitolina.

Hadrian's policies

Instead of expansion by war, Hadrian sought carefully delimited but well-defended frontiers, with client states beyond them where possible. The frontiers themselves, when not natural barriers, were strongly fortified: in Britain, Hadrian's Wall, a complex of ditches, mounds, forts, and stone wall, stretched across the island from the Tyne to the Solway; Germany and Raetia had a *limes* (fortified boundary) running between Mainz on the Rhine and Regensburg on the Danube. Within the frontiers the army was kept at full strength, mostly by local recruiting of legionaries and apparently of auxiliaries, too (so that Vespasian's system of having the latter serve far from their homelands gradually ceased). Moreover, the tendency for auxiliaries to be assimilated to legionaries continued; even the officers became less distinguishable, because equites now sometimes replaced senators in high posts in the legions. To keep his essentially sedentary army in constant readiness and at peak efficiency (no easy task), Hadrian carried out frequent personal inspections, spending about half his reign in the provinces (121–125; 128–134). The transformation of field troops into static garrisons frequently meant entrusting mobile operations to the so-called numeri—light-armed tribal units, often obtained outside the empire—and this contributed to the barbarization of the Roman imperial army.

Hadrian was also responsible for significant developments on the civilian side. Under him, equites were no longer required to do military service as an essential step in their career, and many of them were employed in the imperial civil service, more even than under Domitian. By now the formative days of the civil service were over; its bureaucratic phase was beginning, and it offered those equites who had no military aspirations an attractive, purely civilian career. Formal titles now marked the different equestrian grades of dignity: a procurator was *vir egregius;* an ordinary prefect, *vir perfectissimus;* a praetorian prefect, *vir eminentissimus,* the latter title being obviously parallel to the designation *vir clarissimus* for a senator. Thenceforth, equites replaced freedmen in the imperial household and bureaus, and they even appeared in Hadrian's imperial council.

Hadrian also improved legal administration. He had his expert jurists codify the *edictum perpetuum* (the set of rules gradually elaborated by the praetors for the interpretation of the law). He also appointed four former consuls to serve as circuit judges in Italy. This brought Italy close to a province; not that Hadrian was anxious to reduce the status of Italy—his policy was to make all parts of the empire important. For one part he was exceptionally solicitous: he spent much time in Greece and lavishly embellished Athens.

Hadrian maintained good relations with but was never fully trusted by the Senate. His foreign policy seemed to be unheroic, his cosmopolitanism to be un-Roman, and his reforms to encroach on activities traditionally reserved to senators. Moreover, in his last two years he was sometimes capricious and tyrannous. Like Augustus, he had no son of his own and conducted a frustrating search for a successor. After executing his only male blood relative, his grandnephew, in 136, he adopted Lucius Ceionius Commodus, renaming him Lucius Aelius Caesar. The latter, however, died shortly afterward, whereupon Hadrian in 138 chose a wealthy but sonless senator, the 51-year-old Titus Aelius Antoninus; but, evidently intent on founding a dynasty, he made Antoninus in his turn adopt two youths, 16 and seven years old, respectively—they are known to history as Marcus Aurelius (the nephew of Antoninus' wife) and Lucius Verus (the son of Aelius Caesar). When Hadrian died soon thereafter, Antoninus succeeded and induced a reluctant Senate to deify the deceased emperor. According to some, it was this act of filial piety that won for Antoninus his cognomen, Pius.

Antoninus' reign of quiet prosperity

Antoninus Pius. Antoninus Pius (ruled 138–161) epitomizes the Roman Empire at its cosmopolitan best. He himself was of Gallic origin; his wife was of Spanish origin. For most men his was a reign of quiet prosperity, and the empire under him deserves the praises lavished upon it by the contemporary writer Aelius Aristides. Unlike Hadrian, Antoninus travelled little; he remained in Italy, where in 148 he celebrated the 900th anniversary of

Rome. *Princeps* and Senate were on excellent terms, and coins with the words *tranquillitas* and *concordia* on them in Antoninus' case mean what they say. Other of his coins not unreasonably proclaim *felicitas ternporum* ("the happiness of the times"). Yet raids and rebellions in many of the borderlands (in Britain, Dacia, Mauretania, Egypt, Palaestina, and elsewhere) were danger symptoms, even though to the empire at large they seemed only faraway bad dreams, to use the expression of Aelius Aristides. Antoninus prudently pushed the Hadrianic frontiers forward in Dacia, the Rhineland, and Britain (where the Antonine Wall from the Forth to the Clyde became the new boundary) and carefully groomed his heir apparent for his imperial responsibilities.

Marcus Aurelius. Marcus Aurelius (ruled 161–180) succeeded the deified Antoninus and more than honoured Hadrian's intentions by immediately co-opting Lucius Verus as his full co-emperor. Because Verus' competence was unproved, this excess of zeal was imprudent. Fortunately, Verus left decision making to Marcus. Marcus' action was also dangerous for another reason; it represented a long step away from imperial unity and portended the ultimate division of the empire into Greek- and Latin-speaking halves. Nor was this the only foreboding development in Marcus' reign—formidable barbarian assaults were launched against the frontiers, anticipating those that were later to bring about the disintegration of the empire. Marcus himself was a Stoic philosopher; and his humanistic if somewhat pessimistic *Meditations* reveal how conscientiously he took his duties. Duty called him to war; he responded to the call and spent far more of his reign in the field than had any previous emperor.

At Marcus' very accession the Parthians turned aggressive, and he sent Verus to defend Roman interests (162). Verus greedily took credit for any victories but left serious fighting to Avidius Cassius and the army of Syria. Cassius succeeded in overrunning Mesopotamia and even took Ctesiphon, the Parthian capital; he was therefore able to conclude a peace that safeguarded Rome's eastern provinces and client kingdoms (166). In the process, however, his troops became infected with plague, and they carried it back with them to the west with calamitous results. The Danube frontier, already weakened by the dispatch of large detachments to the East, collapsed under barbarian assault. Pressed on from behind by Goths, Vandals, Lombards, and others, the Germanic Marcomanni and Quadi and the Sarmatian Iazyges poured over the river; the Germans actually crossed Raetia, Noricum, and Pannonia to raid northern Italy and besiege Aquileia. Marcus and Verus relieved the city shortly before Verus' death (169). Then, making Pannonia his pivot of manoeuvre, Marcus pushed the invaders back; by 175 they were again beyond the Danube. At that moment, however, a false report of Marcus' death prompted Avidius Cassius, by now in charge of all eastern provinces, to proclaim himself emperor. Cassius was himself a native Syrian, and his action may represent incipient separatism by the Greek-speaking East. In any case, it undid Marcus' achievements along the Danube because it took him to the East and reopened the door to barbarian attacks. Fortunately, Cassius was soon murdered, and Marcus could return to central Europe (177). But he had barely restored the frontier again when he died at Vindobona (Vienna) in 180, bequeathing the empire to his son, the 19-year-old Commodus, who had actually been named co-emperor three years earlier.

Barbarian assaults

Cornmodus. Commodus (ruled 180–192), like Gaius and Nero, the youthful emperors before him, proved incompetent, conceited, and capricious. Fortunately, the frontiers remained intact, thanks to able provincial governors and to barbarian allies, who had been settled along the Danube with land grants and who gave military service in return. But Commodus abandoned Marcus' scheme for new trans-Danubian provinces, preferring to devote himself to sensual pleasures and especially to the excitements of the arena in Rome, where he posed as Hercules Romanus and forced the Senate to recognize his godhead officially. He left serious business to his favourites; and their ambitions and intrigues led to plots, treason trials, confiscations, and insensate murders. Commodus' assassination on the last day of 192 terminated a disastrous reign; and the Antonines, like the Julio-Claudians, came to an ignominious end. And there was a similar sequel. Commodus' *dnmnatio memorine,* like Nero's, was followed by a year of four emperors.

THE EMPIRE IN THE 2ND CENTURY

The century and three-quarters after Augustus' death brought no fundamental changes to the principate, although so long a lapse of time naturally introduced modifications and shifts of emphasis. By Flavian and Antonine times the principate was accepted universally. For the provinces, a return to the republic was utterly unthinkable; for Rome and Italy, the year 69 served as a grim warning of the chaos to be expected if, in the absence of a *princeps,* the ambitions of a few powerful individuals obtained unfettered scope. *A princeps* was clearly a necessity, and men were even prepared to tolerate a bad one, although naturally they always hoped for a good one.

Nor did the *princeps* have to be chosen any longer from the Julio-Claudians. The great achievement of the Flavians was to reconcile the soldiers and the upper classes everywhere to the idea that others were eligible. The Flavians' frequent tenure of consulship and censorship invested their middle class Italian family with the outward trappings of prestige and the aristocratic appearance of an authentic imperial household. The deification of the first two Flavians contributed to the same end, and so did the disappearance of old republican families that might have outranked the reigning house (by 69 most descendants of the republican nobility had either died or been exterminated by imperial persecution). After the Flavians, the newness of a man's senatorial dignity and the obscurity of his ultimate origin, Italian or otherwise, no longer forbade his possible elevation. Indeed, Domitian's successors and even Domitian himself in his last years did not need to enhance their own importance by repeated consulships. The Antonine emperors, like the Julio-Claudians, held the office infrequently. They did, however, continue the Flavian practice of emphasizing the loftiness of their families by deifying deceased relatives (Trajan deified his sister, niece, and father; Antoninus, his wife; etc.).

Eligibility for the principate

Trend to absolute monarchy. Glorification of the reigning house, together with a document such as Vespasian's Lex de Imperio, helped to advertise the emperor's position; and under the Flavians and Antonines the principate became much more like an avowed monarchy. Proconsular *imperium* began to be reflected in the imperial titulary, and official documents started calling the emperor *dominus noster* (" our master").

The development of imperial lawmaking clearly illustrates the change. From the beginnings of the principate, the emperor had had the power to legislate, although no law is known that formally recognized his right to do so; by Antonine times, legal textbooks stated unequivocally that whatever the emperor ordered was legally binding. The early emperors usually made the Senate their mouthpiece and issued their laws in the form of senatorial decrees; by the 2nd century the emperor was openly replacing whatever other sources of written law had hitherto been permitted to function. After 100 the Assembly never met formally to pass a law, and the Senate often no longer bothered to couch its decrees in legal language, being content to repeat verbatim the speech with which the ruler had advocated the measure in question. After Hadrian, magistrates ceased modifying existing law by their legal interpretations because the praetors' *edictum perpetuum* had become a permanent code, which the emperor alone could alter. By 200, learned jurists had lost the right they had enjoyed since the time of Augustus of giving authoritative rulings on disputed points *(responsa prudentium).* Meanwhile, the emperor more and more was legislating directly by means of edicts, judgments, mandates, and rescripts—collectively known as *constitutiones principum. He* usually issued such *constitutiones* only after consulting the "friends" *(amici Caesaris)* who composed his imperial council. But a ***constitutio*** was nevertheless a fiat. The road to the latter dominate (after 284) lay open.

Political life. Nevertheless, the autocratic aspect of the Flavian and Antonine regimes should not be overstressed. Augustus himself had been well aware that it was impossible to disguise permanently the supremacy that accumulation of powers gained piecemeal conferred; his deportment in his last years differed little from that of Vespasian, Titus, and the so-called five good emperors who followed them. Nor had other Julio-Claudians hesitated to parade their predominance—Claudius, by centralizing the imperial powers, reduced their apparent diversity to one all-embracing *imperium;* Gaius and Nero revealed the autocracy implicit in the principate with frank brutality.

Civilian character of the Flavian and Antonine reigns

What impresses perhaps as much as the undoubtedly autocratic behaviour of the Flavians and Antonines is the markedly civilian character of their reigns. They held supreme power, and some of them were very distinguished soldiers; yet they were not military despots. For this the old republican tradition—that a state official might serve it in both a civilian and a military capacity—was largely responsible. Matters could change after Hadrian separated the two roles. Actually, the 3rd century soon showed what it meant to have a ***princeps*** whose whole experience had been confined to camps and barracks.

As imperial powers became more concentrated, republican institutions decayed; the importance of imperial officials grew, while the authority of urban magistrates declined. Quaestorship, praetorship, and consulship (the last named now reduced to a two-month sinecure) became mere stepping stones to the great imperial posts that counted most in the life of the empire. Governors of imperial provinces and commanders of legions were Roman senators; but they were equally imperial appointees. Clearly, the emperor was the master of the Senate; and it was disingenuous for him to get impatient, as some emperors did, with the Senate's lack of initiative and reluctance to take firm decisions of its own. The emperor might not even consult the Senate much, preferring to rely on his imperial council, which by the 2nd century was no longer composed exclusively of senators.

The Senate, however, while exercising little power, was treated courteously by most Flavians and Antonines. They recognized its importance as a lawcourt, as the body that formally appointed a new emperor, and as a sounding board of informed opinion. Senators came increasingly from the provinces, and, although this meant pre-eminently the western provinces (the Greek-speaking East being underrepresented), the Senate did reflect to some extent the views of the empire at large.

The equites, meanwhile, steadily acquired greater importance as imperial officials. In newly created posts they were invariably the incumbents, and in posts of long standing they replaced freedmen and ***publicani.*** The 2nd century saw equestrian procurators become the solid basis of the civil service—four grades, distinguished by salary, were established. The great .bureaucracy of later times was fairly launched. This development inevitably bred bitter rivalry with the Senate, mitigated somewhat by the similar social backgrounds of the two orders.

Rome as a melting pot

Rome and Italy. By the 2nd century the city of Rome had attracted freeborn migrants from all over the empire; it housed, additionally, large numbers of manumitted slaves. These newcomers were all assimilated, making Rome a veritable melting pot, and they hoped—especially the many who came from the East—to dilute the city's Italian flavour. The vast majority of them were poor, a handful of opulent imperial freedmen being entirely exceptional. But many were energetic, enterprising, and lucky and made their way in the world. Freedmen laboured under a social stigma, although some of them managed to become equites. Their sons, however, might overcome discrimination, and their grandsons were even eligible for membership in the Senate.

Inevitably, there was extensive trade and commerce (much of it in freedman hands) in so large a city, which was also the centre of imperial administration. There was little industry, however, and the urban poor had difficulty finding steady employment. Theirs was a precarious existence, dependent on the public grain dole and on the private charity of the wealthy. Large building programs gave Flavian and Antonine emperors the opportunity not only to repair the damage caused by fire and falling buildings (a frequent hazard among the densely packed and flimsily built accommodations for the urban plebs) but also to relieve widespread urban unemployment. This also made imperial Rome a city of grandeur. Augustus' building program had been vast but mostly concerned with repairing or rebuilding structures already existing, and his Julio-Claudian successors had built relatively little until the great fire made room for the megalomaniac marvels of Nero's last years. It was under the Flavians and Antonines that Rome obtained many of its most celebrated structures: the Colosseum, Palatine palaces, Trajan's Forum, the Pantheon, the Castel Sant' Angelo (Hadrian's mausoleum), the Temple of Antoninus and Faustina, Aurelius' Column, as well as the aqueducts whose arches marched across the Campagna to keep the city and its innumerable fountains supplied with water.

Italy was much less cosmopolitan and sophisticated and, according to literary tradition, much more sober and straitlaced than was Rome. It was the mistress of the empire, although the gap between it and the provinces was narrowing. Hadrian's policies especially helped to reduce its privileged position. His use of circuit judges was resented precisely because with them Italy resembled a province; actually, Italy badly needed them, and their abolition by Antoninus Pius was soon reversed by Marcus Aurelius. Also in Aurelius' reign a provincial fate overtook Italy in the form of barbarian invasion; and a few years later the country got its first legionary garrison under Septimius Severus.

The economic importance of Italy also declined. By Antonine times the eastern provinces had overtaken it, and it was hardly ahead even of those of the west. Gaul, for instance, could rival Italy industrially. In agricultural products, northern Africa and Spain are revealed by the potsherds of Monte Testaccio to have become serious competitors to Italian growers. The emperors, however, were not indifferent to Italy—Domitian, for example, protected Italian viticulture by restricting vine growing in the provinces; Trajan and his successors forced Roman senators to take an interest in the country, which was no longer the homeland of many of them, by investing a high proportion of their capital in Italian land (one-third under Trajan, one-quarter under Aurelius).

Attempts to achieve stability in the provinces

Developments in the provinces. In the empire at large, Flavians and Antonines, like the better Julio-Claudians, aimed at stability in order that its inhabitants might live in security and self-respect. In this they largely succeeded. Gibbon's famous description of the 2nd century as the period when men were happiest and most prosperous is not entirely false. Certainly, by then men had come to take for granted the unique greatness and invincible eternity of the empire; even the ominous events of Aurelius' reign failed to shatter their conviction that the empire was impregnable. The empire was a vast congeries of peoples and races with differing religions, customs, and languages, and the emperors were content to let them live their own lives. Imperial policy favoured a veneer of common culture transcending ethnic differences, but there was no deliberate denationalization. Ambitious men striving for a career naturally found it helpful, if not necessary, to become Roman in bearing and conduct and perhaps even in language as well (although speakers of Greek often rose to exalted positions). But local self-government was the general rule, and neither Latin nor Roman ways were imposed on the communities composing the empire. The official attitude to religion illustrates this—in line with the absolutist trend, emperor worship was becoming slowly but progressively more theocratic (Domitian relished the title of god, Commodus demanded it); yet this did not lead to the suppression of non-Roman or even outlandish cults, unless they were thought immoral (like Druidism, with its human sacrifice) or conducive to public disorder (like Christianity, with its uncompromising rejection of emperor worship and its liability to become a target for riots).

Local autonomy. Where possible, the emperors kept direct administration from Rome to a minimum (except perhaps in Egypt), and the 2nd century was the most flourishing period of urban civilization that the empire ever knew. Administration everywhere was in the hands of the local well-to-do, who alone could afford the costs attaching to it. Local magistrates paid substantial fees on election; nor did their expenses end there, for they remained members of their local council after their term of office, and local councillors (decuriones, later curiales) were expected to contribute handsomely to local amenities. The cost involved inevitably reduced local elections to formalities, and the local councils became self-perpetuating bodies whose members were persons of some consequence. It was from these local worthies that the emperor often found his candidates for the Senate at Rome, an honour that was eagerly sought by individuals but that was a mixed blessing for their local communities, which stood thereby to lose prospective benefactors.

It is impossible not to be impressed by the spectacle of the Roman Empire in its 2nd-century heyday, with its panorama of splendid and autonomous communities. Nevertheless, before the century was over, there was growing difficulty in maintaining flourishing municipal life in a world where the ordinary man was encouraged to regard the emperor as a sort of terrestrial Providence and where the emperor himself with responsible earnestness accepted the role of universal dispenser of justice. The letters of the younger Pliny and of Marcus Cornelius Fronto reveal how seriously the 2nd-century emperors took their duty and strove for orderly government everywhere. But the emperors' very conscientiousness led inevitably to interference with local autonomy. Perhaps the civil service that Augustus founded would have burgeoned in any event and encroached on the self-governing communities that made up the provinces; but the well-meaning efforts of the Antonines hastened such a development. The ultimate effect was to dampen civic ardour and to foster listlessness. Faced with the prospect of increasing direction from above, municipal notables began avoiding local office. Inability to pay the cost involved may also in part explain the growing reluctance of men to undertake municipal responsibilities; although the provincial bourgeoisie remained generally prosperous, economic recession had set in before the 2nd century ended. For whatever reason, local officeholders became less easy to find; and, well before 200, men were being compelled to accept local office. This boded ill for the future.

The emperors' interference withlocal autonomy

Social structure. Information about the lower orders throughout the empire is not very plentiful. So long as economic activity remained at a high level, there was apparently much social mobility. This was just as well, because there were great disparities of wealth and of class. Society was stratified, and the gap between poor and rich in provincial towns somewhat resembled that between plebs and aristocracy, senatorial or equestrian, in Rome. Indeed, it was precisely in Antoninus' reign that Roman law began to distinguish the lower classes (*humiliores*) from the upper (*honestiores*), and, although local customs and traditions were respected, the civil law of Rome was gradually replacing local codes. The 2nd century and the opening years of the 3rd comprised the classical period of Roman law, producing such illustrious jurists as Salvius Julianus, Gaius, Papinian, Ulpian, and Julius Paulus; and the temptation for the communities of the empire to adopt it must have been strong.

Spread of citizenship. Clearly, Romanization was spreading and with it the Roman citizenship, especially from Hadrian's reign on. The number of provincials with citizenship increased so rapidly that 20 years after Commodus' death the emperor Caracalla could enfranchise all the communities of the empire and excite very little comment in doing so. The subjects of the empire found this levelling of status comfortable; they were also grateful for the peace that prevailed over much of the empire, but they were not particularly eager to defend it. Roman citizens in general avoided military service, and the empire obtained its soldiers by offering Roman citizenship as a reward for enlistment. The ever-wider extension of the citizenship ended its usefulness as a bribe, and the recruiting areas steadily contracted to the least Rornanized districts. Finally, recruits had to be obtained outside the empire altogether.

Evidently, the empire did not inspire a sense of duty or high resolve. There were both political and economic reasons. The average nonwealthy man hardly participated in political life, even in his own community, and his share of the prevailing prosperity was small. Slavery was ubiquitous; and, although humanitarian legislation gradually softened its harsher features, its unhappy victims depressed the living standards of the free workers so that poverty was a serious social problem. Drab materialism was the lot of many—in Asia Minor, for instance, despite unparalleled prosperity brought about by its having the whole Mediterranean open to it as at no other time, great unrest developed as a result of extremes of affluence and poverty. Many men sought solace from worldly cares in the mystery religions, and the prevailing polytheism enabled them to switch or multiply their gods without much problem of conscience (except for the increasingly numerous Christian converts).

Growing use of Latin in Iberia and Gaul

Romanization. By the 2nd century considerable Latinization had occurred in the West. Modem Spanish, Portuguese, and French show this was particularly true of the Iberian Peninsula, which had been provincial soil ever since the Second Punic War, and of Gaul, where Latin enjoyed the advantage of some relationship to Celtic. In these regions even the lower orders adopted Latin, although the survival of Basque proves that the older native languages did not perish utterly. Moreover, enemy threats were far enough away and integration far enough advanced to render large garrisons unnecessary. Elsewhere, and especially in central Europe, large forces remained and were themselves potent instruments of Latinization, because in the army Latin was both the official language and also the lingua franca for heteroglot recruits. Furthermore, thanks to the coloniae, urbanization increased; and urbanization promoted Latinization. In the Danubian region, for instance, where the barbarian threat was acute, ceaseless military activity led to the establishment of numerous coloniae, to the spread of Latin (and its survival in modem Romanian), to the disappearance of ancient Illyrian and Thracian (unless modern Albanian preserves them), and to the birth of a strong pro-Roman patriotism, which increased men's eagerness to learn Latin. In areas away from the frontiers and especially in areas lacking the economic resources to generate cities, often only the bourgeoisie acquired Latin; among the lower orders the pre-Roman languages, even if seldom written, continued in use: Celtic in Britain and Switzerland and, to a lesser extent, in Gaul; Berber and some Punic in Africa and Mauretania. Moreover, from Hadrian on—when local recruiting and local service became the rule, and coloniae were no loager new foundations but simply old towns upgraded in status—the army lost much of its Latinizing role. Complete linguistic unity was therefore never achieved in the West.

This was true also of the East, where Greek had the status of an official language. Rome readily accepted and even encouraged Hellenization of the whole region; and, although the Romans were gratified if Orientals adopted Latin, they realized the futility of trying to impose it. In many districts, however, Greek was spoken only by the administrative and propertied classes, just like Latin in the West. Lower orders, especially in inland districts, continued to use their vernaculars: Aramaic in Syria, Coptic in Egypt, and a variety of tongues in Asia Minor.

The official emperor worship became universal, but Rome was no fountainhead of religious ideas; local cults persisted in both East and West, and the East even gave birth to new religions, such as Christianity. The native divinities were worshipped either under their own names or under those of Greco-Roman deities with whom they could be conveniently identified, for there was much syncretism. In religion as in language the army played an important role. The soldiers, with some help from eastern merchants, spread the worship of such deities as Mithra and Dolichenus, with whom they had become acquainted in the East, to the farthest corners of the empire; Mithra became known even in distant Britain, and Dolichenus was assimilated to Jupiter everywhere.

Differences between the Greek East and the Latin West

In the material aspects of life there was much Romanization. Towns in the Latin-speaking provinces looked very Roman in layout and in buildings: their streets were arranged on a checkerboard plan, and they usually boasted forums, triumphal arches, basilicas, baths, and Roman-type temples, theatres, and amphitheatres, graced with Roman sculpture and decoration. The eastern cities were much less receptive to Roman influences; in fact, the Latin West and the Greek East tended to go their separate ways. Differing outlooks and values, divergent interests and degrees of development, mutual suspicions and antipathies combined to keep them apart; and by Marcus Aurelius' day the blueprint for a divided empire had already been sketched in outline, no matter how faintly. Yet, even in the East, Roman influence was not negligible: some Greek cities became partly Roman in aspect, went in for gladiatorial games and similar Roman entertainments, and adopted the Roman civil law, the most enduring of the empire's legacies.

Economic life. Romanization was due chiefly to Rome's political authority, but the conditions fostered by the Pax Romana also helped. Harbour dues and customs duties prevented the Roman Empire from being one large free-trade area. Nor was there complete laissez faire in other respects, despite a general lack of policies for improving the increasingly complex economy by promoting trade and regulating commerce: there was much routine administration directly concerned with production and distribution of goods. The supervision of the enormous and ubiquitous imperial properties, the provision of Rome's food supply, and procurement for the armed services and other branches of government constituted a significant proportion of the empire's economic activity. Nevertheless, in the prevailing peace, the private sector offered great scope for initiative, enterprise, the free play of competition, and general economic development. Industrial and commercial methods, banking, and credit facilities were all improved, and goods moved easily along the highways crisscrossing the empire from frontier to frontier. There was some trade with countries beyond the frontiers, such as Scandinavia and even China (indirectly), although naturally there was far more within the empire itself. In the West, large Roman (or at least Romanized) towns came into being to serve the needs of trade. In the East, Asia Minor and Syria interchanged goods with the whole Mediterranean world, and the Greek cities flourished as never before, Alexandria and Antioch being the greatest of them but with those of Asia Minor not far behind.

Waning of prosperity during the 2nd century

But in economic as in other matters there was premonition of trouble to come. Before the 2nd century ended, prosperity had begun to wane. A clear symptom of this was the reduction in the weight and fineness of the standard silver coin, the denarius. The economy faltered for various reasons: the consistent drain of metal to the East to pay for spices and Oriental luxuries, the maldistribution of wealth, the lack of industrial inventiveness in a slave-based society, the depopulation caused by war (by Aurelius' reign no longer confined to frontier areas). The economic chaos of the 3rd century, however, was still some distance away.

The army. The army that enforced the Pax Romana had expanded little beyond the size envisaged for it by Augustus, despite the enlargement of the empire by Claudius, the Flavians, and Trajan. It reached 31 legions momentarily under Trajan, but it usually totalled 28 under the Flavians and Antonines until the onset of the frontier crisis in Aurelius' reign brought it to 30. This, seemingly, was the limit for which either recruits or money could be found; and it probably explains why Hadrian, and later Commodus, halted further expansion.

The army was used not to prop up a militarist government but to defend the frontiers. Shifts in enemy pressures, however, caused the legions to be distributed differently than in Julio-Claudian times. Under Antoninus Pius, the Danubian provinces (Pannonia, Moesia, Dacia) had ten, and the East (Asia Minor, Syria, Palestine, Egypt) had nine, and both regions also had supporting naval flotillas; of the remaining nine legions, Britain contained three and the Rhineland four. Clearly, the army was thinly stretched elsewhere, with auxiliaries bearing the burden of defense. In much of the empire the sight of a soldier, especially a legionary, was a comparatively rare event, the more so because normally troops not only remained in frontier areas while serving but were also largely recruited there.

The provinces underwent changes in size as well as in garrison. For prudential reasons the emperors refused to entrust many legions to a single commander; they split a province in two as soon as it needed a large military establishment. Thus, the number of provinces was constantly growing; by Hadrian's day subdivision began to anticipate the fragmentation later carried out by Diocletian.

Imperial literature

Cultural life. The literature of the empire is both abundant and competent, for which the emperors' encouragement and financing of libraries and higher education were perhaps in part responsible. The writers, however, with the possible exception of Christian apologists, were seldom excitingly original and creative. As Tacitus said, the great masters of literature have ceased to be. Perhaps Augustus' emphasis on tradition affected more than political ideals and practice. At any rate, men of letters, too, looked often backward. At the same time they clearly reveal the success of the empire in spreading Greco-Roman culture, for the majority of them were natives of neither Italy nor Greece. Of the writers in Latin, the two Senecas, Lucan, Martial, Columella, Hyginus, and Pomponius Mela came from Sapin; Fronto, Apuleius, and probably Florus and Aulus Gellius, from Africa. Tacitus was perhaps from Gallia Narbonensis. The Latin writers in general sought their models less in Greece than in Augustus' Golden Age, when Latin literature had reached maturity. Thus, the poets admired Virgil and imitated Ovid; lacking genuine inspiration, they substituted for it an erudite cleverness, the fruit of an education that stressed oratory of a striking but sterile kind. Authentic eloquence in Latin came to an end when, as Tacitus put it, the principate "pacified" oratory. Under the Flavians and Antonines, an artificial rhetoric, constantly straining after meretricious effects, replaced it. The epigrammatic aphorism (sententia) was especially cultivated; the epics of Lucan, Valerius Flaccus, Silius Italicus, and Statius are full of it, and it found a natural outlet in satirical writing, of which the Latin instinct for the mordant always ensured an abundance. In fact, Latin satire excelled: witness Martial's epigrams, Petronius' and Juvenal's pictures of the period, and Persius' more academic talent. For that matter, Tacitus' irony and pessimism were not far removed from satire.

In the East the official status of Greek and the favour it enjoyed from such emperors as Hadrian gave new life to Greek literature. It had something in common with its Latin counterpart in that it looked to the past but was chiefly written by authors who were not native to the birthplace of the language. The so-called Second Sophistic reverted to the atticism of an earlier day but often in a Roman spirit; its products from the Asian pens of Dio Chrysostom and Aelius Aristides are sometimes limpid and talented tours de force but rarely great literature. In Greek, too, the best work was in satire, the comic prose dialogues of the Syrian Lucian being the most noteworthy and original literary creations of the period. Among minor writers the charm of Arrian and Pausanias, Asians both, and above all of Plutarch abides (although Plutarch's talents were mediocre, and his moralizing was shallow, his biographies, like those of his Latin contemporary Suetonius, are full of information and interest).

Imperial encouragement of Greek culture and a conviction, no longer justified, of its artistic and intellectual superiority caused the East to resist Latinization. This attitude was bound to lead to a divided empire, and thoughtful observers must have noted it with misgivings. The split, however, was still far in the future. Meanwhile, there was a more immediate cause for disquiet. The plethora of summaries and anthologies that appeared implies a public progressively indifferent to reading. In other words, the outlook for letters was poor, and this had an unfortunate effect on the scientific literature of the age, which was in itself of first-class quality. Dioscorides on botany, Galen on medicine, and Ptolemy on mathematics, astronomy, and geography represent expert scholars, expounding carefully, systematically, and lucidly the existing knowledge in their respective fields. But their very excellence proved fatal because, as the reading public dwindled, theirs remained standard works for far too long; their inevitable errors became enshrined, and their works acted as brakes on further progress.

Stoicism was the most flourishing philosophy of the age. In the East a sterile scholasticism diligently studied Plato and Aristotle, but Epictetus, the Stoic from Asia Minor, was the pre-eminent philosopher. In the West, Stoicism permeates Seneca's work and much of Pliny's *Natural History*. Evidently, its advocacy of common morality appealed to the traditional Roman sense of decorum and duty, and its doctrine of a world directed by an all-embracing providence struck a responsive chord in the 2nd-century emperors, though they deeply disapproved of its extremist offshoots, the Cynics: Marcus Aurelius was himself a Stoic.

Imperial art

Imperial art, dealing above all with man and his achievements, excelled in portraits and commemoration of events; Roman sculpture and presumably Roman painting, also, owed much to Greek styles and techniques. It emerged, however, as its own distinctive type. The Augustan age had pointed the way that Roman art would go: Italian taste would be imposed on Hellenic models to produce something different and original. The reliefs of the Augustan Ara Pacis belong to Rome and Italy, no matter who actually carved them. By Flavian times this Roman instinct had asserted itself and with it the old Roman tendency toward lively and accurate pictorial representation. This can be seen from the reliefs illustrating the triumph over Judaea in the passageway of the Arch of Titus. The narrative description dear to Roman art found its best expression in the great spiral frieze on Trajan's Column, where the Emperor can be seen among his soldiers at various times in the Dacian campaigns; the story of the war plays a most important part, although, like most imperial monuments, the column is meant to exalt the leader. Under Hadrian a reaction made sculpture less markedly Italian, as if to conform with the slow decline of Italy toward quasi-provincial status. Also under Hadrian, the emperor was more singled out, being made bigger and more frontal than the other figures, as if to illustrate the growing monarchical tone of the principate. This tendency continued under the Antonines, when there was a magnificent flowering of sculpture on panels, columns, and sarcophagi; but its exuberance and splendour foreshadow the end of classical art.

The artistic currents that flowed in Rome were felt throughout the empire, the less developed areas being influenced most. In the West, provincial sculpture closely resembled Roman, although it sometimes showed variations, in Gaul especially, due to local influences (the native element, however, is not always easy to identify). The Roman quality of portraits painted on Egyptian mummy cases shows that the Greek-speaking regions were also affected, although generally they maintained their own traditions. But by now the Greek East had become rather barren; much of its production was imitative rather than vitally creative. Greece proper contributed little, the centre of Hellenism having shifted to Asia Minor, to places like Aphrodisias, where there was a flourishing school of sculpture.

In at least one respect the East was heavily influenced by Rome. The use of concrete and cross vault enabled Roman architects and engineers to span wide areas; their technological achievements included the covered vastness of the huge thermal establishments, the massive solidity of the amphitheatres, and the audacity of the soaring bridges and aqueducts. The East was greatly impressed. Admittedly, the agoras and gymnasiums in Greek towns are hardly Roman in aspect, but, for most structures of a practical utilitarian kind, the Greek debt to Rome was heavy. Sometimes Roman influence can be seen not only in the fundamental engineering of such buildings as market gateways, theatres, and amphitheatres, but even in such decorative details as composite capitals as well. Roman features abound in exotic Petra, Palmyra, Gerasa, and Baalbek, and even in Athens itself. (E.T.S.)

V. The later Roman Empire

THE DYNASTY OF THE SEVERI (AD 193–235)

Septimius Severus. *Establishment of the dynasty.* After the assassination of Commodus on December 31, AD 192, Helvius Pertinax, the prefect of the city, became emperor. In spite of his modest birth, he was well respected by the Senate but was without his own army. He was killed by the praetorians at the end of March 193, after a three-month reign. The praetorians, after much corrupt bargaining, designated as emperor an old general, Didius Julianus, who had promised them the largest *donativum* (a donation given to each soldier on the emperor's accession). The action of the praetorians roused the ire of the provincial armies. The army of the Danube, which was the most powerful as well as the closest to Rome, appointed Septimius Severus in May 193. Severus soon had to face two competitors, supported, like himself, by their own troops: Pescennius Niger, the legate of Syria; and Clodius Albinus, legate of Britain. After having temporarily neutralized Albinus by accepting him as Caesar, Septimius marched against Niger, whose troops, having come from Egypt and Syria, were already occupying Byzantium. The Danubian legions were victorious, and Niger was killed at the end of 194; Antioch and Byzantium were pillaged after a long siege. Septimius even invaded Mesopotamia, for the Parthians had supported Niger. But this campaign was quickly interrupted: in the West, Albinus, disappointed at not being associated with the empire, proclaimed himself Augustus in 196 and invaded Gaul. He was supported by the troops, by the population, and even by the senators in Rome. In February 197, he was defeated and killed in a difficult battle near his capital of Lyons which, in turn, was almost devastated. Septimius Severus remained the sole master of the empire, but the pillagings, executions, and confiscations left a painful memory. A few months later, in the summer of 197, he launched a second Mesopotamian campaign, this time against the Parthian king Vologases IV, who had attacked Nisibis, which the Romans had conquered two years previously. Septimius Severus was again victorious. Having arrived at the Parthian capitals (Seleucia and Ctesiphon), he was defeated near Hatra but in 198 obtained an advantageous peace: Rome retained a part of Mesopotamia, together with Nisibis, the new province being governed by an eques. After having inspected the East, the Emperor returned to Rome in 202. He spent most of his time there until 208, when the incursions of Caledonian rebels called him to Britain, where he carried out a three-year campaign along Hadrian's Wall. He died at Eboracum (York) in February 211.

Severus' campaigns

The Severan revolution. Septimius Severus belonged to a Romanized Tripolitan family that had only recently attained honours. He was born in Leptis Magna in North Africa and favoured his native land throughout his reign. Married to Julia Domna of Emesa, a Syrian woman from an important priestly family, he was surrounded by Easterners. He had pursued a senatorial career and had proved himself a competent general, but he was above all a good administrator and a jurist. Disliking Romans, Italians, and senators, he deliberately relied on the faithful Danubian army that had brought him to power and always showed great concern for the provincials and the lower classes. Although he had sought to appropriate the popularity of the Antonines to his own advantage by proclaiming himself the son of Marcus Aurelius and by naming his own son Marcus Aurelius Antoninus, he in fact carried out a totally different policy—a brutal, yet realistic policy that opened careers to new social classes. Indifferent to the prestige of the Senate, where he had a great many enemies, he favoured the equites. The army thus became the seedbed of the equestrian order and was the object of all of his attentions. The ready forces were increased by the creation of three new legions commanded by equites; and one of these, the Second Parthica, was installed near Rome. Unlike Vespasian, who also owed his power to the army but who knew how to keep it in its proper place, Septimius Severus, aware of the urgency of external problems, established a sort of military monarchy. The praetorian cohorts doubled their ranks, and the dismissal of the old staff of Italian origin transformed the Praetorian Guard into an imperial guard in which the elite of the Danube army were the most important element. The auxiliary troops were increased by the creation of 1,000-man units (infantry cohorts) and cavalry troops, sometimes outfitted with mail armour in the Parthian manner. The careers of noncommissioned officers emerging from the ranks now opened onto new horizons: centurions and noncommissioned grades could attain the tribunate and enter into the equestrian order. Thus, a simple Illyrian peasant might attain high posts: this was undoubtedly the most essential aspect of the "Severan revolution." This "democratization" was not necessarily a barbarization, for the provincial legions had long been Romanized. Their salaries were increased, and donativa were distributed more frequently; henceforth, soldiers were fed at the expense of the provincials. Veterans received lands, mostly in Syria and Africa. The right of legitimate marriage, previously refused by Augustus, was granted to almost all of the soldiers, and the right to form collegia (private associations) was given to noncommissioned officers. The army was tending to become a privileged caste, issuing from the peasantry. In the 1920s, the Russian scholar Michael Rostovtzeff suggested that this policy marked the beginning of a socially dangerous collusion between the peasants and the army—which was recruited from among them—and indicated a class struggle against the bourgeoisie of the city. But many scholars now believe that Rostovtzeff, perhaps influenced by parallels with the Red Army during the Russian Revolution, overstated his case.

The growth of the equestrian order

The administrative accomplishments of Septimius Severus were of great importance: he clearly outlined the powers of the city prefect; he entrusted the praetorian prefecture to first class jurists, such as Papinian; and he increased the number of procurators, who were recruited for financial posts from among Africans and Easterners and for government posts (praesides) from among Danubian officers. Italy lost its privileges and found itself subjected, like all the other provinces, to the new annona, a tax paid in kind, which assured the maintenance of the army and of the officials. The consequent increase in expenditures—for administration, for the salaries and the donativa of the soldiers, for the maintenance of the Roman plebs, and for construction-obliged the Emperor to devalue the denarius in 194. But the confiscations increased his personal fortune, the res privata, which had been previously created by Antoninus.

Severus' social policy favoured both the provincial recruitment of senators (Easterners, Africans, and even Egyptians), causing a sharp decrease in the percentage of Italian senators, and the elevation of the equestrian order, which began to fill the prince's council with its jurists. The cities, which had been favoured by the Antonines, were more and more considered as administrative wheels in the service of the state: the richest decuriones (municipal councillors) were financially responsible for levying the taxes, and it was for this purpose that the towns of Egypt finally received a *boulē* (municipal senate).

The burden of taxes and forced government service was made weightier by numerous transport duties for the army and for the annona service and was regulated by the jurists through financial, personal, or mixed charges. The state was watchful to keep the decuriones in the service of their cities and to provide a control on their administration through the appointment of curatores rei publicae, or officials of the central goverriment. The lower classes were, in principle, protected against the abuses of the rich, but in fact they were placed at the service of the state through the restrictions imposed on shipping and commercial corporations. The state became more and more a policeman, and the excesses of power of numerous grain merchants (frumentarii) weighed heavily on the little man.

Imperial power, without repudiating the ideological themes of the principate, rested in fact on the army and sought its legitimacy in heredity: the two sons of Septimius Severus, Caracalla and Geta, were first proclaimed Caesars (heirs apparent), the former in 196, the latter in 198; later, they were directly associated in imperial power through bestowal of the title of Augustus, in 198 and 209, respectively. Thus, during the last three years of Septimius Severus' reign, the empire had three Augusti at its head.

Caracalla. Caracalla, the eldest son of Septimius Severus, reigned from 211 to 217, after having assassinated his younger brother, Geta. He was a caricature of his father: violent, megalomaniacal, full of complexes, and, in addition, cruel and debauched. He retained, however, the entourage of the equites and jurists who had governed with his father and enforced to an even greater degree his father's militaristic and egalitarian policy. He increased the wages of the army even further and, at the same time, began a costly building program that quickly depleted the fortune left him by his father. He forced the senators to pay heavy contributions, doubled the inheritance and emancipation taxes, and often required the aurum *coron*ariurn (a contribution in gold), thereby ruining the urban middle classes. To stop the inflation that was depreciating the silver denarius, he created a new coin, the *antoninianus,* whose real value was that of the Marcus Aurelius coin but whose official rate was fixed at twice the value, thus insuring that monetary instability would continue for some time to come. In 212, the famous Constitutio Antoniniana de Civitate gave the right of citizenship to nearly all inhabitants of the empire. This law, known only through a mutilated papyrus, has raised many controversies; but even taking into account the exclusion of numerous barbarians and of a part of the indigenous population of Egypt, the effect of this measure was considerable. It sanctioned the political evolution of several centuries and represented true social advancement for many provincials. It also reinforced imperial unity and complied with the wishes of the great jurists of the time. Each inhabitant of the empire would henceforth have a double citizenship—that of Rome and that of his city of origin. The very diffusion, however, of citizenship status diminished its value, and, in effect, all citizens were reduced to subjects of an absolute prince. On the other hand, the recruitment of legionaries and of municipal magistrates became more difficult, for up to that time acquisition of Roman citizenship had been the principal inducement for undertaking such offices.

Extension of Roman citizenship

Although little endowed with military qualities, Caracalla adopted as his patron Alexander the Great, whom he admired greatly, and embarked on an active external policy. He fought successfully against the Teutonic tribes of the Upper Danube, among whom the Alamanni, as well as the Capri of the Middle Danube, appeared for the first time; he often prudently mixed military operations with negotiation and gave important subsidies and money (in sound currency) to the barbarians, thus arousing much discontent. His ambition was to triumph in the East like his hero of old and, more recently, Trajan and his own father. He invaded Armenia and Adiabene and annexed Osroene in northwest Mesopotamia, joining it to the part of Mesopotamia taken by Septimius Severus. In April 217, while pursuing his march on the Tigris, he was assassinated on the order of one of his praetorian prefects, Marcus Opellius Macrinus.

Macrinus. Macrinus was accepted as emperor by the soldiers, who were unaware of the role he had played in the death of his predecessor. For the first time an eques had acceded to the empire after having been no more than a manager of financial affairs. The senators reluctantly accepted this member of the equestrian order, who, nevertheless, proved to be moderate and conciliatory; but the armies despised him as a mere civilian, and the ancient authors were hostile to him. His reign was brief, and little is known of him. He concluded an inglorious peace with the Parthians, which assured Mesopotamia to Rome through the payment of large sums of money. And to make himself popular, he cancelled Caracalla's tax increases and reduced military expenditures. A plot against him was soon organized: two young grandnephews of Septimius Severus were persuaded by their mothers and especially by their grandmother, Julia Maesa, the sister of Julia Domna (who had recently died), to reach for imperial power. The eldest, Bassianus, was presented to the troops of Syria, who had been bought with gold, and was proclaimed in April 218. Shortly afterward, Macrinus was defeated and killed, as was his son (whom he had associated with him on the throne).

Elagabalus and Severus Alexander. The new emperor was presented as the son of Caracalla, whose name he took (Marcus Aurelius Antoninus). He is better known, however, under the name Elagabalus, the god whose high priest he was and whom he quickly and imprudently attempted to impose on the Romans, in spite of his grandmother's counsel of moderation. Fourteen years old, he caused himself to be detested by his heavy expenditures, his orgies, and the dissolute behaviour of his circle. His fanatic devotion to the Baal of Emesa (Elagabal) was sincere, but he shocked the Romans by his extravagances. The praetorians killed him in 222 and proclaimed as emperor his first cousin, Alexianus, who took the name of Severus Alexander.

Although well educated and full of good intentions, Severus Alexander showed some weakness of character by submitting to the counsel of his mother, Mamaea, and of his grandmother, Maesa. The Scriptores *historiae Augustae*, a collection of biographies of the emperors, attributes to him a complete program of reforms favourable to the Senate, but these reforms are not mentioned elsewhere. As in the time of Septimius Severus, his counsellors were equites. Ulpian, the praetorian prefect, was the greatest jurist of this period, and the basic policies of the founder of the dynasty were carried on but with less energy. This weakening of energy had disastrous results: in Persia, the Arsacids were replaced in 224 by the more ambitious Sāsānid dynasty, who hoped to recover the former possessions of the Achaemenids in the East. Their initial attacks were stopped in 232 by a campaign that was, however, poorly conducted by the Emperor and that alienated the army as a result of its ineptitude. In Rome, there were frequent disorders and, as early as 223, Ulpian had been killed by the praetorians. While gathered on the Rhine to fight the Teutons, the soldiers once again revolted and killed Severus Alexander and his mother. A coarse and uneducated but energetic soldier, Maximinus the Thracian, succeeded him without difficulty in March 235. The Severan dynasty had come to an end.

Rise of the Sāsānids in Persia

RELIGIOUS AND CULTURAL LIFE IN THE 3RD CENTURY

Official religions and Eastern cults. Since the reforms of Augustus and his efforts to restore the traditional religion, few religious changes had taken place. The official ceremonies in honour of the Capitoline divinities Jupiter, Juno, and Minerva, the protectors of the state, were still celebrated by the priests of the sacerdotal collegia of Rome, of the provinces, and of the municipalities, but their religious vigour was waning. In the countryside, local agrarian and fertility cults survived, and in the course of the 2nd century AD there was a renaissance of the ancient indigenous cults in the Celtic countries of Gaul and Britain, in Africa, and in Central Europe. Rather than the great gods, who were too "political," the lower classes preferred the more helpful divinities, such as Hercules and Silvanus. Simplistic superstitions still flourished, and even the educated classes did not hesitate to indulge in the magical practices that the law sometimes condemned. The 2nd-century philosopher and rhetorician Apuleius, for example, was brought to trial for having wooed a rich widow by magic arts.

The cult of the emperor had deeply penetrated the traditional religion; and there was a tendency, especially in the East, to make divinities of the emperors while they were still alive. The Severan period was characterized by the triumph of the Oriental religions and by the first efforts of syncretism. For some time now, the Eastern religions had spoken successfully to the uneasy soul of the masses. To be sure, the Greek gods Demeter and Dionysus still had their mysteries and retained their followers. But the cults of the East were aided by their very strangeness, by the fervour of their ceremonies, and by the hope of a future life they reserved to their initiates, who were fraternally united around a well-organized clergy. The oldest established religions were those of Cybele (the Phrygian Great Mother) and of her ancillary god Attis. Proper worship of the Great Mother, however, was open only to the wealthy, for salvation could be obtained only through the sacrifice of the bull. Other long-established deities were the Egyptian gods Isis and Sarapis, whose clergy were particularly honest and fraternal. The cult of Mithra and that of the Syrian gods had expanded more recently, thanks to the perpetual movement of the troops and of the merchants. Mithra, the Sun, representing the supreme god, appealed to the military classes by promising courageous initiates a glorious life in the hereafter. The religion had numerous sanctuaries (*mithraea*) throughout the empire—in the Danubian and Germanic areas, in Britain, and even in Rome. There were large numbers of followers also of the great Syrian Baals: Zeus Dolichenus (from Doliche in northern Syria); Zeus of Heliopolis—Baalbek; and the highland Baal, the El-Gabal (Elagabal) of Emesa. During the Severan era and at their very court, there was developed that syncretism which tended to fuse into a single supreme god all divinities, and especially the solar gods (Sol, Helios, Sarapis, and Mithra). This tendency toward monotheism was accompanied by a lively atmosphere of religiosity and by a taste for magic and miracles.

The Cult of the Great Mother

The rise of Christianity. During the 1st and 2nd centuries, Christianity spread with relative slowness. The doctrines of Jesus, who was crucified about AD 30, first took root among the Jews of Palestine, where a large number of sects were proliferating--orthodox sects, such as the Sadducees and the Pharisees, as well as dissident and sometimes persecuted sects such as the Essenes, whose ascetic practices have been illuminated by the discovery of the Dead Sea Scrolls. At the end of Tiberius' reign, Christianity had spread to the Gentiles as a result of the preaching of St. Paul in Asia Minor and in Greece. At the same time, Christianity continued to make progress among the Jews of Jerusalem, Alexandria, and Syria and quickly reached even Osroene and the Parthian towns of the Euphrates, where Jewish colonies were numerous. The Roman authorities at first had difficulty in distinguishing the "Christos" believers from the orthodox Jews, but the religion of the former, on leaving its original milieu, quickly became differentiated: to the Romans it appeared illicit because it was mysterious; vile, because its first followers belonged to the lower classes; and dangerous, because, unlike Judaism, which was tolerated as an "ethnic" religion, it was without national ties. The 1st-century historian Tacitus declared that there dwelt in Christians a hatred of humankind. Christians did not participate in the Jewish revolt of 66–73, and under the Flavians, Christianity completely severed itself from its origins. At that time, the East was the centre of the new religion, whose followers were multiplying from Egypt to the Black Sea and were beginning to be noticed in Bithynia and in Greece. Christians seemed fairly numerous in Rome as early as the end of the 1st century. When the age of the Apostles ended, the age of the church began, with its bishops, presbyters, and deacons, with its catechism, preaching, and celebration of the Eucharist. In the 2nd century, Christianity began to reach the intellectuals. Hellenistic culture offered educated Christians the resources of philosophical dialectic and of sophist rhetoric. The example of Philo of Alexandria had shown in the 1st century that it was possible to reconcile the Bible with the great Platonic ideas. By the 2nd century the Christian "apologists" tried to show that Christianity

Beginnings of Christian church organization was in harmony with Greco-Roman humanism and that it was intellectually, and above all morally, superior to paganism.

But the Christians did not succeed in convincing the authorities. The first persecution, that of Nero, was related to a particular incident and had no juridical foundation (the fire at Rome in 64). The concept of Christianity as a crime was undoubtedly established under the Flavians, for about 111, Trajan ordered Pliny, the governor of Bithynia, to put to death all those who declared themselves Christians, without the necessity of their having committed any other crime. At the same time, however, he prescribed that no searches be made for them, and this line of conduct was followed by his successors. Thus, the persecutions remained localized and sporadic and were the result of private denunciations or of spontaneous popular protests. Under Marcus Aurelius, the difficulties of the times often caused the Christians, who refused to sacrifice to the state gods and to participate in the imperial cult, to be accused of provoking the wrath of the gods: martyrs appeared in the East, in Rome, in Gaul, and in Africa. Commodus' reign was more favourable to them, perhaps because certain members of his circle, not a very edifying one in other respects, were Christians or Christian sympathizers. This reprieve, however, was short-lived: Septimius Severus inaugurated the first systematic persecution. In 202 an edict forbade Christian (and Jewish) proselytism. Members of extremist sects were persecuted for preaching continence (which violated Augustus' laws against celibacy), for holding the state in contempt, and especially for refusing military service. Under Caracalla, the situation quieted and the church continued to progress, favoured perhaps by the relative freedom which the law granted to funerary collegia (whence the first catacombs).

Cultural life from the Antonines to Constantine. Latin literature enjoyed its "Silver Age" under the Antonines, with the majority of great authors, such as Tacitus, Juvenal, and Pliny the Younger, having begun their careers under Domitian. They had no heirs: after Tacitus, Roman history was reduced to biography. It was only in the 4th century that history began to flourish again, with Ammianus Marcellinus, a Greek writing in Latin. Satire, the Roman genre par excellence, came to an end with Juvenal; and Pliny the Younger, a diligent rhetorician but with a lesser degree of talent, had only the mediocre Fronto as a successor. Another African, Apuleius of Madauros, was more original, being a rhetorician, scholar, and picaresque novelist (Metamorphoses).

Decline of Latin literature

A Greek renaissance, however, took place during the 2nd century. The second sophistic school reigned in every area, in rhetoric, history, philosophy, and even in the sciences. Schools of rhetoric and philosophy prospered in the East, in Smyrna, Ephesus, Pergamum, Rhodes, Alexandria, and even in Athens, protected and subsidized by the emperors, from Vespasian to Marcus Aurelius. The great sophists were Herodes Atticus, a multimillionaire from Athens; Polemon; and Aelius Aristides, a valetudinarian devotee of Asclepius. Dio Cassius and Herodian were conscientious and useful historians (first half of the 3rd century), as was later Dexippus the Athenian, whose work survives only in fragments. Science was represented by the mathematician Nicomachus of Gerasa; medicine, by Galen of Pergamum; astronomy, by the Alexandrian Ptolemy. Law remained the only Roman science, exemplified under the Antonines by Salvius Julianus and Gaius (the *Institutiones*) and later rising to its zenith in the 3rd century as a result of the works of three Greeks: Papinian, Ulpian, and Modestinus. Philosophy, heavily influenced by rhetoric and ethics, was represented under Domitian and Trajan by Dio (or Chrysostom) of Pmsa, who outlined the stoical doctrine of the ideal sovereign. The biographer Plutarch and Lucian of Samosata were more eclectic, especially Lucian, who resembled Voltaire in his caustic skepticism. Under Marcus Aurelius one of Lucian's friends, Celsus, wrote the first serious criticism of Christianity, "The True Word," known through Origen's refutation of it in the 3rd century. At this time philosophy leaned toward religious mysticism: under the Severans, Ammonius Saccas created the school of Alexandria, and his disciple Plotinus founded the Neoplatonist school, which was to fight bitterly against Christianity. After the apologists and, above all, Tertullian (c. 160–after 222), Christian thought deepened, and theology made its appearance. Clement and Origen (*c.* 185–c. 254), the greatest theologian of the time, were the luminaries of the church of Alexandria; the Roman church still wrote in Greek and was represented by the slightly old-fashioned Hippolytus; and the church of Africa had a powerful personality, Saint Cyprian, bishop of Carthage.

The Christian theologians

The disappearance of the great lyric and poetic styles, the fossilizing of education as it came to be completely based on rhetoric (paideia), and the growing importance of philosophical and religious polemical literature among both pagans and Christians were the basic traits that, as early as the 3rd century, foreshadowed the intellectual life of the late empire.

MILITARY ANARCHY AND THE DISINTEGRATION OF THE EMPIRE (235-270)

Succession of emperors and usurpers. The period from the death of Severus Alexander to the time of Claudius II Gothicus was marked by usurpations and barbarian invasions. After Maximinus the Thracian, who bravely fought the Germans but showed great hostility toward the Senate and the educated elite, the Gordians rose to power as a result of a revolt by wealthy African landowners. A senatorial reaction first imposed civilian emperors, Pupienus and Balbinus together, and then named Gordian III, a youth backed by his father-in-law, the praetorian prefect Timesitheus. Gordian III was murdered by the soldiers during a campaign against the Persians and was replaced, first by Philip the Arabian and then by Decius, both soldiers. Decius tried to restore Roman traditions and also persecuted the Christians, but he was killed by the Goths in 251 in a battle near the Black Sea. From 253 to 268 two Roman senators, Valerian and his son Gallienus, reigned. Valerian revived the persecution of the Christians, but he was captured by the Persians during a disastrous campaign and died in captivity (260). His son then reigned alone, facing multiple invasions and several usurpations. He moved constantly between the Rhine and the Danube, achieving brilliant victories (Milan in 262, the Nestus in 267), but the Pannonian army raised several competitors against him (Ingenuus, Regalianus, Aureolus). Too busy to protect the Gauls against the Franks and the Alamanni, and the East against the Persians, he had to tolerate the formation of the Gallic empire under the praetorian prefect Marcus Cassianius Postumus (259–268) and the Palmyrene kingdom of Odaenathus (Odenathus; 260–267). Some of his reforms were a foreshadowing of the future: the senators were practically excluded from the army; the equites received the majority of commands and of provincial governorships; and the composition of the army was modified by the creation of new army corps and especially of a strong cavalry, which was placed under the command of a single leader and charged with closing the breaches that the barbarians were opening along the frontiers. Upon his father's death Gallienus had put an end to the persecution of the Christians, preferring to fight the new religion through intellectual means; to that end, he favoured the ancient Greek cults (Demeter of Eleusis) and protected the Neoplatonist philosopher Plotinus. These initiatives increased the number of his enemies, particularly among the patriotic senators and the Pannonian generals. While Gallienus was in Milan besieging the usurper Aureolus, he was killed by his chiefs of staff, who proclaimed Claudius II (268), the first of the Illyrian emperors. The new emperor won a great victory against the Alamanni on the Garda lake and overwhelmed the Goths in Naissus (269) but died of the plague in 270. This fatal period brought to light one of the major defects of the empire: the lack of a legitimate principle of succession and the preponderant role of the army in politics. The structures that had created the strength of the principate were weakened, and the empire required deep reforms. Gallienus had felt their necessity but had been too weak to impose them.

Victories over the Germans

The barbarian invasions. The Goths were East Germans who came from what is now Sweden and were followed by the Vandals, the Burgundians, and the Gepidae. The after-effect of their march to the southeast, toward the Black Sea, was to push the Marcomanni, the Quadi, and the Sarmatians onto the Roman *limes* in Marcus Aurelius' time. Their presence was brusquely revealed when they attacked the Greek towns on the Black Sea c. 238. Timesitheus fought against them under Gordian III, and under Philip and Decius they besieged the towns of Moesia and Thrace, led by their kings, Ostrogotha and Kniva. Beginning in 253, the Crimean Goths and the Heruli appeared and dared to venture on the seas, ravaging the shores of the Black Sea and the Aegean, as well as several Greek towns. In 267 Athens was taken and plundered despite a strong defense by the historian Dexippus. After the victories of Gallienus on the Nestus and Claudius at Naissus (Nish), there was, for a time, less danger. But the countries of the middle Danube were still under pressure by the Marcomanni, Quadi, Iazyges, Sarmatians, and the Carpi of free Dacia, who were later joined by the Roxolani and the Vandals. In spite of stubborn resistance, Dacia was gradually overwhelmed, and it was abandoned by the Roman troops, though not evacuated officially. When Valerian was captured in AD 259/260, the Pannonians were gravely threatened, and Regalianus, one of the usurpers proclaimed by the Pannonian legions, died fighting the invaders. The defense was concentrated around Sirmium and Siscia-Poetovio, the ancient fortresses that had been restored by Gallienus, and many cities were burned.

Alamanni invasions

In the West the invasions were particularly violent. The Germans and the Gauls were driven back several times by the confederated Frankish tribes of the North Sea coast and by the Alamanni from the Middle and Upper Rhine. Gallienus fought bitterly, concentrating his defense around Mainz and Cologne, but the usurpations in Pannonia prevented him from obtaining any lasting results. In 259–260 the Alamanni came through the Agri Decumates (the territory around the Black Forest), which was now lost for the Romans. Some of the Alamanni headed for Italy across the Alpine passes; others attacked Gaul, devastating the entire eastern part of the country. Passing through the Rhône Valley, they eventually reached the Mediterranean: and some bands even continued into Spain. There they joined the Franks, many of whom had come by ship from the North Sea, after having plundered the western part of Gaul. Sailing up the estuaries of the great rivers, they had reached Spain and then, crossing the Strait of Gibraltar, had proceeded to Mauretania Tingitana. Gallienus, outflanked, entrusted Gaul and his young son Saloninus to Postumus. who then killed Saloninus and proclaimed himself emperor. The several invasions had so frightened the people that the new emperor was readily accepted, even in Spain and Britain. He devoted himself first to the defense of the country and was finally considered a legitimate emperor, having established himself as a rival to Gallienus, who had tried in vain to eliminate him but finally had to tolerate him. Postumus governed with moderation, and, in good Roman fashion, minted excellent coins. He, too, was killed by his soldiers, but he had successors who lasted until 274.

Difficulties in the East. In the East the frontiers had been fixed by Hadrian at the Euphrates. But under Nero, the Romans had claimed control over the kings of Armenia, and under Caracalla they had annexed Osroene and Upper Mesopotamia. The Parthian empire had been weak and often troubled, but the Sāsānids were more dangerous. In 241, Shiipiir I (Sapor), an ambitious organizer and statesman, mounted the throne: he united his empire by bringing the Iranian lords into line and by protecting the Zoroastrian religion. He also tolerated the Manichaeans, put an end to the persecutions of the Christians and Jews, and thereby gained the sympathy of these communities. In 252, with a large army at his command, Shiipiir imposed Artavasdes on Armenia, attacked Mesopotamia, and took Nisibis. In 256 his advance troops entered Cappadocia and Syria and plundered Antioch, while Doura-Europus; on the Middle Euphrates, was likewise falling to him. Valerian had rushed to its aid, but he could not remedy the situation; and in 259 or 260 he was imprisoned by Shiipiir during operations about which little is known. Mesopotamia was lost and Rome was pushed back to the Euphrates. Cappadocia, Cilicia, and Syria were again plundered, and a puppet emperor was appointed in Antioch. But these victories were transitory: in Osroene, Eddessa had shown resistance, a defense was organized in Cappadocia and Cilicia, and Odaenathus, the prince of Palmyra, took Shiipiir by surprise and forced him back to Iran. Having thus aided the Roman cause, Odaenathus then began to act in his own interest: he continued the fight against the Persians and took the title "King of Kings." The Romans officially entrusted him with the defense of the East and conferred on him the governorship of several provinces, so that the "kingdom" of Palmyra thus extended from Cilicia to Arabia. He was murdered in 267 without ever having severed his ties with Gallienus. His widow Zenobia had her husband's titles granted to their son Vaballathus. Then in 270, taking advantage of the deaths of Gallienus and Claudius II, she invaded Egypt and a part of Asia Minor with her troops. This invasion was followed by a rupture with Rome, and in 271 Vaballathus was proclaimed Imperator Caesar Augustus. The latent separatism of the Eastern provinces and, undoubtedly, some commercial advantages caused them to accept Palmyrene domination without difficulty, as they had, in the past, supported Avidius Cassius and Pescennius Niger against the legitimate emperors. In 272 unity was restored by Aurelian, but Mesopotamia was lost and the Euphrates became the new frontier of the empire.

Disruption of commerce by the barbarians

Economic and social crisis. The invasions and the civil wars explain the gravity of the economic and social crisis at the end of Gallienus' reign. Many regions had been laid waste (Gaul, Dacia, Moesia, Thrace, and numerous towns on the Aegean Sea); many important cities had been pillaged or destroyed (Byzantium, Antioch, Olbia, Lyons); and in northern Italy, Gallia Cisalpina (Cisalpine Gaul) itself had been crushed by the Alamanni. The upheavals led to brigandage on land and piracy at sea. Plague, brought back from the East by the armies, ravaged the land for 20 years between 250 and 270. There ensued a population decline, the seriousness of which cannot be estimated; and the empire as a whole was impoverished, although certain provinces, such as Africa, Britain, Pannonia, Asia, and Syria, remained prosperous throughout the century. Municipal government atrophied, inscriptions and dedications became rare, and the cities withdrew into themselves behind narrowed walls. Commerce was often paralyzed by the barbarians; and the main trade route from London to Byzantium, through Boulogne, Cologne, and the Danube, was unsafe and often impassable. The loss of Doura, the defeats inflicted by Shiipiir, and the Palmyrene claims to power slowed down the caravan trade with the East and the Far East. Commerce, however, remained active in the West between Spain, Narbonensis, and Italy, while Africa retained its relations with Ostia, Rome, Egypt, and Syria. Agricultural and handicraft production suffered from insecurity, from military requisitions, and from the abuses of a hard-pressed administration that was attempting by every means to assure the *annona* yield and to provision the large towns so as to prevent outbreaks of social conflict. The empire became a besieged fortress.

The emperors after Commodus—above all Septimius Severus—had been aware of the danger and had adopted such harsh measures as the requisition of material resources and the mobilization of personnel into the service of the state. The municipalities and even the corporations were crushed by the taxes: the collection of the *annona* was a heavy burden for the financially responsible decurions, landholders, and colonists, who were watched over by brutal and sometimes thieving noncommissioned officers. Only a military and bureaucratic monarchy could assure—but at great price certainly—the essential services and obtain an adherence to vital priorities. The early empire's policy of liberalism was at an end; and some modern scholars, such as Rostovtzeff, have spoken of the instituting of "state Socialism"; yet the latter term is fallacious, for there was neither appropriation of the means of production nor redistribution of income to the benefit of the lower classes. Rather, the late empire was a military dictatorship.

Deep social transformations foreshadowed the society of the late empire. The urban middle classes were overburdened, impoverished, and enslaved; and it soon became necessary to halt the flight of the municipal officials by force. The senators lost their political power; but they did preserve their social prestige, and their latifundial fortunes increased at the expense of the decurions and the small landholders. To avoid the obligations of urban life, they tended more and more to retire to their magnificent country villas. The equites thus became the dominant class. They took over the state administration, directed the important offices, controlled finances and taxation, and wielded military and governmental authority in the majority of provinces. Some were civilians, jurists by education; the most powerful came out of the army, where the centurionship had provided open access to high positions since the time of the Severi. During the 3rd century, the army was the empire's rampart against the barbarians, the safest base of imperial power, and the mechanism for social advancement. The lower classes, the humble peasants, the settlers, and the town plebs, officially protected by a state that considered itself egalitarian, suffered from the general impoverishment and the decrease in production: fiscal necessities tended to bind the peasant to his land, the craftsman to his workshop, and the merchant to his trade. Even if the law did not yet prescribe these restrictions, social evolution was moving in this direction, as shown, for example, by the plight of the increasing number of settlers who were forced to cultivate the lands of the rich and of the state.

THE RECOVERY OF THE EMPIRE AND THE ESTABLISHMENT OF THE DOMINATE (270–337)

Aurelian's conquests

The Illyrian emperors. After Claudius II's unexpected death, the empire was ruled from 270 to 284 by several "Illyrian" emperors, who were good generals and who tried in an energetic way to restore equilibrium. The most remarkable was Aurelian. He first gained hard-won victories over the Alamanni and the Juthungi, who had invaded the Alpine provinces and northern Italy. To cheer the inhabitants of Rome, who had succumbed to panic, he began construction of the famous rampart known as Aurelian's Wall. And while crossing the Danubian provinces, before marching against Palmyra, he decided on an orderly evacuation of Dacia, an undefendable region that had been occupied by the barbarians since the time of Gallienus. In the East, he defeated Zenobia's troops easily and occupied Palmyra in 272. Shortly afterward, an uprising broke out in Egypt under the instigation of a rich merchant, who, like a great part of the population, was a partisan of the Palmyrene queen. In response, Aurelian undertook a second campaign, plundering Palmyra and subjugating Alexandria. These troubles, however, along with the devastation of the great caravan city, were to set back Roman trade seriously in the East. Later, rounding back on the Gallic empire of Postumus' successors, he easily defeated Tetricus, a peaceful man and not very willing to fight, near Châlons-sur-Marne. The unity of the empire was restored, and Aurelian celebrated a splendid triumph in Rome. He also re-established discipline in the state, sternly quelled a riot of artisans in the mints of Rome, organized the provisioning of the city by militarizing several corporations (the bakers, the pork merchants), and tried to stop the inflation by minting an *antoninianus* of sounder value. His religious policy was original: in order to strengthen the moral unity of the empire and his own power, he declared himself to be the protégé of the Sol Invictus (the Invincible Sun) and built a magnificent temple for this god with the Palmyrene spoils. Aurelian was also sometimes officially called *dominus et deus:* the principate had definitely been succeeded by the "dominate." In 275 Aurelian was murdered by certain officers who mistakenly believed that their lives were in danger.

His successor, for once, was chosen by the Senate—at the army's request and on short notice. But Tacitus, an aged senator, reigned only for a few months. After him, Probus, another Illyrian general, inherited a fortified empire but had to fight hard in Gaul, where serious invasions occurred in 275–277. Afterward, Probus devoted himself to economic restoration; he attempted to return abandoned farmland to cultivation and, with the aid of military labour, undertook works of improvement. To remedy the depopulation, he admitted to the empire, as had Aurelian, a great number of defeated barbarian Goths, Alamanni, and Franks and permitted them to settle on plots of land in Gaul and in the Danubian provinces. After the assassination of Probus in 282 by soldiers, Cams became emperor and immediately associated with himself his two sons, Carinus and Numerian. Carus and Numerian fought a victorious campaign against the Persians but died under unknown circumstances. Carinus, left behind in the West, was later conquered and killed by Diocletian, who was proclaimed emperor in November 284 by the army of the East.

The tetrarchy

Diocletian. *The tetrarchy.* Diocletian may be considered the real founder of the late empire, though the form of government he established—the tetrarchy, or four persons sharing power simultaneously—was transitory. His reforms, however, lasted longer. Military exigencies, and not the desire to apply a preconceived system, explain the successive nomination of Maximian as Caesar and later as Augustus in 286 and of Constantius and Galerius as Caesars in 293. The tetrarchy was a collegium of emperors comprising two groups: at its head, two Augusti, older men who made the decisions; and in a secondary position, two Caesars, younger, with a more executive role. All four were related either by adoption or by marriage, and all were Illyrians who had attained high commands after a long military career. Of the four, only Diocletian was a statesman. The unity of the empire was safeguarded, despite appearances, for there was no territorial partitioning. Each emperor received troops and a sector of operation: Maximian, Italy and Africa; Constantius, Gaul and Britain; Galerius, the Danubian countries; and Diocletian, the East. Practically all governmental decisions were made by Diocletian, from whom the others had received their power. He legislated, designated consuls, and retained precedence. After 287, he declared his kinship with the god Jupiter (Jove), whom Diocletian claimed was his special protector. Diocletian, together with his Caesar Galerius, formed the "Jovii" dynasty, whereas Maximian and Constantius, claiming descent from the mythical hero Hercules, formed the "Herculii." This "Epiphany of the Tetrarchs" served as the divine foundation of the regime. The ideological recourse to two traditional Roman divinities represented a break with the orientalizing attempts of Elagabalus and Aurelian. Even though he honoured Mithra equally, Diocletian wanted to be seen as continuing the work of Augustus. And in dividing power, Diocletian's aim was to avoid usurpations, or at least to stifle them quickly—as in the attempt of Carausius, chief of the army of Britain, who was killed (293), as was his successor, Allectus (296), after a landing by Constantius.

The deification of the imperial function, marked by elaborate rituals, tended to set the emperors above the rest of mankind. But it was still necessary to avoid future rivalries and to assure the tetrarchy a legitimate and regular succession. Apparently, some time between 300 and 303, Diocletian found an original solution. After the anniversary of their 20-year reign the two Augusti abdicated (Maximian quite unwillingly), and on the same day (May 1, 305) the two Caesars became Augusti. Two new Caesars were chosen, Severus and Maximinus Daia, both friends of Galerius, whose strong personality dominated Constantius. In repudiating the principle of natural heredity (Maximian and Constantius each had an adult son), Diocletian took a great risk: absolute divine monarchy, which Diocletian largely established, implies the hereditary transmission of power, and the future would soon demonstrate the attachment of the troops and even of the population to the hereditary principle.

Changes in provincial organization

Administrative and financial reforms. In order to create a more efficient unity between subjects and administrators, Diocletian multiplied the number of provinces; even Italy was divided into a dozen small units of the provincial type. This put an end to Italy's privileges, particularly since Rome was no longer the effective capital of the empire, each emperor having his own residence in the part of the empire over which he ruled (Trier, Milan, Sirmium, Nicomedia). Although a few provinces were still governed by senators (proconsuls or consuls), the majority were given to equestrian *praesides,* usually without any military power but responsible for the entirety of civil administration (justice, police, finances, and taxes). The cities lost their autonomy, and the curiales administered and collected the taxes under the governor's direct control. The breaking up of the provinces was compensated for by their regrouping into a dozen dioceses, under equestrian vicars who were responsible to the emperor alone. The two praetorian prefects had less military power but played an important role in legislative, judicial, and above all, financial matters: the administration of the *annona,* which had become the basis of the fiscal system, in fact gave them management of the entire economy. Within the central administration the number of offices increased, their managers being civilians who carried out their functions as a regular career. All officials were enrolled in the *militia,* whose hierarchy was to be outlined during the 4th century.

Persian opposition

Great efforts were devoted to strengthening the borders, and the *limes* were outfitted with fortresses *(castella)* and small forts *(burgi),*notably in Syria. The army's strength was increased to 60 legions (but with reduced personnel); and, in principle, each border province received a garrison of two legions complemented by subsidiary troops. Adopting one of Gallienus' ideas, Diocletian created an embryonic tactical army under the direct orders of the emperor whose escort *(comitatus)* it formed. The troops were most often commanded by *duces* and *praepositi,* rather than by provincial governors, and were mainly recruited from among the sons of soldiers and from barbarians who enlisted individually or by whole tribes. In addition, the landowners had to provide either recruits or a corresponding sum of money. All of these reforms were instituted gradually, during defensive wars whose success demonstrated the regime's efficiency. Constantius put down Carausius' attempted usurpation and fought the Alamanni fiercely near Basel; Maximian first hunted down the Bagaudae (gangs of fugitive peasant brigands) in Gaul, then fought the Moorish tribes in Africa, in 296–298, triumphing at Carthage; and on the Danube, Diocletian, and later Galerius, conquered the Bastarnae, the Iazyges, and the Carpi, deporting them in large numbers to the provinces. In the East, however, the opposition of the Persians, led by the enterprising Narses, extended from Egypt to Armenia. The Persians incited uprisings by both the Blemmyes nomads in southern Egypt and the Saracens of the Syrian desert, and made use of anti-Roman propaganda by the Manichaeans and Jews. Diocletian succeeded in putting down the revolt in Egypt and fortified the south against the Blemmyes. But in 297, Narses, the heir to Shāpūr's ambitions, precipitated a war by taking Armenia, Osroene, and part of Syria. After an initial defeat, Galerius won a great victory over Narses, and in 298 the peace of Nisibis reinstated a Roman protege in Armenia and gave the empire a part of Upper Mesopotamia that extended even beyond the Tigris. Peace was thus assured for some decades.

The wars, the reforms, and the increase in the number of officials were costly, and inflation reduced the resources of the state. The *annona,* set up by Septimius Severus, had proved imperfect, and Diocletian now reformed it through the *jugatio-capitatio* system: henceforth, the land tax, paid in kind by all landowners, would be calculated by the assessment of fiscal units based on extent and quality of land, type of crops grown, number of settlers and cattle, and amount of equipment. The fiscal valuation of each piece of property, estimated in *juga* and *capita* (interchangeable terms whose use varied by region and period of time), required a number of declarations and censuses, similar to those practiced long before in Egypt. Each year, the government established the rate of tax per fiscal unit; and every 15 years, beginning in 312, taxes were reassessed. This complicated system was not carried out uniformly in every region. Nevertheless, it resulted in an improved accounting of the empire's resources and a certain progress in fiscal equity, thus making the administration's heavy demands less unbearable. In addition, Diocletian wrshed to reorganize the coinage and stabilize inflation. He thus minted improved sterling coins and fixed their value in relation to a gold standard. Nevertheless, inflation again became disturbing by the end of the century, and Diocletian proclaimed his well-known Edictum de Maximis Pretiis, fixing price ceilings for foodstuffs and for goods and services, which could not be exceeded under pain of death. The edict had indifferent results and was scarcely applied, but the inscriptions revealing it have great economic interest.

Social effects of Diocletian's reforms

Diocletian's reforms adumbrated the principal features of late empire society—the lack of social mobility and the omnipotence of the central administration. Fiscal considerations required that the *annona* be collected regularly and that all land be productive. The tendency was to bind the settlers more and more to their land, to prevent villagers from leaving their homes, and to fix everyone to his place of birth. The curiales and their properties were bound to their cities, the corporation members to their trades, and the sons of soldiers were obliged to take their fathers' places in the army. The upper classes were less tied, having the advantages derived from public careers, whether legally or fraudulently acquired. The senators, now usually called *clarissimi* ("most honorable"), held the major part of landed wealth, and their authority weighed heavily on the peasants. Many of them never attended the Senate in Rome, which had lost its political role. The senatorial class was renewed by the admission of high officials to the clarissimate, including praetorian prefects and numerous provincial governors. The lower appointments were held by the equites, the *perfectissimi* ("the most excellent"), whose place in the social hierarchy depended on their rank in the *militia.* In general, society was becoming hierarchical, and the official who was well paid, both in money and kind, acquired an influence that would only increase during the 4th century.

Persecution of the Christians. After a period of initial indrfference, Diocletian ended his reign by unleashing against the Christians the last and most violent of their persecutions. Decius and Valerian had already dealt severely with them in the middle of the 3rd century and for the first time had directly struck the church's clergy and property by requiring all inhabitants of the empire to sacrifice to the state gods. There were numerous martyrs, but the persecutions came to a quick end upon the death of Decius in 251 and the capture of Valerian in 260. Gallienus published an edict of tolerance, which enabled the church to resume its progress, thanks to the glory of its martyrs and "confessors," the abundance of its donations (for the rich were now also being reached), and the development of the episcopal organization. At the end of the century the new religion was predominant in certain regions of Asia Minor (Cappadocia), well represented in the East, and even powerful in Rome, where the apostle Peter's successors affirmed their episcopal authority. In Italy, Gaul, and Africa around Carthage, the bishoprics were growing in number, and some councils (or synods) assembled dozens of bishops. The progress of a religion that could not accept the religious basis of the tetrarchy, and certain of whose members were imprudent and provocative, as in the incidents at Nicomedia (where a church was built across from Diocletian's palace), finally aroused Galerius' fanaticism. He, in turn, brought pressure on his Augustus: in 303–304 several edicts, each increasingly stringent, ordered the destruction of the churches, seizure of sacred books, and imprisonment of the clergy, and a sentence of death for all those who refused to sacrifice to the Roman gods. In the East, where Galerius was imposing his ideas more and more on the aging Diocletian, the persecution was extremely violent, especially in Egypt, Palestine, and the Danubian regions.

In Italy, Maximian, zealous at the beginning, quickly tired; and in Gaul, Constantius merely destroyed a few churches without carrying reprisals any further. The persecution lasted as late as 312 in the East. Nevertheless, Christianity could no longer be eradicated, for the people of the empire and even some officials no longer felt the blind hatred for Christians that had typified previous centuries.

The seven competing emperors

Struggle for power. The first tetrarchy had ended on May 1, 305; the second did not last long. After Constantius died at Eboracum in 306, the armies of Britain and Gaul, without observing the rules of the tetrarchic system, had hastened to proclaim Constantine, the young son of Constantius, as Augustus. Young Maxentius, the son of Maximian (who had never wanted to retire), thereupon had himself proclaimed in Rome, recalled his father into service, and got rid of Severus. Thus, in 307–308 there was great confusion. Seven emperors had, or pretended to have, the title of Augustus: Maximian, Galerius, Constantine, Maxentius, Maximinus Daia, Licinius (who had been promoted Augustus in 308 by Galerius against Constantine), and, in Africa, the usurper Domitius Alexander also took the purple.

This situation was clarified by successive eliminations. In 310, after numerous intrigues, old Maximian was killed by his son-in-law Constantine, and in the following year Alexander was slain by one of Maxentius' praetorian prefects. In 311 Galerius died of illness a few days after having admitted the failure of his persecutions by proclaiming an edict of tolerance. There remained, in the West, Constantine and Maxentius and in the East, Licinius and Maximinus Daia. Constantine, the best general, invaded Italy with a strong army of faithful Gauls and defeated Maxentius near the Milvian Bridge, not far from Rome. While attempting to escape, Maxentius drowned. Constantine then made an agreement with Licinius, and the two rallied the Eastern Christians to their side by guaranteeing them religious tolerance in the Edict of Milan (313). This left Maximinus Daia, now isolated and regarded as a persecutor, in a weak position; attacked by Licinius near Adrianople, he fell ill and died soon afterward, in 313. This left the empire with two leaders, Constantine and Licinius, allied in outward appearances and now brothers-in-law as a result of Licinius' marriage to Constantine's sister.

The reign of Constantine. Constantine and Licinius soon disputed among themselves for the empire. Constantine attacked his adversary for the first time in 316, taking the dioceses of Pannonia and Moesia from him. A truce between them lasted ten years. In 316 Diocletian died in Salona, which he had never felt a desire to leave despite the downfall of his political creation. Constantine and Licinius then reverted to the principles of heredity, designating three potential Caesars from among their respective sons, all still infants, with the intention of securing their dynasties (two sons of Constantine and one of Licinius). The dynastic concept, however, required only a single emperor, imposing his own descendance. Although Constantine favoured the Christians, Licinius resumed the persecutions; and in 324 war erupted once again. Licinius, defeated first at Adrianople and then in Asia Minor, was obliged to surrender and, together with his son, was executed. Next, Constantine's third son, Constantius, was in turn named Caesar, as his two elder brothers, Crispus and Constantine the Younger, had been some time before. The second Flavian dynasty was thus founded, and Constantine let it be believed that his father, Flavius Constantius (Chlorus), was descended from Claudius Gothicus.

Constantine's conversion to Christianity

Religious policies. Constantine's conversion to Christianity had a far-reaching effect. Like his father, he had originally been a votary of the Sun and had gone to worship at the Grand Temple of the Sun in the Vosges Mountains of Gaul, where he had had his first vision—a pagan one. During his campaign against Maxentius, he had had a second vision—a lighted cross in the sky—and he had painted on his men's shields a figure that was perhaps Christ's monogram (although he probably had Christ confused with the Sun in his manifestation as *summa divinitas* ["the highest divinity"]). After his victory he declared himself Christian. His conversion, as is so often the case, remains somewhat mysterious, and his contemporaries—Lactantius and Eusebius of Caesarea—are scarcely enlightening and even rather contradictory on the subject. But it was doubtless a sincere conversion, for Constantine had a religious turn of mind. He was also progressive and greatly influenced by the capable bishops who surrounded him from the very beginning.

Until 320–322 solar symbols appeared on his monuments and coins, and he was never a great theologian. But his favourable policy toward the Christians never faltered. Christianity was still a minority religion in the empire, especially in the West and in the countryside (and consequently within his own army), thus excluding the possibility of any political calculation on his part. But it was enthusiastically welcomed in the East, and thanks to Constantine the new religion triumphed more rapidly; his official support led to the conversion of numerous pagans, although with doubtful sincerity because they were indifferent in their moral conviction.

The church, so recently persecuted, was now suddenly showered with favours: the construction of magnificent churches (Rome, Constantinople), donations and grants, exemptions from decurial duties for the clergy, juridical competences for the bishops, and exceptional promotions for Christian officials. Pagans were not persecuted, however, and Constantine retained the title of *pontifex maximus.* But he spoke of the pagan gods with contempt and forbade certain types of worship, principally nocturnal sacrifices. In 331 he ordered an inventory of pagan property, despoiled the temples of their treasure, and finally destroyed a few Eastern sanctuaries on the pretext of immorality.

The Arian heresy

The churches were soon to feel the burden of imperial solicitude: the "secular arm" was placed at the service of a changing orthodoxy, for the emperor was impressionable to arguments of various coteries and became quite lost in theological subtleties. In 314 the Council of Arles had tried in vain to stop the Donatist schism (a nationalistic heretical movement questioning the worthiness of certain church officials) that arose in Africa after Diocletian's persecutions. The Arian heresy raised even more difficulties: Arius, an Alexandrian priest and disciple of Lucian of Antioch, questioned the dogma of the Trinity and of the Godhead of Christ, and his asceticism, as well as the sharpness of his dialectics, brought him many followers; he was convicted several times, but the disorders continued. Constantine, solicited by both sides and untroubled by doctrinal nuances that were, moreover, foreign to most Westerners, wished to institute a universal creed; with this in mind he convened the general Council of Nicaea, or Nicene Council, in 325. He condemned Arius and declared, in spite of the Easterners, that Jesus was "of one substance" with God the Father. Nevertheless, the heresy continued to exist, for Constantine changed his mind several times; he was influenced by Arian or semi-Arian bishops and was even baptized on his deathbed, in 337, by one of them, Eusebius of Nicomedia.

Administrative policies. Between 325 and 337 Constantine effected important reforms, continuing Diocletian's work. The division between the *Iimitanei* border troops and the tactical troops (*comitatenses* and imperial guard) led by *magistri militum* was clarified, and military careers became independent of civil careers. He conferred the clarissimate upon many equestrian officials, created new titles that recorded personal fidelity (counts and patricians: companions and relatives of the emperor), and gave first rank in the central administration to the palace questor, the *magister officiorum,* and the counts of finance *(comes sacrarum largitionum, comes rei privatae).* The diocesan vicars were made responsible to the praetorian prefects, whose number was increased and whose jurisdictions were now vast territories: the prefectures of Gaul, Italy, Illyricum, and the East. To this unification of political power there corresponded a decentralization of administration.

In order to reorganize finances and currency he minted two new coins: the silver *miliarensis* and, most importantly, the gold *solidus,* whose stability would make it the Byzantine Empire's basic currency. And by plundering Licinius' treasury and despoiling the pagan temples, he was able to restore the finances of the state. Even so, he still had to create class-taxes: the *gleba* for senators, and the *chrysargyre,* which was levied in gold and silver on merchants and craftsmen in the towns.

Founding of Constantinople

Constantine's immortality, however, rests on his founding of Constantinople. This "New Rome," established in 324 on the site of Byzantium and dedicated in 330, rapidly increased in population as a result of favours granted to immigrants. A large number of churches were also built there, even though former temples were not destroyed; and the city became the administrative capital of the empire, receiving a senate and proconsul. This choice of site was due not to religious considerations, as has been suggested, but rather to reasons that were both strategic (its proximity to the Danube and Euphrates frontiers) and economic (the importance of the straits and of the junction between the great continental road, which went from Boulogne to the Black Sea, and the eastern commercial routes, passing through Asia Minor to Antioch and Alexandria). Constantine died on May 22, 337.

THE ROMAN EMPIRE UNDER THE 4TH-CENTURY SUCCESSORS OF CONSTANTINE

The rule of Constantine's sons. After some months of confusion, Constantine's three surviving sons (Crispus, the eldest son, had been executed in mysterious circumstances in 326), supported by the armies faithful to their father's memory, divided the empire among themselves and had all the other members of their family killed. Constantine II kept the West, Constantius the East, and Constans, the youngest brother, received the central prefecture (Italy, Africa, and Illyricum). In 340, Constantine II tried to take this away from Constans but was killed. For the next ten years there was peace between the two remaining brothers, and Constans won acceptance for a religious policy favourable to the Niceans, whose leader, Athanasius, had received a triumph in Alexandria. In 350 a mutiny broke out in Autun; Constans fled but was killed in Lyons by Magnentius, a usurper who was recognized in Gaul, Africa, and Italy. Constantius went out to engage Magnentius, and the Battle of Mursa (351) left the two strongest armies of the empire, those of Gaul and of the Danube, massacred, thus compromising the empire's defense. Magnentius retreated after his defeat and finally committed suicide in 355.

The reign of Constantius

Thenceforth, Constantius reigned alone as Augustus, aided by a meddlesome bureaucracy in which mission deputies *(agentes in rebus),* informers, and spies played an important role. He named two Caesars in succession, his two young surviving cousins, Gallus in the East and Julian in Gaul, both of whom were apparently considered only "employees," or *apparitores.* Constantius eventually had to get rid of Gallus, who proved incompetent and cruel and soon terrorized Antioch. Julian, however. was a magnificient success, a fact that aroused Constantius' jealousy and led to Julian's usurpation, for the latter was proclaimed Augustus, in spite of Constantius' opposition, at Lutetia in 361. Civil war was averted when Constantius died in November 361, leaving the empire to Julian, the last ruler of the Constantinian family.

Wars against the Persians and barbarians. At the time of his death in 337, Constantine had been preparing to go to war against the Persians. This legacy weighed heavily on the shoulders of Constantius, a military incompetent when compared to the energetic Sāsānian king Shāpūr II. Nearly every year the Persians attacked and pillaged Roman territory; the Mesopotamian towns were beseiged, and Nisibis alone resisted. There was a lull between 350 and 357, while Shāpūr was detained by troubles in the eastern regions of his own kingdom. The war resumed, however, and Mesopotamia was partly lost when the emperor had to go off to fight Julian. Constantius had fought Shāpūr conscientiously, but his generals were mediocre, except for Urisicinus, and he himself was clumsy. In the meantime, the Rhine and the Danube, the troops of which had been withdrawn in favour of the East, were threatened frequently; and Constantius had made a mistake in sending Chnodomar, the Alamannic king, against Magnentius in 351, for his tribes had gone on to ravage Gaul. Julian, however, soon revealed himself to be a great military leader by winning several well-fought campaigns between 356 and 561, most notably at Strasbourg in 357, and by restoring approximately 70 plundered villages. Constantius defeated the Quadi and the Goths on the Danube in 359, but court intrigues, Magnentius' usurpation, and the interminable war against the Persians allowed the barbarians to wreak great havoc.

Constantius' Arianism

Constantius' religious policies. Constantius was primarily interested in religious affairs, and his interventions created a "caesaro-papism" that was unfavourable to the church, for after the Battle of Mursa the Emperor had become violently Arian. The Christological problem had moved to the forefront. In 360 Constantius obtained a new creed by force from the Council of Constantinople, which, rejecting the notion of "substance" as too risky, declared only that the Son was like the Father and thus left the problem unresolved. Pagans as well as orthodox Nicaeans (Homoousians) and extremist Arians (Anomoeans) were persecuted, for in 356–357 several edicts proscribed magic, divination, and sacrifices and ordered that the temples be closed. But when Constantius visited Rome in 357, he was so struck by its pagan grandeur that he apparently suspended the application of these measures.

The reign of Julian. Julian, who had been spared because of his tender age from the family butchering in 337, had been brought up far from the court and was undoubtedly intended for the priesthood. Nevertheless, he had been allowed to take courses in rhetoric and philosophy at Ephesus and later at Athens; he developed a fondness for Hellenic literature, and he secretly apostatized around 351. When he became sole emperor at the end of 361, he proclaimed his pagan faith, ordered the restitution of the temples seized under Constantius, and freed all the bishops who had been banished by the Arians, so as to weaken Christianity through the resumption of doctrinal disputes. His paganism was irrational, mystical, and complex. Privately, he worshiped the Sun (Helios-King) and the figure of Cybele, the pagan equivalent of the Virgin Mary. Deeply attached to the traditional Hellenism of the Sophists, who ceaselessly invoked Homer and Plato, he was especially influenced by the last of the Neoplatonists, Iamblichus and Maximus of Ephesus, who instructed him in the techniques of ecstasy and direct communication with the gods (theurgy). The gods spoke to him, and he heard their exhortations. Julian sincerely believed that it was his mission to re-establish their worship.

In time Julian would undoubtedly have become a persecutor, for in 362 he had already forbidden Christians from teaching, under the pretext that their faith made them betray the intentions of the ancient authors. This ostracism aroused even the indignation of certain tolerant pagans. His restoration of the pagan temples provoked disorders and judicial violations among Christians. He gave the pagans a monopoly on high posts, and as a consequence, numerous self-seeking Christians became pagans. Within a short while Julian was successful enough in his undertaking to have aroused the fear and hatred of the Christians, who for a long time thought of him as the Antichrist.

In the political realm, Julian wished to return to the liberal principate of the Antonines—to a time before the reforms of Diocletian and Constantine, whom he detested. He put an end to the terrorism of Constantius' eunuchs and *agentes in rebus* and reduced the personnel and expenditures of the court, while he himself lived like an ascetic. And in the provinces, he lightened the financial burden on individuals by reducing the *capitatio;* that on cities, by reducing the *aurum coronarium* and restoring the municipal properties confiscated by Constantius. On the other hand, he increased the number of curiales by reinstating numerous clerks in an attempt to return the

ancient lustre to municipal life. Thus, he earned the gratitude of pagan intellectuals, who were enamoured of the past of free Greece; and Ammianus made him the central hero of his history.

Julian's attempt to defeat Persia

Taking up Trajan's dream, Julian wished to defeat Persia definitively by engaging the empire's forces in an offensive war that would facilitate a national reconciliation around the gods of paganism. But his army was weak—corrupted perhaps by large numbers of hostile Christians. After a brilliant beginning, he was defeated near Ctesiphon and had to retrace his steps painfully; he was killed in an obscure encounter on June 26,363.

Julian's successor, Jovian, chosen by the army's general staff, was a Christian, but not a fanatic. He negotiated a peace with Shāpūr, by which Rome lost a good part of Galerian's conquests of 298 (including Nisibis, which had not surrendered) and abandoned Armenia. He also restored tolerance in religious affairs, for he neither espoused any of the heresies nor persecuted pagans. In February 364 he died accidentally.

The reign of Valentinian and Valens. Once again the general staff unanimously chose a Pannonian officer—Valentinian, an energetic patriot and, like Jovian, a moderate Christian—but he had to yield to the rivalry of the armies by dividing authority. Taking the West for himself, Valentinian entrusted the East to his brother Valens, an inexperienced man whom he raised to the rank of Augustus. For the first time the two parts of the empire were truly separate, except for the selection of consuls, in which Valentinian had precedence.

Although he served the state with dedication, Valentinian could be brutal, choleric, and authoritarian. His foreign policy was excellent: all the while he was fighting barbarians (the Alamanni in Gaul, the Sarmatians and

Quadi in Pannonia) and putting down revolts in Britain and Africa (notably that of the Berber Firmus) with the aid of his top general, Theodosius the Elder, he was taking care to improve the army's equipment and to protect Gaul by creating a brilliant fortification. His domestic measures favoured the curiales and the lower classes: from then on, taxes would be collected exclusively by officials; the protection of the poor was entrusted to "defenders of the plebs," chosen from among retired high officials (honorati). Nevertheless, needs of state obliged him to accentuate social immobility, to reinforce corporation discipline and official hierarchization, and to demand taxes ruthlessly. At first he was benevolent to the Senate of Rome, supervised the provisioning of the city, and legislated in favour of its university, the nursery of officials (law of 370). But beginning in 369, under the influence of Maximin, the prefect of Gaul, he initiated a period of terror, which struck the great senatorial families. Meanwhile, religious peace reigned in the West, tolerance was proclaimed, and after some difficulty, Rome found a great pope in Damasus, who, beginning in 373, actively supported the new bishop of Milan, St. Ambrose, an ardent defender of orthodoxy.

Religious peace in the West, persecutions in the East

In the East, Valens, who was incapable and suspicious, had fallen under the influence of legists, such as the praetorian prefect Modestus. The beginning of Valens' reign was shadowed by the attempted usurpation of Procopius (365–366), a pagan relative of Julian's who failed and was killed by the army, which remained faithful to Valens. Modestus instituted harsh persecutions in Antioch of the educated pagan elite. Valens was a fanatic Arian, who exiled even moderate Nicaean bishops and granted to Arians favours that aroused violent reactions from the orthodox, whose power had increased in the East. Valens' policies made the East prey to violent religious passions.

On the Danube, Valens fought the Visigoths and made a treaty with their king, Athanaric, in 369; but in 375 the Ostrogoths and the Greutingi appeared on the frontiers, pushed from their home in southern Russia by the powerful Huns. In 376 Valens authorized the starving masses to enter Thrace; but being exploited and mistreated by the officials, they soon turned to uncontrollable pillaging. Their numbers continually increased by the addition of new bands, until finally they threatened Constantinople itself. Valens sent for aid from the West; but without waiting for it to arrive, he joined battle and was killed in the Adrianople disaster of 378, which to some critics foreshadowed the approaching fall of the Roman Empire.

The Goths, who were also stirring up Thrace and Macedonia, could no longer be driven out. The provinces remained insecure until 382, when Theodosius, after fighting many hard battles with only an inconclusive result, resigned himself to settling the Goths legally in the Balkan Peninsula as foederati (soldiers in the service of Rome, receiving subsidies and furnishing recruits); there they formed barbarian enclaves.

The reign of Gratian and Theodosius I. Following Valentinian's sudden death in 375, the West was governed by his son Gratian, then 16 years old, who had been given the title of Augustus as early as 367. The Pannonian army, rife with intrigue, quickly proclaimed Gratian's half-brother, Valentinian II, only four years old. The latter received Illyricum under his older brother's guardianship, and this arrangement satisfied everybody. Valentinian's advisers were executed: Maximian was sacrificed to the spite of the Senate, and Theodosius the Elder became the victim of personal jealousies. Gratian announced a liberal principate, supported in Gaul by the wealthy family of the Bordeaux poet Ausonius and in Rome by the Symmachi and the Nicomachi Flaviani, representatives of the pagan aristocracy. His generals defeated the Alamanni and the Goths on the Danube but arrived too late to save Valens.

On January 19, 379, before the army, Gratian proclaimed Theodosius, the son of the recently executed general, as Eastern emperor. Theodosius was chosen for his military ability and for his orthodoxy (Gratian, extremely pious, had come under the influence of Damasus and Ambrose). The East was enlarged by the dioceses of Dacia and Macedonia, taken from Valentinian II. Gratian and Theodosius agreed to admit the Goths into the empire, and Gratian applied the policy also to the Salian Franks in Germany. Theodosius soon dominated his weak colleague and entered the battle for the triumph of orthodoxy. In 380 the Arians were relieved of their churches in Constantinople, and in 381, the Nicaean faith was universally imposed by a council whose canons established the authority of the metropolitan bishops over their dioceses and gave the bishop of the capital a primacy similar to that of the bishop of Rome.

Influx of Goths and Franks

In ecclesiastical affairs, the separation between East and West was codified. The Westerners bowed to this policy, satisfied with the triumph of orthodoxy. Gratian then permitted Ambrose and Damasus to deal harshly with the Arians, with the support of the state. Paganism also was hounded: following Theodosius' lead. Gratian refused the chief priesthood, removed the altar of Victory from the hall of the Roman Senate, and deprived the pagan priests and the vestals of their subsidies and privileges. The pagan senators were outraged, but their protests were futile because Gratian was watched over by Arnbrose.

This militantly orthodox policy aroused the displeasure of the pagans and of the Western Arians: thus, when Gratian left Trier for Milan, the army of Gaul and Britain proclaimed its leader, Maximus, in 383. He conquered Gaul without difficulty, and Gratian was killed in Lyons. Maximus, who, like Theodosius, was Spanish and extremely orthodox, was recognized by the latter. In the meantime, the third Augustus, Valentinian II, had taken refuge in Milan after suffering defeat in Pannonia. He was effectively under the domination of his mother, Justina, an Arian who sought support for her son among the Arians and pagans of Rome and even among the African Donatists. In 388 Maximus, after arriving in Italy, first expelled Valentinian and then prepared to attack Theodosius. The latter, accepting the inevitability of war, strengthened his resolve and gained several victories. Maximus was killed at Aquileia in 388, and thenceforth Theodosius ruled both West and East; he was represented in the East by his son Arcadius, an Augustus since 383. Valentinian II was sent to Trier, accompanied by the Frankish general Arbogast to control him.

Sole rulership of Theodosius

After a few years' respite, during the prefectureships of Nicomachus Flavianus in Rome and Tatian in the East, paganism waged its last fight: Theodosius, influenced by Ambrose, who had dared to inflict public penance on him in 390 after the massacre at Tnessalonica, had determined to eliminate the pagans completely. After a few hostile clashes, the law of November 8, 392, proscribed the pagan religion. Then Arbogast, after Valentinian II's death in 392 under shadowy circumstances, proclaimed as emperor the rhetorician Eugenius. When Theodosius refused to recognize him, Eugenius was thrown into the arms of the pagans of Rome. But this last "pagan reaction" was short-lived; in 394, with his victory at the Frigidus River, between Aquileia and Emona, Theodosius put an end to the hopes of Eugenius and his followers. His intention was to place his son Honorius, proclaimed Augustus in 393, over the West, while returning his eldest son, Arcadius, to the East. But Theodosius' sudden death, in January 395, precipitated the division of the empire.

Theodosius had finally eliminated the clanger of the Goths, although not without taking risks, and had both established a dynasty and imposed the strictest orthodoxy. A compromise peace with the Persians had given Rome, in 387, a small section of Armenia, where he had founded Theodosiopolis (Erzurum). Internally, there were few reforms; and wars, wastefulness, and the burden of administration had caused a noticeable increase in taxation. The ancient authors all paint a gloomy picture of the condition of the settlers, the curiales, and the artisans of the towns. Meanwhile, the laws were becoming increasingly harsh, and revolts (Antioch in 387, Thessalonica in 390) were ruthlessly suppressed. Theodosius owed his success to the support of the orthodox bishops —who took advantage of his faith to introduce “clericalism" into the state—and to the strength of his army, hereafter dominated by barbarian elements: the Franks and Alamanni in the West; the Goths and even the federated Huns in the East. The majority of commanding officers were also barbarians, including such Franks as Richomer, Merovech, Arbogast, and the half-Vandal Stilicho, who through his marriage to Serena, Theodosius' niece, had entered the imperial family.

Social and economic conditions. During the 4th century the emperor's power was theoretically absolute, the traditions of the principate having given way to the necessities of defense.

Hierarchized bureaucracy

Administration. The emperor, who was most often a soldier, was both heir to the Hellenistic basileus (absolute king) and the anointed of the deity. Pagans and Christians alike considered him "emperor by the grace of God," which, strictly speaking, rendered the imperial cult unnecessary. Indeed, only military victory, willed by God, distinguished the legitimate sovereign from the "tyrant." After Constantine, administration was decentralized and headed by praetorian prefects with enormous power. A gargantuan and strictly hierarchic bureaucracy restricted direct action by the emperor, who was separated increasingly from his subjects by a hierarchical court, particularly under Constantius and Theodosius. This overrun administration was recruited from among students of literature and of law for higher posts, and for lesser posts from among "notaries," who knew how to write shorthand. Under Constantius the latter attained even the highest positions, in spite of their modest origins. There was superabundant legislation as well, which tended to increase fiscal income by limiting exemptions and privileges, and to keep each person in the rank assigned him at birth, for taxes were based on social classes. Tax abuses provoked uprisings by the lower classes as well as recourse to patronage and attempts to escape one's class by entering the administration and, above all, to get into the clarissimate, which was lucrative and rich in privileges.

Apart from the tiny elite of Roman senators, for whom public office was only a last resort, and the great landholders sheltered in their villas, where in the West at least they were able to live in independence, officials everywhere formed the upper class of society. The equites occupied the inferior and beginning positions, for gradually during the course of the century all the high officials attained the clarissimate. A career in public service could no longer be compared to the old magistracies. Public service was a powerful factor in social advancement (like the army in the 3rd century), but it was also a costly and sometimes corrupt superstructure, whose upkeep drained the empire. To protect themselves, the poor and weak took refuge in the patronage (*patrocinium*) of the powerful (potentes), a method which, while it shielded them from the authority of the state in spite of the laws, also placed them in positions of personal dependence, which foreshadowed the social arrangements of the Middle Ages. The bishops, who held spiritual authority over growing portions of the population and had available to them both the power of their office and large revenues, began to concentrate the defense of local interests in their own hands and to compete with the rich for the protection of the weak. In the 5th century, they would be the masters and protectors of the cities, particularly in the West.

Settler system

Economy. Economic life was based on ownership of land, and the number of free peasants and middle-sized landowners was decreasing, for both groups were burdened by heavy taxes and threatened by the expansionism of the rich estate (latifundium) owners, the senators and high functionaries. Some free villages (metrocomiae) continued to exist, notably in Syria, and were protected by the state. In areas where urbanization was sparse, the latifundium dominated and was worked by settlers. The udscripticius settler was subordinated completely to his master (*dominus*) and owed him forced labour, whose name (obsequia servilia) showed its true nature. The tributarius settler was a freeholder but still had to look to the patronage of the powerful man whose land he cultivated. The laws specified that the settler could not leave his land, and a recaptured fugitive was treated like a slave, even though he remained a free man in principle. This evolution toward serfdom was ancient; but it had been accelerated by the fiscal reforms (the jugatio, the taxes in kind, and the increases in amounts of forced labour due). In sum, the settler system was one aspect of the general social immobility of the late empire, and it resulted from the enormous needs of the state.

The economy was of three types, which were unequally distributed: 1) the closed economy of the large estates, which dominated in the few regions where urbanization was weak; 2) the produce state economy, in which taxes, wages, and salaries were paid in kind so as to reduce the disadvantages of inflation for the treasury—but the possibility, often resorted to, of replacing payment in kind with payment in money (adaeratio) probably allowed the state to speculate on monetary fluctuations and to satisfy one or the other social category; 3) the monetary economy, the most widespread, which had been restored by Constantine: the gold standard (the *solidus,* or gold pound) was used to establish prices, to pay certain taxes and services, and to assist in the amassing of wealth (coins, bars, ingots); the regular currency, the *nummus,* was a silver-covered copper coin, having various names and values.

Although there was considerable inflation (culminating under Theodosius), in spite of a deflationary fiscal policy, commercial transactions ignored barter and were based instead on currency throughout the empire at the end of the century. The economy was partially under state direction, which was applied to agriculture through bias toward the settler system on imperial estates and to industry through the requisitioning of corporations (artisans, merchants, carriers) and the creation of state workshops (especially for manufacturing military goods). Opinions differ on the intensity of trade, but there was certainly clear progress in comparison to the 3rd century.

Comparison between East and West

It is above all necessary to distinguish between the East and West. The West was in decline: the rural areas had taken over from the cities, where activity had become anemic; and autonomous blocs had formed in Gaul (with the relative prosperity of Britain), Africa, Italy (which suffered a marked decline, except in Cisalpina), and the Danubian countries. The great West–East route of the early empire (from Boulogne to Byzantium, by way of the Rhine and the Danube), as a result of threats by barbarians, had been displaced toward the south, through Lyons, Milan, and Aquileia. On the other hand, the East was less affected by invasions; there, urban life was traditionally more active, and the peasantry resisted the settler system and patronage more effectively. Although the Balkans were devastated after Adrianople (378), elsewhere the wealth of the towns and of the officials sustained active trading. There were three great commercial arteries: 1) the "wheat" road, from Alexandria to Constantinople by way of Antioch; 2) the Far Eastern trade routes, through Osroene (Batnae) or Cappadocia (Somoata) to Antioch and the capital; and 3) the maritime route linking East to West, from Seleucia (the port of Antioch) to Rome. In addition, there were the more dangerous land routes, such as the one across the Balkans (the ancient Via Egnatia through Macedonia) or the Danube route (Sardica, Sirmium, Aquincum, Carnuntum). Although Egypt was impoverished from having been exploited for so long, Asia Minor around Constantinople was prosperous, having numerous towns as well as well-populated rural areas. And of the Eastern provinces, Syria was the richest—thanks to a balanced agriculture, a large and stable population, the industries of Antioch, the textiles of Apamea, Damascus, and Berytus, and above all thanks to commerce, which was centred in Antioch and its port, Seleucia, rebuilt by Constantius. All of this accounts for the intensity of urbanization.

The remnants of pagan culture. The spread of Christianity in no way harmed the flourishing of pagan literature. Instruction in the universities (Rome, Milan, Carthage, Bordeaux, Athens, Constantinople, Antioch, Alexandria) was still based on rhetoric, and literature received the support of senatorial circles, especially in Rome (for example those of the Symmachi and the Nicomachi Flaviani). Latin literature was represented by Symmachus and the poet Ausonius. The last great historian of Rome was Ammianus Marcellinus, a Greek who wrote in Latin for the Roman aristocracy; of his *Res gestae*, the most completely preserved part describes the period from 353 to 378. The works of the abridgers Aurelius Victor and Eutropius are fairly accurate and more reliable than the *Scriptores kistoriae Augustae*, a collection of imperial biographies of unequal value, undoubtedly composed under Theodosius but for an unknown purpose. Erudition was greatly prized in aristocratic circles, which, enamoured of the past, studied and commented on the classic authors (Virgil) or the ancestral rites (the *Saturnalia* of Macrobius). Greek literature is represented by the works of philosophers or sophists: Themistius, a political theoretician who advocated absolutism; Himerius of Prusias; and above all Libanius of Antioch, whose correspondence and political discourses from the Theodosian period bears witness to his perspicacity and, often, to his courage.

The Christian Church. From the time of Constantine the church had perfected its organization, modelled on that of the state. Each city had its bishop; each provincial capital had its Metropolitan, and some had a recognized "primacy": the patriarchs of Alexandria, Antioch, and Constantinople and the bishops of Milan and Rome, the latter claiming an *auctoritas* over the others, which was a heritage of classic Rome. The church had become extremely wealthy and had obtained immunities for its clergy and its bishops. The emperors had assumed the right to interfere in religious affairs, but under Theodosius, Pope Damasus and St. Ambrose reacted: the state was to restrict itself to furnishing the "secular arm," while the church, in the name of evangelical ethics, claimed the right to judge the emperors, a policy that had grave implications for the future. The "caesaro-papism" of Constantius would gain adherents under the Byzantine emperors. Paganism, officially suppressed by Theodosius, survived well into the 5th century in the rural areas, where missionary activity (such as that of St. Martin in Gaul) was only recent, and among the intellectuals, teachers, and senators of Rome. Orthodoxy triumphed over the great heresies (Donatism, Arianism), but other heresies continued to emerge. In the meantime, the Goths had been converted to Arianism by Ulfilas during the period of Constantius and Valens, thus presaging conflicts that would come after the great invasions. Orthodox missionaries had converted Osroene, Armenia, and even some countries on the Red Sea. And in Egypt at the end of the 3rd century there appeared the monasticism of isolated hermits (St. Anthony) and of cenobites grouped in communities (Pachomius). Monasticism rapidly spread to Syria and Asia Minor by toning down its ascetic severity, and in the West St. Martin founded the monasteries of Ligugé and Marmoutier.

Triumph of orthodoxy

The Christian literature of the 4th century is remarkable. Its first representative is Eusebius of Caesarea, a friend and panegyrist of Constantine and a church historian whose creation of a "political theology" sealed the union between the Christian emperor and the church. St. Athanasius wrote apologetic works and a life of St. Anthony. Also prominent were the great Cappadocians: St. Basil of Caesarea, St. Gregory of Nazianms, St. Gregory of Nyssa, and St. John Chrysostom of Antioch, the greatest preacher of his time. The Westerners, too, had great scholars and brilliant writers: St. Hilary of Poitiers, enemy of the Arians and of Constantius; St. Ambrose, administrator and pastor, whose excessive authority was imposed on Gratian and even on Theodosius; and St. Jerome, a desert monk and confessor of upper class Roman ladies, a formidable polemicist who knew Greek and Hebrew and made the first faithful translation of the Old and New Testaments (the Vulgate) as well as of a chronicle of world history, which was a translation and continuation of the work of Eusebius. Finally, St. Augustine, the bishop of Hippo, was a great pastor, a vigorous controversialist, a sensitive and passionate writer (the *Confessions)*, and the powerful theologian of *The City of God*. The century that developed these great minds cannot be considered decadent.

THE ECLIPSE OF THE ROMAN EMPIRE IN THE WEST (C. 395-500) AND THE GERMAN MIGRATIONS

Invasions in the early 5th century. After the death of Theodosius the Western empire was governed by young Honorius. Stilicho, an experienced statesman and general, was charged with assisting him and maintaining unity with the East, which had been entrusted to Arcadius. The Eastern leaders soon rejected Stilicho's tutelage. An anti-barbarian reaction had developed in Constantinople, thus impeding the objectives of the half-Vandal Stilicho. He wanted to intervene on several occasions but was prevented from doing so by a threat from the Visigoth chieftain Alaric, whom he checked at Pollentia in 402, then by the Ostrogoth Radagaisus' raid in 406, and finally by the great invasion of the Gauls in 407. The following year he hoped to restore unity by installing a new emperor in Constantinople, Theodosius II, the son of Arcadius, who had died prematurely; but he succumbed to a political and military plot in August 408. The division of the two *partcs imperii* was now a permanent one.

Honorius. seated in Ravenna, a city easier to defend than Milan, had only incompetent courtiers surrounding him, themselves animated by a violent hatred of the barbarians. Alaric soon reappeared, at the head of his Visigoths, demanding land and money. Tired of the Romans' double-dealing, he descended on Rome itself. The city was taken and pillaged for three days, thus putting an end to an era of Western history (August 410). An Arian, Alaric spared the churches. He died shortly thereafter in the south; and his successor, Athaulf, left the peninsula to march against the Gauls.

Sack of Rome by the Visigoths

Fleeing from the terrifying advance of the Huns, on December 31, 406, the Vandals, Suevi, and Alani, immediately followed by the Burgundians and bands of Alamanni, crossed the frozen Rhine and swept through Gaul, effortlessly throwing back the federated Franks and Alamanni from the frontiers. Between 409 and 415 a great many of these barbarians arrived in Spain and settled in Lusitania (Suevi) and in Baetica (Vandals, whence the name Andalusia). As soon as Gaul had become slightly more peaceful, Athaulf's Visigoths arrived, establishing themselves in Narbonensis and Aquitania. After recognizing them as "federates," Honorius asked them to go to Spain to fight the Vandals. Meanwhile, the Roman general Constantius eliminated several usurpers in Gaul, confined the Goths in Aquitania, and reorganized the administration (the Gallic assembly of 418). But he was unable to expel the Franks, the Alamanni, and the Burgundians, who had occupied the northern part of the country, nor to eliminate the brigandage of the Bagaudae. He was associated with the empire and was proclaimed Augustus in 421, but he died shortly afterward. His son, Valentinian III, succeeded Honorius in 423 and reigned until 455.

The beginning of Germanic hegemony in the West. During the first half of the 5th century the barbarians gradually installed themselves, in spite of the efforts of the Roman general Aetius at the head of a small army of mercenaries and of Huns. Aetius took back Arles and Narbonne from the Visigoths in 436, either pushed back the Salian and Ripuarian Franks beyond the Rhine or incorporated them as federates, settled the defeated Burgundians in Sapaudia (Savoy), and established the Alani in Orléans. The other provinces were lost: Britain, having been abandoned in 407 and already invaded by the Picts and Scots, fell to the Angles, Saxons, and Jutes; a great Suevi kingdom, officially federated but in fact independent, was organized in Spain after the departure of the Vandals, and it allied itself to the Visigoths of Theodoric I, who were settled in the country around the Garonne.

Loss of provinces

The Vandal seizure of North Africa. In 428 the Vandal Gaiseric led his people (80,000 persons, including 15,000 warriors) to Africa. St. Augustine died in 430 in besieged Hippo, Carthage fell in 435, and in 442 a treaty gave Gaiseric the rich provinces of Byzacena and Numidia. From there he was able to starve Rome, threaten Sicily, and close off the western basin of the Mediterranean to the Byzantines.

Invasion by the Huns. Shortly afterward, in 450, Attila's Huns invaded the West—first Gaul, where, after having been kept out of Paris, they were defeated by Aetius on the Campus Mauriacus (near Troyes), then Italy, which they evacuated soon after having received tribute from the pope, St. Leo. Attila died shortly afterward; and this invasion, which indeed left more legendary memories than actual ruins, had shown that a solidarity had been created between the Gallo-Romans and their barbarian occupiers, for the Franks, the Alamanni, and even Theodoric's Visigoths had come to Aetius' aid.

The end of the Roman Empire of the West

The last emperors in the West. After the death of Aetius, in 454, and of Valentinian III, in 455, the West became the stake in the intrigues of the German chiefs Ricimer, Orestes, and Odoacer, who maintained real power through puppet emperors. In 457–461 the energetic Majorian re-established imperial authority in southern Gaul until he was defeated by Gaiseric and assassinated shortly afterward. Finally, in 476, Odoacer deposed the last emperor, Romulus Augustulus, had himself proclaimed king in the barbaric fashion, and governed Italy with moderation under the theoretical tutelage of the emperor of the East. The end of the Roman Empire of the West passed almost unperceived.

Barbarian kingdoms. Several barbarian kingdoms were then set up: in Africa, Gaiseric's Vandals; In Spain and in Gaul as far as the Loire, the Visigothic kingdom; and farther to the north, the Salian Franks and the Alamanni. The barbarians were everywhere a small minority. They established themselves on the great estates and divided the land to the benefit of the federates without doing much harm to the lower classes or disturbing the economy. The old inhabitants lived under Roman law, while the barbarians kept their own "personality of laws," of which the most well-known is the judicial composition, the Wergild. Romans and barbarians coexisted but uneasily. Among the obstacles to reconciliation were differences in mores; social and political institutions (personal monarchies, fidelity of man to man); language, although Latin was still used in administration; and above all religion: the Arianism of the barbarians permitted the Catholic bishops to retain their hold over their flocks. The only persecution, however, was under the Vandals, whose domination was the most harsh.

Two great kingdoms marked the end of the 5th century. In Gaul, Clovis, the king of the Salian Franks (reigned 481/482–511), expelled Syagrius, the last Roman, from Soissons, took Alsace and the Palatinate from the Alamanni (496), and killed Alaric II, king of the Visigoths, at Vouillé (507). His apparently sudden conversion to Catholicism assured him the support of the bishops, and Frankish domination was established in Gaul. At the same time, Theodoric, king of the Ostrogoths, was reigning in Italy. He had been charged by the emperor Zeno to take back Italy from Odoacer in 488, and in 494 he had himself proclaimed king at Ravenna. His Goths, few in number, were established in the north; elsewhere he preserved the old imperial administration, with senators as prefects. Externally, he kept Clovis from reaching the Mediterranean and extended his state up to the valley of the Rhône. Theodoric died in 526. Ten years later Justinian charged his general Belisarius with the reconquest of Italy, a costly, devastating, and temporary operation that lasted from 535 to 540.

Analysis **of** the decline **and** fall. The causes of the fall of the empire have aroused a good deal of discussion. The reasons most often invoked are not definitive; the economic decline of the Roman world was not obvious in the 4th century, nor was the decay of the form of government or the defects of the administration. Nevertheless, the empire was yielding under the weight of its state superstructure and of taxation that was too heavy for the ancient world, where production and the standard of living were both very low. The army, which was extremely expensive, was not large enough; and even the population seemed to have declined. But it was really the massive invasions, which had become incessant during the second half ,of the century, that toppled the empire. It is essential to see why the East resisted, whereas the West was overcome. The East during this period was rich and well populated, and its heavy state structure was healthier than that of the West. The latter was in the hands of the great landholders, who exploited their settlers, who, in turn, had no recourse. The East was also less threatened from the outside and easier to defend: only the lower Danube was vulnerable, with Persia in fact representing no great danger, whereas in the West long frontiers required large numbers of troops and ruinously expensive fortifications. Once the borders were broken through, the vital regions of Gaul and Italy were left defenseless. Even if the East had come to its aid instead of growing increasingly aloof after the failure of Stilicho, the barbarians would undoubtedly still have triumphed; for the population, although it dreaded the barbarians and hated their religion, showed a surprising apathy: bureaucratic absolutism and the patronage of the powerful in the West had killed the idea of the state and the patriotism of ancient Rome. **(P.P.)**

BIBLIOGRAPHY

Origins to 264 BC: P.G. GIEROW, *The Iron Age Culture of Latium:* vol. 1, *Classification and Analysis* and vol. 2, *Excavations and Finds* (1964), a systematic view of the archaeological discoveries made in Latium, dating from the early Iron Age; EINAR GJERSTAD, *Early Ronze: vol. 1, Stratigraphical Researches in the Forum Romanum and Along the Sacra Via* (1953); vol. 2, *The Tombs* (1956); vol. 3, *Fortifications, Domestic Architecture, Sanctuaries, Stratigraphical Excavations* (1960); vol. 4, *Synthesis of Archaeological Evidence* (1966), a monumental work on all the archaeological remains from ancient Rome—the investigation of the material is outstanding, although the historical conclusions have been contested; PIETRO DE FRANCISCI, *Primordia Civitatis* (1959), and RAYMOND BLOCH, *Les Origines de Rome,* rev. ed. (1959; Eng. trans., *The Origins of Rome,* 1960), two overall views of the early centuries of Rome internally and externally; ANDRAS ALFOLDI, *Early Rome and the Latins* (1965), a first-rate study of the relations between Rome and the Latins, up to the time of Rome's subjugation of Latium; T.R.S. BROUGHTON, *The Magistrates of the Roman Republic,* 2 vol., and one suppl, vol. (1951–52), an excellent view of the Roman magistracies of the republican era; PIERRE LEVEQUE, *Pyrrhos* (1957), a monograph (in French) that deals with the personality and ambitions of Pyrrhus, Rome's formidable opponent at the beginning of the 3rd century Bc; RUDI THOMSEN, *Early Roman Coinage,* 3 vol. (1957–61), a balanced, well-done history of the oldest Roman currency.

Rome—264 to 133 BC: Important sections, together with inscriptions, are published in English translation by NAPHTALI LEWIS and MEYER REINHOLD (eds.), *Roman Civilization Sourcebook,* vol. *1, The Republic* (1966); and A.H.M. JONEs, *A History of Rome Through the Fifth Century,* vol. 1, *The Republic* (1968). *(General histories of the period): The Cambridge Ancient History,* vol. 7–8 (1928–30); G. DE SANCTIS, *Storia dei Romani,* 2nd ed., vol. 3–4 (1967–69); H.H. SCULLARD, *A History of the Roman World from 753 to 146 B.C.,* 3rd ed. (1969). *(Roman constitutional history):* A.H.J. GREENIDGE, *Roman Public Life* (1901); W.M.F. JASHEMSKI, *The Origins and History of the Pro-Consular and Pro-Praetorian Imperium to 27 B.C.* (1950); THEODOR MOMMSEN, *Römische Staatsrecht,* 3 vol. (1871–88, reprinted 1952); E.T. SALMON, *Roman Colonization Under the Republic* (1969); L. ROSS TAYLOR, *Roman Voting Assemblies* (1966) and *The Voting Districts of the Roman Republic* (1960); A.N. SHERWIN WHITE, *The Roman Citizenship* (1939). *(Social and economic history):* TENNEY FRANK, *An Economic History of Ronze fo the End of the Republic,* 2nd ed. (1927), and (ed.), *An Economic Survey of Ancient Rome,* 6 vol. (1933–40); M.I. ROSTOVTZEFF, *The Social and Economic History of the Hellenistic World* (1941); ARNOLD TOYNBEE, *Hannibal's Legacy,* 2 vol. (1965). *(Provincial government and imperialism):* E. BADIAN, *Foreign Clientelae, 264–70 B.C.* (1958); TENNY FRANK, *Roman Imperialism* (1914); DAVID MAGIE, *Roman Rule in Asia Minor to the End of the Third Century After Christ, 2* vol. (1950); G.H. STEVENSON, *Roman Provincial Administration till the Age of the Antonines* (1939); C.H.V. SUTHERLAND, *The Romans in Spain, 217 B.C.–A.D. 177* (1939).

Rorne—133 to 31 BC: The chief ancient sources for the period are the works of CAESAR and CICERO and SALLUST'S two monographs on Jugurtha and Catiline; the biographies of prominent Romans of the period in PLUTARCH, *Parallel*

Lives; and the historical narratives of APPIAN *(The Civil Wars)* and of CASSIUS DIO *(Roman History).* All are available in the original, with facing English translation, in the "Loeb Classical Library," the first four in many other translations. An important source collection for the period it covers is A.H.J. GREENIDGE and A.M. CLAY, *Sources for Roman History,* 133–70 *B.C.,* 2nd ed. rev. by E.W. GRAY (1960). The best outline in English is the first half of H.H. SCULLARD, *From the Gracchi to Nero,* 3rd ed. (1970), with excellent notes and bibliography. The classic reference work is WILHELM DRUMANN, *Geschichte Roms in seinem Übergange von der republikanischen zur monarchischen Verfassung,* 2nd ed. by P. GROEBE, 6 vol. (1899), giving biographies (with full source material) of all prominent figures of the period, arranged by families. For a survey of scholarship, with critical bibliography, see E. BADIAN, "From the Gracchi to Sulla (1940–59)," *Historia,* 11:197–245 (1962); part 2 of Badian's *Foreign Clientelae,* 264–70 *B.C.* (1958), treats the political history down to 70 BC. For the social background, see the fundamental work of MATTHIAS GELZER, *Die Nobilitiit der römischen Republik* (1912; Eng. trans., *The Roman Nobility,* 1969); and, on special aspects of it, SUSAN TREGGIARI, *Roman Freedmen During the Late Republic* (1969); T.P. WISEMAN, *New Men in the Roman Senate,* 139 *B.C.–A.D.* 14 (1971); and E. BADIAN, *Publicans and Sinners* (1972). L. ROSS TAYLOR, *Party Politics in the Age of Caesar* (1949), gives the best analysis of the working of the political system after Sulla; RONALD SYME, *The Roman Revolution* (1939), is the classic study of the social and political transformation of the republic into the principate. Special aspects of particular interest are studied in JACQUES HARMAND, *L'Armée et le soldat a Rome de* 107 *à* 50 *avant notre Ére* (1967); E. BADIAN, *Roman Imperialism in the Late Republic,* 2nd ed. (1968); E.S. GRUEN, *Roman Politics and the Criminal Courts,* 149–78 *B.C.* (1968); and the last chapters of E.T. SALMON, *Roman Colonization Under the Republic* (1969).

Rome—31 BC to AD 193: TACITUS' *Annals* and *Histories,* describing the period from AD 14 to 96, are largely lost, including his account of the Flavian period, much of which he himself witnessed. The extant portions, however, written from the viewpoint of a disillusioned member of the Roman Senate, form the authoritative basis for any account of Tiberius, Claudius, Nero, and the year 69. The surviving ancient text that comes closest to covering the whole period is DIO CASSIUS' history of Rome to AD 222, in Greek. It is extant for the years 31 BC to AD 46 (and, for those from 46 to 193, there are epitomes and fragments, some of considerable length). These historical works are supplemented by imperial biographies: SUETONIUS' *Lives of the Caesars* (Julius Caesar to Domitian inclusive), PLUTARCH'S *Galba* and *Otho,* and the *Historia Augusta* (Hadrian and his successors). Suetonius is very informative and the *Historia Augusta,* a late compilation of dubious authorship and varying value, is a main source for the 2nd century. A selective, but very good collection of source material for the period in English is provided by NAPHTALI LEWIS and MEYER REINHOLD (eds.), *Roman Civilization,* 2 vol. (1951–55). *(Modern works): The Cambridge Ancient History,* vol. 10–11 (1934–36), with serviceable bibliographies of earlier work, is still a most helpful study in English. The best one-volume general accounts, both of them recent and with first-class bibliographies, are ALBINO GARZETTI, *L'Impero da Tiberio agli Antonini* (1960), particularly good for political and social developments; and PAUL PETIT, *La Paix romaine* (1967), particularly good on military and economic aspects. For the foundation of the principate, see D.C. EARL, *The Age of Augustus* (1968), a very realistic account; and for the development of the principate, MASON HAMMOND, *The Antonine Monarchy* (1959), careful, but somewhat optimistic. For imperial biographies, see under the individual emperors. Two recent ones, ANTHONY BIRLEY, *Marcus Aurelius* (1966); and B.H. WARMINGTON, *Nero* (1969), are very informative, the latter on the first century and the former on the second. For the economy: TENNEY FRANK (ed.), *An Economic Survey of Ancient Rome,* 6 vol. (1933–40)—vol. 2–5 are fundamental for the study of this period; M.I. ROSTOVTZEFF, *The Social and Economic History of the Roman Empire,* 2nd ed. rev. by P.M. FRASER, 2 vol. (1957), brilliant, but often subjective. For social life: JEAN GAGE, *Les Classes sociales dans l'Empire romain* (1964), comprehensive. For the provinces: THEODOR MOMMSEN, *Römische Geschichte,* vol. 5 (1886; Eng. trans., *The Provinces of the Roman Empire,* 2 vol., 1909), a classic; its European sections have now been edited by T.R.S. BROUGHTON, 1968; G.H. STEVENSON, *Roman Provincial Administration till the Age of the Antonines* (1939), sound. For the provincial communities: F.F. ABBOTT and A.C. JOHNSON, *Municipal Administration in the Roman Enzpire* (1926, reprinted 1968), a standard work; A.H.M. JONES, *The Cities of the Eastern Roman Provinces,* 2nd ed. rev. (1971), essential for the Greek-speaking East. For the armed services: H.M.D. PARKER, *The Roman Legions,* ed. by G.R. WATSON (1958); and C.G. STARR, *The Roman Imperial Navy,* 31 *B.C.–A.D.* 324, 2nd ed. (1960), both standard works. For general culture: JEAN BEAUJEU, *La Religion romaine à l'apogée de l'Empire* (1955), a very useful survey; J.A. CROOK, *Law and Life of Rome* (1967), sound and readable; W.L. MACDONALD, *The Architecture of the Roman Empire* (1965), excellent; RONALD SYME, *Tacitus,* 2 vol. (1958), a mine of information on many aspects of the period; J.M.C. TOYNBEE, *The Art of the Romans* (1965), comprehensive and sensible.

The Later Roman Empire—AD 193 *to c.* 500 *in the West, to c.* 395 *in the East:* The general works treating all aspects of the period are a little old: *The Cambridge Ancient History,* vol. 12, *The Imperial Crises and Recovery, A.D. 193–*324 (1939); and *The Cambridge Medieval History,* vol. 1, *The Christian Roman Empire nnd the Foundation of the Teutonic Kingdoms* (1936). A very detailed (except with regard to events) and excellent work is A.H.M. JONES, *The Later Roman Empire, 284–602: A Social, Economic and Administrative Survey,* 3 vol. (1964). On the problems of civilization and the passage from the Roman to the barbarian worlds, see JOSEPH VOGT, *Der Niedergang Roms* (1965; Eng. trans., *The Decline of Rome: The Metamorphosis of Ancient Civilization,* 1967), a completely remarkable work in all respects. In the absence of recent works on the Severan dynasty, that of G.J. MURPHY, *The Reign of the Emperor L. Septimius Severus, front the Evidence of the Inscriptions* (1945), assembles the epigraphic sources. L. ROSS TAYLOR, *The Divinity of the Roman Emperor* (1931); and FRANZ CUMONT, *Les Religions orientales dans le paganisme romain,* 4th ed. (1929), are classic and reliable. See also the great literary histories of ALBIN LESKY, *Geschichte der griechischen Literatur,* 2nd ed. (1963; Eng. trans., *A History of Greek Literature,* 1966); and H.J. ROSE, *A Handbook of Latin Literature,* 2nd rev. ed. (1949). The best work on ancient "paideia" is that of H.I. MARROU, *Histoire de l'éducation dans l'antiquité,* 5th ed. (1960; Eng. trans., *A History of Educatiort in Antiquity,* 1956). Economic aspects are discussed in F.M. HEICHELHEIM, *An Ancient Economic History,* vol. 3 (1970); and above all by M.I. ROSTOVTZEFF, *The Social and Economic History of the Roman Empire,* 2nd ed. rev. by P.M. FRASER, 2 vol. (1957). On the transformations of society, C.W. KEYES, *The Rise of the Equities in the Third Century of the Roman Empire* (1915); and the most recent and complete work of JEAN GAGE, *Les Classes sociales dans l'Empire romain* (1964), are recommended. On municipal life, F.F. ABBOTT and A.C. JOHNSON, *Municipal Administration in the Roman Empire* (1926, reprinted 1968), includes an excellent text and a wide choice of documents. The religious problems created by Constantine's conversion and the birth of the Christian empire are treated in the classic works of ANDRAS ALFOLDI, *The Conversion of Constantine and Pagan Rome* (1948); and of A.H.M. JONES, *Constantirze and the Conversion of Europe* (1949). Questions of culture and mind of the 4th century are dealt with in the essays of several scholars and brought together by ARNALDO MOMIGLIANO in *The Conflict Between Paganism and Christianity in the Fourth Century* (1963). A lively and well-documented work is SAMUEL DILL, *Roman Society in the Last Century of the Western Empire,* 2nd ed. (1958): and for the history of ideas, see SANTO MAZZARINO, *La fine del mondo antico* (1959; Eng. trans., *The End of the Ancient World,* 1966). The very important work of VOGT (cited above) gives an excellent bibliography (pp. 319–328) on all the problems treated in this section.

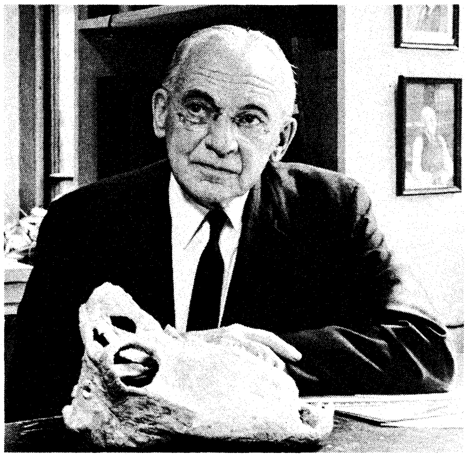
Romer, Alfred Sherwood

Alfred S. Romer's concepts of the nature and order of the evolutionary history of vertebrate animals have strongly affected the outlook of all evolutionary biologists since the early 1930s. This U.S. vertebrate paleontologist and comparative anatomist is most widely known for his books *Vertebrate Paleontology, The Vertebrate Body,* and *Marl and the Vertebrates.* The explicit use of comparative anatomy and embryology in studies of fossil vertebrates underlies his major contributions to biology.

Romer was born in White Plains, New York, on December 28, 1894. His early life and schooling gave no indication of the direction his career was to follow. His father, a newspaper man, moved frequently, and young Alfred's early days were unsettled. In 1909, when he returned to White Plains to live with his father's mother, a more



Romer, *1965.*
By *courtesy of the Harvard University News Service*

stable phase of his youth began, though the family was poor. A rather timid boy, he found adjustment to the new environment difficult. In high school, however, he found a place among his peers. A trait that was to dominate his life emerged—an urge to improve things by becoming involved.

In 1913, after a year of doing odd jobs to earn money for college, Romer, entirely on his own and against family tradition, entered Amherst College. He financed his way in college with the help of a scholarship, various kinds of work, and loans from his college fraternity. History and German literature were his major subjects of study, but he liberally sampled courses in other disciplines. Early in his career, while in New York City, young Romer visited the American Museum of Natural History, and its dinosaur exhibits sparked his interest in fossils. After taking a course in evolution under Frederic B. Loomis to fulfill a science requirement, Romer knew what he wanted to do.

Graduation in 1917, during World War I, found him restless. He joined the American Field Service in France and in the autumn of that year enlisted in the United States Army. On his return to the United States in 1919, he entered graduate school at Columbia University to work under William K. Gregory. Romer completed the work for his Ph.D. in two years and produced a thesis that remains a classic in comparative myology, the study of musculature. With others who were students at Columbia at about this time, Romer was deeply influenced by Gregory and helped to spread his ideas, establishing a school of comparative anatomy, functional anatomy, and evolution that still prevails.

After two years as instructor of anatomy at Bellevue Hospital Medical College in New York, Romer became associate professor in the department of geology and paleontology at the University of Chicago. There he encountered fine collections of Late Paleozoic fossil fishes, amphibians, and reptiles, which set the course for much of his later fieldwork and scientific studies.

Early in his career at Chicago, Romer met and married Ruth Hibbard, who bore him three children and was his companion in fieldwork and travel. *Vertebrate Paleontology* appeared in 1933. In its three editions, this book shaped much of the thinking in the subject for several decades. After 11 years at Chicago, marred only by the problem of training biologically oriented graduate students in a geology department, Romer went to Harvard University as professor of biology in 1934.

His early propensity for leadership emerged when he became director of the biological laboratories in 1945 and of the Museum of Comparative Zoology in 1946. The museum flourished under his guidance.

Romer's scientific career prospered at Harvard with the publication of *Review of the Pelycosauria* (1940), *The Vertebrate Body* (1949), *The Osteology* of *the Reptiles* (1956), and numerous research papers. *The Vertebrate Body* is a comprehensive textbook of comparative anatomy, widely used in colleges and universities throughout the United States. The *Pelycosauria* and *Osteology* treat various aspects of reptilian evolution. Honours began to come to him—honorary degrees, memberships in foreign societies, and medals. Most important to him, however, was the less renowned Society of Vertebrate Paleontology, which he nurtured through its infancy, becoming its first president after it had become formally established in 1940. Later he initiated action that led to the establishment of the Vertebrate Morphology Section of the American Society of Zoologists. He accepted the presidency of the XIVth International Zoological Congress, which met in Washington, D.C., in 1963. He had long since been elected a member of the National Academy of Sciences of the United States. In 1929 and in 1956, he made trips to South Africa and Argentina to collect fossils. Despite the pace of his life—teaching, travel, administration, scientific study, and honours—Romer remained a relaxed, affable man, with a quiet wit and charm, always in demand as a lecturer. His rigorous dedication and depth of knowledge often emerged from light, colloquial presentations and an informal style.

Romer retired from Harvard in 1965 and, with characteristic energy, used his leisure for world travel, fossil collecting, lecturing, attending conferences, and visiting museunis. Scientific papers continued to flow from his pen. His studies extended the understanding of the course of evolution of the lower vertebrates. His basically conservative approach focussed attention upon the significance of form and function in relation to environment as the key to evolutionary progress. Documentation of the slowly changing flow through time, as envisaged by Darwin, emerges clearly from Romer's studies of the evolution of extinct fishes, amphibians, and reptiles.

Romer devoted a lifetime of research to the evolution of the vertebrates, with evidence drawn from comparative anatomy, embryology, and particularly paleontology. For many years he collected fossils of fishes, amphibians, and reptiles from geological deposits in Texas dating to the Permian Age. Close attention to anatomical adaptations as responses to environmental change characterized his method. He traced fundamental changes in structure and function that have occurred during the evolution of fishes to primitive land vertebrates and during the subsequent radiation of these vertebrates to modern amphibians, reptiles, and mammals. He died in Cambridge, Massachusetts, during the night of November 5, 1973.

(E.C.O.)

Rommel, Erwin

A German general of exceptional gifts of initiative and improvisation, Erwin Rommel became the most popular general at home and gained the open respect of his enemies with his spectacular victories as commander of the Afrika Corps in World War II. When, in 1944, his role in the unsuccessful conspiracy to remove Hitler as Germany's rulei was discovered, he was forced to kill himself.

Erwin Johannes Eugen Rommel was born on November 15, 1891, in Heidenheim in the kingdom of Württemberg. His father was a teacher, as his grandfather had been, and his mother was the daughter of a senior official. A career as an army officer began to be fashionable, even among middle class south Germans, after the establishment of the German Empire in 1871; and thus, notwithstanding the absence of a military tradition in his family, Erwin Rommel in 1910 joined the 124th Wiirttemberg Infantry Regiment as an officer cadet.

Early career

In World War I Rommel fought as a lieutenant in France, Romania, and Italy. His deep understanding of his men, his unusual courage, and his natural gift of leadership quite early showed promise of a great career. In the Prussian-German army, a career on the general staff was the normal avenue for advancement, yet Rommel declined to take that road. Both in the Reichswehr of the Weimar Republic and in Hitler's Wehrmacht, he remained in the infantry as a front line officer. Like many great generals, he possessed, possibly gotten from his father, a pronounced talent for teaching and was accord-

Rornrnei, 1941.
Ullstein Bilderdienst

ingly appointed to posts at various military academies. The fruit of his battle experiences in World War I, combined with his ideas on training young soldiers in military thinking, formed the main components of his military textbook *Infanterie greift an* ("Infantry Attacks"), originally published in 1937, which received high initial esteem.

In 1938, after Austria's annexation by Germany, Colonel Rommel was appointed commandant of the officers' school in Wiener Neustadt, near Vienna. At the beginning of World War II he was appointed commander of the troops guarding the Fuhrer's headquarters—not a very satisfying post for an enthusiastic front line soldier. Rommel's chance to prove himself came in February 1940 when he assumed command of the 7th Panzer Division. He had never commanded armoured units before, yet he quickly grasped the tremendous possibilities of mechanized and armoured troops in an offensive role. His raid on the channel coast provided the first proof of his boldness and initiative.

Commander of Afrika Corps

A year later, in February 1941, Rommel was appointed commander of the German troops dispatched to aid the all but defeated Italian army in Libya. The deserts of North Africa became the scene of his greatest successes—and of his defeat at the hands of a vastly superior enemy. In the North African theatre of war the "Desert Fox," as he came to be called by both friend and foe because of his audacious surprise attacks, acquired a formidable reputation, and soon Hitler promoted him to field marshal. He found it difficult, however, to get along with his Italian allies; basically, the British were more to his liking. He was an avid reader of the book on warfare written by Sir Archibald Wavell, the first Allied commander in chief of the Middle East, and Rommel's opponent in North Africa.

Rommel had difficulties not only with his Italian allies but with his own supreme command as well. North Africa was, in Hitler's view. onlv a sideshow. Nonetheless, despite the increasing difficulties of supply and Rommel's request to withdraw his exhausted troops, in the summer of 1942, Hitler ordered an attack on Cairo and the Suez Canal. Rommel and his German-Italian army were stopped by the British at el-Alamein (al-ʿAlamayn, Egypt) 60 miles (96 kilometres) from Alexandria. At that time Rommel won astounding popularity in the Arab world, where he was regarded as a "liberator" from British rule. At home, the propaganda ministry portrayed him as the invincible "people's marshal."

But the offensive against Egypt had overtaxed his resources. At the end of October 1942, he was defeated in the second Battle of el-Alamein and had to withdraw to the German bridgehead in Tunis. In March 1943 Hitler ordered him home. In 1944 Rommel was entrusted with the defense of the French channel coast against a possible Allied invasion. The master of the war of movement then developed an unusual inventiveness in the erection of coastal defense works. Nevertheless, his recommendation to prevent the enemy by all possible means from establishing large bridgeheads, his insistence that strong forces should be kept in reserve immediately behind the coastal defense line for counterattacks, and his prophecy that, unless the enemy could be successfully driven back into the sea, the fate of the invasion battle would be decided on the first day all fell on deaf ears.

Conspiracy against Hitler

As early as the fall of 1943, Rommel, a purely professional soldier whose judgment was not swayed by political predilections, had been convinced that the war could no longer be won and that Hitler was neither prepared to face that fact nor to draw the inevitable conclusion—the necessity of making peace with the Western powers. In the spring of 1944 some of Rommel's friends who had joined the clandestine opposition to Hitler approached Rommel and suggested to him that it was his duty to take over as head of state after Hitler had been overthrown. Rommel did not reject the suggestion; but the men who wanted to extricate Germany from the war never revealed to Rommel that they planned to assassinate Hitler. They knew that Rommel did not accept the idea of murder for political ends; he had invariably disregarded any execution orders given by Hitler. When the invasion began, Rommel tried on several occasions to point out to Hitler that the war was lost and that he should come to terms with the Western powers. On July 17, 1944, at the height of the invasion battle, Rommel's car was attacked by British fighter-bombers and forced off the road. It somersaulted and Rommel was hospitalized with serious head injuries. In August he had recovered sufficiently to be able to return to his home to convalesce. In the meantime, after the failure of the attempt on Hitler's life on July 20, 1944, Rommel's contacts with the conspirators had come to light. Hitler did not want the "people's marshal" to appear before the court as his enemy and thence be taken to the gallows. He sent two generals to Rommel to offer him poison with the assurance that his name and that of his family would remain unsullied if he avoided a trial. On October 14, 1944, Rommel took poison, thus ending his life. He was later buried with full military honours.

BIBLIOGRAPHY. ERWIN ROMMEL, *Infanterie greift an* (1937), is a collection of tactical studies and notes based upon his own experiences in World War I. After World War II his widow and one of his former chiefs of staff published his personal papers and notes: LUCIE-MARIA ROMMEL and FRITZ BAYERLEIN, *Krieg ohne Hass* (1950; Eng. trans., *The Rommel Papers,* 1953). RONALD LEWIN, *Rommel As Military Commander* (1968), is the best study to date; DESMOND YOUNG, *Rommel* (1950), is of great value as the first biography by a British author. FRIEDRICHRUGE, *Rommel und die Invasion: Erinnerungen* (1959); HANS SPEIDEL, *Invasion 1944: Ein Beitrag zu Rommels und des Reiches Schicksal* (1949; Eng. trans., *Invasion 1944: Rommel and the Normandy Campaign,* 1950; British title, *We Defended Normandy,* 1951); and SIEGFRIED WESTPHAL, *Heer in Fesseln: Aus den Papieren des Stabschefs von Rommel, Kesselring und Rundstedt* (1952), are of great value as memoirs.

(W.Go.)

Ronsard, Pierre de

The most eminent and prolific poet of the French Renaissance, Pierre de Ronsard produced verse that epitomized his time, reflecting the diverse topics of interest, tastes, and moods of Renaissance France. To the 20th-century reader he is perhaps most appealing when celebrating his native countryside, reflecting on the brevity of youth and beauty, or voicing the various states of unrequited love, though he is also effective when identifying himself imaginatively with some classical mythological character or situation and when expressing sentiments of fiery patriotism or deep humanity. He was a master of lyric themes and forms, and his poetry remains attractive to composers; some of his odes, such as "Mignonne, allons voir si la rose . . . ," were set to music half a dozen times in the 16th century alone and have become as familiar to the general public in France as folksongs.

He was born on September 11, 1524, at his father's manor house, La Possonnière, near the village of Couture

Ronsard, portrait after an engraving by L. Gaultier, 1557.

in the *département* of Loir-et-Cher. As a younger son of a noble family of the county of Vendôme, he entered the service of the royal family as a page in 1536 and accompanied Princess Madeleine to Edinburgh after her marriage to James V of Scotland. On his return to France two years later, a court appointment or a military or diplomatic career seemed to be open before him, and in 1540 he accompanied the diplomat Lazare de Baïf on a mission to an international conference at Haguenau in Alsace. An illness contracted on this expedition left him partially deaf, however, and his ambitions were deflected to scholarship and literature. For someone in his position, the church provided the only future, and he accordingly took minor orders, which entitled him to hold ecclesiastical benefices, though he was never an ordained priest. A period of enthusiastic study of the classics followed his convalescence; during this time he learned Greek from the brilliant tutor Jean Dorat, read all the Greek and Latin poetry then known, and gained some familiarity with Italian poetry. With a group of fellow students he formed a literary school that came to be called the Pléiade, in emulation of the seven ancient Greek poets of Alexandria: its aim was to produce French poetry that would stand comparison with the verse of classical antiquity.

Poetry of the Pléiade

The title of his first collection of poems, *Odes* (4 books, 1550), emphasizes that he was attempting a French counterpart to the odes of the ancient Roman poet Horace. In *Les Amours* (1552) he also proved his skill as an exponent of the Italian *canzoniere*, animating the compliments to his beloved, entreaties, and lamentations traditional to this poetic form by the vehemence of his manner and the wealth of his imagery. Always responsive to new literary influences, he found fresh inspiration in the recently discovered verse of the Greek poet Anacreon (6th century BC). The more playful touch encouraged by this model is to be felt in the *Bocage* ("grove") of poetry of 1554 and in the *Meslanges* ("miscellany") of that year, which contain some of his most exquisite nature poems, and in the *Continuation des amours* and *Nouvelles Continuations*, addressed to a country girl, Marie. In 1555, he began to write a series of long poems, such as the "Hymne du Ciel" ("Hymn of the Sky"), celebrating natural phenomena, abstract ideas like death or justice, or gods and heroes of antiquity; these poems, published as *Hymnes* (following the 3rd-century-BC Greek poet Callimachus, who had inspired them), contain passages of stirring eloquence and vivid description, though few of them can hold the modern reader's interest from beginning to end. Reminiscences of his boyhood inspired other poems, such as his "Complainte contre fortune," published in the second book of the *Meslanges* (1559), which contains a haunting description of his solitary wanderings as a child in the woods and the discovery of his poetic vocation. This poem is also notable for a celebrated denunciation of the colonization of the New World, whose people he imagined to be noble savages living in an unspoiled state of nature comparable to his idealized memories of childhood.

Court poetry

The outbreak of the religious wars found him committed to an extreme royalist and Catholic position, and he drew upon himself the hostility of the Protestants. To this period belong the *Discours des misères de ce temps* (1562) and other *Discours*, attacking his opponents, whom he dismissed as traitors and hypocrites, with ever-increasing bitterness. Yet he also wrote much court poetry during this period, encouraged by the young king Charles IX, a sincere admirer; and on the King's marriage to Elizabeth of Austria in 1571, he was commissioned to compose verses and plan the scheme of decorations for the state entry through the city of Paris. If he was by now in some sense the poet laureate of France, he made slow progress with *La Franciade*, which he intended to be the national epic; this somewhat half-hearted imitation of Virgil's great Latin epic, the *Aeneid*, was abandoned after the death of Charles IX, the four completed books being published in 1572. After the accession of Henry III, who did not favour Ronsard so much, he lived in semiretirement, though his creativity was undiminished. The collected edition of his works published in 1578 included some remarkable new works, among them the so-called "Elegy Against the Woodcutters of Gâtine" ("contre les bucherons de la forêt de Gastine"), lamenting the destruction of the woods near his old home; a sequel to *Les Amours de Marie;* and the *Sonnets pour Hélène*. In the latter, which is now perhaps the most famous of his collections, the veteran poet demonstrates his power to revivify the stylized patterns of courtly love poetry. Even in his last illness, Ronsard still wrote verse, sophisticated in form and rich with classical allusions. His posthumous collection, *Derniers Vers*, poignantly expresses the anguish of the incurable invalid in nights spent alone in pain, longing for sleep, watching for the dawn, and praying for death. He died December 27, 1585, at the priory of Saint-Cosme, near Tours.

Ronsard perfected the 12-syllable or alexandrine line of French verse, hitherto despised as too long and pedestrian, and established it as the classic medium for scathing satire, elegiac tenderness, and tragic passion. He was a man of powerful intellect and wide learning, and in his lifetime he was recognized as the prince of poets, as well as a figure of national significance. This prominence, scarcely paralleled until Victor Hugo in the 19th century, faded into relative neglect in the 17th and 18th centuries; but his reputation was reinstated by the Romantic critic Sainte-Beuve, and it has remained secure for the last 100 years.

MAJOR WORKS

Les Quatre Premiers Livres des Odes, 4 books (1550), also including the first *Le Bocage; Les Amours* (1552), with 5th book of *Odes; Livret de Folastries* (1553); *Les Amours*, 2nd ed. (1553), with 39 new sonnets; *Le Bocage* (1554); *Les Meslanges* (1554, dated 1555); *Continuation des amours* (1555); *Les Hymnes*, 2 books, (1555–56); *Nouvelle Continuation des amours* (1556); *Les Oeuvres de P. de Ronsard*, 4 vol. (1560), first collected works; subsequent editions added to by Ronsard appeared in 1567, 1571, 1572–73, 1578, and 1584; *Institution pour l'adolescence du roy trhs Chrestien Charles neufviesme de ce nom* (1562); *Discours des mishres de ce temps à la Royne nzhre du Roy* (1562); *Remonstrance au peuple de France* (1562); *Résponce . . . aux injures et calomnies* (1563); *Élégies, mascarades et hergerie* (1565); *Les Quatre Premiers Livres de La Franciade*, 4 books (1572); *Les Oeuvres de P. de Ronsard*, 5th ed. (1578), including *Les Amours diverses*, *Les Amours de Marie: seconde partie, sur la mort de Maria*, and the *Sonnets pour Hélène; Les Derniers Vers de P. de Ronsard* (1586).

There are translations of the *Sonnets pour Hélène* by Humbert Wolfe (1934) and W. Van Wyck (1932). See also *Songs and Sonnets*, trans. by Curtis Hidden Page (1903); and *Salute to Ronsard*, ,selected poems trans. by E.J. Dennis (1960).

BIBLIOGRAPHY. The major collected edition of Ronsard's works to be published in this century is the *Oeuvres complètes*, critical edition with introduction and commentary by PAUL LAUMONIER for the *Société des Textes Français Modernes*, 18 vol. (1914–70); the volumes after Laumonier's death were completed by R. LEBEGUE and ISIDORE SILVER. This gives the original text of each poem (with the variants, due to subsequent revision by Ronsard, in footnotes) and in the order originally published. It is indispensable for the study of Ronsard's development as a poet. The edition by GUSTAVE COHEN, in the "Pléiade" series, 2 vol. (1938), offers a reliable text (following the edition of 1584) in a compact form. HUMBERT WOLFE, *Pierre de Ronsard: Sonnets pour Hélène, with English Renderings* (1934), is a complete translation, in sonnet form; there are some misunderstandings, but the renderings are often felicitous. The *Lyrics of Pierre de Ronsard Chosen and Translated by Charles Graves* (1967), presents in a pleasant and scholarly form a selection of the odes and sonnets, of the Elegy to Mary, Queen of Scots, and of the Epitaph upon himself. CLAUDE BINET, *Discours de la vie de Pierre Ronsard* (1586), is the basis of all study of Ronsard's biography; it is best read in the critical edition by PAUL LAUMONIER (1910). PAUL LAUMONIER, *Ronsard, poète lyrique*, 2nd ed. (1923), is a complete survey of the themes and forms used in Ronsard's lyric poetry; PIERRE DE NOLHAC, *Ronsard et l'humanisme* (1921), is a full examination of Ronsard's relations with classical scholars. MORRIS G. BISHOP, *Ronsard, Prince of Poets* (1940), is a useful biography without being definitive; D.B. WYNDHAM LEWIS, *Ronsard* (1944), should be used with caution, the approach being very personal, the quotations sometimes inaccurate, and the translations of them often incorrect. Recent studies, in English, of important aspects of Ronsard's poetry include: D.B. WILSON, *Ronsard, Poet of Nature* (1961); DONALD STONE, JR., *Ronsard's Sonnet-Cycles: A Study in Tone and Vision* (1966); ELIZABETH ARMSTRONG, *Ronsard and the Age of Gold* (1968); and ISIDORE SILVER, *The Intellectual Evolution of Ronsard*, vol. 1 (1969). A complete bibliography of Ronsard up to about 1950 may be found in A. CIORANESCU, *Bibliographie de la littérature française du seizième siècle*, pp. 609–625 (1959).

Roosevelt, Franklin D.

Franklin Delano Roosevelt, the 32nd president of the United States, held office from 1933 to 1945 during the New Deal era and World War II. The modern role of the United States government, in both its domestic and foreign policies, owes much to the changes that Roosevelt helped bring about. To counter the Great Depression of the 1930s he enlisted the powers of the federal government to promote the economic welfare of the U.S. people. He was a leader in the Allied struggle against the Axis powers in World War II, preparing the way for the United States to assume a continuing role in world security. He was the only president to be re-elected three times.

UPI Compix

Franklin D. Roosevelt, 1937.

EARLY LIFE AND POLITICAL GROWTH

Roosevelt was born at Hyde Park, New York, on January 30, 1882, the only son of James and Sara Delano Roosevelt. The Roosevelts lived in unostentatious and genteel luxury, dividing their time between the Hudson River Valley and European resorts. They often took young Franklin to Europe; he was taught privately at home and was reared to be a gentleman, responsible toward those less fortunate. At 14, Roosevelt, a rather shy youth, entered Groton School (Groton, Massachusetts), modelled after the great public schools of England, where wealthy young men were trained to exercise Christian stewardship through public service.

Schooling and training

After he entered Harvard in 1900, Franklin Roosevelt threw himself into undergraduate activities. His strenuous extracurricular and social life left him relatively little time for his studies, in which his record was undistinguished. He was, however, influenced by his economics professors, who modified traditional laissez-faire views with advocacy of government regulation; but, even more, Roosevelt fell under the spell of the progressive president, his glamorous distant relative Theodore Roosevelt, a fifth cousin.

During his final year at Harvard, Franklin became engaged to Theodore Roosevelt's niece, Eleanor Roosevelt, who was then active in settlement work in New York City; they were married on March 17, 1905. Eleanor helped open young Roosevelt's eyes to the deplorable living conditions of the underprivileged in the slums.

New York social life interested Roosevelt more than did his studies at Columbia University School of Law. As soon as he passed the New York bar examination, he discontinued his schooling. This indifference to the legal profession carried over into Roosevelt's years as a clerk with the distinguished Wall Street firm of Carter, Ledyard & Milburn, defense counsel in several spectacular antitrust cases.

Early political activities. His admiration for his cousin Theodore, who continued to urge young men of substance to enter public service, led Roosevelt toward politics. His opportunity came in 1910 when the Democratic leaders of Dutchess County, New York, persuaded him to undertake an apparently futile campaign for the state senate. Roosevelt, whose branch of the family had always been Democratic, hesitated only long enough to make sure his distinguished Republican relative would not speak against him.

State senator. He campaigned so strenuously that, with the aid of a Republican schism and his famous name, he won the election. Roosevelt, not quite 29, quickly won statewide and even some national attention by leading a small group of Democratic insurgents who refused to vote for the nominee of Tammany Hall, the New York City organization. For three months Roosevelt helped hold the insurgents firm, until Tammany switched to another candidate.

First political campaign

Roosevelt became the foremost champion in the New York Senate of the upstate farmers, and in the process he converted to the full program of progressive reform. From the New York City legislators, whom he had earlier scorned and now continued to fight, he learned much of the give-and-take of politics. Among them were James J. Walker, later mayor of New York City; Robert Ferdinand Wagner, who became a leading U.S. senator; and Alfred E. Smith, later governor of New York. Roosevelt gradually abandoned his patrician airs and attitude of superiority.

Before the end of 1911, Roosevelt supported the presidential boom for Gov. Woodrow Wilson of New Jersey, the leading Democratic progressive. An attack of typhoid fever kept Roosevelt from participating in the 1912 campaign, but, even without making a single public appearance, he was re-elected to the state senate. This was because of publicity by an Albany newspaperman, Louis McHenry Howe, who saw in the tall, handsome young Roosevelt a promising politician. Howe served Roosevelt for the rest of his life with a jealous loyalty.

Assistant secretary of the navy. For his work on behalf of Wilson, Roosevelt was rewarded in March 1913 with an appointment as assistant secretary of the navy under Josephus Daniels. Roosevelt loved the sea and naval traditions, and he knew more about them than did his superior, with whom he was frequently impatient. Roosevelt tried with mixed success to bring reforms to the navy yards, which were under his jurisdiction, meanwhile learning to negotiate with labour unions among the civilian employees. After war broke out in Europe, Roosevelt became a vehement advocate of preparedness; following U.S. entrance, he built a reputation as an effective administrator. In the summer of 1918 he made an extended tour of naval bases and battlefields overseas. During much of his seven years as assistant secretary, he had been less than loyal to Daniels, but in the end he came to appreciate his superior's skill in dealing with Southern congressmen and his solid worth as an administrator.

Vice-presidential nomination

Paralytic attack. At the 1920 Democratic convention Roosevelt was nominated for vice president. He campaigned vigorously with the presidential nominee, James M. Cox, on behalf of U.S. entrance into the League of Nations. After a Republican landslide, Roosevelt became a vice president of the Fidelity & Deposit Company of Md., a bonding company, entered into numerous business schemes (some of a speculative nature), and remained active in Democratic politics. Suddenly, in August 1921, while on vacation at Campobello Island, New Brunswick, Roosevelt was severely stricken with poliomyelitis. He suffered intensely and for some time was almost completely paralyzed, but he soon began predicting (as he did for some years) that he would quickly regain the use of his legs. His mother wished him to retire to Hyde Park, but his wife and his secretary, Louis Howe, felt it essential to his morale that he remain active in his career and in politics. Because Roosevelt could not himself go to political gatherings, his wife attended for him, acting as his eyes and ears (a service she frequently performed for him during the rest of his life). Under the tutelage of Howe, she overcame her shyness and became an effective political worker and speaker. Because he could not run for office for the time being, Roosevelt was able to function effectively as a sort of premature "elder statesman," trying to promote unity between the urban and rural wings of the Democratic Party. Himself a rural Democrat, he nominated Gov. Al Smith of New York, the favourite of the city faction, at the 1924 and 1928 Democratic conventions.

Smith urged Roosevelt to run for governor of New York in 1928 to strengthen the ticket. Roosevelt was reluctant; he still could not walk without braces and assistance. In the years since 1921 he had worked incessantly to try to regain the use of his legs—for several winters he swam in warm Florida waters and, beginning in 1924, in the mineralized water at Warm Springs, Georgia. Wishing to share with others the beneficent effect of the warm water and a systematic program of therapy, Roosevelt in 1927 established the Warm Springs Foundation, a nonprofit institution for the care of polio victims. He wished to develop Warm Springs further and to continue treatments in the hope of regaining full use of his legs.

Governor of New York. Nevertheless, despite these concerns and his feeling that 1928 was not a propitious year to run on the Democratic ticket, Roosevelt succumbed to strong persuasion and accepted the nomination. When he began campaigning by automobile, he demonstrated that he had retained his youthful buoyance and vitality; he also showed that he had matured into a more serious and human person. Opponents raised the question of his health, but his vigorous campaigning effectively disposed of the issue. Smith was defeated in Herbert Hoover's landslide, and he failed to carry New York state; but Roosevelt won by 25,000 votes.

Program as governor

Succeeding Smith as governor, Roosevelt decided he must establish his own type of administration. He did not keep Smith's closest adviser nor did he depend upon Smith for advice. Smith, already stung by his defeat for the presidency, was hurt and alienated. Whereas Smith had built his reputation on administrative reform, Roosevelt concentrated upon a program to give tax relief to farmers and to provide cheaper public utilities for consumers. The appeal of this program in upstate New York, coupled with the effects of the deepening Depression, led to Roosevelt's re-election in 1930 by the overwhelming plurality of 725,000 votes.

During his first term as governor, Roosevelt's policies, except on the power issue, were scarcely further to the left than those of President Hoover in Washington, D.C. But during Roosevelt's second term, as the Depression became more catastrophic in its effects, he acted to mobilize the machinery of the state government to aid the economy. In the fall of 1931 he obtained legislation establishing the Temporary Emergency Relief Administration, the first of the state relief agencies. Throughout his four years, he was successful in most of his bouts with the Republican legislature, sharpening skills that would prove vital in the future. And, increasingly, beginning with some slight speculation in November 1928, he was being talked of as the most likely Democratic presidential nominee in 1932. After his spectacular victory in 1930, he was so conspicuous a target for the Republicans and for rival Democratic aspirants that he had no choice but to begin immediately and quietly to obtain support for the convention. Because it then took a two-thirds vote in the Democratic convention to nominate, a leading contender could be stopped with relative ease. It soon became apparent that Roosevelt's strongest opposition would come from urban and conservative Eastern Democrats still loyal to Smith; his strongest support was in the South and the West.

Progressives and intellectuals found Roosevelt's overall program attractive, but many feared that he was weak because he sidestepped Republican challenges to oust corrupt Democratic officials in New York City. The opposition became stronger when John Nance Garner of Texas, speaker of the House of Representatives, won the California primary.

PRESIDENCY

At the 1932 convention Roosevelt had an early majority of the delegates but seemed blocked by a combination of the Smith and Garner forces. On the third ballot, Garner allowed his delegates to be thrown to Roosevelt; in return, Garner was nominated for the vice presidency.

Election to the presidency

First term. In the campaign of 1932 the Depression was the only issue of consequence. Roosevelt, displaying smiling confidence, campaigned throughout the country, outlining in general terms a program for recovery and reform that came to be known as the New Deal. In a series of addresses carefully prepared by a team of speech writers, popularly called the brain trust, he promised aid to farmers, public development of electric power, a balanced budget, and government policing of irresponsible economic power. He declared in his most notable speech in San Francisco: "Private economic power is . . . a public trust as well." His program appealed to millions who were nominally Republicans, especially Western progressives. Roosevelt received 22,822,000 popular votes in the election to Hoover's 15,762,000; the electoral vote was 472 to 59. The Democrats also won substantial majorities in both houses of Congress.

Inauguration as president. Roosevelt took office on March 4, 1933. Following the election, President Hoover had sought Roosevelt's cooperation in stemming the deepening economic crisis that culminated in the closing of banks in several states during February 1933. But Roosevelt refused either to accept responsibility without the accompanying power or to subscribe to Hoover's proposals for reassuring business; Hoover himself granted that his proposals would mean "the abandonment of 90 per cent of the so-called new deal."

When Roosevelt took office, most of the nation's banks were closed, industrial production was down to 56 percent of the 1929 level, 13,000,000 or more persons were unemployed, and farmers were in desperate straits. Even the congressional leaders were so shaken that for the time being they were ready to follow Roosevelt's recommendations.

In his inaugural address Roosevelt promised prompt, decisive action and somehow conveyed to the nation some of his own unshakable self-confidence. "This great Nation will endure as it has endured, will revive and will prosper," he asserted, ". . . the only thing we have to fear is fear itself." For the moment, people of all political views were Roosevelt's allies, and he acted swiftly to obtain enactment of the most sweeping peacetime legislative program in U.S. history.

The Hundred Days. Through a broad array of measures, Roosevelt first sought quick recovery and then reform of the malfunctions in the economic system that he thought had caused the collapse. He tried to aid each of the main interest groups in the U.S. economy and, at a time when the Democrats were the minority politi-

Attempts to maintain a consensus

cal party, to hold the backing of many who were previously Republicans. His choice of Cabinet members indicated his efforts to maintain a consensus; it was geographically and politically balanced, containing both liberal and conservative Democrats, three Republicans, and, for the first time, a woman--Secretary of Labor Frances Perkins.

He also directed his legislative program toward a broad constituency. The prelude was the enactment of several conservative measures, to inspire confidence among businessmen and bankers. First Roosevelt ended depositors' runs on banks by closing all banks until Congress, meeting in special session on March 9, could pass a cautious measure allowing those in a sound condition to reopen (Roosevelt also strongly favoured banking reform, but it came later). In March, Roosevelt redeemed one of his most important campaign pledges by introducing a program of drastic government economy. He firmly believed in economy and never became a convert to the Keynesian views so often attributed to him. The emergency banking and economy acts brought him the enthusiastic support of an overwhelming proportion of the electorate but, he pointed out at the time, could do little to bring real recovery.

Roosevelt was already preparing, and he soon sent to Congress, a series of messages and draft bills proposing the program that comprised the early New Deal. Roosevelt first obtained from Congress federal funds for the relief of human suffering. Congress established the Federal Emergency Relief Administration (FERA), which granted funds to state relief agencies for direct relief. It also established a Civilian Conservation Corps (CCC), which at its peak employed 500,000 young men in reforestation and flood-control work; it was a favourite project of Roosevelt's and remained popular through the New Deal. Mortgage relief aided other millions of persons, both farmers and homeowners. The key loan agency of the New Deal was the previously established Reconstruction Finance Corporation (RFC), the powers of which were broadened so that it could make loans to small enterprises as well as to large. Although at the time Roosevelt did not envisage public spending as the primary role of these relief agencies, the agencies poured so much money into the economy that within several years they were stimulating recovery.

Recovery measures. The two key recovery measures of the New Deal were acts to restore farm prosperity and to stimulate business enterprise. The first act, in 1933, established the Agricultural Adjustment Administration (AAA), the objective of which was to raise farm prices and increase the proportion of the national income going to farmers. The principal means was through subsidies given to growers of seven basic commodities in return for their willingness to reduce production. The subsidies were to be paid from a processing tax on the commodities. Roosevelt accepted this scheme as a temporary expedient, which Congress would enact because a majority of farm organization leaders favoured it. He also hoped to raise farm prices through mild inflation. Roosevelt envisaged a program, following farm recovery, of extensive rural planning—moving farmers from submarginal to better lands and luring some of the unemployed from metropolises to rural and village life. In 1935 Roosevelt obtained the Resettlement Administration, which gave some aid to smaller, poorer farmers. When the Supreme Court invalidated the processing tax in 1936, he switched the AAA program to one of soil conservation. Nevertheless, throughout the New Deal, farm leaders and Congress succeeded in maintaining an agricultural program the major emphasis of which was to raise farm prices. Thanks to this legislation and several years of drought, production fell, and farm income gradually improved. But not until 1941 did it reach even the inadequate level of 1929.

National Industrial Recovery Act

The demand of businessmen for government stabilization and of labour for a shorter workweek led Roosevelt to recommend to Congress the National Industrial Recovery Act (NIRA) of 1933. It was a two-pronged program. On one side was a $3,300,000,000 appropriation for public works. Had this money been poured into the economy rapidly, it would probably have done much to bring recovery, but Roosevelt wanted to be sure it would be spent soundly on self-liquidating public works, through the Public Works Administration (PWA). Because careful planning took time, the PWA did not become an important factor until late in the New Deal. On the other side of the NIRA was a National Recovery Administration (NRA), to administer codes of fair practice within given industries. At first under a "blanket code," then under specific codes negotiated by representatives of each industry and labour, minimum wages, maximum hours, and fair trade practices were established within each industry. The codes were designed to stabilize production, raise prices, and protect labour and consumers. Consumers received scant protection, but labour received guarantees on wages and hours and also the right to bargain collectively. During the summer of 1933 there was a quick flurry of recovery as manufacturers produced goods in anticipation of sale at higher prices under the codes, the boom collapsed by fall because prices had risen faster than purchasing power.

By February 1934 the code making was over, but far too many—557 basic codes and 208 supplementary ones—had come into existence, containing innumerable provisions that were difficult to enforce. By 1935 the business community, which had demanded the NRA at the outset, was becoming disillusioned with it and blaming Roosevelt for its ineffectiveness. In May the Supieme Court, in the Schechter decision, invalidated the code system. Despite shortcomings, however, the NRA had aided several highly competitive industries, such as textiles, and brought important reforms that were re-enacted in other legislation: federal wages-and-hours regulation, collective-bargaining guarantees, and abolition of child labour in interstate commerce.

In the fall of 1933 Roosevelt had already turned to other expedients for bolstering the economy. He experimented with "managed currency," driving down the gold content of the dollar and tripling the price of silver through large purchases. These efforts brought only small price increases at home, but they improved the position of the United States in foreign trade by making dollars cheaper abroad. In January 1934 Roosevelt stabilized the gold content of the dollar at 59.06 percent of its earlier value. Managed currency created a significant precedent, even though it did little to bring recovery at the time.

Opposition from the right and left

Altogether, by the fall of 1934 Roosevelt's program was bringing a limited degree of recovery, but it was alienating conservatives, including many businessmen. They contended that much of the program was unconstitutional, that it created uncertainties for business that hampered recovery, and that the lowering of the gold content of the dollar had deprived holders of government obligations of their just return. At the same time, many of the underprivileged who were still in serious difficulties felt that the New Deal had not gone far enough. They were ready to listen to demagogic leaders offering still more. In the 1934 mid-term election they voted overwhelmingly for Democratic candidates for Congress; but there was a danger that in the 1936 presidential election they might vote for a third-party candidate to the left of Roosevelt.

Reform measures. To meet the threat to his political coalition from the left, Roosevelt emphasized reform in his annual message to Congress in January 1935. This was less a shift from a first to a second New Deal than it was a rush to enact reform measures that Roosevelt had long been planning. In 1933 he had obtained the Tennessee Valley Authority (TVA), to provide flood control, cheap hydroelectric power, and regional planning for an impoverished region. At his recommendation also, Congress had enacted two laws to protect investors: the Truth-in-Securities Act of 1933 and an act establishing the regulatory Securities and Exchange Commission (SEC) in 1934.

Additional legislation in 1935 did much to undermine the appeal of demagogues to the needy, especially the Social Security Act, which included unemployment insurance and old-age insurance. For workers still unemployed, Congress created the Works Progress Administration (WPA), to provide relief that would stem the erosion of their skills and self-respect (between 1935 and 1941 the WPA employed an average of 2,100,000 workers, and by the end of 1935 it was already bringing a marked measure of recovery by pouring billions of dollars into the economy). For workers who were employed, the National Labor Relations Act (the Wagner Act), only belatedly accepted by Roosevelt, strengthened the government guarantees of collective bargaining and created a National Labor Relations Board (NLRB) to adjudicate labour disputes. The Public Utility Holding Company Act, also of 1935, regulated the control holding companies had over operating public utility companies. A new 1935 tax measure, labelled by its opponents the "soak-the-rich" tax, raised the levies on persons with large incomes and on big corporations and became a significant factor in redistributing U.S. income.

Second term. These measures effectively undercut the left-wing opposition to Roosevelt, but they further alienated conservatives. He ran for re-election in 1936 with the firm support of farmers, labourers, and the underprivileged; and the epithets that the extreme right hurled at him merely helped unify his following. The Republican nominee, Gov. Alfred Mossman Landon of Kansas, a moderate, could do little to stem the Roosevelt tide. Roosevelt received 27,752,000 popular votes to Landon's 16,680,000 and carried every state except Maine and Vermont.

Re-election in 1936

Supreme Court fight. The only hope of conservatives to thwart the New Deal was for the Supreme Court to invalidate its key measures. Following the Schechter decision, the court in 1936 ruled against the AAA processing taxes, and cases challenging the Social Security Act and the Wagner Act were also pending. Roosevelt, beginning his second term with a massive mandate, was determined to remove this threat. Believing that the measures were well within the scope of the Constitution and that the reasoning of the justices was old-fashioned and at fault, he proposed early in 1937 the reorganization of the court, including the appointment of as many as six new justices. The proposal, labelled by opponents as a court-packing scheme, touched off a vehement debate in which many of Roosevelt's previous supporters in and out of Congress expressed their opposition. Meanwhile, in the spring of 1937, the Supreme Court upheld both the Wagner Act and the Social Security Act. With the need for the court plan dissolving, its enemies managed by summer to bring about its defeat. This was a severe political blow for Roosevelt, even though the new decisions by the court opened the way for almost unlimited government regulation of the economy.

Growing opposition. Roosevelt's prestige dropped further in the summer of 1937, when much of the public blamed him for labour difficulties that grew out of organizing drives in the steel, automobile, and other mass-production industries. Operating under the protection of the Wagner Act, the unions engaged in strikes that often resulted in violence. Roosevelt himself preferred paternalistic government aid to all workers, such as the wages-and-hours guarantees of the Fair Labor Standards Act of 1938. But union membership jumped to about 9,500,000 by 1941, while most middle class people returned to the Republican Party.

A sharp economic recession in the fall of 1937 added to Roosevelt's troubles. There had been substantial recovery by 1937; but Roosevelt, wishing to balance the budget, had curtailed government spending drastically, sending the economy plummeting back toward 1932 levels. Businessmen blamed the New Deal spending policies; Roosevelt blamed the businessmen and inaugurated an anti-monopoly program. In October 1937 massive government spending began again, and by June 1938 the crisis was past.

From 1938 on, many of the conservative Southern Democrats heading key congressional committees openly opposed the New Deal. In 1938 Roosevelt tried unsuccessfully to defeat several of them in the primaries and was inveighed against as a dictator trying to conduct a "purge." Democrats won the November elections, but the Republicans gained 80 seats in the House and seven in the Senate, permitting a coalition of Republicans and conservative Democrats that could thwart the President.

Nevertheless, the second Roosevelt administration saw the passage of some notable reform legislation, extending and improving earlier legislation and moving into some new fields. These years also saw the development of soil conservation to stem erosion and the large-scale construction of public works, including public housing and slum clearance. Many New Deal innovations, such as social security, the agricultural program, the TVA, and the SEC, had now become accepted as permanent functions of the federal government.

Foreign policy. By 1939 foreign policy was overshadowing domestic policy. Even before taking office, Roosevelt had endorsed Hoover's refusal to recognize Japanese conquests in Manchuria. From the outset of his administration, Roosevelt was deeply involved in foreign-policy questions, mostly relating to the Depression. In the early summer of 1933 he refused to support international currency stabilization at the London Economic Conference, but by 1934 he had stabilized the dollar and had begun helping France and Great Britain to keep their currencies from being undermined by dictator nations. In November 1933 Roosevelt recognized the government of the Soviet Union in the mistaken hope that he could thus promote trade. Greater opportunities seemed to exist in negotiating reciprocal trade agreements with numerous nations—a program that began in 1935—and in fostering more cordial relations with Latin American nations. In his first inaugural address Roosevelt had pledged himself to the "policy of the good neighbor." Secretary of State Cordell Hull had interpreted this to mean no unilateral U.S. intervention in Latin America; but, gradually, as European war became imminent, the Good Neighbor Policy led to collective-security and mutual-defense agreements.

In the early New Deal years, Roosevelt not only pursued programs of economic nationalism but, like most Americans, was also intent upon keeping the United States out of any impending war. He thus supported a series of neutrality laws, beginning with the Neutrality Act of August 1935. Roosevelt moved toward a new policy in 1937, after Japan began a major thrust into northern China. In October, speaking in Chicago, he proposed that peace-loving nations make concerted efforts to quarantine aggressors. He seemed to mean nothing more drastic than the breaking off of diplomatic relations, but the proposal created such national alarm that during ensuing months he was slow to develop a collective-security position. He quickly accepted Japanese apologies when the U.S. gunboat "Panay" was sunk on the Yangtze River in December 1937. Relations between the United States and Japan gradually worsened, but the rapid domination of Europe by Adolf Hitler of Germany was more threatening.

The outbreak of war. When World War II began in Europe in September 1939, Roosevelt called Congress into special session to revise the Neutrality Act to permit belligerents to buy arms on a "cash-and-carry" basis. With Hitler's aggressions and the fall of France in the spring and early summer of 1940, Roosevelt and Congress turned to defense preparations and "all aid short of war" to Great Britain. Roosevelt even gave Great Britain 50 overage destroyers in exchange for eight Western Hemisphere bases. Isolationists, fearing U.S. involvement in the war, debated hotly with those who felt the national self-interest demanded aid to Britain.

The third and fourth terms. In the 1940 presidential campaign the Republicans nominated Wendell L. Willkie, who agreed with Roosevelt's foreign policy. Both candidates pledged to keep the nation out of foreign war; but isolationists tended to support Willkie, while those favouring strong measures against Hitler swung toward Roosevelt. By a closer margin than before—27,244,000 to 22,305,000 popular votes and 449 electoral votes to 82—Roosevelt was elected to an unprecedented third

Re-election in 1940

Through 1941 the nation moved gradually closer toward actual belligerency with Germany. After a bitter debate in Congress, Roosevelt in March 1941 obtained the Lend-Lease Act, enabling the United States to finance aid to Great Britain and its allies. Preventing submarines from sinking goods en route to Europe gradually involved more drastic protection by the U.S. Navy; in the fall Roosevelt authorized the navy to "shoot on sight" at German submarines. Meanwhile, in August, on a battleship off Newfoundland, Roosevelt met with Prime Minister Winston Churchill of Great Britain and signed a joint press release proclaiming an Atlantic Charter to provide national self-determination, greater economic opportunities, freedom from fear and want, freedom of the seas, and disarmament.

U.S. entry into the war. Yet it was in the Pacific that war came to the United States. Japan, bound in a treaty of alliance with Germany and Italy, the so-called Axis, extended its empire in East Asia. Roosevelt, viewing these moves as part of Axis world aggression, began to deny Japan supplies essential to its war making. Throughout 1941 the United States negotiated with Japan, but proposals by each side were unsatisfactory. Roosevelt did not want war with Japan in the fall of 1941, but he miscalculated in thinking the Japanese were bluffing. By the end of November he knew that Japanese fleet units and transports were at sea and that war was imminent; an attack in Southeast Asia and perhaps on the Philippines seemed likely. To Roosevelt's angered surprise, the Japanese, on December 7, 1941, struck Pearl Harbor, Hawaii. On December 8, at Roosevelt's request, Congress voted a war resolution within four hours; on December 11, Germany and Italy declared war on the United States.

Roosevelt made concessions to the conservatives in Congress in order to obtain support in prosecuting the war. Several New Deal agencies were abolished. At a press conference Roosevelt asserted that "Dr. Win the War" had replaced "Dr. New Deal" but that this was to be only for the duration of the war. Roosevelt also fought resourcefully although not always successfully against inflationary pressures.

One of the immediate problems after Pearl Harbor was to build up massive production for war. Roosevelt had begun experimenting in 1939 with various defense agencies to mobilize the economy. Eventually, a workable organization had evolved. At the time of Pearl Harbor, U.S. war production was already nearly as great as that of Germany and Japan combined; by 1944 it was double the total of all Axis nations.

Relations with allies. During the war, Roosevelt concentrated upon problems of strategy, negotiations with the nation's allies, and the planning of the peace. From the outset, he took the lead in establishing a grand alliance among all countries fighting the Axis.

Wartime leader

Roosevelt met with Churchill in a number of wartime conferences at which differences were settled amicably. Debate at the earlier conferences centred upon the question of a landing in France, which the British succeeded in postponing repeatedly; the great Normandy invasion was finally launched in June 1944. Meanwhile, the United States had followed the British lead in invading North Africa in November 1942, Sicily in July 1943, and Italy in September 1943. At one of the most significant of the meetings, at Casablanca, Morocco, in January 1943, Roosevelt, after previous consultation with Churchill, proclaimed the doctrine of unconditional surrender of the Axis. He seemed to want to avoid the sort of differences of opinion among the Allies and misunderstanding by the Germans that had made trouble at the time of the 1918 Armistice. There is no tangible evidence that the doctrine in any way lengthened the war.

Relations with the Soviet Union posed a difficult problem for Roosevelt. Throughout the war the U.S.S.R. accepted large quantities of lend-lease supplies but seldom divulged its military plans or acted in coordination with its Western Allies. Roosevelt, feeling that the maintenance of peace after the war depended upon friendly relations with the Soviet Union, hoped to win Joseph Stalin's confidence. Roosevelt seemed to get along well with Stalin when he and Churchill first met with the Soviet leader at Teheran, Iran, in November 1943. In their optimism, Roosevelt and Churchill seemed not to see realistically that the sort of peace being foreshadowed at Teheran would leave the U.S.S.R. dominant in Europe.

Meanwhile, the Axis had been suffering serious defeats in both Europe and the Pacific. By February 1945, when the Big Three met again at Yalta in the Crimea, the war seemed almost over in Europe. As for Japan, the United States expected a last-ditch defense that might require another 18 months or more of fighting. Work in developing an atomic bomb was well advanced, but its power was expected to be only a fraction of what it actually turned out to be. Consequently, Roosevelt and his military advisers were eager to obtain Soviet aid in Asia; and, in return for Stalin's promise to enter the war against Japan, Roosevelt and Churchill offered concessions in the Far East. As for eastern Europe, earlier decisions were ratified, and plans were made for the establishment of democratic governments. Had the arrangements for eastern Europe been followed by Stalin in the manner expected by Roosevelt and Churchill, there would have been little room for criticism. But the understandings were not precise enough, and they received different interpretations in the U.S.S.R. By mid-March false Soviet accusations against the United States led Roosevelt to send a sharp telegram to Stalin.

Declining health and death. Roosevelt hoped that the establishment of an effective international organization, the United Nations, could maintain the peace in years to come. He planned to attend a conference of 50 nations at San Francisco, opening April 25, 1945, to draft a United Nations charter. But, since January 1944, his health had been declining. His political opponents had tried to make much of this during the campaign of 1944, when he ran for a fourth term against Gov. Thomas E. Dewey of New York. A final burst of vigour on Roosevelt's part, however, seemed to refute the rumours. Roosevelt won by 25,602,000 to 22,006,000 in popular votes and 432 to 99 in electoral votes. But his address to Congress after he returned from Yalta had to be delivered sitting down. He went to Warm Springs for a rest, and there, on April 12, 1945, he died of a massive cerebral hemorrhage.

Re-election in 1944

EVALUATION

During Roosevelt's years as president, he had relatively little time for personal life. He continued his interest in his lands at Hyde Park. His zest for sailing and his enjoyment in collecting stamps and naval books and prints continued unabated. His tight schedule and the incessant publicity imposed upon him limited the time he could give to his wife, who became an important figure in her own right, and to his five children: Anna Eleanor, James, Elliott, Franklin D., Jr., and John A. As a public figure he was, at the same time, one of the most loved and most hated men in U.S. history. Opponents ascribed to him shallowness, incompetence, trickiness, and dictatorial ambitions. His supporters hailed him as the saviour of his nation's economy and the defender of democracy not only in the United States but throughout the world. It was generally conceded that as a political leader he was unexcelled in winning and holding popular support and in retaining, in his administration, leaders of diverse views. Many experts have expressed the opinion that despite occasional confusion and overlapping authority, his administration was unusually effective. He brought even more than this to the office: in 1932 he stated what remained his view through peace and war, "The Presidency . . . is pre-eminently a place of moral leadership."

(1956–70); and FRANK B. FREIDEL, ***Franklin D. Roosevelt,*** 3 vol. of a projected six-volume work (1952–), are the most detailed biographies. A.M. SCHLESINGER, JR., ***The Age of Roosevelt,*** 3 vol. to date (1957–), is a brilliant survey of both the man and era; W.E. LEUCHTENBERG, ***Franklin D. Roosevelt and the New Deal, 1932–1940*** (1963), is an authoritative brief account.

(F.Fr.)

Roosevelt, Theodore

Theodore Roosevelt, 26th president of the United States, author, explorer, and amateur soldier, left a permanent mark upon American politics. He made the presidency a more powerful office, persuaded Congress to regulate the railroads, challenged the power of large industries, and engaged the nation diplomatically in Asia and Europe. Roosevelt was the first president who envisioned the federal government as a protector of the public interest, and as an umpire in the growing conflicts between big business and big labour.

By courtesy of the Library of Congress, Washington, D.C.

Theodore Roosevelt.

Roosevelt was born in New York City on October 27, 1858, of a moderately wealthy family of Dutch ancestry; his mother, Martha Bulloch of Georgia, was of Scots-Irish and Huguenot descent. He received an excellent education from private tutors and at Harvard College; he was one of the very few presidents endowed with an encompassing intellectual curiosity. In 1880 he entered Columbia University Law School. But historical writing and politics soon lured him away from a legal career. During the same year he married Alice Hathaway Lee of Boston and after her death, in 1884, married Edith Kermit Carow, with whom he lived for the rest of his life near Oyster Bay, Long Island.

Early political and military career. A physical weakling during his youth, by persistent exercise Roosevelt developed a rugged physique and became a lifelong advocate of strenuous activity. He was a born competitor against both nature and his fellowman, and he used the same enormous energy in public life. Conflict, which he thoroughly enjoyed, came easily to this man endowed, according to a friend, the historian Henry Adams, with one of the attributes of divinity, that of being "pure act" (which apparently meant that he could not sit still and that he did not need to think). Another of his friends remarked that Roosevelt was compelled to be the centre of every stage, the bride at every wedding, the corpse at every funeral. At the age of 23 he successfully ran for the New York State Assembly, in which he soon became one of the Republican leaders, known for his opposition to corrupt, party-machine politics. Misfortune then struck in the form of three successive political defeats. But after two years spent ranching in the Dakota Territory he re-entered public life and continued his reform activities as a member of the U.S. Civil Service Commission (1889–95) and as the president of the New York City Board of Police Commissioners (1895–97). As assistant secretary of the navy under Pres. William McKinley he vociferously advocated war with Spain. When war was declared in 1898, he abruptly resigned, organized the 1st Volunteer Cavalry, known as the "Rough Riders," and took them to Cuba that year. Roosevelt's leadership was spectacular. Disdaining army red tape and even orders, his colourful exploits, especially his impulsive charge up San Juan Hill, made him something of a national hero.

"Rough Riders"

Roosevelt returned home just when Thomas C. Platt, the Republican boss of New York, was looking for a respectable candidate for governor. Platt distrusted him as the "perfect bull in a china shop"; but upon Roosevelt's promise that he would not attack the machine, he was easily elected. An excellent governor, he removed several corrupt politicians from office and over Platt's opposition secured a corporation franchise tax and a civil service system. Enraged, Platt manoeuvred Roosevelt into the 1900 nomination for vice president on the McKinley ticket and thus secured his elimination from state politics.

Accession to the presidency. Roosevelt's enemies compared his election to the vice presidency to a nun's "taking the veil," and the prediction soon proved accurate. He found himself completely bored by this powerless office until September 14, 1901, when McKinley died after being shot by an assassin, and he himself became president. He now had the opportunity to put into effect his political ideas, some of which differed considerably from those of his Republican predecessors.

Roosevelt viewed the presidency not only as an office of tremendous power for formulating legislative and administrative policy but also as a major force in determining the very quality of American life. Abraham Lincoln and Andrew Jackson, both of whom had used the presidency to initiate great changes in American society, were his favorite presidents. Not since Lincoln's day was the power of the office used with such vigour. Some of his opponents called him "Theodore Rex" and likened him to Oliver Cromwell and Napoleon.

Although Roosevelt announced that there would be no change in policy, it soon became apparent that a new life-style had been introduced at the White House. Guest lists there were expanded to include cowboys, prizefighters, explorers, and some of the more distinguished artists of the nation. Young, college-educated men were appointed to administrative positions. Presidential speeches overflowed with indignation and moral righteousness. It soon became apparent that Teddy—as he was known nationwide—was enjoying himself immensely. Whether campaigning, advising Congress, or belabouring a hapless opponent, few presidents have pursued their way with more personal zest.

But for all the office's satisfactions, Roosevelt also had reasons for subdued reflection. He was always conscious that he had become president by accident, and his chief ambition was to be elected in 1904, and he was continuously worried about the possibility of defeat. A highly sensitive politician, he was aware that William Jennings Bryan's defeat for the presidency in 1896 had not quieted the popular demands he represented for control of the trusts, regulation of railroads, and a reduction of import duties. But he also knew that both houses of Congress were controlled by conservative Republicans bitterly opposed to all reforms. He met this perplexing situation by asking for little legislation and by using executive power in appeasing the rising popular discontent—hence the format of the "Square Deal."

The Square Deal. In 1902 Roosevelt took three steps that virtually assured his re-election. From Congress he asked for the establishment of a Bureau of Corporations with powers to inspect the books of all businesses engaged in interstate commerce. Even this limited measure was resisted by leading Republican conservatives; the President secured its passage only by promising not to ask for any further regulatory measures. But this bargain did not keep Roosevelt from further executive actions, and on February 18, in one brilliant stroke, he revived the all but forgotten Sherman Anti-Trust Act by bringing successful suit against the Northern Securities Company, a giant combine of railroads put together by four of the greatest industrialist capitalists, J.P. Morgan, John D. Rockefeller, Edward H. Harriman, and James Hill. Roosevelt pursued his policy of "trust-busting" by bringing suit against 43 other major corporations during the following seven years. Although he himself did not place much faith in breaking up the trusts, preferring their regulation, the Northern Securities action met with tremendous popular approval. Because of the prominence

Attacks on industrialists

of the men involved, its symbolic value was evident; and in the popular view big business, which had threatened to devour the small man, had finally met its master.

In the fall of 1902 Roosevelt again set an important precedent by intervening in the anthracite coal strike. Roosevelt's social views were not particularly advanced for his day. He accepted the legality of big labour unions as he accepted that of big business and felt that both contributed to the general welfare. But he believed the rights of the general public as represented by the government were superior to either. Thus, when the strike threatened to result in cold homes, schools, and hospitals, he requested that representatives of capital and labour meet in the White House and accept mediation. By threatening to use the army to operate the mines he won an arbitration agreement that included a modest pay increase for the miners. Never before had the federal government intervened in a labour struggle except to assure the operation of a governmental service or to protect property. Roosevelt promptly labelled his actions against industry and indirectly for labour a manifestation of a "Square Deal" between labour and capital. In the long run, however, the most significant aspects of his actions were the precedents they set for governmental intervention in the affairs of business and labour for the public interest.

Once overwhelmingly elected in 1904 as president "in his own right," Roosevelt immediately asked Congress for substantial powers to regulate interstate railroad rates. The Hepburn Act of 1906, giving the Interstate Commerce Commission authority to set maximum rates, created the first of the government's regulatory commissions and thus was a milestone on the long road to the modern social-service state.

Consumer protection and conservation laws

Roosevelt's pressure on Congress also led to the passage of the Pure Food and Drug and the Meat Inspection acts (1906) which laid the basis for the modern concept of consumer protection. But when asked after retirement which of his many achievements he considered most important to the national welfare Roosevelt named his conservation policy. Responding to the rapid disappearance of the federal domain, Congress had empowered the President 15 years before to convert portions of the remaining land to national forests. Under Roosevelt's three predecessors only some 40,000,000 acres (16,000,000 hectares) had been transferred. Roosevelt and his chief conservation agents, Secretary of the Interior James R. Garfield and Chief Forester Gifford Pinchot, not only rapidly accelerated the pace but broadened the powers of the act to reserve for future generations parks, and mineral, oil, and coal lands, as well as waterpower sites. In seven years, 194,000,000 additional acres (78,000,000 hectares) of the federal domain were closed to commercial development. Had it not been for Roosevelt's vigorous use of a slumbering statute, today's ecological problems would be infinitely more severe.

Foreign policy. In international affairs Roosevelt believed that strong nations survived while weak ones perished. He also sensed that the relatively peaceful period that had preceded his administration was being replaced by one in which force was the principal arbiter. Every year he asked for larger naval appropriations, and to induce Congress to grant him new ships he occasionally exaggerated the seriousness of international incidents. By the end of this term Roosevelt had built the U.S. Navy into a major sea force. He also encouraged his secretary of war, Elihu Root, to continue his reform of army administration.

In the developing world power struggle Roosevelt regarded Germany as the chief potential threat to the United States. The other dominant naval power, Britain, had international aims very close to those of the U.S. But threatened German expansion, particularly in the Caribbean and in Latin America, was probably the main cause of Roosevelt's armed intervention in the Caribbean. It also prompted his extension of the Monroe Doctrine—according to which the United States regarded European interference in any American nation as an unfriendly act—and even his hesitant participation in European affairs at the Algeciras Conference of 1906.

Roosevelt Corollary to the Monroe Doctrine

Twice during Roosevelt's years in office European powers threatened intervention in Venezuela and once in the Dominican Republic, presumably to collect debts owed to their nationals. To meet a threat of possible permanent intervention Elihu Root and Roosevelt framed a policy statement in 1904 that eventually became known as the Roosevelt Corollary to the Monroe Doctrine. The corollary stated that not only would the United States prohibit non-American intervention in Latin American affairs but it would police the area and guarantee that these nations met their international obligations. The corollary sanctioning American intervention was to be applied in 1905 when, without Congressional approval, Roosevelt forced the Dominican Republic to accept the appointment of an American "economic advisor," who quickly became the financial director of the small state.

Quoting an African proverb, Roosevelt once said that the proper way to conduct foreign affairs was to "speak softly and carry a big stick." Roosevelt was to use big-stick diplomacy again in the acquisition of the Panama Canal Zone from Colombia in 1903, in the formation of a provisional government in Cuba in 1906, and to some extent in the quarrel with Canada over the Alaskan and Canadian border. During the Canal affair he actually wrote an undelivered message to Congress recommending that the nation take possession of the isthmus "without any further parley with Colombia." He also played a notable part in inspiring the subsequent Panamanian revolution that assured American control of the zone and enabled the United States to start construction of the canal before the presidential election of 1904.

If Roosevelt's dealings with small countries were often brusque, his negotiations with major powers were characterized by far more caution. The American Pacific position, he said in 1903, "is such as to insure our peaceful domination of its waters." But the steadily rising powei of Japan caused him to revise that estimate. His efforts to resolve the Russo-Japanese War of 1904–05 included bringing both countries to the Portsmouth Peace Conference and mediating between them. His direct motive, however, was to construct a balance of power in East Asia that might peacefully aid American interests. The friction caused by the anti-Japanese sentiment in California he helped to allay by the so-called Gentlemen's Agreement of 1907, restricting Japanese immigration to the United States. By another informal executive agreement Japan accepted the American position in the Philippines while the U.S. recognized the Japanese conquest and occupation of Korea. Later, in 1910, Roosevelt became convinced that the Philippines were indefensible against a Japanese thrust and that there was no hope of American "dominance" in East Asian waters.

European policy

During his last years as president, Roosevelt was worried by the possibility of a general European war. Since he saw British and American interests generally coinciding, he was strongly inclined to support Britain whenever it would not jeopardize official neutrality, violation of which would have brought strong protest from Congress and the country. The secret instructions given to the American representatives to the Algeciras Conference of 1906, called to prevent a European war over Morocco, were theiefore ambiguous. The envoys were told to maintain American neutrality but also to do nothing that would imperil the existing Franco-British understanding, the continuation of which was "to the best interest of the United States. . . ." But for all the talk of neutrality Roosevelt had in effect deviated from the traditional position of neutrality in non-American affairs. American representatives had attended a strictly European political conference, their actions favoured Britain and France as against Germany, and by signing the agreement the United States presumably undertook to sustain it. Algeciras pointed unerringly toward United States entry into World War I on the side of the allied powers.

Last years as president. The end of Roosevelt's presidency was anything but calm. His crusade against "race suicide," prompted by his alarm at the decreasing birthrate, his public indictment of amateur naturalists, and his order to the government printers to use a simplified system of spelling all developed into national arguments. Especially after the financial panic of 1907 his quarrels with Congress became more vehement. His rather high-handed disciplining of a Negro regiment involved in a riot at Brownsville, Texas, and his suggestion that congressmen who were opposed to increasing the secret-service funds had something to hide, all produced bitter controversy. But most of the congressional trouble came from the split that had developed in his party between the Roosevelt progressives and the party's conservatives, who blamed the financial panic of 1907 on Roosevelt's attacks on big industry. Roosevelt did more than leave a divided party behind him; when he chose William Howard Taft as his legatee and assured the country that Taft would carry out "my policies," he made sure that the party schism would continue into the next administration.

Participation in 1912 election

Later years. After leaving the White House in March 1909, Roosevelt took a ten-month hunting trip through central and northern Africa and made a grand tour of Europe. On his return, he was reluctantly drawn into politics. Though he attempted to support both his old progressive friends and Taft, who had often allied himself with the conservative leadership of the Republican Party in order to carry out progressive policies, the two men soon were violently opposed over policy matters. The conflict became personal in October 1910 when Taft authorized an anti-trust suit against the United States Steel Corporation regarding a merger to which Roosevelt as president had tacitly agreed. Personal animosity and the developing split in the Republican Party finally prompted Roosevelt to contest Taft's 1912 renomination. The resulting bitter campaign and convention practically insured a Democratic victory. Roosevelt himself made that outcome inevitable by founding the Progressive Party and running for president as an independent after he had lost the Republican nomination. In seeking votes, the former president, through both logic and necessity, was forced to radical proposals. Both the Progressive platform and its candidates' campaign for a "New Nationalism" looked forward to a powerful regulatory and social-service state, prefiguring the New Deal policies of President Franklin D. Roosevelt. The results of the campaign were as expected, with Woodrow Wilson, the Democratic candidate, winning by a large electoral vote.

Since the Progressive Party had managed to elect only a handful of candidates to minor offices, Roosevelt knew immediately that it was doomed. He kept it alive for bargaining purposes and, in the meantime, occupied himself with an expedition into the Brazilian jungles and with writing. After World War I broke out he became a strong partisan of the Allied cause, demanding a stiffer foreign policy toward Germany and national preparedness at home. Although ambitious for the 1916 Republican nomination, he was ready to support almost any candidate who opposed Wilson and who was not personally involved in his own defeat in 1912. Amid much bitterness he abandoned the Progressive Party and vigorously supported the Republican candidate, Charles Evans Hughes, but again his efforts ended in failure. His anger against Wilson increased when his offer to lead a volunteer division to France was rejected. Although he had previously supported an international peace-keeping organization, he was adamantly opposed to Wilson's League. By 1918 he felt the Republicans might nominate him for president in 1920. But the years of inordinate activity had taken their toll, and he died suddenly in his sleep on January 6, 1919.

Self image

Evaluation. Few presidents have reflected the dominant temper of their times as vividly as Theodore Roosevelt. America at the turn of the century was prosperous, confident, energetic, expansionist, and experimentally minded. So was Roosevelt. But though a compulsive activist, Roosevelt the politician was usually very cautious. He viewed himself as a middle-of-the-roader and a "half loaf" man, settling for what he thought was possible. Consequently, his tendency to compromise was criticized by contemporary radicals of both the left and the right.

Roosevelt alienated many people by the difference between his rhetoric, invariably highly seasoned with morality, and his performance, usually tempered by expedience. His penchant for impulsive actions and his bullying of small nations and individuals too helpless to reply infuriated others. In particular, he has been criticized by historians for his part in bringing on the Spanish-American War and the acquisition of the Philippines, and for his high-handed treatment of Colombia over the Panama Canal. Some historians have labelled his business policy as one that favoured the small man oratorically but in reality benefitted the large corporations. The majority of authorities, however, impressed with the new spirit he brought to the federal government and with the legislative achievements that laid the groundwork for the solution of many modern problems, have accorded him a more favourable judgment. If not ranked among the four or five great American Presidents, he is placed among the very small group of the near great.

MAJOR WORKS

HISTORY: *The Naval War of* 1812; *or the History of the United States Navy During the Last War with Great Britain* (1882); *The Rough Riders* (1899).

POLITICS: *Essays on Practical Politics* (1888); *American Ideals and Other Essays, Social and Political* (1897); *The Strerzuous Life: Essays and Addresses* (1900); *The New Nationalism* (1910); *Progressive Principles* (1913); *America and the World War* (1915); *Fear God and Take Your Own Part* (1916); *The Foes of Our Own Household* (1917); *The Great Adventure: Present-Day Studies in American Nationalism* (1918).

BIOGRAPHY: *Life of Thomas Hart Benton* (1887); *Gouverneur Morris* (1888); *Oliver Cromwell* (1900).

AUTOBIOGRAPHY: *Theodore Roosevelt: An Autobiography* (1913).

OTHER WORKS: *Hunting Trips of a Ranchman* (1885); *Ranch Life and the Hunting-Trail* (1888); *New York* (1891); *The Wilderness Hunter* (1893); *History As Literature, and Other Essays* (1913); *Through the Brazilian Wilderness* (1914); *A Book-Lover's Holidays in the Open* (1916).

BIBLIOGRAPHY. WILLIAM HENRY HARBAUGH, *Power and Responsibility: The Life and Times of Theodore Roosevelt* (1961), is the most objective and best of the one-volume biographies. HENRY F. PRINGLE, *Theodore Roosevelt,* rev. ed. (1956), although brilliantly written, is perhaps prejudiced against its subject. The most comprehensive work on the early life is CARLETON PUTNAM, *Theodore Roosevelt: The Formative Years,* 1858–1886 (1958), the first of a projected four-volume work. Particularly brilliant short interpretations are JOHN M. BLUM, *The Republican Roosevelt* (1954; with new preface, 1962); and G. WALLACE CHESSMAN, *Theodore Roosevelt and the Politics of Power* (1969). Other special studies of value are GEORGE E. MOWRY, *Theodore Roosevelt and the Progressive Movement* (1946); G. WALLACE CHESSMAN, *Governor Theodore Roosevelt* (1965); HOWARD K. BEALE, *Theodore Roosevelt and the Rise of America to World Power* (1956); and STEFAN LORANT, *The Life and Times of Theodore Roosevelt* (1959).

For a general history of Roosevelt's times, see GEORGE E. MOWRY, *The Era of Theodore Roosevelt,* 1900–1912 (1958); and HAROLD U. FAULKNER, *The Quest for Social Justice, 1898–*1914 (1931). Some of Roosevelt's 2,000 published works including books and hundreds of articles on history, politics, travel, and natural history, and perhaps a few of his personal letters numbering over 150,000 should be consulted. The most comprehensive collection of his works is the *Memorial* edition, 24 vol. (1923–26). A superb collection of his more important letters appears in ELTING E. MORISON, *The Letters of Theodore Roosevelt,* 8 vol. (1951–54).

(G.E.M.)

Ropes and Cables

Rope is an assemblage of fibres, filaments, or wires compacted by twisting or braiding (plaiting) into a long, flexible line. Wire rope is often referred to as cable. The basic requirement for service is that the rope structure remain firmly compacted and structurally stable, even while the rope is bent, twisted, and pulled. The prime property of a rope is its strength; *i.e.*, its ability to sustain a pulling force that may be exerted in order to move or resist the force of a weighty object.

The texture and the nature of the rope is determined by the fibres or filaments used in its construction. Natural fibres vary in colour, fineness, stiffness, strength, and stretchability. Ropes of such fibres will vary accordingly.

Cotton ropes, for example, are softer, weaker, and stretchier than manila or sisal ropes. Manila ropes are stronger, for a given size, than hemp or jute ropes. Sisal ropes are usually lighter in colour and somewhat stronger than henequen ropes. Since even short fibres are adaptable to an operation in which numbers of fibres are bunched together, overlapped or twisted around one another, and in compacted form extended into long flexible yarns, practically any fibre can be made into a rope. The rope strength attainable with any given fibre can be regulated by the size (bulk) of the rope.

Ropes made of filaments drawn from thermoplastic materials, such as ropes made from metallic wires, differ from natural-fibre ropes in that any particular filament contributing to the rope form runs throughout the entire length of the rope and reflects its characteristics more readily. A thick filament or wire is stiffer than a fine one of the same material; its use would then result in a less flexible rope for a given size.

Rope structure

The basic twisted rope structure requires at least two stages of twisting, the second in the reverse direction from the first in order to give torsional stability. The braided or plaited rope structure provides torsional balance by crossing and recrossing rope components in maypole fashion, such that each component passes alternately over and under, and at opposing angle to, one or more of the others.

Natural-fibre, man-made filament and wire ropes ordinarily start with a diameter of 3/16 inches (about 5 mm). Structurally stable rope structures smaller in size are designated cords, and when torsional balance is of no consequence, the designation may be twine or yarn. Cables are torsionally balanced structures formed by twisting several ropes together.

Compared to fibre ropes of a given size, natural or man-made, wire ropes are considerably stronger, will respond to load with little stretch, are much stiffer, and are proportionately heavier. Man-made filament ropes are considerably stronger than natural-fibre ropes but are generally stretchier under load.

FIBRE ROPES

History. Implements and weapons from the Paleolithic Period suggest that knowledge of twisting or plaiting strips or thongs from animal hides into cords, and even coarser vines and fibrous barks into thicker, stronger rope structures, had already been known to primitive man. The animal drawings in European caves and the carvings ascribed to the late Paleolithic Period even show what are perhaps twisted rope bridles made from skin strips or tendons. When Neolithic man began to build with stone and bronze, facing the problems of moving and lifting heavy objects on land and on water, he would have applied such knowledge to develop even stronger and longer twisted and plaited rope structures.

The progressive art of rope making accordingly represents the evolution of a process beginning with plaiting thongs into cords in the distant past to twisting heavy rope structures requisite for the development of massive construction and sea transportation in the eastern Mediterranean.

To rope making, too, may be ascribed the beginning of other developed arts. Before the end of the Paleolithic Period, thong plaiting had already engendered mat and basket weaving, later spinning and weaving of fine twisted yarns modelled after the coarse yarn structures of ropemaking. The knowledge of how to transform short fibres or strips into extensive lengths by twisting or plaiting was ready as growing civilizations discovered and learned to use fibres, animal and vegetable hairs, silken filaments, plant barks, and stems.

The method of making coir yarns and cords, practiced even today in Southeast Asia, demonstrates the fundamental nature of this art. Where coconut palms grow in abundance, the natives still occasionally practice a primitive technique of twisting. The fibres are rolled together with the palm of a hand on the bare thigh into a twisted yarn form, and, with a similar motion, two such yarns are rolled into a twisted cord.

Egyptian rope making

The rope maker, as an established artisan, attained a height of skill with the age of the pyramids in Egypt. Beginning about the 4th dynasty (3500 BC), enormously heavy stone blocks and colossal statues were dragged and moved by slaves, backs bent to heavy, strong ropes. Scenes in pyramids and tombs ascribed to later dynasties depict a well-developed rope-making process, which involved twisting strips cut from leather hides or fibres from papyrus reeds. The twisting whorl had already been established for twisting strands, cords, and even small ropes. Whether the largest ropes were twisted from strands or plaited is not clear.

An account by Herodotus (Book VII, 34 and 37) of the invasion of Greece in 480 BC by Xerxes discloses further advance in the art of rope making, as described by the bridge of boats used to cross the Hellespont. Many small boats or barges were lashed together by six cables—two of white flax of Phoenician make and four of papyrus of Egyptian manufacture--each about 1.5 miles (2.4 km) long. The flax cable was stated to have weighed one talent per cubit, corresponding to 38 pounds per foot, or 57 kilograms per metre, with a possible diameter as much as 14 inches (about 36 cm). It is problematical whether each cable was a single-twisted rope structure in the sense of modern technology, or a series of ropes lashed together to form the cable.

The knowledge of the art of rope making apparently was not limited to the Mediterranean countries. Rope making in India was such a specialized trade that as early as the 4th century BC, ropes were being made to suit specific uses. One may anticipate that jute, indigenous to the area, was used together with coir. In China, during the Han period (206 BC to AD 221), ropes made of silk filaments had already been fashioned for the emperor's funeral carriage. According to tradition, the emperor Shen Nung had encouraged the growth of hemp as early as the 28th century BC. This fibre, originating in the temperate zones of Asia, was discovered later in Europe. By 200 BC, Mediterranean ships were rigged with rope made of hemp grown in the valley of the Rhine. By the end of the 1st century AD, hemp had become the prime cordage material—a position held until the middle of the 19th century.

Abaca fibre

In 1830, when the Philippine Islands were opened to foreign commerce, American rope makers found that abaca fibre could be made into ropes (called manila) that were even stronger than hemp and more suited for marine work than any other fibre rope made theretofore. The use of this fibre expanded at the expense of hemp, giving manila ropes a position of superiority that lasted until the introduction of nylon for rope making in the 1950s, followed by polyester and polypropylene. These three man-made fibres constitute the main fibres of this category used for high-strength rope today.

Natural fibres. The natural fibres used for ropes are classified according to the nature of the plant and the location of the fibres within the plant structure. Cotton is a fine seed hair. Coir, on the other hand, is the coarse seed hair of the coconut, also used for rope. Hemp, jute, flax, kenaf, and ramie are fibres constituting the inner bark of stems or main stalks of reedlike plants. These fibres, long and multiple celled, are designated bast fibres. Abaca (manila), sisal, henequen, and phormium (New Zealand flax) are the coarse fibres extending lengthwise through the pulpy tissues of long leaves or leaf stems of tropical plants, which are also long and multiple celled.

The process for obtaining the fibre from the plant structure is determined by the difficulty of separating it from the adhering plant tissue. The bast fibres are quite adherent and are therefore separated by fermentation—a process called retting—followed by mechanical scraping, washing, drying, and baling. Hemp is derived from the plant *Cannabis sativa.* The coarse variety used for cordage is generally dew retted; *i.e.*, left in open fields exposed to the weather after being cut and stacked like bundles of grain. For finer grades, the plants are water retted; *i.e.*, immersed in natural bodies of water or tanks, to accelerate the process. Jute from the plants *Corchorus capsularis* and *Corchorus olitorius* is water retted, as is kenaf, a jutelike fibre from the plant *Hibiscus cannabinus.*

The leaf fibres manila, sisal, and henequen, generally used for the largest and strongest ropes, are readily removed from the leaf by a mechanical scraping process called decortication. Manila, also designated abaca, is the fibre from the leaf stem of the plant ***Musa textilis***, growing mainly in the Philippines. Since this fibre is removed readily from the plant, it is generally stripped away with a knife by hand, rather than by machine decortication. Sisal, from the plant ***Agave sisalana***, cultivated extensively in Africa and Brazil, and the coarser, darker variety Henequen from the plant ***Agave fourcroydes***, grown mainly in Mexico, are machine decorticated.

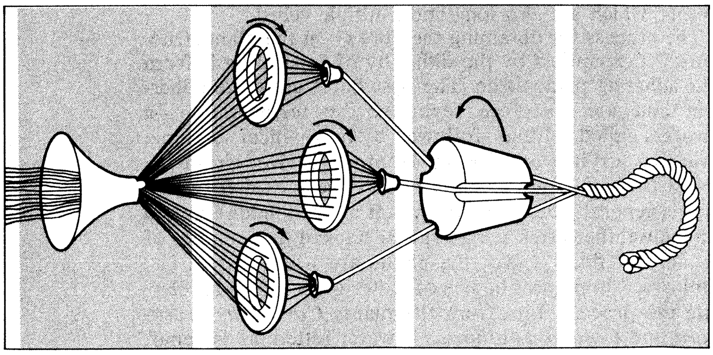
Man-made rope fibres. The man-made fibres used for rope are generally supplied in the form of yams built up by combining fine, high-strength filaments suited to textile spinning and weaving. Nylon, polyester, and polypropylene polymers are extruded through fine-holed dies while molten, then, while the extruded filaments are hot and plastic, they are stretched (drawn) to requisite fineness. The stretching process rearranges the molecules, orienting them to develop the high strength requisite for rope. The fineness of the filaments is expressed in denier; their strength in grams per denier. Nylon yarn in multiples of six denier filaments (a 9,000-metre length weighing six grams) develops a strength of at least 6.5 grams per denier, which is suitable for rope manufacture. Polypropylene rope is made of coarser filaments generally manufactured by the rope manufacturer. Such filaments may be as coarse as 600 denier in size (0.012-in., or 0.3-mm diameter).

Extrusion process

Nylon is the generic term for the polymer obtained from hexamethylene diamine and adipic acid (nylon 6,6) or the caprolactam (nylon 6). Polyester identifies the filaments obtained from the polymeric ester of ethylene glycol and terephthalic acid, marketed under various trade names such as Dacron, Terylene, etc. Polypropylene is the generic term for the polymer of propylene, a product from the petroleum industry. Both nylon and polyester filaments are supplied by chemical manufacturers. Because of its lower melting temperature, polypropylene, on the other hand, is generally extruded into filament form by the rope manufacturer and when used for rope is generally more wirelike in form and stiffness. Such filaments are designated as monofilaments. Finer filaments supplied by the chemical manufacturers are designated multifilament yarns.

Glass, which in recent years has received attention as a rope material because of its extremely high strength and low stretchability, is a form of silica that constitutes the composition of other glass forms. Because of extreme brittleness, the glass filaments must be well lubricated to retain their form through handling in subsequent manufacturing and service operations. The glass-fibre rope used commercially is protected from bending and abrasion stresses by bonding the glass filaments with resins.

Manufacturing process. Rope making is divided into four phases: (1) The fibres or filaments are prepared for spinning (twisting) into yarns. (2) The fibres or filaments are spun or bunched into yarns and yarns into cords for the manufacture of man-made filament ropes. (3) A number of yarns are twisted into strands (forming). (4) Three or more strands are twisted into rope (laying).



Processes through which fibre passes in the manufacture of rope.

Ordinarily, each phase is accomplished with the twist in the reverse direction from the twist in preceding phase. When the rope twist is seen to spiral in direction upward to the right as the rope is held vertically, it is designated as right-laid or Z-twist; if upward to the left, as left-laid (S-twist).

Rope twists

Preparing the fibres (slivering). The goal of fibre preparation is to convert the fibres, which are hairlike in form and several feet in length, into endless ribbons of parallel fibres, wherein each fibre is overlapped uniformly by adjoining fibres. The ribbon or stream of fibres is called the sliver.

The fibres taken from the bales as bundles, called hanks, are made parallel on combing (hackling) machines or, if very short, on carding machines. As the fibre bundles are spread to enter the machine, faster moving steel pins comb through the fibres in the direction of the fibre bundle, arranging the fibres in parallel order and removing extraneous debris. The fibres are at first retained while being combed, but soon moving at the faster speed of the combing pins, some fibres are pulled through the bundle faster than others, thereby extending and overlapping the separate fibre bundles. This process of extending and overlapping is called drafting or drawing. When the fibres emerge from the first combing machine, which is called the breaker, the separate bundles of fibres will have been converted into sliver form. At this stage, the lubricant and preservative liquid is added to the fibre bundles. This not only facilitates the subsequent combining and drafting operations but, retained in the rope, improves its serviceability.

In subsequent combing and drawing operations, emerging slivers are now combined (doubled) and repeatedly combed and drawn in at least four more similar operations, the machines for each operation being provided with combing pins that are progressively finer in size. The doubling operations afford opportunity for mixing the fibres and redistributing them so that on a chance basis the thinner sections of one sliver will coincide with the heavier sections of another and thereby provide uniformity with respect to the number of fibres in the cross-section and the degree to which the ends of the fibres overlap.

Spinning. Spinning is the operation whereby the fibres in sliver form are once more drawn out and, by twisting, converted into a cylindrical form called a yarn, in which form the fibres are compressed against each other. The greater the twist, the greater the friction holding the fibers together, and (until the fibers are damaged by overtwisting), the greater the yarn strength or tenacity. The amount of twist imparted to the yarns in spinning is determined by the nature of the fibres. A rigid fibre will be damaged more readily than a pliant fibre and will withstand less twist. A smooth filament will slide more readily against contacting filaments and will require more twist to compress the fibres adequately.

The three essential operating components of the spinning machine are (a) the chain of pins, or gills, which hold the sliver as the fibres are drawn out by faster moving drawing rollers, (b) the flyer, which twists the yarn about a bobbin retained by a spindle, and (c) a winding mechanism, which winds the twisted yarn onto a large bobbin.

Rope-yarn spinning machines are designated as horizontal or vertical, depending upon whether the twisting flyer rotates about a horizontal or vertical spindle. Machines for spinning rope yarns of coarse natural fibres are also identified as chain gill (spinning jenny) or screw gill; the term "gill" identifying the comb of steel pins retaining the sliver. The screw-gill spinner, of British origin, is a machine in which the combs are moved by a screw thread. In the chain-gill machine, of American origin, the combs are linked together to form an endless chain of pinned combing bars.

In the spinning operation, the sliver is placed on the combing pins, led through retaining rollers or nippers about the flyer, and hence to a wind-up bobbin large enough to provide yarns in continual lengths of several thousands of feet.

The spinning of man-made filament yarns requires no combing pins. The most recently developed spinning machine used in the manufacture of such yarns, called the Twister-Winder, has no mechanical flyer but imparts twist as the yarn loop is spun about in lariat fashion.

Stranding machines

Stranding. Strands, also known as readies, are formed by twisting the yarns, or smaller size cords, together into the visible components of the rope structure. The respective yarns, unwinding from bobbins free turning on a suitable creel or frame, are "bunched" together, twisted, and wound onto large size bobbins. The stranding machines, called formers or bunchers, vary in size and form depending on ability to accommodate continuous strand lengths as well as on production rates, flyer speeds, and related weights. Their components correspond to those in the yarn-spinning machines with respect to the twisting and winding functions. One strand former, designed for heavy rope manufacture, has a full bobbin capacity of 1,500 pounds (about 680 kg), and is used to twist strands ranging in size from 1-inch to 2%-inch (2.54 to 6.67 cm) diameter, the 1,500 pounds of 1-inch diameter strand providing a continuous length of approximately one mile (about 1.6 kilometres).

***Rope** laying.* The twisted rope consists generally of three S-twist strands, twisted (laid) together in the direction of opposing twist (Z-twist), to maintain a torsional balance in the rope structure. The most common, three-strand rope, is also designated plain or hawser-laid rope; a four-strand rope, shroud-laid rope.

The rope-laying operations require machines similar to strand-forming machinery. The strands, on bobbins, are pulled through a compression tube and twisted into rope by a revolving flyer. As twisted, the rope is wound onto a heavy steel bobbin, also turning with the flyer. The three subassemblies of the rope-laying machine, arranged in tandem horizontally, are identified as the foreturn flyers (rotating strand bobbins), the capstan flyer (pulling mechanism), and the receiving flyer (rope-twisting and storage bobbin mechanism). The length of rope twisted in such a laying machine is limited by the dimensions of the receiving flyer.

In another type of horizontal rope-laying machine, the strand bobbins are arranged in tandem within a flyer. As each strand is pulled off its bobbin, it is overtwisted and in this condition combined with its adjacent strands into rope. This machine requires no receiving bobbin in its flyer; the rope is coiled directly into a reel form. The rope length, accordingly, is limited only by the strand length. Such machines may be designed with component parts arranged horizontally or vertically to minimize required floor space.

Rope-walk method

Rope making by the "rope walk" method is practiced extensively throughout the world even today, more than a century after the availability of rope forming and laying machinery. The rope-walk method requires three major pieces of equipment: a traveller with twisting hooks to form strands, a traveller with one or more hooks to twist the rope, and a foreboard to restore strand turns lost in laying the rope. Both travellers ride on rails, moved by a transmission rope drive, which also turns the twisting hooks. The strands formed on the strand traveller and stretched out for their entire length are secured to the twisting hook on the rope twisting traveller, now called the afterturn, at one end of the strand. At the other end of each strand, the strands are individually fastened to the foreboard twisting hooks, now called the foreturn. A grooved block called a top holds the strands separated at the afterturn and guides the strands into the proper positions as the strands make up the rope twist. When three or four strands are twisted together in their entirety, the rope laying is completed. The rope is then removed from the twisting hooks at either end of the rope walk and wound into shipping coil form.

In addition to the twisted structures, ropes in the size range of one-inch to five-inch (2.54-cm to 12.7-cm) diameter are also made in which four sets of strands, equally paired left twist and right twist, are braided into an eight-strand plaited structure. Another braided rope structure, identified as double-braided rope, consists of a layer of heavy twisted yarns, braided about a coarse braided rope core, to envelop and cover the core. Such braided ropes require specialized machinery and are used to best advantage where rope flexibility and torsional balance are prime service requirements.

Applications. To the extent that rope provides a flexible device for transmission of force from a source to a site of application, all ropes are used with a common purpose. Once used, all ropes are subject to deterioration — from mechanical stressing to environmental degradation. The rope user is always cautioned to exercise care to retard deterioration.

Breaking strength

When a rope is pulled, it stretches continuously, reducing in girth until a point is reached when the rope can stretch no longer and it breaks. This point identifies the breaking strength of the rope. The breaking strength, as the major identifiable rope property, with its stretch, is used to gauge the serviceability of the rope. The constructional factor, for a given fibre or filament, that can most influence the strength of the rope is the degree of twist in the rope and strands; the greater the twist, the lower the strength. Repeated loading in tension, short of breaking the rope, will have no adverse effect on the rope strength. Actually, provided the tensile load is not great enough to break inner strand yarns, repeated loadings may result in higher breaking strengths, due to better mutual adjustment of yarn and strand tensions as the rope is repeatedly stretched.

Natural-fibre ropes deteriorate most readily because of fibre degradation associated most commonly with mold growth. Man-made filament ropes deteriorate most readily when exposed to sunlight, elevated temperatures, or damaging chemicals, all of which accelerate filament decomposition.

Rope kinks or strand kinks (cockles) result from an unbalanced twist relationship in the rope structure, the consequence of improper handling. In this respect, the braided or plaited rope structure is superior to the twisted structure.

Considering the characteristics described, the rope user has considerable choice in the selection of a rope suited to optimum serviceability. The marine rope user, who consumes the major portion of manufactured rope tonnage, formerly preferred heavy twisted manila rope but now finds greater serviceablility in nylon or in polypropylene because of its higher strength and lighter weight. If stretch or flexibility are also important considerations, ropes of composite filaments or plaited structures enhance these characteristics.

The foregoing criteria are applied to many rope structures related to specific uses. Water skiing rope, for example, is generally polypropylene of braided structure to minimize kinking; mountain climbing rope, of nylon to develop high strength yet retain firmness; sail rope, of spun (short filament) polyester, braided or twisted to minimize stretch.

WIRE ROPE

History. It seems quite well established that wire rope was developed by Wilhelm Albert (1787–1846), a mining official of Clausthal in the Harz Mountains in Saxony, in a series of experiments extending over the years 1831–34. Even when first tried for hauling and hoisting in his mine, it proved so superior to hemp rope in serviceability and cost that its use soon became widespread in European mining. Known as the Albert Lay, the rope structure he developed was brought to England in 1839 by Lewis Gordon.

In England, wire rope structure and its manufacture became subject to extensive patent litigation. Stranded wire rope had already found extensive use not only in mines but also in railroad transportation and in heavy lifting where hemp ropes were proving too bulky and unwieldy.

Stranded wire rope

In the United States, John A. Roebling (1806–69), who had emigrated from Thuringia in 1831, appears to have been the first to start making stranded wire rope. Such rope replaced the heavy hemp ropes used on the Delaware and Hudson, and the Morris Canal portage inclines. The earliest wire ropes were over a mile (1.6 km) in length and three inches (7.6 cm) in diameter. It was not until after the Civil War that wire rope manufacture was begun on a really extensive industrial scale.

The stranded wire rope structure as developed corresponded to the present wire rope form in that individual wires were twisted about a hemp rope core to form the strand, six such strands then being twisted about a larger hemp rope core in reverse direction to form the rope. Before this, wire rope had already been made in the form of a selvagee—a bundle of individual wires stretched out into a long length and arranged parallel to one another, then bound together and covered with tarred hemp yarns. The stiffness of this structure precluded its adoption for hoisting and bending service, where flexibility and ease in handling are requisite. The selvagee structure, however, was adopted by the British Admiralty in 1838 for the standing rigging for the Navy's wooden ships. Its application for the construction of suspension bridges began in the United States with the erection of a 408-foot- (124-metre-) span footbridge over the Schuylkill River at Philadelphia in 1816. For this purpose, the suspension cables were each made up of six wires, each ⅜ inch diameter. The first wire footbridge in Europe was made at Geneva, over the Fosse River, completed in 1823.

Developments in wire rope making have kept pace with metallurgical developments. The major portion of wire rope manufactured now uses high-strength steel wire. Ropes for marine service, where corrosion resistance is paramount, are also made of phosphor bronze and stainless steel wires.

Manufacturing process. The manufacture of wire rope is basically similar to making rope from the natural yams or man-made filaments. The individual wires are first twisted into strands wound around a core; six strands usually, twisted about a core rope, are then laid into the rope. The cores are cord or rope structures made of steel wires; sisal, manila, henequen, jute, or hemp fibres; or polypropylene monofilaments. The function of the core is to provide a firm cushion for positioning the wires in the strands, to maintain a firm rope structure, and to provide some internal lubrication to extend the rope serviceability, particularly when bending stresses are involved.

The wire, as used in the rope-making operations, is received wound in coils and is first rewound onto spools or bobbins adapted for the strand-forming machines. In this rewinding, the outgoing end of one coil is attached to the new coil, either by twisting or welding, to insure a continuous length of wire in the strand.

Stranding

The design of the stranding machine resembles that of the strand former used in fibre and filament rope making, with the exception that the path of the bends to which the twisted strand will be subject as pulled and wound are of larger radius in order to cope with the stiffer wire structure without damaging or kinking the wires. The spools or bobbins containing the individual wires are arranged horizontally in tandem, within rotating flyers that provide the twist. As formed, the strand is tightly wound on a reel.

The strand diameter is attainable by adjusting the number of wires in relation to their size. Strand flexibility is enhanced when a larger number of finer wires are used. A strand made with coarser wires, however, allows the rope to better withstand abrasion and surface wear. Coarse wire strands are usually twisted with seven wires. The strand for general purpose, flexible wire rope usually requires 19 wires. Strands for especially flexible ropes are generally made with 37 wires.

In addition to these strand structures, there are many special structures combining smaller and larger diameter wires. The Warrington strand interposes *6* fine wires with *6* coarse wires to constitute the 12 surface wires in a 19 wire strand. The Seale strand maintains a coarse wire outer surface of 9 wires, and a concentric inner layer of 9 fine wires about a single coarse wire core, in a 19 wire strand: There are also combinations of Warrington and Seale strands; each structure designed to provide better serviceability under the operating conditions encountered.

The strands, wound on bobbins or reels, are now brought to the closer or layer, where the six strands are twisted together about a rope core, into rope form. These layers, similar to fibre rope layers, are designed with twisting components arranged horizontally or vertically. The largest size layer will provide a rope up to four inches in diameter, in a continuous length of approximately 2,000 feet, and with a weight of 27 tons: in metric units, a diameter of 10 cm, a length of about 600 metres, and a weight of 24.5 metric tons. As the six bobbins rotate within the rotating platform, the strands are compacted and twisted together about the rope core, laying or closing the rope. The strands, as the rope, are pulled through the laying machine by a pair of grooved drums turning as capstans. The finished rope, wound on a slow-turning reel, is now ready for use.

Lang lay ropes

Most wire ropes are layed with a right twist; each of the six strands respectively formed with a left twist. Such ropes are designated "regular Iay" or right, regular lay. Ropes twisted in opposing directions, designated left, regular lay, also find commercial use. In addition to the regular lay, ropes are also made with "Lang" lay. This designates a right or left twist rope lay, with the strand twist corresponding in direction to the rope twist. Lang lay ropes are named after John Lang, the manager of an English rope factory. With this construction, a greater portion of the strand surface wires are exposed, thereby affording greater area to withstand surface wear and to provide longer service life when severe bending stresses are encountered. The disadvantage of this construction lies in its torsional unbalance. In service, the Lang lay rope will untwist much more readily than regular lay rope, if the ends are free to rotate.

With either regular or Lang lay, the rope structure may be identified as "preformed" or "nonpreformed". The nonpreformed rope is twisted as described in the foregoing. In the manufacture of preformed wire ropes, both the strands and their wires are shaped during the respective rope- and strand-twisting operations, so that the helical twisted form to be assumed in the rope structure is preformed within the strander or layer, before the twisted structure is completed. The result is a rope in which the component strands and wires retain no residual stresses that would cause them to spring out of position when the rope is loose. This method also relieves the rope's tendency to rotate as it bends over a sheave. Both these features contribute to longer service life. The preformed rope is easier to splice and is much less likely to form kinks.

Applications. Most wire ropes are used in hoisting and hauling operations and machinery for these purposes, such as cranes, power shovels, elevators, mine hoists, etc. A flexible rope structure to cope with fast movement and bending stresses is an overall consideration. In other uses, such as support guys, stays, and barrier ropes, this property is not so much a consideration, and a 6×7 (six strands of seven wires each) structure will serve, as against a 6×19 rope.

Similar considerations prevail for marine ropes, which are usually galvanized. A stiff 6×7 structure is suited to

Comparative Properties of ½-inch (12.7-mm) Diameter Ropes

	nominal breaking strength (pounds)	approximate weight per foot (pounds)	stretch to breaking point (percent)
Natural fibres (3-strand twisted)			
Manila	2,650	0.075	13
Sisal	2,120	0.075	13
Henequen	1,590	0.075	15
Cotton	1,450	0.073	17
Man-made filaments (3-strand twisted)

rigging, mooring, and towing; but a 6×37 structure may be required when flexibility and ease in handling become overriding requirements.

Wire rope also finds extensive use in the form of lifting slings, cargo and construction nets, support spans in electric power transmission, and bridge and building construction.

The properties of wire rope in relation to the properties of natural and man-made fibre ropes are given in the Table.

WIRE AND WIRE PRODUCTS

Manufacture. The steel for wire manufacture may be made either by the open-hearth or the electric-furnace process. The steel mill provides the material for wire drawing in the form of hot-rolled rods, in long coiled lengths of 300 to 1,000 pounds, rod diameters ranging from 5 gauge (0.207-inch diameter) to 7/0 gauge (0.490-inch diameter). The metric equivalent would be weights of 140 to 450 kg, in diameters ranging from 5.26 to 12.4 mm.

As the rod is uncoiled, it is progressively descaled, washed, and coated with material to facilitate its being drawn through a die. When drawn, the wire is lubricated or coated with a protective finish, then recoiled and ready for use in wire rope or other manufactured products. Depending upon the grade of steel used, the wire can attain an ultimate strength as high as 250,000 pounds per square inch or 17,600 kg per square centimetre.

The rod as received may require a preliminary heat treatment to improve the grain structure of the steel. In this operation, a number of rods are pulled slowly through a furnace well above a critical temperature established to bring out the required strength and hardness and cooled under controlled conditions in air or in molten lead or salt baths.

Pickling

In the next operation, the rod is immersed in a "pickling" solution to remove dirt and scale. The pickling solution may be a dilute solution of sulfuric acid compounded with an organic inhibitor to allay attack on the cleaned steel. The pickling solution is kept hot. The descaling may be accomplished with other acids, molten alkaline salts, or even by metallic-grit blasting. Descaled, the rod is washed thoroughly to remove and neutralize descaling material and is then immersed in a coating liquid containing lime with other ingredients that coat the rod. It is then baked and allowed to cool. The lime coating serves as a lubricant and flux, protecting the wire from surface damage during drawing.

The wire drawing die provides a conical-shaped hole, a portion of which is bored with precision to correspond to the required wire diameter. The extent of reduction in size from rod to wire bears on the quality of the wire. The wire drawing may accordingly be done in a single step or in multiple steps. In its simplest form, the die may be a conical-shaped hole in a tool steel block. In more involved form, it may consist of a tungsten carbide insert in a steel casing, set into a water-cooled jacket. Wire drawing is essentially a stretching process, the reduction in diameter providing correspondingly greater length. Each drawing further increases the strength and toughness of the wire.

Steps in wire drawing

The wire-drawing process consists of three steps: (1) The rod is first pointed to enable it to pass through the smallest bore die that will be used to attain wire size. (2) The pointed rod is run through the successive dies and drawing blocks; each die also provides prelubrication of the rod or wire, using soap, metallic stearates, or lime with grease or tallow. (3) The drawn wire is coiled on the drawing block, which consists of a rotating drum, water cooled, turning fast enough to take up and coil the wire as it is stretched. The coil is built up on a winding reel (called a stripper), which is a movable component part of the block.

Although the wire is cold-drawn, there is so much heat generated by the drawing friction that both die and water block are water cooled. The lubricant protects against die erosion and wire damage. The conversion of rod to wire is generally done in several successive stages of drawing, as a continuous process; each successive block turning at a progressively higher speed to take up the increased length attained with each drawing. When the proper wire coil length is reached, the stripper reel is lifted from the block and the coil of wire is released.

The wire, now designated bright wire, may be further annealed by heat treatment to relieve drawing stresses or treated with a surface lubricant for strand-forming operations. When a protective finish is required, the wires may be galvanized or tinned in a hot-dip or electrodeposition process. The galvanizing process reduces the tensile strength of the bright wire by 10 percent.

Wire diameter is almost universally given in terms of steel wire gauge number. Sizes range from gauge no. 37, with a diameter of 0.0085 in. (0.22 mm) to gauge no. 7/0, with a diameter of 0.49 in. (12.4 mm).

Other steel wire products. Other steel wire is fabricated into many products, the most important being nails, fencing, springs, reinforcing and prestressing concrete wires, and suspension bridge wire.

Nails. A wide range of sizes and styles of wire nails is now available. Wires are cut and shaped automatically from coils of wire of proper size. The usual bright finish is attained by a tumbling process. Protective treatments are galvanizing, tinning, bluing by oxidation, or cement coating.

Woven fencing. Fence-weaving machines are designed to cross weave horizontal wires (laterals or line wires) with vertical or diagonal wires (stays), in fabric-weaving fashion, so that the wire crossings form triangular, square, rectangular, hexagonal, or diamond-shaped meshes for farm and industrial uses. The wire sizes range from 9- to the 20-gauge wire used for light poultry netting. There are basically two types of woven fencing; the stiff stay, in which the stay is in one length constituting the width of the fencing, and the cut stay in which a short stay is twisted about or welded to the lateral to form the mesh. Fencing of this construction constitutes exceptionally strong reinforcement for concrete.

Chain link fence is twisted from 6- to 11-gauge wires called pickets, which are spirally wound and interwoven to form a continuous link fabric. The ends of the adjoining pickets are twisted or folded together to provide fencing free of knots or ties except at the top and bottom.

Ornamental fencing (lawn fence) uses crimped stays formed into semicircles at one end. The line wires are locked into the crimp of each picket; the ends of the pickets are twisted or welded into twisted 2-wire line wires, called cables.

Barbed-wire fencing. The high-speed machinery producing this fencing twists two wires (line wires) together and, at regular intervals of three to six inches (7.6 to 15.2 cm) apart, winds barbs about one or both of the line wires. The barbs are cut diagonally to produce the points. Most barbed wire is made with no. 12%-gauge line wires and 14-gauge barbs.

Springs. The common requirement for springs is that the wire be in an annealed, hard-drawn, or pretempered condition and that steel carbon content be 0.45 to 0.90 percent. This allows the spring to be fashioned easily, then to be heat-treated to develop elastic characteristics required for service.

Prestressed concrete tendons. Cold-drawn, uncoated steel wires of no. 6 gauge and heavier and twisted wire strands as large as $1\frac{11}{16}$-inch diameter are used as tendons in prestressing concrete. By stressing the tendons, either before or shortly after pouring, the concrete develops a better capability to resist tensile stresses. The wire must be stress relieved to develop proper ductility and have a tensile strength in the range of 235,000 to 250,000 pounds per square inch.

Bridge wire. The manufacture of wire for this purpose requires careful quality control to insure compliance with demanding specifications. For example, the wire must be uniformly galvanized so that the adherent zinc coating will not peel off as the wire is bent. The stretch must be at least 4 percent in a 10-inch (25.4-cm) length. Bridge wire is drawn to 0.196-inch (about 5 mm) diameter, from high-carbon steel rod, and is handled in coils five feet (about 1.5 metres) in diameter.

Rosales

In comparison with other orders of flowering plants, the rose order (Rosales) is not particularly large in terms of either the number of families it includes (three) or in the number of its species (about 3,200). It is, however, one of the most frequently encountered flowering plant groups in the temperate zones of the world, especially in cultivation. Some of the most important food plants occur in the order, and numerous ornamentals are of this alliance, among them roses (Rosa), flowering cherries (*Prunus*), mountain ash (*Sorbus*), spirea (Spiraea), firethorn (Pyracanthn), hawthorn (*Crataegus*), and various species of cinquefoil (*Potentilla*). Members of the order are most characteristic of the upper latitudes or higher altitudes, being common in the temperate zones of both the New and Old World, but there are also important tropical species.

GENERAL FEATURES

Woody nature of the order

Life-form, distribution, and abundance. In life-form, the order is extremely diverse, ranging from small herbs (strawberry and cinquefoil) to shrubs and woody climbers (roses and spirea) to small trees (mountain ash) and giant tropical trees (*Parinari,* Licania). There are many more woody or partly woody species than there are herbaceous kinds. Tropical lowland representatives in the New World are mostly woody shrubs to quite large trees, some more than a hundred feet tall, with extremely hard, often useful wood. These woody kinds are especially characteristic of the family Chrysobalanaceae.

Members of the rose order have a natural distribution over much of the world, but the group is especially abundantly represented in eastern Asia (Japan and China), North America (north temperate areas), and Europe. The largest genera are *Rubus* (blackberries and raspberries), with several hundred species; Crataegus (hawthorns), with a like number of species; *Potentilla* (cinquefoils), with 300 species; and Rosa itself, with about 150 natural kinds. The precise size of these genera is very difficult to state, especially in the blackberry and hawthorn groups. In these, there have been widespread hybridization and recombination of species formerly isolated from each other ecologically. With the destruction of forests and other barriers to interbreeding, two or more species have often come together, bred with one another, and the hybrids have backcrossed with the parents. The consequence is that estimates, for example, of blackberry–raspberry species range from 25 to 1,000 or more different kinds, depending upon the taxonomic recognition given to the many forms. If each variant is considered a species or a subspecific unit of some rank, the number of kinds becomes almost infinite, and such a classification system serves no useful purpose.

Economic importance. Numerous economically important food plants belong to the rose order, including apples (*Malus*), pears (Py*rus*), peaches (Amygdalu), apricots, and plums (all three, *Prunus*). That is, most of the more important fruits produced in the temperate areas belong to this one order and to one of the families, the rose family (Rosaceae). Apple culture, based on crosses and selection from the common crab apples, is the economic base for several parts of the United States, including the northwestern states and New York, Michigan, and Virginia. In the southern U.S., strawberries (*Fragaria*) and peaches replace apples as the major fruit crops of the rose order.

Besides the many food plants of the order, there are also large numbers of ornamentals in temperate gardens. Of these, none is more widesyread, ayyreciated, or diverse in form than the cultivated roses. There are numerous wild species, but, except when planted for livestock enclosures, they are seldom used. The hundreds of cultivated varieties, however—climbers and bushes, dwarfs and standards, singles and doubles, and those with petals of every hue—grace the gardens of cottage and castle, ghetto and suburb. The damask rose is widely grown in Bulgaria for the valued perfume, called attar of rose and rosewater, which is distilled from the fresh flowers. An uncommon but historically interesting economic use was recognized and began to be exploited during World War II, when the fruits of wild rose species were gathered for their very high vitamin C content. The practice has continued among present-day advocates of herbs and health foods.

Many members of the Rosales order have less well known values. Ninebark (*Physocarpus*) is a shrub that in dense stands helps to prevent soil erosion and provides shelter for birds. Mountain ash trees (*Sorbus*) produce orange fruits that feed many birds and can even be used for jelly making. Shadbush (*Amelanchier*) bears fruits used by birds, and its leaves, bark, and young twigs feed deer and rabbits. Hawthorns (Crataegus) provide excellent cover for wild animals, and the fruits make up a substantial part of the diet of some birds. The wood of the black cherry (*Prunus*) is important in cabinetmaking. The heavy, hard, close-grained wood of the hawthorn makes excellent tool handles, canes, and charcoal.

Medicinal uses

Contributions of the order for medicinal purposes are numerous, especially among the herbaceous species. Agrimony (Agrimonia), for example, was looked upon in past ages as a general cure-all for any sort of wound, snakebites, and even for removing warts. It has also been used commonly as a substitute for or as an additive to tea, and the entire plant yields a pale- to intense-yellow dye, depending on the season it is collected. It is still believed to be useful in the treatment of diarrhea, liver ailments, and as a gargle. The active principle is a tannin.

The petals of certain rose species are strongly odorous by virtue of a volatile oil they produce. This property gives rose petals value as flavouring for cough syrups and candies. Dried lose petals are often kept in potpourri jars or among clothing items, where their fragrance is slowly released. Fresh rose petals impressed in the surface of butter contained in a tightly covered container overnight in a cool place impart a delicate rose odour and taste to the butter. This, spread on small thin shapes of bread and garnished with a fresh rose petal, makes rose-petal sandwiches, often served with tea.

The leaves of hawthorn have been used as an adulterant of tea. Its flowers and fruits have astringent properties, which form the basis of their medicinal use as a cardiac tonic and as a diuretic for some kidney ailments. The fruits added to brandy produce a highly regarded liqueur.

In addition to the temperate-zone fruits of the rose family, there are also a few now widely cultivated species from the tropics and subtropics. The loquat (Eriobotrya) originally came from China, but it grows easily in warm places from southern Florida south. The coco plum (Chrysobalanus), a native fruit in the tropics and subtropics, grows along sandy shores from Florida through the West Indies, south to Brazil. The sweet, dry, but rather tasteless fruits are borne on small shrubs or low trees of the strand and riverbanks. In Mexico, the bark, leaves, and rooks are used medicinally as an astringent; the leaves and fruits are the source of a black dye; and the

oily pits are used for food, or they are strung on sticks to serve as candles. Oiticica oil is a product expressed from fruits of one of the species of the family Chrysobalanaceae that grows in northeastern Brazil, where it has long been used medicinally and for illumination. Large quantities of the oil are imported by the United States for use in place of tung oil in paints, in making printing inks, and in making linoleum.

NATURAL HISTORY

Life cycle—reproductive features. The evolutionary success of the rose order rests on a variety of adaptive advances over its progenitors. The embryo, for example, uniformly fills the seed and is not dependent on an enveloping endosperm (nutrient tissues in the seed), as are the embryos of some less advanced families.

The wide range of fruit types in the order also is thought to have had a high selective advantage in its evolution, because a variety of different forms would increase the chances of successful dispersal and establishment. In addition to the familiar edible types of fruits (*e.g.* apples and pears, cherries and plums, and strawberries), many species groups produce fruits with hooks and barbs that ensure their transport on animal's hair or on man's clothing from place to place.

Asexual reproduction

More important than the foregoing, however, is the frequency of a form of asexual reproduction known as apomixis, a term often used loosely to include all forms of nonsexual reproduction. Some species in the order may reproduce exclusively bv such nonsexual methods as runners (strawberries) or horizontal leafless stem structures called rhizomes (raspberries) and still retain their capacity, entirely or in part, to reproduce sexually by seed. Other species have lost all capacity for sexual reproduction. Obviously, apomictic reproduction confers considerable evolutionary advantage, for a species may achieve extensive distribution even in the absence of its principal pollinators or under conditions unfavourable to seed development and germination.

On the other hand, apomixis often produces such a multitude of forms that classification is more a matter of arbitrariness than a scientific attempt to express evolutionary relationships. In the rose and the apple subfamilies (Rosoideae and Maloideae), much of the taxonomic confusion, such as that concerning the genera *Rubus* and Crafaegus, is the result of hybridization, polyploidy (having multiples of the basic number of chromosomes), and apomixis. Two sexual species, each of which may have a multiple set of the normal chromosome complement, can hybridize but produce largely sterile offspring. The latter, however, can become well established in nature, with well-developed geographic distributions, by either total or partial apomixis. At the same time, a doubling of the chromosome complement (polyploidy) may re-establish partial or full fertility. All these routes to survival of new forms appear to have operated during the evolutionary history of the rose order. Grafting and budding are man-made asexual means employed for the perpetuation of desirable varieties of apples, pears, peaches, and other related fruits.

Although knowledge of the cytology (the study of cells, especially of chromosomes) of the order is incomplete, much has been recorded about chromosome numbers in the family Rosaceae. The spirea subfamily (Spiraeoideae) has a basic chromosome number of 8 or 9, and it may be interpreted as more stable evolutionarily than some of the other subfamilies. The rose subfamily (Rosoideae), which includes the highly variable raspberry genus (*Rubus*), has at least three basic chromosome numbers, 7, 8, or 9. The apple subfamily (Maloideae), including the taxonomically confusing hawthorns (Crafaegus), has a basic number of 17, and the plum group (subfamily Prunoideae) has 8 as its base number of chromosomes. The 17 chromosome pairs that are the basic number in the apple group have been explained by some researchers as being the result of hybridization and subsequent polyploidy between ancestral species of the spirea group (with its nine pairs of chromosomes) and the plum group (with its eight pairs).

Ecology. The ecological preferences of the Rosales order are diverse and wide-ranging. Altitudinally, species of herbs, shrubs, or small trees extend from sea level to Alpine meadows beyond the tree line. Many species are weedy, occurring in association with man's activities, and some are clear indicators of soil sterility. Fruit-eating birds drop seeds or other propagula (*e.g.*, whole fruits or plant pieces that can grow to establish new plants) along fencerows or in hedgerows, so blackberries, hawthorns, and wild cherries are commonly found in such places. Members of the order are found in deserts, in the tropical rain forest, and in every intermediate situation.

Not infrequently the distribution of a species is determined by the chemical nature of the soil, for many species are able to succeed only on soils derived from limestone. The cultivated fruits of the order, for the most part, prefer well-drained situations, and, for that reason, much of the commercial production is in hilly or rolling countryside. Soil type is less important, for these fruit trees thrive on even heavy clay soils, but they must be well aerated and freely draining.

FORM AND FUNCTION

Leaf position and forms

Vegetative characters. In habit the species of Rosales are about as diversified as possible, with every life-form from small creeping herbs to giant hardwood trees. Many of the included groups have thorns and prickles, but this is scarcely a universal or even distinguishing characteristic. Much more typical is the alternating position of the leaves on the stems; only rarely do they occur opposite each other. The leaves are often compound (*i.e.*, with several leaflets to a common leafstalk), as in roses, strawberries, and cinquefoils, but the pome-fruited members such as apples and peaches have simple leaves. Stipules, small leaflike appendages at the base of the petiole (leafstalk), also are characteristic of the order. They sometimes fall very soon after expansion, or they are not obvious because they are often joined with the petiole, as in the roses.

Hairlets on various parts of the plants are usually one-celled and either glandular or, more commonly, not. The leaves sometimes bear nectaries (nectar-producing glands) on the petiole, on the blade surface, or on each tooth along the leaf margin. Crystals of calcium oxalate are found in the leaves of many species, either solitary or in clusters. The wood in species of the Northern Hemisphere has small, numerous vessels (water-conducting cells) that often have spirally thickened walls, simple perforations (*i.e.*, open-end walls joining the cells into tubes), and wood fibres that have many bordered pits (tiny openings along the sides of the cells; the "borders" are structural complexities that distinguish this type of pit from "simple pits" found in many other plant groups).

On the basis of anatomy, only the plumlike species can be separated from the other groups of the rose family. The family Chrysobalanaceae, however, is quite distinct anatomically in numerous respects. The stomates (small pores in leaf surfaces) are of a type distinct from the rest of the order, and the leaf hairs are arachnoid (cobwebby) or even stellate (with radiating branches, starlike) or peltate (with a shield-shaped structure at the apex). Glands are often present at the base of the leaf in many species, and silica bodies (deposits of the glassy mineral silica) are found in leaf or young stem cells of many species. Wood vessels are large and occur as solitary elements lacking the spiral thickenings of the vessels in the rose family.

Reproductive structures

Flower and fruit characters. Flowers of the rose order are almost always bisexual; that is, with stamens (male reproductive structures) and pistil (the female reproductive structure) in each flower. When this is not true, the male flowers occur on one plant and the female ones on another individual of that species (the dioecious condition). The flowers are regular (*i.e.*, radially symmetrical) in most genera, but several of the Chrysobalanaceae have irregular (bilaterally symmetrical) flower structure, either in the perianth (the collection of both sepals and petals) or in the reproductive parts. The flowers are borne singly or in a wide variety of inflorescence (flower-cluster) types, which are either determinate or indeterminate. Determinate inflorescences mature from the top downward; that is, the central or terminal flower blooms first, and, since this is located at the growing tip of the inflorescence, no further buds are produced. Indeterminate inflorescences mature from the bottom upward, and new buds are continually produced at the growing tip of the inflorescence.

Sepals and petals usually are present, but, in some species, one or both series are lacking. The perianth parts are usually joined with each other, in part, to form a cupular to elongate tubular structure called a floral cup or hypanthium, the wall of which may also involve the bases of adnate (fused, joined) stamen filaments. At the bottom of the cup, there is often a ring of secretory or glandular tissue that produces nectar.

The stamens are commonly numerous, occurring in one to several whorls of five stamens each and arising from the inner surface or rim of the hypanthium. The filaments are free from each other except in several genera of the family Chrysobalanaceae, in which they are joined basally to varying degrees. In one genus the filaments are joined completely in a ribbonlike structure on one side of the flower.

The gynoecium (female structural complex—the pistil or collection of pistils) in this order is usually superior; that is, the sepals, petals, and stamens are attached below the base of the ovary. The large group of stone- or pome-fruited genera (apples, plums, pears), however, have a distinctly inferior ovary with the perianth and stamens arising above the compound, two- to five-parted gynoecium. The remainder of the genera have two to ten carpels (structures comprising the ovary) in each superior gynoecium. The style, or styles when multiple, is terminal on the ovary or arises from its base. The erect or pendulous ovules (seed precursors) number one or more per carpel.

Fruits of the rose order are small and dry achenes (dry one-seeded structures that do not split open along definite lines) as in the strawberry and cinquefoil, follicles (dry structures that split open along one definite suture) as in spirea, pomes (fleshy fruits with cores) as in the apple and quince, drupes (fruits with stony pits) as in the plum and peach, or an aggregation of drupelets as in the blackberry and raspberry. The seeds have small embryos and endosperm is usually lacking.

Biochemical features. Although concerted biochemical studies of the Rosales have not been undertaken, there are numerous data, some of which have special interest for taxonomists. A few examples may be instructive, but generalities at the level of the order are virtually impossible at present.

Certain amino acids occur with such widespread frequency in stem tips as to be of little systematic (*i.e.*, relating to the classification of species) value. On the other hand, one of these (arginine) is the amino acid commonly present in the family Rosaceae. Elsewhere it makes only sporadic appearance. Similarly, certain fatty acids such as licanic acid are characteristic of some members of the family Chrysobalanaceae.

While relatively few sugar alcohols are found naturally, some are distinctive of major flowering-plant groups. Thus, sorbitol is infrequent generally but common among members of the rose family as a precursor of starch. It has been reported that leaves of certain Rosaceae, kept in the dark for a period to eliminate stored starch, will manufacture starch in the leaves when they are floated on a sorbitol solution.

Cyanide formation

Members of another class of compounds yield cyanide plus a simple sugar when they are broken down by enzyme action. These cyanogenetic materials are probably of systematic importance by virtue of their distribution, but the supporting data are incomplete. It is interesting to note, however, that these compounds are apparently almost totally restricted to the advanced vascular plants. Of those with cyanide-generating capabilities, the family Rosaceae has more species (150) than any other family. There may also be plant populations that produce cyanide within species that are otherwise not cyanogenetic. Still more significant is the distribution of this characteristic within the rose family: cyanogenesis is common among the pome-fruited species and the plum subfamily but is much less frequent in the rose and spirea subfamilies.

Numerous groups of species of the rose family are dangerous because of the cyanide compounds contained in various parts of the plant. Mountain mahogany (species of *Cercocarpus*), evergreen, small-leaved shrubs of arid areas in the western United States, is browsed by animals, often with impunity, but at some sites the concentration of cyanide is high enough to be fatal to livestock. Similarly, but much more dangerous to livestock and to humans, several kinds of wild cherry, peach pits, and bitter almonds are poisonous. Ordinarily, grazing animals avoid such poisonous foliage as that of chokecherry (Prunus virginiana) and wild black cherry (Prunus serotina), but either by accident or by elimination of other more desirable browse, animals are sometimes lost to cyanide poisoning from these plants. The cyanide is higher in wilted leaves and branch tips than it is in mature or dried leaves.

Some phenolic compounds also are distinctive of the family Rosaceae or of some of its subgroups. Isoflavones, for example, have been found only in the families Rosaceae and Leguminosae (also called Fabaceae, order Fabales), which is not surprising to phylogeneticists who consider the two families to be closely related.

EVOLUTION

Fossil record. As with most flowering-plant groups, fossil remains become increasingly common in the Tertiary Period (beginning about 65,000,000 years ago). Fossils are frequent in both European and North American formations of Eocene to Pleistocene age (*i.e.*, from about 54,000,000 to within the last 2,000,000 years). It is significant to note that fossilized parts have been found of plants readily assignable to all the subfamilies of the rose family and of the largely tropical family Chrysobalanaceae as well.

The genus Spiraea is known from fossils of its fruits, and there are leaf remains probably assignable to this group also. Ninebark (Physocarpus), a genus of modern-day shrubs, is represented in fossils of the mid-Tertiary. In the pome-fruited subfamily (Maloideae), seed remnants have been recognized of the hawthorn (*Crataegus*) and pear (Pyrus) genera. Leaf fossils are described for the quince (*Cydonia*), serviceberry (*Amelanchier*), and hawthorn. In the rose subfamily (Rosoideae), fruits of cinquefoil (Potentilla) and raspberry (*Rubus*) are known from the Pliocene Epoch (2,500,000 to 7,000,000 years ago) and Oligocene Epoch (26,000,000 to 38,000,000 years ago) of western Europe. The stone-fruited subfamily (Prunoideae) is represented by fossil fruits of both plum (Prunus) and peach (*Amygdalus*) in the Pliocene of Germany and France. The family Chrysobalanaceae is represented by leaf fossils in the late Eocene flora of west central Oregon. This group, now largely tropical, was a part of a flowering-plant assemblage that unquestionably flourished in a tropical environment there, about 50,000,000 years ago.

Phylogeny. The fossil record characteristically is not very helpful either for relating the family to other families or the order to other orders. The speculations that follow are based more on comparative morphology and anatomy than they are on fossil evidence.

Evolutionary position

The order Rosales is considered to be one of the more primitive orders, derived from the Magnoliales through the modifications of one intermediate order, the Dilleniales. The genus Spiraea has sufficient similarities to the latter order and to the Saxifragales to indicate common ancestry. Likewise, the family Chrysobalanaceae is seen by many as the connecting link between the Rosales and the Fabales.

Within the order, the most primitive family is often considered to be the Chrysobalanaceae, with its superior ovary composed of a single carpel and the style arising from the ovary base. The family Rosaceae is probably even more basic, ranging as it does from having quite simple floral structures to very complex, from woody to herbaceous life-forms, and with so many fruit types that give the family as a whole great selective advantage potentially over groups with less adaptive flexibility. The rose family consists of at least four subfamilies, which differ principally in the characters of their fruits. The family Neuradaceae probably is most nearly related to the rose family through the rose subfamily, but it is quite distinct in the wall structure of its pollen grains, as well as in the structure of its flower and fruit.

CLASSIFICATION

Distinguishing taxonomic features. The features that distinguish the Rosales from related orders are several. Vegetatively, many species have compound or divided leaves that commonly are stipulate. The flower parts are usually in fives, arranged in concentric circles. Although the relationship among the floral organs varies from hypogyny (superior ovary) to epigyny (inferior ovary), the most characteristic condition is perigynp (half-inferior ovary), the sepals, petals, and stamens arising from the rim of a cupular to tubular hypanthium. The stamens are usually in many whorls, and the gynoecium consists of free to united pistils.

Annotated classification. The classification presented here is a recent one that is relatively conservative in approach. Only three families are included, in contrast to as many as 17 families in older treatments. Likewise, the family Rosaceae has been divided by some authors into six separate families, which are treated here as four subfamilies. Although it represents perhaps the narrowest view taxonomically of what the order includes, it is thought to be more natural evolutionarily than more inclusive treatments.

The following is a more technical, highly abbreviated summary of the descriptions of the major groups comprising the order Rosales.

ORDER ROSALES

Usually stipulate, often woody plants with pentamerous (parts in 5s) flowers, many free stamens, and hypogynous to epigynous arrangement of the floral organs. Seeds usually lacking endosperm. Wood vessels with simple perforations. Three families with 115 genera and 3,200 species distributed in Africa, Northern Hemisphere, and Neotropics.

Family Rosaceae

Trees, shrubs, and perennial or (rarely) annual herbs with simple or compound, mostly stipulate leaves, the seeds, bark, and leaves with abundant hydrocyanic acid, as well as amygdaiin, prunasin, prulaurasin; chromosomes 7, 8, 9, or 17 in each egg and sperm cell. Flowers usually complete, sometimes apetalous (without petals), mostly perigynous, rarely epigynous or almost hypogynous, usually with a disk, the hypanthium flat, cupular, urceolate (urn-shaped), or tubular; perianth mostly 5-parted, rarely 3- or 4- or more than 5-parted, the calyx (sepals) sometimes with an outer calyx of an equal number of alternating members; stamens indefinite in number, or 2 to many times as many as the sepals, arranged in 2 or more series, stamens rarely equal in number to the sepals or only 1; carpels numerous to only 1, mostly free at the base of a concave floral cup or of the expanded, invaginated apex of the floral axis, 1- or (rarely) incompletely 2-celled; ovules 2 or 1, infrequently several or numerous, anatropous (inverted and straight), rarely almost orthotropous (erect); fruit a follicle, achene, or drupe, sometimes united with the floral cup or expanded floral axis to form a compound fruit; endosperm sparse or lacking, rarely abundant. About 100 genera and 3,000 species, almost cosmopolitan, mostly in temperate zones, especially richly developed in the Northern Hemisphere.

Subfamily Spiraeoideae

Shrubs, rarely trees, perennial herbs, or half-shrubs, stipules often lacking; carpels 1 to 8 but mostly 5, free or incompletely connate (fused) basally or rarely higher, sometimes adnate (joined) dorsally to the inner wall of the more or less concave floral cup, which is bowl- or bell-shaped, rarely almost plane, the ovules 2 to numerous, arranged in 2 rows; fruits mostly follicles, rarely achenes or capsules. Seventeen genera in South America, Mexico, North America, Siberia, Asia, and Malaysia.

Subfamily Rosoideae

Shrubs or perennial herbs, rarely trees or annual herbs; carpels few to many, free on the expanded, capitate to more or less cylindric floral axis, or the carpels basal, mostly free but rarely weakly united with each other and with the floral cup, the ovules 1 or rarely 2, mostly with only 1 integument; fruit an achene, rarely a drupe, often united in a compound structure with the remnants of the floral cup or of the swollen axis apex. About 34 genera and 2,000 species, in most temperate to subarctic areas of the world.

Subfamily Maloideae

Shrubs or trees with simple, distinctly stipulate leaves; carpels 2 to 5, dorsally united to varying extent with the inner wall of the hollow floral tube, free among themselves or at most only incompletely connate, sometimes the carpels incompletely 2-celled by development of false walls, the styles free or (rarely) more or less united, the ovules erect-apotropous and mostly 2, rarely 1 or 3 per carpel, or horizontal and 20 to 24 per carpel; floral cup thickened at maturity in a more or less fleshy compound fruit enclosing the carpels. About 14 genera and 600 species in temperate Asia, East Indies, Mexico and Central America, and in North America.

Subfamily Prunoideae

Trees or shrubs with simple leaves, the stipules often small and deciduous, hydrocyanic-acid-derived glycosides often present; petals sometimes absent; carpel 1, very rarely 2 or 5, free at the base of the flat, bowl-shaped to tubular floral cup, the styles usually terminal, the ovules usually 2, pendulous; fruit a drupe with succulent, rarely leathery, mesocarp (middle layer of fruit tissues) and almost always a stony endocarp (internal layer of fruit tissues), the seeds solitary or exceptionally 2 in 1 carpel. Three genera with about 100 species, mostly in the North Temperate Zone, especially in east Asia; also in the Old World tropics.

Family Neuradaceae

Prostrate, sympodially branching (with 1 fork of a dichotomy assuming the status of the main plant axis), annual, xerophytic (with dry-habitat adaptations) herbs with lobed or sinuate (wavy-margined) simple, alternate leaves, the stipules mostly lacking; flowers solitary, 5-parted, more or less epigynous; carpels connate with each other and adnate with the inner wall of the mature, dry floral cup, the ovary (because of bisection of each carpel) 10-celled, with 10 persistent, indurate (hardened) styles, the ovules 1 or 2 in each cell, apotropous, the seeds lacking endosperm, germinating within the fruit. Three genera with 10 species in Africa and northwest India.

Family Chrysobalanaceae

Trees and shrubs, rarely half-shrubs with alternate, sometimes 2-ranked, almost always stipulate leaves; flowers rather inconspicuous, usually in various kinds of inflorescences but rarely solitary, mostly perigynous, the floral tube cupular to tubular, mostly with a disk, the perianth 5-parted or the petals sometimes absent; stamens many to 2, sometimes in concentric circles of 5 to 10 stamens in each; in irregular flowers the stamens often rudimentary and staminodial (sterile or partly so) on the side of the flower opposite to the ovary, the filaments free or more or less united; carpels 3 or 2, of which only 1 usually develops, the ovary rarely central, almost always unilateral and excentric because of the lateral union of the more or less elongate gynophore (stipe or stalk of the ovary) with the floral cup, the carpel 1-celled, rarely 2-celled by the development of a false wall, the style basal, sometimes with an indistinctly 3-lobed stigma. About 12 genera and 300 species, pantropical but mostly in the Amazon region of South America.

Critical appraisal. This classification, as noted earlier, is a most conservative one, differing from others in the few families included in the order. The difficulty in extending the ordinal concept beyond these three families is that distinctiveness of the order is lost as family after family is added. This treatment is based on what appears to be a logical point of separation from related families. Some recent authors include up to 19 families, some of which are subdivided by other workers into still other families. Solution of this situation may not be possible in a manner satisfactory to even the majority of botanists. Much of the present lack of agreement is based on the interpretation of abundant data of many kinds. Biochemical, paleobotanical, and anatomical researches perhaps hold greatest promise for further refinement of the order.

Rosenzweig, Franz

Franz Rosenzweig, German-Jewish religious existentialist, was one of the most influential modern Jewish theologians. He was born December 25, 1886, in Kassel, Germany, the only child of Georg and Adele (*née* Alsberg) Rosenzweig. His father was a well-to-do dye manufacturer and member of the city council; his mother, a deeply sensitive and cultured woman. Franz grew up in an environment of civic responsibility and cultivation of literature and the arts; religious beliefs and observance were no longer evident, beyond perfunctory participation on some occasions. In his university days the gifted young man first started to study medicine (at Gottingen, Munich, and Freiburg) but after a few semesters turned to his real interest: modern history and philosophy (at Berlin and Freiburg). In 1910 he embarked on a study of Hegel's political doctrines. His doctoral dissertation (1912) was to become a section of *Hegel* und der *Staat* ("Hegel and the State"), a comprehensive work completed some years later. Yet while steeped in this research, Rosenzweig developed a critical attitude toward Hegel's overemphasis on history and his treatment of the individual person's life as irrelevant to the "whole." In rejecting Hegel, Rosenzweig opposed the philosophic movement known as German Idealism, with its attempt to construct reality out of abstract concepts. Increasingly he tended toward an "existential" philosophy that found its starting point in the experience and concerns of the concrete individual person.

Rejection of Hegel

Rosenzweig, death mask, 1929.

Some of his friends (especially the jurist and historian Eugen Rosenstock-Huessy), who were equally critical of the academic philosophy of the day, had found the solution to the problem of man in religious faith (specifically, conversion to Christianity) and in a dialogical relationship between man and God. After an intense inner struggle Rosenzweig decided in July 1913, to relinquish his Jewish heritage (barely known to him), to accept his friends' interpretation of modern Protestantism as an existential, dialogical faith, and to undergo Baptism. At this critical point in his life, however, he attended the Day of Atonement service in a small, traditional synagogue in Berlin (October 11, 1913). The liturgy of this fast day focusses on the motifs of human sinfulness and divine forgiveness, the realization of life as a standing before God, the affirmation of the oneness of God and of his love, The drama of the liturgy had a powerful effect on Rosenzweig. What he thought he could find only in the church—faith providing an orientation in the world—he found that day in the synagogue. He felt he had to remain a Jew. There followed a period of self-examination to determine whether the emotional experience of that Day of Atonement would stand up to rational criteria. After this clarification, Rosenzweig was determined to devote his life to the study, teaching, and practice of Judaism. The academic year 1913–14 was entirely devoted to an intensive reading of classical Hebrew sources and to attending lectures by Professor Hermann Cohen, an eminent German-Jewish thinker, the founder of the Neo-Kantian school in philosophy.

The making of *The Star of Redemption*

With the outbreak of World War I, Rosenzweig joined the armed forces and spent most of the duration of the war at the Balkan front, in an anti-aircraft gun unit. The not-too-demanding service allowed Rosenzweig time for study and writing. In 1916–17 he engaged in an exchange of letters with Rosenstock-Huessy on core theological problems in Judaism and Christianity, published in *Judentum und Christentum* (Eng. trans., *Judaism Despite Christianity,* 1969), wrote newspaper articles on political and strategic questions, drew up a plan for a reform of the German school system, and wrote "Zeit ist's" ("It Is Time"), a program for a reorganization of Jewish education and scholarship (included in *On Jewish Learning,* 1955). In 1918, while attending an officers' training course near Warsaw, in German-occupied Poland, he had opportunity to observe the life and the customs of east European Jews and was deeply impressed by the vitality and richness of their faith. Upon returning to the trenches he felt ready to embark on what was to become his magnum opus: an existentialist religious philosophy demonstrating the mutual relationships between God, man, and the world. This "new thinking" is based on human experience, common sense, and the reality of language and dialogue. The central point of the architectonically arranged work in which this thought is expressed is the act of "revelation" in which God in his love turns to man and awakens within him the consciousness of an "I." *Der Stern der Erlösung,* completed in 1919, appeared in 1921 (Eng. trans., *The Star of Redemption,* 1971). The work has been ignored by the various trends in academic philosophy, but highly regarded by existentialist and, especially, younger Jewish theologians.

The paralytic years

In early 1920 Rosenzweig married Edith Hahn of Berlin and wrote "Bildung und kein Ende" (included in On *Jewish Learning* as- "Towards a Renaissance of Jewish Learning"), outlining a plan for a Jewish adult study centre. Later in the year he was appointed head of such a centre (the Freies Jiidisches Lehrhaus) in Frankfurt am Main. There students were encouraged to examine classical Hebrew sources, searching for what is vital and relevant. The school became a model for similar institutions elsewhere in Germany. Rosenzweig's active directorship did not last long; early in 1922 he was afflicted with a progressive paralysis (from a form of sclerosis). In September 1922 his son Rafael was born. The child brought comfort to the father, whose paralysis affected his whole body, including the vocal organs. In a true heroism of the spirit, although unable to speak or write in a direct physical sense, he managed to continue living as an active scholar, writer, and friend, deeply concerned for his fellowman and community. With the help of his wife, a system of signals between them, and a specially constructed typewriter, he produced important essays and an annotated German version of the medieval Hebrew poetry of Judah ha-Levi. From 1925 on he embarked, together with Martin Buber, the eminent German-Jewish philosopher and biblical interpreter, on a new German translation of the Hebrew Bible (Old Testament). The translation occasioned a series of articles by him on aspects of biblical thought and style. As a hobby he also wrote reviews of records of classical and sacred music. Nowhere in these works of his paralytic years did the reader detect that the author was mortally ill. Everywhere in them there is evidence of a fresh, keen spirit, intellectual clarity, religious faith, and a sense of humour. He died at Frankfurt on December 10, 1929. His influence on Jewish religious thought grew remarkably in the decades after his death.

(N.N.G.)

Rossetti Family

An Anglo-Italian family in Victorian England, the Rossettis formed a remarkable group. All its members were endowed with unusual intelligence, were equally at home with the languages and literary traditions of both England and Italy, and were united among themselves by close ties of affection and mutual understanding. The talents and characteristics they shared were combined with creative gifts of a high order in Dante Gabriel Rossetti and his sister Christina Georgina Rossetti, both of whom wrote inspired poetry. The literary critic Sir Edmund Gosse did not exaggerate in acclaiming Christina as "[a] wonderful woman who stands almost alone in the forefront of the world's female poets." Dante Gabriel Rossetti was not only both poet and painter but was also possessed of great personal magnetism. His creation of a stimulating intellectual climate, his divination and encouragement of talent in others, and his poetry cast him in a role in England comparable with that of the poet Charles Baudelaire in France.

The elder Rossettis. The father of Dante Gabriel and Christina was Gabriele Pasquale Giuseppe Rossetti, an exiled Italian patriot and man of letters. Born in 1783 at Vasto in the Abruzzi, he was the son of a blacksmith and was clever enough to be able to study at the University of Naples. In 1807 he was librettist at the San Carlo opera house in Naples and was later appointed curator of Ancient Marbles and Bronzes in the Museo e Gallerie Nazionale di Capodimonte, Naples.

Gabriele frequently improvised spirited verses on contemporary politics; one indignant outburst directed against Ferdinand II, the tyrant king of Naples who had revoked the Constitution in 1821, added to Gabriele's membership in the revolutionary society Carbonari, provoked the sentence of death.

After a time in hiding, he escaped to England via Malta in 1824. There he supported himself by giving Italian lessons and in 1831 was appointed professor of Italian at King's College, London, a post he held until 1847, when his sight was seriously impaired. When Gabriele became professor, he received fellow exiles, busied himself with propaganda for a liberally governed and united Italy, and—studying the writings of Italy's 14th-century national poet Dante Alighieri-elaborated a theory of Dante's profound symbolic meaning (*La Beatrice di Dante,* 1842). His love of Italian poetry and in particular his reverence for Dante's *La vita nuova* and *La divina commedia* were transmitted to Gabriele's sons and daughters.

In 1826 he had married Frances Mary Lavinia Polidori, deemed the cleverest and best looking of four daughters of another Italian teacher and man of letters, Gaetano Polidori, Tuscan by birth but Londoner by adoption. Since Polidori had married an English girl, it is possible to consider the children of Gabriele and Frances as three parts Italian and one part English. Frances wished for a husband and children distinguished by intellect—yet later remarked that, though her wish had been granted, she could have done with "a little less intellect in the family so as to allow for a little more common sense!"

The Rossetti children

There were four Rossetti children: Maria Francesca (born February 17, 1827–died November 24, 1876); Gabriel Charles Dante, who later called himself Dante Gabriel (born May 12, 1828–died April 9, 1882); William Michael (born September 25, 1829–died February 2, 1919); and Christina Georgina (born December 5, 1830–died December 29, 1894). All were born in London and baptized in the Church of England.

The younger Rossettis. *Maria.* Maria, who for a long time taught Italian and was a household authority on niceties of grammar and translation, also produced a scholarly commentary, *A Shadow* of *Dante* (1871). Dante's conception of a spiritual and ideal love strongly influenced Maria's brother Dante Gabriel.

Dante Gabriel. After a general education in the junior department of King's College (1836–41), where he may have had lessons from the watercolourist John Sell Cotman, he hesitated between poetry and painting as a vocation. When about 14 he went to "Sass's," an old-fashioned drawing school in Bloomsbury (Central London), and thence, in 1845, to the Royal Academy schools, where he became a full student.

Meanwhile, he read omnivorously—romantic and poetic literature, Shakespeare, Goethe, Byron, Scott, and Gothic tales of horror. He was fascinated by the work of the American writer Edgar Allan Poe, and a dramatic illustration of Poe's poem "The Raven" was one of a number of early drawings inspired by his reading. In 1847 he discovered the 18th-century English painter, poet, and visionary William Blake through the purchase of a volume of Blake's designs and writings in prose and verse; the volume has since been known as the Rossetti MS. The diatribes of Blake against the painter and art critic Sir Joshua Reynolds delighted Rossetti and encouraged him to attempt lampoons of his own against convention and the triviality of early Victorian paintings of anecdotal subjects, those of Sir Edwin Landseer being a special target of his derision.

By the time he was 20, he had already done a number of translations of Italian poets and had composed some original verse, but he was also much in and out of artists' studios and for a short time was (in an informal way) a pupil of the painter Ford Madox Brown. He acquired some of Brown's admiration for the German "Pre-Raphaelites," nickname of the austere Nazarenes, who had sought to bring back into German art a pre-Renaissance purity of style and aim. It remained to initiate a like reform in England.

Aims of the Pre-Raphaelites

Largely through Rossetti's efforts, the English Pre-Raphaelite Brotherhood was formed in 1848 with seven members, all Royal Academy students except for William Michael Rossetti. They aimed at "truth to nature," which was to be achieved by minuteness of detail and painting from nature outdoors. This was, more especially, the purpose of the two other principal members, William Holman Hunt and John Everett Millais. Rossetti expanded the Brotherhood's aims by linking poetry, painting, and social idealism and by interpreting the term Pre-Raphaelite as synonymous with a romanticized medieval past.

In this the High Church movement, leaning toward the ritual and ornament of the Gothic period, influenced him, its aesthetic aspect attracting him apart from any question of religious belief. He entitled his manuscript poems *Songs of an Art-Catholic;* and, while his first two oil paintings—"The Girlhood of Mary" and "Ecce Ancilla Domini" ("The Annunciation")—were simple in style, they were elaborate in symbolism. The "art-catholic" appears, though not with any specifically religious intent, in the rich word-painting and emotional force of his poem "The Blessed Damozel," published in 1850 in the first issue of *The Germ,* the Pre-Raphaelite magazine.

Poor engravings of 14th- and 15th-century frescoes in the Campo Santo at Pisa had vaguely suggested an ideal for the Brotherhood to follow. But Rossetti gained a better idea of the past from seeing the work of the early Flemish masters at Bruges, which he visited in company with William Holman Hunt in 1849.

Exhibited in 1850, "Ecce Ancilla Domini" received severe criticism, which Rossetti could never bear with equanimity. In consequence, he ceased to show in public and gave up oils in favour of watercolours, which he could more easily dispose of to personal acquaintances. He also turned from traditional religious themes to scenes from Shakespeare, Robert Browning, and Dante, which allowed more freedom of imaginative treatment. After 1856 he was led by Sir Thomas Malory's *Morte Darthur* and Tennyson's *Idylls of the King* to evoke an imaginary Arthurian epoch, with heraldic glow and pattern of colour and medieval accessories of armour and dress.

The 1850s were eventful years for Dante Gabriel Rossetti. They began with the introduction into the Pre-Raphaelite circle of the beautiful Elizabeth Siddal, who served at first as model for the whole group but was soon attached to Rossetti alone and, in 1860, married him. Many portrait drawings testify to his affection for her.

Second phase of Pre-Raphaelite movement

In 1854 he gained a powerful but exacting patron in the art critic John Ruskin. By then, as Christina Rossetti signalized in some quietly humorous verses, the Pre-Raphaelite Brotherhood was at an end, splintered by the different interests and temperaments of its members. But Dante Gabriel Rossetti's magnetic personality aroused a fresh wave of enthusiasm. His contributions to the Oxford and Cambridge magazine in 1856 brought him into contact with the then Oxford undergraduates Edward Burne-Jones and William Morris. With these two young disciples he initiated a second phase of the Pre-Raphaelite movement. The two main aspects of this fresh departure were a romantic enthusiasm for a legendary past instead of the realism of "truth to nature" and the ambition of reforming the applied arts of design. Rossetti's influence not only led to easel pictures illustrating Arthurian legend but also into other fields of art. A new era of book decoration was foreshadowed by Rossetti's illustration for the Moxon edition of Alfred Lord Tennyson's *Poems* (1857). His commission in 1856 to paint a triptych ("The Seed of David") for Llandaff Cathedral was a prelude to the ambitious scheme of 1857 to decorate the Oxford Union debating chamber with mural paintings of Arthurian themes.

Though Rossetti and his helpers (Burne-Jones, Morris, and others) failed through want of technical knowledge and experience, the enterprise was fruitful in suggesting that the scope of art could be expanded to include the crafts. The idea of an association to make by hand objects of practical use superior to the mechanical products of Victorian industry became Morris' great ambition. The outcome, in 1861, was a firm of "fine art workmen." The firm known as Morris, Marshall, Faulkner & Co. depended mainly on Morris, Burne-Jones, Rossetti, the architect Philip Web, and Madox Brown for the design of stained glass, wallpapers, chintzes, tiles, embroideries, and furniture. Although Morris was the moving spirit, Rossetti's designs for stained glass for a number of new churches were among the early successes of the firm.

William Michael. Meanwhile, the support of the Rossetti family devolved upon Dante Gabriel's brother William Michael Rossetti. Since 1845, when at the age of 16 he became a clerk in the Excise (later Inland Revenue) Office at £80 a year, he had been a mainstay. His appointment as art critic to *The Spectator* magazine *in* 1850 and subsequent modest advancement in the civil service enabled him, in 1854, to establish his father, mother, and two sisters in a more comfortable home. His mother and his sister Maria helped by giving lessons in Italian, though efforts to start a school, first in Camden Town and then at Frome in Somerset, came to nothing.

William Michael was 45 when he married, in 1874, and would have continued to keep his mother and Christina as part of his household if his wife, Lucy, daughter of Ford Madox Brown, had not demurred. But, though quietly self-sacrificing in the family interest, he was by no means a nonentity. He had sterling qualities as a critic and Pre-Raphaelite historian. Independent in judgment, he hailed Walt Whitman's controversial *Leaves of Grass* (1855) as a work of genius, in spite of the scoffing remarks of his brother Dante Gabriel. His enthusiasm for Blake was no less great than Dante Gabriel's. He was the judicious editor of numerous collections of the work of English poets and could make learned comparison between such medieval writers as Geoffrey Chaucer and Giovanni Boccaccio. He dealt conscientiously with a vast amount of family correspondence and material relating to Pre-Raphaelism and his brother's place in the movement, proving himself an indispensable chronicler.

Christina. If William Michael was in many ways a contrast to Dante Gabriel—in his calm and rational outlook, financial prudence, and lack of egotism, for example—Christina Rossetti in certain ways resembled the elder brother. She, too, was a born poet. No invasion of Polidori aunts could distract her from the exquisite lines she often wrote while standing at the washstand of her bedroom. Like Dante Gabriel, she combined a melancholy and tormenting conscience with a lively sense of humour and a keen critical perception. She suffered much from ill health and, in the 1870s, from the painful and disfiguring Graves' disease (a disease of the thyroid gland); but religious scruple also caused suffering.

Effectof religion on the family

Religion affected the members of the family differently. William Michael, who had imbibed Gabriele's antipapalism, disliked and rejected religion in any form. On the other hand, Maria Francesca was devout, with a yearning toward convent life that impelled her to join the (Anglican) Community of All Saints three years before her death, which occurred in 1876. Christina was haunted by an ideal of spiritual purity that demanded self-denial. This, perhaps combined with a sectarian strictness, has been suggested as the reason for her never having married. There may have been other reasons, too, but ostensibly she broke off her engagement to James Collinson, a painter whom her brother had introduced into the Pre-Raphaelite Brotherhood, because he left the Church of England and became a Roman Catholic. Fourteen years later, in 1864, she refused Charles Bagot Cayley, one of her father's old pupils, supposedly because he had no religious belief, though they remained on friendly terms until Cayley's death, in 1883.

Christina began to write poetry at an early age; the verses written before she was 17 were printed in 1847 on Gaetano Polidori's private press. The transience of material things is a motif that recurs throughout her poetry. The verses beginning "Passing away, saith the World, passing away," from *Old and New Year Ditties 111,* were hailed by the poet Algernon Swinburne as "the noblest of sacred poems in our language." The title poems of two major collections, *Goblin Market . . .* (1862) and *The Prince's Progress . . .* (1866), are more than fairy tales: the vendors of magic fruit in the one are symbols of temptation; the "progress" in the other represents the pilgrimage and trials of the soul.

Dante Gabriel's later years. From 1860 onward, such trials were part of Dante Gabriel's much disturbed life. His marriage to Elizabeth Siddal, clouded by her constant ill health, ended tragically in 1862 with her death from an overdose of laudanum. Grief led him to bury with her the only complete manuscript of his poems. That he considered his love for his wife similar to Dante's mystical and idealized love for Beatrice is evident from the symbolic "Beata Beatrix," painted in 1863.

Dante Gabriel's life and art were now greatly changed. He moved from riverside premises in London's Blackfriars to Chelsea. The influence of new friends—Swinburne and the American painter James McNeill Whistler—led to a more aesthetic and sensuous approach to art. Literary themes gave way to pictures of mundane beauties, such as his model and mistress of long standing, Fanny Cornforth, gorgeously apparelled and painted with a command of oils he had not previously shown. These paintings were popular, and Rossetti grew affluent enough to employ studio assistants to make copies and replicas. He collected antiques and filled his large, ill-kept Chelsea garden with a menagerie of animals and birds. He had enjoyed a modest success in 1861 with his published translations, *The Early Italian Poets;* and, toward the end of the 1860s, when his weakening eyes inclined him to give up painting for a while, his thoughts turned to poetry again. At that time, he and Christina were frequent visitors to Penkill Castle in Scotland, home of their friend Alice Boyd. There Dante Gabriel composed new poems and planned the recovery of the manuscript poems buried with his wife in Highgate Cemetery. Carried out in 1869 through the agency of his unconventional man of business, Charles Augustus Howell, the exhumation visibly distressed the superstitious Dante Gabriel. Publication followed in 1870. The *Poems* were well enough received until a misdirected, savage onslaught by "Thomas Maitland" (pseudonym of the journalist-critic Robert Buchanan) on "The Fleshly School of Poetry" singled out Rossetti for attack. Rossetti responded temperately in "The Stealthy School of Criticism," published in the *Athenaeum;* but the attack, combined with remorse and the amount of chloral and alcohol he now took for insomnia, brought about his collapse in 1872. He recovered sufficiently to paint and write, though the last ten years of his life were passed in semi-invalid seclusion. Until 1874 he spent much time at Kelmscott Manor (near Oxford), of which he took joint tenancy with William Morris in 1871. His lovingly idealized portraits of Jane Morris at this period were a return to his more poetic and mystical style. But his links with Morris were severed when the Pre-Raphaelite shareholders in his firm were bought out in 1875, the firm becoming simply Morris & Co. Dante Gabriel's life in Chelsea was subsequently that of a recluse, varied only by visits to his mother and sister and the company of his old friend Ford Madox Brown, a number of late disciples, and Theodore Watts-Dunton, a lawyer and man of letters who did his best to put Rossetti's financial affairs in order. He occupied himself with a replica of an early watercolour, "Dante's Dream" (1880), a revised edition of *Poems* (1881), and *Ballads and Sonnets,* containing the completed sonnet sequence of "The House of Life," in which he described the love between man and woman with tragic intensity. From a visit to Keswick (in northwest England) in 1881, he returned in worse health than before. He died on April 9, 1882, at Birchington-on-Sea (in southeast England), tended at the last by members of the family and a few loyal intimates.

John Ruskin described Dante Gabriel Rossetti as "a great Italian lost in the Inferno of London," though in fact he was never happy out of London and never visited Italy. With his appreciation of Italian poetry went a mastery of the various forms and rhythms of English as a poetic medium, ranging from the ballad style to the philosophical reflections of *The Burden of Nineveh* (1856). Quite different in tone is the easy and genial style of his intimate correspondence, which ranks him among the great letter writers. As a painter he claims respect, in present-day perspective, as the initiator of a form of symbolism influential in continental Europe as well as England and as a catalyst in the development of the concept of design.

MAJOR WORKS

Christina Rossetti

POETRY: *Goblin Market and Other Poems* (1862); *The Prince's Progress and Other Poems* (1866); *Sing-Song: A Nursery Rhyme Book* (1872, enlarged 1893); *A Pageant and Other Poems* (1881); *Verses* (1893); *New Poems* (1896); *Poetical Works* (1904).

OTHER WORKS: *Commonplace and Other Short Stories* (1870); *Annus Domini* (1874), a book of prayers; *Seek and Find* (1879), religious meditations; *Time Flies* (1885), a reading diary of mixed verse and prose; *The Face of the Deep* (1892). a commentary on the Apocalypse.

~anteGabriel Rossetti

POETRY: "The Blessed Damozel," with six sonnets and four lyrics in *The Germ,* the Pre-Raphaelite periodical (1850); *The Early Italian Poets from Ciullo d'Alcamo to' Dante Alighieri (1100–1200–1300) in the Original Metres Together with Dante's Vita Nuova* (1861); *Poems* (1870); *Ballads*

and Sonnets (1881), including "The House of Life," "The White Ship," and "The King's Tragedy."

PAINTINGS: "The Girlhood of Mary" (1849; Tate Gallery, London); "Ecce Ancilla Domini" ("The Annunciation"; 1850; Tate Gallery, London); "Found" (1854; Samuel and Mary R. Bancroft Pre-Raphaelite Collection, The Wilmington Society of the Fine Arts, Wilmington, Delaware); "Paolo et Francesca" (1855; Tate Gallery, London); "The Tune of the Seven Towers" (1857; Tate Gallery, London); "The Wedding of St. George and Princess Sabra" (1857; Tate Gallery, London); "Arthur's Tomb" (1860; Tate Gallery, London); "Beata Beatrix" (*c.* 1863; Tate Gallery, London); "Monna Vanna" (1866; Tate Gallery, London); "Dante's Dream" (1871; Walker Art Gallery, Liverpool); "The Blessed Damozel" (1871–79; Lady Lever Art Gallery, Port Sunlight, England); "The Bower Meadow" (1872; City of Manchester Art Galleries); "Proserpine" (1874; Tate Gallery, London); "Astarte Syriaca" (1877; City of Manchester Art Galleries).

OTHER ART WORKS: "How They Met Themselves" (1851–60; Fitzwilliam Museum, Cambridge), drawing; "Portrait of Miss Siddal" (1855; Ashmolean Museum, Oxford); "Maids of Elfinmere" (1855; wood engraving, engraved by Dalziel); "The Palace of Art," sometimes called "St. Cecilia" (1857; engraved by Dalziel), wood engraving; decoration of the Oxford Union with William Morris and Sir Edward Burne-Jones (1857, now largely obliterated). The major collection of Rossetti's drawings is in the City Art Gallery, Birmingham.

Gabriele Rossetti

Two volume commentary on the ***Divina Commedia*** (unfinished, 1825 and 1826); ***Sullo spirito antipapale che produsse la Reforma . . .*** (1831); ***Disquisition on the Antipapal Spirit which Produced the Reformation: Its Secret Influence on the Literature of Europe in General, and of Italy in Particular,*** trans. by C. Ward, 2 vol., 1834); ***Iddio e l'uomo, salterio*** (1833), poems; ***Il mistero dell'amor platonico nel medio evo,*** 5 vol. (1840), a philosophico-literary treatise; ***La Beatrice di Dante*** (1842; complete ed., 1935), study of Dante; ***Il Veggente in solitudine poema polimetro*** (1846; ***A Versified Autobiography,*** trans. by W.M. Rossetti, 1901); ***Versi*** (1847); ***L'Arpa evangelica*** (1853), lyrics; ***La vita mia*** and ***Opere inedite e rare*** (1910; 3 vol., 1931, both ed. by D. Ciampoli).

William Michael Rossetti

Inferno (1865), blank verse translation; ***Fine Art, Chiefly Contemporary: Notices Reprinted with Revisions*** (1867), art criticism; ***Troylus and Cryseyde*** (1875), parallel text to Chaucer; ***Filostrato*** (1883), parallel text to Boccaccio; ***Ruskin: Rossetti: Preraphaelitism. Papers 1854–62*** (1899); ***Preraphaelite Letters and Diaries*** (1900); ***Dante and His Convito: A Study with Translations*** (1910).

BIBLIOGRAPHY. A comprehensive bibliographical reference to members of the family is contained in WILLIAM E. FREDEMAN, ***Pre-Raphaelitism: A Bibliocritical Study*** (1965). Of primary importance for the study of Rossetti's art is VIRGINIA SURTEES, ***The Paintings and Drawings of Dante Gabriel Rossetti: A Catalogue Raisonné,*** 2 vol. (1971). Another standard work is H.C. MARILLIER, ***Dante Gabriel Rossetti*** (1899). Kelmscott Manor, now restored by the Society of Antiquaries, recalls the joint tenancy of Rossetti and Morris in many details of furnishing and decoration. Major editions of literary works are: ***The Works of Dante Gabriel Rossetti,*** rev. ed. by WILLIAM MICHAEL ROSSETTI (1911); and ***The Poetical Works of Christina Rossetti,*** ed. with memoir and notes by W.M. ROSSETTI (1904, reprinted 1971). R.D. WALLER, ***The Rossetti Family (1932),*** is an account of Gabriele Rossetti and the family in his lifetime (1824–54). The nearest complete collection of D.G. Rossetti's correspondence published to date is the ***Letters of Dante Gabriel Rossetti,*** ed. by OSWALD DOUGHTY and J.R. WAHL, 4 vol. (1965–67). W.M. ROSSETTI edited and added a memoir to ***The Family Letters of Dante Gabriel Rossetti,*** 2 vol. (1895, reprinted 1970) and ***The Family Letters of Christina Georgina Rossetti*** (1908, reprinted 1968). Numerous selections of letters and reminiscences illuminate different phases of D.G. Rossetti's career; the letters and diaries arranged by W.M. ROSSETTI in ***Ruskin: Rossetti: Preraphaelitism. Papers 1854–62*** (1899, reprinted 1971), give a vivid commentary on Ruskin as patron, Madox Brown as friend, and Miss Siddal as an inspiration. H. TREFFRY DUNN, ***Recollections of Dante Gabriel Rossetti and His Circle*** (1904, reprinted 1971), describes the Cheyne Walk (Chelsea) period when Dunn was Rossetti's assistant. WILLIAM BELL SCOTT, ***Autobiographical Notes . . . , 2*** vol. (1892, reprinted 1970), gives somewhat unkind emphasis to Rossetti's disturbed condition at Penkill and subsequent collapse. THOMAS GORDON HAKE, ***Memoirs of Eighty Years*** (1892), includes reminiscences of Rossetti by his doctor friend. JANET CAMP TROXELL (ed.), ***Three Rossettis*** (1937), studies the brothers and sister through their letters and has much interesting detail of the stay at Penkill and the arrangements for exhuming Rossetti's manuscript poems. HALL CAINE, ***Recollections of Dante Gabriel Rossetti*** (1882), describes the reclusive last years. His letters, often grotesquely amusing, to Fanny Cornforth were edited by P.F. BAUM (1940); in the biographies of other Pre-Raphaelites, D.G. Rossetti inevitably figures. The unsympathetic view of him in EVELYN WAUGH, ***Rossetti: His Life and Works*** (1928), was followed by the overt hostility of VIOLET HUNT in ***The Wife of Rossetti*** (1932). Against this prejudice HELEN ROSSETTI ANGELI, daughter of W.M. Rossetti, came to her uncle's defense in ***Dante Gabriel Rossetti: His Friends and Enemies*** (1949). OSWALD DOUGHTY, ***A Victorian Romantic: Dante Gabriel Rossetti,*** 2nd ed. (1960), is an effort to give overall proportion. LONA MOSK PACKER, ***Christina Rossetti*** (1963), supplements the ***Life*** by MACKENZIE BELL of 1898 with fresh research and revised psychological analysis.

(W.Ga.)

Ross Ice Shelf

The world's largest tabular body of floating ice, the Ross Ice Shelf lies at the head of Ross Sea, an enormous indentation in the continent of Antarctica far beyond the waters of the South Pacific. The ice shelf lies between about 155° W and 160" E longitude; and about 78" S and 86" S latitude. Estimates of its area range from about 192,000 to 208,000 square miles (496,000 to 540,000 square kilometres), making it approximately the size of France. The shelf has had considerable historic importance, having served as a gateway for explorations of the Antarctic interior, including those carried out by many of the most famous expeditions. The behaviour of such a vast sheet of ice is of exceptional interest to scientists for the light it sheds on such matters as the formation of icebergs, and the glacial budget of Antarctica, and also because its movements are analogous to those of huge geological formations. For those familiar with the region, the whole vast area has an austere but magnificent beauty. (For related information, see ROSS SEA; ANTARCTICA; ICEBERGS AND PACK ICE.)

Exploration. The great white barrier wall of the shelf's front, first seen in 1841 by the British rear admiral and polar explorer James Clark Ross, rises in places to 160 or 200 feet high and stretches about 500 miles between fixed "anchor points" on Ross Island to the west and the jutting Edward VII Peninsula on the east. With its immense, gently undulating surface reaching back nearly 600 miles southward into the heart of Antarctica, the ice shelf provides the best surface approach into the continental interior. The McMurdo Sound region on the west thus became headquarters for British expeditions in the early 1900s, including R.F. Scott's 1911–1912 epic sledging trip to the South Pole. In the early 1960s, it was the site of the headquarters of the United States Antarctic Research Program (USARP), the United States Navy's Operation Deep Freeze, and the New Zealand Antarctic Research Program. Eastern barrier regions were headquarters for the Norwegian Roald Amundsen's first attainment of the South Pole on December 14, 1911; for Richard E. Byrd's three U.S. expeditions of 1928–41 at Little America I–III stations; for the U.S. naval expedition Operation High Jump at Little America IV in 1946–47; for U.S. International Geophysical Year expeditions at Little America V in 1955–57; and for summer research groups in the 1960s.

The shelf as a base for expeditions

Physiography and glaciology. The Ross Ice Shelf lies between spectacular, clifflike escarpments of the central Transantarctic Mountains on the west and the grounded West Antarctic ice sheet on the east. Ranges more than 13,000 feet in elevation, including the Royal Society and Queen Alexandra ranges and the Queen Maud Mountains, form an enormous bedrock "dam" holding back the high polar-ice sheet of East Antarctica. The dam is breached at a number of places so that polar ice locally escapes in spectacular giant ice streams, principally the Byrd, Beardmore, Mulock, Nimrod, Scott, Amundsen, Ready, and Liv glaciers, to feed the ice shelf below. Byrd Glacier, the largest, flows at 7.5 feet per day, making it the fastest known Antarctic valley glacier.

The Ross Ice Shelf has been likened to a vast triangular raft, relatively thin and flexible and only loosely attached to adjoining lands. It appears from the air as an incredibly vast flat plain, disturbed here and there by intensely crevassed areas (marking local grounded-ice conditions, or zones of differential shear where physical forces have torn the ice apart). Pioneering studies on ice-sheet seismology, made on Byrd's second Antarctic expedition (1933–35), demonstrated that a large northeastern section of the shelf (Roosevelt Island) is actually grounded. Gentle tidal changes continually break the shelf ice from moorings to grounded ice, thus forming around the inland margin of the shelf a system of filament-like "strand" cracks that are continually rehealed by freezing of intruded seawater. Giant rifts develop behind the barrier and occasionally rupture completely to spawn the huge tabular icebergs that are so characteristic of the Antarctic Ocean. (Little America I–IV stations, in Bay of Whales calved in this manner and disappeared by 1954.)

Movement and deformation of shelf ice

The shelf ice, confined between walls, moves seaward by spreading as a result of both surface accumulation and an input of land ice. The ice (which may, in fact, be technically defined as an easily deformable crystalline rock) buckles where the shelf impinges against the bedrock buttresses of Roosevelt and Ross islands. Under compression, the ice is deformed into the great upwarped and downwarped structures known, respectively, as anticlines and synclines, as well as a great variety of faults and joints that duplicate those seen in more familiar crustal rocks.

Although the barrier's position appears almost stationary, it actually undergoes continual change by calving and melting that accompany northward movement of the shelf ice. The net mass budget of Ross Ice Shelf (a technical expression that reflects the net surface ice accumulation plus the inflow of land ice plus the increments by bottom freezing; less, on the other hand, the loss by calving, surface melting, and bottom melting) seems to be in approximate equilibrium, but some factors, particularly bottom melting or freezing and calving rates, are of highly uncertain quantity. The mean ice thickness is about 1,100 feet along a line at about 79" S latitude across the ice shelf. (In a southward direction along about 168" W longitude, the thickness gradually increases to more than 2,300 feet.) Ice velocity reaches a maximum of more than 3,000 feet per year in central sectors of this line and averages about 2,180 feet per year. The total ice discharge across the line is estimated to be 45 ± 5 cubic miles per year. The net surface accumulation on the ice shelf and on that part of the West Antarctic ice sheet draining into it is believed to be about $46 \pm 10 \times 10^{13}$ pounds per year. Added to this is the input to the shelf of an estimated $11 \pm 3 \times 10^{13}$ pounds per year by valley glaciers from the polar plateau to the west. Although at the leading edges of the ice sheet bottom melting may be high, perhaps as much as 30 inches per year near Little America Station, at a distance of from 30 to 60 miles to the south, the bottom regimen probably changes from one of melting to one of freezing. Recent estimates suggest that at distances of from 100 to 200 miles from the barrier 15 to 20 inches of ice may be added each year by bottom freezing. An estimated net of 4×10^{13} pounds per year is added to the whole shelf by bottom freezing. Estimates such as these suggest that the Ross Ice Shelf drainage system has a positive net budget. The net budget of Ross Ice Shelf itself depends additionally on the calving rate which is presently unknown.

Ice growth rates

Geology. The terrain of the adjoining Transantarctic Mountains consists of Precambrian to Early Paleozoic metamorphic, sedimentary, and granitic rocks dating from 500,000,000 years or more ago. These are unconformably (*i.e.*, erosionally) overlain by flat-lying Devonian to Jurassic strata laid down from 350,000,000 to about 190,000,000 years ago and known as the Beacon Group. Geophysical studies suggest that the Beacon rocks, or other sedimentary rocks perhaps of a Mesozoic or Tertiary basin (from 225,000,000 to perhaps a few million years ago), underlie Ross Ice Shelf.

At the glacial maximum, the ice shelf probably became grounded and spread as an ice sheet far northward, reaching possibly to Pennell Bank (74" S), which is believed to be a terminal moraine, or ridge of glacier-deposited material. At that time, it probably overrode islands (such as White and Black islands) and reached far up on the slopes of Mount Discovery and Ross Island. Morainal evidence shows that four times within the last 1,200,000 years (in ice ages known as Ross Sea Glaciation I–IV stages), ice pushed westward up the McMurdo dry valleys from the direction of the Ross Sea. With the melting of the ice sheet of Ross Sea Glaciation IV, an ice shelf again formed in Ross Sea.

Future scientific work, it appears, will focus on gaining a third-dimensional view of the Ross Ice Shelf environment, by geophysical measurements and especially by drilling, to study not only this glacial sequence as recorded by sediments on the sea floor but also the deeper bedrock structure and the unique biological environment beneath an ice shelf about which little is now known.

BIBLIOGRAPHY. M. MELLOR (ed.), *Antarctic Snow and Ice Studies* (1964), contains several papers on the Ross Ice Shelf; M.B. GIOVINETTO and J.H. ZUMBERGE, "The Ice Regime of the Eastern Part of the Ross Ice Shelf Drainage System," *Int. Ass. Scient. Hydrol.* no. 79 (1968).

Rossini, Gioacchino

The leading composer of Italian opera during the early part of the 19th century, Gioacchino Antonio Rossini virtually embodied the history of opera in Italy, and then in France, for nearly half a century. His comic opera *Il* barbiere di Siviglia (*The* Barber of Seville) and **his** serious opera *Guillaume* Tell (William Tell) remain prime examples of their respective genres.

George Eastman House Collection

Rossini, photograph by Étienne Carjat, *c.* 1868.

Every salient fact in the life of Rossini was a theatrical event—to be born on February 29 and to die on Friday the 13th seems to bespeak a sense of humour and a sense of theatre. His birth, his family background, his childhood, his personal life, his career, his retirement, all had connection with the theatre. Admired throughout Europe during his lifetime, he was cast into the shadows only for a moment by the popularity of the opera composer Giuseppe Verdi.

Born in Pesaro, Italy, on February 29, 1792, Gioacchino Antonio Rossini was the son of Giuseppe Rossini, an impoverished trumpeter who played in miscellaneous bands and orchestras, and Anna Guidarini, a singer of secondary roles. Thus Rossini spent his entire childhood in the theatre. A lazy student, the young Gioacchino found it easy to learn to sing and play. By the age of 15, he had learned the violin, horn, and harpsichord and had often sung in public, even in the theatre, to earn some money. At 14 he entered Bologna's Liceo Filarmonico (now the Conservatorio Statale di Musica G.B. Martini) and composed his first opera—*Demetrio* e *Polibio* (staged in 1812)—for the Mombelli, a family of singers.

When his voice broke and he was unable to continue singing, Rossini became an accompanist, then a conductor. He had already realized the importance of the German school, perceiving the new elements by which Haydn and Mozart had enriched music. These influences can be found in the early cantata he wrote for the Liceo Filarmonico, performed there in 1808. During the next 20 years (from 1808) this genial lazybones was to compose more than 40 operas.

The Italian period. By taste, soon by obligation, Rossini threw himself into the genre then fashionable: opera buffa (comic opera). His first opera, La *cambiale* di *ma*trimonio (The Bill of Marriage, 1810), was performed in Venice and had a certain success, although his unusual orchestration made the singers indignant. Back in Bologna again, he gave the cantata La morte di *Didone* (Dido's Death, 1811) in homage to the Mombelli family, who had helped him so much, and scored a triumph with the two-act opera buffa L'equivoca stravagante (*The* Extravagant Misunderstanding, 1811). The following year, two more of his comic operas were produced in Venice.

Rossini had already broken the traditional form of opera buffa: he embellished his melodies (he was the true creator of bel canto, a florid style of singing), animated his ensembles and finales, used unusual rhythms, restored to the orchestra its rightful place, and put the singer at the service of the music. In 1812 Rossini wrote the oratorio Ciro in Babilonia (Cyrus in Babylon) and La scala di *seta* (The Silken Ladder), another comic opera.

Operas for La Scala

The same year, Marietta Marcolini, who had already sung in Rossini's operas and who was interested in the young composer, recommended Rossini to the committee of La Scala opera house, Milan. It was under contract to them that he wrote La pietra del *paragone* (The *Touch*stone, 1812), a touchstone of his budding genius. In its finale, Rossini—for the first time—used the crescendo effect he was later to use and abuse indiscriminately.

By this time Rossini's experience in writing seven operas and several cantatas and his intimate contact with the theatre had given him a profound knowledge of his profession. Singers no longer held terrors for him. He was now ready for his major works. Venice, the most refined city in Italy, was to offer him his true glory. After the comic opera *Il* signor Bruschino (1813), written for the Teatro San Moisè, he next wrote—for La Fenice—his first serious opera, Tancredi (1813), in which he tried to reform opera seria (the formula-ridden, serious operas of the 18th century), and he composed an authentically dramatic score. This work, spirited and melodious, was an instant success. Tancredi's famous song, "Di tanti palpiti," was whistled all over town. La Malanotte, the famous singer, was also bent on proving to him the quality of her natural charms, and rumours began to abound. The success of L'Italiana in Algeri (The Italian Girl in Algiers, 1813) followed, showing further refinements in his reforms of opera buffa. These two successes opened wide the doors of La Scala. With Aureliano in Palmira (1814) the composer affirmed his authority over the singers; he decided to prescribe and write the ornaments for his arias, but the work was not a success. After *L'Italiana* he wrote *Il* Turco in *Italia* (The Turk in Italy, 1814) for the Milanese and a cantata for Princess Belgioioso, "one of the most likeable of protectresses," as the French novelist Stendhal referred to her. His next work, *Sigismundo* (1814), was a failure.

Neapolitan operas

Rossini's fame soon spread to Naples, where the reigning impresario was Domenico Barbaia, an ambitious former coffeehouse waiter, who by gambling and running a gaming house had amassed a fortune and was now in charge of the two great Neapolitan theatres. Barbaia realized Rossini's growing fame and went to Bologna to offer him a contract. Impressed by the terms of this contract—security, two operas a year—as well as by Barbaia, a millionaire rather than the customary fourth-rate impresario on the verge of bankruptcy, Rossini did not hesitate to accept. How could anyone refuse a tempting impresario whose favourite was none other than the imposing diva Isabella Colbran? Her first Rossini opera, *Elisabetta, regina d'Inghilterra* (Elizabeth, Queen of England, 1815), was a triumphant success. Rossini admired Colbran very much and soon fell in love with her. The brilliant success of Elisabetta prompted an invitation from Rome to spend the carnival season of 1816. The first of Rossini's Rome operas was unsuccessful. So was the second, *Almaviva*, soon to become *Il* barbiere di *Siviglia*. The Romans, who knew and lsved Giovanni Paisiello's version of Beaumarchais's play, took a dislike to this new setting, but when it was given elsewhere in Italy it was received with unbounded success. Written in 16 days, the work is a piece of inspired inventiveness that has delighted opera lovers ever since. There followed La *cenerentola* (Cinderella, 1817). As with The Barber, this work uses a coloratura contralto for the heroine's role; it, too, proved no less successful. In between these two comedies came *Otello* (Othello; Rome, 1816), a setting of Shakespeare's play that held the stage until superseded by Verdi's greater opera of the same name. La gazza ladra (*The* Thieving Magpie, 1817), a semi-serious work, was a triumph in Milan.

Armida, a grand opera requiring a trio of tenors and a dramatic soprano (Colbran) appeared in 1817. Rossini was now finding interpreters that suited his music. Colbran, the tenor Manuel Garcia, the bass Filippo Galli ("the most beautiful voice in Italy"), the contralto Benedetta Pisaroni (whose art had no equal in depth) were his usual exponents and carried forward his art of bel canto.

La donna del *lago* (based on Sir Walter Scott's poem "The Lady of the Lake") failed at its premiere in 1819 but soon came into favour. After several more or less successful works, he left Naples for Vienna, along with Colbran (whom he had just married), anxious to meet Beethoven. Disappointed by the economic situation of the composer of Fidelio, he returned to Venice, where he attempted to crown his Italian career with Semiramide (1823). The old-fashioned Venetians, however, did not understand the astonishing work, his longest and most ambitious, and so he resolved not to write another note for his countrymen. Following his resolution, he decided to leave Italy.

The Parisian period. Rich, married, unstable, and by nature an epicurean, Rossini wanted to travel. He arrived in Paris in November 1823 and was enthusiastically welcomed in the French capital. The Academy in Paris received him; all of the town fawned upon him. At the end of the year, he visited London, where he conducted and sang in concerts with his wife and met King George IV. Back in Paris, he embarassed the old musicians. "Rossini," wrote the Escudier brothers, Paris music publishers,

> was then 31 years old and in his prime. His countenance revealed a lofty and congenial expression. His subtle, quick penetrating eye held one magnetically before him. His smile, benevolent and caustic at the same time, reflected his whole disposition. The clear line of his aquiline nose, his vast and prominent brow, which his prematurely receding hairline entirely revealed, the even oval of his face enclosed in jet-black sideburns, all formed a kind of virile and fascinating beauty. He has a marvelously shaped hand, which he displayed somewhat coquettishly through his cuff. He dressed in a simple manner, and, under his clothes, which were more proper than elegant, the appeerance of a newly disembarked provincial into the capital.

If the old nicknamed him "Monsieur Crescendo," the young very quickly paraded their admiration for him. Paris was then the centre of the world and Rossini knew it. After some of his works had been staged, he composed *Il* viaggio a Reims (The Journey to Reims), a cantata improvised for the coronation of Charles X.

For a long while Rossini hoped to modify his style: to replace the comparative artificiality and coldness of florid opera coloratura with declamatory and lofty singing—that is, with truth and intensity. In order to do that, he also had to reform the orchestra and give more importance to the chorus. Thus appeared Le *Siège* de *Corinthe* (The Siege of Corinth, 1826), a revision of the earlier Maometto *II* (1820), which was saluted by the prominent composer Hector Berlioz. Le *Siège* was followed by *Moïse* (Moses, 1827) and Le *Comte* Ory (Count Ory, 1828), an adaptation of opera buffa style to French opera.

Final work for the theatre

His final opera, ***Guillaume Tell*** (1829), is on the noble themes of nationalism and liberty, and Rossini's music is worthy of the elevated subject. The Parisian public gave him an ovation, and, in a single work, he had responded to all the critics in the most elegant manner. Then he decided, at the age of 37, not to write again for the theatre. ***Tell*** was to have been the first of five operas for the Optra, but the new government following the Revolution of 1830 set aside his contract.

The reasons for his musical silence remain only suppositions. Some cite his legendary laziness as the cause, while others point to the Parisian hostility to his work and Rossini's resulting sulkiness. Another cause might have been his jealousy over the Parisian success of the opera composer Giacomo Meyerbeer.

In 1845, Madame Colbran passed away. In 1847 Rossini married Olympe Pélissier. During his retirement he had written, returning to his first loves, some religious pieces: the *Stabat Mater* (1832), *Petite Messe solennelle* (1864), and a few songs and piano pieces the good taste of which endeavoured to establish their reputation. Rossini never agreed to their publication.

After a period in Italy, he returned to Paris in 1855, never again to leave it. His parents being deceased, his new wife less demanding than the preceding one, and he himself a wealthy man whose retirement was assured, Rossini gave way to the sweetness of life and to being a wise man who permitted himself to shine in society with a few clever expressions and witticisms. His bons mots, in fact, are legendary, as were his caustic wit and low humour. At his Paris home and later at his villa in Passy, Rossini gave superb gourmet dinners attended by many of the greats of the musical and literary world of the mid-19th century. In 1860 the renowned German composer Richard Wagner visited him, and their fascinating conversation was recorded by Wagner in his essay "Eine Erinnerung an Rossini." Rossini died at Passy of pneumonia on November 13,1868.

For years Rossini was virtually known only by the omnipresent ***Barber of Seville*** and an occasional revival of ***William Tell.*** From the 1950s more and more of his operas were revived, particularly at festivals, and nearly always with public and critical acclaim.

MAJOR WORKS

OPERAS: Some 35 including ***La pietra del paragone (The Touchstone,*** first performed ***1812)***; ***Tancredi (1813)***; ***L'Italiana in Algeri (The Italian Girl in Algiers, 1813); Il Turco in Italia (The Turk in Italy, 1814); Elisabetta, regina d'Inghliterra (Elizabeth, Queen of England, 1815); Il barbiere di Siviglia (The Barber of Seville, 1816); La cenerentola (Cinderella, 1817); Armida (1817); La gazza ladra (The Thieving Magpie, 1817); La donna del lago (The Lady of the Lake, 1819); Semiramide (1823); Le Siège de Corinthe (The Siege of Corinth, 1826); Moïse (Moses, 1827); Guillaume Tell (William Tell, 1829).***

CHORAL MUSIC: ***Il viaggio a Reims*** (cantata with ballets, completed ***1825); Stabat Mater (1832,*** revised ***1842); Petite messe solennelle (1853).***

CHAMBER MUSIC: Five string quartets ***(1808).***

SONGS: Various, among them ***Les Soirées musicales*** (published ***1835).***

PIANO: ***Péchés de vieillesse (Sins of Old Age),*** about ***180*** pieces for piano or for various instruments, voice, and piano.

BIBLIOGRAPHY. There are very few works devoted to Rossini. All of them are in fact inspired by A. AZEVEDO, G. ***Rossini, sa vie et ses oeuvres*** (1864), an extremely well-documented work written by an unconditional admirer; and STENDHAL, ***Vie de Rossini (1824;*** Eng. trans. ***1956,*** new ed. 1970), a study of the man and his early works by a contemporary. In English, HERBERT WEINSTOCK, ***Rossini*** (1968), is a full and authoritative account of Rossini's life.

(J.-L.Ca.)

Ross Sea

The Ross Sea forms a southern extension of the Pacific Ocean, which, along with the vast ice shelf (see ROSS ICE SHELF) at its head, makes a deep indentation in the circular continental outline of Antarctica. The sea is a generally shallow marine region, approximately 370,000 square miles (960,000 square kilometres) in area, centred at about 75° S, 175" W, and lying between Cape Adare in northern Victoria Land on the west and Cape Colbeck on Edward VII Peninsula on the east. The northern limit lies approximately along the edge of the continental shelf and the southern limit along a great barrier wall of ice marking the front of the Ross Ice Shelf. (For related information see Ross ICE SHELF; ANTARCTICA; ICEBERGS AND PACK ICE.)

Focal point for exploration

Exploration. The Ross Sea is one of the least iced and most accessible of Antarctica's fringe seas. Relatively easy access made this region the traditional avenue for mounting expeditions into the continental interior, from the 1901–1904 British National Antarctic Expedition under R.F. Scott to the U.S. Operation Deep Freeze of the 1960s and early 1970s. The sea was first penetrated on January 5, 1841, by the HMS "Erebus" and HMS "Terror," commanded by James Clark Ross on an unsuccessful attempt to reach the south magnetic pole. It then remained unprobed until January 24, 1895, when a Norwegian expedition on the ship "Antarctic," searching for new whaling grounds, put a party ashore at Cape Adare for the first landing in Victoria Land.

Activity in the area increased after winter survival was proved possible by the Norwegian Carsten Borchgrevink and his party of Laplanders at Cape Adare in the winter of 1899–1900. Ross Island and McMurdo Sound in the southwest comer of the sea became the focal point for inland exploration by early 20th-century British parties, led by Scott and E.H. Shackleton, in their searches for the geographic and magnetic poles; and the Bay of Whales, in the southeastern comer of the sea, became the base for the south polar quest of Roald Amundsen's Norwegian Antarctic Expedition (1910–1912). The Japanese South Polar Expedition, on the "Kainan Maru," revisited the Bay of Whales in 1911–1912. It was used again by Richard E. Byrd's United States Antarctic Expedition of 1928–1930 in establishment of "Little America I" station and several times after. Since the International Geophysical Year (1957–59), Ross Sea activities have shifted to the McMurdo Sound region. All coastal regions have been geologically explored, at least in reconnaissance, largely by American and New Zealand parties. The southern Victoria Land region near McMurdo Sound has become the most thoroughly known on the continent. Rich with history and scenery, the Ross Sea is now regularly traversed by tourist vessels.

Geology and physiography. Overshadowed by the towering ranges of Victoria Land, the floor of the Ross Sea extends northward as a broad shelf before plunging into the deeps of the Southeast Pacific Basin along a line from Scott Island to Cape Colbeck. The broader, western half of the sea shoals to less than 1,000 feet in several wide areas, the southwesternmost culminating in the small and rocky volcanic pile of Franklin Island. Most of the floor is less than 3,000 feet deep.

Coastal terranes consist, in large part, of strongly folded and variably metamorphosed sandstone and slate, probably dating from the Late Precambrian (over 570,000,000 years old). Fold trends in northern Victoria Land (Robertson Bay Group) are generally oriented southeasterly, truncated at the Ross Sea coast, and project toward similar terranes with similar fold trends in Marie Byrd Land. The flat-lying Beacon Group of Victoria Land has no known counterpart across the Ross Sea. The coastal region is dotted with modern volcanos and older dissected volcanic piles of an extensive alkaline–basalt area (McMurdo Volcanics) consisting of Cape Adare, Cape Hallett, Mount Melbourne, Franklin and Ross islands, on the western coast, and a number of lesser known centres in western Marie Byrd Land, on the eastern coast.

Possible origins of the continental embayment

Several possibilities exist with regard to the origin of the Ross Sea continental embayment. Early geologists believed the Ross Sea to extend as a subglacial trench, the hypothetical Ross–Weddell Graben, to connect with the Weddell Sea. Since then, discovery of the intervening Ellsworth Mountains has disproved the hypothesis. Geophysical studies on the Ross Ice Shelf indicate the presence of an underlying thick section of seismically low-velocity, probably sedimentary, rocks. The embayment, therefore, may be either a down-faulted block of continental rocks, including the Beacon Group, or it may be a downwarped basin filled with sedimentary rocks.

Various types of glacial-marine sediment carpet the floor of the sea and suggest that much of it was formerly occupied by grounded ice. The many irregularities are probably glacial moraines, and it has been postulated that the vast Pennell Bank is a terminal moraine from the maximum ice advance. Paleomagnetic dating of sediment cores shows that the first influx of glacial sediments occurred at least 5,000,000 years ago. Micropaleontological studies support evidence from the Antarctic continent itself that glacial onset was much earlier, perhaps several tens of millions of years ago. Probes in 1972–73 by the deep-sea drilling vessel "Glomar Challenger" into the marine sediment record of the Ross Sea were expected to provide some answers to such diverse questions as the age of uplift of the nearby Transantarctic Mountains; the ages of onset of glaciation and of fluctuations in the great Antarctic Ice Sheet; and the nature of sedimentation and of organic evolution in polar marine environments.

Biology and oceanography. Flora and fauna is typical of other southerly antarctic marine regions. The nutrient-rich sea water supports abundant planktonic life which in turn provides food for larger forms, including fish, seals, whales, and sea- and shore-birds. Among the latter, hordes of Adélie and emperor penguins populate rookeries at a number of places around Ross Sea.

The Ross Sea is strongly influenced by the coastal East-Wind Drift that sets up a vast, clockwise gyre accompanied by deep-water upwelling. Surface currents move generally westward along the ice-shelf front and thence northward along Victoria Land, where they meet the West-Wind Drift. Movements are complicated by shoals and tidal currents. Water less than 1,000 feet deep has a minimum temperature of about 28.2" F (—2.1" C). Mean surface water temperature in McMurdo Sound is about 28.8" F (—1.8" C). Salinities vary directly with sea-ice formation, decreasing to values of 34.37 ‰ (parts per thousand) with melting in summertime and increasing to 34.84 ‰ when maximum ice formation occurs in McMurdo Sound. (A.B.Fo.)

Rothschild Family

The most famous of all European banking families, the Rothschilds, whose very name was long synonymous with prodigious wealth, exerted for almost two hundred years a considerable influence on the economic history of Europe. Their continuing success, though far less marked than during the 19th century, when they were the world's most powerful bankers, is still based on intimate cooperation between the remaining branches of the family and their ability to engage in large-scale finance.

The founder of the house was Mayer Amschel, born in the Jewish ghetto of Frankfurt am Main on February 23, 1744. The family's name derived from the red (rot) shield on the house in the ghetto in which Mayer's ancestors had once lived. Intended for the rabbinate, Mayer studied briefly, but his parents' early death forced him into an apprenticeship in a banking house. Soon after becoming court factor to William IX, landgrave of Hesse-Kassel, Mayer set the pattern that his family was to follow so successfully—by preference to do business with reigning houses and to father as many sons as possible who could take care of the family's many business affairs abroad.

Starting as dealers in luxury items and traders in coins and commercial papers, Mayer and his sons eventually became bankers to whom the French Revolutionary and Napoleonic Wars of 1792–1815 came as a piece of great good fortune. Mayer and his oldest son, Amschel Mayer, supervised the growing business from Frankfurt, while Nathan Mayer established a branch in London in 1804, James (or Jacob) settled in Paris in 1811, and Salomon Mayer and Karl Mayer opened offices in Vienna and Naples, respectively, in the 1820s. The wars, for the Rothschilds, meant loans to warring princes; smuggling as well as legal trading in key products such as wheat, cotton, colonial produce, and arms; and the transfer of international payments between the British Isles and the Continent that Napoleon vainly attempted to close to British trade. Peace transformed the growing Rothschild business: the banking group continued its international business dealings but became more and more an agent in government securities (Prussian or English, French or Neapolitan), in insurance-company stocks, and in shares of industrial companies. Thus, the family successfully adapted to the Industrial Revolution and participated in economic growth throughout Europe with their railway, coal, ironworking, and metallurgical investments. The banking group continued to expand after the 1850s and, in particular, achieved an important position in the world trade of oil and nonferrous metals. But its previous "oligopolistic" position was seriously threatened by new joint-stock banks and "commercial," or deposit banks both in England and in France, as well as in the German states. By the last quarter of the 19th century, the Rothschild group was no longer the first banking consortium. Other groups, in Europe and in the United States, had become stronger, richer, more enterprising.

The five brothers

Yet the two guidelines laid down by Mayer Amschel for the Rothschild business operations (which, indeed, became a family tradition)—to conduct all transactions jointly and never to aim for excessive profits—helped to compensate to a notable extent for the inevitable risks inherent in handing down a business to future generations not all of whose members are qualified to run it. Amschel Mayer (died 1855), Nathan (died 1836), James (died 1868), Salomon (died 1855), and Karl (died in Naples in 1855)—the founders of the Rothschild consortium—were themselves unequally endowed: Nathan and James

Prominent members of the early Rothschild family: (left to right) Mayer Amschel, engraving by an unknown artist; Amschel Mayer, lithograph by Robert Theer (1808–63) after an engraving by Franz Lieder (1780–1859); Nathan Mayer, detail of a lithograph by Karl von Stur, 1886; James, engraving by an unknown artist.

stood out among their brothers by the force of their personalities, particularly Nathan, who was hard, deliberately boorish, and sarcastic. James, who was his brother's equal in all these things, possessed an alleviating air of some refinement as a result of living in the more polished atmosphere of Paris. The five founders in turn had unequal successors. For example, if Alphonse in Paris (died in 1905) was a worthy successor to his father James, his own son, Edouard (died in 1949), was not as strong a figure as his position required. But Édouard's son (Guy, born in 1909) and his two cousins (Alan, 1910, and Elijah, 1917) have shown exceptional adaptability and ambition, thus confirming the constant element in the group's history for a ceniury and a half: a remarkable capacity for seizing opportunities and for adapting as much in business as in politics.

The second generation

In separating the circumstantial from the personal, individual aspects of the dynasty's hegemony during the 19th century, it must be noted that, although the first group of Rothschilds arrived as strangers in their new countries, unfamiliar with the languages and the customs and subject to the jealousy and competition of local bankers, they stood out from those around them by their fierce will to acquire a place in the sun. By the second generation, when the sons of the five founding brothers (notable among them Anthony and Lionel Nathan in London, Alphonse and Gustave in Paris) entered the business, the Rothschilds were polished and refined, as well as naturalized and nationalized to the point of blending into leadership positions without losing any of their family attributes. It ıs possible that the young Rothschilds' education and the extremely worldly existence of the heads of the various houses helped to create this true mutation. On the other hand, the Rothschilds were influencing the national economy and politics of their countries as greatly as they were being influenced themselves. Alphonse, for example, as the head of the international banking syndicate that in 1871 and 1872 placed the two great French loans known as liberation loans after France's defeat by Prussia, could boast without immodesty that his influence had maintained the chief of the French government, Adolphe Thiers, in power. At the same time, on the other side of the Channel, in the autumn of 1875, Lionel, in London (where he had been a member of the House of Commons since 1858), was able to give Prime Minister Disraeli on a few hours notice the £4,000,000 that allowed the British government to become the principal stockholder in the Suez Canal Company. Obviously, the two cousins had become important citizens in their respective countries.

There were frequent marriages between Rothschild cousins. and marriages generally were—with very rare exceptions––with Jews. As a result, in spite of the number of their descendants and the complexity of their family tree, the Rothschilds, particularly those of Vienna and Paris during the Nazi period, preserved the kind of family unity necessary to weather great misfortunes.

The Rothschilds were much honoured. Mayer's five sons were made barons of the Austrian Empire, a Rothschild was the first Jew to enter the British Parliament, and another was the first to be elevated to the British peerage. The head of the British branch of the family has always been considered the unofficial head of British Jewry. Members of the British and French families—the only ones still engaged in banking after the seizure by the Nazis of the Austrian house—have distinguished themselves as scientists and often as philanthropists.

Rotterdam

t one time it was ıp e to refeı to Rotterdam as a harbour with a it attached, t :hi is no longer true of the of The Netherlands. During the 1960s, Rotterdam outstripped London and New York harbours to become the busiest seaport in the world in tonnage of goods handled. Its position at the mouths of the Rhine and Maas (Meuse) rivers made it for centuries the water gate to the North Sea and the world for the industrial heartland of northern Europe. In the last years of the 19th century it began to handle shipments of oil, and its present-day petrochemical industries, offshoots of this shipping, have replaced shipbuilding and repair as the city's major economic activity.

Post-World War II reconstruction

Though its life is heavily oriented toward its harbour, Rotterdam as a city has literally risen from its ashes following the virtually complete devastation of its centre by German and Allied bombing during World War II. A totally new inner city came from the drawing boards, with a spacious and functional architecture oriented toward the river and a series of experiments at complete city planning that have attracted both professional and touristic admiration. The Lijnbaan Shopping Centre, known as the "Fifth Avenue of Europe" when it was erected in 1953, became the prototype for similar centres in Europe and America that allowed only pedestrian traffic.

A major concern of the planners was to provide the approximately 700,000 Rotterdamers with opportunities for a richer quality of life than is ordinarily encountered in a heavily industrial environment. A sense of openness in the new city and a proximity to recreational areas represent a distinct change from the 19th-century slums that infested much of the prewar city. Amsterdam remains the largest city and the cultural centre of the nation, but Rotterdam is experiencing a growing artistic life, perhaps best symbolized in De Doelen, a music centre completed in 1966 whose acoustical perfection has become world famous.

History. The name Rotterdam was mentioned for the first time in 1283, when a small tract of reclaimed land, or polder, was created by draining the mouth of the Rotte River. A fishing village sprang up, but its favourable position on a curve in the Maas River was the basis for further development. The outer portion of the dike soon became a home port for merchant vessels trading with England, France, and Germany.

Early settlement and growth. As early as 1328 the growing community was granted the prerogatives of a settled town. In 1340 the town received permission to dig a canal to the Schie, and it became the major port of the province. Industry began to develop, and in 1358 the first of many annexations of adjacent districts took place. Gradually a triangular walled town took shape and remained clearly recognizable as "the old town" until the German bombardment in May 1940.

Maritime growth in the 17th century

Although the connection with the sea remained poor until the second half of the 19th century, Rotterdam rapidly expanded as a harbour and an industrial city because of its geographical position. In the 17th century, when the discovery of the sea route to the Indies gave an enormous impetus to commerce and shipping, Rotterdam expanded its harbours and accommodations on the silty soil along the Maas. Before the end of the century it was, after Amsterdam, the second merchant city of the country. The cultural prosperity of this Golden Age in Dutch art did not completely pass up Rotterdam, for inside its walls lived painters such as Pieter de Hooch. Its most famous son was the Humanist philosopher Desiderius Erasmus.

New commercial emphasis. Rotterdam adjusted laboriously to the changed circumstances after the French occupation, which, from 1795 until the fall of Napoleon in 1815, had halted most trade. It no longer was a shipper of staple goods but was able to change to an economic life of transshipment and commissions. The colonial monopoly that had made Rotterdam an entrepreneur of goods to and from the the far-flung Dutch colonies had

The harbour at Rotterdam.
Dick Huffman—Pix

ceased to exist, and free trade had won. In response to this, Antwerp's position as a major shipping competitor began. The advent of the larger steamships made necessary a better connection with the sea. The New Waterway was dug directly through the dunes to the sea between 1866 and 1872.

Railroad connections, too, came late for Rotterdam. A line to the northern part of the country was finished in 1847 and, in 1856, to the eastern region, where commercial relations with Germany were becoming increasingly important. It was not until 1877, however, that the city was connected with the southern Netherlands by a railroad over the Maas. The viaduct, which runs directly through the city, is still unique.

The 20th century. The simultaneous construction of a traffic bridge across the Maas opened the south bank, where large harbour facilities, extending westward, sprang up between 1892 and 1898. From 1908 to 1914 a number of other facilities were built on the north bank. Between 1906 and 1930 the Waal Harbour was built, its 741 acres (300 hectares) making it the largest dredged harbour in the world.

The care for the city was always in painful contrast with the attention paid to the harbour. Around 1860 a major redevelopment featuring wider streets was accomplished, but an enormous influx of working people during the next 50 years nullified these efforts and raised the population from 100,000 in 1857 to 400,000 in 1907. Flagrant speculative building took place, saddling the city with extensive slums. It was only after World War I that architectural and city planning was able to produce attractive working class districts.

World War II devastation

World War II brought about a traumatic break in the history of Rotterdam. The city suffered a German aerial bombardment on May 14, 1940, that completely destroyed its centre, and resulted in an area of 500 acres (200 hectares) going up in flames. More than 1,000 people were killed, nearly 25,000 houses and 11,000 other buildings were destroyed, and 77,000 people were made homeless. After the German occupation, Rotterdam underwent more than 100 Allied air raids, which killed nearly 900 people and destroyed about 2,500 more homes. The city's harbour was largely saved from the bombing of 1940, but in September 1944 the Germans caused great devastation before their retreat, reducing its capacity by one-third.

The contemporary city. In the years since World War II, Rotterdam's inner city has acquired the functions and the status of an extremely modern city.

Physical layout. The triangular pattern of the traditional city has been radically broken. About 700 acres of once-fallow land now hold a completely replanned development detached from the past. The reduced acreage used for buildings in the reconstruction have provided space for broad streets, more open traffic routes, and public squares.

The essential functions of an inner city—predominantly office buildings, banks, and shopping centres—have been used to determine the utilization of land. Buildings with similar functions have been brought together systematically. The two large shopping centres, which differ in quality and price of merchandise, are on both sides of the Coolsingel, the major boulevard. The theatre and the concert hall are opposite one another on a large square that has an underground parking garage. Banks are arranged at points convenient for commercial and individual use, and wholesale merchants are brought together in a special building, the largest such business premise in Europe. These centres are connected with the other parts of the city by large shopping streets. The city hall (1918), spared in the holocaust, and the 15th-century Grote of St. Laurenskerk, which was burned in 1940 but has been restored, and a number of architecturally impressive commercial buildings form the landmarks of the new inner city.

New residential areas

This rearrangement necessitated the construction of new residential areas. North of the city, space was found in several incorporated villages. East of Rotterdam, a new satellite city, Alexanderstad, which lies 22 feet below sea level and is the lowest point in The Netherlands, houses 175,000 people. Along the southern edge of the city a belt of residential quarters was built. One of them, situated close by the oil refinery in the village of Hoogvliet, has a large and important shopping centre. Each of these new residential quarters has been designed as an independent social unit, and, as a result, Rotterdam itself has lost a considerable degree of its traditional character as a bedroom city.

Demography. Within the municipality itself a maximum population of about 700,000 has been reached. Many people who work in the area of Rotterdam reside in the rapidly growing neighbouring municipalities. Incorporation of these into the boundaries of the core city no longer fits the administrative philosophy of The Netherlands. Rotterdam and those municipalities that belong to the harbour and industrial districts are merged into a larger regional district, Rijnmond. Its population consists largely of working class people.

The economy. Rotterdam's economy is almost completely based on shipping. Lying at the heart of the densely populated and industrialized triangle of London, Paris, and the German Ruhr district and at the mouth of two important rivers, Rotterdam is open to the North Sea, the world's most heavily navigated sea. Throughout the centuries the people of Rotterdam have assisted nature by providing deep channels and harbours that can receive the largest ships comfortably. The harbour and the industries as well as the city have been revived and extended on a grand scale in the years since World War II. Before 1940 Rotterdam had specialized almost exclusively in harbour activities, and, as a result, it experienced repeated cyclical economic crises, notably the worldwide depression of the 1930s.

Attempts to attract industry

In 1947, therefore, the authorities set out deliberately to attract industry. It had to be an industry that could benefit from Rotterdam's position, and the answer was found in the oil-processing, or petrochemical, industry. Its development gave an enormous stimulus to shipping, which in turn initiated a period of tempestuous growth in the harbour district. Whereas in 1940 the total area of Rotterdam's harbour and industrial district amounted to about 6,500 acres, in slightly over 20 years it increased to about 25,000 acres. The harbours and grounds are owned by the municipality and are rented to business.

The amount of sea-transported goods assessed in this harbour is the largest in the world, amounting in 1970 to approximately 225,000,000 tons, about 60 percent of it crude oil or oil products. It is the largest grain and general-cargo harbour on the continent. As a transshipment port, it is the junction of world shipping and river transports for inland Europe, with about 225,000 Rhine barges a year in addition to trains, cars, and pipelines. It is the home port of 40 percent of the international Rhine merchant fleet. On the north bank of the 19th-century New Waterway, a large harbour was under construction in the early 1970s that would add about 1,200 acres to the harbour, an area to be used exclusively for forms of containerized merchandise. In addition, Rotterdam is a free port, meaning that goods move in and out of the port without duty, and raw materials can be brought in, processed, and reshipped with a similar exemption from duty charges.

Industrial districts

The expansion of the oil industry made necessary construction of three new large industrial districts, Botlek, Europoort, and Massvlakte, all situated on the south bank of the New Waterway. The construction of the Botlek district had begun in 1947, bordering the old harbour, through which large seagoing vessels can reach it. The district had been rented completely long before its completion, so construction of the Europoort district, nearly three times the size of Botlek, was begun. It, too, was completely filled in a short time with oil-storage facilities and petrochemical and other chemical plants. With this expansion to the west, the harbour had almost reached the sea. The only possible consequence was the construction of still another district, the Maasvlakte, which is built into the sea and gives access to the largest ships with the deepest draft. For some time, part of this district has been reserved for such metallurgical industry as blast furnaces, but the growing concern for the quality of the environment has raised increasing opposition to polluting industries.

The New Waterway, dating from the 1870s, was no longer sufficient for new industrial districts, which must be accessible to the largest tankers. South of the Waterway are the new Caland and Hartel canals, which can be freely navigated by mammoth tankers. To make these canals accessible, a channel 72 feet deep has been dredged far into the sea to accommodate tankers of 500,000 tons. In the future, tankers of 700,000 tons will find their harbour at the north side of the Maasvlakte.

Petrochemical transportation

Because of this development, Rotterdam has become a vitally important industrial centre of western Europe. There are five refineries, whose total capacity increased between 1968 and 1970 from 40,000,000 to 62,000,000 tons. Pipelines transport raw oil to Amsterdam, Antwerp, and West Germany, refinery products to West Germany, naphtha to South Limburg—the former Dutch mining district, which has switched to the chemical industry—and ethylene gas to Terneuzen in the southern island district of Zeeland, where industrial development is beginning.

Ground and air transportation. As much as the river is essential for navigation, it is an obstacle for land traffic. It divides the city in half, and cross-river connections have never caught up with the growing traffic. The city has a tunnel and a bridge, the latter to be replaced eventually by a second tunnel. Around the city a diamond-shaped beltway is being constructed to eliminate through traffic. The north–south legs of this beltway cross the river east of the city over a bridge, the Brienenoordbrug, which has the largest clear span in Europe, 974 feet, and west of the city by the Benelux Tunnel. Public transportation is maintained by trams and buses, which do not cross the river. Most of them connect with the main stations of a partially underground metro system, opened in 1968, that runs from the Central Station under the river to the new residential areas on the south side. East–west connections of the metro are in the preparatory stage.

Northwest of the city is the Zestienhoven Airport, opened in 1956, which serves planes engaged in the European air traffic. It also is used to supply intercontinental transportation from other airports, is a base for charter flights and has facilities for private aviation.

Government. Rotterdam is governed by a 45-member elected municipal council, in which all shades of political persuasion, including the Communist, are represented. Seven full-time aldermen carry out the executive functions of the municipality together with the mayor, who holds his appointment from the crown.

Cultural life and recreation. For a long time, culture and recreation were among the weakest aspects of life in Rotterdam. Reconstruction and renewal of the city and harbour, however, gave a strong stimulus to these features. Because of a lack of material, the reconstruction of the Schouwburg Theatre, begun during the war, was accomplished with the debris from the destroyed city. Plans for a new municipal theatre were in preparation in the early 1970s. A subsidized theatrical company, the Nieuw Rotterdams Toneel, which is one of the most important companies of The Netherlands, performs in the Schouwburg. For smaller performances, two small theatres, the Piccolo and Hofplein, are run by the city. The south side has its own theatre, the Grote Schouwburg, with a large variety of programs.

Drama and music

Opposite the Schouwburg is the concert hall, De Doelen, opened in 1966. Through its perfect acoustical quality, its accommodations, and its carefully considered programming, De Doelen quickly came to play an important role in international musical life. The Rotterdam Philharmonic Orchestra, which gives 80 largely sold out concerts a year, performs permanently in De Doelen. Rotterdam has a centuries-old tradition of organ playing, which draws many people to the Grote of St. Laurenskerk and to the splendid organ of De Doelen.

Artistic and historical collections and buildings

Rotterdam is particularly noted for the plastic arts, both historical and contemporary. The Boymans-van Beuningen Municipal Museum has a famous collection that includes works by Hieronymus Bosch, Pieter Brueghel the elder, Jan van Eyck, Vincent van Gogh, the Rotterdamer Kees van Dongen, and other Dutch and Flemish masters. It often organizes expositions of international importance. The city is gradually acquiring an open-air collection of sculptures by an international array of artists, including works by Auguste Rodin, Alexander Calder, Marino Marini, Henry Moore, and Naum Gabo. The work "Destroyed City" by the Russian-French sculptor Ossip Zadkine symbolizes the destruction of the city in 1940. A famous bronze statue of Erasmus was made by the 17th-century master Hendrik de Keyzer.

The most important of the other museums are the Museum voor Land en Volkenkunde (Museum for Geography and Ethnography), which has a collection of objects of fine and applied art from non-European countries, and the Maritime Museum Prins Hendrik (Prince Henry Maritime Museum), whose displays and large collection of ship models illustrate the history of navigation. The Historisch Museum (Historical Museum), a splendid building from the 17th century, was spared during the bombing. Its annex in the Delfshaven ward of the city has a workshop in which pewter is fashioned after old models. Still standing also is the church in which America's Pilgrims said farewell to Europe before starting out on the first stages of their long sea voyage.

Rotterdam holds a central position in education. Since 1913 it has had a school of economics, which has been expanded into a school for social sciences and, since 1970, a medical school. Technological education is quite varied, with a technical high school and, in the heart of the city, eight training schools. These have a regional function and are united in a single building. There is a school for training dock workers in their increasingly specialized jobs. Finally, Rotterdam has a school for the plastic arts.

Recreational and sporting facilities

For a city that seizes more and more of the surrounding grass and foliage for harbours and industry, outdoor recreation is a great problem. Rotterdam has only one old park, which is situated along the river. In the rest of the city, most grass and foliage has been artificially laid out. A forest of 630 acres (255 hectares) was planted when 34,000,000,000,000 cubic yards of sand, which came from the dredging of the Waalhaven on the south side, were deposited into a polder to the east of the city. After World War II a similar belt of woods was laid out on the south side between old and new residential areas; it has a variety of recreative functions. The municipal parks are part of an experiment in "fencing forests" to protect the living quarters in the industrial districts against air pollution.

Two large lakes in the eastern part of the city offer facilities for many kinds of water sports. Their artificial beaches draw hundreds of thousands of visitors on warm summer days. Many Rotterdamers travel to the North Sea beaches that are close by in the Hook of Holland at the mouth of the New Waterway. Since 1914 it has belonged to the district of Rotterdam. The Blijdorp, opened in 1940, is one of the most modern gardens in Europe. For spectator sports, the city has 250 fields. In 1970 the sports palace Ahoy, seating up to 10,000 spectators, was opened on the south bank.

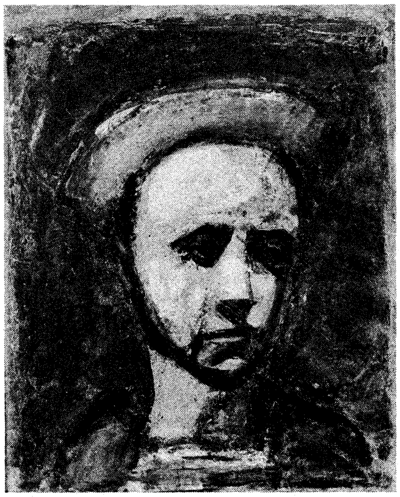
Rouault, Georges

Among the major artists of the 20th-century school of Paris, the French painter Georges Rouault was an isolated figure in at least two respects: he practiced Expressionism, a style that has never found much favour in France, and he was chiefly a religious painter—one of the most convincing in recent centuries—at a time when most modern painters were preoccupied with aesthetic problems. Both statements, however, need qualification. Rouault was not as fiercely Expressionistic as some of his Scandinavian and German contemporaries; in some ways his work can be regarded as a late flowering of 19th-century Realism and Romanticism (which helps to explain his wide popularity). And he was not an official church artist; his concern with sin and redemption was deeply personal.



"The Workman's Apprentice (Self-Portrait)," in oils by Georges Rouault, 1925. In the Musée National d'Art Moderne, Paris.

Giraudon

Apprenticeship to a glazier

Georges-Henri Rouault was born in Paris on May 27, 1871, in a cellar during a bombardment of the city by the forces opposed to the Commune. His father was a cabinetmaker. A grandfather took an interest in art and owned a collection of Honor6 Daumier's bitterly satirical lithographs; Rouault said later that he "went first to school with Daumier." In 1885 he enrolled in an evening course at the Paris École des Arts Décoratifs. From 1885 to 1890 he was apprenticed in a glazier's workshop; his mature style as a painter was undoubtedly influenced by his work on the restoration of medieval stained-glass windows, including those of Chartres Cathedral. In 1891 he entered the Ecole des Beaux-Arts, where he soon became one of the favourite pupils of the Symbolist painter Gustave Moreau, in a class that also included the young Henri Matisse and Albert Marquet. After the death of Moreau in 1898, a small Paris museum was created for his pictures, and Rouault became the curator.

During this early phase of his career Rouault's style was academic. But around 1898 he went through a psychological crisis, and, during the following years, partly under the influence of Vincent van Gogh, Paul Gauguin, and Paul Cézanne, he evolved in a direction that made him, by the 1905 Paris Salon d'Automne, a fellow traveller of the Fauves (Wild Beasts), who favoured the arbitrary use of strong colour. At this time and up until the beginning of World War I, his most effective medium was watercolour or oil on paper, with dominant blues, dramatic lighting, emphatic forms, and an expressive scribble.

Religious evolution

Rouault's artistic evolution was accompanied by a religious one, for he had become, around 1895, an ardent Roman Catholic. He became a friend of the Catholic intellectuals Joris-Karl Huysrnans and Léon Bloy and took to heart the latter's warning that modern art had to "go on its knees." Through another friend who was a deputy public prosecutor, he began to frequent, as had Daumier, the Paris law courts, where he had a close-up view of human beings apparently fallen from the grace of God. His favourite subjects became hideous prostitutes, tragic clowns, and pitiless judges.

Paintings on the Passion of Christ

Without completely abandoning watercolour, after 1914 Rouault turned more and more toward the oil medium. His paint layers became thick, rich, and sensuous, his forms simplified and monumental, and his colours and heavy black lines reminiscent of stained-glass windows. His subject matter became more specifically religious, with a greater emphasis on the possibility of redemption than he had put into his pre-1914 work. In the 1930s he produced a particularly splendid series of paintings on the Passion of Christ; typical examples, well-known through best-selling reproductions, are "Christ Mocked by Soldiers,""The Holy Face," and "Christ and the High Priest". During these years he got into the habit of reworking his earlier pictures; "The Old King", for instance, has to be dated 1916–36.

Between World Wars I and II, at the instigation of the

Paris art dealer Ambroise Vollard, Rouault devoted much time to engravings, illustrating Les Rkincarnations *du* Pkre *Ubu* by Vollard, Le Cirque de *l'étoile filante* by Rouault himself, Les *Fleurs du mal* by Charles Baudelaire, and *Miserere* et *guerre* (his masterpiece in the genre), with captions by Rouault. Some of this work was left unfinished for a time and published later. In 1929 he designed the sets and costumes for a production by Sergey Diaghilev of Sergey Prokofiev's ballet The Prodigal Son. In 1937 he also did the cartoons for a series of tapestries.

During and after World War II, he painted an impressive collection of clowns, most of whom have features—long noses, pursed mouths, and domed foreheads—that make them virtual self-portraits. He also executed some still lifes with flowers; these are exceptional not only because of their quality but also because of the subject, for three-quarters of his lifetime output is devoted to the human, or divine, figure. In 1947 he sued the heirs of Vollard to recover a large number of works left in their possession after the death of the art dealer in 1939. Winning the suit, he established the right of an artist to things never offered for sale, and afterward he publicly burned 315 canvases that he felt were not representative of his best work.

During the last 10 years of his life, he renewed his palette, adding some greens and yellows unusual for him, and painted some almost mystical landscapes: a good example is "Christian Nocturne". Rouault died in Paris on February 13, 1958.

MAJOR WORKS

"The Road to Calvary" (1891; Wadsworth Atheneum, Hartford, Connecticut); "The Ordeal of Samson" (1893; Los Angeles County Museum of Art); "Duet" (1904; Musée d'Art Moderne de la Ville de Paris); "Head of Christ" (1905; Walter P. Chrysler, Jr. Collection, New York); "Aunt Sallys" (1907; Tate Gallery, London); "Judges" (1908; Statens Museum for Kunst, Copenhagen); "Portrait of Mr. X (1911; Albright-Knox Art Gallery, Buffalo, New York); "Christ Mocked" (1912; Musée d'Art Moderne de la Ville de Paris); "The Old King" (1916–36; Carnegie Institute, Museum of Art, Pittsburgh); "Three Clowns" (1917; Joseph Pulitzer Jr. Collection, St. Louis, Missouri); "Crucifixion" (1918; Henry P. McIlhenny Collection, Philadelphia); "Pierrot" (1920; Stedelijk Museum, Amsterdam); "Circus Trio" (1924; Phillips Collection, Washington, D.C.); "The Workman's Apprentice (Self-Portrait)" (1925; Musée National d'Art Moderne, Paris); "Christ Mocked by Soldiers" (1932; Museum of Modern Art, New York); "The Holy Face" (1933; Musée National d'Art Moderne, Paris); "Christ and the High Priest" (1937; Philips Collection, Washington, D.C.); "Christ and Fishermen" (1937; Musée du Petit Palais, Paris); "Sunset" (1937; Worcester Art Museum, Massachusetts); "The Three Judges" (1937–38; Tate Gallery, London); "Head of Christ" (1938; Cleveland Museum of Art); "Diplomat" (1938; Musées Royaux des Beaux-Arts de Belgique, Brussels); "Christ Mocked" (1942; Staatsgalerie, Stuttgart); "De Profundis" (1946; Musée National d'Art Moderne, Paris); "Head of a Clown" (1948; Museum of Fine Arts, Boston); "Christian Nocturne" (1952; Musée National d'Art Modem, Paris); "Decorative Flowers" (1953; private collection, Paris).

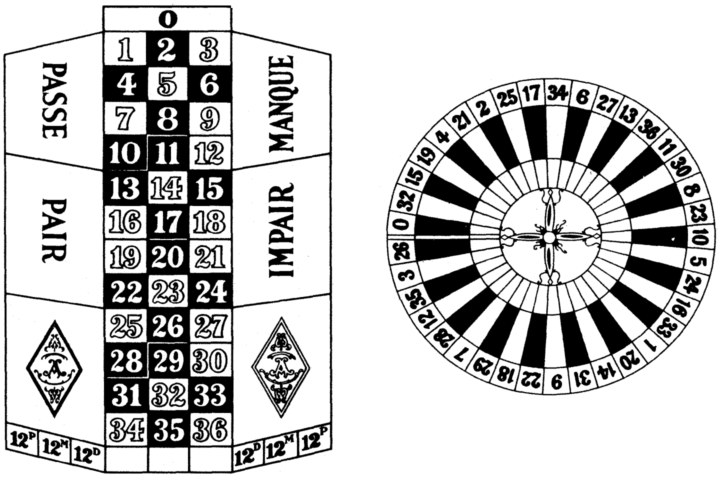
Roulette

Roulette is a casino gambling game of obscure but probably French origin. It is universally played in the gambling casinos of Europe, North and South America, Asia, and Africa. Roulette is a banking game, and all bets are placed against the bank—in this case the "house" or proprietor of the game. As a big-time betting game its popularity has been superseded in the United States and the Caribbean Islands by others, notably craps and black jack.

History. Roulette is said by some historians to have been invented in 1655 by the French scientist Blaise Pascal during his monastic retreat and first played in a makeshift casino in Paris. Others say that it was invented by a French monk to help break the monotony of monastery life. Still others say it originated in an old Chinese game whose object was to arrange 37 statuettes of animals into a "magic square" of 666, but they fail to describe the method of play. They add that the game was later played in Tibet and eventually by French Dominican monks, one of whom transposed the statuettes into numbers, from 0 to 36, and arranged them haphazardly along the rim of a revolving wheel. Whatever its antecedents and origins, it was only in the late 18th or early 19th century that roulette emerged as a glamourous attraction in the casinos of Europe, where it has long been associated with the gaming rooms at Monte Carlo.

Equipment. The roulette table is composed of two sections, the wheel itself and the betting layout, better known as the roulette layout. There are two styles of roulette tables. One has a single betting layout with the roulette wheel at one end; the other has two layouts with the wheel in the centre.



Roulette layout and (right) roulette wheel with 37 compartments, both European style.

European- and American-style layouts and wheels

Heading the layout design, which is printed on green baize, is a space containing the figure 0 (European style), or the figures 0 and 00 (American style). The main portion of the design is comprised of 36 numbered rectangular spaces, coloured red and black alternately, and arranged in three columns of 12 spaces each. Directly below the numbers are three blank spaces (on some layouts these are marked 2 to 1 and are located on the players' side of the table). On either side of these, or along one side of the columns, are rectangular spaces marked 1st 12, 2nd 12, and 3rd 12. On European-style layouts these terms are 12^{p} (premidre), 12^{m} (milieu), and 12^{d} (*dernière* douzaine). Six more spaces are marked red (rouge), black (noir), even (pair), odd (impair), 1–18 (low or manque), 19–36 (High or passe).

The roulette wheel consists of a solid wooden disk slightly convex in shape. Around its rim are metal partitions known as separators or frets, and the compartments or pockets between these are called canoes by roulette croupiers. Thirty-six of these compartments, painted alternately red and black, are numbered from 1 to 36. On European-style wheels, a 37th compartment, painted green, carries the sign 0, and on American wheels two green compartments carry the signs 0 and 00. The wheel, its spindle perfectly balanced on a single ball bearing, spins smoothly, in an almost frictionless manner.

The standard roulette table employs five, six, or seven sets of wheel checks (usually called chips). Each set is differently coloured, each consists of 300 chips, and there is one set for each player. The chips usually have a single basic value, although some casinos also sell chips of lesser value. The colour of the chips indicates the player, not the value of the chips. If a player wishes to buy chips of slightly higher value, the croupier places a marker indicating that value on top of the table's stack of chips of the colour corresponding to the chips purchased. Most casinos have high value chips that can be wagered at any gaming table. Unlike roulette chips, these have their numbered values printed on them.

Payoff odds

Bets. It is possible to place the following bets in roulette: (1) straight, or single-number (en plein), in which the chips are placed squarely on one number of the layout, including 0 (and also 00 on American layouts), so that the chips do not touch any of the lines enclosing the number; a winning single number bet pays 35 to 1; (2) split, or two-number (*à* cheval), in which the chips are placed on any line separating any two numbers; if either wins, payoff odds are 17 to 1; (3) street, or three-number (transversale pleine), in which the chips are placed on the outside line of the layout, betting the three numbers opposite the chips; payoff odds on any of the three numbers is 11 to 1; (4) square, quarter, corner, or four-number (en *carre*), in which the chips are placed on the intersection of the lines between any four numbers; payoff odds are 8 to 1; (5) line, or six-number (transversale six), in which the chips are placed on the intersection of the side line and a line between two "streets"; payoff odds are 5 to 1; (6) column, or twelve-number, in which the chips are placed on one of the three blank spaces (some layouts have three squares, marked lst, 2nd, and 3rd) at the bottom of the layout, thus betting the 12 numbers above the space; payoff odds are 2 to 1; (7) dozens, or twelve-number, in which the chips are placed on one of the spaces of the layout marked 12, betting the numbers 1–12, 13–24, or 25–36; payoff odds are 2 to 1; (8) low-number or high-number, in which the chips are placed on the layout space marked 1–18 (*manque*) or on the space marked 19–36, (passe); payoff is even money; (9) black or red, in which the chips are placed on a space of the layout marked black (noir), or on a space marked red (rouge; some layouts have a large black or red diamond-shaped design instead of the words); payoff is even money; (10) odd-number or even-number, in which the chips are placed on the space of the layout marked odd (impair), or on the space marked even (pair); payoff is even money.

On layouts with a single zero (European style), the 0 may be included in a two-number bet with any adjoining number, in a three-number bet with 1 and 2 or with 2 and 3, and in a four-number bet with 1, 2, and 3 at the regular odds for these bets; with the American style 0 and 00, a five-number line bet also is possible, the player placing his chips on the corner intersection of the line separating the 1, 2, 3, from the 0 and 00, with payoff odds of 6 to 1.

The play. The game begins when one of the croupiers (dealers) in attendance calls, "Make your bets." The players begin making their bets (as many may bet as can get near the table) by placing chips on the spaces of the layout, on any number, group, or classification they hope will win.

Role of the croupier

The croupier starts the wheel spinning in a counterclockwise direction, then spins **a** small ivory or plastic ball on to the bowl's back track in the opposite direction. Players may continue to place bets while the wheel and ball are in motion until, as the ball slows down and is about to drop off the back track, the croupier calls, "No more bets!"

When the ball falls and comes to rest between any two metal partitions of the wheel, it marks the winning number (or a zero or double zero), the winning colour, and any other permitted bet that pertains to a winning number or symbol. The dealer immediately announces the winning number and its colour, and he points with his index finger to the corresponding number on the layout. He first collects all losing bets, not disturbing the chips that are resting on winning spaces. Then he pays off the winner or winners with the correct amount of chips due to each winning bet.

House **odds.** When using the American-style wheel with the 0 and 00, the advantage for the bank arises when either the 0 or 00 shows. Only bets on the winning symbol (0 or 00) and the line or five-number bet (combination bet 0, 00, 1, 2, 3) are paid. Thus the bank should win 2 parts in 38 or $5\frac{5}{19}$ percent of all bets. The only exception is the line or five-number bet where the house percentage is $7\frac{17}{19}$ percent.

Roulette as played in Europe, Africa, South America, and Asia is the same as that played in the United States, with the exception that the wheel and layout contain only a single zero (0). When the zero appears, all even-money bets, such as Red, Black, Odd, or Even, are "imprisoned." On the next spin of the wheel, if the zero appears again the house collects half of each imprisoned bet; if not, it collects all losing bets and returns the original bets to any winners. The bank's percentage on red, black, odd or even is $1\frac{13}{37}$ percent, and on all other types of bets it is $2\frac{26}{37}$ percent.

Systems. The oldest and most common betting system is the Martingale or "Doubling-up" system, in which bets are doubled progressively. This probably dates back to the invention of the roulette wheel, but every day of the week some gambler somewhere reinvents it, or some variation of it, and believes he has something new. Over the years hundreds of "sure-fire" winning systems have been dreamed up, but regardless of what system is used, in the long run it cannot overcome the house's advantage of the 0, or 0 and 00. This house advantage is the only system that works in the long run.

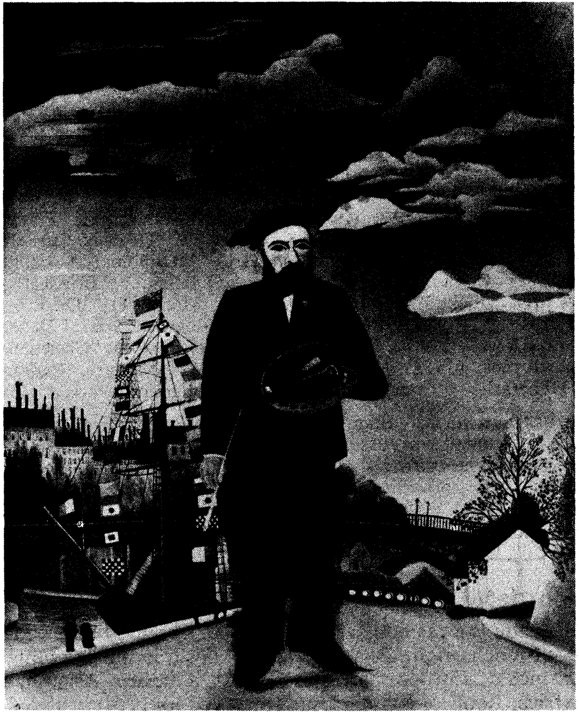
(J.S.)

Rousseau, Henri

The French painter Henri Rousseau represents a special case in modern art. His painting, virtually untaught, was of the primitive, "Sunday painter" genre; yet, despite its definite technical naïveté, it reached brilliant heights of expression and imagination and was greatly admired by the most advanced painters. An unsophisticated man and by profession a petty clerk, he lived most of his life in obscurity, but in his last years he moved, unchanged, in the most sophisticated artistic circles of his day.

Giraudon



Rousseau, self-portrait, oil painting, 1890. In a private collection, Paris.

Born in 1844 in Laval, France, and raised there, Rousseau, the son of a tinsmith, was from a modest background. **A** mediocre student, he left the secondary school in Laval without having completed his studies and soon entered military service, in which he remained for four years. During his term of service he met soldiers who had survived the French expedition to Mexico (1862–65) in support of Emperor Maximilian, and he listened with fascination to their recollections. Their descriptions of the subtropical country were doubtless the first inspiration for the exotic landscapes that later became one of his major themes. The vividness of Rousseau's portrayals of jungle scenes led to the popular conception, which Rousseau never refuted, that he travelled to Mexico. In fact, he never left France.

Civil-service career and early paintings. Released from military service upon the death of his father to support his widowed mother, he settled in 1868 in Paris. The following year he married the daughter of a cabinetmaker, Clémence Boitard. In Paris he began a career as a petty official, eventually becoming, in 1871, a tax collector in the Paris toll office; from this post came the name by which in later years he was well-known, *le douanier,* or "customshouse officer," in spite of the fact that the toll office had no real customs functions. Working as a bureaucrat and busy with family affairs, he still somehow found time to draw and paint. Although no works remain as evidence, he had probably drawn and painted since childhood, and his stated ambition was to be a painter in the style of the academicians of his day. In 1884 he obtained permission to copy paintings at the Louvre. In 1886 he exhibited his first painting, not at the official Salon, which would never have admitted a painter of such naïveté, but at the Salon des Indépendants, an annual exhibition established by young painters to allow themselves and other painters to exhibit and still be free from the narrow official requirements of style and subject matter.

"Carnival Evening" and the early Salon des Indépendants

The picture with which Rousseau made his debut, "Carnival Evening," was, in fact, a masterpiece of primitive painting and an impressive beginning for the artist. This work exhibits an approach to representation that is typical of the primitive artist––everything is literally and deliberately drawn; every branch of the trees is traced, the clouds have a curious solidity, and greater attention is paid to the details of costume than to the figures themselves. The design of the painting, however, is effectively poetic, and a striking quality of atmosphere and mood is achieved through the accurate and sensitive observation of the colours of the evening and through the literal treatment of trees and clouds that is ultimately unreal and contributes to an air of mystery.

In spite of this auspicious beginning, Rousseau's work still went largely unnoticed, except for the consistent ridicule of the critics, for the next seven years. During this period he exhibited some 20 paintings at the Salon des Indépendants, but he remained essentially an amateur, dividing his time among painting, work at the toll house, and family life. His wife, who had been ill for some time, died in 1888, and within several years he lost all of his family except for a daughter, whom he sent to live with relatives.

The exposition of 1889

This period of personal hardship was also a period of increased artistic activity. An important event in Rousseau's life at this time was the Universal Exposition, held in Paris in 1889. Being a simple man but one with great imagination, he was profoundly impressed by what he saw there. It is probable that the reconstructions of Senegalese, Tonkinese, and Tahitian landscapes at the exposition provided further inspiration for the exoticism of his later paintings. His enthusiasm for the fair was so great that he wrote a vaudeville play entitled ***A Visit to the Exposition of 1889,*** which, however, he did not succeed in having produced. In this play, as in other theatrical works he wrote, his naïveté revealed itself even more than in the technical aspects of his painting. Also. revealed, however, was an intense desire to express himself artistically; he even attempted to compose music. Still, his only real gift was for painting. Like his contemporaries the Impressionists, he was attracted by landscapes, and at this time he wished to imitate nature. His painting "The Toll-House" (*c.* 1900; Courtauld Institute Galleries, London) shows his place of work; an early photograph of the same location shows that Rousseau conferred on his depiction a profound lyricism while remaining loyal to reality. The most important work of this period in Rousseau's career is his self-portrait "Myself: Portrait-Landscape." Standing in the foreground, palette in hand, Rousseau is surrounded by the Parisian landscape, painted with great accuracy. This is obviously intended as a "portrait of the artist" in the academic tradition; the seriousness of purpose is impressive in spite of the naïveté of execution.

"The Sleeping Gypsy"

Later paintings and recognition. In 1893 Rousseau retired from the toll house to devote himself entirely to painting. Soon afterward, he met Alfred Jarry, a brilliant young writer, also from Laval, whose nonconformity shocked his contemporaries. He was struck by Rousseau's unusual work and introduced the self-taught artist to the circle of intellectuals associated with the avant-garde review ***Le Mercure de France.*** It was this review that first published an article praising Rousseau. The article was written in connection with his painting "War," an allegory exhibited at the 1894 Salon des Indépendants, which demonstrated Rousseau was much more than a minor landscapist. This work also marked the beginning of the recognition of Rousseau as a serious painter. His most important painting of this period was "The Sleeping Gypsy" (1897). It portrays a female Gypsy asleep in a moonlit desert with a huge lion standing over her, seemingly transfixed and unwilling to touch her. The landscape is completely bare except for the Gypsy's jug and mandolin. This painting is exceedingly primitive in its technique; the Gypsy lies stiffly on the ground, still clutching her walking staff, and her smiling face is childishly rendered. The stripes of her dress and the hairs of the lion's mane are individually traced in a naïve but decorative, almost abstract manner. The painting, however, is wonderfully expressive. The Gypsy's smile, the lion's staring eye, the bare, unearthly landscape, and the whimsical twist at the end of the lion's tail unite opposing feelings of peace and danger, solemn mystery and whimsy, into a powerful expression of magical enchantment. When he exhibited the painting, Rousseau wrote to the mayor of his native Laval asking him to purchase it; he intended it to be a tribute to his native town. The mayor, however, was merely amused at the idea. Rousseau, by this time, had enormous confidence in his own work and considered himself to be a great painter. Not only was he unaware of his lack of conventional technical skill, but he believed that his work resembled that of the academic painters. He still dreamed of official glory, but his painting was appreciated only by young avant-garde painters such as Robert Delaunay, Picasso, and their common defender, the poet Guillaume Apollinaire, who also became Rousseau's principal supporter.

In 1905 Rousseau was invited to the Salon d'Automne (a semi-official exhibition created after a schism among the academicians), where his painting "The Hungry Lion" was hung in the same room with the works of some of the most popular painters of the day, who were called Fauves (Wild Beasts): Henri Matisse, André Derain, and Maurice de Vlaminck. The work of these men, with its pure colours and lack of conventional realism, was similar to Rousseau's. At last the critics began to speak of him. Ambroise Vollard, the most important dealer in modern paintings in Paris, bought pictures from him, and Rousseau emerged from the shadows.

Rousseau lived in a humble quarter of Paris, where he gave painting lessons in his home. His second wife died in 1903 (he had married her in 1899). Because of his aggrandized self-image in the midst of such poor surroundings, he seemed to be an eccentric to the people of his district. Among avant-garde artists, however, he became an object of affectionate admiration and curiosity, and he was a popular figure in the most advanced intellectual circles. In 1908 Picasso organized in his studio an unforgettable banquet in Rousseau's honour—partly a joke on the innocent seriousness of the *Douanier* but more a tribute to his indisputable genius—to which the most sophisticated artists and critics of his day were invited.

The exotic landscapes

During these last years Rousseau painted chiefly exotic landscapes, of which "The Hungry Lion" was the first major example. He excelled in these works, creating with his primitive approach a unique mode in depicting this type of scene. The paintings are characterized by a profusion of exotic plant growth painted with great attention to detail; many varieties of plants, undoubtedly studied at the Paris botanical garden, are distinctly differentiated, with obvious fascination for the different leaf forms. Although crowded together, the plants are deliberately treated, with each leaf painted separately and each branch of leaves constituting a beautiful abstract pattern. In the midst of this vegetal density, colourful birds flit about and mysterious animals stare out at the viewer. There is usually some dramatic incident taking place in the centre, such as a lion attacking its prey, which is in keeping with Rousseau's continued predilection toward the grandiose historical, dramatic narratives of the academic tradition of painting of his time.

"Yadivigha's Dream"

Shortly before his death, in 1910, Rousseau painted the most ambitious of these jungle paintings and one of his greatest works, "Yadivigha's Dream." In this impressive fantasy, an enchanting nude rests on a red-plush Victorian sofa in the middle of a dense jungle. Huge flowers wave about her head, two lions and an elephant peer out of the undergrowth, and a darkskinned musician plays a flute behind her. Rousseau's explanation of this scene is that the lady, having fallen asleep on the sofa, dreams fhat she is transported to this improbable region. The very simplicity of Rousseau's conception and of his cast of mind allows a directness of purpose that accounts for the astonishing unconventionality of, the subject. The painting, which exhibits all of Rousseau's descriptive and expressive skill, is also a supreme revelation of his powerful and uncommon imagination.

Rousseau died on September 2, 1910. His career had been remarkable in the history of art, and his work not only inspired a revival of true primitive painting in the 20th century but also influenced a branch of modem art.

MAJOR WORKS

"Landscape with Tree Trunks" (1887; Barnes Foundation, Merion. Pennsylvania): "The Present and the Past" (*c.* 1889; Barnes Foundation); "Myself: Portrait-Landscape" (1890; Museum of Modern Art, Prague); "L'Octroi" (c. 1890; Courtauld Institute Galleries, London); "The Artillerymen" (c. 1893; Solomon R. Guggenheim Museum, New York); "War" (1894; Louvre, Paris); "The Child Among Rocks" (c. 1895; Philadelphia Museum of Art, Philadelphia); "The Sleeping Gypsy" (1897; Museum of Modern Art, New York); "Banks of the Seine" (c. 1898; private collection, Paris); "Spring in the Valley of the Bièvre" (c. 1904; Metropolitan Museum of Art, New York); "The Hungry Lion" (1905; private collection, Switzerland); "L'Herbage" (c. 1906; Fogg Art Museum, Cambridge, Massachusetts); "The Repast of the Lion" (1907; Metropolitan Museum of Art, New York); "The Snake-Charmer" (1907; Louvre); "La Bougie Rose" (1907; Phillips Collection, Washington, D.C.); "Football Players" (1908; Solomon R. Guggenheim Museum); "The Rabbit's Feeding" (1908; Barnes Foundation); "The Muse Inspiring the Poet" (1909; State Pushkin Museum of Fine Arts, Moscow); "Promenade au Luxembourg" (1909; State Pushkin Museum of Fine Arts, Moscow); "The Muse Inspiring the Poet" (1909; Kunstmuseum, Basel, Switzerland); "Vase of Flowers" (1909; Albright-Knox Art Gallery, Buffalo, New York); "View of the Île Saint-Louis" (1909; Phillips Collection); "Yadivigha's Dream" (1910; Museum of Modern Art, New York); "The Cascade" (1910; Art Institute, Chicago); "Landscape" (c. 1910; State Pushkin Museum of Fine Arts, Moscow); "Tropical Forest with Monkeys" (1910; John Hay Whitney Collection, New York).

BIBLIOGRAPHY. W. UHDE, Henri Rousseau (1914), the foremost contemporary work (in French) fundamental to studies of Rousseau; C. ZERVOS, Henri Rousseau (1927), a work (in French) written by an eminent critic of modern art, with excellent reproductions; D.C. RICH, Henri Rousseau (1942), a serious study containing valuable information on Rousseau's paintings preserved in the United States; H. CERTIGNY, *La Vérité* sur *le Douanier* Rousseau (1961). D. VALLIER, Henri Rousseau (1961; Eng. trans., 1964), the most important monograph; Tout *l'oeuvre* peint de Henri Rousseau: documentation et catalogue *raissoné* (1970), a scientific study containing all of Rousseau's paintings, classified for the first time in chronological order, with an appendix where the works attributed to Rousseau appear.

Rousseau, Jean-Jacques

Jean-Jacques Rousseau was one of the greatest of the European thinkers of the 18th century whose writings inspired the leaders of the French Revolution and influenced what became known as the Romantic generation. As a philosopher, he tried to achieve a synthesis between Christianity and the Rationalist and Materialist thought of his time. He named this synthesis "materialism of the wise" or "theism" or "civil religion." In politics, his theory of "social contract" went beyond both the economic liberalism of English thinkers and the Positivist attitude of Montesquieu, a French political philosopher. His effort toward a "natural education" and his search for a freely accepted "contract" between teachers and pupils have been the seed of all modern pedagogical movements. His thought has had broad influence because he expressed himself not only in political and philosophical treatises but also in beautifully written novels and autobiographical works.

Rousseau, drawing in pastels by Maurice-Quentinde La Tour, 1753. In the Musée d'Art et d'Histoire, Geneva.

Genevan background

Formative years. Jean-Jacques was born on June 28, 1712, the son of Isaac Rousseau, a citizen of Geneva and a watchmaker, and Suzanne Bernard, niece of a Calvinist minister. His mother died a few days after his birth. His education began exceptionally early; at the age of six, he was reading books from his father's library. He began with novels and comedies but immediately passed on to the works of historians such as Plutarch and some of the great moralists. Discussions in his father's workshop and in workers' clubs filled him with republican principles and with puritanical interpretations of the Bible. His Confessions (1782) and his Lettre *à d'Alembert* sur *les* spectacles (1758; "Letter to d'Alembert on the Theatre") are the most precise documents on life in Geneva during the 18th century and on his self-education.

The working class elite in Geneva was concentrated in the Saint-Gervais area, situated in the "lower city," as opposed to the "upper city" of the wealthy merchants and bankers. In the time of Jean-Jacques, the Saint-Gervais part of Geneva was periodically the scene of social troubles. In 1722 Isaac went into exile because he had a quarrel with a member of an influential family; he left his two sons, Jean-Jacques and his older brother François, in the care of their maternal uncle, Gabriel Bernard. François was apprenticed, and Jean-Jacques was sent to live outside Geneva with a minister, J.-J. Larnbercier, who taught him the classics. In September 1724 he returned to his uncle in Geneva and soon after began work as a clerk. In April 1725 he was apprenticed to Abel Ducommun, an engraver, who treated him roughly. Rousseau reacted by reading prohibited books during his working hours, and he joined a gang of youngsters. On March 14, 1728, he fled from Geneva by means of a network organized by the Roman Catholic clergy of Savoy.

From his Genevan childhood, Rousseau retained a few simple but profound ideas calling for the sovereignty of the people, taxation through popular vote, the necessity of free and periodic popular assemblies, but the dangers of the delegation of power. Nevertheless, after he left Geneva, Rousseau had to shed both the Calvinism and the republicanism of his father.

Relationship with Mme de Warens

Rousseau found his way to Annecy, in Savoy, and to Mme de Warens (Louise-Elkanore de la Tour du Pil), who had left her husband and become a convert from Pietism to Roman Catholicism. Under her protection he was sent to Turin, to the Hospice of the Holy Spirit, which he entered on April 12, 1728. According to the register of the hospice, he abjured the heresies of Calvin on April 21 and was received into the Roman Catholic Church two days later, though in the ***Confessions*** he describes a much longer resistance to conversion and says that he finally succumbed in order to escape the pernicious moral atmosphere of the hospice. For several months he stayed in Turin, working as an engraver and as a lackey. He returned to Mme de Warens in the spring of 1729 and went for a time to a seminary, but he soon found that he had no vocation to the priesthood. He then set himself up as a teacher of music to girls from some of the wealthiest families in Annecy and later in Neuchâtel. In 1731 a trip to Paris for a few days led to nothing. Rousseau returned on foot to Mme de Warens, who by this time had moved to Chambéry. She offered herself to him as his mistress in 1733, saying that she thought it would be good for him; he accepted, though he felt himself more her son than her lover. He stayed with her until 1740, and she found him a position in the tax office of Chambéry and then at a small farm nearby called Les Charmettes. It was during this period that he became a diligent but unsystematic reader and that he first began to write.

In May 1740 he went to Lyons to tutor the children of M. Jean-Bonnet de Mably, *prévôt des maréchaux* ("provost marshal") and elder brother of Etienne Bonnot de Condillac, a noted philosopher and psychologist, and of the Abbé de Mably, a well-known political writer; but when his year's contract was over he was not asked to return. In 1741 or 1742 Rousseau set out again for Paris with the scheme for a new system of musical notation, the rough draft of a comedy *(Narcisse),* and two letters in verse dedicated to friends in Lyons. He failed to gain the success he had hoped for in Paris, but the publication in 1743 of his *Dissertation sur la musique moderne* and his *Épître à Bordes* together with the composition of an opera, *Les Musesgalantes* (1745), a comedy, *Les Prisonniers de guerre,* and some works on chemistry opened for him the doors to the wealthy family of Claude Dupin, a *fermier général* (banker) and counsellor to the King. Rousseau attempted to court Mme Dupin and failed. He then left Paris for Venice and became the private secretary to the French ambassador, with whom he quarrelled so violently, however, that he lost his post and returned to Paris in August 1744.

Years in Paris with the Encyclopédistes. Early in 1745 he took up with Thérèse Levasseur, a chambermaid at the hotel where he was staying. He had several children by her, who were all sent to a foundling home. Eventually, in 1768, he married her in a civil ceremony. Shortly after returning to Paris, he also met and established a friendship with Denis Diderot, then still a young philosopher going through an intellectual evolution from Skepticism to Materialism; he was to have a profound influence on Rousseau. A performance of *Les Muses galantes* in the home of La Poplinière, a *fermier général,* and his work on the score of the *Fêtes de Ramire,* an opera with words by Voltaire and music by Jean-Philippe Rameau, once again admitted him to the Dupin family. They employed him as secretary from 1745 to 1752. He did research for Mme Dupin, who was preparing a book on the subject of women, and he helped Dupin in a project to refute *De l'esprit des lois* (1748; Eng. trans., *The Spirit of Laws,* 1750) by Montesquieu.

Work on the *Discours sur les sciences et les arts*

At the same time, however, Rousseau was working for himself. Encouraged by Diderot, who was then in prison in Vincennes, he competed for the prize offered by the Dijon Academy in 1750 for an essay on the question whether the restoration of the sciences and the arts had tended to purify morals. His essay, known under the abbreviated title of *Discours sur les sciences et les arts,* won first prize; its publication at the end of the year made him famous. The published version did not completely reveal the boldness of Rousseau's ideas, however *—e.g.,* the subtitle *Libertk* was not used, and several passages directed against the tyranny of kings and the hypocrisy of the clergy were left out. Nevertheless, he attacked the sciences and especially arts and literature as enslaving and corrupting and as instruments of propaganda and sources of greater wealth in the hands of the rich. His attacks contained the seeds of criticism that would be applied to all the institutions of monarchic Europe. He wrote:

> Princes always view with pleasure the spread among their subjects of the taste for the arts and for superfluities that do not result in the exportation of money. For, besides fostering that spiritual pettiness so appropriate to slavery, they know well that the needs that people create for themselves are like chains binding them. . . . The sciences, letters, and arts . . . wind garlands of flowers around the iron chains that bind them [the people], stifle in them the feeling of that original liberty for which they seemed to have been born, make them love their slavery, and turn them into what is called civilized people.

The *Discours* provoked a series of violent disputes that continued for three years following its publication. Rousseau took advantage of this continuing debate to reveal progressively his ideas. He criticized the system of a mercenary army and advocated the organization of a people's militia. Not satisfied with merely denouncing luxury, he began to search for its causes in the existing social structures. In his *Observations* (1751) he noted:

> The primary source of evil is inequality; inequality has made possible the accumulation of wealth. The words rich and poor are only relative terms; wherever men are equal, there will be neither rich nor poor. Wealth inevitably leads to luxury and idleness; luxury permits a cultivation of the arts, and idleness that of the sciences.

During this period Rousseau pursued his work as a musician and a theorist of music. He wrote all the articles pertaining to music for the *Encyclopédie,* edited by Diderot and Jean d'Alembert, and later published them in his own *Dictionnaire de musique.* In 1752 he composed an opera, *Le Devin du village (The Cunning-Man, 1766),* which was first performed before the royal court at Fontainebleau. It was a great success; Rousseau was to be presented to Louis XV the next day to receive a pension, but he refused to go. The favourable reaction to this work contributed to the increasing popularity of Italian music, which Rousseau described as more natural and more passionate than French music, and earned him the opposition of Rameau and the partisans of French music. Defending himself against the accusation that his music and writing were in contradiction to the message of his *Discours,* Rousseau wrote in his *Prkface de Narcisse* (1752) that because he was not able to suppress the poison of the arts and literature, he was serving as an antidote to the poison, directing the weapons of corruption back on corruption itself. To prove the sincerity of his words, he sold all his valuables, stepped down from his position as cashier at Dupin's bank, and from then on earned his living by copying music; he called this action his "great reform." As a result of his criticism of French music and of tyrannical government, Rousseau was placed under police surveillance, beginning in 1753.

Political thought

In the same year he ventured to reveal his true political thoughts in response to questions raised by the Dijon Academy concerning the origin of inequality among men and whether it is authorized by natural law. In his *Discours sur I'origine et les fondements de l'inégalité parmi les hommes* (1755), he gave a hypothetical description of man's natural state, proposing that, although unequally gifted by nature, men at one time were in fact equal: they lived isolated from one another and were subordinated to no one; they avoided each other as wild animals do. According to Rousseau, geological cataclysms brought men together for the "golden age" described in various myths, an age of primitive communal living in which men learned good together with evil in the pleasures of love, friendship, songs, and dances and in the pains of jealousy, hate, and war. The discovery of iron and wheat initiated the third stage of human evolution by creating the need for private property:

> It is iron and wheat that have civilized men and ruined the human race . . . . From the cultivation of land, its division necessarily followed. . . . When inheritances increased in number and extent to the point of covering the entire earth and of bordering one on the other, some of them had to be enlarged at the expense of others. . . . Nascent society gave way to the most horrible state of war.

He further proposed that this warring state forced wealthy landowners to resort to a system of laws that they imposed to protect their property.

Rousseau did not pretend that man ought to recapture the primitive equality of his natural state, for he knew that a return to the past was impossible; but, in an article commissioned by Diderot for the *Encyclopédie* and published separately in 1755 as ***Le Citoyen: Ou Discours sur l'économie politique,*** Rousseau sought ways to minimize the injustices that result from social inequality. He recommended three ways: first, equality in political rights and duties, or the respect for a "general will" according to which the private will of the wealthy would not impinge upon the freedom or the life of anyone; second, public education for all children grounded in devotion for one's country and in moral austerity according to the model of ancient Sparta; third, an economic and financial system combining the resources of public property with taxes on inheritances and luxuries.

In the summer of 1754, Rousseau made a short visit to Geneva, where he was well received. He once again became a Calvinist and recovered his citizen rights. In Paris he continued for a while to support the Encyclopédistes and Philosophes in their struggle against the forces of the church and the Parlement (the "superior" court of judicature under the *ancien régime*). He gradually, however, detached himself from them. Though he did not return to the traditional Catholic faith, he still did not wish to join his friends in their criticism of all religions. Rousseau elaborated a "theism" of the heart. According to him, only the rich could afford the luxury of atheism, whereas the poor needed the solace that could be found only in popular songs and religion. Moreover, the Encyclopédistes, having common interests and goals with the bourgeoisie and the rising class of technicians and scientists, were trying to increase productivity rather than to relieve the miseries of the people.

The novel *Julie*

Seclusion at Montmorency. Rousseau became increasingly exasperated with life in Paris and wished to escape it. Mme Louise-Florence-PCtronilleTardieu d'Esclavelles d'Épinay, daughter of a *fermier général* and a friend of the Encyclopédistes, offered him the use of l'Ermitage, a country house near Montmorency. He moved there in 1756 to devote himself to longer works, especially a treatise he planned to call ***Institutions politiques*** and another to be called *Matérialisme du sage,* in which he hoped to insert a spiritual goal into the materialistic methods of education. His projects, however, were sidetracked. In the forest of Montmorency, Rousseau dreamed of love and conjured up an outline for a novel based on the correspondence between two young lovers. By accident he met the Comtesse d'Houdetot, sister-in-law of Mme d'Épinay. Their relationship went no further than a kiss by moonlight, but his passion gave an unexpected turn to the plans for his novel, which eventually became ***Julie: Ou La Nouvelle Héloïse*** and had a broader moral, philosophical, religious, and even economic context than he had first conceived. Out of this passion there arose misunderstandings with Mme d'Épinay, which quickly, other causes intervening, led Rousseau to break with her and her lover, Baron de Grimm, a former friend and an important Franco-German literary critic. He left l'Ermitage in December 1757 and settled in Montlouis, another house near Montmorency, which belonged to the Maréchal de Luxembourg, one of the most devoted of Rousseau's powerful friends. He stayed at Montlouis until June 1762; there he completed ***La Nouvelle Héloïse*** which was published in 1761.

Another incident caused Rousseau to break completely from Diderot and the Encyclopédistes. Jean le Rond d'Alembert, at Voltaire's instigation, had written the article "Genève" for the *Encyclopédie,* in which he asserted that the clergymen of Geneva were "Socinians" (referring to the anti-trinitarian followers of two 16th-century Italians known as Socinus) and that they no longer believed in Christ's Resurrection. Furthermore, he proposed that a theatre be set up in Geneva to serve as a propaganda centre for philosophical ideas. Rousseau secretly prepared a reply to this article, the ***Lettre à d'Alembert sur les spectacles,*** which was published in 1758. In it Rousseau showed that the French classical theatre from Molière to Voltaire had been the prisoner of the aristocratic conception of social and cultural life. It did not "purge" evil passions and did not "chasten" morals; on the contrary, it led to idleness and corruption, and the people of Geneva should distrust it if they wished to defend their liberty. In the preface to the letter, Rousseau responded to Diderot, who had written that "only the wicked one lives alone," alluding to Rousseau's seclusion at Montmorency. Rousseau rebutted that social and worldly life was the source of wickedness. Diderot considered the letter a desertion, a betrayal at a time when Rousseau should have been defending the ***Encyclopkdie.***

Émile and ***Du contrat social***

Still at Montlouis, Rousseau began working on his two great projects, which both appeared in 1762. The ***Matérialisme du sage*** became a long reverie about education and acquired the title ***Émile: Ou de l'kducation.*** It has appeared to many that Rousseau was trying to make amends for abandoning his own children by helping other parents raise their children properly. He advised them to shed their social prejudices and to "follow nature." Mothers should breast-feed and should strengthen the bodies of their children by means of severe tests of physical strength and endurance. His method of education was to slow down intellectual growth: it called for the child to demonstrate his own interest in a subject and ask his own questions; at the stage of puberty, however, the sensitivity of the youth should be educated. The adolescent would hopefully accept a free and reciprocal "contract" of friendship with his teacher, who could then help him uncover the joys of religion and the difficulties of coping with society. Émile, who laboriously acquired a sense of property while cultivating his garden, discovered the hard life of a worker when he became apprenticed to a carpenter. Then, through Sophie, Émile discovered the nature of love. He had to leave her, however, to complete his political education, which required looking through the world for the country that would best suit his future family.

In ***Du contrat social*** Rousseau developed the political principles that are summarized at the conclusion of ***Émile.*** Starting with inequality as an irreversible fact, Rousseau tried to answer the question of what compels one man to obey another man or by what right does one man exert authority over another. He concluded that only a contract tacitly and freely accepted by all allows each one "to bind himself to all while retaining his free will." Freedom is inherent in freely accepted law: "To follow one's impulse is slavery but to obey the self-prescribed law is liberty." In order to prevent this law from profiting solely the rich, the condition in which each one has something and no one has too much must exist. The conclusion derived from these principles is that the people alone are sovereign and that they exercise their sovereignty through a government that may be revoked at any time. He stressed the necessity of adapting the forms of government to existing historical and geographical conditions. After analyzing the workings of the Roman Republic, he concluded that "civil religion" is a political necessity. Such a religion consists of two dogmas: first, tolerance of all religious opinions; second, recognition that Providence will reward the good citizens and punish the bad. This religion lays a firm foundation for total commitment to the collectivity.

Attacks on his works and his way of life

Exile in Switzerland and England. *Émile* and *Du contrat social* were condemned by the Parlement of Paris in June 1762 as contrary to the government and to religion. Rousseau had to flee to Switzerland, but there, too, he and his works were banned. He defended himself in his *Lettre à Christophe de Beaumont* (1763), an attack on the Archbishop of Paris, who had condemned *Emile,* and in his *Lettres écrites de la montagne* (1764; "Letters Written from the Mountain"), a reply to J.-B. Tronchin, procurator general of the Genevan Republic, who had written in defense of the executive council of Geneva for having ordered the burning of *Émile* and of *Du contrat social.* In September 1764 Rousseau was asked by Matteo Buttafoco, a friend of Pasquale Paoli, leader of the Corsican nationalists, to prepare a constitution for Corsica. He never completed the task, though he did make a rough draft. On the last day of 1764 he received an anonymous pamphlet, *Le Sentiment des citoyens* ("The Feeling of the Citizens"), attacking him savagely as a hypocrite, a heartless father, and an ungrateful friend. It was written by Voltaire, and its effect on Rousseau was terrible. When he recovered from the shock, he decided to write his autobiography, the *Confessions.*

The *Lettres écrites de la montagne* had turned the Protestant ministers even more strongly against him, and in September 1765, after his house had been vandalized, he decided to leave Môtiers in the territory of Neuchâtel, where he had been living. He fled to the Île Saint-Pierre on Bernese territory, and then, through the help of François-Louis de Bourbon, the prince of Conti, obtained a special passport allowing him to go to England, where he arrived in January 1766. David Hume, a British Empiricist, took him under his patronage, but Rousseau, whose reasoning powers had been affected by his tribulations, began to suspect that Hume had been won over by the Parisian Philosophes into a plot to ruin his name. This fear and Hume's excessive zeal to justify himself publicly at Rousseau's expense led to an open quarrel between them, which excited and amused all cultivated Europe. In May 1767 Rousseau fled in panic to France.

Last years in France. Rousseau took the name Renou and moved to the Château de Trye, near Gisors, lent to him by the Prince of Conti. While he was at Trye his *Dictionnaire de musique,* which he had been working on for years, was at last published. He left Trye abruptly in June 1768, again in a panic, going first to Bourgoin near Lyons, where he married Thérèse Levasseur, and then to Monquin. During this period he wrote his *Confessions.* In 1770 he moved to Paris to defend himself against the "conspirators." There he resumed his own name but was left unmolested. To justify himself to the world, he read extracts from his *Confessions* in various Parisian salons until, at the request of Mme d'Épinay, he was ordered to desist by the police lieutenant of Paris.

In 1771 he was asked by the Confederation of Bar—noble Polish nationalists—to advise them how the Poles should reform their institutions, and he wrote *Considérations sur le gouvernement de Pologne.* Still eager to justify himself, he wrote the *Rousseau juge de Jean-Jacques: Dialogues.* He tried in December 1775 to place this work under God's protection on the high altar of the Cathedral of Notre-Dame but was prevented from doing so by the iron grille surrounding the choir. It seemed to him that God had joined his persecutors, and for a time he was in despair. During the last two years of his life his madness weighed less heavily on him; he led a secluded life with Thérèse, accepted some young visitors, and wrote the most serene and delicate of his works, *Les Rêveries du promeneur solitaire* ("Reveries of a Solitary Walker"), which contains descriptions of nature and of man's feelings for nature. In May 1778 he moved to Ermenonville, to a pavilion on the estate of the marquis René de Girardin, where he died about six weeks later, on July 2. He was buried on the Île des Peupliers in the lake at Ermenonville, but his remains were moved to Paris to the Panthéon during the Revolution.

MAJOR WORKS

NOVELS: *Lettres de deux amants habitants d'une petite ville au pied des Alpes, reccreillies et publiées par J.J. Rousseau,* 6 vol. (1761, in subsequent editions called *La Nouvelle Héloïse; Eloisa;* or *A Series of Original Letters Collected and Published by J.J. Rousseau,* trans. by William Kenrick, 4 vol., 1761); *Emile: Ou de l'dducation, 4* vol. (1762; *Emilius and Sophia: Or, A New System of Education,* trans. by William Kenrick, 4 vol., 1762–63).

AUTOBIOGRAPHICAL WORKS: *Rousseau juge de Jean-Jacques. Dialogues . . . premier dialogue. D'après le* manuscrit de *M. Rousseau, laissé entre les mains de M. Brooke Boothby* and edited by him (1780); *Les Confessions, suivies des rêveries du promeneur solitaire,* 2 vol. (1782; *The Confessions of J.J. Rousseau: with the Reveries of the Solitary Walker,* trans. from the French, 1783; *Confessions, etc.,* Everyman Library, 2 vol., 1960).

ESSAYS: *Discours qui a remporte' le prix à l'Académie de Dijon en l'année 1750. Sur cette question . . . si le rétablissement de sciences et des arts a contribué a épurer les moeurs; Par un citoyen de Genève* (1750; *A Discourse, to Which the Prize Was Adjudged by the Academy of Dijon . . . on This Question . . . Whether the Re-establishment of Arts and Sciences Has Contributed to Purify Our Morals,* trans. from the French by R. Wynne, 1752); *Discours sur l'origine et les fondaments de l'inégalité parmi les hommes* (1755; *A Discourse upon the Origin and Foundation of the Inequality Among Mankind,* 1761); *Emile for Today: The Emile of Jean Jacques Rousseau,* selected, trans., and interpreted by William Boyd (1956); *Le Vicaire savoyard, tiré du livre intituld Emile* (1765; *Rousseau's Admissions Concerning the Gospel and the Character of Christ,* being an extract from Rousseau's *Emile,* 1830); *Du contrat social: Ou, principes du droit politique* (1762; *A Treatise on the Social Compact: Or, The Principles of Political Law,* trans. from the French, 1764); *Considérations sur le gouvernement de Pologne, et sur sa rdformation projettke* (written 1771, published 1782); for further examples of Rousseau's political works, see *The Political Writing of Jean Jacques Rousseau,* ed. by C.E. Vaughan, 2 vol. (1962).

LETTERS: *Lettre sur la musique française* (1753); *J.J. Rousseau . . . à M. d'Alembert . . . sur son article Genève dans le VII^e^ volume de l'Encyclopédie, et particulièrement, sur le projet d'e'tablir un théâtre de come'die dans cette ville* (1758; *Politics and the Arts: Letter to M. d'Alembert on the Theatre,* trans. and ed. by A. Bloom, 1960); *Lettres écrites de la montagne* (1764); for further examples of Rousseau's voluminous correspondence, see the *Catalogue de la correspondence de J.-J. Rousseau, lettres expédiées et reçues, conservée à la bibliothèque de la ville de Neuchâtel* (1963).

MUSICAL WORKS: *Dictionnaire de musique* (1768; *A Dictionary of Music . . .*, trans. by William Waring, 1779?).

Bibliography: JEAN SENELIER, *Bibliographie générale des oeuvres de J.J. Rousseau* (1949); *Annales de la Société Jean-Jacques Rousseau* (1905–71).

Works: Oeuvres complètes de Jean-Jacques Rousseau, "Bibliothèque de la Pléiade," 4 vol. (1959–69); *Correspondance complète de Jean-Jacques Rousseau,* ed. *by* R.A. LEIGH, 16 vol. (1965–72).

Biography: JEAN GUEHENNO, *Jean-Jacques Rousseau,* new ed., 2 vol. (1962; Eng. trans., 1966), a vivid, accurate biography; F.C. GREEN, *Jean-Jacques Rousseau: A Critical Study of His Life and Writings* (1955), a good study of the relationship between Rousseau's life and writings; LOUIS JOHN COURTOIS, *Chronologie critique de la vie et des oeuvres de Jean-Jacques Rousseau* (1923–24).

Political thought: ROGER D. MASTERS, *The Political Philosophy of Rousseau* (1968); MICHEL LAUNAY, *Jean-Jacques Rousseau, écrivain politique* (1972), the first chronological bibliography of the writings of Rousseau, showing the relationship between his politics and literature.

Religion: PIERRE M. MASSON, *La Religion de Jean-Jacques Rousseau, 3* vol. (1916), a valuable work.

Philosophy: ERNST CASSIRER, "Das Problem Jean-Jacques Rousseau," in *Archiv fur Geschichte der Philosophie* (1932; Eng. trans., *The Question of Jean Jacques Rousseau,* 1954, reprinted 1963), a very clear and prestigious Kantian interpretation; PIERRE BURGELIN, *La Philosophie de l'existence de J.-J. Rousseau* (1952).

Literature: JEAN STAROBINSKI, *Jean-Jacques Rousseau: La Transparence et l'obstacle suivi de 7 essais sur Rousseau,* 2nd ed. rev. (1971), the best psychological and literary interpretation of the thought of Rousseau.

(M.C.L.)

Rubber

Rubber is an organic substance—obtained from natural sources or synthesized artificially—which has the desirable properties of extensibility, stretchability, and toughness. Previously known as caoutchouc, a term that has become limited to the chemically pure form of the substance, rubber acquired its name from its ability to erase pencil marks.

Initially, all rubber was natural. Formed in a living tree, it consisted of the solids separated (coagulated) from the milky fluid latex, which occurs under the bark of many tropical and subtropical trees and shrubs. Today, more than half the rubber on the market, apart from one specialty lubber, is manufactured synthetically by means of chemical processes that were partly known in the 19th century but had not been applied successfully until World War II.

NATURALRUBBER

History. On his second voyage to the New World in 1493–96, Christopher Columbus saw Indians in Haiti play a game with balls made from the gum of a tree. The first mention of rubber being used for purposes other than sport was made in 1615, when a Spaniard related how the Indians, having gathered the milk from incisions made in various trees, brushed it onto their cloaks and obtained crude footwear and bottles by coating earthen molds and allowing them to dry.

The first serious accounts of rubber production and the primitive native system of manufacture were given in the 18th century when a member of a French geographical expedition sent to South America in 1735 described caoutchouc as the condensed juice of the *Hevea* tree. The first accurate account of the botanical characteristics of the *Hevea* species was given in 1775.

At the outset, not chemical knowledge but the ability to devise a suitable method of rubber manipulation was of paramount importance to the development of the rubber industry. Two Frenchmen, a physician and a chemist, attempted to discover a cheap and effective solvent for crude rubber brought from South America and introduced the use of turpentine and ether as solvents.

Invention of the "mackintosh"

Macintosh and Hancock. Important progress came at the beginning of the 19th century from the separate experiments of a Scottish chemist, Charles Macintosh (1766–1843), and an English inventor, Thomas Hancock (1786–1865). Macintosh's contribution was the rediscovdry, about 1820, of coal-tar naphtha as a cheap and effective solvent. His experiments were successful; he placed a solution of rubber and naphtha between two fabrics and in so doing avoided the sticky or brittle surfaces that had been common in earlier single-texture garments treated with rubber. Manufacture of these double-textured, waterproof cloaks, henceforth known as "mackintoshes," began soon afterward.

The work of Hancock, who became Macintosh's colleague and partner, is of even greater importance. He first attempted to dissolve the rubber in turpentine, but his hand-coated fabrics were unsatisfactory in surface texture and smell. He then turned to the production of elastic thread. Strips of rubber were cut from the imported lumps and applied in their crude state to clothing and footwear. In 1820, in an effort to find use for his waste cuttings, Hancock invented a masticator. Constructed of a hollow wooden cylinder equipped with teeth in which a hand-driven, spiked roller was turned, this tiny machine, originally taking a charge of two ounces of rubber, fulfilled Hancock's greatest hopes. Instead of tearing the rubber to shreds, it produced enough friction to weld the scraps of rubber into a coherent mass that could be applied in further manufacture.

Goodyear and vulcanization. Early manufactured rubber softened with heat and hardened with cold (particularly annoying in the U.S., where climate was more extreme than in England). It also was tacky, odorous, and perishable. These fundamental weaknesses were removed by the invention of vulcanization in 1839 by the U.S. inventor Charles Goodyear (1800–60). Developing a compound of rubber, lead, and sulfur and a heat treatment (or curing) process, Goodyear created a product, at first called fireproof gum, afterward vulcanized rubber, that exhibited impressive durability.

Vulcanization made the modem rubber industry possible by permitting use of the substance in combination with machinery and in tires for bicycles, and later for automobiles. Though subsequent discoveries have refined Goodyear's original techniques, the vulcanization process remains fundamentally the same as it was in his day.

Founding of the tire industry

Rise of the rubber industry. Most European countries had established rubber industries by the decade 1820–30. Vulcanization and the increased use of steam and electric power brought a large demand for rubber. A pneumatic wheel was patented as early as 1845. The invention was ahead of its time, and it was left to John B. Dunlop, a British veterinary surgeon, to found the tire industry by patenting and developing pneumatic tires for bicycles and tricycles in 1888. His work had a great influence on popularizing cycling, both as a hobby and as a means of transport. At the end of the century some of the largest tire companies were commencing operations manufacturing solid rubber tires for horse-drawn carriages.

In 1876 the Englishman Sir Henry Wickham collected rubber seeds from the wild trees of the Amazon jungles and had them planted in Kew Gardens. The young trees were subsequently transferred to Ceylon and the Malay Peninsula where they formed the base of the natural rubber plantation industry that produces nearly 3,000,000 tons a year.

Rubber and the automotive industry. The first decade of the 20th century saw the establishment of the motorcar in Europe and the U.S. The dependence of the automotive industry for its tires, as well as many other components, on the drops of latex exuding from trees halfway across the world seems extraordinary in retrospect. Yet, despite the rapid expansion of the auto industry, especially in the U.S., it remained entirely dependent on natural rubber until about 1940. The change from steel wheels to rubber tires on agricultural tractors in the early 1930s added still more to the demand for rubber in the years before World War II.

Development of a synthetic rubber industry

When World War II began, Germany and the Soviet Union were the only two countries with the means of making synthetic rubber; all the other combatants were dependent upon natural rubber from southern Asia. After Japan entered the war, Asian sources, except for Ceylon, were cut off. The U.S., faced with necessity, developed a synthetic rubber industry almost overnight, achieving a production of 800,000 tons per year. At the war's end, with natural rubber again available, the U.S. synthetic rubber industry went into a sharp decline. By the early 1950s, however, a superior and more uniform synthetic became available. This new synthetic rubber, exported to the British and other European markets, stimulated development of a synthetic rubber industry in England. Synthetic rubber equalled natural in world volume in the early 1960s and moved ahead thereafter, as indicated in Table 1.

Table 1: World Consumption of Natural and Synthetic Rubber in Selected Years (long tons)

year	natural rubber consumption	synthetic consumption*
1955	1,890,000	1,063,000
1964	2,260,000	2,748,000
1970	2,888,000	4,530,000†
1972	3,120,000	5,365,000

*All types. †Estimated.

Since World War II, rubber—natural or synthetic—has retained its place as one of the world's most important commodities. While vlastics have made some inroads into markets previously monopolized by rubber, new uses and expansion in traditional applications have brought steady expansion of the industry.

The rubber tree. (For a detailed discussion of the botany of the rubber plant, see EUPHORBIALES.) Commercially, natural rubber is obtained almost exclusively from Hevea brasiliensis, a tree indigenous to South America, where it grows wild to a height of 120 feet (36 metres). Cultivated in plantations, however, the tree grows only to about 80 feet (24 metres) because carbon, necessary for growth, is also an essential constituent of latex. Since only atmospheric carbon dioxide can supply carbon to the plant, that element has to be rationed between the two needs when the tree is in active production. And with foliage limited to the top of the tree (to facilitate tapping), the intake of carbon dioxide is less than in a wild tree. Because other latex-producing trees do not compare with Hevea brasiliensis for efficiency, industry botanists have concentrated their efforts exclusively upon this species.

Other natural sources of rubber

Because of their historical importance, however, other natural sources of rubber of considerable value in presynthetic days deserve brief mention. *Castilla,* a plant of the family Moraceae of the order Urticales (elm), yielded a large quantity of rubber at one tapping, then required a rest for several months. Manihot, a genus of the family Euphorbiaceae, though best known as the source of tapioca, provides another variety of latex. Outside Brazil, producers have constantly searched for alternate sources of rubber. The watery content of many plants contains some rubber; two of importance are guayule (Partheniurn argentaturn), a shrub grown mainly on the U.S.–Mexican border, its chief drawback being its high gum content (up to 50 percent); and the Russian dandelion (kok-saghyz), yielding a latex with a 30 percent dry-rubber content. Both were exploited during World War II.

Modem production. Hevea brasiliensis has long been cultivated. Seeds are carefully selected, often from widely scattered areas to avoid inbreeding. Widespread planting provides a greater selection of young plants with elimination of weak growths. In the scientific layout of plantations, the natural contours of the land are followed and the trees protected from wind. Precautions against disease include inoculation. Cover crops planted adjacent to the rubber trees hold rainwater on sloping ground and help fertilize the soil by fixing atmospheric nitrogen. Standard horticultural techniques, such as nursery growing of hardy rootstocks and grafting on top of them, hand pollination, and vegetative propagation (cloning) to produce a genetically uniform product, are also employed.

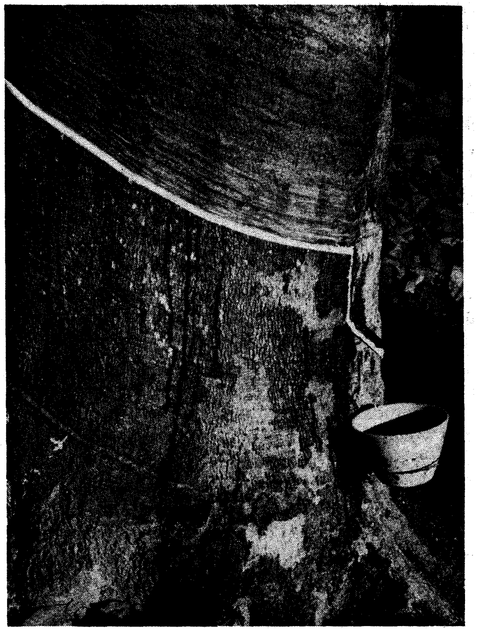
Plantations. Rubber trees grow only within a well-defined area of the tropics—about ten degrees north or south of the Equator—and in most types of soil. Heavy annual rainfall of about 100 inches (250 centimetres) is essential, with emphasis on a wet spring. In consequence, growing areas are limited. Southeast Asia is particularly well situated for rubber culture; so are Liberia and Nigeria in West Africa. Malaysia is the biggest producing area and is considered the centre of the world industry because of the concentration of commercial and technical interests in the capital city of Kuala Lumpur.

Malaysian rubber production

The plantations of Malaysia achieved prominence about 1900; from that time their products steadily replaced the wild rubber of Brazil. Yield initially was about 300 pounds of rubber per acre per year. By effective management, research, and the use of chemical stimulants, the average has been increased to 1,500 pounds (680 kilograms) per acre. An average of 3,000 pounds (1,360 kilograms) is anticipated in the near future; eventually, scientists believe, 6,000 pounds (2,720 kilograms) will be possible. About one ounce (28 grams) of rubber is obtained per tree per tapping before the latex coagulates and flow stops. If this coagulation can be prevented, the latex continues to flow; a chemical, Ethrel, applied to the bark has been shown to be capable of doing this. In consequence, the small collection cup that was emptied every day or two is being replaced by larger polyethylene plastic bags that require attention only every 10 to 14 days.

Tapping. The standard method of tapping a rubber tree for latex is to score it with a knife to a depth of one millimetre for half the circumference of the trunk, slanting the cut down from the left to right at an angle of 30 degrees starting at the highest point convenient to the tapper; each subsequent cut is made immediately below its predecessor. Trees are often rested for a period after heavy tapping. Production commences when a tree is from five to seven years old; with care, the tree's life may extend to more than 30 years.

By courtesy of UniRoyal, Inc., New York



Trunk of a rubber tree showing latex flowing from tapping cut into the collection cup on a plantation in Malaysia.

The watery latex from the scored tree oozes out from between the outside cork layer of the bark and the cambium inner layer, where new cells are formed. Although the function of latex in maintenance of the trees has not been explained satisfactorily, a great deal is known of its composition. Three types of particles are suspended in the watery medium: one rubber and two nonrubber. Of the two latter, the more abundant is the neutral gray particle known as a lutoid, and the other, more highly coloured and named after its discoverer, is called the "Frey Wyssling" particle.

Treating slabs of rubber

Coagulation. After collection, the latex is sieved to remove foreign objects; then water is added. Next, the rubber is coagulated from the latex by the addition of dilute acetic or formic acid and is deposited on aluminum partitions in horizontal tanks having aluminum partitions that allow the rubber to be removed in slabs rather than in a single lump. When necessary, the slabs are washed by passing them between horizontal rollers, moving at different speeds and flushed with a copious supply of water. Excess water is removed by passing the rubber through a succession of rollers. Subsequent treatment depends upon the type and grade of rubber desired.

Wild rubber was originally recovered by heating latex over a fire while stirring it with a stick. The water was removed by evaporation, leaving behind a solid ball of rubber. This method was not welcomed by the market, however, because the solid balls of rubber were hard to store and, in the early days, because of the fear that stones, metals, and other dense objects would be included to falsify weight.

Rubber types and grades. Rubber may be processed into pale crepe, smoked sheet, or skim rubber. The various ways of grading rubber are subject to controversy.

Pale crepe. After emerging from the coagulation tanks, the wet slabs of rubber are run through a succession of creping mills that roughen the rubber's surface and gradually reduce its thickness to facilitate drying. The sheets are then laminated to the desired thickness and allowed to air-dry. Pale crepe, which varies in colour from off-white to deep cream, is used wherever colour is an important factor. Impurities in the rubber give it its colour, which can be controlled by regulating the strength of the acid when the first rubber is deposited by coagulation; the stronger the acid, the more impurities will be precipitated. The lighter coloured rubber can be sold at a premium. A bleaching process is also used. In general, pale crepe is used only where colour is decisively important, as some of its physical properties (tensile strength, for example) are inferior to those of sheet.

Smoked sheet. Slab rubber can sometimes be sheeted out—that is, run through sets of plain rolls until the last set, which prints a simple pattern, such as crisscross. The sheet is then hung up to dry in smoke from burning wood or oil to obtain the "smoked sheet" of commerce. The best quality has an amber or brown shade.

Skim rubber. Normal coagulation methods leave ten percent of the rubber behind in the liquid of the coagulation tank. That residual rubber can be recovered by skimming, but it contains a much higher proportion of impurities and so is less desirable.

Pale crepe, smoked sheet, and skim rubbers are generally made up into bales, most frequently weighing *225* or *250* pounds *(102* or *113* kilograms) and bulking as a cube about two feet *(60* centimetres) to a side. The rubber is coated with clay or similar material to prevent sticking, and the bales are bound with metal strapping.

International grading standards. The three types of rubber described above are graded according to international standards published by the Rubber Manufacturers Association, Inc. of New York. Blending different grades of the same type or of entirely different types of rubber is quite a common practice of manufacturers to obtain the best properties for some specific purpose. The user also may blend bales from different deliveries of the same type of rubber to obtain a more uniform product. It is uneconomical to wash and strain low grades to raise their quality.

Grading has traditionally relied upon visual inspection and, for that reason, has received serious criticism over the years. Consequently, efforts have been made to find a more scientific basis for grading. In *1950,* the Technically Classified Rubber system was devised, employing nine grades based on the physical properties, viscosity and rate of cure. But because viscosity of natural rubber varies with age, industry would not accept the system. Furthermore, a premium was charged for grading; and the plan was initially confined to top-grade rubber. By the time it was extended to the lower grades, it was too late to halt declining interest. Rubber-growing interests always regard top grade as standard and others as off-grades, whereas important sections of the manufacturing industry, such as tire makers, purchase the lower grades.

The Technically Classified Rubber system

In *1965* Standard Malaysian Rubber, a much more ambitious and practical system, based on technical specifications and defined packing requirements, came into use. With some later modifications and extensions, the fundamental principle has taken hold, and rapidly increasing quantities of rubber have been marketed under this system, amounting in *1970* to about *250,000* tons or *10* percent of the total natural rubber produced (more than *20* percent of the Malaysian output). Grading is based on chemical analysis and controlled by the Rubber Research Institute of Malaysia.

Fundamentally, classification is by dirt content, but other chemical standards are imposed. For each grade there are maximum amounts allowable for various impurities. The Plasticity Retention Index has proved the most controversial quality criterion of the Standard Malaysian Rubber system. That index measures the chemical degradation of the rubber over time; the better the rubber, the less it should break down and, consequently, the higher the Plasticity Retention Index. Though the originators of the Standard system now feel that sufficient experience exists to accept the Index as an essential part of their standard, major rubber growers disagree. They say they have been able to provide first-class rubber that fails this test and samples of poor rubber that pass. Nevertheless, the Standard system has been a great advance over visual inspection and has formed the cornerstone of technical rubber grading.

Chemical and physical properties. Rubber has the empirical formula C_5H_8, indicating a molecule in its simplest form with five carbon and eight hydrogen atoms. Many of these simple molecules commonly combine together, producing a structure whose atomic weight varies within wide limits, depending upon conditions. The composition of raw rubber has been chemically determined both by breaking down the molecule into its simplest form, or C_5H_8 monomer, and by the reverse process of building up rubberlike materials from monomers (polymerization).

Rubber has certain peculiar and useful properties of which the most outstanding is its ability to stretch seven to eight times its original length. During extension, rubber gives out heat; as it contracts, it absorbs heat. The extent to which a piece of rubber can contract after being extended or stretched depends on temperature.

Rubber in solvents

The behaviour of rubber in certain solvents is peculiar. In most organic solvents it swells, part going into solution readily (the sol portion) and part resisting (the gel portion). Mastication of rubber encourages its diffusion in the solvent appreciably, producing "rubber solution," the viscosity of which is substantially reduced by further mastication or by the addition of small amounts of other liquids.

When defining the properties of rubber, care must be taken to distinguish between the chemically pure substance and the commercial product. Commercial latex contains a significant proportion of nonrubber material, much of which remains in the coagulated solid. Dried rubber typically contains *92* to *94* percent chemically pure C_5H_8, *0.13* to *1.20* percent water, *2.50* to *3.20* percent acetone extract, *2.50* to *3.50* percent nitrogenous substances, and *0.15* to *0.50* percent ash.

The nonrubber substances in commercial rubber affect its properties to a greater extent than their proportion would suggest. A high moisture content causes mold to form, damaging market value where appraisal is based on appearance, even though usefulness is not impaired.

The acetone extract contains unsaturated fats and fatty acids, which have a softening effect and also accelerate vulcanization even when present in quite small proportions. The yellow colouring material of pale crepe is found to some extent in the acetone extract. Antioxidants occur in minute amounts but have a very beneficial effect on the aging qualities. Proteins, present in varying degrees, have little effect except upon vulcanization, which they accelerate. Complicated alcohols and other organic substances occur in small proportions.

The ash found in latex contains all the mineral matter and varies in quantity and nature according to circumstances. A certain amount of sand and soil is inevitable. More harmful are the traces of copper and manganese, which act as catalysts for chemical reactions that result in the degradation of rubber. Their action depends upon their state of combination. For example, Cambodian rubbers are always high in manganese, but because the manganese is combined organically it has no deleterious effect.

Physical tests of rubber

Chemical examination of rubber is a tedious operation requiring great skill. Hence, it is usually done only where absolutely required as, for example, in arbitration disputes. Of greater practical value and far easier to perform is the physical testing of commercial rubber. It is carried out on vulcanized compounds and varies in type according to the proposed use of the product (*i.e.*, resistance to or conduction of electric current, resistance to water, acids, and other chemicals). Two important physical tests involve measurement of modulus of elasticity and tensile strength. Modulus of elasticity, defined as the response of rubber to a force applied in a given direction, is generally measured by stretching a piece of rubber of known cross section, the stress being the force applied and the strain, the extension, which, of course, will vary with temperature. Modulus may be measured at *100,200,300, 500,* or *600* percent extension or at any other appropriate elongation. The result is recorded in kilograms per square centimetre or pounds per square inch. Modulus is normally a function of the state of cure, and as such is considered more important than tensile strength, which is the ultimate stress required to break a standard specimen, again expressed in the same units. Elongation at break is usually measured at the same time.

One other physical property of cured rubber is frequently quoted because of its simplicity, namely, hardness. It is generally measured by pressing the point of a cone-shaped instrument called an indenter into the rubber and measuring the depth of penetration on an International Rubber Hardness scale.

For specific uses, special laboratory tests have been devised. For example, tire-tread compounds are tested for abrasion and skid resistance. Dynamic testing (*i.e.*, with the rubber in motion) attempts to simulate service conditions; but until it is accepted more widely, full-scale service testing, which is expensive and time-consuming, will continue.

Distinctive uses of natural rubber. Though natural rubber performs well in most applications, some of the newer synthetics surpass it for specialized purposes. For example, acrylonitrile rubber has much better oil resistance, butyl rubber is much less permeable to air, and silicone rubber withstands higher temperatures.

Natural rubber is still preferred in applications that demand elasticity, resilience, tackiness, and low heat buildup. Natural rubber also is chosen when it has no particular technical advantage over synthetics but is competitive for price or availability. Natural rubber is indispensable for the treads of tires for racing cars, bus and truck tires, airplane tires, and any other form of transport where conditions are particularly severe and where a buildup of heat inside the tire could cause a failure. Broadly speaking, the larger the tire, the greater the proportion of natural rubber used in its construction, to minimize heat buildup.

The resilience of rubber is utilized in engine mounts and suspension units of automobiles, and its ability to withstand severe loads for long periods in compression has led to its use in building foundations. These properties, in addition to good cold-temperature resistance, also make it useful in bridge bearings.

Distinctive uses of natural rubber latex. Latex represents rubber in its most tractable form. Criticism has long been made of the time and effort spent at plantations in removing water from latex to obtain solid rubber and the subsequent effort made at its destination to render the rubber processable. Dried latex, in fact, has some better physical properties than conventional solid rubber, but the cost of transporting a material containing 60 percent water across the world would be excessive. Concentration of latex to a content of 60 to 70 percent dry rubber is performed either at the source or in the user country by means of centrifuging, evaporation, or a process known as creaming, in which an agent is added to the latex that causes the rubber particles to swell and rise to the surface of the liquid.

Creaming as a concentration Process

Latex is an excellent adhesive and is widely used in its natural state, but for most industrial uses it needs additives and vulcanization. Accelerating agents for vulcanizing and other essential fillers are added. One of the oldest uses of latex is in the production of such dipped goods as rubber gloves and prophylactics. The process consists of dipping formers of the correct size and shape into compounded latex, then drying, repeating the operations, and vulcanizing.

Rubber (elastic) thread also is produced from latex. Initially, strips were cut from a thin sheet to form a thread of square cross section. Later, the much superior round thread was obtained by extruding compounded latex into a bath of coagulant through glass nozzles.

Foam rubber has been one of the most important latex products since its discovery in the 1920s. The confinement of thousands of gaseous bubbles in natural rubber cells provides ideal resilience. In the simple manufacturing process, excess ammonia is removed from the latex, and, after a vigorous stirring with dispersions of soap, sodium fluorosilicate is added to the frothy mixture as a gelling agent, along with accelerating agents, zinc oxide, and antioxidant. After the liquid has stood in a mold for several minutes to permit gelling, it is vulcanized. In practice, the process requires the most careful control and the judgment of experienced personnel.

Foam products were made originally in individual molds, which progressed along a conveyor in series and into each of which a predetermined quantity of foam was inserted, the mold closing during its progress to the oven. Washing, drying, and finishing completed the process. For large-scale production, a new method has supplanted this early method, which is still in active service. The process consists of filling a fixed mold with a metered quantity of foam, sealing it with its lid, and evacuating the air; the foam expands to partly fill the resulting vacuum, and then is frozen; next, carbon dioxide gas is passed in to fill the remaining vacuum in the foam, and the temperature is raised to 104" C (219" F) for curing.

The carpet industry has made increasing use of latex not only as a separate foam rubber underlay but as an undercoating on the carpet itself and as an anchoring matrix for tufted carpets. The latex may be either a vulcanizable natural rubber compound or a synthetic self-curing compound.

Foams frequently comprise a blend of natural and styrene-butadiene rubbers, the latter reducing the cost with some reduction in resilience.

SYNTHETIC RUBBER

History. In 1826 Michael Faraday assigned the empirical formula C_5H_8 to rubber. For the next 100 years or so chemists endeavoured to reproduce this molecule synthetically without success. It was only when the search for chemical equivalence was abandoned and adequate physical properties were emphasized that synthetic rubber came into being. The choice fell upon butadiene, C_4H_6, a compound related to natural rubber, to form the basis for synthetic rubber. Though Germany produced synthetic rubber (called methyl rubber) during World War I, it was an inferior substitute by present-day standards. Subsequently, Germany produced Buna rubbers, the first two letters "bu" standing for butadiene, and the last two, "na," for the chemical symbol for sodium, the catalyst used for polymerization.

Buna rubber and its successors

In Germany during World War II, product control remained in the hands of the chemical manufacturer, who gave first priority to quality and ease of production, without much regard for the subsequent difficulties of the user. In the U.S., the rubber producer was also the user; hence a more workable product was developed.

Wartime U.S. synthetic rubber was made from butadiene and styrene. Originally known also as Buna, its name was changed to GR–S (Government Rubber–Styrene) when the government took control. This was the forerunner of modem synthetic rubber. Although ideas for better or cheaper products developed, the government held to the GR–S formula for the duration of the war to avoid complications. Meantime, German chemical engineers perfected low-temperature polymerization, producing a more uniform product. The process, which has come into universal use, is known as redox, coined from the words reduction and oxidation. The two products are often referred to, respectively, as "hot" rubber and "cold" or low-temperature polymer synthetic rubber.

Types of synthetic rubber. In addition to styrene–butadiene, there are many specialized rubbers, sometimes difficult to classify because of the varying systems of nomenclature. Table 2 gives the equivalents that have been used: Some of the newer rubbers—*e.g.*, silicone, polyurethane, and Hypalon—have no official or generally agreed symbols.

The approximate world production in millions of tons of various popular types of rubber is given in Table 3. Adding in the smaller amounts of other special-use rubbers brings the annual total to more than 8,000,000 tons.

The world distribution of synthetic rubber production in 1970 is given in Table 4 as percentage of total production.

Table 2: Types of Synthetic Rubber

common name	original code name	American government code	current code	chemical description
Synthetic (unspecified)	Buna S	GR-S	SBR	styrene–butadiene
Butyl		OR-I	IIR	polyisobutylene–polyisoprene
Butadiene			BR	polybutadiene (solution polymer–stereospecific)
Neoprene (trade name)		GR-M	CR	polychloroprene
Nitrile	Buna N	GR-N (previously GR-A)	NBR	acrylonitrile–butadiene
Polyisoprene			IR	polyisoprene (solution polymer–stereospecific)
Thiokol (trade name)		GR-P		polysulfide
EPR				ethylene–propylene
EPDM				ethylene–propylene terpolymer

Styrene–butadiene rubber. This general purpose synthetic rubber, a polymer of butadiene and styrene, exceeds all others in consumption. Its symbol, SBR, covers a range of materials in which proportions of the two ingredients vary. Most styrene–butadiene lubber is manufactured by the emulsion process, in which the styrene and butadiene are brought together in a water solution of soap that acts to disperse, or emulsify, the materials in the solution. Other materials in the solution include catalysts, which initiate the reaction, and stabilizers, which prevent deterioration of the final product. A "short stop" agent is added to stop the reaction at the optimum point, when about 60 percent of the ingredients are converted to synthetic rubber. A modifier produces a material of the desired plasticity, and a coagulant is added to deposit the rubber from the latex.

Table 3: World Production of Popular Types of Rubber (1970)

	total	
	long tons (000,000)	short tons (000,000)
Natural	2.75	3.08
Styrene–butadiene	3.25	3.64
Butyl	0.30	0.34
Polybutadiene	0.70	0.78
Neoprene	0.35	0.39
Nitrile	0.20	0.22
Polyisoprene	0.25	0.28

Table 4: World Distribution of Synthetic Rubber Production (1970)

	percentage of total production
United States	44.3
Japan	13.8
France	6.3
United Kingdom	6.1
West Germany	6.0
Netherlands, The	4.1
Canada	4.1
Italy	3.0
East Germany	2.3
Brazil	1.5
Poland	1.2
Romania	1.1
Czechoslovakia	1.0
Others	5.2
World total	100.0

Styrene, a liquid, boils at 145° C (293" F), but butadiene, a gas at normal temperatures, boils at —4° C (25° F); butadiene may be stored in liquid form under pressure. Both liquids are pumped continuously into reactors and mixed with water, soap, and catalyst by constant agitation at controlled temperature. After the short stop is added, the unconverted butadiene and styrene are recovered and re-used. Then the antioxidant is added and the coagulant to deposit the rubber.

Varieties of SBR, each with its own properties, can be produced either by altering the ratio of the two ingredients; by using hot or cold polymerization; or by varying other elements in the manufacturing process. For example, with 23.5 percent SBR, fatty acid–soap emulsifying agents give a faster curing rubber, while the rosin acid–soap types yield a less tacky final product. Oils of different grades added to the reaction mixture of styrene and butadiene determine the final product's toughness.

A convenient feature of styrene–butadiene rubber is its final packaging in 34-kilogram (75–pound) polyethylene plastic bags, shaped for easy handling and shipping. If the minimum temperature in the user's mixing machine approximates 140" C (284" F), the rubber, bag and all, can be tossed into the mixer where the polyethylene will soften and disappear.

For many purposes SBR directly replaces natural rubber, the choice depending simply on economics. Its particular qualities include abrasion and crack resistance and generally better aging properties. Its limitations are poor strength (without such reinforcing fillers as carbon black), low resilience, low-tear strength (particularly at high temperatures), and poor tack (*i.e.*, it is not tacky or sticky to the touch). These characteristics determine its use in tire treads; its proportions decrease as need for heat resistance increases, until 100 percent natural is reached in the heaviest and most severe uses, such as tires for buses and aircraft, and for "off-the-road" vehicles. SBR, however, is used in great quantities for tire carcasses; generally some natural rubber is admixed to produce the necessary tack in assembly.

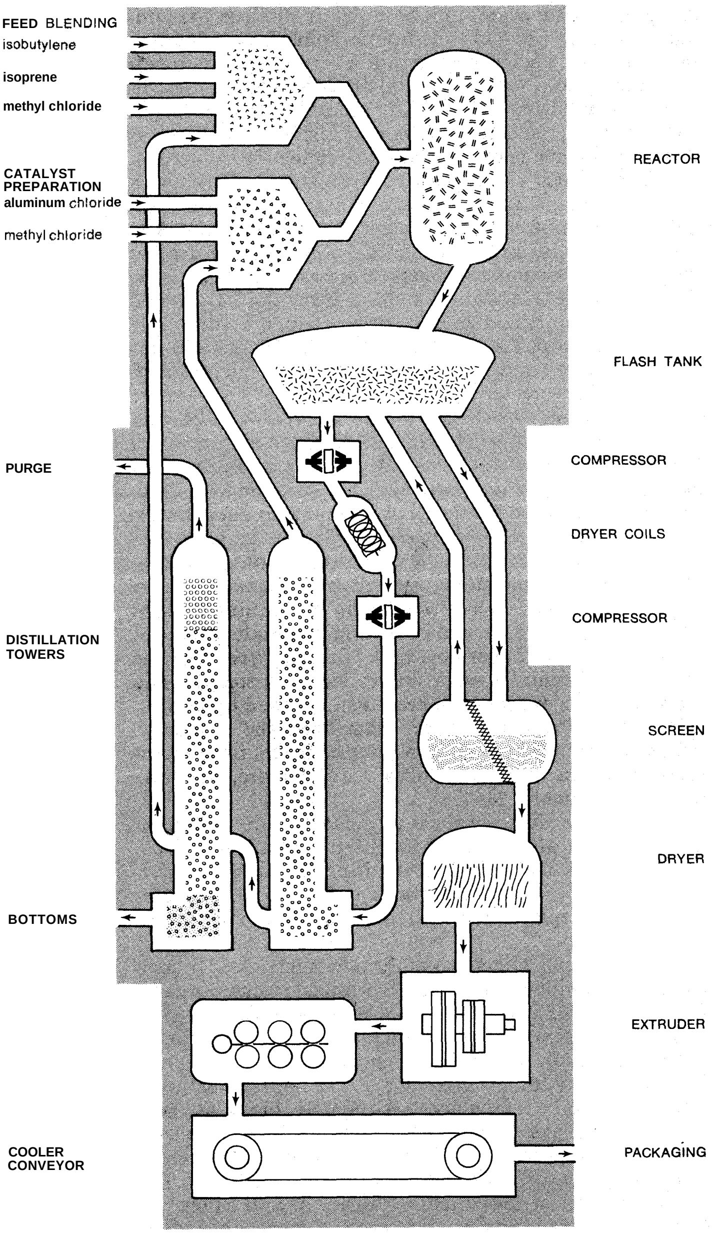
Butyl rubber. Butyl rubber (its symbol IIR) is essentially polyisobutylene, a polymer of isobutylene, which is an isomer of butylene. (Isomers are molecules with the same number of atoms but with different molecular structure and properties.) Isoprene is added during manufacture. Marketed in 1943, after ten years of research work, butyl rubber has enjoyed widespread acceptance because of some of its special properties: low permeability to gases, excellent resistance to oxygen and ozone at normal temperatures, and good resistance to vegetable oils. Butyl rubber is not readily attacked by acids, alkalies, and other chemicals harmful to natural rubber. In addition, it is elastic, odourless, nontoxic, light in colour, and can be worked on normal rubber machinery. Its electrical insulating properties are excellent.

Properties of butyl rubber

Butyl rubber has several disadvantages, especially its incompatibility with natural rubber and the main synthetics. In addition, butyl rubber has a strong affinity for foreign matter and must be carefully stored and screened before manufacture. Finally, it stiffens at low temperatures.

The polymerization of isobutylene is carried out at —95° C (—139" F), with aluminum chloride as a catalyst. Isobutylene and the desired proportion of isoprene are fed continuously into a medium of methyl chloride. After antioxidant is added, crumbs of butyl rubber form directly, without any latex stage. Zinc stearate (to prevent agglomeration, or formation of clumps of butyl rubber) also goes into the mixture. Excess reactants are recovered and re-used.

Because of its excellent air retention butyl rubber quickly took over from natural rubber for inner tubes in all but the largest sizes. Butyl rubber also plays an important part in the inner liners of tubeless tires. Despite excellent road-holding properties under wet conditions, and quiet, comfortable riding qualities, all-butyl tires have not proved commercially successful because of their poor tread durability. Butyl rubber, however, is used for many automobile components, such as window strips, because of its excellent resistance to oxidation. In its resistance to heat, butyl rubber also plays an indispensable part in tire



Principal steps in processing butyl rubber.
Drawing by D. Meighan

manufacture, forming the container for the hot water or steam required to vulcanize the inside of tires.

Polybutadiene. Polybutadiene (its symbol BR) is produced by a hydrocarbon solution process, in contrast with the water-emulsion method for styrene–butadiene rubber (SBR). Indeed, in making polybutadiene, water must be rigorously excluded to enable the catalyst to work. The resulting polybutadiene has better physical properties, particularly tensile strength and resilience, than styrene–butadiene rubber.

The main outlet for polybutadiene is in tire treads. Its high resistance to abrasion, low heat buildup, and resistance to cracking are strongly in its favour, particularly when blended with natural or styrene–butadiene rubber in giant tires. Its lower skid resistance when wet and lower tear resistance limit its proportions in car tires. Polybutadiene can absorb large proportions of oil and carbon black, thus reducing the cost of the final product and improving skid resistance appreciably. It is increasingly used to add strength and flexibility to plastics, highly resilient foams, and footwear; its low temperature performance favours outdoor uses.

Polyckloroprene (neoprene). Polychloroprene (its symbol CR) is the scientific name for the synthetic that bears the proprietary name Neoprene (which, however, has become generic). One of the first synthetic rubbers to be discovered, neoprene was first marketed in 1931. It is prepared by treating acetylene (C_2H_2) with cuprous chloride to form monovinyl acetylene, which, with hydrochloric acid, yields chloroprene. Competitive methods of production exist. It is manufactured in solid form (chips) and as latex.

Because of its general properties of high tensile strength, high resilience, good resistance to oxygen, ozone, and tearing, as well as an oil resistance only slightly inferior to nitrile (see below), neoprene is used extensively in the wire and cable industries, hose, extruded automobile parts, and for protective clothing. It also has excellent resistance to flame.

Nitrile. The original Buna N of German war production, the name nitrile (its symbol NBR) covers a range of copolymers of butadiene and acrylonitrile, the members differing from one another in their acrylonitrile content. The "standard" NBR material contains from 33 to 36 percent acrylonitrile, and others from 20 to 50 percent. The outstanding property of nitrile is its oil resistance, which increases in pace with its acrylonitrile content—but at the expense of low-temperature flexibility. Production is by an emulsion process quite similar to the styrene–butadiene rubber process; it can be made as solid sheets or liquid latex. Nitrile requires the addition of carbon black or other reinforcement to produce satisfactory physical properties, thus reducing the overall cost of nitrile, which is more expensive than conventional rubbers.

Nitrile's
oil
resistance

Nitrile is mostly used where high oil resistance is required, as for seals, gaskets, or other items subject to contact with hot oils. The rolls for spreading ink in printing and hoses for oil products are other obvious uses. Nitrile's reaction to oil is selective, however; it has excellent resistance only to some types. Nitrile applied to woven and unwoven fabrics improves finish and provides waterproofing. It blends readily with the plastic polyvinyl chloride, a mixture whose use for artificial leather and for paper coating is increasing.

Polyisoprene. The first true equivalent of natural rubber was achieved in 1955 by the polymerization of isoprene. Its product was polyisoprene (its symbol IR). Its manufacture follows the hydrocarbon solvent method for making polybutadiene (BR). Synthetic polyisoprene can replace natural rubber for most purposes, except when the nonrubber constituents of natural become advantageous. The decision is therefore usually based on economics, and since the basic monomer isoprene is expensive, either synthetic polybutadiene or natural rubber is usually favoured.

Silicone. A specialty rubber, silicone is limited in use by its cost; but its exclusive ability to retain its physical properties at extreme temyeratures, from −74" C (−101° F) to 315° C (599° F), makes up for its high cost. It is the first "inorganic" rubber; the polymer has a backbone of silicon and oxygen instead of the conventional carbon chain.

Although the raw material silica is cheap and plentiful, the manufacturing process is difficult and expensive. A range of products is available, their properties largely influenced by the molecular structure of the silicone. Its retention of electrical properties, resistance to oxygen and ozone, and inertness at extremely high temperatures recommend uses in aircraft and outer space equipment, and in the automobile field. Its inertness and nontoxicity encourage use for food and surgical applications.

Polysulfide rubber (Thiokol). Polysulfide rubber is the technical term for the substance bearing the trade name Thiokol, which has become generic. Originally synthesized in 1927, it is known for its excellent resistance to organic solvents and is marketed as a liquid, a putty, and in solid form. Its tensile strength does not compare with conventional rubbers, but it offers excellent resistance to weathering and permeabiiity over a wide range of temperature.

Ethylene–propylene rubber. A versatile new synthetic, ethvlene–propylene rubber exhibits excellent resistance to oxygen, ozone, acids, alkalies, and other chemicals over a wide range of temperature. It has good electrical properties and is quite lightweight, with an enormous capacity for acceptance of oil, thereby reducing the final cost. The addition of carbon black used as a filler, along with the oil, acts to raise the low tensile strength. In the early 1970s, ethylene–propylene was not yet sufficiently developed for a full assessment of its potential.

Polyurethane rubber. Polyurethane rubber includes a large range of materials of varied compositions, properties, and uses. In this group of rapidly growing importance, some of the polymers help significantly to bridge the gap between rubber and plastics. All are based on isocyanates, organic compounds that combine with other organic compounds such as alcohols, esters, ethers, and amides. The wide variety of materials available, when properly controlled, offers a series of polymers with a broad range of properties and forms.

Casting, mixing, and milling of polyurethanes

Polyurethanes may be cast from the liquid or semiliquid state, or mixed, milled, and vulcanized like other rubbers. Although they have high tensile strength and good resistance to abrasion and to oil and other solvents, they are not suited for normal tire service because of their rapid drop in abrasion resistance as temperature increases. Polyurethane is, however, finding increased use in small, solid tires. Probably the most popular uses of polyurethane are as foams and surface coatings: rigid foams for lining refrigerators and flexible foams as a substitute for natural rubber and durable finishes for floors and furniture.

Chlorosulfonated polyethylene (Hypalon). Chlorosulfonated polyethylene is normally known by its trade name of Hypalon. It is made by introducing first sulfur dioxide into a solution of polyethylene under strictly controlled conditions and then chlorine at higher temperature. Chlorine content may vary between 20 and 45 percent and sulfur from 0.5 to 2.75 percent. The physical properties depend much more upon the sulfur than the chlorine content. Rubbery compounds are produced with low sulfur and metallic oxide curing. Hypalon is outstanding in its resistance to weathering, ozone, heat, flame, and chemicals. Cost alone restricts its wider adoption.

Fluorocarbon polymers. Probably the best known fluorocarbon polymer is PTFE—polytetrafluoroethylene—although similar products share polytetrafluoroethylene's outstanding qualities of heat resistance, minimal friction, and freedom from surface adhesion. Originally these materials could not be extruded or vulcanized, but rubbery polymers have been developed that can be worked on conventional equipment. A recent use that has popularized this polymer is as a lining for cooking utensils; its nonsticking quality facilitates removal of cooking residues by simple washing.

Reclaimed rubber. Reclaimed rubber, or vulcanized rubber reworked to render it suitable as raw material, has become an important element in the industry. The starting point in reclaim rubber manufacture is the cured rubber scrap, natural or synthetic in origin, which is segregated into separate incompatible rubbers and then graded according to quality and intended use. Reclamation methods differ in sophistication, so that an appreciable range of reclaims is available.

It is not profitable to use reclaim unless it costs no more than half as much as virgin rubber, and when that new rubber is low-cost synthetic, the market for reclaim suffers.

Digestion of scrap rubber

Reclaim is manufactured in various ways. The simplest is digestion of scrap (to which oil has been added) either in caustic soda or in zinc chloride (the more modern method) to remove nonrubber products; it then is milled. Under the newer, continuous "reclaimator" method, any fabric is first removed mechanically; the rubber then is ground, mixed with oil, and extruded.

COMPOUNDING

Blending rubbers in prescribed proportions and adding chemicals in accordance with a "formula," or schedule, is called compounding. Initially, these formulas were guarded with great secrecy, often unnecessarily. Such secrecy has largely disappeared; most suppliers disclose the contents of their products. Although some manufacturers prefer to show each constituent of a formula as a percentage of the whole, the more usual practice is to list ingredients in relationship to 100 parts of rubber hydrocarbon.

The materials added to rubber are known variously as drugs, pigments (not necessarily confined to colours), and fillers. Since all rubbers, natural and synthetic, with the exception of some already containing fluorine, require addition of chemicals, a filler is not to be mistaken for an adulterant or cheapener. Of course, the vulcanizing agent, sulfur, must be added. But by itself it is slow, so that it needs accelerators, which, in turn, can be speeded up with secondary accelerators, or activators. To delay the decomposition of rubber products, antioxidants and antiozonants are required. (These and all other such protective materials are termed antidegradants.) To increase strength, rubbers need reinforcing agents—*e.g.*, carbon blacks, which are available in a wide range and impart a black coloration. Other materials may be added, as well as oils for processing, plasticizing, or softening. Finally, inert materials may be added for bulk, thus reducing cost.

Carbon-black filler

Reinforcing and filling materials. The outstanding material used for the last 50 years or more for improving elasticity and tensile strength of rubber has been carbon black. Early carbon black was made by burning natural gas in multiple fine jets and collecting the product on cold metal. Under the modem method, "furnace type" black is made by burning oil in a controlled atmosphere. The many grades of blacks have been distinguished by initials; HAF (high abrasion furnace) has been the mainstay. Every pound of rubber used in tire treads requires at least one-half pound of black; tubes require more, and carcasses only slightly less.

To abate the dust nuisance associated with the use of carbon black, alternatives have been investigated, especially silica in finely divided condition. Though considerably more expensive than carbon black, it has had success as a partial replacement in treads for large off-the-road tires.

Inert inorganic fillers basically add substance, though clays and whiting have some technical value; organic fillers, more akin to rubber, are now increasingly used.

Colouring agents. Pigments for colouring rubber must withstand curing temperatures and not interfere with or be affected by other ingredients. In high-temperature cures, therefore, the choice is limited to inorganic substances: zinc oxide and some titanium dioxide, plus a trace of ultramarine (to kill any creamy tinge) to achieve whiteness; iron oxide, to produce browns and reds. For rubbers curing at lower temperatures, a wide choice of organic dyes is available. For colour work, any added antioxidant must be nonstaining (see DYES AND DYEING).

Plasticizers and softeners. Adding mineral oils to aid processing is as old as the industry. Usually 5 to 8 percent of oil was added to natural rubber. The introduction of synthetics, with their greater affinity for oil, has led to more scientific standards.

Studies have shown that increasing the oil content of natural rubber improves certain of its properties, particularly traction of tires on snow-packed roads. In addition to mineral oils, a wide variety of softeners has been used, including coal-tar by-products such as bitumen, and Vaseline, fatty acids, and wood resins. Pine tar has always been popular with natural rubber because of its value in dispersing carbon black.

Vulcanizing agent. The outstanding vulcanization agent and the one longest used is sulfur. Cheap, effective, and relatively free from problems, it is added in proportions of up to 3 percent, and much higher for hard rubbers. Sulfur has one peculiarity: regardless of how little or how much is used in vulcanizing, some remains uncombined and is known as free sulfur, which migrates to the surface forming an unattractive sulfur bloom. Insoluble sulfur, considerably more expensive, can be substituted to avoid blooming.

Sulfur bloom

Accelerators of vulcanization. Accelerators or catalysts form an ever-growing list. Mercaptobenzothiazole, which revolutionized vulcanization in the 1920s, is still in use, although much safer and more efficient products have been developed since. As a class, accelerators have enabled curing times and temperatures to be reduced significantly, rendering the operation more efficient and permitting the introduction of valuable materials that would be destroyed under the earlier conditions.

Antioxidants. These, as their name implies, resist the action of oxygen. They form an important section of the group of materials known as antidegradants, which encompasses all materials resisting the deterioration of rubber. The amount of antioxidant added per pound of rubber has steadily risen, including the amounts indigenous to natural rubber and the amounts introduced as stabilizers in styrene–butadiene and other synthetics during manufacture.

Antioxidants may be divided into two main classes: amine derivatives, among which the more powerful are generally complicated condensation products with aldehydes or ketones, which cannot be used in light-coloured stocks because of staining; and phenol derivatives, which stain less and are more efficient. A third and smaller class of antidegradants fulfill such specific purposes as resisting the catalytic action of copper in breaking down rubber.

Derivatives of p–phenylenediamine occupy a prominent position among modem materials. Despite their excellent resistance to oxygen and ozone and good flex resistance, great care has to be taken to minimize staining and more particularly to ensure freedom from skin irritation.

Zinc oxide. Versatile zinc oxide belongs in a category by itself. Mention has been made of its use as a colouring agent. Although its use as a reinforcing agent has declined, zinc oxide finds its way into most formulas, primarily because of its activating powers. It makes accelerators more efficient and generally gives stability to products. Its high density makes it an expensive addition because volume rather than weight is the criterion in filling molds. Stearic acid should be associated with zinc oxide, for although as a fatty acid it might be considered a softener, it is normally added in such proportions as to convert the zinc oxide to zinc stearate, which is thereby made more effective.

Other compounding materials. Resins fulfill a variety of important functions. Mention has been made of wood resin softeners, and also of phenolic resins for high-temperature curing. Other resins are added to rubber to make it tacky and still others to stiffen it.

Several waxes may be added either as softeners or to form protective blooms on the surface of the product.

With the introduction of faster accelerators in manufacture, retarders have been developed; they are designed to make processing safer without slowing down vulcanization.

Peptizers, organic sulfur compounds that save mixing time by breaking down the huge molecular structures of the raw rubbers, are effective in small amounts. They are selective, however, and their performance is dependent on the presence or absence of other materials. Their relatively high cost must be justified by the mixing time saved.

Polyac and Elastopar

Where butyl rubber is used in compounding, the material Polyac serves as a promoter, a substance a minute quantity of which when heated with the polymer speeds subsequent action with the accelerator. A somewhat similar substance is Elastopar, used with styrene–butadiene rubber, but not effective below 149" C (300" F). Both promoters act vigorously and because of the difficulty of control are not always acceptable. To overcome that difficulty, they are sold mixed with an excess of inert material.

Lubricating additives cover a wide range. Dusting powders applied to uncured rubber prevent pieces from sticking together and ease their removal from molds. The standard materials are talc or french chalk. Zinc stearate is much more expensive but has the outstanding advantage of not causing cracking because it is soluble in rubber and, therefore, does not act as a foreign substance at the point of contact between two rubber surfaces. Liquid lubricants fall broadly into two categories: suspensions of talc, clay, or soap in water or alcohol; and the higher costing silicones, which have proved their effectiveness as mold release agents.

Vast quantities of solvents are consumed by the industry. Basically, they are petroleum distillates often known as naphthas, added in the factory to provide or restore tack to uncured rubber. Other solvents include aromatics obtained from coal tar and such chlorinated hydrocarbons as trichlorethylene and carbon tetrachloride.

PROCESSES

Mastication. Mastication is the process of reducing the size of the large organic molecules in natural rubber to increase its plasticity and thus facilitate subsequent mixing. Mastication may be accomplished in a specially designed machine, on open mills, or by merely giving the rubber an extra two minutes in a mixer before the addition of other ingredients. The process, therefore, is not precise but depends upon the condition of the rubber. The necessity of mastication may be minimized by the prior controlled storage of rubber at elevated temperatures, the use of low-viscosity rubber, or the use of special plasticizers.

Mixing. Open mills originally performed mixing. They were machines with two adjacent rollers mounted horizontally and rotating in opposite directions; the clearance between the rollers (the nip) was adjustable. Open mills, however, are slow, hazardous, and not amenable to temperature control; their replacement by internal mixers (see below) was accelerated by the increasing incorporation of powdery carbon black. Open mills still are used for warming up rubber before extrusion or sheeting, for low-temperature mixing, masticating, and other specialized work.

Internal mixers

An intemal mixer consists of two horizontally mounted rotors with blades that intermesh and shear the compound against the lining, with most of the mixing done in the small clearance between the outside of the rotors and the lining of the mixer. Mixing is regarded as complete at the end of a given time period, after a given temperature is attained, or after a certain amount of power is consumed. The mixed batch, normally in the form of discrete lumps, is sheeted out by dropping it on a mill mounted immediately below the mixer.

Forming. Uncured solid rubber not required in sheets is shaped or formed, generally in an extruder or tuber. The apparatus is frequently compared with a sausage machine because raw material is fed into a hopper at one end and forced through an aperture at the other, along a barrel containing a tightly fitting screw. Temperature is controlled by hot or cold water circulating around the barrel, and a variety of dies can be fitted to the head to produce the desired shapes. The rubber must be consistent in plasticity, for the cut of the die is correct for only one set of conditions, including temperature and speed. Extruders, defined by screw diameter, range from 1½ inches (38 millimetres) up to as much as 12 inches (305 millimetres) for very large tire treads.

The compounded rubber is warmed up before being shaped, generally on open mills. The process is extravagant in use of time and material for setting up before the specified dimensions are obtained; and when the product is cut, it shrinks on cooling, with "belled ends," sections that have to be discarded. Extruders may be used in twin or triple formation, each with its own rubber stock, to provide hot unions—*e.g.*, a tough tread on top of a more resilient base or a tread with flexible sidewalls.

Injection molding. The waste and delays associated with extrusion have led to more efficient processes such as cold feed mixer-extruders and injection molding machines similar to those used for plastics. With modification to guard against incipient cure in the barrel, they extrude the rubber, not through a die, but directly into a mold where it is given a very short cure. Success depends on extremely long runs, which are not common. Multiheads that allow four molds to be operated from one machine increase output.

Calendering. Calenders have two main functions: one, to produce sheet rubber of accurate and consistent gauge from a few thousandths to ⅛ inch (3 millimetres) or

Rolling plies and coating fabrics

more by plying up (using multiple plies); and, two, to rubberize fabric with great accuracy. In its crudest form, a calender is essentially a two-roller mill, although the rollers are normally mounted vertically. Modem calenders comprise three or four rollers ground very accurately.

In the typical three-roller calender for rubberizing fabric, all rollers lie in the same vertical plane, the top and bottom rotating in the same direction. Warmed-up rubber is fed into the nip between the two top rollers; it follows around the middle roller, and is applied to fabric entering the machine between the two lower rollers. The speed of the centre roller can be varied in relation to the bottom: when it is even with the bottom roller, it coats the fabric; when it is higher, it frictions, or forces the rubber into the interstices of the fabric.

A three-roller calender treats only one side of fabric at one pass. To rubberize both sides, the alternatives are a second pass, the use of a second calender (preferably in train with the first) or a four-roller calender, which coats both sides in one operation. The four rollers may be in line vertically, or the top roller may be offset to form an inverted "L." A calender must be supported with an array of auxiliary equipment, including variable-speed motors; efficient means of feeding both rubber and fabric and collecting the treated material, spreading the fabric across the roller under uniform pressure; accurate gauging; and temperature control. The rollers are traditionally cored to permit the flow of cold water or steam, as required. In a more modern method of temperature control, the rollers are drilled longitudinally forming a series of bores that allow steam or water to circulate within an inch of the surface.

Vulcanization. Reference already has been made to the principles of vulcanization and the chemicals used in the process. The simplest form of vulcanizer is the heater or autoclave, a vessel capable of retaining moderate pressures of steam and air (or inert gas). Simple shapes, and particularly thick sections of uncured rubber, may be exposed directly to steam, or molds with their cavities filled with uncured rubber may be inserted in the vessels. So-called bag-o-matic curing is the modem method of tire vulcanization, except for extremely large off-the-road tires. Bag-o-matic curing is entirely automatic and has reduced cure times for car tires from about two hours to 12 to 14 minutes. Heat is applied to the inside of the uncured tire through the medium of a one-quarter-inch gauge bladder, which has supplanted the much heavier and less efficient air bag. Time, temperature, and pressure are controlled automatically.

Bag-o-matic curing

Smaller rubber products are normally formed in a mechanical press, usually the daylight press on which a number of individual molds can be mounted. The molds are held in a closed condition by a hydraulic ram operating in a vertical plane. Another technique employs a single press that accommodates one mold, possibly with several cavities, the two parts of the mold being held together by mechanical pressure. The operation of the single press is largely automatic.

Cold curing, or vulcanization at ambient temperature, is still practiced but only where it is unavoidable, as in repairing belts *in situ.* Special accelerators can perform at room temperatures, but controlled heat, time, and pressure are always preferable.

Infrared and high energy radiation. These methods of vulcanization are of scientific rather than commercial interest. Use of internally generated heat to cure thick articles saves considerable time. Because of the poor conductivity of rubber, heat applied to the surface only penetrates slowly. The initial expense of equipment, plus operating costs, has limited interest to specialized high-temperature operations.

MAJOR APPLICATIONS

Tires and tire products. Automobile tires absorb 60 to 70 percent of the available rubber. As the outside diameter of tires has dropped progressively, widths of treads have increased, providing wider contact area with the ground and improved stability. The major strength of the wide-tread radial tires is built in transversely to the direction of motion; a series of inextensible narrow bands under the centre of the tread prevents its spreading. The conventional tire, in contrast, has cross plies. Increasing varieties of carcass materials are available: cotton, rayon, nylon, polyester, steel wire, and glass fibre, the last two for radial tires.

Tire-making remains a blend of craftsmanship and automation. Despite advances in mechanization, personal skill and experience are dominant in extruding, calendering, and in assembling all the components together in the process of tire building. The carcasses are constructed by laying ply upon ply of rubberized "fabric" on a cylindrical drum, followed by the other components, and ending with the tread and sidewalls (generally together as one unit). Adhesion in the uncured state relies upon the natural tack of the rubber.

Rainwear and shoes. Rainwear represented the first commercial use of rubber. Vulcanization overcame the obstacles encountered by Macintosh and the process of rubber coating fabric has continued into modem times. Doughs of rubber, naphtha, and other ingredients are fed between the roller transmitting the fabric and a "doctor" blade that spreads the rubber onto the fabric and controls thickness. The treated fabric then passes over a heated framework and is wound into rolls. If the heat is not sufficient to cure the rubber, an additional operation is performed.

Spreading has largely given way to the greater speed and accuracy of calendering, as has rubber to oil-soap treatment for shower-proofing and to plastics for more serious protection.

Shoes consume more rubber than any other commodity except tires. Styrene–butadiene types of rubber with high styrene content are favoured for soles because their wear characteristics render carbon black unnecessary. Attachment of soles to uppers by stitching has been largely replaced by either polymer adhesives or direct vulcanizing, a process requiring expensive equipment but providing rapid curing of two-and-one-half to three minutes. One-piece soles and heels made of rubber resins have been used successfully in children's footwear. Microcellular rubber, which feels soft and comfortable in wear, also has gone into soling.

Industrial uses. One highly important industrial use of rubber is in belting. The tendency for each piece of machinery to have its own electric motor has limited the use of driving belts, but the conveyance of coal and other minerals over thousands of yards has provided valuable business for the manufacturer. Strength is obtained by plying up any of the tire textiles, with polyester preferred where nonstretch is critical. Where fire is a hazard, the outer cover of belting is usually polyvinyl chloride. Cure may be either continuous or by sections, in long, specially constructed presses. The development of travelling sidewalks for passengers at airports and similar traffic centres opens up new and substantial possibilities.

Hoses of all shapes and sizes form an important sector of the rubber business. Small ones, such as garden hoses, are being replaced by polyvinyl chloride largely on a weight basis; otherwise an endless variety exists. The type of synthetic used depends on the material to be transmitted; some hoses must carry corrosive chemicals at high and low temperatures. Type of construction varies with the weight of the fluid to be transported and its pressure. Small all-rubber hoses may be molded to complicated shapes, but generally they are an extruded product. If reinforcement is required, it is primarily cord fabric plaited just ahead of the extruder. An outer cover, possibly of different composition, designed to resist abrasion, follows, and if further reinforcement is required, wire is wound spirally. Small hoses with strong walls that do not collapse under heat may be coiled and so vulcanized, but the larger types must be cured straight to prevent collapse.

Rubber-cable insulation

Cables consume a substantial amount of rubber as insulation. Wire (normally copper) is drawn through an extruder and the insulation applied. Butyl rubber is preferred because of its resistance to heat and moisture; an outer cover of either butyl rubber or neoprene is added, but both are increasingly being replaced by polyvinyl chloride.

Rubber is useful for many more industrial or engineering purposes, generally to insulate against sound or vibration or both, as in building and bridge foundations. A wide range of rubber springs and flexible seals performs valuable service; rubber fenders are ideal to protect the sides of ships and docks because the rubber retains its resilience for a score or more years despite destructive workings of the sea, oxygen, ozone, and other agencies.

BIBLIOGRAPHY. H.J. STERN, ***Rubber: Natural and Synthetic***, 2nd rev. ed. (1967), is the most up-to-date comprehensive work on the subject. Another good basic text is M. MORTON (ed.), ***Introduction to Rubber Technology*** (1959). Two classic, but somewhat dated works are C.C. DAVIS and J.T. BLAKE (eds.), ***The Chemistry and Technology of Rubber*** (1937); and G.S. WHITBY (ed.), ***Synthetic Rubber*** (1954). See also L. BATEMAN (ed.), ***The Chemistry and Physics of Rubber-Like Substances*** (1963), which contains an excellent article on the botany of the rubber tree; and W.J.S. NAUNTON (ed.), ***The Applied Science of Rubber*** (1961). For history, see P. SCHIDROWITZ and T.R. DAWSON (eds.), ***History of the Rubber Industry (1952).*** Current statistical information may be found in the monthly periodicals, ***Rubber News*** and ***Rubber Statistical Bulletin.***
